## FOREWORD

*Symorg* is a symposium traditionally organized and hosted by the Faculty of Organizational Sciences – University of Belgrade ever since 1989 with the aim of profoundly adding to the current body of knowledge in the fields of management and information systems.

We are pleased to present the *Proceedings of the XVI International Symposium of Organizational Sciences - Symorg2018* with the double-blind peer-reviewed papers presented at the Symposium. Following almost three decades of tradition in organizing this Symposium, participants had an opportunity to share and exchange their knowledge and experiences in a highly creative environment.

The main topic of this Symposium was the transformation of business affected by the digitalization. Accordingly, we named it ‘Doing Business in the Digital Age: Challenges, Approaches and Solutions’. Simultaneously with 14 different tracks related to the main topic, the Symposium included four round tables, one project-related workshop and an undergraduate case study hackathon competition.

It seems that today more than ever before, we are witnessing major changes in business operations of many organizations. This Symposium aimed to provide the answers to a myriad of problems arising from new business models created by blurring the lines separating the digital and the physical world. As new disruptive technologies and ever-changing needs of important business stakeholders reshape the world of business, digital transformation becomes almost a necessity. Our ambition was to create new visions and catalyze this transformation.

The Proceedings are the result of an extraordinary effort made by the authors, reviewers, track moderators and the Symposium organizers. All the accepted papers in the Proceedings are organized in the following 14 sections:

- Leveraging Technology in Digital Business
- Management in the Digital Age
- Data Processing and Analytics in the Digital Age
- Organization and Business Models in the Digital Age
- Quality and Business Excellence
- Transformation of Financial Services
- Digital Trends in Marketing and Strategic Communications
- Technology Entrepreneurship and Ecosystem
- Entrepreneurship and SME in the Digital Age
- Creativity, Innovation and Intellectual Capital in the Digital Age
- Human Capital in the Digital Environment
- Digital Public Administration
- Operations Management for a Digital World
- Environmental and Social Impact of Digitalization.

We would also like to thank all the institutions, associations, keynote speakers and individuals who supported and enriched the Symposium, especially the Ministry of Education, Science and Technological Development, sponsors, delegates and volunteers.

Belgrade, May 30, 2018

Editors:  
Nevenka Žarkić Joksimović, Ph.D.  
Sanja Marinković, Ph.D.

# GENERAL DATA PROTECTION REGULATION: IMPACT AND IMPLICATIONS ON MOBILE OPERATORS

Mirjana Stojanovic\*<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, e-mail: stojanovic.p.mirjana@gmail.com

**Abstract:** *The EU General Data Protection Regulation significantly expands the rights of the individuals related to the data privacy. At the same time, it defines the new obligations and responsibilities of the companies collecting and processing personal data. The goal of this paper is to provide the analysis of the new regulation in the context of mobile operators' business. It summarizes the main challenges and identifies the main steps for the practical implementation of the compliance. Finally, it emphasizes the potential for the different business benefits if the compliance to the new regulation is implemented in a correct way.*

**Keywords:** *GDPR, mobile operators, personal data, data privacy*

## 1. INTRODUCTION

Expansion of the digital services which has been happening last years in the different industries has led to the enormous amount of the data related to the users of those services, their habits, preferences, health, financial status, spending patterns and other personal information. For the digital services providers this set of data represents a potential for the highly personalized offering and consequently for a new business/new revenue. Furthermore, personal data became a tradeable asset in the digital economy ("new oil of Internet") and this emerging market of personal information raised a large number of economic, technical, social and ethical issues with particular concerns about privacy (Spiekermann, Acquisti, Böhme, & Hui, 2015).

After 4 years of debate, in April 2016, EU Parliament finally approved new General Data Protection Regulation. The EU General Data Protection Regulation (GDPR) replaces the Data Protection Directive 95/46/EC and was designed to harmonize data privacy laws across Europe, to protect and empower all EU citizens data privacy and to reshape the way organizations across the region approach data privacy ("Home Page of EU GDPR," n.d.). Enforcement date of the new regulation is 25th of May 2018. The GDPR expands the scope of data protection and the definition of personal data and every organization that collects and processes the data related to EU citizens must comply with it, no matter where they are based or where the data is stored.

This implies that organizations should adopt different internal measures that meet the principles of data protection by design and default (Tankard, 2016). Besides the technical/technological and organizational changes that are required, regulation related to the handling of personal data has its economic value and consequences (Acquisti, Taylor, & Wagman, 2016).

In the first part this paper provides a brief overview of the EU General Data Protection Regulation, reactions, and consequences that it has provoked and then focus particularly on the impact and implications that the GDPR has on mobile operators and their current and future business.

## 2. LEGAL FRAMEWORK

GDPR is intended to be a strong and coherent data protection framework in the EU, backed by strong enforcement, given the importance of creating the trust that will allow the digital economy to develop ("Regulation (EU) 2016/679 of the European Parliament and of the Council," n.d.). Main actors which rights and obligations are defined by the regulation are the following:

- **Data Subjects** – Natural persons to whom apply the protection afforded by GDPR, in relation to the processing of their personal data
- **Data Controller** - A natural or legal person, public authority, agency, or other body which, alone or jointly with others, determines the purposes and means of the processing of personal data
- **Data Processor** - A natural or legal person, public authority, agency or other body which processes personal data on behalf of the controller ("Regulation (EU) 2016/679 of the European Parliament and of the Council," n.d).

The GDPR is applicable to:

- the processing of personal data by controllers and processors in the EU, regardless of whether the processing itself takes place in the EU or not
- the processing of personal data or monitoring of behaviour of data subjects in the EU regardless of whether as controller or processor is established in the EU or not.

Key principles and key changes comparing to the previous legislations addressing this matter are summarized in the rest of this chapter.

## 2.1. Rights of Data Subjects

In order to protect individuals and their personal data, GDPR defines the following (“Regulation (EU) 2016/679 of the European Parliament and of the Council,”n.d):

**Transparency and easier access to data (Right to access):** Individuals must be allowed to get in an easy way the clear and understandable information on how their data is processed. This means that data subjects have the right to know which personal data concerning them is being collected and processed, where and for what purpose including the information about third parties to whom this data has been or will be disclosed. Furthermore, if requested, the controller shall provide a copy of the relevant personal data collected about the data subject, free of charge, in an electronic format. Controller may only charge for such a request in excessive cases.

**Consent (Right to choose):** Explicit consent of data subject's is required before processing of the sensitive data. Request for consent must contain the explanation of the purpose for data processing. Consent must be revocable and both giving and withdrawing the consent should be the data subject in an easy way. When the data subject is minor, parental approval is mandatory. The controller must be able to prove that the consent has been given.

**Right to object:** Data subject has the right to object to processing of his/her personal data on certain grounds, in addition to the right to object to processing for the purposes of profiling or direct marketing.

**Right to change/rectify:** Data subject has the right to update incomplete/incorrect details

**Right to be forgotten:** If an individual wants her/his data to be deleted, and if there is no legitimate basis for retaining and further processing it, the data must be erased.

**Right to data portability:** Individuals must be able to easily transfer the data between the different service providers (data processors/controllers).

**Rights to be notified and compensated:** Individuals must be notified in case of data breach which may have serious impact on them and have the right to be compensated for material and immaterial damages caused by non-compliant processing.

## 2.2. Accountability and obligations of the Data Processors and Data Controllers

While protecting and expanding the rights of the Data Subjects and increasing the level of control they have over their personal data, the new regulation is at the same time introducing direct obligations for the service providers in the role of data processors/data controllers, making them accountable for the GDPR-compliant way of working.

They have to implement appropriate technical and organizational measures to ensure that their products, services and internal business processes are designed following the data-protection principles (**Data protection by design**) and that by default, only personal data which are necessary for each specific purpose of the processing are collected, stored and processed (**Data protection by default**) (“Regulation (EU) 2016/679 of the European Parliament and of the Council,”n.d).

Where a type of processing is likely to result in a high risk to the rights of data subjects (e.g. in case of particular new technologies or in case of automated processing which includes profiling), the controller shall, prior to the processing, carry out an assessment (**Data privacy impact assessment**) and undertake all the measures envisaged to address the risks, to ensure the protection of personal data and to demonstrate compliance to the GDPR (“Regulation (EU) 2016/679 of the European Parliament and of the Council,”n.d).

Data processors/controllers are further obliged to maintain the records of all processing activities under their responsibility, to cooperate with supervisory authority and if a personal data breach occurs, to notify the

supervisory authority, not later than 72 hours after having become aware of it ("Regulation (EU) 2016/679 of the European Parliament and of the Council,"n.d).

GDPR increases the power of the supervisory authority (regulator) and defines different corrective actions including penalties that regulator can apply towards data processors/controllers in case of non-compliance to the regulation. For serious infringements, a fine can go up to 20,000,000 EUR or up to 4% of the annual worldwide turnover of the preceding financial year, whichever is greater.

### **2.3. Reactions and interpretations**

From one point of view, the GDPR is seen as the regulation that encourages digital transformation and represents a demand for effective data management practices and a holistic overview of all data held within a company which will enable a proactive cyber-security (Zerlang, 2017). From the others, some concepts are considered as already obsolete, inadequate, or controversial.

Concept that has been particularly commented is Data Protection/Privacy by Design. Two main remarks can be summarized as the following: it presents too abstract a framework to inform design; and it is often applied too late, i.e. after many critical design decisions have been already made in defining the business opportunity (Edwards, McAuley, & Diver, 2016).

Recommendations for the improvement goes from promoting a deeper understanding (R&D community, education, media, policy makers) and including privacy considerations in the standardisation process (Danezis et al., 2015) to the proposals to transform Privacy by Design approach to much wider Social Impact Assessment methodology with practical guidance to be applied at product/service concept stage as well as throughout the system's engineering (Edwards et al., 2016).

Conclusion that is common and indisputable is that the GDPR will force businesses to restore order to their operations and while it will deliver restrictions, it will also provide many benefits to businesses (Krystlik, 2017). In the process of achieving compliance, organisations will face many challenges, but at the same time many opportunities (Mansfield-Devine, 2016).

Remaining part of this paper analyse those challenges and opportunities in the case of mobile operator. (N.B. This analysis is limited to the data subjects using services of mobile operator and the protection of their privacy, not to the employees in the role of data subjects).

## **3. MOBILE OPERATORS AND PERSONAL DATA**

Mobile network operator is a service provider of telecommunication services over wireless (mobile) network. In addition to the core telecommunication services as voice and data traffic, mobile operators are quite often including in their offer partner services (e.g. mobile payment of parking services).

Being in data controller/data processor role, mobile operator is collecting and processing huge amount of the data that according to the GDPR are considered as personal information. Besides two main identifiers, International Mobile Subscriber Identity (IMSI) and Mobile Subscriber ISDN Number (MSISDN), mobile users are associated with several others as name, physical address, personal ID, name of the company (in case of business users), etc. There are some other demographic data (age, gender...) that can be left voluntarily during the registration or interaction with the customer care, however most of personally identifiable information related to subscribers is collected or generated while providing the services.

One of the main relationships between the mobile operator and the end-user is billing relationship regardless the user's choice to pay before (prepaid) or after using the services (post-paid). Charging and billing data generated by corresponding network elements are very extensive and include different information about the call/message/data session as the time stamp, location and the mobile device used by end-user, called number, or visited site, streamed/downloaded content etc. In case of roaming there is an info about visited network, and consequently about the country visited by the end-user (data subject). To get better/cheaper rate plans, users often opt in for the packages which require explicit definition of the "favourite numbers", i.e. family, friends, community. Significant volume of the personal data can be generated during network monitoring activities or for statistical/analytical purposes.

Extensive set of collected data is mainly used for internal purposes: charging, billing, reporting, customer segmentation, campaign management, personalized offering, customer experience management, etc or unused at all. Disclosing of personal data to third parties might occur only in limited number of predefined

cases related to the legal obligations (e.g. lawful interception or emergency positioning) or in cases where subscriber has allowed/approved this either by opting in for partner services (e.g. mobile advertising) or by defining other subscriber(s) who can get a subset of his/her personal data (e.g. location).

During last years, users have become suspicious of the organizations that collect, store, and use their data. The primary concern of consumers is that organizations might sell their personal data to third parties without their consent. Decrease of trust happened in all segments, but it is much lower in communication services providers than in case of social media companies or digital disrupters (e.g. Uber). In emerging markets, communication services providers are still the most trusted organisations by consumers for handling personal data while in mature markets they are second to bank/credit cards companies (van den Dam, 2017).

### 3.1. GDPR compliance in case of mobile operators

The implementation of the GDPR indicates the need for various actions, planning, the assignment of new responsibilities and the acquisition of new expertise. The twelve aspects identified as the practical implications of the GDPR changes with the most relevance to all personal data intensive companies are summarized below (Tikkinen-Piri, Rohunen, & Markkula, 2017):

1. Specifying data needs and usage
2. Considering conditions for data processing in international context
3. Building privacy through data protection by design and default
4. Demonstrating compliance with GDPR requirements
5. Developing processes to deal with data breaches
6. Reckoning with sanctions for non-compliance
7. Designating a DPO (Data protection officer)
8. Providing information to data subjects
9. Obtaining consent on personal data usage
10. Ensuring individuals' right to be forgotten
11. Ensuring individuals' right to data portability
12. Maintaining documentation (Tikkinen-Piri et al., 2017).

Although mobile operators already follow much strict legislation than most of the other companies handling personal data, compliance to GDPR still imposes numerous challenges to them, mainly due to the number of systems manipulating subscribers' data and the diversity and complexity of the relations they have with the subscribers. Practical aspects of GDPR implementation specified above are hereafter analysed in the specific technical and business environment of the mobile operators and grouped within four action streams as outlined in the table below and explained in the following subchapters.

**Table 1:** GDPR implementation in case of mobile operators

Action Stream	Practical Aspects of GDPR implementation
New competence and new resources allocation	Designating a DPO, Developing processes to deal with data breach Reckoning with sanctions for non-compliance
Inventory of subscribers' personal data and subscribers' personal data handling processes	Specifying data needs and usage Demonstrating compliance with GDPR requirements Ensuring individuals' right to be forgotten Ensuring individuals' right to data portability Maintaining documentation
User interface and Consent management	Providing information to data subjects Obtaining consent on personal data usage Ensuring individuals' right to be forgotten Ensuring individuals' right to data portability
Suppliers and partners management	Building privacy through data protection by design and default Building privacy through data protection by design and default Considering conditions for data processing in international context

### 3.2. New competence and new resources allocation

First step in implementing GDPR compliance is to build and/or acquire the competence related to this matter. This is a prerequisite for performing data privacy impact assessment, the analysis of the gap between the current and GDPR-compliant implementation and to define new processes and procedures.

Procedures related to the possible data breaches must be defined, as the mobile operators have the obligation to notify regulators and the affected individuals (data subjects) about data breaches as early as

possible. All of this require a dedicated team responsible for defining data protection strategy and implementing measures and activities needed to ensure compliance with GDPR. A formal leading role for all data protection activities is the Data Protection Officer (DPO).

Besides the human resources, mobile operators must plan and allocate significant financial resources for the practical implementation of the GDPR and to calculate the financial risk exposure in case of non-compliance.

### **3.3. Inventory of subscribers' personal data and subscribers' personal data handling processes**

In many of the current implementations, subscribers' personal data are collected, handled, and kept in separate silos (core network department, CRM/customer care, billing) without complete alignment between them, despite the existence of the centralized data warehouse system.

To be able to demonstrate GDPR compliance, operator must be able to prove that the subscribers' personal data are correctly handled, to verify that the processing flows are auditable at any time and to prevent loss of personal data, or loss of track of those personal data ("Enabling GDPR Compliance for Operators - TM Forum Project Charters Space - TM Forum Confluence," n.d.). To achieve this, operator must:

- identify the different platform and processes within those platforms which manipulate personal data
- identify the parties engaged into the processes
- identify the flows and directions
- identify the processes of each party
- define tools & processes to constantly keep updated those information for each platform ("Enabling GDPR Compliance for Operators - TM Forum Project Charters Space - TM Forum Confluence," n.d.).

Following the requirement for data minimisation, mobile operator must review and re-evaluate their current policies for the collection, generation, storage, processing, deletion, and disclosure to the third parties of the subscribers' personal data, to categorize the data that is collected and processed and to decide what is really needed for the business operations and for the lawful purposes. Personal data for which neither business nor legal justification cannot be found must be deleted. Important part of this process is to define the access policy to all the personally identifiable information/data that will remain and to separate the data set that is kept for legal purposes only in order to avoid that this information is accidentally processed in some other scenarios.

Making review and inventory of the subscribers' personal data, should also include review of the consents received so far. The way of performing customer segmentation or preparing personalized offering and targeting subscribers with them, should be revised in the context of GDPR clauses related to the profiling of data subjects.

Data model in this personal data inventory must be user-centric to secure that individuals' right to get a copy of his/her data or right to be forgotten and right to data portability can be satisfied in a correct and efficient way. Data model must include relationships between minors and parents/guardians.

### **3.4. User interface and consent management**

Strict requirements related to the rights of individuals (data subjects) combined with variety of services from mobile operators' portfolio make the area of user interface and consent management the most demanding for the implementation of GDPR compliance.

The solution outlined by the global industry association (TM Forum) suggests the introduction of the Privacy Control Point which will provide ("Enabling GDPR Compliance for Operators - TM Forum Project Charters Space - TM Forum Confluence," n.d.)

**User presentation** - A central GDPR dashboard to support data transparency and clear and easy presentation of the personal data to the end user and interfaces to support inclusion of a dashboard in the existing (or new) omni-channel solution for the end-users' interaction.

**Privacy and consent management** – Individual user could have many services, including those that are not provided solely by the operator (i.e. partners' services). Consent requested and collected from the end-user must be at the individual service level and aligned with the user and service lifecycle.

### **Logging of all privacy related operations**

**API Access** – controlled access to and exposure of subscribers personal data (including consents) either internally, i.e. within the operator’s domain or externally, from/to partners domain (“Enabling GDPR Compliance for Operators - TM Forum Project Charters Space - TM Forum Confluence,” n.d.).

Such an approach assumes the logical architecture based on “traditional” concepts, as APIs. Representative example is TMF644 Privacy management API which provides standardized mechanism for privacy profile types, privacy profiles and privacy agreements such as creation, update, retrieval, deletion and notification of events (“TMF644 Privacy Management API REST Specification R16.0.1 - TM Forum,” n.d.).

The most challenging aspect of the scenario described above is to secure the data transparency and the right to withdraw the consent and/or erase the personal data in case of partner services. In the absence of a central logging facility that acts as a trusted third party, it can be extremely difficult to trace which partner organisations have accessed individual data sets (e.g. if partner further disclosed the data to another partner/3<sup>rd</sup> party) and to provide relevant information/response to an individual who requests information or action on his/her data.

Potential answer to this demand are solutions based on the latest file-distribution, blockchain and encryption technologies. In a purely decentralised peer-to-peer environment of equal partners, without requiring any centralised instance or further authorisation steps, the provider of data is empowered to trace the access to the data by partners in the distributed and shared data pool. This trace of access is without any doubt and cannot be denied (Roth, 2017).

Application of the blockchain technology in mobile network is still in a very early stage or “proof-of-concept” phase. To apply it in the live network and on commercially available services would be a crucial change and this would require close cooperation of the main industry players and regulators. However, the number of use cases in which mobile operator could benefit from the blockchain technology is constantly increasing (5G service enablement, IoT), thus this change might happen in the near future and the blockchain might become a long-term solution for the privacy and consent management.

### **3.5. Suppliers and partners management**

Mobile operator is the primary contact point for the subscriber and from GDPR perspective accountable for proper handling of subscriber’s personal data. However, the ecosystem in which mobile operator does the business, inevitably include different entities as suppliers and partners. There are different technical barriers which prevent operator to have the full control on how the subscribers’ personal data are handled in the whole ecosystem (example given in the chapter 3.4), but from the legal perspective, operator can and should include GDPR related clauses and liabilities in all the agreements with the partners and suppliers.

Following the obligation for data protection by design and default, operators should include corresponding technical requirements in all requests for purchasing new equipment to ensure that the tools and support for privacy protection will be provided as a part of standard functionalities and not as customer specific adaptations/product customizations. This is especially valid for the new Business Support Systems (solutions that support customer-facing activities as billing, order management, customer relationship management, etc...) and Operations Support Systems (solutions that support back-office activities as operation of mobile network, provisioning and maintaining of customer services). Vendors/suppliers should have privacy impact assessment built into their product development lifecycle and should advise operators about the privacy impact of new technologies.

GDPR conditions for personal data transfers to a third country or an international organisation should be carefully evaluated in cases when companies acting as the providers of technical support or managed services to mobile operator, have their global service centres abroad. Before allowing export of any subscriber database or its part, that might be required as a part of operation and maintenance or troubleshooting processes, anonymisation or pseudonymisation of subscribers’ personal data must be secured. (Pseudonymisation is the new concept introduced in GDPR, which refers to personal data processing in a way that the data cannot be attributed to a specific data subject without additional information (“Regulation (EU) 2016/679 of the European Parliament and of the Council,”n.d).)

## 4. DISCUSSION

The EU General Data Protection Regulation demand from mobile operators to implement numerous technical, organizational, and procedural changes, to acquire new skills and to make significant financial investment. Still, it should be considered as a business opportunity, rather than a new obligation or a problem. If the GDPR related challenges are addressed by mobile operators in a proper way, this could bring them important business benefits summarized in the table below.

**Table 2: Potential benefits of the GDPR implementation in case of mobile operators**

<b>Results of GDPR implementation (internal perspective)</b>	<b>Potential business benefits</b>
Common user-centric data model	To simplify reporting and other business processes To reduce the risk of revenue leakage caused by misalignment between different subscriber databases
Removal of unnecessary data and of redundant data processing flows	To decrease operational costs
Clean inventory of subscribers' personal data	To improve operational efficiency
Clear policies and procedures for handling subscriber data	
<b>Results of GDPR implementation (external perspective)</b>	<b>Potential business benefits</b>
Demonstration of the GDPR compliance	To further strengthen the brand To improve customer satisfaction and loyalty To reduce churn and/or acquire new subscribers from the competitors To monetize the trust by developing and offering new digital services

### 4.1. Monetization of trust and new business opportunities

In the current circumstances, mobile operators worldwide are experiencing a decline in revenue from traditional services (voice and SMS) due to the increased usage of the communication services provided by OTT (Over-the-top) players like Skype, Viber, WhatsApp...By positioning themselves as the trusted communication services provider, mobile operators can justify the price of their services and further develop new digital business opportunities, including those in which they will offer to partners to leverage on their privacy protection infrastructure (e.g. privacy control point and corresponding API).

At the same time, telecommunications industry is preparing for the fifth generation (5G) of wireless technology which will significantly increase the speed and coverage and reduce the latency in mobile network. 5G is expected to play important role in the digitalization of the different industries, as manufacturing, automotive, agriculture, energy and utilities, public safety, healthcare, public transport, media, and entertainment etc. Evolution of mobile operator from the traditional provider of telco services to the digital enabler means that significant growth of IoT connections is expected, both in consumer and industrial segments. This opens the potential for the new revenue streams and at the same time, much broader concerns about privacy than in case of traditional telco services.

For the user centric and data centric 5G use cases to be accepted and to function as a viable business model, user trust in their data privacy is paramount (Khajuria & Skouby, 2017). As the protection of personal data will be very relevant for 5G adoption, all the efforts and investments that mobile operators make to achieve GDPR compliance could help them to monetize future 5G-enabled business opportunities.

## 5. CONCLUSION

This paper presents an overview of the new EU regulation related to the protection of personal data, with focus on implications it is going to have on the mobile operators and their business. It identifies the main steps to be done and even provides some ideas for implementation. Thus, it can be considered as a sort of guideline for the providers of telecommunications services who want to achieve GDPR compliance. Highlighted is the fact that the GDPR, if properly implemented, could bring several benefits to the mobile operators, and open the possibilities for improving their operations and capturing new revenue streams.

Possible future research associated to this topic can address the end-user expectations and concerns in terms of privacy in the 5G-enabled use cases and propose the way on how the mobile operators can respond to them successfully.

## TELECOM CRM EVOLUTION IN THE DIGITAL AGE

Bojana Savić<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, e-mail: maticbojana86@gmail.com

**Abstract:** *Telecommunication companies have great pressure for very fast adaption to new market conditions and new technologies in order to satisfy customers. Since customer became center of the telecom world, the topic processed in this paper is telecom customer relationship management in the digital era, challenges and possible solutions. This article shows analysis of market trends and common implementation of CRM systems in telecom companies and it gives an overview of key pain points in standard solutions. The purpose of the paper is to suggest a way for improvement CRM processes trough considering appropriate system architecture plan.*

**Keywords:** *customer relationship management, CRM, digital CRM, digital, telecommunication*

### 1. INTRODUCTION

Nowadays, telecommunication companies are part of an industry which grows very fast. Especially in the domain of mobile services where new technologies and products are changing the way of business, a way of communication, a way of living at all.

It is very clear by hart that there is more and more population using mobile phones and, in addition to that, statistics tell the same – at the end of 2017, there were around 5 billion mobile subscribers worldwide according to GSMA, with more than 50% subscribers using the mobile broadband network (3G/4G). Mobile data traffic, as the most important thing, today is based on broadband with really high speed. Even that will be changed soon by introducing 5G network. It has been expected that 5G will be commercially live in next few years and it will bring a situation where latency will be minimal or it will be no latency at all (for example, the surgeon would be able to run robotic glove in order to perform surgery on distance).

Telecommunication companies are in the middle of this storm and there is a big question for them: should this kind of company gives only connectivity to users and other companies or they can do something more. Everyone develops new strategies to take advantage of new potential customers and to have more than good customer retention program. Companies need to put a lot of effort on customer relationship management as a process, but also very important is to take care to have CRM tool which can fulfill all needs.

The goal of this paper is to analyze Serbian telecommunication market and to suggest a way for improvement CRM processes trough considering appropriate architecture. The more specific goal is to point out on weaknesses of common implementations of CRM tools and how new technologies can help.

### 2. CUSTOMER RELATIONSHIP MANAGEMENT

Customer relationship management (CRM) is an IT tool which allows the company to gather and analyze information about customers such as previous sales, answered and not answered calls to customer center, solved and not solved problems, active products and services (Nguyen, Sherif, & Newby, 2007). Collecting all this information has a purpose to keep the customer satisfied with current operator trough two simple steps (Ferdous & Rahaman, 2009):

- To use pattern and trends in order to offer the right product to the customer
- To create churn and behavioral prediction model

Facts which are listed in this paper point out that care about existing customers is the most important thing today. With proper care about existing customer, first of all, they will stay loyal to the operator and at the end will bring the revenue. The second one, through the word-of-mouth customers will recommend their operator to others. Living in the age of the Internet, word-of-mouth should not be neglected since all situations, good and bad, are spread through the network in seconds (Eunjin & Byungtae, 2005).

Revolution in IT brought us CRM tools where it is easy to define profitable and non-profitable subscribers, but not with the idea to let go non-profitable ones. Nowadays, customer retention programs are number one priority for mobile operators. CRM process and CRM tool should be modeled with special attention on a fact that today is social media age. Currently, technologies which make the difference in CRM are social media, especially social media free tools (Harrigan & Miles, 2014). A new way of CRM, digital CRM or e-CRM has a positive impact on customer loyalty which was researched by (Azila & Noor, 2011).

In probably all areas of industry, the center was moved from marketing and similar things to customer. The customer now is in the middle of all happenings. Empowering customers and putting them in the center has brought new challenges for customer relationship management (Lipiäinen, 2015).

Next chapters show detailed architecture common in the telecommunication industry, which reveals main pain points.

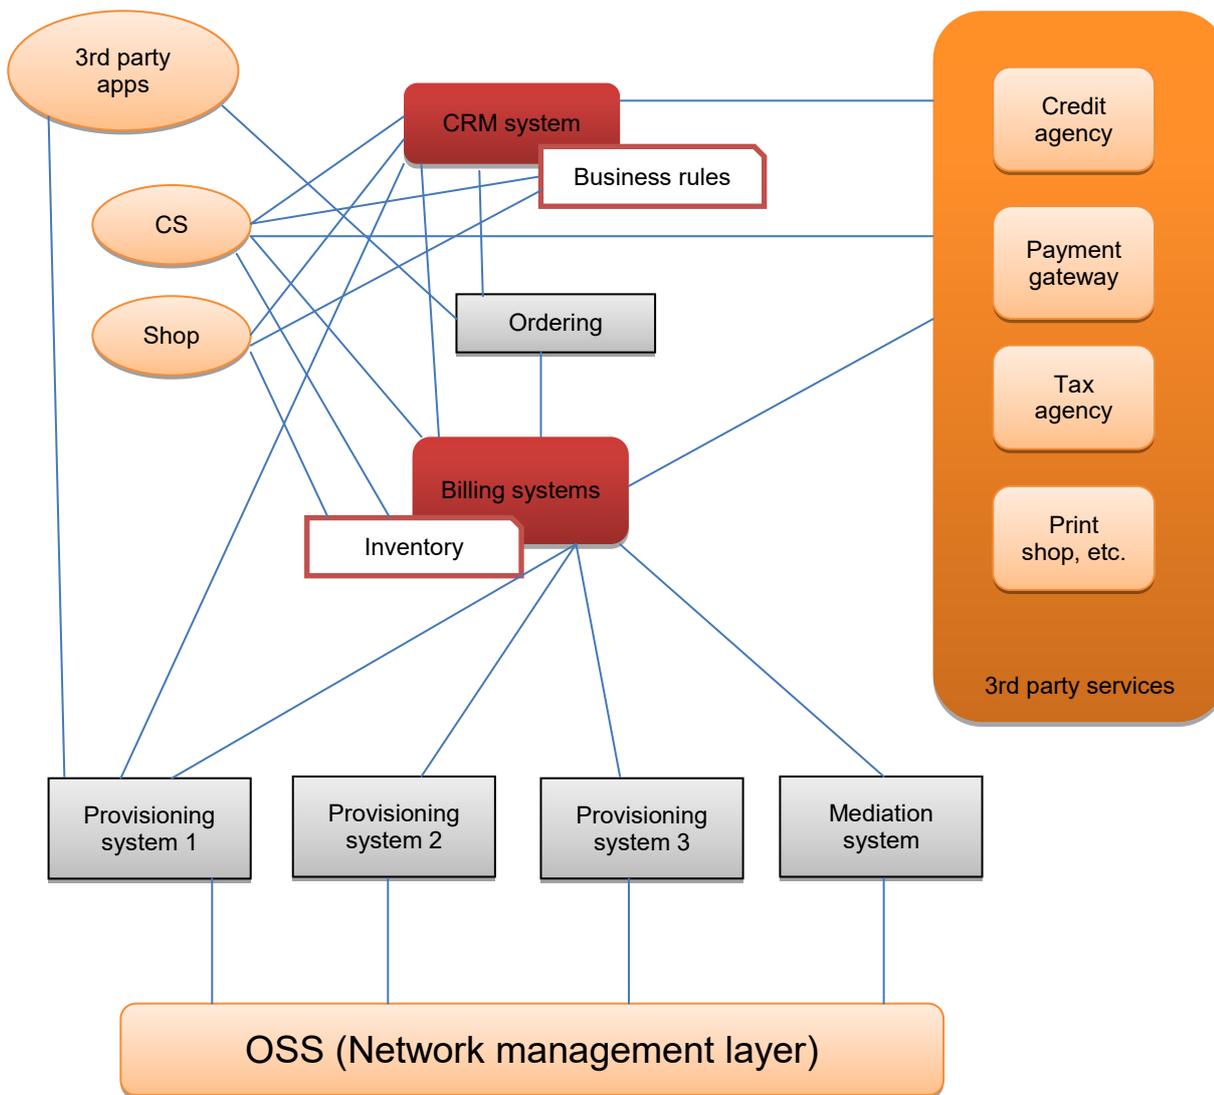

## **2.1. Traditional CRM**

In telecommunication companies, there is one main split between systems: OSS and BSS. OSS or Operational Supporting Systems represents a group of systems and software that are used for managing firstly core network side, network infrastructure. On the other hand, BSS or Business Support Systems is a group of more IT systems with a role to support business processes and systems dealing with the customer directly. CRM tool usually belongs to Business System Support (BSS) stack. In BSS stack should count systems responsible for billing and charging, customer care, sales support, order fulfillment, dependent on implementation.

Till a few years ago in the industry of communication, it was considered that architecture should be billing centric. And it is true that for the majority of customers, things like rating, charging, invoicing was on the top of the list of priorities.

Traditional CRM in the past was a system which has only basic information about the customer and it was used as a kind of support to billing systems. There was no much attention to put information in one place and in a structured way, so agents on the first line can cope with every situation.

The following figure shows the very simplified architecture of BSS stack and role of CRM in it like it was common in last decade. Simplification in this view is necessary in order to focus on a problem pointed out in this paper.

**Figure 1:** Presentation of simplified common traditional BSS architecture in TelCo

This kind of implementation was good in past years since customer need was to come to shop or call customer service and get information or activate services. But already some time this architecture is completely unsustainable since, firstly, there are more channels for interaction with the customer. Customer needs are higher but this set up is bad for few general reasons:

- High costs for maintaining
- No clear definition of which functionality belongs where
- Integration was done per case trough time which led to, so-called, spaghetti architecture
- Silo architecture is present meaning that each system functions for itself
- Processes are not and cannot be automated which means high manpower costs
- Double work is highly present, as well as duplication of systems, functionalities, and data
- Time to market is very low
- Bad customer experience and customer service

Also, there are more specific reasons why this architecture is not usable anymore. For example:

- Inventory is on billing system as the central point. That causes that billing systems need to be very responsive and scaled for a huge number of calls from external systems, like CRM
- Inventory can be synchronized back to CRM in order to lower pressure on the billing system, but in that case, there is no real-time information about customer actions or customer state at all
- Bad information modeling is present since each system has own database with same data but in a different form

The situation in a big and complex company, such are companies in the telecom industry, became that it is easier to drop off the whole stack of systems and build completely new ones. The idea of upgrading and adding new functionalities is a nightmare. Every new functionality, even a small change in one system

usually means changes on surrounding systems, too. But systems cost millions and there is no that company that can afford often replacement of these systems.

## 2.2. Digital CRM

The term “digital CRM” is actually a concept which is incorrectly formulated. There is no such thing as digital CRM. Everything is digital in modern systems. By this term, usually, it is considered content in digital form and a way of communication with customers and other stakeholders. CRM could be considered as a tool for the process of digitizing all gathered information about the customer (Nguyen et al., 2007). The majority of information today is on social networks. Successful social CRM implies that traditional CRM should be upgraded and extended in a way to cover social networks (Harrigan, Soutar, Choudhury, & Lowe, 2015).

The main goal for existing telecommunication companies should be to put the customer in the center and to adopt customer care in a way where all parts would be satisfied – company, employees and customers.

The worldwide market situation has been changed on several fronts:

- A new technology appears almost every day. Those technologies can help in daily business but it is not always true. In order to be competitive and innovative, companies need to afford themselves to put human resources in research and development of prototypes. Not every new thing is good, neither applicable to the business of the company.
- Customers want something more, something new. They want personalized approach and that everything can be done online and fast, for the start.
- Since the market is very saturated and there are no much more new things to offer in simple communication, companies need to figure out new revenue streams. Usually, those revenue streams are not core business, but telecommunication operators have a big advantage since they are ones who provide connectivity. This is a place where new technologies can find a place: IoT (smart homes), augmented reality, big data, machine learning. For example, a huge amount of information is collected in CRM and surrounding databases, so technology based on BigData is more than desirable to be used for creating such models which can help company itself or even be sold to a third party (statistical data, not data about the customer).
- Growing of new competitors is also an alive thing. Today MVNO (mobile virtual network operator) is a modern and profitable business without a lot of risks since it is completely virtualized. That operators don't have to invest in the most expensive thing – infrastructure.
- As it is mentioned in this paper, mobile data usage has constant grow. Also, new network capabilities are coming pretty fast for such kind of services. So, when LTE (4G) was introduced set of completely new products appeared. Now, 5G is ready to be launched.

All above is a reason why operator needs a new way of doing BSS. Since the customer is in the center of events today, customer relationship management could also be in the center of BSS architecture in a telecommunication company. Digital CRM implies that all channels used for an interaction are connected and integrated, so CRM can have all information: basic information about the customer, billing information, geolocation, active inventory, previous sales, information about complaints through all channels, etc. (Nguyen et al., 2007)

In previous years customers used a lot of channels for interaction. As it is stated by (Padam & Sridhar Marella, 2017): “As the Internet of Things is evolving and devices go online, completely new channels add data and interactions to CRM”. The multichannel approach is necessary in order to track all customers' activities. Actually, not just multichannel, but omnichannel. Multichannel is different from omnichannel in one, but the thing which makes a difference. Multichannel is an approach where it is considered that customer use different channels for one activity, but those channels are not aware of activities through other ones. On the other hand, omnichannel is called a situation where all channels for customer integration are highly integrated. From the perspective of customer experience, it is mandatory for a company to have integrated solution because it is the only way to prevent misusing of systems and to provide perfect customer care.

## Role of CRM in a Changing Digital World

**Figure 2:** Role of CRM in a changing digital world (Padam & Sridhar Marella, 2017)

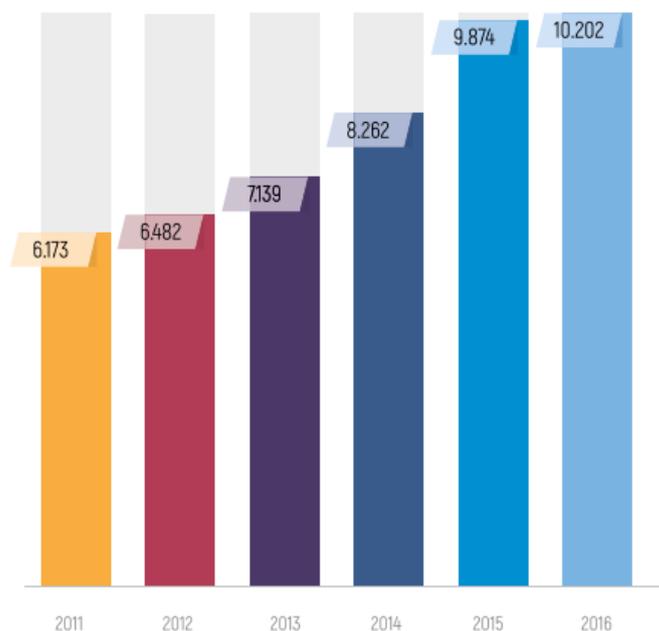

### 3. MARKET OVERVIEW

In Serbian market current situation is similar to the worlds with few deviations and market specifics. First of all, it is needed to show in which direction Serbian market goes and to recognize problems in order to be clear what kind of CRM is desired and why.

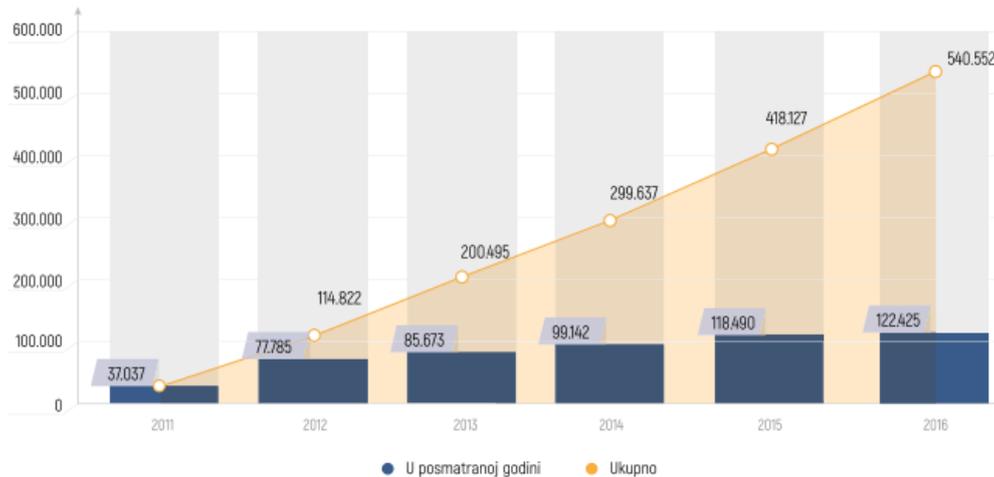

Serbian regulatory agency (RATEL) has been announced detailed report for the 2016 year. From the report few things dominate (RATEL, 2016):

- Total number of subscribers in a mobile network is on the same level in past 4 years and it's around 9.1 million
- Number of subscribers per 100 number of citizens is in stagnation but penetration is still huge: 128,52%
- Postpaid subscriber database is growing compared to prepaid
- The number of sent SMS and MMS is rapidly decreased
- Mobile data usage has constant growth
- Network coverage with LTE is better from year to year in case of all operators

Information from this report shows that Serbian market is obviously very saturated and there is no a lot of room for gaining new customers. Option for attracting new customers is only through the process of mobile number portability. So, operators need to convince the customer to give up on the previous one and to trust new operator. From the year of 2011 when MNP has been introduced in the market, a number of ported subscribers grows, which is shown on following graphs.

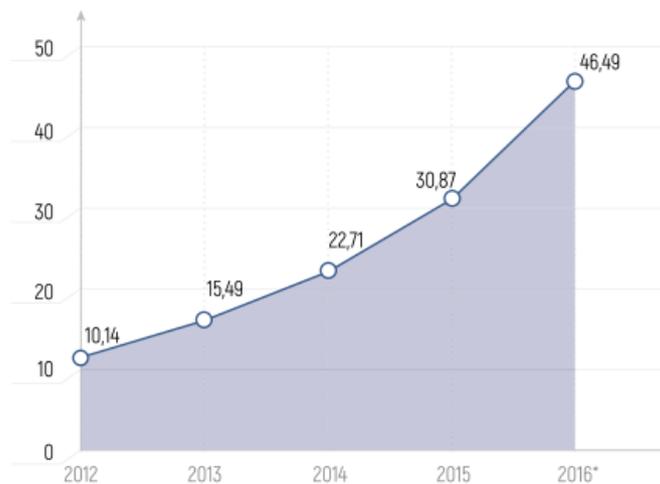

**Figure 3:** Average number of ported subscribers per month trough years (RATEL, 2016)

**Figure 4:** Ported subscribers per year and in total (RATEL, 2016)

Considering type and usage of customers that situation pretty follows modern West European markets. A number of postpaid subscribers grow compared to prepaid and finally, in the market from 2016, there is more postpaid than prepaid subscribers. Usage of voice traffic has been increasing due to the fact there are more postpaid subscriptions, but the usage of SMS and MMS is rapidly lowering. The main word in messaging part was taken over by applications based on internet usage (Viber, WhatsApp, Facebook Messenger, etc.). Today, life is unthinkable without applications which make us each day work much easier. For all of them, one thing has been in common: data usage. Figures tell how much data traffic has been increased in Serbian market:

**Figure 5:** Amount of data transferred in million GB (GPRS+UMTS+LTE)

Those graphs and numbers show that customer care became the most important thing in contact with customers. It is very simple – in Serbian market there are no new customers. Already every third man in Serbia has two mobile numbers. The market is saturated and new customer can be reached only if he decides to leave current operator and sign the contract with new.

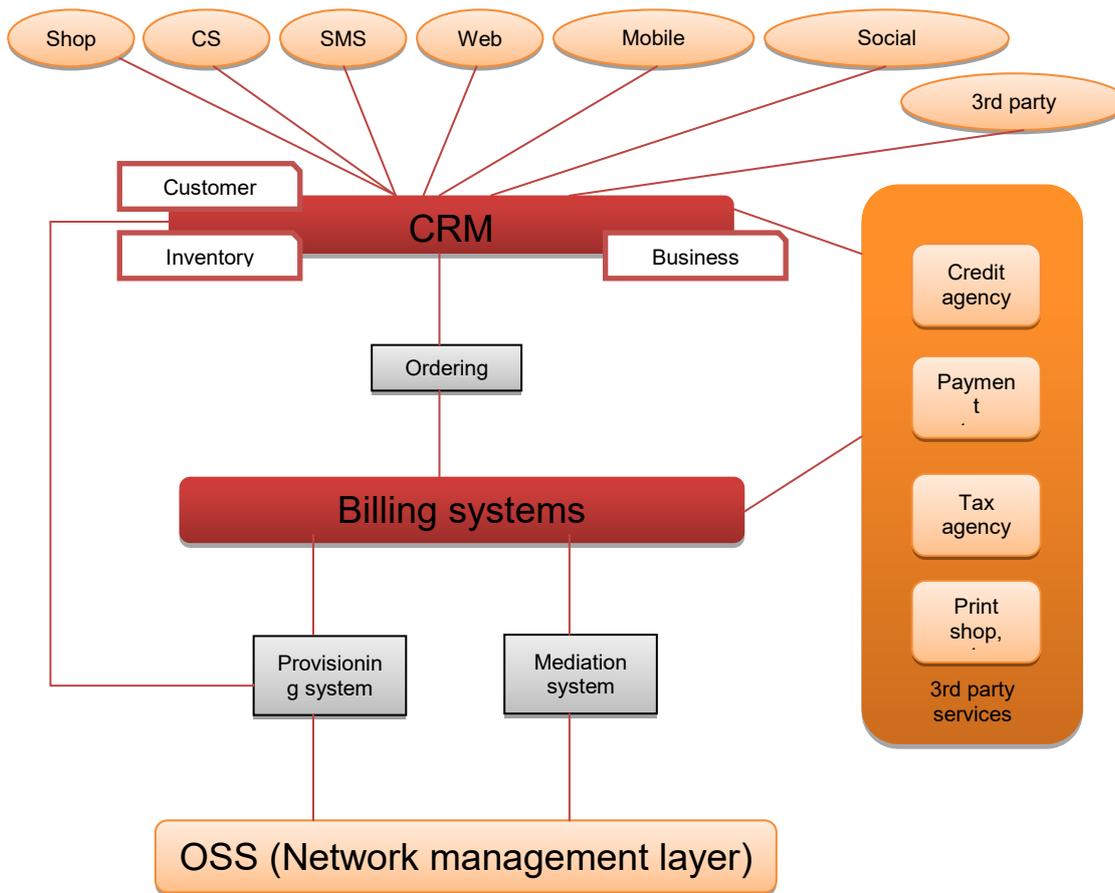

Need for good customer care and customer retention program puts CRM, as a process and as a tool, in the top of the list priorities in Serbia. And not just CRM, but CRM which can respond fast and with accurate data in every moment. It is crucial for communication with a customer that operator knows immediately about customer's action through any channel in order to afford appropriate support and answers to all possible questions.

The current implementation of CRM and whole BSS stack in Serbia is similar to the world's situation:

- No clear architecture design
- A lot of unnecessary interfaces causing spaghetti
- No automation of processes
- Time for launching products is too long
- No real-time data in CRM

#### 4. PROPOSED CRM ARCHITECTURE

One of the possible architectural designs is shown in the following the figure.

**Figure 6:** CRM centric architecture with omnichannel

Proposed architecture covers the most of pain points numbered in this paper. But, first of all, it is a way to answer on challenge how to cope with legacy systems. Idea is to put the right thing in a right place in order to let old BSS systems to do what they meant for. In shown case CRM is a place where all rules are implemented, CRM contains complete customer inventory and CRM is responsible for holding accurate customer data. This means that CRM is the only system which communicates with backend systems and all customer-facing systems should contact CRM in order to perform any action. No matter is it just check balance or activation of a new customer.

Good thing also is that introducing new solutions independent from the technology to BSS stack is possible and easy. That could satisfy a need for new revenue streams. If API which CRM expose is simple enough company can choose either to connect 3<sup>rd</sup> party apps or to create their own apps. Applications and channels mentioned in the previous figure are mandatory these days, but it should not be the end of story. Possibilities for creating new products with new technologies for one telecommunication operator are enormous.

The solution, of course, isn't perfect in all aspects. For this kind of implementation, it is very important to have stable and reliable CRM. Redundancy is mandatory as well as that system need to have more instances working in parallel, to be scaled in a good manner, to have great performances and very low response time. But even the most stable system sometimes goes down and no matter what backup processes need to be figured out. Backup solution by default brings disagreement in data so sync processes also need to be placed in order to support exceptions.

As it is already stated, today, in existing company, with all legacy systems, changing the way of business as proposed is not an easy job. It is very demanding to improve processes by changing systems with running a business as nothing happens. "In the online environment, the introduction and maintenance of CRM require a complex process of planning, analysis, strategy design and implementation" (Gurău, Ranchhod, & Hackney, 2003).

## 5. CONCLUSION

The assumption for a successful business is to have real-time communication and to manage interaction in a proper manner to all stakeholders (Despotović-Zrakić, Vasiljević, & Milinović, 2016). CRM is not a system which is important only for customer interaction but for all stakeholders, internal and external. Also, as (Lipiäinen, 2015) concludes: “CRM meant not only a technical solution to assist the customer process but also served as a modus operandi to take care of customers”. It would be great for one company if one CRM system could be set up as a wrap up of customer and interfaces with the customer. It would result in all information in one place. The following figure summarizes story about differences and roles of CRM in traditional manner and CRM in the digital age.

Also, idea is that company should establish good and clean BSS environment where each system will be optimized for its main purpose. The way of implementation has to follow market standards and market trends in order to have systems in an environment where it is easy to introduce a new product or even a new system. For example, for establishing new systems in the environment it would be helpful to create so-called northbound and southbound gateways. These gateways should be placed with a strict definition of the interface, followed by good documentation. Northbound gateway to be set up for connection of user interfaces. On the other side, southbound gateway to be designed for modular connection to backend systems. That approach would be very useful since new system will connect with only one legacy point which is already connected with all necessary backend systems.

Time-to-market for telecommunication companies needs to be very fast since that part of the industry is one of the most dynamic ones. Beside that lean BSS architecture is needed, introducing of configurable product catalog is must have at this moment. That kind of product catalog would allow shorter time-to-market for new products and services and let employees have time for exploring new technologies.

This paper is completely focused on digitalization, but important thing that in the era of digital transformation, communication companies surely should not marginalize phone call toward customer service or to any other – it is still the primary way of communication.

\*Corresponding author, e-mail: aleksandra.vukmirovic@bbs.edu.rs

**Abstract:** *This paper discusses Serbia potential in the domain of information and communication technology application in contemporary business with an emphasis on marketing function. The conducted research about the use of information and communication technologies in the Republic of Serbia and desk analysis, proved presence of the basic preconditions for steps necessary for implementation of digital marketing concepts for the everyday business of companies in Serbia, regardless of whether they do online business or not.*

**Keywords:** *marketing, internet, information-communication technologies, Big Data, research*

### 1. INTRODUCTION

There is a large number of professional and popular papers that emphasize something that is already intuitively recognized - a great influence of information and communication technologies (ICT) in modern business, starting with Joseph A. Schumpeter: Preface to Business Cycles, 1939 edition (Schumpeter, 1939; Zysman, 2005; Schermerhorn, Hunt, & Osborn, R., 2005; Applegate, Austin & McFarlan, 2007; Lukić, 2015; Van Grembergen & De Haes, 2009; Vukmirović et al., 2016; Vukmirović, 2017).

Of course, Serbia as a candidate for EU membership and participating in negotiation process has also become influenced with the global economic flows. The indicators that show the level of technological development in Serbia are summarized through the following indicators (Digital Innovation Profile Serbia, 2018):

- ITU Global ICT Dev. Index 2017: rank 55 /176, score 6.61 /10
- Global Innovation Index 2017: rank 62 /127
- Innovation Efficiency Ratio: ratio 0.6; rank 67 /127
- Business Sophistication & Innovation: rank 110 & 95 /138
- Global Human Capital Report 2017: rank 60 /138

Main goal of the research presented in this paper is to determine the potential for the implementation of the modern ICT technologies in the Republic of Serbia. Research indicates the need for adopting the legal regulatory, specific laws and normative acts for implementation of data science technologies.

The results of the existing research indicate the significant potential that new technologies bring to the Serbian economy. Observed through the use of Internet technologies and social media, Serbian citizens are already using high-speed internet with the help of available technologies and services (primarily used to search information about goods and services and for reading online newspapers and magazines). There is a growing presence of both individuals and businesses on social media. The use of social networks such as Facebook and Twitter is steadily increasing in Serbia. When it comes to companies (enterprises) in the Republic of Serbia, research shows great interest and great dispersion in the use of ICT in everyday business (Kovačević, Pavlović, & Šutić, 2017).

The conclusions that we considered are based on the analysis of the existing research, primarily one about the use of information and communication technologies in the Republic of Serbia, which was conducted by the Statistical Office of the Republic of Serbia in 2017, according to Eurostat methodology, on the territory of the Republic of Serbia, on a sample of 2800 households/individuals and 1655 enterprises.

The reference period for most of the questions given to companies was January 2017, while some of those referred to the entire 2016. It is important to emphasize this fact considering the speed at which certain technological solutions are being implemented in everyday business. The analysis also used the results of studies of Digital Innovation Profile Serbia centric ICT innovation ecosystem snapshot National Expert Assessment conducted by the Innovation Division of the ITU Telecommunication Development Bureau.

Recommendations derived from this study for further development of the ICT sector are accepted and we await its implementation

## **2. MARKETING CONCEPT IN THE MODERN ERA**

Decades back, the former small businesses that had few customers, produced only one type of product, and offered it on the market always in the same way. With the development of industry and technology, there was a need for expansion. In this endeavor to expand, there have been major problems in the market research. Companies have struggled for long to find an appropriate system for collecting information about their customers, products and services, and at the same time attempted to solve the problem of storing the information they collected. Even if they collected the necessary data, it took hours, days, and even months to process and analyze them.

These problems are not limited to the field of production, the problem of analysis and data management is manifested in all spheres of today's business, such as medicine, astronomy, politics, etc. The big problem is that we are facing with an increasing number of data, of which only 20% are structured and stored in rational databases, while the rest of the data (documents, images, videos...) stays unstructured. Companies need to consider different types of data sources. Some of them are sensors on which machines generate specific data, while other sources of information are those generated by people, such as data from social networks or click-stream data from different websites. In addition, the continuous development of technologies and mobile devices leads us to new data sources.

Digital data from a rapidly growing number of new technological data sources, such as mobile devices, social media and other digital applications are flooding the world. The advancements in computational, storage and analytical technology, as the tools necessary to handle and use that flood of data are now becoming available and more economical (Radenković et al., 2017).

The combination of enormous volumes of digital data and technological advancement are creating the new Marketing Era – Era of Big Data in Marketing (Apilleti & Forno, 2014; Aquino, 2012; Arthur, 2013).

Big Data is data so large, varied and dynamic that it cannot be handled by conventional data processing technology. By using advanced technologies to combine and analyze this type of data, information can be made visible that was undiscoverable in the past. According to authors, such as Mayer-Schönberger and Cukier (2013), firms, government and science can significantly benefit from this revolutionary way of knowledge discovery.

The private and science sectors are starting to use new technologies such as Big Data in their everyday marketing activities. Big companies from retail, such as Walmart (Bryant, Katz, & Lazowska, 2008), Sears (Henschen, 2012), and Amazon (Kelly, 2013) are now using Big Data in an attempt to better understand the customers and their purchasing choices. Nowadays financial institutions are using Big Data to accurately predict behavior on the market and investment performance. Online companies like Google, eBay, Alphabet (Amazon) and Facebook have created their marketing models based on the huge volumes of digital data determined on individuals' behavior, sentiment, information requests and preferences.

Regardless of the problem of the unauthorized use of private data by third-party companies facing Facebook these days and issues related to unfair competition due to the dominant position in the market, these large companies have established rules that the rest (followers) have to follow or at least try to get out.

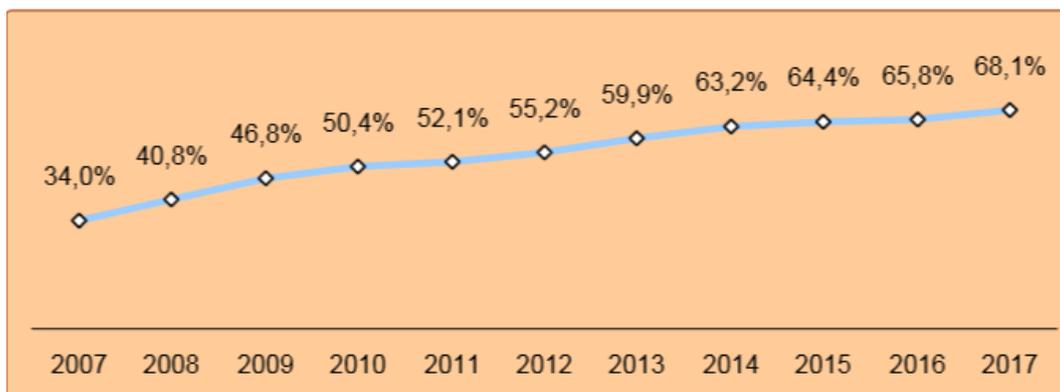

In addition, in view of generating a large number of diverse data, companies are facing the problem of storing and analyzing large amounts of data, collected from different sources, in different formats. When we have so many different types of data, it is impossible to manage the data in a traditional manner. Data management needs to be thought differently, and that is exactly why we believe we entered the Big Data Marketing Cycle. Big Data enables companies to collect, manage, process, and store large amounts of data at high speeds. Big Data is a combination of evolution of the technology from 50 years ago.

## **3. ICT POTENCIAL IN THE REPUBLIC OF SERBIA**

According to the research entitled Use of Information and Communication Technologies in the Republic of Serbia, conducted by the Republic Statistical Office in 2017, in accordance with the Eurostat methodology, on the territory of the Republic of Serbia, on a sample of 2800 households / individuals and 1655 enterprises. The reference period for most of the questions asked to companies was January 2017, while some issues were related to the entire 2016. This is important point, taking into account the speed at which certain technological solutions are implemented in every day's' business.

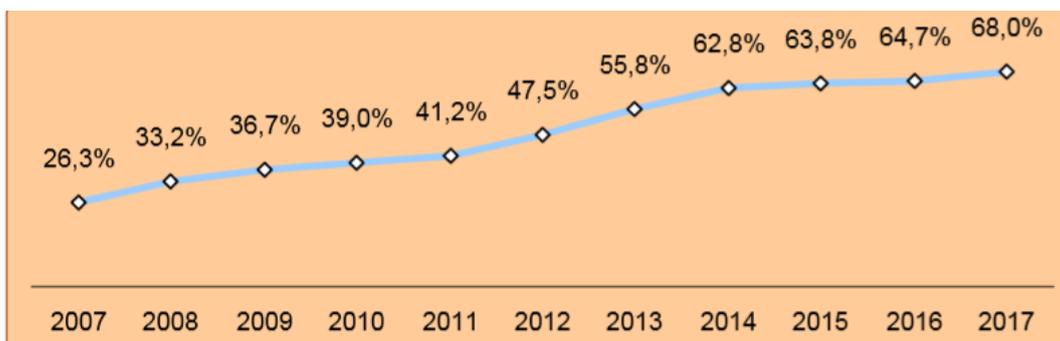

Profile of the Serbian household in the field of ICT applications: 90.5% of households own a mobile phone.

Serbia has some of the highest penetration rates for mobile services in the Balkans and a competitive mobile market with three competing operators. The fixed telephony market has been liberalized relatively late (in 2010). The penetration of fixed broadband access to the Internet is still relatively low compared to the European average. The FTTH (fiber to the home) Council in Europe has recognized Serbia for reaching a commendable penetration of FTTH levels in excess of 1% (Digital Innovation Profile Serbia (2018) - ICT centric innovation ecosystem snapshot National Expert Assessment, Innovation Division of the ITU Telecommunication Development Bureau). 68.1% of households in Serbia possessed at least one computer in 2017, which was an increase of 2.3% as compared to 2016 (Figure 1) (Kovacevic, Pavlovic, & Šutić, 2017).

**Figure 1:** Percentage of households in Serbia owning at least one computer, per year

Computer use in households varies depending on traditional demographic factors: territorial integrity, standards and education of the household head. The biggest gap in the presence of computers in households is present when the stratification is done according to household's monthly income. Households with above-average monthly income (over 600 euros) own a computer in over 95% of cases, while the shares of households with income lower than average (up to 300 Euros) is only 50%. This data indicates that potential consumers with higher purchasing power in Serbia are virtually completely online. It is similar with the penetration of the Internet in households, where it was noted that 68% of Serbian households have an internet connection in their homes (Figure 2).

**Figure 2:** Percentage of households in Serbia having an Internet connection, per year

As a reason they do not have internet access at home, the 70.0% of households said there was no need for the internet, 24.4% of households stated that equipment is expensive, while 22.8% of households said they lack the skills.

The method of accessing the Internet (types of connection) in households is shown in Figure 3. It is important to emphasize that 61.9% of households in Serbia have a broadband internet connection. Also, there is a growing presence of mobile devices with access to Internet services, which is in line with global trends. That fact points out what is the direction for development of integrated marketing programs in these regions.

The habits of Internet users in Serbia are increasingly moving from information to communication - social media and making calls (voice and video), while, roughly a quarter of the online population uses internet technology for purchasing and little less than that for online banking.

The survey found that almost 20% of the internet population in Serbia finds a way to store an ever-increasing amount of data that they manipulate on a daily basis, either for private or business purposes, using cloud technologies (Google Drive, Dropbox, Windows Skydrive, iCloud).

When it comes to companies in Serbia, it is important to emphasize that 100% of companies use a computer in their business. In addition, 81.9% of enterprises use mobile broadband internet connection (3G or 4G) with usage of portable devices.

80.4% of companies operating in Serbia owned the website in 2017. (93.6% of the big size, 92.1% of medium-sized enterprises and 76.9% of small businesses own a website).

Observing B2B transactions in Serbia it can be concluded that:

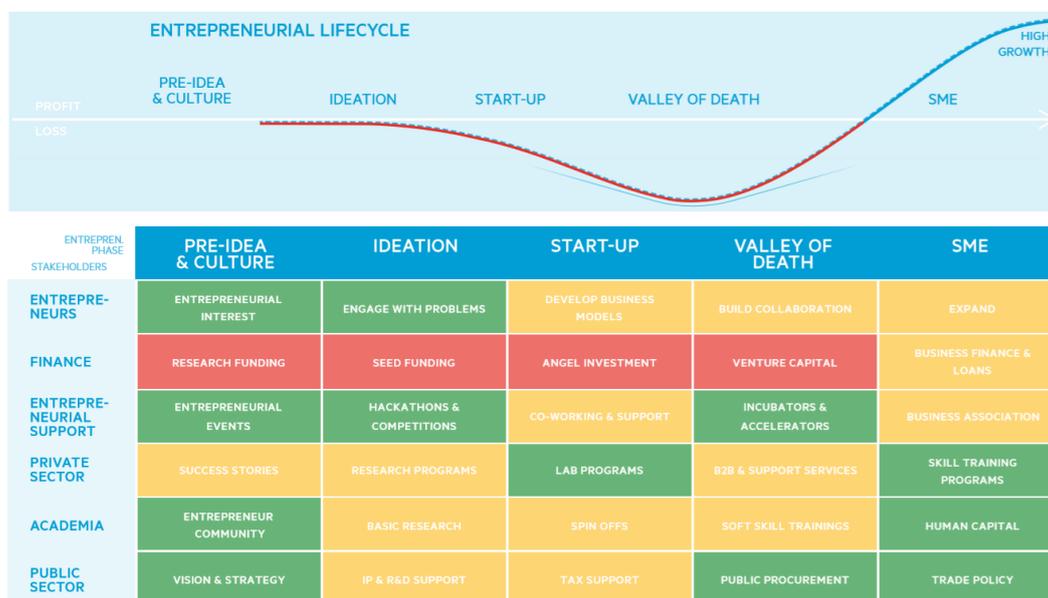

- 41.4% of companies in 2016 ordered products / services via the Internet
- 23.8% of companies during 2016 received orders via the internet.

Social networks are increasingly present in everyday business in Serbia – 39.2% of companies used one of the social networks for their business needs.

Willingness to use open-source operating system has stagnated in recent years, and in 2017, 20% of the companies use open-source Linux operating system, which is at the level from 2013. It is interesting to note that large enterprises are leading in the use of open-source technologies in Serbia (41%). 9.3% of companies in Serbia use cloud-based services which are paid on the Internet.

#### 4. FURTHER STEPS

These results indicate that there is no time for waiting- Serbian companies must take a step. Serbia's small core of highly-skilled and experienced IT development companies can generate growth and opportunity, helping Serbia's brands to become attractive to foreign investors, and inspiring other IT firms in the country. Major areas of strength for Serbian companies are financial services applications and industrial applications / process control. Serbia is starting to emerge as a distinct and positive brand in these areas (Digital Innovation Profile Serbia, 2018).

**Figure 3:** Innovation Journey Map – Serbia (Digital Innovation Profile Serbia, 2018)

If we begin with Innovation Journey Map – Serbia we see that the Innovation Journey Map sets out the work that needs to be done within the ecosystem in order to harness innovation on a transformative journey from pre-ideation to high growth. It describes each stakeholder's role (green), inadequate (yellow) and missing / weak (red.) Figure 3. We can conclude that the digitization of the Serbian language market place has taken great power. The fact that much has yet to be done just, still gives a chance for those businesses which have not been part of this process to catch their last chance to do so.

## 5. RECOMMENDATION FOR ACTION

Regardless of the limitations and perhaps disappointed expectations by some, Serbian companies had to welcome influx of new (big data and other) technologies.

Further Steps on micro level:

- Creating Strategic Documents - Big Data and AI Initiative,
- Open Data; Developing private-public-academic partnerships
- Education - education system - including dual education - not only for highly qualified

Further Steps on macro level:

- Companies cannot achieve all this alone. It is on the state to help them
- What has been done so far by the state (Digital Innovation Profile Serbia (2018))
- Connecting schools to AMRES (Academic Network of the Republic of Serbia)

The recently launched initiative 'Development of ICT infrastructure in education, science and cultural institutions' is in the process of connecting all schools in the country to the Academic Network. 1800 institutions in Serbia receive free and secure internet, active protection, and online support, including access to international electronic education services.

The 'Smart and Safe' platform, recently launched by the Ministry of Trade, Tourism and Telecommunications, aims to raise awareness of the importance of citizen engagement with the education system and the greater digital economy. The platform launches educational and promotional projects designed to support digital literacy, digital competencies and digital security culture throughout Serbian society.

The National contact center for the children safety on the internet, launched by the Ministry of Trade, Tourism and Telecommunications is based on regulations governing the protection and safety of children using new technology. This unique resource offers advices, help, information and research to children, parents, teachers and other relevant individuals in regard to online safety.

Digital Innovation Profile Serbia (2018), ICT centric innovation ecosystem snapshot National Expert Assessment, among the others states that the Republic of Serbia should support the ICT sector in its effort to succeed in this matter (Digital Innovation Profile Serbia 2018):

- Economic results and other data indicate the necessity for government's action in support of the ICT ecosystem with following:
- Establishing incentive structures as part of an environment designed to help ICT innovation converge with other technological innovations – with the clear objective of overall strengthening of the Serbian ecosystem.
- Affordable and accessible high-speed broadband is an important enabler for competitiveness across many areas including education, health, entertainment – and for general social cohesion. This places Serbia among countries that need to develop broadband infrastructure further and promote digital technologies in business.
- The primary objective of the Republic of Serbia is to achieve sustainable and dynamic economic development across technology and manufacturing in line with European Union targets, while able to withstand competition from its members. To achieve this, the government has adopted a number of strategies designed to boost ICT and progress towards a knowledge-based economy. The 'Strategy for the Development of Next Generation Networks (NGN) in the Republic of Serbia to 2023' has been drafted, which includes fibre as an essential element of the future infrastructure to meet growing demands for bandwidth.

## 6. CONCLUSION

Finally, it can be concluded that modern approach to marketing undoubtedly indicates that the development of marketing functions is directly correlated with the development of information and communication technologies, and that the results of the research indicate that this degree of dependency will increase even further. The perspectives of Serbia cannot be seen in a different way, which is also shown in the analysis of the research that has been synthesized in this paper, that further on points to the necessity of applying modern information ICT in everyday business and marketing. Internet and mobile technologies, Big Data and further development of artificial intelligence will accelerate the application of modern (not only informational) technologies in everyday business. This implementation has already encompassed all the spheres of a modern society, and not only in areas where expansion primary happened, such as social media. The boundary between online and traditional business (brick and mortar) is being lost increasingly. Amazon, for example, switched from e-business to other more profitable spheres of business, such as film production.

The car industry records show dramatic changes, which are not only characterized by the transition to a new motor fuel, but also by the basic service - switching from the purchase of cars as a vehicle to the future car that becomes a means of communication. Airbnb, Uber, Tesla and numerous successful start-up companies point out that business models based on new technologies dramatically change the traditional ways and philosophy of business. They have also accelerated development of infrastructure (Big data, cloud, mobile platforms and the use of business intelligence (BI), which, on the other hand, leads to the abolition of existing and creation of new, different jobs). Also, Crypto currencies change the basic operating premise of global economy.

This paper recommends the legal and strategic frame for the usage and implementation of data science technologies on institutional level and by private sector companies. Research has indicated the need for updating the education system in order of better implementation of e-business technologies such as Big Data, artificial intelligence and etc. Framework methodology for the development of Big Data concept for conducting research in the Republic of Serbia was presented.

By considering the objectives of the digital sector in Serbia (see (Digital Innovation Profile Serbia, 2018), it can be concluded that companies in this region have yet to capture a connection with the European average standards.

# MOBILE APPLICATION DEVELOPMENT FOR INTEROPERABLE LOYALTY MANAGEMENT SYSTEM

Natasa Paunovic\*<sup>1</sup>, Nenad Anicic<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, e-mail: natasa.n.paunovic@gmail.com

---

**Abstract:** *This paper presents an approach for development of interoperable mobile loyalty application that resolves three aspects of interoperability: syntactic, semantic and technical. The main goal is to develop loyalty management system as an interoperable and digital system. This system will allow the development of different applications and enable communication with various loyalty programs provided by different companies. The case that is being considered is implementation of loyalty mobile application in Android OS. This application uses mobile application architecture as one of interoperability frameworks. This type of architecture helps to connect all participants in loyalty management system and makes data exchanging process between them much easier. Some significant features are described in implementation of a loyalty application.*

**Keywords:** *interoperability, loyalty system, Mobile application architecture, Android, qr code*

## 1. INTRODUCTION

Loyalty system can be understood as a new business philosophy and a strategy, which allows getting new customers, retaining the trust of customers, personnel and partners in the process of mutually beneficial cooperation based on participants' voluntary actions. The main idea through this cooperation process with customers, personnel and partners is to offer them product or service that will satisfy their needs (Jokinen, 2014). Existing loyalty systems are composed of different applications that are independently built (at different times, by different teams, using different technologies). There are problems in the exchange of data when more applications are in the interconnected relationship. Development of interoperable applications solves problems in exchanging data.

There are various software solutions for loyalty programs, which are integrated and which are not considering the aspect of interoperability. Related work (Software Advice, 2018) presents lists of software with customer loyalty programs, focusing on specific company. Our goal is to develop the loyalty management system as an interoperable system. This system would allow the development of various applications and it would enable communication with different loyalty programs, provided by different companies. We also strive to be innovative and to reinforce technology in a modern way. To achieve this, we use mobile application architecture to innovate processes and business models.

The term "interoperability" is defined as the ability of two or more systems or components to exchange information and to use exchanged information (Benson & Grieve, 2016). In the context of business applications, interoperability is defined as the ability of a system or product to work unmodified with other system or product, without the need for special efforts from the user (Techtarget, 2018).

The interoperability is categorized in two basic categories: syntactic and semantic interoperability (ECOTECH, 2018.). If two or more systems are capable of communicating and exchanging data, they are exhibiting syntactic interoperability. Specified data formats and communication protocols are fundamental. XML, JSON or SQL standards are some of the tools of syntactic interoperability. This is also true for lower-level data formats, such as ensuring alphabetical characters are stored in a same variation of ASCII or a Unicode format (for English or international text) in all communicating systems. Semantic interoperability is the ability of two or more systems to exchange and automatically interpret the information, exchanged meaningfully and accurately, in order to produce useful results, defined by the users of both systems. To achieve semantic interoperability, both sides must refer to a common information exchange reference model. (Ecotech, 2018.)

This paper represents the possible approach, through the example of the implementation of modern mobile architecture, to provide the answer to the question of the problem of interoperability. This work certainly would not be possible without defining a real problem, which has been mentioned in Section 2. Proposed approach and the mobile application architecture have been discussed in Section 3, while implementation of loyalty mobile application and most of the code excerpts with detailed picture have been given in Section 4 of the paper. Conclusion and potential further work are presented in Section 5.

## 2. DESCRIPTION OF THE PROBLEM

This section describes problems that need to be resolved, so we can achieve interoperability of applications. One of them is a problem of description of real system for loyalty programs.

Nowadays, people use some loyalty program daily. In general, they get traditional paper or plastic card that identifies the card holder as a participant in a loyalty program. Unfortunately, people usually forget where they put their cards or they simply lose it. In addition, there are a lot of loyalty programs and people are participating in more loyalty systems by different companies. As a result, they are losing interest in loyalty card programs.

Also, companies or facilities that offer loyalty programs to their customers, don't have well-developed monitoring system and access control for customers and employees.

Therefore, there is a need to develop a loyalty application that should be interoperable and distributed (Figure 2). Loyalty application would enable communication between customers and agents from central Loyalty Management systems. Also, it's necessary to provide communication between agents of different companies that could cooperate together and provide some discounts or rewards for customers. This would require companies to agree with a form of cooperation or a contract that defines a discount or a reward. For customers, it is important to have more cards from different companies, that provide different loyalty programs. They want to have an insight into their own card transactions and they want to be able to monitor history of their transactions.

Loyalty application should have some features such as: recording transactions, different rewards based on customer, partner, program, tier and product, web portals for administration, standard email and communications set up within the program (Simplicity, 2018).

There are three main entities in the loyalty system: customer, loyalty application and point-of-sale. Customer uses mobile device to access loyalty application in order to see his different cards with stamps. Companies provide loyalty programs and define rewards and discounts for customers. Point of sale are places that execute giving stamps to customers. Point of sales can be distributed across different regions and they communicate to each other, if they belong to the same region. Gateways are agents that enable communication and synchronize data between central end points and point of sales. The loyalty application is connected through gateway and it exchanges data with point of sales.

The loyalty application should cover three aspects of interoperability on technical, syntactic and semantic level:

- Technical interoperability: At this level of interoperability, there are communication protocols for data exchange between the systems and through those the communication infrastructure for the exchange of bits and bytes happens. The basic networks and protocols are defined unequivocally.
- Syntactic Interoperability: If two or more systems are able to exchange data, they show syntactic interoperability. There are basically defined data formats and communication protocols. Examples of syntactic interoperability are XML and JSON standards. Syntactic interoperability is required for ensuring a higher level of interoperability.
- Semantic interoperability: Ensures that two or more computing systems are capable of exchanging information automatically, in a meaningful and precise way and to interpret shared information, so that useful results would be produced, in accordance with the requirements of end-users. To achieve semantic interoperability, both parties must respect the reference model for information exchange. During the exchange of information, the content requirement is definitely defined: a set of sent information, in terms of meaning, must be recognized and mapped into a set of information received (Kubicek, 2011).

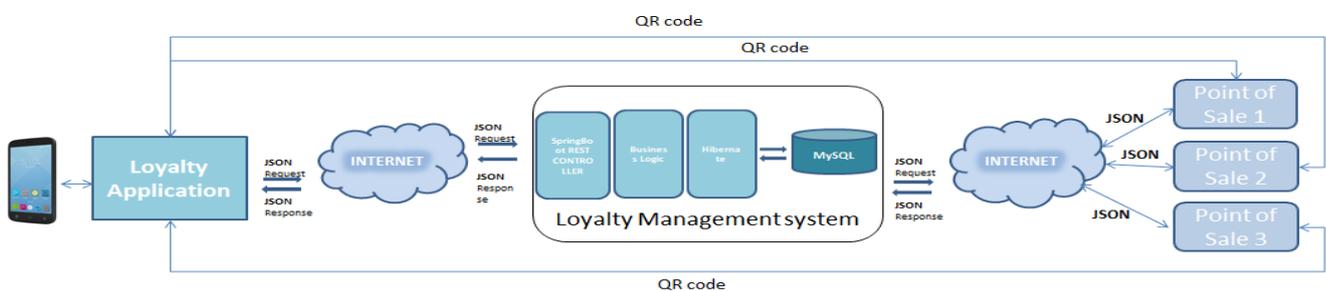

## 3. PROPOSED APPROACH

There are several ways to achieve interoperability. Generally accepted ways to solve interoperability issues are: standards, interoperability frameworks, frameworks for the architecture of company information systems; semantic technologies based on ontologies, as well as the service orientation (Tu, Zacharewicz, & Chen, 2016).

Following steps, in order to solve interoperability problems of applications, are:

- Need to define logical and physical design of information system. Logical design of an information system is an abstract representation of the data flows, inputs and outputs, while physical design relates to the actual input and output processes of the system.

- Using framework for interoperability. The interoperability framework can be defined as a set of standards and guidelines that describe the way in which organizations have agreed or should agree to cooperate together. The interoperability framework is not a static document, but over the time, it must adapt to changes in technologies, to standards and administrative requirements (EUROPEAN COMMISSION, 2017). Framework for interoperability is a part of the architecture of information systems and it deals with the integration and connection of elements. In this paper, focus will be on mobile application architecture, due to the need to make the application available for customers.
- Create interoperability gateway. The interoperability gateway is a channel designed to interface the Internet Protocol (IP) network with applications. Applications are connected to HTTP protocol and data can be interchanged.
- Mapping and data transformation. Data transformation is the process of converting data from one format (e.g. a database file, XML document or Excel sheet) to another. Data transformation is necessary to ensure that data from one application or database is intelligible to other applications and databases, which is a critical feature for applications' integration. The first step of data transformation is data mapping. Data mapping determines the relationship between the data elements of two applications and establishes instructions for the way the data is transformed from the source application before it is being loaded into the target application. In other words, data mapping produces the critical metadata that is needed before the actual data conversion takes place (MuleSoft, 2018.).

**Figure 1:**An approach proposed for mobile application development for interoperable loyalty management system

Based on mobile architecture, loyalty application should cover all loyalty programs provided by different companies. On the Figure 1, you can see a mobile application, connected with Loyalty Management system via IP gateway. In addition, the loyalty application communicates with point of sale through different qr codes. Point of sales have data for their own customers and they provide synchronization data with Loyalty Management system. Transformation of the data is released by using JSON format and REST service. Loyalty Management system is independent application which consists of business logic layer, REST API service and database layer. Database layer communicates with MySQL database.

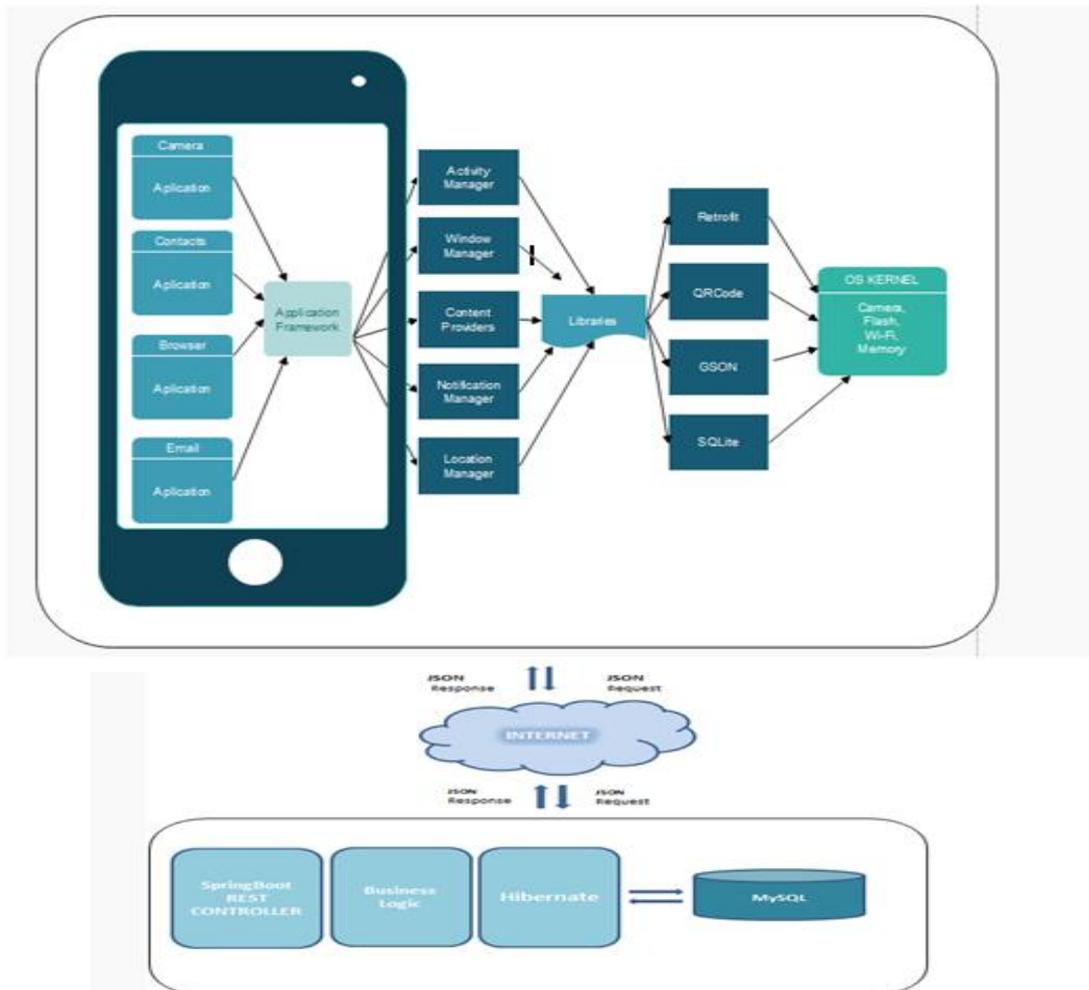

### 3.1 Mobile application architecture

Mobile application architecture is one of the aspects of general architecture. The applications should be implemented in a syntactic, semantic and technical way that leads to interoperability improvements. Mobile application architecture is used as the main part of the interoperability framework and the focus will be on it. In the other hand, server architecture will be presented on abstract level, in order to show how mobile application architecture solves interoperability issues in technical, syntactic and semantic level, using interoperability gateway.

Mobile application architecture, consisted of application, application frameworks, libraries and kernel, is shown in Figure 2. Applications can be divided into two parts – native apps that provide OS and user apps. In the Figure 2, presented are the applications such as camera, contacts, e-mail and browser. The application framework provides many higher-level services to applications. This framework implements the concept that apps are constructed from reusable, interchangeable and replaceable components. This concept has been taken a step further in a sense that application is also able to publish its capabilities along with any corresponding data, so that they can be found and reused by other applications. The application framework includes the following services: Activity Manager which controls all aspects of the application lifecycle; Window Manager handles screens; Content Providers allows applications to publish and share data with other applications; Notifications Manager allows applications to display alerts and notifications to the user; Location Manager provides access to the location services, allowing an application to receive updates about location changes (Techotopia 2016.). Libraries provide support for tasks such as string handling, networking, file manipulation, scanning, database access etc. They are specific for mobile development and they differ in the OS. Kernel OS provides a level of abstraction between the device hardware and it contains all the

essential hardware drivers, such as camera, wi-fi, display etc. Also, the kernel handles all the things, such as networking and a vast array of device drivers, which resolves the issue of interfacing to peripheral hardware (Techotopia, 2016).

In the middle of the Figure 2, there is a gateway which connects mobile and server side. Gateway uses network connection standards such as HTTP protocol (Podila, 2013) and provides exchanging data at the technical level. On the bottom of the Figure 2, server that gets requests, transforms data, extracts data from database, makes and sends response to mobile application is represented. This way, it covers interoperability issues on syntactic level by using JSON data interchange format. On the both sides, a common model of designed information system is applied. This model represents agreement between all applications on terms, that they can semantically parse. That way, it resolves interoperability issues on semantic level.

**Figure 2:** Mobile application architecture

#### 4. IMPLEMENTATION OF LOYALTY MOBILE APPLICATION

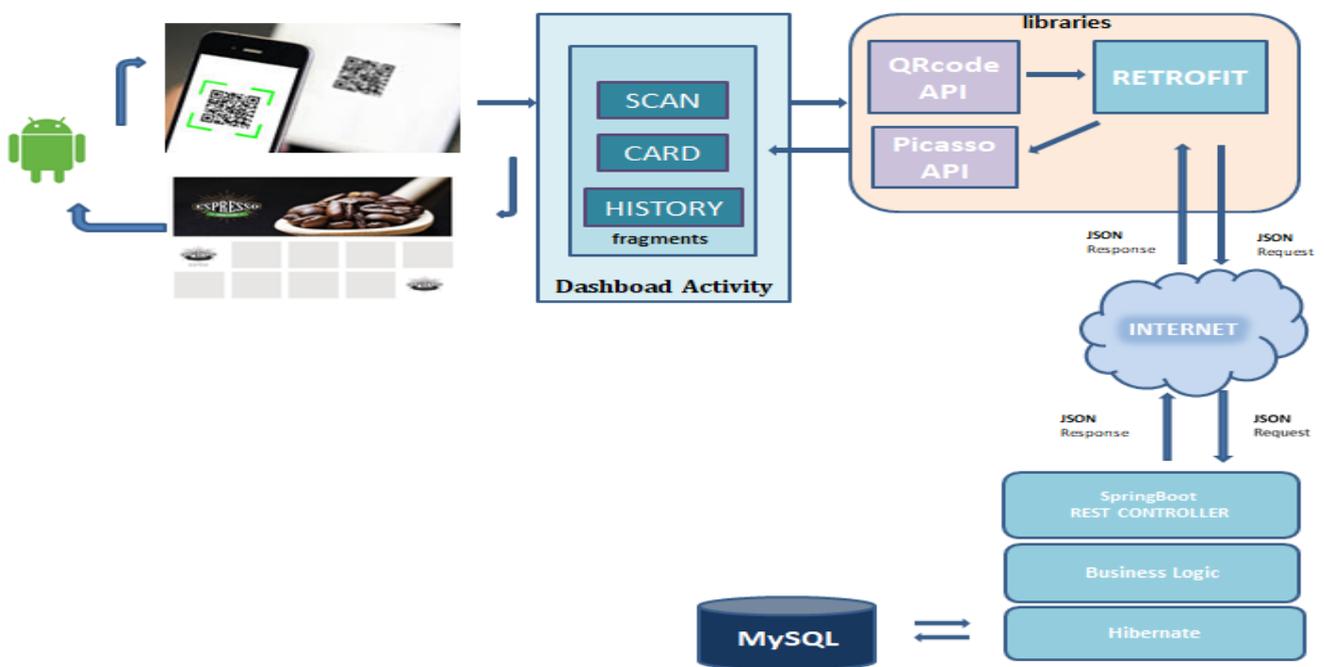

In this section is demonstrated implementation of mobile loyalty application based on Android OS. The mobile application becomes an important software delivery model which integrates front-end user interfaces with back-end RESTful services (Ma, Li, Fan, Lee, & Hsueh, 2016). The loyalty application uses mobile application architecture as framework for interoperability. Logical and physical design was used to develop the methods and model for enhancing interoperability among applications. In general, it is needed to define standard model which will describe state and behavior of observing system.

Implementation of loyalty mobile application resolves interoperability issues of applications on technical, syntactic and semantic level. Figure 3 shows simple overview of the loyalty application in Android OS. The loyalty application is useful and simple solution that represents a digital platform, where every employee could have his own digital signature and where he could set his stamp on customer's account. This application helps digital transformation, which means conversion of analog physical objects, such as

traditional paper or plastic card, into digital objects on mobile device. The loyalty application is consisted of different loyalty programs provided by different companies. Customer with mobile device and installed app goes to some stores and when he scans QR code for the first time, he gets a ready card, with validated stamps by server.

On the Figure 3, Android user who scans QR Code is presented. The loyalty application uses QRCodeReaderView application as an internal project to provide scanning. This includes Camera API, which is specific for OS kernel. When user scans code, the value is taken and sent via Retrofit. Retrofit library provides API calls and processes requests and responses. Format for data exchange is JSON. On the server side is REST controller, which serves user and communicates with business logic layer. On business logic layer, the common model is defined, that has shared data dictionary and defined types of data. This model helps the transformation of data between mobile application and server-based application. Hibernate layer communicates with MySQL database, executes SQL queries and mapping properties.

When QR code is validated, server makes JSON response with stamp and sends customer's card as an object. This object is rendered by Picasso library and shown as card with stamp on the customer's user interface. Customer has a lot of cards from different companies. Also, customer in app installed on his device can see histories of his rewards or discounts.

**Figure 3:** Loyalty application with main focus on mobile application architecture

#### 4.1 Realization

The loyalty application is implemented in Android OS. When an application is created, build system automatically takes all the source files (.java and .XML), then applies the appropriate tool (for example, gets java class files and converts them to Dalvik Executable files with .dex extension) and groups all of them into one compressed file with APK extension. Significant part for developers is build.gradle (Module:app), which sets default configuration, such as minimal version of Android system on which the application can be installed, version name and code, build types. Build.gradle tool determines and imports the dependent libraries such as Retrofit, Picasso, Card View etc.

The settings.gradle file is located in the root project directory and executed before any build.gradle and even before project's instances are created. The settings.gradle informs gradle which modules it should include when building the app. In addition to the standard app module, qrcodereaderview module is also included.

```
include ':app', 'qrcodereaderview'
```

Below it will be explained how to interoperate these two modules in process of scanning qr codes.

- QRCodeReaderView class uses ZXING lib (Barcode Scanner) and integrates a QR decoder view. In this class, methods such as: start and stop camera using by CameraManager; set autofocus interval, set front or back camera and creating a qr code reader are implemented. Also, listener is specified and listens when qr code is read.

```
Public class QRCodeReaderView extends SurfaceView implements SurfaceHolder.Callback,
Camera.PreviewCallback { public interface OnQRCodeReadListener { void onQRCodeRead(String text,
PointF[] points); }
```

- In the ScanFragment (Figure 4) class of loyalty app, QRCodeReaderView is defined and OnQRCodeReadListener is implemented.

- QRCodeReaderView represents view for user's interface and it is defined in XML format.

```
<com.dlazaro66.qrcodereaderview.QRCodeReaderView android:layout_margin="10dp"
android:id="@+id/qrdecoderview" android:layout_width="match_parent"
android:layout_height="match_parent" />
```

This view in fragment is defined and binded using ButterKnife annotations

```
@BindView(R.id.qrdecoderview) QRCodeReaderView qrCodeReaderView;
```

- OnQRCodeReadListener override onQRCodeRead method which gets value of scanned qr code. After that, given value is sent to server that will check it and validate it.

```
@Override public void onQRCodeRead(final String text, PointF[] points) {
LawaApp.getApi().scanning(Constants.CLIENT_TYPE, LAWAPref.GENERAL.getPref().getString(Keys.UserK
.ID), TimeUtils.writeDateAndTime(dateTimeNow), text.trim(), clientGroup, new Callback<List<Scan>>() {}}
```

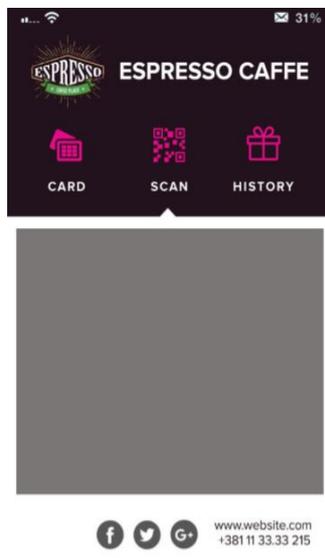

Figure 4: Screen fragment

## 5. CONCLUSION AND FUTURE WORK

This paper presents an approach for development of interoperable mobile loyalty application that resolves three aspects of interoperability: syntactic, semantic and technical. Proposed approach has several steps. First of all, it is necessary to pass through the logic and physical design of the IS to determine the state and behavior of the system that is being observed. The ultimate goal of design is to get a common standard model through which applications can communicate and share data. Following, to apply framework in this case of mobile architecture and to define gateway for transmission data. The last step is making decisions how to map data between applications.

To verify proposed approach, an example of the mobile application is presented. It is a loyalty application implemented in Android OS. The main focus is on mobile application architecture, but it also describes cooperation with server side. It is shown as an implementation of one functionality of mobile application: scanning qr codes. The loyalty application has also local database which synchronizes data with server when is in offline mode. In that case, it implements two gateways, one with loyalty application on mobile side and two with server side. This feature enables the user to use application without Internet. The development of application core took about two months, gathering materials and implementation took additional ten days, while the extra week was spent for fixing bugs and code optimization.

There are several ways for future development. In one of the following stages, it's planned to create a location service for getting current user's location, based on mobile application architecture which will be interoperable with loyalty application. Location service feature can offer customers discount and deals when they check in, walk into a store and scan their qr codes. Also, there is a concept of an application with recommendation service. For example, this app may recommend location of the store to customer, if he is near it and it can provide discount that way.

# SAFE AGILE FRAMEWORK IN E-BUSINESS PROJECT MANAGEMENT

Jelena Mihajlović-Milićević\*<sup>1</sup>, Zorica Bogdanović<sup>1</sup>, Marijana Despotović-Zrakić<sup>1</sup>  
<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia  
\*Corresponding author, e-mail: jm0302@gmail.com

**Abstract:** *The aim of the paper is to explain the fundamental concept of Scaled Agile Framework (SAFe) and to help to understand which methodology should be used in project management in e-business. A large number of organizations has published and claimed to be "agile" or to plan to use the agile method, but there is some confusion regarding using of this concept. The main goal of the paper is to clarify what SAFe actually means and which necessary steps must be performed toward SAFe implementation. Also, this paper analysis risks which must be taken into account during the design and implementation of SAFe. The focus has been given on SAFE implementation in software projects. In conclusion, the benefits of implementation of SAFE in large organizations are described.*

**Keywords:** *Scaled Agile Framework, project management, Agile Release Train, agile methods, SAFE implementation, Scaled Agile, Inc.*

## 1. INTRODUCTION

The goals of the paper are to show the framework for scaling agile principles, its key elements and factors, to explain the benefits of managing projects in e-business using SAFe, and to clarify briefly the implementation of SAFe. Understanding the methodology such as SAFe, and its implementation in proper manner in e-business opens the plenty of possibilities and provides a foolproof opportunity for continuous success and maintaining competitiveness in the global market.

One of the first decisions we face when launching each project is "What development methodology should we use?". Agile methodologies have begun to develop 15 years ago. Agile is a specific type of rapid development and it is newer than the "traditional" waterfalls (Lotz, 2013).

A large number of organizations has published and claimed to be "agile" or to plan to use the agile methods. Agile software development has made a quiet revolution in project access and management. Due to the general trend of accepting optimization and reduction of activities which are not of a high priority and do not bring value, agile methods are most often well accepted by the senior management and the project team (Jovanović, 2017).

Implementation of agile methods significantly alleviates organizations to develop software for customized services and products in e-business. By using agile methods, organizations gain a competitive edge and the ability to adapt to current market trends. Furthermore, in this way the organizations can even improve their flexibility.

Scaled Agile Framework is an agile framework for project management. The product is made by Scaled Agile, Inc. In Scaled Agile Inc. SAFe development activities are based on the key belief that: "better systems and software make the world a better place." Their mission is to help those who build these systems through the development and publishing of the SAFe framework, as well as through the accompanying certification, training, and courses ("What Is SAFe?", 2017).

SAFe aids e-businesses to deal with significant challenges in developing and delivering software designed for large-scale systems in the shortest implementation time. It is an online knowledge base with proven patterns for achieving success. SAFe synchronizes and provides synchronization, collaboration and delivery products for multiple Agile teams. Scalable and configurative, SAFe allows each organization to adapt it to its own business needs. SAFe is suitable to support small solutions which are used by 50 to 100 users, as well as complex systems with thousands of people. It describes the roles, responsibilities, artifacts, and activities necessary for the implementation of Lean-Agile development.

The main goal of the paper is to show the framework for scaling agile principles, its key elements and factors, to explain why it is important to manage projects in e-business using SAFe, and to briefly clarify the implementation of SAFe.

## 2. SAFe

The philosophy of SAFe is simple: the ultimate responsibility for the adoption, success and continuous improvement of the efficient and agile (Lean-Agile) development lies in existing managers and managers of the company. Only they can change and continuously improve the systems in which they all work. In order to achieve this, leaders must be trained and in parallel they become trainers themselves, with improved ways of thinking and working. Some of them need to offer a new leadership style, the one that really teaches, empowers and engages individuals and teams to achieve their greatest potential (Knaster & Leffingwell, 2016).

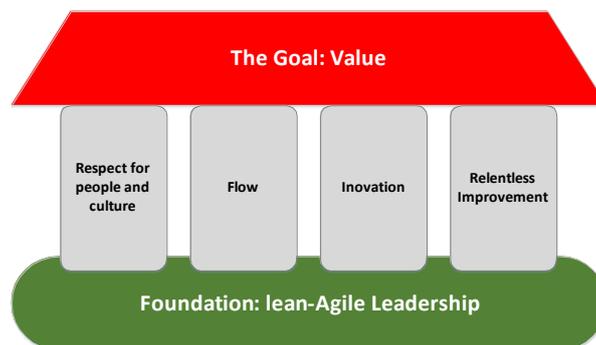

SAFe Lean-Agile Leaders are lifelong learners and teachers who assist teams in building better systems through understanding and exposing Lean-Agile thinking (Lean-Agile Mindset), SAFe principles and thinking about systems (Campbell-Pretty, 2016). Such leaders show the following behavior:

- Introduce and guide the changes
- Know the path
- Lifelong learning
- Develop people skills
- Inspire and align with the mission
- Minimize constraints
- Decentralize decision making
- Motivate workers to develop a constant need for learning

The Community of Practice (CoP) was formed within the framework of SAFe. It is an informal group of team members and other experts who work within a program or enterprise with a mission of sharing practical knowledge in one or more relevant areas. They regularly cooperate with the goal of sharing information and improving the skills and further they actively work on improving their knowledge from their domain ("Communities of Practice", 2017).

The entire work under this methodology is based on Core Values, which represent the basic beliefs of a person or organization. Basic values are the guiding principles that dictate behavior and action. Basic values can help people to recognize what is right and what is wrong, what to focus on. Moreover, they can support companies to determine whether they are on the right track and whether they fulfill their business goals. Lean-Agile set of views, Lean-Agile leaders, SAFe principles as well as the extensive advantages that Lean-Agile development provides to everyone, play important roles in defining what makes SAFe successful (Leffingwell, 2016).

Most of Lean's thoughts are presented in SAFe House of Lean. Lean's house is made up of six key constructions. "Roof" is the goal of achieving value; "pillars" support this goal by respect for people and culture, flow, innovation, and improvements. Lean-Agile Leadership provides the basis on which pillars and goal are built up. The details of Lean's house are shown in the Figure 1.

**Figure 1:** House of Lean

SAFe is based on series of unchangeable, basic Lean and Agile principles. These are the basic principles, basic truths and the economic fundamentals that set off roles and practices making SAFe so effective. These nine principles are:

- have an economic view i.e. observe the situation from the economic point of the view
- apply systematic thinking
- anticipate variability
- progress incrementally with fast integrated learning cycles
- evaluate the system objectively
- perform graphical presentation of the scope of work and its limitations

- cadence application, domain-level planning synchronization
- accelerate the internal motivation of members
- decentralize the decision-making system

## 2.1. SAFe Portfolio

All of the above mentioned principles have been used to present a broad range of development environments through four configurations that companies can adapt and implement in their business. Those are:

- Basic SAFe
- SAFe Portfolio
- Large Solution SAFe
- Full SAFe

The SAFe Portfolio has been most frequently applied. The SAFe Portfolio assists to align the execution of the portfolio with the company strategy by organizing agile development around the flow of values through one or more value streams. This provides business agility through principles, practices, portfolio strategy, as well as investment financing, agile program guide, and Lean management. The architecture of the SAFe portfolio consists of three levels: portfolio, program, and team (Figure 2).

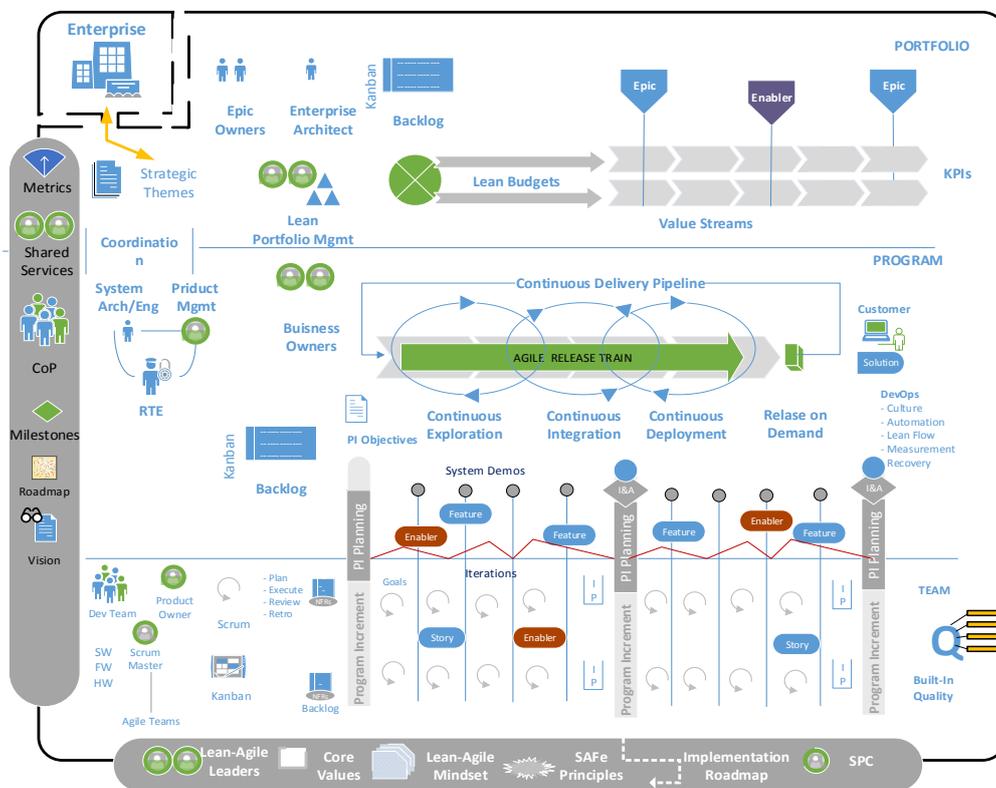

Figure 3: SAFe Portfolio

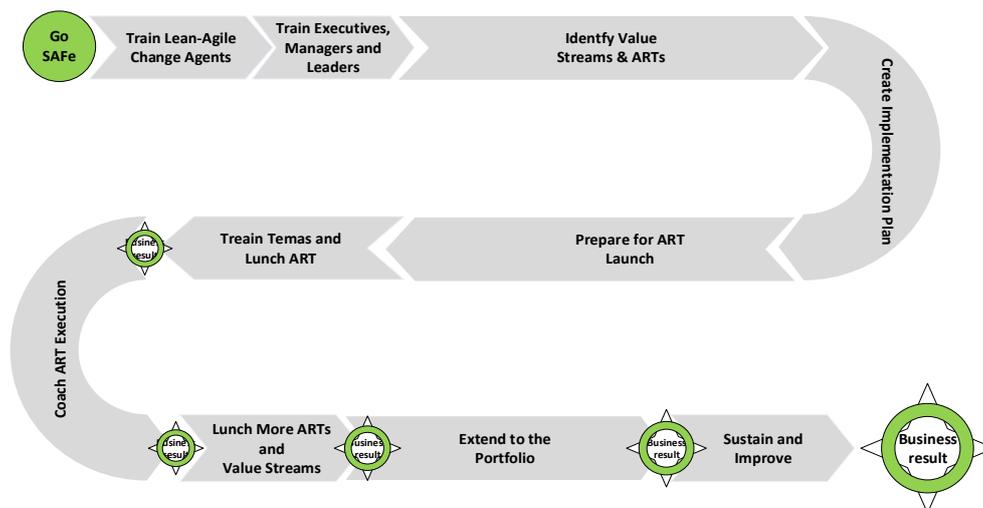

The PORTFOLIO level organizes and finances a set of value streams. The portfolio provides funds for solution development through Lean-Agile budgeting and the necessary coordination and management of value streams ("Portfolio Level", 2017). The portfolio level contains principles, practices, and roles needed to initiate and manage a set of development values. This defines financial assets and investments in value streams and their solutions. This level also provides Agile portfolio operations and Lean's management of people and resources needed to supply a solution. The portfolio level harmonizes the company's strategy with portfolio execution by organizing the Lean-Agile company around the flow of value through one or more value streams. By providing basic budgeting and necessary management mechanisms, it allows investment in solutions to guarantee a return on investment (ROI) in order to realize the strategic goals of the company.

The PROGRAM level contains the roles and activities necessary for continuous provisioning of the solution through the Agile Release Train (ART). At the program level, development teams, stakeholders, and other resources are dedicated to an important, ongoing mission to develop a solution. ART describes teams, roles,

and activities of the program level that gradually bring a continuous flow of values ("Program-Level", 2017). ART is a virtual organization formed to pass functional boundaries, to eliminate unnecessary handover steps, and to accelerate the achievement of value using the SAFe Lean-Agile principle in practice. Although called a programming level, ART is long lasting and hence (therefore) has a more persistent self-organization, structure, and mission than a traditional program. Usually, the program has a definite start and end date, as well as temporarily allocated resources.

The TEAM level contains roles, activities, events, and processes that Agile teams build and deliver in the context of the Agile Release Train (ART). All SAFe teams are part of ART, the primary level of the program level. The roles and functions of ART, including Release Train Engineers, product managers, system architects, engineering, system team, and common services facilitate all teams on the train. As a result, they are fully capable of defining, developing, testing and delivering working and tested systems in every iteration. Each Agile team is responsible for defining, building and testing Stories from their backlog team. Stories are short descriptions of small parts of desired functionality written in the user's language. By using a common cadence and synchronizing the iteration, teams are adjusted to a series of fixed length iterations to ensure that the entire system repeats itself. Teams use ScrumKSP or Kanban to deliver high-quality systems, which routinely produce a system demo every two weeks. This ensures that all ART teams create an integrated and tested system, which stakeholders can evaluate and respond to it to quick feedback. Each team has five to nine members and includes all the roles needed to build a quality increase in value in every iteration. The roles of ScrumKSP include a scrum master, a product owner, dedicated individual contributions, and all the experts on the subject for whom the team needs to deliver the value. The role of the Kanban team is less strictly defined, although many SAFe Kanban teams also implement ScrumKSP roles ("Team Level", 2017).

Before realizing the benefits of SAFe, organizations must adopt Lean-Agile way of thinking and understand and apply Lean-Agile principles, then identify value flows and Agile Release Trains (ART), implement Lean-Agile portfolio, build quality, and afterwards establish mechanisms for continuous delivery of values and DevOps. The Figure 3 shows the steps in the implementation of SAFe ("SAFe Implementation Roadmap", 2017).

**Figure 4: SAFe Implementation**

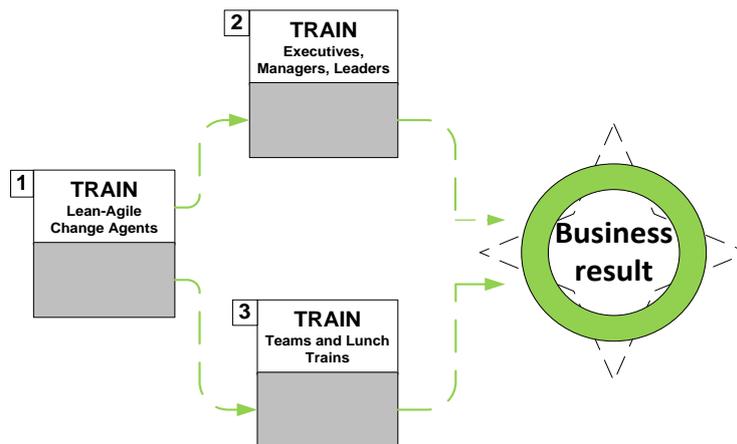

Implementing of the changes, which are necessary to achieve Lean-Agile technology in an enterprise, is a significant challenge for most organizations. Implementation of Lean-Agile thinking and understanding, and applying Lean-Agile principles as well as effective implementation of SAFe in practice leads to e-business improvement. An appropriate culture must also be developed. Although SAFe knowledge is accessible to everyone, it does not define or prescribe the process of organizational change management, which is usually required for successful application-transformation. This is left to be determined by the company, because only the company knows its specific context, and the company must carry out the transformation.

Although there are no identical adoptions and it is rarely to have a perfectly sequential implementation step by step in any company, the best results are achieved if they follow a path similar to that one shown in Figure 3. Successful implementation includes the following 12 steps ("SAFe Implementation Roadmap", 2017):

- Achievement of the turning point
- Train Lean-Agile Change Agents
- Train executives, managers, and leaders
- Creation of the Lean-Agile Center of Excellence

- Identifying the flows of values and ART
- Creating an implementation plan
- Preparations for ART launch
- Training teams and launching ART
- Training of ART exercises
- Launching more ART and value streams
- Portfolio expansion
- Maintenance and improvement

Many companies have already gone through this path, and lessons learnt have become more and more available. Based on learning from hundreds of SAFe implementations, Scaled Agile, Inc. as the founder of SAFe, developed the basic implementation form SAFe 1-2-3 (Figure 4) for the successful adoption of SAFe. The form provides a simple roadmap, which helps to align with a common implementation strategy (“Implementing 1-2-3”, 2016).

**Figure 5: SAFe Implementation Strategy**

### 3. SAFE RISK MANAGEMENT

The successful introduction of agile techniques at the project level is not the only challenge in this venture. Effective integration into e-business processes at a higher organizational level represents an additional risk in this process. The risk is part of our lives. In a rapidly developing world, the risks we need to manage develop rapidly too. They must be managed in order to minimize their threats and to maximize their potential.

Risk management involves understanding, analyzing and addressing risks in order to achieve the goals of organization. Therefore, risk management must be proportional to the complexity and to the type of organization (“MSF Risk Management Discipline”, 2002).

The ideal solution for risk management at three levels introduced by SAFe, the level of a team, programs, and portfolios, does not exist. However, the categorization of risk is necessary for the proper treatment.

The majority of experts agree to manage risk at the code level at the team level during the Program of Increment Programming (Leffingwell, 2016). Higher-level risks (project or program) with potential to affect the entire Agile Release Train (ART) should be escalated to the level of the program. Teams do not have to analyze or to take into account the repeating risk, as all risks once occurred will be identified, listed, and planned to mitigate at the appropriate level. (Although there may be some risks at the portfolio level, managing them should be covered by managing the project portfolio of the organization or PPM).

A widely used risk mitigation tool within SAFe is ROAM board (“ROAM & Risk Management Under SAFe”, 2017). It is utilized during PI planning to identify and analyze risks and problems. To ensure that all risks are covered, the aim of this technique is to Resolve, Own, Accept (by product management team), or to Mitigate (therefore acronym ROAM). Potential issues that are solved on the ROAM board at the team level are not transferred to the Program Panel at the program level. Reducing of the identified risks can follow the course similar to that in an agile project. The main advantage of using the ROAM table is that it ensures that all risks are covered - after a ROAM session; the work should be committed to solving all the identified problems in one way or another. Another advantage is that ROAM can simply be transferred to a shared online tool, facilitating collaboration between geographically distributed teams.

#### **4. SAFE CHALLENGES**

In the most companies, which are constantly innovative and expanding, the balance between costs and control, i.e., maintenance of high quality has to be provided. Enterprises usually have a complex structure necessary to produce a large number of products (and this number is constantly increasing). Without adjusting and increasing the number of employees, such required intensity or even imposed changes would lead to the collapse (Schwaber & Sutherland, 2016).

In these e-business oriented systems, the application of the SAFe methodology brings the necessary order, systematization and the results are always the best product delivered on time to the right place, to the right customer in the right quality and the right amount.

The SAFe methodology enables the use of a proven, public framework, with clearly defined roles and artifacts for applying the Lean and Agile methodology at the enterprises. SAFe's knowledge and tools are transparent and SAFe trainers are always available. The digitized program board allows process monitoring all the time and quick identifications on the control panel, i.e., whether progress is normal or unusual. Lean-Agile leaders point out managers to look at tasks or problems from a new perspective. Well-defined roles and terminology within SAFe are used as essential indicators for those new in the framework. If the changes are being implemented very quickly, they can represent a shock to employees. On the other hand, rapid integration has enabled people to participate in the Agile system. Employees are guided by trainers who consistently transmit the value of change, and help people accept their roles with a new way of working. It is important to establish an acceptable relationship between trainers and employees (Leffingwell, 2016). The implementation of SAFe increased transparency and visibility and as results, effectively identified errors, obstacles, weak tools and bad engineering habits are possible. Transparency is invaluable, everything is visible to everyone, communication and conversations are more valuable than monitoring indicators. SAFe forms a powerful community that keeps up with the ever-increasing growth rate of industry; it forms a system that can deliver more products without increasing the number of employees, and thus remains competitive.

Nevertheless, understanding and explaining agile methodology is not easy. Agility and speed of change leave the impression of a division of responses without one or more centralized authorities, which is a contradiction to the management methodologies that have been present throughout the business for decades, and not only in the IT industry.

However, this is not true. Agile methodologies offer more flexible and quicker workflows, methods that are easier to adapt to changes and new circumstances but require very strict precision, from the periods in which the divisions work to responsibilities between employees. They required the application of enormous knowledge and lifelong learning. Moreover, this kind of management is more complex than some of the previous ones. It requires greater involvement of all members of one system. It is particularly important to understand the application of these methodologies in e-business. One of the main forces of SAFe is - people. Before starting a professional life, human resources are formed at universities. Changes, speed, scalability, innovation, lifelong learning - all of these qualities in the 21<sup>st</sup> century have become an imperative. The question that arises is how to operate in such an environment? In addition, how to design young intellectuals to manage in turbulent and for sure challenging circumstances? These are the reasons why the education of young professionals should introduce learning about agile approaches. Moreover, the introduction of education on agile methodologies and their application is necessary, because it is an environment in which it will work.

#### **5. CONCLUSION**

The contribution of this paper is to systematize knowledge about SAFe, since it is a new framework, and that there is not much literature on this topic. The paper analyzes SAFe, highlighting the advantages of its application, but also its weakness. The main purpose of agile project management is to deliver products in a shorter period and to provide better quality for less money. This fits perfectly into the concept of e-business. By increasing the transparency and visibility of the company, it is easier to identify mistakes, obstacles, weak tools and bad engineering habits. Transparency is priceless and in SAFe everything is visible to everyone, and communication and conversations are more valuable than monitoring indicators. The Agile Manifesto says: "The most effective way of transmitting information within a development team is face-to-face communication." In SAFe, it leads to the next level with the planning of promotion programs, routine, "face to face" communication, with a standard agenda that includes a presentation of the business context and vision followed by a teamwork.

Agile should carry less risk than the traditional "waterfall" approach. It should help the project team in their joint work to do the job in the best way. Keys to success are contained in a communication, team dedication, strong leadership and good planning.

The results obtained with the use of SAFe are usually: 20 to 50% increase in productivity, more than 50% increases in quality and 30-75% is shortening the time of market entry (Yakyma, 2016). It also achieves a measurable increase in employee engagement and satisfaction of employers.

A representative example of the implementation of SAFe is Intel. Intel is one of the largest publicly released SAFe applications based on the number of ARTs. Intel has conducted training of 2000 employees within three months and by 2017. developed the Lean-Agile practice. Intel has built a strong community that speaks a common language. Intel's efforts are helping Lean-Agile to maintain a steady increase in the growth rate of the industry. Lean-Agile helps Intel to deliver more products without increasing the number of employees, so it can remain competitive and continue to follow the Moore's law.

From all written above, we can conclude that scaling is not easy, but it is worth the effort because the results are excellent.

# DESIGNING A COLLABORATIVE FILTERING RECOMMENDATION SYSTEM IN E-COMMERCE

Boban Davidović<sup>\*1</sup>, Dušan Barać<sup>1</sup>, Božidar Radenković<sup>1</sup>  
<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia  
<sup>\*</sup>Corresponding author, e-mail: boban.da87@gmail.com

**Abstract:** *This paper discusses an approach for designing a collaborative filtering recommendation system within web stores. The main goal is to improve the level of conversion and increase customers attention and total sales by providing them with most relevant content and services. Data is collected from users activities within webshop: which products a user added, how many times the user entered the same product and total time spent on a product page. Based on collected user data it is possible to find most similar users and offer items that similar users were interested in. Further, we describe steps in designing recommendation system, architecture and possible application of the systems.*

**Keywords:** *Recommendation system, collaborative filtering, e-commerce*

## 1. INTRODUCTION

In modern e-commerce solutions, when it comes to optimization of conversion rate and increasing the customers' attention, only the most relevant content and services have to be delivered. Users expect to be provided with the exclusive content adapted to their needs and characteristics. However, this is quite complex and involves comprehensive approach including a variety of technologies, techniques, and concepts.

Accordingly, recommendation systems have been extremely important in last few years as they could be used in different areas, such as articles, social content, movies, books, news, and products as well. Recommendation systems have become an integral part of all the well-established online stores today. The main role of recommender systems is to search through a large volume of dynamically generated data in order to provide users with personalized content and services. They can especially be useful in e-commerce systems since the system is suggesting users which products user might be interested in and good recommendations can lead to a direct increase in sales.

This paper focuses on designing a recommendation system within an e-commerce solution, based on data collected through users' actions in a web store. The goal of the research is to investigate possibilities of using collaborative filtering techniques in order to improve conversion rate and results of content recommendation within web stores.

## 2. LITERATURE REVIEW

Recommendation systems have been in focus of many research papers. Most existing recommender systems use content-based or collaborative filtering methods or hybrid methods that combine both techniques (Aciar et al., 2007). The collaborative filtering approach to the recommendation is based on recommending items based on other similar users behavior (Balabanović & Shoham, 1997). Table 1 summarize approaches and examples from the literature.

All articles from Table 1 are based on using recommendation systems in different environments. Some of them are also based on e-commerce websites, but their main focus is data collected through sales and product ratings. Most of the researchers that use recommendation systems in e-commerce are focused on user data that is collected through sales or product reviews. This approach works well and it is already investigated. In this paper data collected from user actions on product pages are used. The benefit of this approach is that user actions from e-commerce websites are used, so there are much more data available for mining compared to a traditional approach, where only sales data or product reviews are tracked. It happens often that users browse through e-commerce websites and not buying on that website for various reasons (like for example price). But, those users can be used for collecting data and to learn more about visitors.

**Table 1:** Related literature overview

Context	Description
Book recommendation system (Tewari et al., 2014)	Combining features of content and collaborative filtering and association rule mining in order to recommend books to users.
Videos recommendation system (Deldjoo, et al. 2016)	Content-based recommender system for recommending videos based on extracted visual features of the video.
Recommendation systems in social networks (Wei et al., 2017)	Improving recommendation accuracy in a cold-start situation by using additional sources of information, such as friends relationships and user-generated tags.
Product recommendations from social networks data (Zhao et al., 2016)	Solution for a cold-start product recommendation, which aims to recommend products for e-commerce websites to users at social networking sites in "cold-start" situations.
Product recommendations theoretical approach (Wang & Zhang, 2013)	Proposed proportional modeling approach to the recommendation research field and a new opportunity model to explicitly incorporate time in an e-commerce recommender system.
Recommendation systems in B2C systems (Li & Karahanna, 2015)	Reviewing recommendation systems on B2C e-commerce systems. Identify gaps and future directions.
Personalized recommendations in B2C (Ji et al., 2004; Zhang & Jianxin, 2007)	Customer shopping model for B2C customers. Classification-based recommendation system for personalization in B2C e-commerce applications.
Recommendation systems effects on consumer beliefs / social context (Benlian et al., 2012; Weisberg, 2011)	Recommendation systems effects on effective and trusting dimensions of consumer beliefs. Relationship between past online purchases and purchasing intentions.
Recommendation system for e-commerce systems (Phi et al., 2016; Castro-Schez et al., 2011)	Focusing on the item-to-item and user-to-item recommenders.
Collaborative Filtering (Koren & Bell, 2015)	Improvements and recent progress of collaborative filtering methodology.
User-based collaborative filtering (Ma et al., 2015)	Revised the user-based collaborative filtering technique and proposed two recommendation approaches fusing user-generated tags and social relations.

### 3. DESIGNING A COLLABORATIVE FILTERING RECOMMENDATION SYSTEM IN E-COMMERCE

The goal of the research is to build an e-commerce recommendation system that uses users actions as the input. Further, the output of the system should be suggested products that the user is interested in. The recommendation system uses collaborative filtering where the system looks for similar users and based on that, the system recommends products that similar users were interested in.

Main user actions that were tracked are: which products user added, how many times the user entered the same product and total time spent on a product page.

**Figure 1:** Recommendation system design

Figure 1. presents steps in the design of recommendation system: (i) collecting user actions, (ii) processing and analyzing data using Nearest Neighbors method, (iii) recommend products based on user similarity.

### 3.1. Collecting user actions

Collecting users actions data is a first step in building a recommendation system. Table 2 describes data collected from different users are shown. Part of the data is presented below in a way so it can be used for recommendation system.

**Table 2:** User behavior table

	User	Product	Time spent	Product clicks	Added to cart	Purchase
Case 0	1	1	38	2	1	1
Case 1	1	2	22	1	0	0
...	...	...	...	...	...	...
Case X	4	9	10	1	0	0

The fields represent collected user behavior data separated by the user, which is marked as a case. It is shown how many times each user clicked on a specific product and how much time the user spent on a product page. Also, it shows how many times each user added product to a cart and how many times user purchased a specific product.

### 3.2. Processing and analyzing data

Recommendation system method that is used is Nearest Neighbors. Nearest neighbor method principle is to find a predefined number of training samples closest in distance to the new point and predict the label from those. The distance is any metric measure - standard Euclidean distance is the most common choice. In this case ball, tree data structure is used, since that is optimized for a large amount of data comparing to K-dimensional Tree (Omohundro, 1985). A non-parametric procedure has been introduced by Fix and Hodges in pattern recognition literature as the voting k-nearest neighbor (k-NN) rule (Fix & Hodges, 1951). According to this rule, an unclassified sample is assigned to the class represented by a majority of its k nearest neighbors in the training set (Denoeux, 1995).

Using Nearest neighbor indices and distances for each record in object X (user behavior array) are printed. A part of the printout is shown on the following figure.

**Table 3:** Indices and distances for each element

Indices	Distances		
0 17 12	0.0	5.56776436	6.55743852
1 15 23	0.0	3.87298335	5.56776436
2 11 16	0.0	2.82842712	3.0
3 9 20	0.0	3.31662479	4.12310563
4 10 12	0.0	18.1934054	22.22611077
5 19 11	0.0	2.64575131	2.82842712
6 3 20	0.0	4.47213595	4.58257569
7 9 8	0.0	2.23606798	4.24264069
...			...
27 26 20	0.0	1.41421356	1.41421356

In the table above left column represents users ids in a list and right column represents how similar are those users. The nearest neighbor of each user is the user itself, at a distance of zero. The third and fourth elements are the elements with closest distances to the specific element. As we can see from the third row in the table above, user 1 is very similar to users 15 and 23. We can see in the fourth row that user 3 is also very similar to user 9.

When a new user comes to the e-commerce store, we have a situation of cold start problem. Many papers discuss on cold start items (items generated without knowledge about previous users' behavior). However, this is not within the scope of the paper.

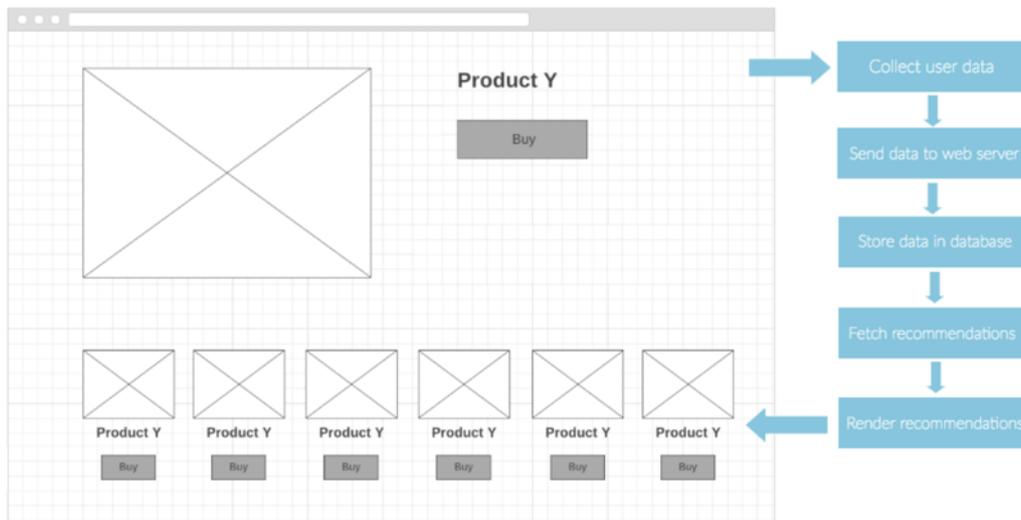

### 3.3. Processing and analyzing data

Products are recommended to a current user based on calculation how similar is current user to other users that already visited e-commerce website. Accordingly, when a user  $X$  visits product  $Y$ , the system will take that as an input from user  $X$ . That input will be used to compare user  $X$  with other users in the system. The recommendation system is able to predict what other products user  $X$  might be interested in. Example recommendation that that system outputs like this: [7.68114575, 8.83176087, 9.53939201] -> [7, 9, 3].

The output that is shown above shows us how similar is user  $X$  with the other users in the system. As we can see in the example above a new user is the most similar with a user 7 (closest distance), a little less similar with a user 9 and after that to user 3.

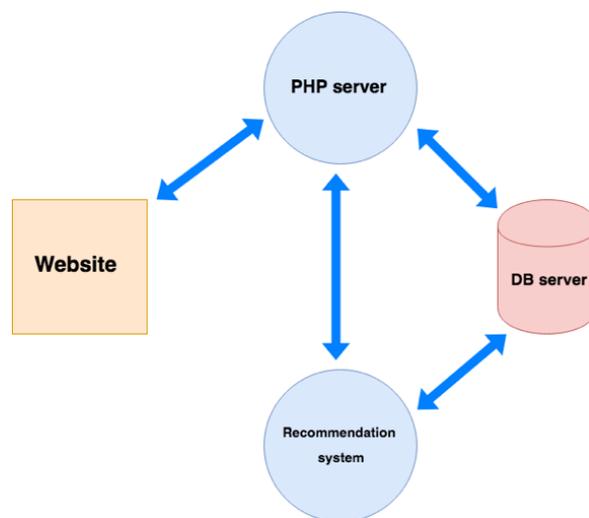

Based on the example above, the system determines which users are similar to the current user and the system can choose products for the current user that similar users were interested in. If two users are similar and one of them added a product to the cart or purchased the item, we can also expect for the similar user to do the same. The recommendation system is showing all products that the most similar users purchased. If user  $X$  is the most similar to user 7 (as in the example above) then the recommendation system will show all items that user 7 purchased as recommended. In the current implementation, the recommendation system always uses only users who had made a purchase for comparison with other users (those users are the only ones that have a real value for the e-commerce system). The more data from users is collected, more correct a recommendation system will predict products that user  $X$  is interested in.

As mentioned above, this system can be implemented in a real-time e-commerce website. In order to implement there are few steps involved: (i) implement collecting user behavior data using JavaScript, (ii) send collected data to a web server, (iii) store data in the database, (v) fetch recommendations from recommendation system API call (v) render recommendations on the page. That is shown in the figure below.

**Figure 2:** Recommendation system design

The developed system includes following software architecture elements: (i) HTML website, (ii) PHP server, (iii) database server and (iv) recommendation system server. HTML website is making a request to a PHP server (using JavaScript) and PHP server is getting user information from the database server. PHP server gets recommendations from recommendation system server. Communication between these entities is shown in Figure 3.

**Figure 3:** Recommendation system architecture

#### 4. DISCUSSION

This system is different from the other recommenders in e-commerce systems (Benlian et al., 2012; Weisberg et al. 2011), because it tracks all data available from user behavior that can lead to better understanding what user might be interested in. The system main focus is not on using previous purchases from users. Instead, the main focus is on the helping user who hasn't yet made its purchase or new purchase is not related to old one. The scenario where the user purchases one item and comes again to purchase the similar item does not happen very often.

Nowadays, a lot of researchers integrate social media into e-commerce systems and use them for creating recommendations as users are enabled to log in using social media and like products with social buttons. In (Li et al., 2013) authors proposed a social recommender system that can generate personalized product recommendations based on preference similarity, recommendation trust, and social relations. Compared with traditional collaborative filtering approaches, advantages of the proposed mechanism is reflected in its comprehensive consideration of recommendation sources. This paper is not considering data from social networks. It is focused mainly on user behavior collected data.

Numerous studies have investigated recommendation systems as they play an important role in e-commerce websites since those systems increase sales and income for the shop owners. For example, (Lin, 2014) performed an empirical research that investigated to which extent recommendation systems increase sales within B2C platform in China market. He found out that user recommendations are more effective than system recommendations in driving product sales.

The main contribution of this paper is reflected in a proposed approach for recommendation systems in e-commerce websites focused on user behavior. Common recommendation systems for e-commerce websites use only sales as a parameter for recommending products. In implemented recommendation system complete user behavior is tracked. After finding a similarity between the current user and other users in the system, a recommendation system is able to predict in a real-time which products will be interesting for the current user.

We acknowledge that the proposed solution does have some limitations and can be improved. There are many different data that can be collected from a user behavior in order to find out how interested are users in the product, for example, user's social media interaction on pages. Also, product reviews and sales can be tracked together with users browsing data. In addition, time factor should be considered in users behavior, so only recent users actions should be considered. Below there is a list of advantages/disadvantages of the developed model:

**Table 4:** Advantages/disadvantages of the developed model

<b>Advantages</b>	<b>Disadvantages</b>
Real-time recommendations	Not considering the time factor
Focus on user behavior	Not considering social media interaction on pages
Does not require many data	Not considering product reviews and sales data
Recommendation based on similar users behaviour	Many user behavior data not tracked/mentioned
Ease of adding more user behavior parameters into the system	
Fast recommendations	

## 5. CONCLUSION

Recommendation systems are now used everywhere. All e-commerce platforms have some kind of recommended products lists. Most of those lists are purely based on product popularity, which actually represents a number of sales. Because of that, many e-commerce websites have a problem with products that used to be attractive to users, but they are not anymore. Those products are shown in popular products lists unless they are manually removed by e-commerce system administrator.

There are a lot of opportunities to add intelligence and personalization in every part of every system, creating experiences that seem like a friend that knows you, what you like, and what others like and understands what options are out there for you. Recommendations are discovery, offering surprise and delight with what they help uncover for you. Every interaction should be a recommendation (Wei, et al., 2017, Smith and Linden, 2017). Recommendation systems do not consider users behavior and how much time a user spends on the specific page and how many times the user enters pages. Also, it is important to know how many times user added product to the cart, even if a purchase was not been made. In the time when many retailers sell a large number of goods online, it is important to use recommendation systems that will help users navigate through the site and find what they look for.

The expected future of recommendation systems in e-commerce is to track complete users behavior and make some conclusions about the user. Based on that, recommend specific items to the user. Also, in the future, we will probably see increased usage of recommendation systems, not just for some products list as it is used now. In the future, complete e-commerce systems will be adjusted based on the users' behavior and expectations.

## OVERVIEW OF TRAVEL DEMAND FORECASTING METHODS USING SEARCH ENGINE QUERIES

Nemanja Bošković<sup>\*1</sup>, Sandro Radovanović<sup>1</sup>, Milija Suknović<sup>1</sup>  
<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia  
<sup>\*</sup>Corresponding author, e-mail: nemanja.boskovic17@gmail.com

**Abstract:** *Travel demand was always very unpredictable, depending on many factors. Up until the emergence of several search engines, it was very difficult to forecast travel demand. Demand prediction is important to hotel management teams that can use produced information to adapt room prices and impact total revenue. Search engines Google and Baidu became an integral part of tourist research, as search queries about particular destination became key performance indicators. Since there are no available papers that cover all present methodologies for demand forecasting, this paper intends to fill this gap. This paper assesses relevant methods that use search queries for demand fluctuation prediction. Using econometric models such as ARMA, ADL, TVP and VAR, it is shown that there is a strong relationship between queries and actual demand. There are several hundreds of potential queries that can be used as input for the models, and picking those with highest predictive power is not easy. It is shown that search engine data has strong predictive power if appropriate queries are used as input for predictive models. Successful predictions will lead to better price management and in the end higher revenue for hotel businesses.*

**Keywords:** *demand forecasting, dynamic pricing, revenue management*

### 1. INTRODUCTION

The global travel industry gross bookings reached \$1.6 trillion in 2017, making it one of the largest and fastest growing sectors in the world. Factoring in indirect economic contributions, travel and tourism now accounts for a staggering 10.2 percent of global GDP. This continuous growth that was seen from 2010 onwards, is underpinned by several key factors mutual for all global markets and many other factors bound locally. Although some industry experts are pointing out concerns about the high growth, trying to indicate cyclical history of the industry and potential downturn, there are more of those who are bullish on the industry. There are some key indicators of strong outlook on the travel industry that are not connected to the economic dynamics and point to the strong growth in the long run. Revenue management is one part of the hotel business that can be improved using available data and mathematical approaches that will yield improvement in the decision-making. In order to achieve improvements, we must first recognize other factors influencing total revenue.

The first and most important factor is the demand. Currently, very few hotel chains in the world use some sort of demand forecasting that helps them define the price for the future periods. There is high variability in demand in the short-term as well as long-term. There are many factors influencing demand level such as: economic environment, transportation availability, one-off events etc. If hotel management could predict the rise in demand in the next week, they could raise the price of available rooms and still sell them. There is surplus coming from this intelligent decision-making that can be captured. There are several papers dedicated to demand forecasting in travel (Yang et al., 2014; Bing et al., 2012). In the next chapter we will discuss some of the methods, their strengths, limitations and underlying assumptions.

Second important factor is the offer of the competitors. In travel and hospitality, there is a fixed amount of demand for a certain period. Customers are getting informed online and choose the place where they want to stay, based on the supply. A customer would naturally choose the cheaper option if the services of both options are identical. Hotel businesses must identify the characteristics they offer and find their respective competitors who offer same or similar services and compete with them for winning over customers. In the current environment, most businesses use traditional approaches to mapping out their competitors and occasionally following their actions. There is no standardized approach to dealing with changing prices of the competitors and making informed decisions based on them. The last argument creates motivation for future research.

There are several technological trends present in the hotel industry which was part of the research conducted in order to assess impact of technology on the industry. Research (Guttentag, 2013) was conducted on a new business model proposed by Airbnb, which is the first disruptive use of technology in the hotel industry. It represents an innovative accommodation product that has shifted perceptions of

hospitality throughout the hotel industry. While Airbnb remains a topic of significant attention within the sector, there is little understanding of the degree to which it is used as a hotel substitute, or how Airbnb guests view the service relative to hotels. This study offers important insight into these questions by showing that many Airbnb guests use the service in place of a hotel, and especially mid-range hotels. Secondly, IATA statistical report shows 10% increase in number of passengers carried by low-cost carriers in 2017. compared to 2016. Increase in all other price categories were below 5% for the same compared periods. Also, most of the traditional airline metrics such as Revenue passenger kilometres (RPK), Available Seat-Kilometres (ASK) and load factor, all show higher growth than other price categories. This indicates strong overall growth in low-cost segment of air flights. Thirdly, (De Pelsmacker, Tilburg, & Holthof, 2018) is a research on digital marketing efforts and results of over 200 hotels in Belgium. Authors focused on eCRM and concluded that online reviews, TripAdvisor profile nurturing, responsive digital footprint all affected room occupancy favorably. This indicates relevance of digital marketing and customer relationship management.

## 2. METHODOLOGY

Purpose of (Bing Pan et al., 2012) was to determine if search query volume was useful in forecasting demand for hotel rooms. The authors used search volume data on five related queries to predict demand for hotel rooms in a specific tourist city and employed three autoregressive moving-average (ARMA) family models and created their ARMAX counterparts involving Google search data to evaluate the usefulness of these data. The authors also evaluated three widely used econometric models – ADL, TVP, and VAR – for comparison.

### ARMA models

ARMA model takes the form:

$$\ln y_t = \mu + \sum_{i=1}^p \varphi_i \ln y_{t-i} + \varepsilon_t + \sum_{i=1}^q \theta_i \varepsilon_{t-i} \quad (3)$$

AR model is a specific for of the (3) where  $q = 0$ :

:

$$\ln y_t = \mu + \sum_{i=1}^p \varphi_i \ln y_{t-i} + \varepsilon_t \quad (4)$$

ARIMA has the form:

$$\Delta^d \ln y_t = \mu + \sum_{i=1}^p \varphi_i \Delta^d \ln y_{t-i} + \varepsilon_t + \sum_{i=1}^q \theta_i \varepsilon_{t-i} \quad (5)$$

### ADL model

ADL model regresses lagged depended variables to arrive a at current predicted value, models derived and used in this study has the form of:

$$\ln y_t = \mu + \sum_{i=1}^p \varphi_i \ln y_{t-i} + \sum_{i=1}^5 \sum_{j=0}^p \alpha_{ij} \ln x_{i,t-1} + \varepsilon_t \quad (6)$$

### TVP model

TVP model used in this study established a relationship between the demand for hotel rooms and the Google search data. The model includes measurement and transition equations:

$$\ln y_t = \alpha_{0t} + \sum_{i=1}^5 \alpha_{it} \ln x_{it} + \varepsilon_t \quad (7)$$

$$\alpha_{jt} = \alpha_{j,t-1} + \mu_{jt} \quad (j = 0, \dots, 5) \quad (8)$$

## VAR model

VAR model differs from others in the sense that it treats variables and endogenous, which results in capturing the dynamic nature of demand. It is expressed as:

$$Y_t = C + \sum_{i=0}^p A_i Y_{t-i} + e_t \quad (9)$$

All three ARMAX models consistently outperformed their ARMA counterparts, validating the value of search volume data in facilitating the accurate prediction of demand for hotel rooms. The data used was composed of 5 different keywords labeled as room searches focusing on one city particularly. After the models were used, authors tested their accuracy using mean absolute percentage error (MAPE) and root mean square percentage error (RMSPE):

$$MAPE = \frac{1}{m} \sum_{t=1}^m \left( \frac{|\hat{y}_t - y_t|}{y_t} \right) \quad (10)$$

$$RMSPE = \sqrt{\frac{1}{m} \sum_{t=1}^m \left( \frac{\hat{y}_t - y_t}{y_t} \right)^2} \quad (11)$$

these two measures have been applied to evaluate the forecasting performance of tourism demand models (Song & Witt, 2006; Vu & Turner, 2006).

Authors made the point that web search improves predicting accuracy so in our own research we can assume relevancy of Google search data in some degree. Also, fellow colleagues developed a simple but powerful model that will be a starting point for further research, taking into account some of the limitations stated in their paper. Only 5 keywords were used in the model and since travel involves complicated decision-making, including more queries in the model would likely increase forecasting accuracy.

## 3. METHOD FOR CHOOSING QUERIES

Proceeding in our research on demand forecasting models, we came across interesting paper that had approach to forecasting which eliminated limitations of the 5 query approach (Yang et al., 2014) in their paper "Forecasting Chinese tourist volume with search engine data" had similar approach but they invested more effort into selecting relevant queries. Using iterative approach, they calculated the correlation coefficient between Hainan monthly visitor volumes and each of the search queries with different lag periods. Authors chose search queries that had correlation coefficient above the threshold of 0.76 arriving at 10 Google search queries and 25 Baidu queries. Threshold was set to optimize accuracy-parsimony trade-off. Using this approach, authors could identify an interesting pattern of Chinese tourists. Lags with significant correlations were in the range of 0-6 meaning tourists do not search for travel data more than 6 months before the trip. More detailed analysis showed that most Chinese visitors to Hainan first searched travel agent information, about six months before the trip. Then they searched for flight information four months before the trip, and finally one month before departure, they would look up weather and shopping opportunities. This confirmed the assumption that decision-making of travelers follow a pattern which was recognized using lags and search queries.

Yang, Pan, Evans, and Lu (2014) used co-integration analysis of search index and destination visitors. Using a shift and sum method, they created a composite index which they compared to destination visitor index.

$$\log T_{t1} = c_0 + \beta_1 \log T_{t1}(-12) + u_t \quad (12)$$

$$\log T_{t1} = c_0 + \beta_1 \log Gl_{t1} + u_t \quad (13)$$

$$\log T_{t1} = c_0 + \beta_1 \log Bl_{t1} + u_t \quad (14)$$

Formulas 12-14 represent a model where  $T_{t1}$  is predicted value, visitor volume estimate,  $Gl_{t1}$ , is search index from Google and  $Bl_{t1}$  is Baidu search index .

To conclude, (Yang et al., 2014) reviewed present models for predicting visitor volume, but most importantly contributed to the field in two ways. Firstly, it was proven that Local search engine Baidu has more predictive power in Chinese visitor forecasting than Google, which can be attributed to the cultural factors. The second contribution is the approach for selecting keywords that have highest predictive power. This approach lays the ground for future research in this field. In terms of application, the paper provides a new way of predicting tourist volumes for hotel managers and policy makers. There is another application of the model, where managers can use it to predict the increase in tourist volume and use this as the basis for benchmarking of their own performance, for example if the model shows 15% increase in volume and the certain unit has 5% increase, it shows weak performance. Authors stated this last application in their paper but there are some market factors which have significant power over variations. Model is not taking into account purchasing power, behavior and preferences of the customers, thus out of 15% of volume increase, there could be 12% coming from financially strong customers which are simply not using perhaps hostels, making 3% increase in hostel visitors volume justified.

As a next step, authors propose using tweets, blog posts, and social media posts to be used in the analysis. The combined power of several data sources could improve prediction accuracy which will lead to better tourism management. This will be taken as input for future research.

#### **4. CONCLUSION**

The travel industry is taking a big swing in recent years, increasing to 10.2 percent of global GDP in 2017. Growth is stable since 2010. and even though there are authors who alarm about industry's cyclical nature, there are more of those who have a positive outlook on the future years. This high growth combined with new technologies created every day and increased amount of data in all of the sectors of travel, are leading to increased interests in the development of new business practices and techniques that can affect some parts of core decision making and increase revenues and bottom-line. Even though many sectors of the travel industry are growing and showing endless possibilities for data scientists and data engineers, we focused on hotel businesses for one simple reason and that is, availability of domain knowledge through personal contacts. There are several identified trends in the hotel industry that are changing it significantly. This paper recognized several of them. Innovative business model of Airbnb, eCRM emergence and intense growth of low-cost airline flights which is driving low-cost lodging revenues. All these trends indicate high presence of tech-related innovations thus making future of the industry depending on technological development, which motivated us to investigate new ways of improving businesses in the travel industry using technology. Hotels have a simple business model to begin with, but a very complicated decision-making if there is an outreach for good revenue optimization. Since hotels are of fixed location, they are limited by the demand for lodging in their destination. Naturally, if hotels could predict future demand, they could modify their room prices (increase them) and still sell them. This can lead to increased revenue and overall profitability since cost factor is not affected by the price. There are several fields of application of intelligent systems and algorithms that improve hotel businesses. In the early 80s focus was on revenue optimization techniques which were based on stochastic models. Later, with more data present, the focus was shifted to forecasting models. With the rise of search engines such as Google and Baidu, foundations for extremely powerful models were laid. Several authors developed linear models that used search engine queries and analyze time-series data to arrive at fairly accurate forecasting models. In our assessment of such models, we focused firstly (Pan et al., 2012) who used ARMA, ARIMA, ARMAX and three econometric models ADL, TVP and VAR to test if search queries are improving model accuracy. Research showed that query data is improving model accuracy which leads to the conclusion that data provides fine information about the decision-making process of travelers. There were some limitations in this approach. Authors used only 5 queries as input for the model, which is just a part of all the queries used by travelers. Second paper we assessed (Yang et al., 2014) used a structured approach based on correlations testing to determine search queries relevant to predictions. Besides identifying key queries, authors could explain lags between queries and travel date and formulate logical decision-making of travelers. Base model for prediction was index based co-integration analysis which resulted in accurate predictions. Final contribution of this particular research is benchmarking application where management can compare predicted demand increase and actual sales increase for the period to arrive at the conclusion about their performance relative to the average. By assessing some of the models present, we have laid foundations for future research in the field of travel.

**Abstract:** *Tampered documents can cause irreparable damage to governments and businesses. It can be impossible to determine how the document has been tampered, opening up the whole system for large losses due to fraud. Mitigating document fraud and document tampering should be a top priority for any business system. We propose a framework which can be used to keep track of all document changes, while at the same time allowing verification of documents across a distributed system. This eliminates document fraud and document tampering by providing an easy way to perform document verification among all users of the framework. The framework is based on cryptographic hashes and blockchain for persistence. Each hash is mapped to a physical document stored inside a document repository. If a document's hash isn't present on the framework's blockchain, it has been tampered and can be disregarded. Our framework provides a starting point for enterprise document verification based on known blockchain principles and best cryptographic practices.*

**Keywords:** *blockchain, authenticity, verification, document management*

## 1. INTRODUCTION

Main benefit in the usage of paper documents was the ability to easily verify them and check to see if they have been tampered. Archival purposes were also much simpler due to the way documents could be replicated by hand or printing machines. In some occasions, it would be necessary to verify the authenticity of the copy. During the copying process, either by hand or by machine, it is easier to tamper the original document. The verification process was performed by an authorized body, either appointed by the government or by the company, depending on the document type. Documents were archived in physical locations, so that they could be retrieved and cross-referenced if needed.

With the advent of digital technologies, new ways to prove their authenticity needed to be created. Digital documents could no longer be easily verified and authenticated. The ability to tamper them even after they have been created has been improved with the usage of computers. One approach to solve this issue was to keep double copies of the documents – either both double digital, with one document kept at a secure location, or having paper copies of each digital copy. Either way can prove to be resource intensive, as well as not efficient or environmentally unfriendly. Archival of digital documents can also prove to be a problem, since digital storage devices can fail earlier than paper, destroying the archived data.

By the utilization of cryptographic hash functions which use the documents as input we can keep track of different document versions safely. A cryptographic hash function is a one-way transformation which produces data depending on the input (Menezes, van Oorschot, & Vanstone, 1996). Each document change produces a new hash, thus eliminating the tampering process without amending the original document. The framework is document agnostic, allowing to store any kind of documents which can be successfully verified using cryptographic hashes.

The process of amending original document allows us to perform changes on the original document while keeping track of its changes. Patches are signed off by authorized users before being committed to the database. Each authorized user contains an asymmetric cryptographic key pair (Menezes, van Oorschot, & Vanstone, 1996) which can be used for safe sign offs and identity verification. Signing them off allows us to keep track of document integrity throughout its lifecycle, while at the same time preventing future tampering in case of signing off without approved cryptographic keys.

Document and patch storage needs to be safe from tamper to prevent loss. In case of loss, no documents can be verified. Usage of blockchain combined with document repositories can minimize tamper and improve overall security of the document verification system.

Using the blockchain for storage of document and patch signatures provides a linear read-only access to previous records. Blockchain is a linear distributed database where entries (blocks) are added to it after a

consensus between blockchain users has been reached (Nakamoto, 2008). Benefits of linear access are fast access to the data and the ability to perform advanced analysis on the data, such as blockchain filtering and rotation (Zivadinovic, 2017).

Storing whole documents and their patches on the blockchain would prove to be cumbersome due to their size (Lunde, 2012). Because of performance issues, documents and patches are kept inside document repositories. Document repositories represent file storage devices where files representing documents and patches are stored (Green, 1993). Each one of them can be used as input to produce a hash value. The resulting hash value is used for future blockchain operations.

The framework shown in the following chapters should be treated as a proof of concept and a starting point for a complete implementation, not as a complete solution.

First two sections, "Existing document verification systems" and "Blockchain operations" are concerned with the overall review of current document verification blockchain solutions, as well as their core architecture.

The "Document verification framework structure" section applies the presented findings from previous two sections with the technical architecture and choices made during the development of this document verification system.

Use cases for the presented document verification system are presented in the fourth section. Two use cases are presented, one focused on citizen and government usage, while the second one is focused on company accountability and its inventory keeping of government regulated goods.

Last chapter, "Conclusion", represents an overall impact of the presented system.

## 2. EXISTING DOCUMENT VERIFICATION SYSTEMS

One of the first works on the topic of blockchain and document verification is a paper written by Aravind Ramachandran and Dr. Murat Kantarcioglu (Ramachandran & Kantarcioglu, 2017) using Ethereum smart contracts (Wood) and Open Provenance Model (Moreau, Freire, Futrelle, McGrath, Myers, & Paulson) for tracking and correlating data. Their work is based on the interconnectivity between data for scientific research and keeping it safe from fraud, such as data fabrication. Results from this paper can be further refined and applied to all document management and document verification systems where we have documents consisting of multiple legs, such as multiple forms required for a single request.

Discovered document verification systems are mostly concerned with verifying identification documents. Governments of some countries, such as Australia (Government of Australia). One common thing between all reviewed document verification systems is that none of them openly provides the business process insights concerning verification. Another one worth mentioning is the Trudatum (Coinfirm Ltd., 2018) blockchain file verification service.

Gemalto offers its *Gemalto ID Verification* solution to perform document verification (Gemalto). Their system works with different types of user identification documents, such as passports, visas and ID cards. Document verification is performed upon a centralized database of templates. The procedure utilized by Gemalto is called "*Know Your Customer*" (KYC) to combat identity or financial fraud, as well as comply with international regulations. Its main usage is in government entities and large private companies (Gemalto).

Another company providing document verification is *Jumio* with its product *Netverify* Document Verification (Netverify). Similar to *Gemalto ID Verification*, *Jumio* provides the end user with the means to acquire and verify identification documents. *Netverify* Document Verification consists of the backend system and the mobile application utilizing different algorithms to perform data gathering from a document photograph. An additional benefit is masking of credit card numbers and other sensitive information, which is a prerequisite for PCI compliance (Jumio).

The Australian government provides a document verification system called *Document Verification Service* (Government of Australia) which allows different legal entities (such as companies) to check if the provided identification documents are valid and if there are additional government records connected to them. This system can only be used with Australian government issued documents and can provide several results concerning their status:

- Matched
- Not matched
- Document invalid or not electronically captured

Resulting data can be used by the legal entity to determine further identification methods, if needed.

Trudatum is a new software solution specifically made to work with files and documents. Their system works by leveraging the blockchain for file signing and verification. Trudatum is based on proprietary technology and at the time of writing, their services aren't available to the public, even though they have a successful pilot project behind them (Biggs, 2018).

### **3. BLOCKCHAIN OPERATIONS**

Addition and modification operations represent the basis of the methodology used to form blocks of the blockchain. Even though the focus of this paper is on document verification, the presented operations are required to form a complete picture of the methodology used to verify documents on the blockchain.

Request acceptance by the blockchain means that the issued request has been propagated in full through the network utilizing the blockchain. The process of adding document hashes presents a fundamental step in the blockchain document verification methodology. Without it, we are unable to extend the blockchain with new document hash entries, thus being unable to verify the documents in question.

The process to add new document hashes to the blockchain is the following:

1. Create a document
2. Add it to the document repository
3. Generate its hash value
4. Send a request containing the necessary information to the blockchain endpoint
5. Parse the response from the blockchain endpoint

The request contains the public key of the author signing off the document and the document's hash value. On a successful response, we have confirmation that the document is now being tracked on the blockchain.

Modifying documents already tracked by the blockchain allows us to make amends to them. Amending documents is more space efficient since we track only the changes on the document, not the whole new document. When modifying, we use the blockchain to track the hash value of the patch which is applied to the document. A patch represents a set of changes needed to evolve a document from one state to another.

Tracking document patches on the blockchain is similar to adding document hashes:

1. Modify the document locally
2. Generate a patch from the changes
3. Generate its hash value
4. Add the patch to the repository
5. Send a request containing the necessary information to the blockchain endpoint
6. Parse the response from the blockchain endpoint

The request needed to publish a patch to the blockchain contains the public key of the author which signed off the patch, the hash value of a document we wish to patch, the hash value of the document with the previous patch applied (if it exists) and the hash value of the document with the latest patch we have applied.

If the system returns a successful response, the patch is now active and the parent document has been amended. Previous versions of the document in question are now invalid – only the document with the applied patches up to the last one is valid.

The list of patches which need to be applied to transform the document to the latest state can be extracted from the blockchain by following the parent references of requests. This process is called document restoration. It is possible in all cases of modification, except in the cases of deletion where all file formats, when empty, produce the same hashed value.

Deleting documents is the same as modifying them. In case of deletion, patch files contain the necessary data which is used to delete their content. The original document location on the repository is unchanged. Only its content becomes blank. Deleting the document from the repository is out of scope, but can be extended by adding checks for its presence.

When the document's content has been deleted, depending on the file format of the document, it can be possible to recreate it by following the blockchain backwards from the deletion patch.

Document verification, the core of this paper, is performed opposite of the process of adding document hashes to the blockchain:

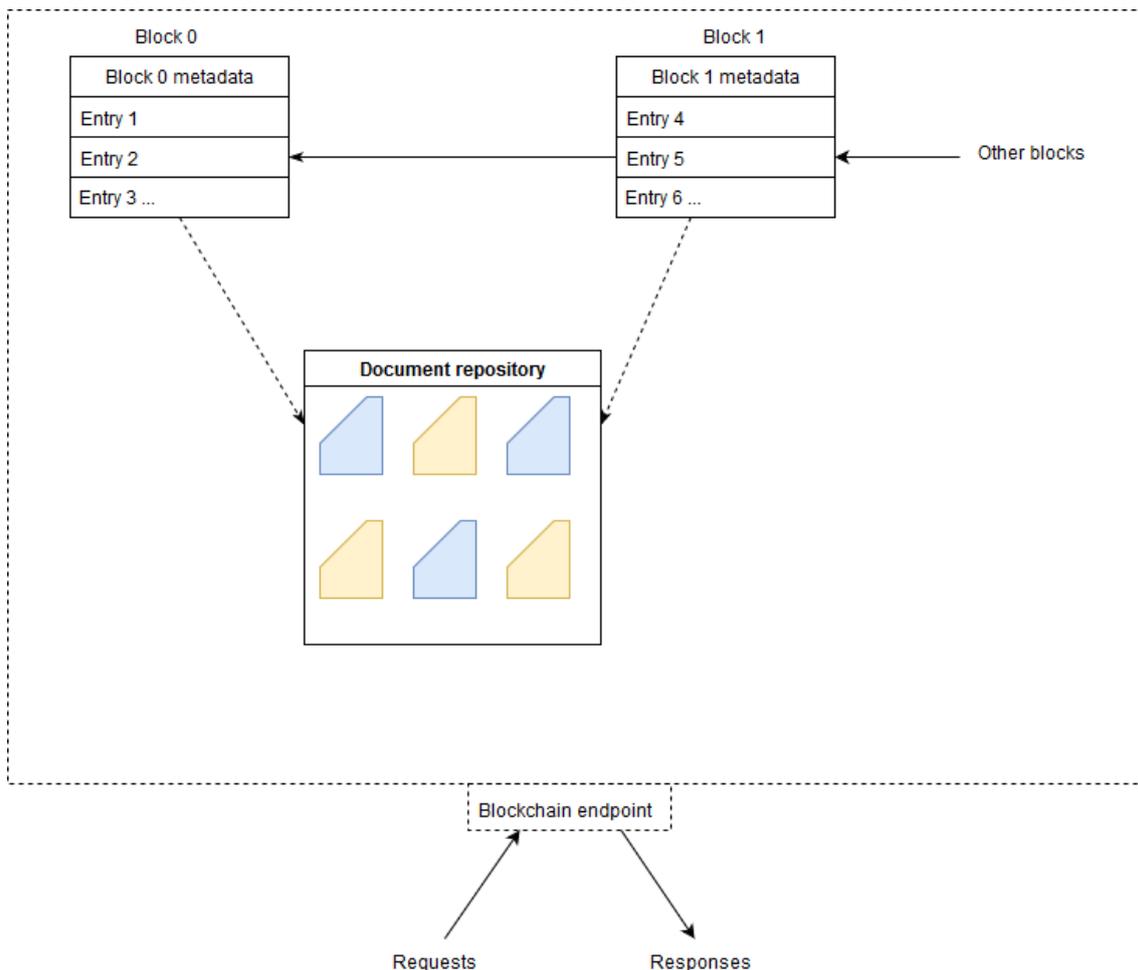

1. Generate the hash value for a document you wish to verify
2. Send a verification request to the blockchain endpoint which contains the hash value
3. Parse the response from the blockchain endpoint

The parsed response can be either positive or negative. In case of a positive response, we have proof that the document we are verifying exists in the blockchain and that it hasn't been amended by patches.

#### 4. DOCUMENT VERIFICATION FRAMEWORK STRUCTURE

The overall system consists of several components:

1. Blockchain
2. Blockchain endpoint
3. Document repository

**Diagram 1:** Framework architecture

As mentioned in the introduction, blockchain is a linear distributed database where entries (blocks) are added to it after a consensus between blockchain users has been reached. Blockchain is distributed across multiple nodes. A node is a computer running an instance of the software used to manage the blockchain. All nodes have the same copies of the blockchain. Nodes are denoted by the blockchain itself, since they all contain copies of it.

Blockchain configuration is stored in the block metadata. The metadata represents an index into the blockchain, which allows search and filtering of data. Metadata is represented by the following data structure:

```

{
  id: 0,
  parent: null,
  time: ["2018-02-12T17:03:12+00:00", "2018-02-12T18:03:12+00:00"]
  count: 3
}

```

**Figure 1** : Block metadata format

Where *id* is the number of the block in the blockchain sequence, *parent* represents the previous block *id* in the blockchain, *time* represents an array of start and end time of entries which the block contains and *count* denotes the number of entries inside the current block.

In order to add new blocks and entries to the blockchain, majority of nodes needs to perform a consensus vote in order to determine whether the data will be added or not. The consensus vote depends on the consensus algorithm implemented, but for simplicity, we are assuming that the consensus is reached when 50% plus one node approve the addition of data. On successful consensus vote, the incoming request gets added to the current active block as an entry. The current active block is determined by the time period it represents.

Positive consensus vote is achieved when the incoming data to the node gets evaluated by the software used to manage the blockchain. The evaluation is done across different criteria, depending on the application. When evaluation has been completed, the resulting data is propagated across the network of nodes.

Backbone of the communication between nodes is handled by the blockchain endpoint. Blockchain endpoint is a set of network configurations and infrastructure connecting blockchain nodes between each other and allowing access to the blockchain from outside. The end user using the blockchain would need to access only the blockchain endpoint, without having knowledge of the internal structure. The request would get routed to all nodes of the system and wait for their response.

Document repository represent file storage devices where files representing documents and patches are stored. In the diagram above, blue files represent documents, while yellow files represent patches. Documents and patches do not need to alternate between each other, as shown in the picture. Entries contain references to the hash values of documents and patches.

Patches should conform to the *Unix diff* unified format (Free Software Foundation). This allows a standardized way to apply patches to documents, as well as makes the patches human readable for inspection.

Entries represent parsed requests which have been consented by the nodes and written into the blockchain. An example entry is shown below:

```

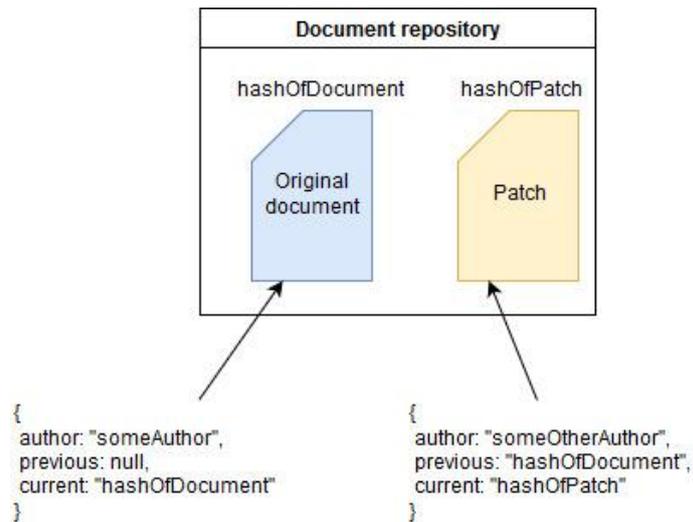

{
  author: "someOtherAuthor",
  previous: "hashOfDocument",
  current: "hashOfPatch"
}

```

**Figure 2** : Entry format

Where the field *author* represents the sign-off public key of the author, *previous* points to the hash value of the last patch (if it exists) and *current* is the actual hash value of the document or patch.

The diagram below represents mapping between the document repository and the blockchain. It is visible that the entries inside the blockchain contain all the necessary data to identify and reference to documents inside the document repository.

**Diagram 2 :** Blockchain and document repository mapping

Hash values used throughout this paper are assumed that they have been generated by the *SHA256* algorithm, while the cryptographic key pairs are assumed that they are based on the *RSA* cryptosystem with 2048 bit key length. The sign-off key is the public key of the key pair. Author verification is performed by choosing some data which is going to be used as the base line. Encrypting it by the private key in the entry and decrypting it by the author's private key should prove the public key's affiliation to the author – but only if the resulting decrypted data is the same as the input.

## 5. USE CASES

### 5.1. E-government

Having a distributed index of documents which cannot be tampered by any way without notifying the system of changes can prove to be the backbone of e-government. This would benefit both the citizens and the clerks of the country where its implemented.

The citizens would have an open way to check the validity of their documents by simply issuing the requests to the e-government blockchain and retrieving a positive or a negative response from the system.

On the government side, government procedures which monitor the blockchain can perform real-time updates when the documentation becomes expired. One concrete example is the driving license: in case of its expiration, the system would publish a patch request that invalidates the driving license in some way (such as setting a flag in the document). This, in turn, would amend the original driving license the citizen wants to verify, thus rendering it invalid – since it isn't the latest version inside the blockchain.

Another example is would be to check the status of your requests issued to the government (such as requests for granting citizenship). Querying the blockchain connected to e-government allows the request issuer to see how and where the request has been progressed.

When abstracted, requests are nothing more than regular documents which need to be approved or rejected due to some reason (e.g. missing additional documentation) by different entities. Each approval or rejection would be a patch to the original request, which can be read by the person which issued the original request.

In both examples the patches performed by the e-government cannot be changed in the future, without amending them across the whole blockchain. This means that the business process to handle document validity and to handle government requests cannot be modified by external modifications (e.g. by bribery) due to the distributed nature of the blockchain where a consensus on change needs to be reached (according to some consensus algorithm). In case of external modification, the system can be easily audited to determine where the anomaly has appeared.

### 5.2. Company accountability

The previous use case assumed that the blockchain is being hosted inside one entity (the government). It is also possible to host the blockchain both across companies and other entities, such as regulatory

committees. This would allow direct transparency into the subject matter without tampering. The condition to prevent tampering is selecting a consensus algorithm or having the critical number of blockchain nodes inside the company.

When the critical number of nodes belongs to the company (or the consensus algorithm is set in their favor), entities controlling the remainder cannot perform a takeover of the blockchain by issuing false data or denying incoming blockchain requests.

This node distribution can be useful for tracking government regulated goods (such as tobacco products or alcohol) between suppliers. Since the government has read-only access to the incoming blockchain requests, this removes the requirement of companies to produce reports concerning the sales and distribution of government regulated goods. An additional benefit is that the company's financial reports become easier to generate for the company. Furthermore, the government, since it has direct input into the current state of government regulated goods, can create more accurate tax rates and other regulation costs.

## 6. CONCLUSION

In this paper, we have proposed a framework which can be used for the development and research of document verification systems based on the blockchain. This system, by design, lowers the risk of document tampering and allows fast document verification. Documents are stored in document repositories, while their unique hashes are kept inside the blockchain. In order to add a document to the blockchain, a special request needs to be performed. Document modifications are performed by adding patches to the document repository and keeping track of their hash values inside the blockchain. When patches are added, the documents which are being amended need to be referenced. Verification is done by issuing a request containing the hash value of the document and receiving a positive or a negative response. Each request forms an entry inside a block. Each block delimits a specific time period. To perform any work on the blockchain, a consensus between nodes participating in the blockchain must be established.

## IMPROVING ROBERT C. MARTIN'S STABILITY SOFTWARE METRIC

Miloš Milić<sup>\*1</sup>, Vojislav Stanojević<sup>1</sup>, Siniša Vlajić<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, e-mail: mmilic@fon.bg.ac.rs

**Abstract:** *This paper discusses the problems of applying Robert C. Martin's Stability software metric when the influence of efferent or afferent couplings ( $C_e$  or  $C_a$ ) on stability of a package is relativized. The problem of relativisation occurs in the cases when a package has ( $C_a=0$  and  $C_e>0$ ) or ( $C_a>0$  and  $C_e=0$ ). This problem has been defined by means of an overdetermined system of four equations containing two unknown variables and solved by applying the least squares method. The obtained solution allowed introduction of new stability software metric, we named BU Stability software metric. The new software stability metric improves Robert C. Martin's Stability software metric since it solves the problem of relativization of  $C_e$  and  $C_a$ . Finally, evaluation of BU Stability software metric is carried out to demonstrate that it cancels out the effect of relativization of  $C_e$  and  $C_a$ .*

**Keywords:** *Software quality, Software System, Afferent coupling, Efferent coupling, Software stability, Robert C. Martin's Stability software metric, BU Stability software metric*

### 1. INTRODUCTION

According to ISO/IEC 25010 (2011), software quality is one of the most important factor in the development of sustainable and reliable software systems. Pressman (2005) defines software quality as "an effective software process applied in a manner that creates a useful product that provides measurable value for those who produce it and those who use it". The benefits of the software quality are reflected in increased productivity of software development and maintenance and decreased cost and time-to-market.

The software quality attributes, such as maintainability, stability, reusability, extensibility, etc., are strongly related to software package dependency. Milic et al. (2017) points that software quality standard define the software quality attributes in terms of software metrics. According to Martin (2011, 2006), some of the well-known software metrics related to software package dependency are: Afferent coupling, Efferent coupling, Instability, Distance from the Main Sequence, and Package Dependence Cycles.

In this paper our attention is paid to Robert C. Martin's Stability software metric. Prior to pointing at the problems associated with the indicated metric, a brief explanation of the concept of software stability is given. The software stability, according to ISO 9126 (2001), "characterizes the sensitivity to change of a given system, i.e. the negative impact that may be caused by system changes". Yau and Collofello (1980, 1985) said that software stability is resistance to propagation of changes (ripple effect) that the software would have when it is modified. Meyer (1997) identifies this as modular continuity. Fayad and Altman (2001) points at the importance of identifying the areas in the project that are stable during the development of a software project. The Tang and Xuan (2012) paper that analyses dependency between component based software packages was very helpful for our understanding of software package dependency and its influence on software package stability. In the previous studies presented in Vlajić (2007, 2011), we have tried to define a formal basis for making stable and sustainable software systems, through explanation of the design patterns by the symmetry concepts and software entropy in the context of software maintenance.

This paper makes a critical analysis of Robert C. Martin's Stability software metric that quantitatively expresses the stability of a software package via Efferent and Afferent couplings ( $C_e$  and  $C_a$ ). This metric exhibits deficiencies in two cases: a) the package has efferent but does not have afferent couplings ( $C_a=0$  and  $C_e >0$ ) and b) the package has afferent but does not have efferent couplings ( $C_a>0$  and  $C_e=0$ ). In the first case the influence of  $C_e$  on stability of the package is relativized, while in the second case the influence of  $C_a$  on stability of the package is relativized.

On the basis of these deficiencies, the problem has been defined by means of an overdetermined system of four equations having two unknown variables. It is well known that such systems, in general, do not have solutions. Therefore, there was a need to define 'solution' of such system. In that sense we have employed the least squares method, as presented in Nocedal and Wright (2006). The obtained solution made it possible for us to define a new software metric, called BU Stability software metric since it has been created at Belgrade University (BU), Faculty of Organizational Sciences, Department of Software Engineering.

The evaluation of the BU Stability software metric carried out at the end of the paper shows that this metric cancels out the effect of  $C_e$  and  $C_a$  relativization. BU Stability software metric will not impair Robert C. Martin's Stability software metric in the case when  $C_e > 0$  and  $C_a > 0$ , in other words when there isn't problem of  $C_a$  and  $C_e$  relativization. Furthermore it is demonstrated in the cases when ( $C_a=1$  and  $C_e > 0$ ) and ( $C_a > 0$  and  $C_e=1$ ).

## 2. ROBERT C. MARTIN'S STABILITY SOFTWARE METRIC

The object-oriented Stability software metric, as described by Robert C. Martin (2011, 2006), is one of the most frequently used metrics for determination of package stability (component stability). By means of stability metric we obtain a quantitative measure of package stability which is significant for the maintenance, re-use and upgrade of the package. According to Robert C. Martin (2011, 2006), this metric has the following form:

$$I = \frac{C_e}{C_a + C_e}, \quad (1)$$

where I is mark for Instability.

Stability software metric is based on Afferent couplings ( $C_a$ ) and Efferent couplings ( $C_e$ ) among the classes of the considered package (whose stability is being measured) and classes that are outside of this package. More precisely speaking,  $C_a$  refers to the number of classes outside the considered package that depend on classes within this package.  $C_e$  refers to the number of classes inside this package that depend on classes outside this package. Stability metric has the range [0,1]. If  $I = 0$ , the package has maximum stability. If  $I = 1$ , the package has maximum instability.

## 3. PROBLEM

Let us assume that we have packages Px, Py, and Pz containing classes  $X_1$ , Y, and  $Z_1$  respectively. Class  $X_1$  depends on the class Y, while class Y depends on the class  $Z_1$ . The dependencies between classes determine dependencies between the packages. Thus Px depends on Py, while Py depends on Pz (Fig. 1). Instability of package Py is  $I=1/2=0.5$ , since  $C_e = 1$  and  $C_a = 1$ .

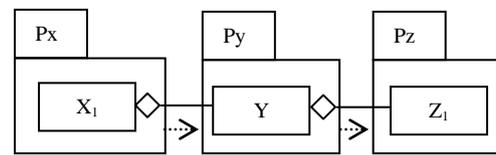

Figure 1: Package Py having  $C_e=1$  i  $C_a=1$

If a class  $Z_2$  is added to package Pz, whereby class Y depends on class  $Z_2$  (Fig. 2), then instability of package Py increases:  $I = 2/3=0.66$ , since  $C_e=2$  and  $C_a=1$ .

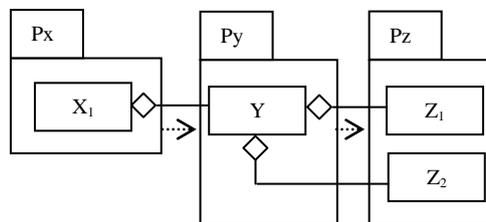

Figure 2: Package Py having  $C_e=2$  and  $C_a=1$

An increase of the number of classes ( $n$ ) in package Pz would increase the instability of Py package. In an extreme case when  $n \rightarrow \infty$ , then  $I \rightarrow 1$ :

$$I = \lim_{n \rightarrow \infty} \frac{n}{1 + n} = 1. \quad (2)$$

If in Fig. 1 class  $X_2$  is added to package  $P_x$ , whereby class  $X_2$  depends on class  $Y$ , then instability of package  $P_y$  decreases:  $I = 1/3 = 0.33$ , since  $C_e = 1$  and  $C_a = 2$ .

An increase of the number of classes ( $m$ ) in package  $P_x$  would decrease the instability of  $P_y$  package. In an extreme case when  $m \rightarrow \infty$ , then  $I \rightarrow 0$ :

$$I = \lim_{m \rightarrow \infty} \frac{1}{m + 1} = 0. \quad (3)$$

Stability of package  $P_y$ , when ( $C_a=1$  and  $C_e>0$ ) and ( $C_a>0$  and  $C_e=1$ ), is presented in Table 1:

**Table 1:** Stability of package  $P_y$  when ( $C_a=1$  and  $C_e>0$ ) and ( $C_a>0$  and  $C_e=1$ )

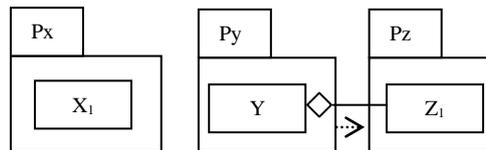

$C_a$	$C_e$	$I = C_e / (C_a + C_e)$
1	$n$	$\rightarrow 1$
1	$n-1$	...
1	...	...
1	5	0.83
1	4	0.80
1	3	0.75
1	2	0.67
1	1	0.50
2	1	0.33
3	1	0.25
4	1	0.20
5	1	0.17
...	1	...
$m-1$	1	...
$m$	1	$\rightarrow 0$

We can conclude that increasing of  $C_e$  leads to increasing instability of package  $P_y$ , while increasing of  $C_a$  leads to decreasing instability of package.

Deficiency of stability metric  $I$  is exhibited in two cases, addressed in Subsections 3.1 and 3.2.

### 3.1. Problem 1 – Relativization of $C_e$

In the first case, if the dependence between classes  $X_1$  and  $Y$  disappears ( $C_a=0$ ), see Fig. 1, instability of package  $P_y$  becomes 1 (Fig. 3), since  $I=1/(0+1)$ .

**Figure 3:** Package  $P_y$  having  $C_e=1$  and  $C_a=0$

If class  $Z_2$  is added to package  $P_z$ , instability of package  $P_y$  remains 1 ( $I=2/(0+2)$ ). We can conclude that the increasing  $C_e$  does not change instability of package  $P_y$  which is always 1, since  $I=C_e/(0+C_e)$  for  $C_a=0$ .

**We consider that deficiency of stability metric  $I$  is caused by  $C_e$  relativisation when  $C_a=0$  and therefore should be removed from the metric.**

The relativization of  $C_e$ , when  $C_a=0$  is presented in Table 2:

**Table 2:** Relativization of  $C_e$  when  $C_a=0$

$C_a$	$C_e$	$I = C_e / (C_a + C_e)$
0	1	1
0	2	1
0	3	1
0	4	1
0	5	1
0	...	1
0	$n-1$	1
0	$n$	1

### 3.2. Problem 2 – Relativization of Ca

In the second case, if the dependence between classes Y and Z<sub>1</sub> disappears (Ce=0), see Fig. 1, instability of package Py becomes 0 (Fig. 4), since  $I=0/(1+0)$ .

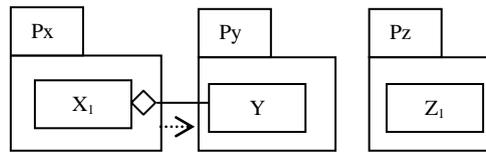

Figure 4: Package Py having Ce=0 and Ca=1

If class X<sub>2</sub> is added to package Px, instability of package Py remains 0 ( $I=0/(2+0)$ ). We can conclude that the increasing Ca does not change instability of package Py which is always 0, since  $I=0/(Ca+0)$  for Ce=0.

**We consider that deficiency of stability metric I is caused by Ca relativisation when Ce=0 and therefore should be removed from the metric.**

The relativization of Ca, when Ce=0 is presented in Table 3:

**Table 3: Relativization of Ca when Ce=0**

Ca	Ce	$I = Ce/(Ca+Ce)$
1	0	0
2	0	0
3	0	0
4	0	0
5	0	0
...	0	0
m-1	0	0
m	0	0

We can summarize problems 1 and 2, i.e. the problems of relativization Ce and Ca, in Table 4:

**Table 4: Stability of package Py when (Ca=0 and Ce>0) and (Ca>0 and Ce=0)**

Ca	Ce	$I = Ce/(Ca+Ce)$
0	n	1
0	n-1	1
0	...	1
0	5	1
0	4	1
0	3	1
0	2	1
0	1	1
1	0	0
2	0	0
3	0	0
4	0	0
5	0	0
...	0	0
m-1	0	0
m	0	0

The problem of relativization Ce (when Ca=0) and Ca (when Ce=0) will be solved if we determine stability metric  $I_r(\delta_1, \delta_2)$ , i.e. variables  $\delta_1$  and  $\delta_2$  of  $I_r$ , so that stability metric  $I_r(\delta_1, \delta_2)$  satisfies a condition (US<sub>1</sub>):  $1 > \dots > a > b > c > d > \dots > 0$ . This problem is presented in Table 5.

Stability metric  $I_r$  is denoted by letter  $I$  implying instability, and also by letter  $r$  implying relativization of Ce and Ca.

**Table 5:** The problem of relativization of Ce and Ca when ( $Ca=0$  and  $Ce>0$ ) and ( $Ca>0$  and  $Ce=0$ )

Ca	Ce	$lr(\delta_1, \delta_2) = (Ce + \delta_1)/(Ca + Ce + \delta_2)$
0	$n$	$\rightarrow 1$
0	...	...
0	2	$lr_1(\delta_1, \delta_2) = a$
0	1	$lr_2(\delta_1, \delta_2) = b$
1	0	$lr_3(\delta_1, \delta_2) = c$
2	0	$lr_4(\delta_1, \delta_2) = d$
...	0	...
$m$	0	$\rightarrow 0$

#### 4. SOLUTION

The stability metric  $lr$  can be represented by a system:

$$\begin{aligned} lr_1(\delta_1, \delta_2) &= a, \\ lr_2(\delta_1, \delta_2) &= b, \\ lr_3(\delta_1, \delta_2) &= c, \\ lr_4(\delta_1, \delta_2) &= d, \end{aligned} \quad (4)$$

where  $1 > a > b > c > d > 0$ .

Taking into account values of Ce and Ca from Table 5, we obtain a system of four equations containing two unknowns:

$$\begin{aligned} (2 + \delta_1)/(2 + \delta_2) &= a, \\ (1 + \delta_1)/(1 + \delta_2) &= b, \\ \delta_1/(1 + \delta_2) &= c, \\ \delta_1/(2 + \delta_2) &= d, \end{aligned} \quad (5)$$

which can be written in the form:

$$\begin{aligned} \delta_1 - a\delta_2 - 2a + 2 &= 0, \\ \delta_1 - b\delta_2 - b + 1 &= 0, \\ \delta_1 - c\delta_2 - c &= 0, \\ \delta_1 - d\delta_2 - 2d &= 0. \end{aligned} \quad (6)$$

The overdetermined systems, like (6), in general have no solutions. Nevertheless, we introduce the concept of 'solution' of system (6) following the idea of the least squares method. As a solution of system (6) we will imply ordered pair  $(\delta_1, \delta_2)$  giving minimum function of square deviation.

$$F(\delta_1, \delta_2) = (\delta_1 - a\delta_2 - 2a + 2)^2 + (\delta_1 - b\delta_2 - b + 1)^2 + (\delta_1 - c\delta_2 - c)^2 + (\delta_1 - d\delta_2 - 2d)^2 \quad (7)$$

Such solution is obtained by solving the system of equations:

$$\begin{aligned} \frac{\partial F}{\partial \delta_1} &= 0, \\ \frac{\partial F}{\partial \delta_2} &= 0. \end{aligned} \quad (8)$$

In the present case, the system has form:

$$\begin{aligned} 2(\delta_1 - a\delta_2 - 2a + 2) + 2(\delta_1 - b\delta_2 - b + 1) + 2(\delta_1 - c\delta_2 - c) + 2(\delta_1 - d\delta_2 - 2d) &= 0, \\ -2a(\delta_1 - a\delta_2 - 2a + 2) - 2b(\delta_1 - b\delta_2 - b + 1) - 2c(\delta_1 - c\delta_2 - c) - 2d(\delta_1 - d\delta_2 - 2d) &= 0. \end{aligned} \quad (9)$$

This system can be simplified to a system:

$$\begin{aligned} 4\delta_1 - (a+b+c+d)\delta_2 &= 2a+b+c+2d-3, \\ (a+b+c+d)\delta_1 - (a^2+b^2+c^2+d^2)\delta_2 &= 2a^2+b^2+c^2+2d^2-2a-b, \end{aligned} \quad (10)$$

which is linear with respect to  $\delta_1$  and  $\delta_2$ . The previously described system (10) will be illustrated by the case when, e.g.  $a = 0.6$ ,  $b=0.55$ ,  $c=0.45$  and  $d=0.4$ . In this case system (10) is reduced to:

$$\begin{aligned} 2\delta_1 - \delta_2 &= 0 \\ -2\delta_1 - 1.025\delta_2 &= 0.205, \end{aligned} \quad (11)$$

whose solution is:  $\delta_1 = 4.1$ ,  $\delta_2 = 8.2$ .

This solution represents solution of stability metric  $lr$  **(4.1, 8.2)**, which can be presented as:

$$Ir = \frac{Ce + 4.1}{Ca + Ce + 8.2}, \text{ or}$$

$$Ir = \frac{Ce + \delta_1}{Ca + Ce + 2\delta_1}, \text{ for } \delta_1 = 4.1. \quad (12)$$

If we introduce substitution:

$$Ce' = Ce + \delta_1, \quad (13)$$

$$Ca' = Ca + \delta_1,$$

Ir can be represented in the following form:

$$Ir = \frac{Ce'}{Ca' + Ce'}, \text{ with } Ce' = Ce + \delta_1, Ca' = Ca + \delta_1, \delta_1 = 4.1. \quad (14)$$

**Software metric  $I_r$**  improves the Stability software metric of Robert C. Martin, since it solves the problem of relativization of  $C_e$  (when  $Ca=0$ ) and  $Ca$  (when  $C_e=0$ ).

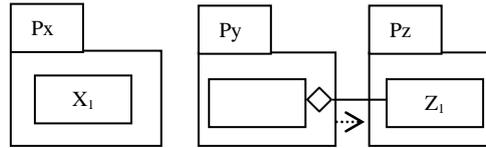

**Remark:** As we have seen, determination of variables  $\delta_1$  and  $\delta_2$  was dependent upon solvability of system (10). Now, we shall show that this system always has a solution for any set of values  $a, b, c$ , and  $d$  satisfying condition  $1 > a > b > c > d > 0$ . Indeed, since determinant of the system is:

$$D = (a+b+c+d)^2 - 4(a^2+b^2+c^2+d^2) = -[(a-b)^2 + (a-c)^2 + (a-d)^2 + (b-c)^2 + (b-d)^2 + (c-d)^2],$$

obviously  $D \neq 0$  for  $1 > a > b > c > d > 0$ , thus system (10) has a unique solution in relation to  $\delta_1$  and  $\delta_2$ .

## 5. EVALUATION

If software metric  $I_r$  is applied for obtained solution of the first problem (Fig. 5), where  $C_e$  is relativized, in the case when  $Y$  is related to  $Z_1$  and the relation between  $X$  and  $Y$  does not exist, instability of package  $P_y$  will be:  $I_r = 5.1/9.2 \approx 0.55$ .

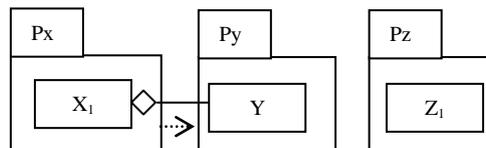

**Figure 5:** Package  $P_y$  having  $C_e=1$  and  $Ca=0$

In the case when class  $Z_2$  is added to package  $P_z$ , instability of package  $P_y$  will be  $I_r = 6.1/10.2 \approx 0.6$ . With increasing of  $C_e$ , instability of package  $P_y$  will keep increasing, converging towards 1. We consider that software metric  $I_r$  improves software metric  $I$  and cancels out the effect of  $C_e$  relativization, when  $Ca=0$ , since instability of package  $P_y$  is increasing with increasing of  $C_e$  (Table 6).

**Table 6:** Cancellation of the effect of  $C_e$  relativization when  $Ca=0$

Ca	Ce	Ca'	Ce'	$I_r = Ce' / (Ca' + Ce')$
0	$n$	4.1	$n+4.1$	$\rightarrow 1$
0	$n-1$	4.1	$n+3.1$	...
0	...	4.1	...	...
0	5	4.1	9.1	0.69
0	4	4.1	8.1	0.66
0	3	4.1	7.1	0.63
0	2	4.1	6.1	0.60
0	1	4.1	5.1	0.55

If software metric  $I_r$  is applied for obtaining solution of the second problem (Fig. 6), where  $Ca$  is relativized, in the case when  $X_1$  is related to  $Y$  and relation between  $Y$  and  $Z_1$  does not exist, instability of package  $P_y$  will be:  $I_r = 4.1/9.2 \approx 0.44$ .

**Figure 6:** Package  $P_y$  having  $C_e=0$  and  $Ca=1$

In the case when class  $X_2$  is added to package  $P_x$ , instability of package  $P_y$  will be:  $I_r = 4.1/10.2 \approx 0.4$ . With increasing of  $Ca$ , instability of package  $P_y$  will keep decreasing, converging towards 0. We consider that

software metric  $I_r$  improves software metric  $I$  and cancels out the effect of  $Ca$  relativization, when  $Ce=0$ , since instability of package  $Py$  is decreasing with increasing of  $Ca$  (Table 7).

**Table 7:** Cancellation of the effect of  $Ca$  relativization when  $Ce=0$

$Ca$	$Ce$	$Ca'$	$Ce'$	$I_r = Ce'/(Ca'+Ce')$
1	0	5.1	4.1	0.45
2	0	6.1	4.1	0.40
3	0	7.1	4.1	0.37
4	0	8.1	4.1	0.34
5	0	9.1	4.1	0.31
...	0	...	4.1	...
$m-1$	0	$m+3.1$	4.1	...
$m$	0	$m+4.1$	4.1	$\rightarrow 0$

**Software metric  $I_r$**  represents a solution of the problem of  $Ca$  and  $Ce$  relativization and it can be presented as:  $I_r = Ce'/(Ca'+Ce')$ , with  $Ce' = Ce + \delta_1$ ,  $Ca' = Ca + \delta_1$ , for  $\delta_1 = 4.1$  (Table 8).

**Table 8:** Solution of the problem of  $Ce$  and  $Ca$  relativization when ( $Ca=0$  and  $Ce>0$ ) and ( $Ca>0$  and  $Ce=0$ )

$Ca$	$Ce$	$Ca'$	$Ce'$	$I$	$I_r$
0	$n$	4.1	$n+4.1$	1	$\rightarrow 1$
0	$n-1$	4.1	$n+3.1$	1	...
0	...	4.1	...	1	...
0	5	4.1	9.1	1	0.69
0	4	4.1	8.1	1	0.66
0	3	4.1	7.1	1	0.63
0	2	4.1	6.1	1	0.60
0	1	4.1	5.1	1	0.55
1	0	5.1	4.1	0	0.45
2	0	6.1	4.1	0	0.40
3	0	7.1	4.1	0	0.37
4	0	8.1	4.1	0	0.34
5	0	9.1	4.1	0	0.31
...	0	...	4.1	0	...
$m-1$	0	$m+3.1$	4.1	0	...
$m$	0	$m+4.1$	4.1	0	$\rightarrow 0$

It should be stressed that software metric  $I_r$  will not disturb the existing software metric  $I$  in cases when  $Ce>0$  and  $Ca>0$ , i.e. when the problem of relativization of  $Ce$  and  $Ca$  does not appear. In addition, e.g. when ( $Ca=1$  and  $Ce>0$ ) and ( $Ca>0$  and  $Ce=1$ ), the corresponding values of metrics  $I$  and  $I_r$  are decreasing (Table 9) from 1 towards 0. The ratio between the corresponding values in both metrics is maintained. This means that ratio  $I(i)/I(i+1)$ ,  $i=1, 2, \dots, r$ , remains the same as the ratio  $I_r(i)/I_r(i+1)$ . For example, if  $i=p+2$ , then  $I(p+2)>I(p+3)$ ,  $0.80>0.75$ ; the same ratio remains for  $I_r$ , i.e.  $I_r(p+2)>I_r(p+3)$  or  $0.61>0.58$ .

**Table 9:** Stability of package  $Py$  when ( $Ca=1$  and  $Ce>0$ ) and ( $Ca>0$  and  $Ce=1$ )

Row	$Ca$	$Ce$	$Ca'$	$Ce'$	$I$	$I_r$
1	1	$n$	5.1	$n+4.1$	$\rightarrow 1$	$\rightarrow 1$
2	1	$n-1$	5.1	$n+3.1$	...	...
...	1	...	5.1	...	...	...
$p$	1	...	5.1	...	...	...
$p+1$	1	5	5.1	9.1	0.83	0.64
$p+2$	1	4	5.1	8.1	0.80	0.61
$p+3$	1	3	5.1	7.1	0.75	0.58
$p+4$	1	2	5.1	6.1	0.67	0.54
$p+5$	1	1	5.1	5.1	0.50	0.50
$p+6$	2	1	6.1	5.1	0.33	0.46
$p+7$	3	1	7.1	5.1	0.25	0.42
$p+8$	4	1	8.1	5.1	0.20	0.39
$p+9$	5	1	9.1	5.1	0.17	0.36
...	...	1	...	5.1	...	...
$r-1$	$m-1$	1	$m+3.1$	5.1	...	...
$r$	$m$	1	$m+4.1$	5.1	$\rightarrow 0$	$\rightarrow 0$

## 6. CONCLUSION

We have improved Robert C. Martin's Stability software metric in the cases when the influence of the efferent and afferent couplings upon stability of a considered package is relativized. At first, Robert C. Martin's Stability software metric has been explained:  $I = \frac{Ce}{Ca+Ce}$ .

Then, the deficiency of this metric has been identified and illustrated. This deficiency occurs when a considered package has either no afferent or no efferent coupling ( $Ca=0$  or  $Ce=0$ ). If I stability metric has no afferent coupling ( $Ca=0$ ) and has efferent coupling ( $Ce>0$ ), then the efferent couplings is relativized. If I stability metric has no efferent coupling ( $Ce=0$ ) and has afferent coupling ( $Ca>0$ ), then the afferent couplings is relativized.

The indicated problem has been represented by means of an overdetermined system of four equations containing two unknown variables and solved by applying the least squares method. The solution has been presented in terms of software metric  $I_r$ :  $I_r = \frac{Ce'}{Ca'+Ce'}$ , with  $Ce' = Ce+\delta_1$ ,  $Ca' = Ca+\delta_1$ ,  $\delta_1 = 4.1$ .

Software metric  $I_r$  improves software metric  $I$  because  $I_r$  solves the problem of relativization of  $Ce$  (when  $Ca=0$ ) and  $Ca$  (when  $Ce=0$ ), which was identified as a deficiency of software metric  $I$ . It was stressed that software metric  $I_r$  will not disturb software metric  $I$  in the cases when  $Ce>0$  and  $Ca>0$ , i.e. when the problem of  $Ce$  and  $Ca$  relativization does not occur. This was demonstrated in the cases when ( $Ca=1$  and  $Ce>0$ ) and ( $Ca>0$  and  $Ce=1$ ). Since the obtained software metric has been created at **Belgrade University (BU)** we named it "**BU Stability software metric**".

**Abstract:** *In this paper we have described how a html content can be dynamically replaced using different libraries and frameworks. Practical example of dynamic content rendering was realized through jQuery, JsRender and Angular. Differences and similarities as well as advantages and disadvantages will be presented in the analysis where different aspects, such as load time, ease of maintenance, adjusting to changes must be taken into consideration. Analysis of selected libraries and frameworks was conducted in order to make a decision whether to use or not to use a framework.*

**Keywords:** *Dynamic content, JavaScript, jQuery, JsRender, Angular*

## 1. INTRODUCTION

JavaScript programming language is almost an inevitable part of nowadays web applications. Providing dynamic and interactive experience for the user has become an imperative. The number of JavaScript frameworks which help us achieve this, has increased considerably in the last few years. Choosing the appropriate framework has become a challenge. (Crockford, 2008)

Flexible and interactive applications that quickly respond to user requests have a lot of dynamic content. Rendering such content may take some time. In order to improve a web page's interactivity and usability the shortening of rendering time can be achieved by simply updating part of the page instead of the entire web page. There are various ways to do this and they will be presented in this paper. Analysis of these technologies is based on various factors such as load time, ease of maintenance, adjusting to changes. (Ambler & Cloud, 2015)

A brief overview of client and server-side rendering and importance of JavaScript in Web applications development is given in the second chapter. An example of dynamic content rendering is realized by using jQuery, JsRender and Angular. The solution of the same problem, in different ways, is shown by using each of them. Specifics for each technology are shown through snippets of code.

Many authors conducted a comparative analysis of JavaScript frameworks. A detailed study was conducted by Pano, Graziotin and Abrahamsson (v6. 2018) in order to identify and understand the factors that influence the choice of a JavaScript framework. According to them, actors leading to the adoption of a JavaScript Framework are customer, developer, team and team leader. Factors leading to the adoption are performance expectancy, effort expectancy, social influence, facilitating conditions and price value. (Pano, Graziotin, & Abrahamsson, 2018)

Analysis conducted in the fourth chapter is aimed at making a decision whether to use or not to use a framework considering dynamic content rendering. Conclusions and our vision of future work are described in the fifth chapter.

## 2. DYNAMIC CONTENT RENDERING

Unlike traditional web applications that mostly relied on server-side rendering, modern web applications generally involve client-side rendering. Server-side rendering implies that browser make a request to the server and gets rendered HTML. It is often necessary to render only a certain component on a page as opposed to loading of the entire page from server. This feature is one of the basic characteristics of Single-page applications. Impression of a "native" environment in the browser (like a desktop application), without page reloads in order to quickly respond to user actions. Remarkable user experience is just one of the advantages of this approach. Client-side rendering implies using JavaScript to render content in the browser. (Brikman, 2015)

“JavaScript is a programming language used primarily by Web browsers to create a dynamic and interactive experience for the user.” (Flanagan, 2011) ECMAScript is the official name for JavaScript. In a common context JavaScript applies to a programming language, while ECMAScript applies to language specification. The current version of JavaScript is ECMAScript 8, from June 2017. (Rauschmayer, 2014) Unlike earlier, static, nowadays web pages mean more interactions, features like floating menus, add sound, display advertisements, animations, etc. Those features can be realized by different tools, and JavaScript is one of the most prominent ones. (Kiong, 2018)

Simple, multi-paradigm (scripting, object-oriented, imperative, functional) programming language, easy for learning – JavaScript has become an inevitable part of nowadays web applications. There are many JavaScript plugins, libraries and frameworks, and some of them are the subject of this paper.

## 2.1. jQuery

jQuery is defined as “fast, small, and feature-rich JavaScript library”. (jQuery, 2018) Initial release of jQuery was on 2006, and since then until today stands for the most popular JavaScript library. (Miles, 2016)

The major components of jQuery:

- The DOM selection – methods which help finding elements in document object model
- DOM manipulation – manipulation methods that modify previously found elements
- Events – handling events as a precondition for creation a dynamic website
- Form – methods for easier sending information back to a server
- CSS and animation – methods for handling classes, locations and dimensions of elements
- Ajax - methods for exchanging data with a server
- Helpers – to iterate over a collection, determine the type of object and many others (Miles, 2016)

One of the main ideas was to save coding time (no more writing plumbing code) and focuses on essential functionalities which can be seen in the JQuery’s motto “write less, do more”. (Miles, 2016)

## 2.2. JsRender

Described as “A lightweight, powerful and highly extensible templating engine”, JsRender supersede jQuery Templates plugin. (JsRender, 2018) Optimized for high-performance rendering, without DOM dependency, JsRender is used for data-driven rendering of templates to strings. (JsRender, 2018)

JsViews platform adds data binding to JsRender templates and together provide fully-fledged MVVM platform for creation interactive single page applications and websites. JsRender can be used with or without jQuery. (JsRender, 2018)

Template can be defined from a string,

```
var template = $.templates("City: {{:city}}");
```

or in a script block as markup. (JsRender, 2018)

```
<script id="myTemplate" type="text/x-jsrender">
City: {{:city}}
</script>
```

With render function we can render a template as below.

```
var city = {city: "Belgrade"};
var html = template.render(city);
```

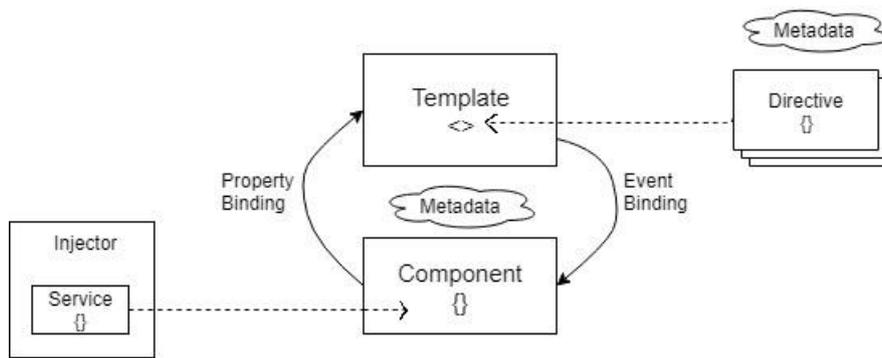

An array also can be passed, then template renders for each element in the array. (JsRender, 2018)

There are many tags in JsRender which enable iterate over arrays, over object’s properties, conditional inclusion and other useful features.

## 2.3. Angular

Client-side web application as one of the models for modern applications tend to be more flexible and interactive with quickly responds to user requests. (Clow, 2018) One of the most popular frameworks for this

purpose is Angular. Defined as “a platform and framework for building client applications in HTML and TypeScript” (Architecture overview, 2018) Angular is one of the most popular JavaScript frameworks.

**Figure 1:** Architecture overview

Main building blocks of an Angular application and their relations are shown in Figure 1. NgModules as a fundamental building block provides a compilation context for components. Application is defined by a set of NgModules. Components define views and use services which provide specific functionality. In order to take advantage of lazy-loading NgModules loading on demand. Data and logic are located in classes defined by component associated with a HTML template. To modify HTML elements a template combines HTML with Angular markup. Two-way data binding is supported. For some data or logic which needs to be shared across components and not connected with a specific view, it is possible to create service class. Metadata are provided by @Injectable decorator that allows services to be injected into components as a dependency. (Architecture overview, 2018)

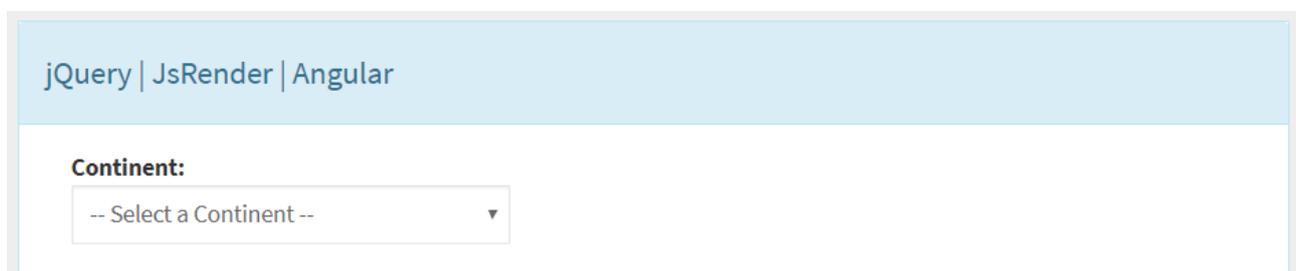

### 3. AN EXAMPLE OF DYNAMIC CONTENT RENDERING IN SELECTED TECHNOLOGIES

The HTML page has many interconnected components. Some of them change more often than others. In order to improve a web page's interactivity and usability it is possible to avoid rendering of the entire page, but only to render a certain component on a page. User interactions on one component can cause rendering of another component on the page. The related components affect one another, and their synchronization can be realized in several ways. Hiding, changing content are just some of the most common user interactions that will be presented.

Problem setting

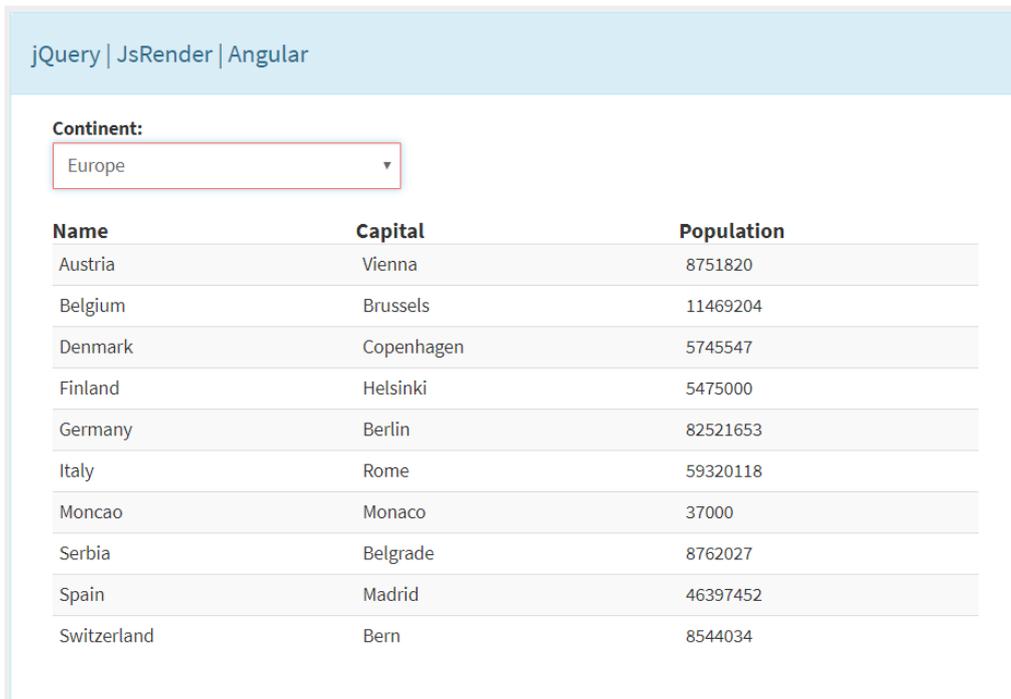

It is necessary to create drop-down list whose elements are continents. After choosing a particular continent, a table with countries belonging to the selected continent should be displayed. Continent is determined by name and collection of countries, while a country is determined by name, capital and population.

At the beginning, the look of the component is shown in Figure 2.

**Figure 2:** The look of a component

After choosing a particular continent, a table with countries is displayed as is shown in Figure 3.

**Figure 3:** Displayed table with countries

Solution of the problem

### 3.1. jQuery

Bootstrap is used to stylish a HTML page.

```
<div class="panel-body">
  <div id="continent-container" class="container">
    <div class="row col-md-3">
      <label>Continent:</label>
      <select id="continent" class="form-control">
        <option id="-1" disabled selected>-- Select a Continent --</option>
      </select>
    </div>
  </div>

  <div id="countries-container" class="container col-md-12"> </div>
</div>
```

Drop-down list is created by select element. Initially there is only one option. The received data, continents, should be added as options. One of the ways is presented in code snippet below.

```
$.each(continents.continents, function (index, continent) {
  $("#continent").append($("#<option>", { id: continent.continentId})
    .text(continent.continentName));
});
```

The append() method was used. This method “insert content, specified by the parameter, to the end of each element in the set of matched elements”. (append, 2018) Prepend() method is similar, the difference is that content is inserted as a fist child.

After adding continents to drop-down list, it is necessary to define what happens by selecting a particular continent or in jQuery’s language define what happens on click on the continent element.

```

var selectedContinentId = $(this).find('option:selected').attr('id');

var selectedContinent = $.grep(continents.continents, function (continent) {
    return continent.continentId == selectedContinentId;
})[0];

```

To find a selected continent, in order to find belonging countries, the method `grep` was used. This method “finds the elements of an array which satisfy a filter function”. (jquery.grep, 2018)

```

if (selectedContinent != undefined && selectedContinent.countries.length > 0) {

var $table = $('<table id="countries-table" class="table table-striped"></table>');
var $thead = $('<tr> <th> Name </th> <th> Capital </th> <th> Population </th> </tr>');
var $tbody = $('<tbody></tbody>');

$.each(selectedContinent.countries, function (index, country) {
    var $tr = $('<tr> <td>' + country.countryName + '</td> <td>' + country.capital +
        '</td> <td>' + country.population + '</td>');
    $tbody.append($tr);
});

$table.prepend($('<br/>'));
$table.append($thead).append($tbody);
$("#countries-container").append($table);
}

```

As shown in code snippet above, after defining table, table head and table body, for each country of a selected continent a new row is being created and added in table body. In the end, created table is added to `countries-container`.

### 3.2. JsRender

Panel body is almost identical as in the previous example, except that a select element initially has no options. The received data, continents, should be added as options. At the beginning the template was created.

```

<script id="continent-template" type="text/x-jsrender">

    <option id="-1" selected>-- Select a Continent --</option>
    {{for continents}}
    <option id="{>#data.continentId}">{{#data.continentName}}</option>
    {{/for}}

</script>

```

After passing an array to JsRender, the template will be the same for every element in the array. Inner content in script will not be parsed as JavaScript by adding the `text/x-jsrender` attribute on the script. (Matthews & Gliser, 2015) To get the compiled template it was used `$.templates()` method with a jQuery selector. Next step is for render to obtain template according to the given data (continents), and get the HTML output as a string. In the end we inserted that output into the continent element. (JsRender, 2018) The previously described procedure is shown in code snippet below.

```

var template = $.templates("#continent-template");
var htmlOutput = template.render(continents);
$("#continent").empty();
$("#continent").html(htmlOutput);

```

As in the previous example, after adding continents to drop-down list, it is necessary to define what happens by selecting a particular continent. Finding a selected continent is identical as in the previous example. It is necessary to create a new template for countries.

```

<script id="country-template" type="text/x-jsrender">
  {{if countries.length > 0}}
  <br />
  <table class="table table-striped">
    <thead>
      ...
    </thead>
    <tbody>
      {{for countries}}
      <tr>
        <td>{{>#data.countryName}}</td>
        <td>{{>#data.capital}}</td>
        <td>{{>#data.population}}</td>
      </tr>
      {{/for}}
    </tbody>
  </table>
  {{/if}}
</script>

```

Countries of selected continent are given to template for rendering and output has been inserted into the countries container as shown below.

```

$("#countries-container").empty();

if (selectedContinent[0] != undefined) {
  var template = $.templates("#country-template");
  var htmlOutput = template.render(selectedContinent[0]);
  $("#countries-container").empty();
  $("#countries-container").html(htmlOutput);
}

```

### 3.3. Angular

Defining classes is the first step.

Continent class

```

export class Continent {
  constructor(public continentId: number, public continentName: string, public
    countries: Country[]) {
  }
}

```

Country class

```

export class Country {
  constructor(public countryId: number, public countryName: string, public capital:
    string, public population: number) {
  }
}

```

Panel body is similar to the previous examples.

```

<div id="continent-container" class="container">
  <div class="row col-md-3">
    <label>Continent:</label>
    <select id="continent" [(ngModel)]="selectedContinent" class="form-control">
      <option [ngValue]="null" disabled>-- Select a Continent --</option>
      <option *ngFor="let continent of continents"
        [ngValue]="continent">{{ continent.continentName }}
      </option>
    </select>
  </div>
</div>

```

Using the ngFor directive it is possible to iterate over continents collection. Current element is defined as continent. Each element of collection becomes an option which value is continent as object and text is continent's name. An example of two-way binding is given in [(ngModel)] = "selectedContinent". HTML element select is associated with selectedContinent variable from TypeScript component and the change on either side is reflected on the other. A HTML component is associated with TypeScript component.

```

export class AppComponent {

  public continents: Continent[];
  public selectedContinent: Continent;

  constructor() {
    this.continents = ...
    this.selectedContinent = null;
  }
}

```

The previously described connection between elements and properties is now clearer.

As in the previous example, after adding continents to drop-down list, it is necessary to define what happens by selecting a particular continent. Finding a selected continent is much simpler than in previous examples. If conditions defined by ngIf are met, access to the countries of a selected continent implies iteration through an array. Unlike previous examples where we had to find selected continent object in continents collection, now we just need to take selectedContinent variable and we can access the associated attributes. Previously explained two-way binding will provide up-to-date information at any time.

```

<br *ngIf="selectedContinent && selectedContinent.countries.length > 0"/>
<div id="countries-container" class="container col-md-12" *ngIf="selectedContinent
  && selectedContinent.countries.length > 0">
  <table class="table table-striped">
    <thead> ... </thead>
    <tbody>
      <tr *ngFor="let country of selectedContinent.countries">
        <td>{{ country.countryName }}</td> <td>{{ country.capital }}</td>
        <td>{{ country.population }}</td>
      </tr>
    </tbody>
  </table>
</div>

```

#### 4. ANALYSIS OF DYNAMIC CONTENT REPLACEMENT IN SELECTED TECHNOLOGIES

Each framework is oriented towards the concrete problem, but all of them serve the same purpose - to make dynamic and interactive experience for the user. Frameworks give liberty to developers to focus on functionalities without taking too much care about the structure. The most frequent comparisons are ones in which frameworks are compared between each other. In order to make a decision whether to use or not to use a framework, some relevant factors can be closer examined as given below.

#### 4.1. Based on load time aspect

Measuring page's loading time in used example, JsRender showed the best results. Not far behind JsRender is jQuery which took a little longer time to load, and following jQuery is Angular which showed the slowest results in this scenario. The difference in performance on the side of the user would be more obvious with the more complex example. The application usually contains lots of feature modules which are loaded all at once. Often there is no need for this, so lazy loading can help reducing the size of bundle when the app loads initially implies reducing loading time which improves user experience. Computer hardware specification is constantly improving and has better performances as well as browsers' JavaScript engines, so the concern about the speed is becoming a minor problem.

#### 4.2 Based on ease of maintenance aspect

Today's applications have hundreds of lines of code in whose realization participate independent teams. Maintaining these applications is getting harder and harder. Developers often forget that it is not only important to write code that solves the problem, but also the one that is efficient. Maintaining a code is about finding better ways to resolve a problem. The code is usually maintained by someone who has not written it which slows down the process. Duplicated coding, divergence from coding standards and bad code structure are often the cause of severe and long-lasting maintenance which has a significant impact on the budget. Maintenance is much easier and faster in an Angular than in jQuery or JsRender. Automatically generated code that synchronizes the Model and the View is one of the benefits of using Angular. Based on this example it can be concluded that jQuery generates more lines of code than the other two. One of other flaws of jQuery is that a HTML element was built by string concatenation and the browser will still have to parse it. Also, jQuery code is not readable and maintainable as code in templates used in the JsRender, and especially in the Angular. It is easier to maintain JsRender code, but as it is most often combined with jQuery functions, that is what makes it more difficult to maintain a complete application.

#### 4.3 Based on adjusting to changes aspect

In order to stay competitive, applications should adapt to constant changes and new challenges. Customer requests are often changed and companies must be ready to meet them, otherwise they could lose a competitive advantage. Depending on how the code is structured, changes will be more difficult or easier to apply. Let's consider the problem of calculating the average population of countries.

In jQuery that would mean adding a new html element by string concatenation and additional calling of append() method. The average is calculated by iteration through all the countries of the selected continent as is shown below.

```
var averagePopulation = ((selectedContinent.countries.map(function (country) {
    return country.population; })).reduce(
    function (sum, population) { return sum + population; })) /
    selectedContinent.countries.length).toFixed(2);

var $tfoot = $('<tfoot><tr><th></th> <th> Average population </th> <th>' +
    averagePopulation + '</th> </tr></tfoot>');

$table.append($thead).append($tbody).append($tfoot);
```

In Angular it is necessary to add *tfoot* element in html

```
<tfoot>
<tr>
  <th></th>
  <th>Average population</th>
  <th>{{ averagePopulation() }}</th>
</tr>
</tfoot>
```

and calculate average population in TypeScript.

```

averagePopulation(): string {
  return (this.selectedContinent.countries.reduce((sum, country) => sum +
    country.population, 0) / this.selectedContinent.countries.length).toFixed(2);
}

```

In JsRender example this would imply changing the template.

```

<script id="country-template" type="text/x-jsrender">
  {{* window.total = 0}}
  {{* window.length = 0}}
  {{if countries.length > 0}}
    ...
    {{for countries}}
    {{* total += data.population}}
    {{* length += 1}}
    ...
  {{/for}}
</tbody>
<tfoot>
  {{* window.average = (total/length).toFixed(2)}}
  <tr>
    <th></th> <th>Average population</th> <th>{{*: average}} </th>
  </tr>
</tfoot>
{{/if}}
</table>
</script>

```

Angular proved to be the easiest to adjust, then JsRender, then jQuery.

## 5. CONCLUSIONS AND FUTURE WORK

From the conducted analysis and practical example, several conclusions can be outlined. Answer the question whether to use or not to use a framework depends on array of different but interconnected factors, analyzed in this paper. On the basis of previously mentioned facts, the question might arise why we do not always use Angular when it has been proved to be the best solution for most problems. When developing a lightweight application without too much user interaction and dynamics, Angular would be a costly solution. If the separate, static, pages are the basics of the site and intended to be presented to search engines Angular would not be a good solution. When discussing the choice, the time and the human (in terms of developer's knowledge) limitations should be considered. Finding a pattern which could help about this decision looks like a tough task. The user usually does not describe his needs precisely and constantly has additional requirements, most of which cannot be foreseen. There are always some requirements or functionalities that could be done in a better way in other technology. That is why technologies are often combined which most often leads to acceptable solution. However, combining technologies is not universal solution and it could cause additional issues which should be examined in detailed.

In order to make the right decision, it is necessary to look at all the constraints, to precisely determine what should be achieved, taking into consideration the variability in the future. Finding the intersection between mentioned constraints and possibilities that technology delivers is crucial for fining the optimal solution for a given problem.

For the purpose of this research jQuery, JsRender and Angular were considered. Next step would be to include more components in analysis, categorize them according to different types of requests and repeat the previous analysis.

## DEVELOPMENT OF AN E-RECRUITMENT PORTAL USING MEAN STACK TECHNOLOGIES

Tamara Naumović<sup>\*1</sup>, Stevan Milovanović<sup>1</sup>, Svetlana Mitrović<sup>2</sup>  
<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia  
<sup>2</sup>Project Management College  
<sup>\*</sup>Corresponding author, e-mail: tamara@elab.rs

**Abstract:** *This paper presents the development of an e-recruitment portal using MEAN stack technologies. The goals of the portal are job and internship advertising, easy and efficient search and e-recruitment. The developed portal is an aggregator of business proposals and intermediary in the process of e-recruitment. Students and workers looking for employment have the ability to send curriculum vitae via electronic applications. Valid applications collected via the portal are being forwarded to potential employers. Use of the developed model enhances the process of connecting employers with those who seek employment. Finally, the paper points out the specifics and advantages of using MEAN stack technologies for developing e-recruitment portals.*

**Keywords:** *E-business, electronic employment offers, e-recruitment, portal for e-recruitment, aggregator*

### 1. INTRODUCTION

Employers often face the need to find competent candidates who can meet hiring needs with their knowledge and skills. Many companies, for the purpose of employing suitable candidates, use the Internet as a mean of entering the e-market of labor. Anyone looking for a job, over the Internet, on e-market of labor, can easily obtain information about employment offers in their field of interest. Web portals play an important role in facilitating and accelerating mediation in the employment process. For people seeking an employment, the existence of "job search" portals is of high importance (Stevenson, 2008). Portals of this kind are mostly aggregators of employment offers of different companies. For the ones seeking a job, they provide an overview of job and internship offers (Mitrović, 2010).

E-market of labor provides job seekers with the ability of quick search of a large number of employment offers. Usually, companies in the employment process prefer collecting electronic business curriculum vitae (e-CV) through e-recruitment portals (Mitrović, 2011). In this way, job seekers can leave their biographies to potential employers. Web portals can be a medium for e-recruitment of candidates suitable for a job (Unadkat, 2012). The advantages of using a portal for e-recruitment are to quickly find and obtain job information, easy and simple communication between job seekers and employers, and the possibility of employment in remote locations (Radenković et al., 2015). Furthermore, portals for e-recruitment provide more information about companies and job offers and have an advanced possibility of matching candidates' skills and job requirements.

This paper presents an e-recruitment portal. The idea for creating this portal has emerged after observing the work of Association of students of information sciences FONIS, established in 2001. on the Faculty of Organizational Sciences. The main goal of this work is developing a unique aggregator web portal that will help connect companies with students and narrow the channel by which students get the employment information.

### 2. MODEL OF E-RECRUITMENT VIA WEB PORTAL

#### 2.1. E-recruitment

Before we explain the model of e-recruitment and its use, let's revise the e-recruitment as a term. E-recruiting stands for the use of internet for attracting, recruiting, and retaining job seekers and employees and also individuals who are content in their current position (these are called "passive candidates"). Also known as Internet recruiting, virtual recruiting and online recruitment.

E-recruitment emerged as an idea in late '90s, early 2000s with exponential growth of at home Internet usage and proliferation of dot-coms, as Betsey Stevenson explains (Stevenson, 2006). In July, 2000 Alan Kruger wrote "The Internet is rapidly changing the way workers search for jobs and employers recruit

workers. The resulting speed and ease of filling jobs have significant implications for unemployment, pay and productivity". He further concludes that those who lack access to Internet job market may suffer restricted job opportunities (Kruger, 2000).

To fully comprehend the meaning of e-recruitment let's look at the definition Lievens and Harris provide: "any method of attracting applicants to apply for a job that relies heavily on the Internet" (Lievens & Harris, 2003). This summarizes the whole idea behind e-recruitment. The means, methods, approaches of this type of recruitment constantly evolve and expand, so in this paper we will focus on the web portal model of e-recruitment.

## **2.2. Web portal as a model of e-recruitment**

Model of e-recruitment via web portals represents a unique access point for e-recruitment, job seeking, information and services such as job application, FAQ, statistics, etc. The user gets access to complete their applications without the need of individual access to each of the services. The content of the portal is dynamic, updated often with search possibility.

Given the circumstances that portal models are based on attracting a great number of users by offering free content, revenue models are often based on one or combination of following models:

- Advertising. A great number of users allow the portal to sell ad space.
- Membership. Even though users get the content for free, it is possible to charge membership on certain extra content.
- Partnership programs. Users can be directed to partners websites and create income for the portal.

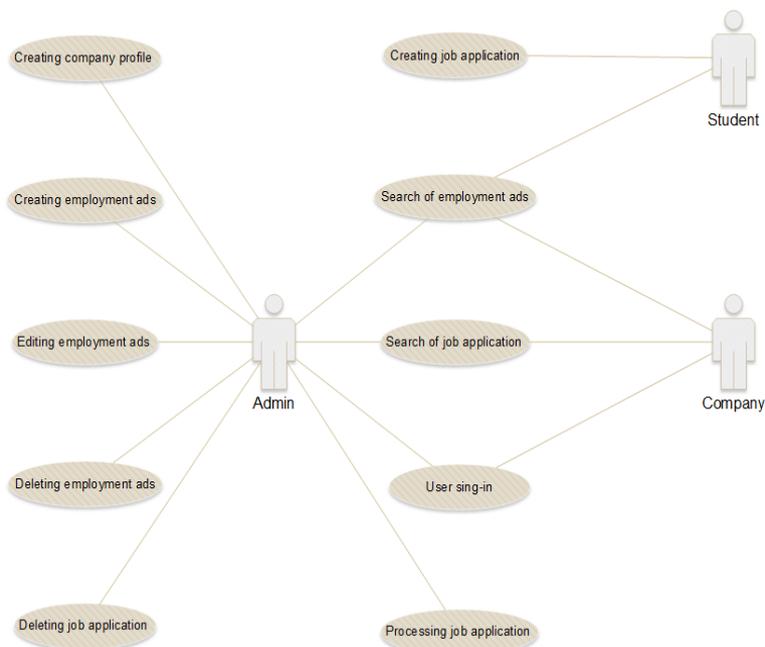

Beside admin users who manage the system, end users of the portal are companies and students. Because of that, the portal allows different usage possibilities. Admin users can sign-in, manage records about the companies, job and internship ads, and applications. Admin users have a privileged access to the system, which allows them to manipulate the data within. Under the term manipulate, we consider the ability to create company profiles, keeping and managing records about applications for a certain company, as well as the processing of the applications, creating and keeping records about ads created for the company and their further management.

To a company, the portal allows logging into the system, where it shows all the records of the company, including created ads and submitted applications. Company users are allowed to create and moderate existing ads, but ads can only be submitted for admin approval.

A student is a guest user of the portal and doesn't have the possibility of logging in, because the idea of the portal is to ease the access to the given information. Portal allows guest users to see published ads with all of the provided information, perform a search with certain criteria and submit the application. As the student doesn't have their own account, further notifications and information are given through e-mail service, to the e-mail address provided in the application.

For the purpose of filtering employment information, the proposed e-recruitment portal has the following main functionalities (Figure 1):

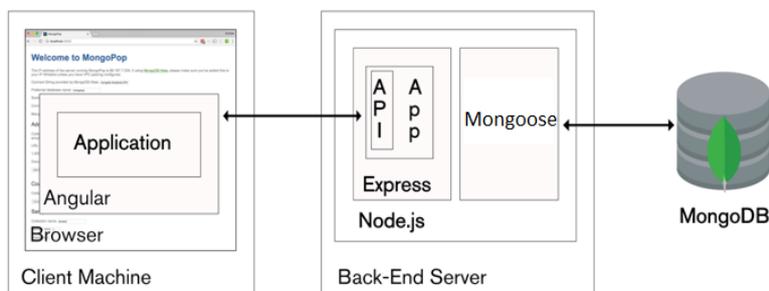

- User sign-in
- Creating company profile
- Creating employment ads
- Editing employment ads
- Deleting employment ads
- Search of employment ads
- Creating job application
- Deleting job application
- Processing job application
- Search of job application

**Figure 1: Use case diagram**

### 3. E-RECRUITMENT PORTAL ARCHITECTURE

E-recruitment portal has been created using MEAN Stack technologies (Haviv, 2014): MongoDB as a database, Express.js as the Node.js (Internet 1) framework for backend and Angular as frontend of the application. MEAN Stack represents significant change in standard architecture – from relational databases to NoSQL (Strauch, 2009), from MVC oriented architectures to client single-page applications (Đorđević, 2015). E-recruitment portal architecture is shown in Figure 2.

**Figure 2: E-recruitment portal architecture**

In the first section (on the left), the client part of the portal is shown, whose main components have been developed in Angular. It contains all UI components, all services needed for data display and sending data to the server. Server part (in the middle), is based on Node.js server, which listens to all HTTP requests. The backend of the portal consists of Node.js implemented using the Express.js framework, crucial for creating API of the portal, then Mongoose (Rahić, 2017), MongoDB tool for object modeling (MongoDB Architecture Guide, 2017), used for creating all object models used through the portal. The last part of the portal is MongoDB. It contains all collections populated by BSON documents needed for proper functioning of the portal. Collections used for implementation of this portal are (Figure 3):

1. Collection of internship ads
2. Collection of categories
3. Collection of subcategories
4. Collection of internship applications
5. Collection of users
6. Collection of messages

```

2 messages
3 potkategorijas
4 praksas
5 prijavas
6 users

```

**Figure 3:** List of database collections

MongoDB represents JSON documents in a binary-encoded format called BSON behind the scenes (Holmes, 2015). BSON extends the JSON model to provide additional data types, ordered fields, and to be efficient for encoding and decoding within different languages. The MongoDB BSON implementation is lightweight, fast and highly traversable. Like JSON, MongoDB's BSON implementation supports embedding objects and arrays within other objects and arrays (Leite, 2015). MongoDB can even 'reach inside' BSON objects to build indexes and match objects against query expressions on both top-level and nested BSON keys. This means that MongoDB gives users the ease of use and flexibility of JSON documents together with the speed and richness of a lightweight binary format (Internet 3; MDN, 2017). Documents are built with a name or key and value pairs. An example of one document is shown in Figure 4.

## 4. IMPLEMENTATION OF AN E-RECRUITMENT PORTAL

### 4.1. Main page

The home page consists of a navigation menu, which contains a path to other parts of the application, and lists of ad practices and jobs. The main page for the guest user is shown in Figure 5 and for the administrator in Figure 6.

**Figure 5:** Main page for the guest user

**Figure 6:** Main page for the administrator user

The guest user is able to search jobs using the filter shown below the navigation menu. Filters represent the categories of published jobs. Categories are set by entering ad data. A guest user is allowed to sign in to ad,

while admin or user with standard access is not. Clicking on the Login button will open the registration form within the ad itself.

The job application contains mandatory fields such as name, surname, e-mail, and link to e-CV and other optional fields that extend the application. By clicking on the button, the user sends an application for the job. The Sign in button is disabled until all mandatory fields are entered. After successfully completing the login form and clicking the Login button on the ad, the user gets a notification in the pop-up window.

The screenshot shows a job application form for a 'Software Engineer Mobile Android' position at 'NAMICS'. The position is 'Senior'. The form contains the following fields and sections:

- NAME\***: Text input field.
- PREZIME\***: Text input field.
- MEJL\***: Text input field.
- TELEFON**: Text input field.
- LINKEDIN**: Text input field.
- PORTFOLIO**: Text input field.
- LINK DO TVOG CV-A\***: Text input field.
- OKAČI NEGODE, NPR. DROPBOX**: Text input field.
- PROPRATNA PORUKA**: Large text area for a message.

There are two green buttons: 'Prijavi se' (top) and 'Prijavi se na oglas' (bottom).

Figure 7: Job application form

## 4.2. Custom CMS

In order to administrator log in into the system, email address and password are required. This form is not available through the navigation menu, in order to prevent the abuse of the portal. After a successful login, the admin is redirected to the home page. The admin console page consists of a special navigation menu that contains a path to the ad management page, a login management page, a page for creating new users, and a logout page (Figure 8).

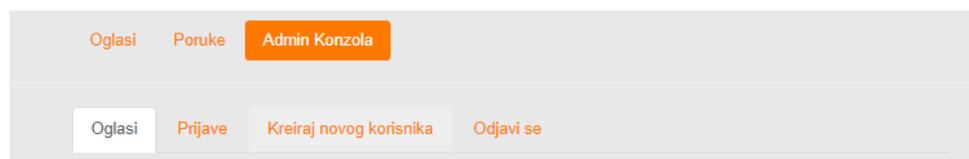

Figure 8: Appearance of a navigation user with an administrator access

### 4.2.1. Ad management

The ad management page consists of two parts: forms for adding new and editing existing ads, and a list of all published ads (Figure 9).

**Figure 9:** The ad management page

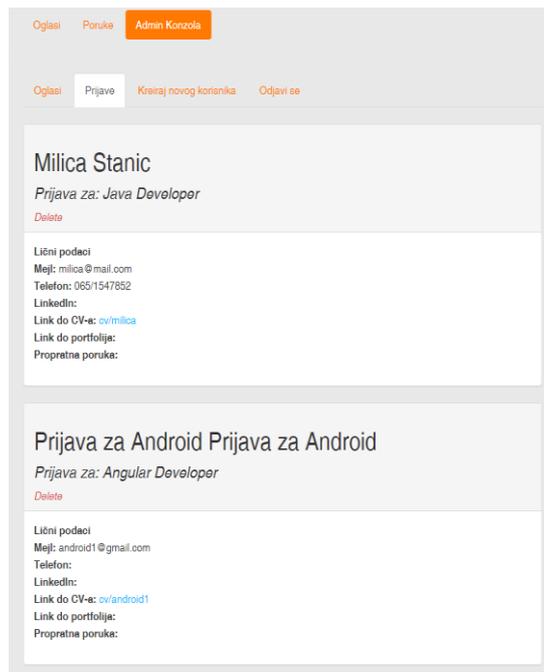

By filling out the form and clicking the Save button, the user adds a new ad to the database. All form fields are required. Fields Tags and Categories allow a search of ads. By selecting technologies in the Category field, a menu with predefined tags opens, which the user can mark (Figure 10). The Save button is disabled until all the fields are filled, which partly optimizes the validation of the form.

After successfully saving the chosen options, the user receives a notice in the form of a pop-up window. Within the ad list, each ad has the Edit and Delete option in the bottom right corner. By clicking Edit link, the form is filled in with existing ad data and editing of ads is allowed. If the user wants to delete the ad, they need to click on the Delete link, after which a pop-up window will appear where the user needs to confirm the deletion of the ad. The user is prevented from deleting ads in case that some users had applied for that ad.

**Figure 10:** A menu with predefined tags

#### 4.2.2. Application management

By selecting Login in the navigation menu, the login management page will be shown. This form contains a list of all submitted ads (Figure 11). Admin user is allowed to view and delete applications. Changing the login is not possible, in order to prevent the abuse of the platform.

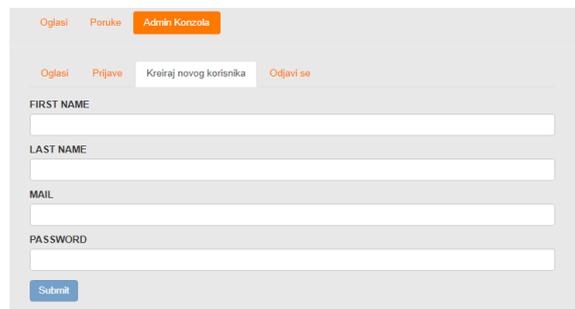

**Figure 11:** Login management page

Each application to the ad contains information entered through the application form and the name of the ad for which the application is filled in. To the administrator, an overview of all applications has been provided, while company users are allowed to review applications related only to their company. If the user wants to delete the application from the system, it is necessary to click on Delete in the Application header. After the user selects the option to delete, a pop-up window appears in order for the user to confirm the deletion.

### 4.2.3. User management

Only administrators can create new users (Figure 12). All form fields for creating a new user are required. The Submit button is disabled until all fields are filled properly.

**Figure 12:** The page for creating new users

## 5. CONCLUSION

This paper presents an e-recruitment portal developed using MEAN stack technologies. The contribution of the paper is twofold. Firstly, an e-recruitment portal for advertising jobs and internships specifically to student population can make their search easier and quicker. The existence of multiple job portals and multiple channels for advertising internships make the process of finding a suitable one hard and time-consuming. Developing a portal as a service of a student organization is suitable because the students can find a suitable job or internship through a single channel. Secondly, this paper presents a case study of the usage of MEAN stack technologies for developing web portals. The choice of technologies allows an easy and rapid application development while creating a scalable and flexible application that can easily adapt to future changes.

In further development, it is planned to create a section Company in which it would be possible to search for companies ads that have created profiles on the portal. There will be an improved section of statistics in which companies can see statistics related to practices, such as the number of views, the number of applications and other. Furthermore, section Questions will show all guest users' questions for specific ad.

In order to reduce manual processing of job applications, an e-mail service will enable direct sending of job applications to companies.

## DEVELOPMENT OF AN IOT SYSTEM FOR FIRE-FIGHTING IN SMART HOMES

Ivan Jezdović<sup>\*1</sup>, Aleksandar Ivković<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

<sup>\*</sup>Corresponding author, e-mail: ivan@elab.rs

**Abstract:** *This paper shows an example of an IoT system for fire-fighting in smart homes. As support to this system, web application for tracking of sensors detection and warnings is shown. The devices that register smoke and flame and inform fire departments are implemented. The web application should enable early detection of fire and extinguish early fire while informing the house owner of the situation via SMS or via GSM call. All data is followed in real time through web application which is used by fire department. Aim of this system is to detect and prevent fire disasters in real time.*

**Keywords:** *Internet of things, smart homes, home security, fire protection, fire-fighting*

### 1. INTRODUCTION

The term Internet of Things (IoT) was reportedly coined by Kevin Ashton, more than 15 years ago. The new world of IoT is creating widespread connectivity which includes devices such as cameras, toasters, garage doors, environmental and security systems inside homes and business through remote control of different sensors such as temperature, light, motion and detection (The Internet of Things and the fire service, 2017). The IoT offers promising solutions to convert conventional systems into modern ones. The technology is based on wireless sensor network, actuators, GPS and mobile devices and units. IoT is a global network of devices which communicate among each other, have their identities, physical attributes, intelligent interface and are integrated into the information network (Vujovic, 2015).

Smart home technologies (SHTs) comprise sensors, monitors, interfaces, appliances and devices networked together to enable automation and remote control of the domestic environment (Cook, 2012). Controllable appliances and devices include heating and hot water systems (boilers, radiators), lighting, windows, curtains, garage doors, fridges, TVs, and washing machines (Robles & Kim, 2010). Control functionality of these devices is provided by software on computing devices (smartphones, tablets, PCs) or through dedicated hardware interfaces (e.g. wall-mounted controls). Global consumer research carried out in seven countries worldwide, including UK and Germany, suggests a high level of market support. Over half of consumers surveyed expressed a general interest in smart homes, and 50% believe SHTs will have an impact on their lives over the next few years (GFK, 2016). Market forecasts project over half a million households in Germany will have smart appliances or devices by 2019, driven by widespread adoption of smart phones. However actual levels of uptake of smart home technologies are still low, and smart product sales are dominated by internet-connected TVs (Harms, 2015). Market growth mostly depend on users who are perceiving potential benefits and acceptable levels of risks. Smart home technologies can greatly improve energy management, security, safety, enhanced leisure and entertainment services and personal independence through healthcare provision and assisted living. (Chan et al., 2009; Nyborg & Røpke 2011). The most significant barrier to adoption of SHTs is upfront cost, privacy, security of data, reliability and interoperability of different technologies. Also there could be a social impact such as increased laziness in domestic life.

The Internet of Things (IoT) has led much of the world becoming smarter and more connected. Fire protection is among the various areas that can realize the true benefits of Internet of Things. Fire prevention and fire safety equipment are undergoing a massive revolution thanks to the Internet of Things. Internet of Things devices are connected to low power wide area or cellular networks to enhance prevention, increase response time and keep the first firefighters on the scene safe. The National Fire Protection Agency reports that 1.170.000 fires took place only in the U.S. during 2017, which resulted in 2.430 civilian deaths and \$11.8 billion in property damage. Despite improved safety equipment and training, the greatest danger that firefighters face are the unknown factors they must deal with on the scene. Many departments already employ smart technology, such as thermal cameras. IoT goes even one step further, it enables leaders on the ground to see what is happening on the scene while tracking every team member's location in real time. IoT can integrate with existing alarms, personal safety devices and fire suit technology with only minor adjustments. Tracking technology keeps firefighters safer by reporting each member's exact location directly

to the shift commander, but these devices don't work using GPS technology because of its low reliability inside a concrete or steel structure. Lightweight RFID based trackers are used instead. By using the exact location and thermal cameras commander can map the area and offer guidance for other team members (Firefighting with IoT, 2017).

The model of firefighting system in smart homes is developed that should enable early prevention of loss caused by the fire and smoke. A web app should enable monitoring in real time, reducing the response time and automatically extinguishing small fires. With complete implementation of the system it should reduce costs, increase efficiency regarding the intervention, increase security inside home and improve living conditions overall.

## 2. LITERATURE OVERVIEW

The fire service and other emergency first responders are currently benefiting from enhanced-existing but also from newly-developed technologies. Firefighters are operating in the sensor rich environment that is creating great amount of potentially useful data. The "smart" firefighter is going to be able to fully exploit selected data and to perform work tasks in a highly effective and efficient manner (Sundmaeker, Guillemin, & Friess, 2010).

Firefighting safety field has made remarkable progress in recent years in the building of information network, and has many results in application, and part of application patterns have taken shape in terms of IoT. The overall society has great expectation and demand pressure to the improvement of Fire IoT management level, and provided a great market potential for its application.

The modern firefighting system is based on wireless sensor network in combination with Internet of Things. Due to modern and advanced technology the system minimizes the losses caused by fire. There is significant variety of information accessible by fire brigades and great potential lies within Internet of Things. The Fire Protection Research Foundation's executive director Casey Grant says "Real-time information will greatly assist emergency responder situational awareness, which is especially critical during an event when time is precious" (Xin & Quanyi, 2010).

Fire automatic alarming systems are very popular nowadays. These systems are widely used in most civil and industrial buildings in China. With only one additional internet interface and one management software in a single building, fire detection can be realized. Distant monitoring systems (DMS) are the link for to the buildings with the alarming system. Distant monitoring systems are based on modern communication network and allow real-time monitoring of all information. This is just the beginning of such systems which can be technically improved further. This improvement has been achieved by the rapid development of "Golden Shield" firefighting teams in China, by taking advantage of public security private network and specialized communication network. Progress in automatic office work, sharing and using of firefighting information as well as rapid response of firefighting teams have been achieved (Vijayalakshimi & Murugananad, 2017).

Fire protection management consists of 4 main parts:

1. Regulations - all public and some civilian buildings must have fire safety regulations in case of emergency.
2. Supervision - supervision management contains archives of fire management, fire safety inspection, fire control inspection and so on.
3. Response capacity of fire emergency - it contains response plan establishment, full-time firemen and voluntary fire brigade formation and response plan drills. Comprehensive fire emergency response plan can not only do a lot of help to assist commanders while giving commands, making decisions and deployment but also to ensure the fire officers and soldiers get familiar with environment immediately and deploy rationally.
4. Publicity and education training - building should have fire safety bulletin boards in the striking place, which disseminate fire hazards and the measures to be taken when the fire breaks out. Regular fire safety training should be organized to ensure that all occupants know the emergency evacuation process. (Ying-conga & Jingb, 2013)

Only two companies today successfully sell and implement smart IoT solutions. ZigBee and Aeris solutions are the leaders in IoT fire prevention systems. Aeris offers comprehensive solution meant to enhance security in emergency situation, and mostly prevent firefighting staff from injures or even death. The most important capabilities of Aeris' products are team members tracking in real time using the most advanced technology that is fireproof, light to carry into the scene and extremely reliable. Robotic response is another capability. These robots may be able in some cases to arrive on the scene faster than humans. They are supplied with oxygen and sensors to help and identify victims inside the fire and are able to map and clear

the rooms before the firefighters arrive on the scene. The main downsides of Aeris are price. These systems are too expensive and they still involve a lot of human interaction to function properly (Gao, 2016). ZigBee technology made a revolution in fire prevention. They made five systems that can work independently or together as a single unit. It involves fire control room as an intermediary between the building and fire department. Since the fire breaks out, thermal monitoring system sends a fire signal into the fire control room of the building and activates ZigBee's hydrant extinguishing system to extinguish the early fire. When the control room confirms the disaster, a fire signal is sent to the fire department. Where ZigBee's IoT terminal is used to find the shortest route to the fire scene.

The five systems of ZigBee are as follows:

1. Thermal imaging fire monitoring system
2. ZigBee IoT alarm system
3. Wireless ZigBee fire hydrant monitoring and related technology
4. Mobile terminal information sharing system
5. ZigBee IoT terminals and radio frequency positioning rescue technology (Jang & Gao, 2010).

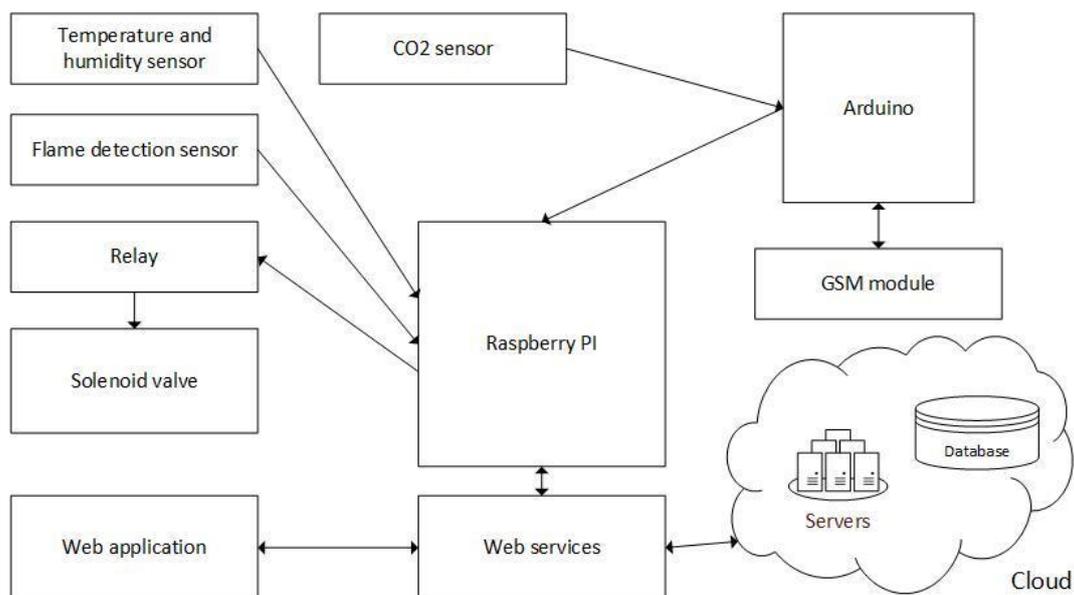

Downside of such a system is its price, even as a single system. It requires a lot of human involvement, it is not customizable enough, and it can only be implemented in the early phase of building construction, otherwise costs can be as triple as normal.

The requirements for the firefighting system monitoring developed in this paper are as follows:

- Sensors for gathering information on the scene
- Database server for real-time tracking
- Automation of extinguishing process
- Fire department and firefighting personnel

### 3. MODEL OF IOT SYSTEM FOR FIRE-FIGHTING IN SMART HOMES

This paper presents a system that allows early detection of fire, alarming the fire department and activating the countermeasures. The system consists of a smoke detection sensor, a temperature sensor, a flame detection sensor, a relay, a solenoid valve, GSM module, Arduino microcontroller and a Raspberry Pi microcomputer. In the case of smoke detection, the fire department is alarmed through the web application and the location and smoke pollution information is sent to the screen of the brigade in charge. In addition to informing the fire department, using the GSM module, a mobile call is placed to the smart home owner. If the situation gets worse and early fire and smoke turn into real fire, the flame detector sends a signal to the control unit that activates the relay which activates a solenoid valve. Valve brings water to sprinklers in order to extinguish fire and prevent severe damage to the smart home.

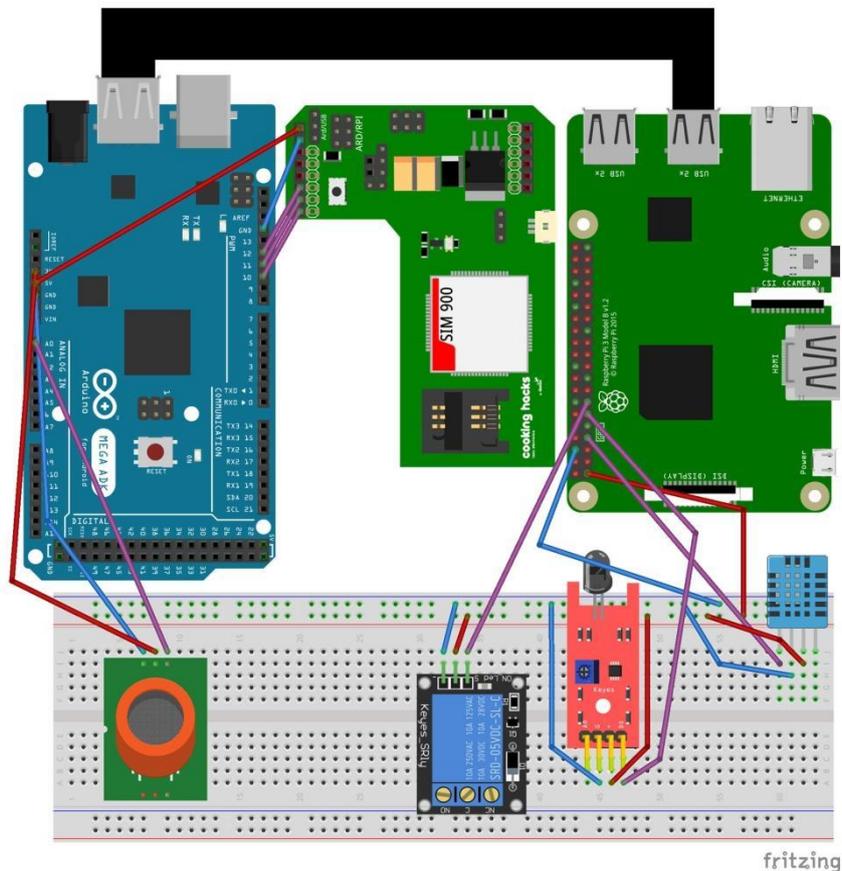

**Figure 1:** Model of fire fighting system in smart homes based on Internet of Things

When such events happen all information is sent to fire departments in order to improve the service and better prioritise emergency situations in the future. All necessary data is passed through a web application.

Using this kind of model it is very easy to determine levels of CO<sub>2</sub> in the air or detect flame. This information is crucial to take next steps to protect the household and its residents. The use of this model allows complete automation of fire extinguishing. Additional information is provided by the temperature sensor and the humidity sensor. These sensors can be very useful in early detection of a fire.

Data is sent via web services to the server and it is stored in non-relational MongoDB database. MongoDB is an open-source database management system based on documents. It is classified as a NoSQL database that avoids the traditional structure of relational database-based databases. The basic structure consists of JSON documents with dynamic schema, or BSON format (binary JSON). Sensibility of the flame detection sensor is set to maximal, so it would detect any light in the room.

**Figure 2:** Physical connection of devices

On the figure 2 are shown Raspberry Pi microcomputer and Arduino microcontroller connected with sensors and actuators. Blue lines represent cables that are connected to the ground (negative pole) on Raspberry Pi. Red lines represent cables that are connected to power source of 3.3v or 5v on Raspberry Pi. Purple lines represent cables that transfer data between devices.

Raspberry Pi has a web server running. Arduino is connected to Raspberry Pi and sends data read from CO<sub>2</sub> sensor. Temperature and humidity sensor, relay and flame detection sensor are connected to Raspberry Pi while GSM module is connected to Arduino. Because of big amount of data the non-relational database is used and it is located on the cloud.

#### **4. DEVELOPMENT OF WEB APPLICATION FOR FIRE-FIGHTING SYSTEM**

In order to implement such system in regular household few requirements have to be met. Whole house has to be covered with stable Wi-Fi connection, constant power and water supply. In addition to this requirements, the house owner should have mobile phone with GSM and SMS capabilities.

This paper presents a web application that allows firefighters in the control centre to monitor the state of carbon monoxide in smart homes. The web application is developed by using Bootstrap framework. Application logic on server side is developed in PHP programming language. Parts of the application logic which are executed on the client's side are developed using JavaScript. AJAX is used for data insight in real time. All communication with web server takes place through sending and receiving HTTP requests that carry data in JSON format.

Along with carbon monoxide information, in case of emergency, application shows CO2 level, address and option to send fire fighting vehicles to the location. Location is visualised, using Google maps as it is shown on Figure 3. Based on location, system calculates ETA by checking the location of the nearest emergency vehicle.

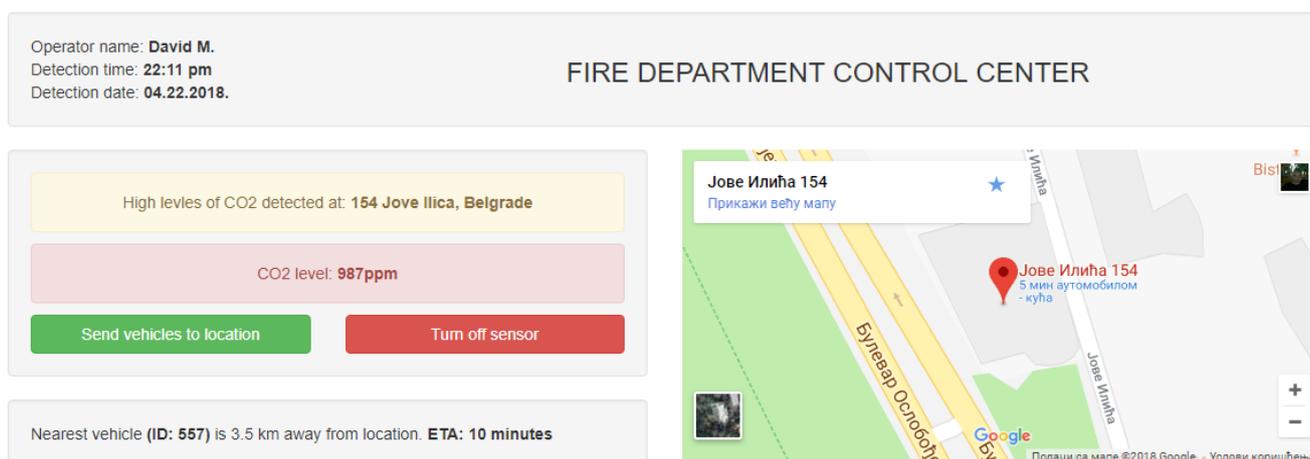

Figure 3: Fire department web application

At the same time while sending the information to the fire department, the system, uses GSM module which is connected to the Arduino and calls home owner to inform the about potential fire disaster.

As an alternative to web application it is possible to develop mobile application. Within mobile application user would have an insight to the data from the sensors inside the smart home, with some additional functions like push notifications.

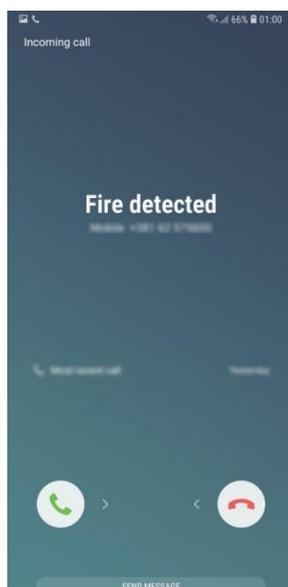

Figure 4: Call initiated via GSM module

## 5. CONCLUSION

In this paper, development of an IoT system for fire-fighting in smart homes is shown. System was developed on Department of e-business at Faculty of Organizational Sciences, University of Belgrade. Architecture of the proposed model is defined. Furthermore, implementation for firefighting system in smart homes was presented.

Main advantages of this solution are simplicity, low cost of equipment and possibility of implementation in other smart environments like smart buildings, offices and storages. Important advantage of this solution compared to other solutions is versatility. This system can easily be implemented into civilian homes without a need for major construction works. Model can be improved with additional sensors. Expanding the sensor network will increase data collection which will lead to improvement of system precision and it will allow better recognition of early fire.

One of disadvantages of this system is that it requires advanced technical knowledge needed for implementation. In order for system to work with optimal performance participation of the city administration is needed to enable communication between smart homes and emergency services.

While other solutions mostly relies on human involvement and low automation, system shown in this paper overcomes these difficulties by using solenoid valve which is connected to water source. Solenoid valve is able to send water to sprinklers and quickly extinguish early fire, which makes it completely automated system.

Real-time data is shown inside the fire department which includes temperature, gas level, and data gathered from flame detector. This way quick intervention of fire brigade is always provided to those who need it.

This system can be improved by analysing all the collected data from sensors. Analysing large amounts of data in real time and using machine learning can allow the fire department to detect the fire before it actually starts. This new approach gives a reliable solution that can permit to detect fires risks, in order to avoid severe damage of this disaster, when it happens. Application of IoT in fire monitoring is an excellent solution that leads to smart city development.

# DEVELOPMENT OF A SMART AGRICULTURE AUTOMATION SYSTEM BASED ON INTERNET OF THINGS AND USE OF RASPBERRY PI

Nikola Cvetković<sup>1</sup>, Minja Marinović\*<sup>1</sup>, Nemanja Spajić<sup>1</sup>  
<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia  
\*Corresponding author, e-mail: marinovic.minja@fon.bg.ac.rs

**Abstract:** *Smart agriculture is overtaking traditional ways of food production. Modern life dictates very fast rhythm and there is not enough time for dealing with house jobs and managing a home garden. With help of Raspberry Pi and Internet of Things (IoT) this becomes reality. This paper presents implementation of Raspberry Pi device with the use of IoT in home conditions as well as a design of the smart agriculture system which is divided into software and hardware part. Smart sensors are also a part of proposed solution. Their usage is giving a big advantage in food production and monitoring. Temperature and humidity data are available in every moment which gives the opportunity for proper and timely reaction. Proposed implementation is given in order to provide a standard solution for creating a smart agriculture system for home use.*

**Keywords:** *Raspberry Pi, Internet of Things, smart agriculture, automation, monitoring*

## 1. INTRODUCTION

New technologies are being developed on daily basis and its usage is growing and progressing. Similar changes and innovations can be noted in food production too. If food supply is looked, it is evident that today's offer of food is quite diverse and abundant, but at the same time the risk of the unknown effects of food consumption has risen. These unknown risk factors have led to the idea of using new technologies in the process of producing and growing food in homes with none or minimum effort. As the awareness of people's health has increased in recent decades, most people began to take care of their nutrition. Although the supply of various foods is high, today, in most cases, consumers do not know what they are actually buying and whether the food is contaminated with some harmful ingredients that could endanger their lives. One of the solutions to this problem is that people produce organic food that is part of everyday nutrition for themselves. Although this process requires a lot of time, the development of IoT and connected computers and various sensors, allows that most of the process of growing the plants can be automated, whilst saving a large amount of time. One type of computer that uses its application in diverse number of spheres, because of its compatibility and price is Raspberry Pi.

This paper describe implementation of Raspberry Pi computer with the use of IoT and smart sensors in home gardens. Connecting and programming a smart agriculture system is not so hard and provides a lot of benefits for their owners. The number of these systems will be increasing over time.

Paper is organized as follows. After the introduction, Section 2 is devoted to literature review and description of used hardware and technologies. Section 3 refers to use of Raspberry Pi in general, and especially in smart agriculture. Design of the smart agriculture system which include main objectives, hardware and software architecture of the system will be presented in the Section 4. Implementation of the presented smart agriculture system will be explained in the Section 5. The conclusions and directions for further research are given in Section 6.

## 2. LITERATURE REVIEW

"Internet of Things" represents an inter-networking of various physical objects, vehicles, buildings and other devices with embedded electronics, software, sensors and connectivity that allow objects to collect and share data (Brown, 2016). IoT allows objects on the network to be viewed and controlled remotely, with the aim to create a more direct integration of the computer system and the physical world (Harvard Business Review, 2016; Vermesan & Friess, 2013). In this way, with the reduction of human intervention, greater efficiency is achieved, along with the accuracy and economic benefit. The whole structure of Internet of things, in order to do a simpler analysis and design, can be divided into three parts or levels: hardware, infrastructure, applications and services. The first and lowest IoT part is hardware for connection of physical devices. Only those devices that are connected can share information and learn from experience. The goal of this part is to build devices and systems with built-in computer functionality and intelligence for proactive

thinking and behavior. Infrastructure as the second IoT part allows devices to connect to a wireless or some other computer network. This connection should enable an environment for development of IoT applications through channels for information and device information management and decentralized management channels. The third and highest IoT part are applications and services for obtaining data from the device, processing and delivery. Improvement of this applications and services is necessary for development of smart environments and the meaningful application of IoT in different areas. (Radenkovic et al, 2017)

In recent years, the development of information and communication technology (ICT) resulted in the emergence of two important concepts that affect the world around us: Internet-of-Things (IoT) and Cloud computing (Ashton, 2009; Evans, 2011; Mell & Grance, 2011). Innovations have improved capabilities to precisely monitor environmental conditions and to make proper actions according to received data. In last few decades, people are becoming unnecessary for more and more things everyday. Machines, robots and computers with the use of modern technologies are present in every branch of the economy.

The literature concerning issues related to automation of home gardens and use of Raspberry Pi is extensive. One of the first papers that present the use of wireless sensors and use of new technologies in agriculture is presented by Wang et al, (2006). Wireless Sensor Networks (WSN) are widely used in monitoring and predicting of data in agriculture business. WSN system construction and its implementation in agriculture for growing a roses is presented by Rodriquez et al, (2017). Detailed description of nanostructured (bio) sensors for smart agriculture is presented by Antonacci et al, (2018). Authors (Schumann-Bölsche & Schön, 2015) are considering applying of Raspberry Pi and sensor technology to some parts in Africa in order to help and improve their humanitarian logistics. Precision agriculture application with a cost effective and standardized sensing system for remote monitoring and disease monitoring is presented by Sawant et al (2017). A case study for a private IoT enabled platform for research in precision agriculture and ecological monitoring domains is presented by Popovic et al, (2017). Authors (Mohanraj et al, 2016) proposed the advantages of using new technologies in Indian agricultural sector, which enables the rural farmers to replace some of the conventional techniques. Large field monitoring was unthinkable until recently. Automation of large field monitoring with the use of sensors and Raspberry Pi is presented by Balamurugan and Satheesh (2017). In order to get a desired quality of wine, Morais et al, (2018) designed, developed and implemented monitoring system in order to measure wine temperature, pH, redox potential and wine's dissolved oxygen. One of the review papers that offers IoT applications in agriculture is presented by Talavera et al, (2017).

In literature, can be found a lot of papers with implementation of such infrastructure in various fields. One of them is application of IoT with the use of Raspberry Pi for creating a renewable energy monitoring system (Pereira et al, 2018). On the other hand, Perumal et al, (2017) used Raspberry Pi for monitoring building system. Building monitoring system is consisting of monitoring power consumption, temperature, light and humidity. Some authors (Vujovic & Maksimovic, 2015) suggested use of IoT and Raspberry Pi for automation of homes and buildings in order to discover fire. Also, one of the implementation is done in biometrics (Shah and Haradi, 2016).

### **3. RASPBERRY PI IN SMART AGRICULTURE**

Raspberry Pi is a single-board computer, with the size of a credit card, developed in the United Kingdom with the intention of promoting basic computer skills and sciences in schools and developing countries. Although primarily developed for educational purposes, due to its portability and the ability to interact with the outside world, Raspberry Pi became very popular and began to be used for various purposes. A large number of developers and applications use Raspberry Pi for home automation. These developers are trying to modify the Raspberry Pi and make it a very affordable solution for monitoring energy and its consumption. Due to the relatively low cost of this computer, Raspberry PI has become a popular and economical solution, in contrast to more expensive commercial solutions (Rao and Uma, 2015). As Raspberry Pi is popular in a large number of different spheres, it has found its application in agriculture as well. A great deal of significance has been contributed by a huge number of sensors, such as temperature, humidity, soil moisture sensors and many others that can make a big contribution to the improvement and automation of agriculture.

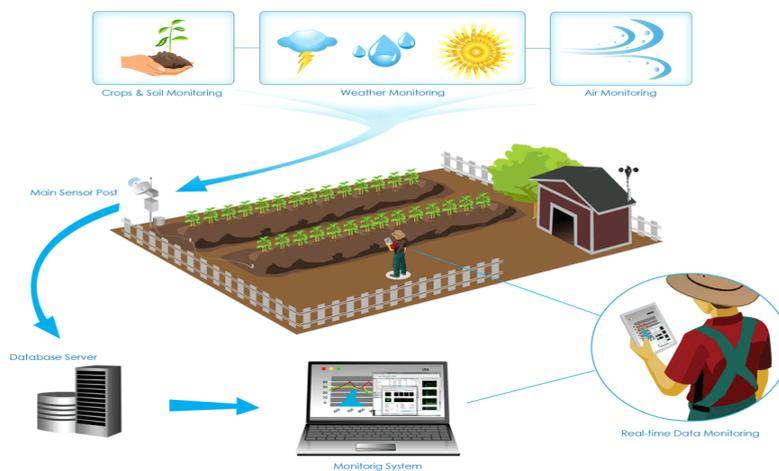

"Smart agriculture" based on IoT technologies enables farmers and manufacturers to reduce investment time and increase productivity by controlling the quantity of fertilizers, controlling irrigation, regulating temperature, etc. In IoT based smart agriculture, a system is built for monitoring the crop field with the help of sensors and automating the irrigation system. The farmers can monitor the field conditions from anywhere. IoT based smart farming is highly efficient when it is compared with the conventional approaches.

The application of smart IoT based agriculture doesn't have to target just large agricultural corporations, but also can be new starter for rising trends, such as organic production, family farming and many others. When it comes to environmental issues, smart IoT based agriculture can provide great benefits including more efficient water use as well as optimization of inputs and treatments.

#### 4. SMART AGRICULTURE SYSTEM DESIGN

The impression is that people have recently raised their awareness about healthy eating habits, but still they are not sure whether healthy foods that are marketed are actually "healthy". In this case, the only solution is the independent production, where it can be known for sure the origin of the food. One of the difficulties for that scenario is the necessary time to dedicate for something like that. Solution to this problem is a smart agriculture system, which will automate process of monitoring the condition of crops, collecting and process data, together with the automation of individual processes such as irrigation. The goals that automated smart agriculture system needs to fulfill are:

- Management of the agricultural land without electricity,
- Automated soil irrigation,
- Preservation of temperature and humidity data on soil

**Figure 1:** IoT system for smart home gardening

In order to accomplish these goals, it is necessary to use different types of smart sensors along with Raspberry Pi. Smart sensors are devices which interact with physical environment. Received environment inputs then use built in computer resources of sensor to perform some of the predefined functions at the moment of input detection. The collected data is first processed and then forwarded. As the basic integral element of Internet of Things, smart sensors manage to improve the accuracy of collected data from the environment and make this process automated. Smart sensors, combined with other components such as amplifiers, converters and analog filters are used for control and monitoring mechanisms in different environments. Management of the garden without electricity is enabled by using a solar panel that is connected to a battery which is a power source in smart agriculture system. In this way, it is enabled to install this system in places without the possibility of connection to the electricity. As timely watering is one of the most important processes for breeding the plants, drop by drop watering system is the one that has proven to be very efficient. This system is used in most cases. The name "drop by drop" tells us that it is a system that pours every plant equally. Electro valve is a valve in which water flow can be regulated with use of electricity. Also, this system can be used for feeding the plant, if a tank from which irrigation water is used supplies certain fertilizers that promote the growth and health of the plant. In order to track the humidity and soil temperature, it is necessary to integrate smart sensors.

Smart agriculture system design can be divided into hardware and software part. The hardware part represents the infrastructure that consists of inter-connected physical devices, such as source of energy, which is in this case a battery powered by a solar panel, pipes for soil irrigation, smart sensors for measuring humidity and temperature of soil as well as automatic irrigation valve and Raspberry Pi as the main device in the system. All parts of the smart system are connected to the Raspberry Pi with its GPIO pins for collection of inputs. When the infrastructure is set up and connected, in order to allow for the collection and processing of data from all devices of the system, it is necessary to program Raspberry Pi. By developing an APIs for collecting data from different devices, it is possible to undertake certain actions in automation process. The

SIM card implemented in the Raspberry Pi is used to manage the system from remote devices such as home computer or a mobile phone.

## 5. SMART AGRICULTURE SYSTEM IMPLEMENTATION

Implementation of smart agriculture system is main goal of this paper. The implementation can be divided into several steps, such as preparing the ground, setting up energy sources, setting smart sensors and linking them to Raspberry Pi, as well as programming it in order to collect and process data.

In the first step, it is necessary to prepare the arable surface by installing the pipes for automated water irrigation. In length, with a meter distance between them, pipes are implemented. The arranged pipes are connected with the water source, precisely one hundred litres barrel. On the connection with the barrel, 12V electric valves are installed. Their purpose is to regulate the soil irrigation and automate it using Raspberry Pi. In order to secure the power source, solar panel is placed at the appropriate place to collect solar energy. The solar panel is then connected via controller to the 12V and 100Ah battery that is a power source of the smart agriculture system. The sensor for measuring the temperature and humidity of the air is set to the meter from the ground level, while the sensors that measure the condition of the earth, are placed directly into the soil, closer to the plants, in order to have accurate information. Humidity and temperature sensors are an indispensable item for keeping records and analyses for some future ventures that can comprise a larger amount of plants. The DHT11 sensor is digital sensor for measuring temperature and humidity. SparkFun Soil Moisture Sensor is the analogue sensor for measuring soil moisture. DS18B20 is digital waterproof sensor for measuring soil temperature. All of these sensors are connected to Raspberry Pi by cable and "breadboard", while they are connected to the battery to receive a power source.

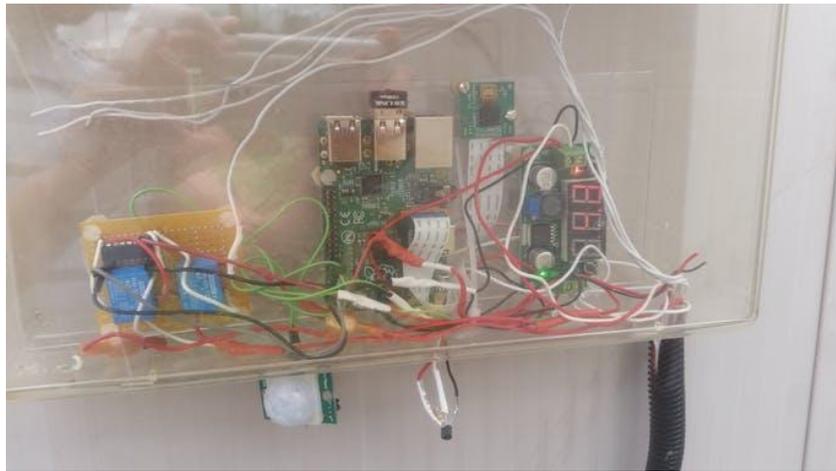

**Figure 2:** Sensors for implementation an IoT in smart agriculture

When everything is set up and properly connected to Raspberry Pi, it is necessary to "program" Raspberry so that the data is collected and processed and so that can later help in undertaking certain actions. The mentioned data is collected with the use of GPIO pins. Each sensor has at least three outputs, such as electricity, grounding and data output. The last one (data output) is used for connection to the mentioned GPIO pins of Raspberry, which can enable quickly data collection and processing by the Raspberry. Since the Linux operating system is used on Raspberry Pi, the python programming language and the Flask framework for routing are used in order to enable the server to collect and process data from a Raspberry. This server contains five methods:

- `get_temperature`
- `get_humidity`
- `get_soil_temperature`
- `get_soil_moisture`
- `do_irrigation`

`get temperature` is a method that returns the current temperature in the json format `{'current temperature': 20}`. `get humidity` is a method that returns the current air humidity in the json format `{'current humidity': 49}`. `get_soil_temperature` is a method that returns the current soil temperature in the json format `{'current_soil_temperature': 29}`. `get_soil_moisture` is a method that returns true or false depending on whether the earth is moist or not. `do irrigation` is a method that takes time in minutes as the input parameter for irrigation of plants.

**Figure 3:** Connection of Raspberry Pi with sensors and controllers

For further management of the smart garden, it is necessary to install an application in order to get information's about the current vegetable state and plants in generally. This application is not something that should be complicated, instead of simple, transparent and easy for use application. It can be "One page" application that gives all the necessary information in one place, so it can be helpful with making conclusions on what is happening and eventually to help with prevention of some possible losses. This application will have two tasks:

- to provide real time information on temperature and humidity of soil at any time, as well as a button for regulation of irrigation that can be either automatic or manual (automatic means that whenever the land is dry system for irrigation is turned on for 10 minutes)
- to store collected data for temperature and humidity of soil in the database on every half hour, so it can be used for further analysis and preparation of bigger projects.

Also, it is possible to ensure that the collected information's are sent as a SMS.

## 6. CONCLUSION

Monitoring of temperature and humidity of air and soil with the use of IoT is definitely the future for either home gardens or for bigger projects and farms. Necessary actions in case of a deviation from normal values are covered. It is evident that Raspberry Pi is bringing so much advantage in smart agriculture and producing of organic food in home conditions for personal use. The same technology can be applied to large-scale gardens in which organic foods can be produced in order to find their place on stalls across markets and green markets. Implementation of smart agriculture system with the use of Raspberry Pi and IoT is presented for personal and home use. Evaluation and comparison between traditional production and technology monitored production as well as possible advantages of using blockchain technology are set as a goal for further research.

## DEVELOPMENT OF AN EDUCATIONAL GAME: AUGMENTED REALITY APPROACH TO EDUTAINMENT

Luka Petrović<sup>1</sup>, Danijela Stojanović<sup>1</sup>, Aleksandra Labus\*<sup>1</sup>  
<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia  
\*Corresponding author, e-mail: aleksandra@elab.rs

**Abstract:** *In this paper, the authors examine the problems, capabilities, and benefits of implementing augmented reality technologies in higher education and integrating them into formal e-learning in the form of edutainment. The main goal is to design and develop an educational interactive game that features augmented reality and would enrich the teaching process with interesting content as well as motivate students and stimulate their acquisition of knowledge. The developed game is based on current internet mobile technologies, with AR aspects realized through the use of the Vuforia platform, and is implemented as a part of a smart classroom. It includes a web application for teachers to create tasks, small parts of the curriculum that are being tested, a mobile application that students use to interact with the game and solve tasks, an augmented reality module that supports distance learning and a component for integration with Moodle LMS. This paper will focus on the AR aspects of the game and the benefits that can be gained with its use in education. The game has been implemented within the educational process at Faculty of Organizational Sciences, University of Belgrade*

**Keywords:** *Augmented Reality, Internet of things, game-based learning, edutainment.*

### 1. INTRODUCTION

The educational process is ever changing and evolves over time. This progress stems a requirement to fulfill the needs of the students that change over time (Education, 2011). With the coming of the digital age and the daily innovations which represent it, it has never been harder or more important to redesign current methods of teaching and formulate a new approach that will accommodate a society living on the thin line between the real and digital worlds (Bowen, 2015). There is a need for modern education in all age groups with special focus on children starting their education as they are a generation born into the modern world and are introduced to many forms of technology since birth (Yelland, 2006). Technologies of augmented reality in education are increasingly being used and show great potential and contribution to the teaching process from the pedagogical aspect.

Many innovations in education come from the constant rapid development of Informational and Communicational technologies, especially Internet (Gyorgy, Suciu, Alexandru, & Militaru, 2014; Labus, Despotović-Zrakić, Radenković, Bogdanović, & Radenković, 2015). The effects of implementing internet technologies in e-learning have been a focus of many studies (Means, Toyama, Murphy, & Baki, 2013).

There are numerous articles and research papers with incorporating smart technologies or new methods in education as their focus of attention but a lot of them approach the subject matter from a purely theoretical view (Cook & Das, 2004) while other works don't always demonstrate the full integration of game-based learning in conventional education systems (De La Guía, Lozano, & Penichet, 2013; Kipper, 2013; Shen, Wu, & Lee, 2014). In this research, we try to contribute to filling this gap by developing a game within a smart learning environment and that aims to enhance the user's perception by utilizing the power and popularity of augmented reality.

### 2. LITERATURE REVIEW

#### A. Augmented reality

Augmented reality is a technology that has an astounding number of applications such as business, medicine, gaming and other forms of entertainment and education (Liou, Yang, Chen, & Tarng, 2017). Using AR in educational games leads to hybrid games, games in which digital and physical objects can interact with one another (Mircea et al., 2011). It is a new medium, combining a multitude of different computer aspects to offer a unique approach to continuous and implicit user control (Lee, 2012). This approach can enhance the quality and speed of training by providing a different view into the subject matter (Kamphuis,

Barsom, Schijven, & Christoph, 2014). An example of this is the use of AR in medical training (Gu & Duh, 2011). By switching from 2D images to 3D models generated by smart devices, medical students can better grasp the concept of many elements in their field of study like anatomy. Advances in mobile devices and their graphics processing and rendering increases the gaming potential of mobile phones . By combining mobile 3D game engines with Augmented Reality technologies it is possible to create a platform that is capable of enriching our reality any time any place. One such example is described in (Sherstyuk, Vincent, Berg, & Treskunov, 2011). In this example, authors describe the process of interacting with a 3D model of a patient. Thanks to mobile technologies, the model is not only rendered in 3D it is also responsive and fully functional. In this way, many hardware limitations of physical tools are circumvented and students are capable of gaining practical knowledge in a far greater capacity.

Currently, most of the innovative approaches to education are implemented as part of higher education. This is because universities have the necessary technologies and skilled personnel that are not only capable of conducting such classes but also willing to research new approaches to teaching (Begg, Dewhurst, & Macleod, 2005). That being said, it isn't restricted to universities as there are attempts to do the same on a high school level (Papastergiou, n.d.).

### B. Educational games

Studies have shown that there is a great need for a better way to provide education. Due to rising demand for highly educated people, educational institutions cannot provide the necessary supply. This leads to creating more efficient means of teaching that can speed up the process and increase its quality (Savander-Ranne, Lunden, & Kolari, 2008). Many studies have shown that alternative and modern approaches to teaching yield better results (Stojanovic, Bogdanovic, Nedeljkovic, 2016). Some of the techniques that have been recently looked into are the use of modern technologies in the form of teaching tools and the use of edutainment in the teaching process (Knežević, Despotović-Zrakić, Labus, Jezdović, Ivković, 2016). Educational games find themselves used in research papers more and more and their potential is heavily discussed. They are interesting to students and possess the ability to motivate them beyond normal lecture capacity. This makes researchers explore their beneficial influence on the learning process (Petrović, Jezdović, Bogdanović, & Despotović-Zrakić, 2017). Use of games to facilitate learning is not a new concept and was used for a long time. The first form of such games is physical games. These games use physical objects to bring knowledge to students (Zagal, Rick, & Hsi, 2006). Since then, educational games have come far. Innovations in technology have created new forms of games that follow the trends and maintain their appeal to a younger audience, with the latest trend being mobile and AR games (Gros, 2007). Using video games in a teaching environment is nothing new (Alshanbari, 2013). Studies have shown that playing video and computer games can have a positive effect on players' cognitive abilities like decision making, speed thinking and reaction speed (Prensky, 2003). Another aspect of gaming that can be used to facilitate better learning is competitiveness. The competitive side of gaming leads to better motivation and a greater amount of effort being poured into performing actions whether they are of educational character or not (Burguillo, 2010). They also help focus attention to a single point which can be used for a more effective transfer of knowledge, with lesser losses of information due to "white noise" of distracting happenings all around us (Griffiths, 2002). In psychology, the greatest form of this is called "flow" and it describes a state of full immersion into an activity that focuses all of a person's concentration into a single goal (Csikszentmihalyi, 1975b, 1975a). When used in conjunction with gaming and "flow", education can be an interesting, motivational, immersive and above all else a productive activity, for example, a goal-driven educational game (Kiili, 2005). Using new technologies to change traditional types of games and adapt them to new trends makes them more interesting to newer generations and increases their effects (Petrović, Stojanović, Labus, Bogdanović, & Despotović-Zrakić, n.d.)**Error! Reference source not found.** With the development of 3D games, we can see a rise in their popularity over the 2D type (Koops, Verheul, Tiesma, de Boer, & Koeweiden, 2016).

There are several parameters that can be used to evaluate the quality of an educational game (Aslan & Balci, 2015):

- Acceptability: the level of completion of the learning goals;
- Challenge: the level of motivation;
- Clarity: the level of understanding;
- Interactivity: the level of interaction between the student and the game;
- Reward: it enables the student's satisfaction after the completion of goals.

### C. Internet of Things

Internet of things has found itself being used for various purposes, like traffic, data analysis and for our purposes the most important one of all – education. There can be many implementations of IoT in education but the most often example is in universities.

Many classrooms today are connected to the Internet and have the advanced technological equipment, such as tablets or interactive boards. This type of classroom is called the smart classroom (Song, Zhong, Li, Du, & Nie, 2014). These classrooms are equipped with all kinds of tools and technologies necessary to provide an enhanced learning experience that builds on top of the classical face to face model with a virtual, off-site approach by providing a flexible and inspirational environment (Mikulecký, 2012). These classrooms are the ideal place to implement educational games as they meet the necessary technological requirements (Xiliang, Xin, Yafei, & Mengkun, n.d.). By relying on the recent internet and mobile technological boom, limitations of smart environments are pushed even further. Using smartphones, as they are currently the equivalent of a pocket-sized computer- a fact that was unimaginable even as recent as 10 years ago, learning can happen everywhere, physical presence can become a thing of the past (Suo, Miyata, Morikawa, Ishida, & Shi, 2009).

### **3. DESIGN**

#### **A. Project requirements**

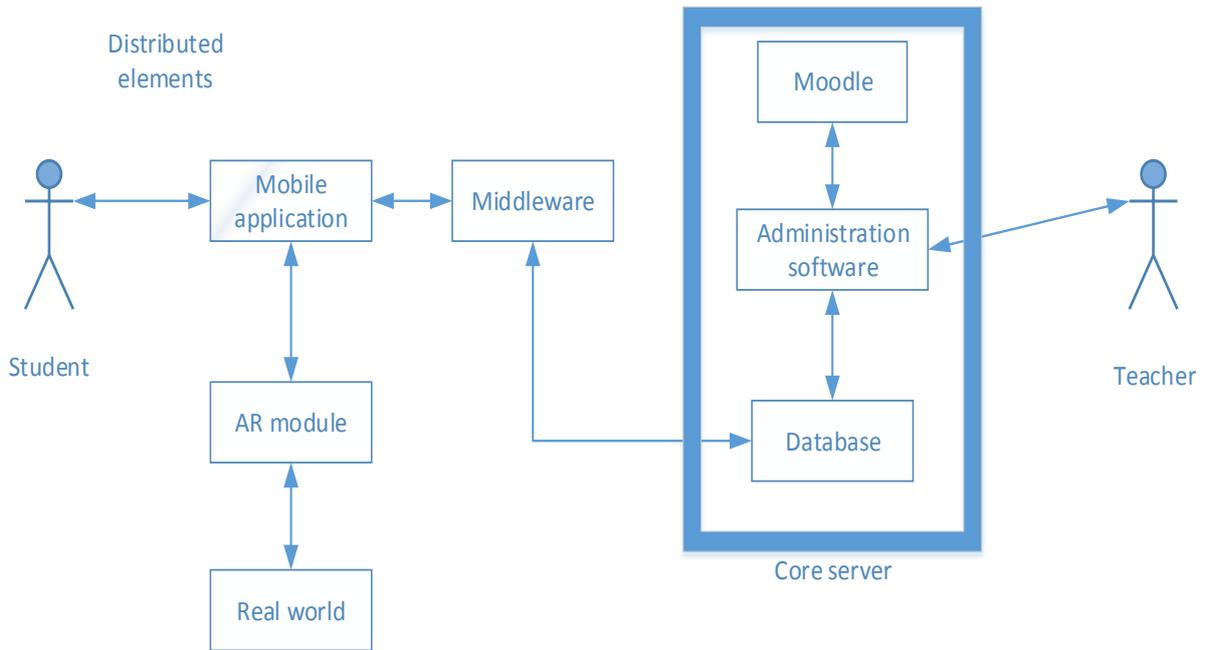

The goal of our study was to create a tool that would transform the antiquated teaching mechanics into an exciting and immersive experience as well as monitor the effects it has on the student's motivation and knowledge acquisition. During our research, we have explored the processes of envisioning and designing methods to bring our idea into fruition as well as developing hardware and software components based on current technological standards that are necessary for implementation into a real environment. Based on its potential in education, augmented reality technologies have been chosen as a core of the solution. The result was an educational game based on AR that tests the players' knowledge on a given subject in a fun and inviting manner and monitors their progress and achieved results. The game aims to motivate students to embrace learning as a positive influence in their life by presenting it as a challenge set on a medium that the user is already accustomed to.

#### **B. Game concept**

The concept of the game revolves around the process of giving the correct answers to given questions. What differs in comparison to a standardized test is the way in which the examinees not only solve the problems but also the method of submitting their answers. By designing questions in an interactive way that forces the students to apply their acquired knowledge in a practical manner that is both fun and educational, tests can be taken to a new level. One approach to this is creating workstations or polygons for each assignment and distributing them to remote locations. This creates a goal-driven approach or in game terms manifests the illusion of "quests". Polygons can consist of any number of elements, from simple images to be used with AR modules to IoT infrastructures that demonstrate some core features of smart objects. Another approach might be through a computer or in recent times mobile education, with apps instead of pen and paper. This too can test both the theoretical knowledge i.e. quizzes or simulate some real-world situation for the student to manage. Our approach was a mixture of aforementioned solutions joined together, a model that is composed of a server which represents the core of the system and many distributed platforms made for solving each task in a different way, but obeying the standards of the central unit and integrating into it.

#### **C. Architecture**

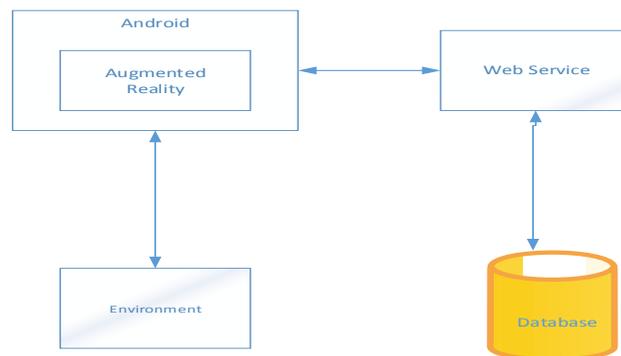

The architecture of the developed system is shown in figure 1. The system is split into core and distributed elements with a middleware to connect them much like a bridge would. Among the core elements, we have a virtual machine to house the central web server. The server host many items that are integral to the system such as an administrative tool in the form of a web application that is used by a teacher to administer the whole testing and grading process. The most important part of this tool is to create the logical form of assignments that are presented to students during testing as well as serving as building schemas for their physical representation. Other components that make the central server their home are the main database used for storing all transactions and the many web services used by all of the system's various components. It is the services that are the gateway between the centralized core and the distributed network of participants and locations. The most important tool from the aspect of the player is the controller. Representing the middleware, the controller serves as a means of communication between the player and a black box that is the game. It is present in the form of a mobile application on a smart device such as a phone or tablet. Using its User Interface it can collect input from the user and has integrated features to connect to the APIs of the server and physical data of the environment. The last segment of the system is a collection of the many distributed locations, mostly smart environments adapted for the purpose of solving at least one task. Communication between components is realized through the use of web services, RFID tags (Miglino, Ferdinando, Fuccio, Rega, & Ricci, 2014), and QR codes (Kan, Teng, & Chen, 2011). User management and grading are interconnected with Moodle LMS.

**Figure 1:** The architecture of the game

### Mobile application

The mobile application is the player's gateway into the complex system of the game. It is the only way to interact with the physical objects necessary to solve tasks as well as the only interface that receives tasks from the server. In order to accommodate a wide range of task types, it uses task metadata to adapt to the current type and generate only the capabilities necessary at the moment (Simić, Despotović-Zrakić, Labus, Radenković, Bogdanović, 2015). It does this by being split into modules that are used as building blocks to form a whole during the loading of a new task, as seen in figure 2. The application can be divided into two parts, the Vuforia part, that enables the use of augmented reality, and the Android part that facilitates everything else.

**Figure 2:** Mobile application structure

Augmented reality module is used to enhance the user's view of the real world and it does so by interacting with a camera view and analyzing every frame, trying to find a designated image within it. If an image is recognized 3D elements are overlaid over it. There are three types of AR modes available:

- Cloud Recognition which holds all target images as well as metadata files in a cloud server. This mode recognizes a target and reads the accompanying metadata file. This file contains names and positions of 3D models that should be rendered.
- Virtual Button which recognizes only a single target but in exchange supports user interaction. On successful target recognition, first of a list of 3D models is rendered as well as 2 buttons, left and right. When hovering underneath a button, the displayed model is changed either to the left or right of the list position of the previously displayed model.
- Explore which works similarly as Cloud Recognition in that its targets and metafiles are stored in the cloud. The main difference lies in views rendered on recognition. Unlike the first type, Explore only has 1 model available, a text panel and title and text that are displayed inside it are contained in metadata text files.

To successfully implement the game, it is necessary to prepare an environment for it. At the very least it is needed to prepare a location for all the image targets present. If there is a need to also collect data from the environment in some way, this environment includes workstations on multiple locations and equipment for students (Petrović, Jezdović, Stojanović, Bogdanović, & Despotović-Zrakić, 2017).

Workstations are equipment present on site for each task. If the task is envisioned to be solved with the aid of external factors and devices, then all the necessary hardware and software must be set. Since the game is played in multiple locations, they are scattered throughout the envisioned playing field.

Location of each task can be anywhere, in the classroom, in the faculty building, or outside. For example, a task can be related to measuring the temperature, and the equipment can be placed in a classroom. Or, a task can be related to plant watering, so the workstation will be placed in the garden.

#### Administration software

The administrative tool is used by teachers to organize tests (playing of the game), to create new tasks or modify existing ones, review achieved results for a given student and grade them. By using this tool, we prepare data that is available to other parts of the system through our web services. In figure 3 we can see the screen used for reviewing achieved results.

Takmicar	Rezultat	Datum	Ocena	Kurs
asasa	5858	2017-01-10 00:00:00	6	IOT

**Figure 3:** Results overview screen

#### Moodle integration

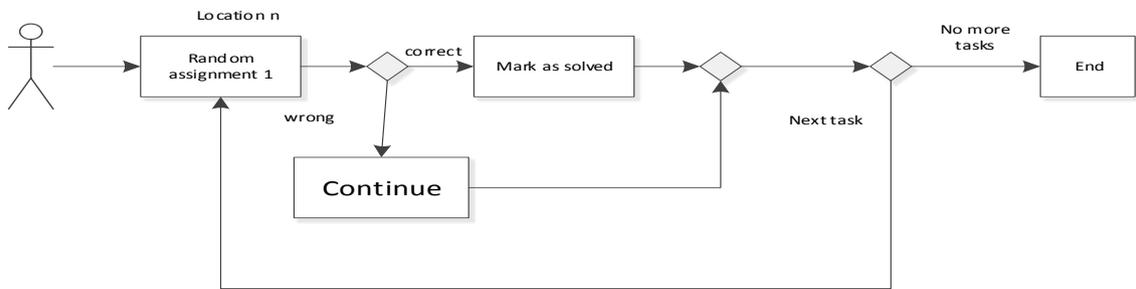

In both the mobile and web tools authentication is done via Moodle. By entering credentials a call to a public Moodle API is made with a request for authentication tokens. Only after confirmation of identities has taken place users can begin their work. Another call to the Moodle service is activated after the game ends. The client application sends the achieved results to the server for professors to grade with the help of the web application. After the grades have been set, they are set as Moodle assignment scores.

#### D. Game scenario

The test is split into groups of 1 or more assignments, let's call them subjects. The students, or in this context players, are given a mission to clear as many subjects as they possibly can within the time limit. They are given assignments in sequential and random order with questions from all subjects mashed together. To complete the subject, students are required to correctly answer exactly 1 assignment from that subject's subset. Once an answer is submitted its validity is put to the test. A correct one will award the player full points for that question as well as mark the subject solved. Any subject that is marked as solved will no longer be among the possible questions for that student. On the other hand, if the answer was not correct, there is no change and players are given the next task. There is no direct penalty for solving a task incorrectly as it might be received and correctly solved at a later point in the game, however, the time required to redo it decreases the acquired points at the end of the game (as the remaining time is part of the grade). New tasks are generated from a collection of all assignments from the unsolved subjects so in the case of a wrong answer the user can get that same question, another question from the previously tested subject or a question from a completely different subject. A potential penalty occurs if the player cannot correctly finish a task even after multiple attempts. In this scenario, not only is the utilized time deducted from the score, so are the points that each completed task brings.

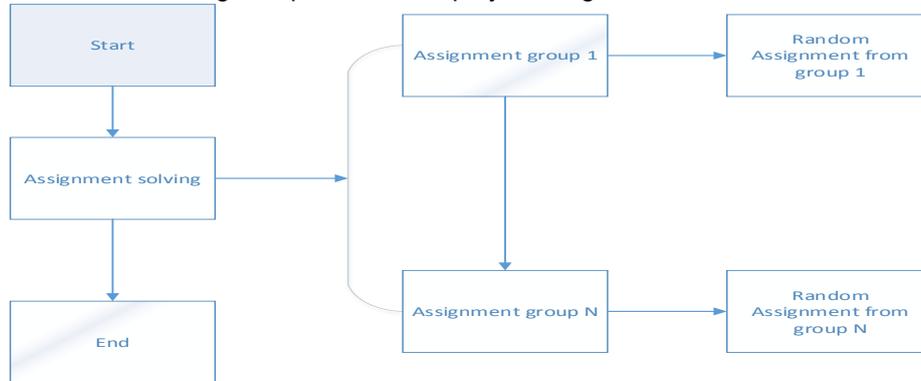

To begin the game, students have to go to the predefined start location and acquire a player controller that is already configured. After inputting their credentials and successfully logging in to their Moodle account, they proceed to choose the option to begin testing. After starting the game, the timer begins the countdown. By

getting random tasks, students are sent to different locations and their paths diverge from the start. Next is the process of solving tasks one by one in a similar fashion until a task from each group is solved or time runs out. Each assignment has information that it presents to the player by displaying it in the controller at the moment it has been received. Among the info present is the location which the player has to go to, the question which needs to be answered as well as metadata needed to generate all the necessary components. Metadata is used to generate user interfaces that the player sees, such as the way of inputting the solution (keyboard, RFID tag, QR code) or interfaces for connecting to the environment (AR, IOT...) After arriving at the specified location, students proceed to interact with the environment in a way defined in the text of the task and its metadata. Productive interaction will yield data necessary to complete a task prove mastery over the subject. Each task is also scored according to the difficulty of completion. Completing harder tasks rewards more points but it may cost more time. The final score of the test is determined by the number of subjects closed, difficulty points of each task and the remaining time. As previously stated, the game is played in iterations, which is shown in figure 4.

**Figure 4:** The game scenario

Since not all tasks are of the same difficulty, they cannot be graded in the same way, so the final score is calculated based on the remaining time and the sum difficulty level of each successfully completed task. The detailed game process is displayed in figure 5.

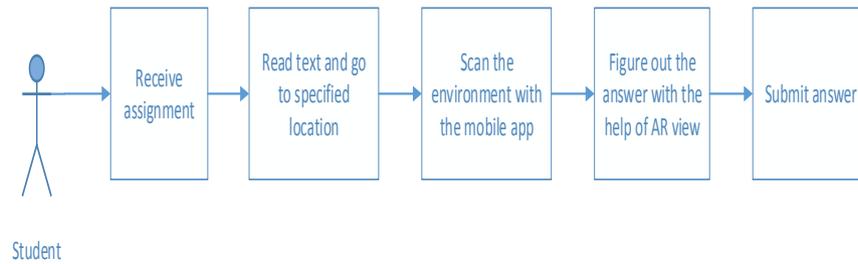

**Figure 5:** Task overview

Throughout the game, the student can review the solved assignments. After completion of all the assignments, or after the time has elapsed, the score that student achieved is calculated, shown to the student, and inserted into the administration application and Moodle.

An extra feature of the game is a hint option. Tasks are equipped with messages meant to point the student in the right direction in case there is trouble coming up with an answer. To use the help or not is up to the players themselves. Solving tasks awards grade points that make the final grade but there is another use for them. By collecting enough points a special button is made available. By pressing it students sacrifice points that have been used in the button but gain help on a complicated problem. Choosing this option lowers their final result but possibly awards another closed subject.

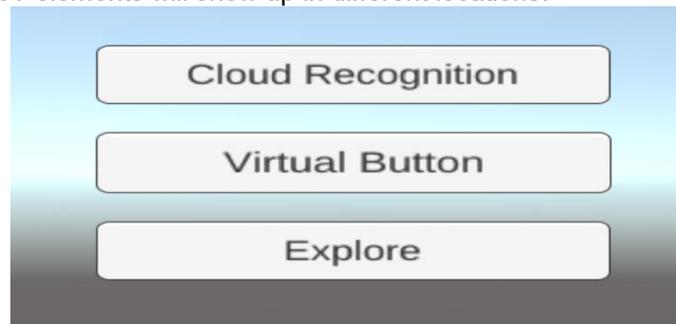

#### E. Assignments

A schema of an assignment is shown in figure 6. The displayed assignment is from the AR type. The student is required to scan the environment with the AR camera provided as part of the handheld device and recognize elements that are generated in the view. Based on his conclusions he reaches the answer and submits an answer.

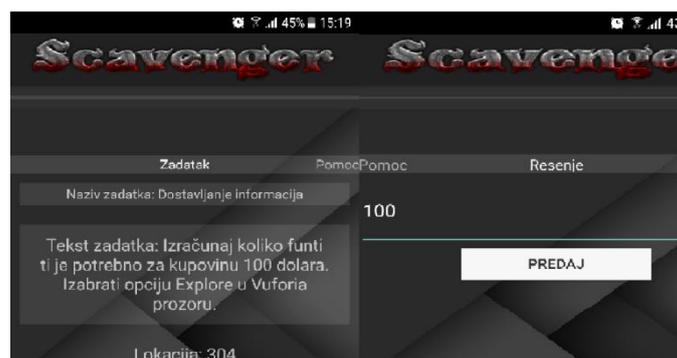

**Figure 6:** AR Assignment workflow schema

As an example, an AR assignment called Diagram completion will be presented. After arriving at the designated location, multiple pairs of IoT platform diagrams and QR codes will be present. A question can be seen on the first of multiple available screens of the mobile application and its text will tell the player how to activate the AR features of the game and that he needs to scan the diagrams and find the complete one. After reading the instructions and navigating to the AR screen players choose one of three available AR modes (see figure 7) and aim the camera at the first diagram and on-screen multiple 3D models of IoT elements will show up in different locations.

**Figure 7:** Vuforia module selection

Each diagram is missing at least one key component. Students need to find a diagram that when combined whose missing components are present in its 3D render. Such a combination of diagram and models is considered complete and is the correct one. Submission of the solution is done by navigating to the next application screen and pressing the button to scan the QR code paired with the previously selected diagram. QR tags hold codes for solving tasks. Tags paired with correct answers will match the assignment codes and mark the assignment as completed during check-up while all others will fail to match. Navigation through the application windows is done by swiping left and right on the device screen. Based on the task metadata, the mobile application will generate only the needed windows (figure 8). Generally, there are 3 windows present, the information window that holds the text of the question and necessary instructions as well as the location while the other two windows are dynamic and represent the window for solving and the solution input window respectively. In the showcased example AR camera has been used for the former, while for the latter a QR code scanner was generated.

**Figure 8:** Task text and textual solution input

Another example of an AR task is named Model recognition. This task also tests the knowledge of the IoT models but is of lesser difficulty. The goal is to simply find the item that was specified in the text.

The process is the same as in the previously described example with small differences. Firstly there is only one diagram present on location, with a multitude of QR tags marked with numbers. After opening the AR window, 3 models will show up on screen, an IoT object and 2 buttons to change the center object. By using the primary model as number 1 and increasing the enumeration of every next model to the right of it by 1, or decreasing it by going left we can get the answer. We number models until we reach the required one and scan the QR code marked with that same number. In both examples, it is possible to look at the augmented reality from all sides and angles but it is also possible to rotate and scale models by interacting with the screen. This feature makes it easier to see details if necessary.

**Figure 9:** Vuforia task example

#### **4. RESULTS**

For the evaluation of the developed game, a pilot testing was organized at the Faculty of Organizational Sciences, University of Belgrade, within the Department of Electronic Commerce (e-lab) during the Summer School attended by undergraduate 4th-year students. The goal was to test the efficiency of using the developed game while learning about the Augmented Reality technologies. The research was conducted in accordance with the code of professional ethics. All students willingly agreed to contribute to this research.

The research involved 7 students who attended the Internet of things course. After using the application, students filled in a poll in which they gave their opinion on the way each task was solved. The questionnaire had 10 questions and the students could demonstrate their opinion on the offered five-step scale from "I completely agree" to "I completely disagree".

Each student received a mobile phone on which a mobile application was installed. Their tasks were to launch the application, log in to the Moodle system, and press the button in the displayed menu - launch the game. The system then selected one of the tasks randomly. If the student does not solve the exact task, they have the ability to re-test within a given time again. After the expiration of the time or after solving all the tasks, it was necessary to press the button "finish the game". Two of the offered tasks were Vuforia type.

The student had the task of reading the text on the screen of the mobile phone, then going to the assigned location from the task. Within the application, it was needed to move the screen to the right and click on the scan, then select the option specified in the text of the task and position the device so that the image is visible on the camera. The students needed to select a 3D model that matched the task's solution, double-click the "back" button, move the screen to the right and click on the scan. The device had to be positioned to see the QR code corresponding to the selected model. The last step was to move the application screen to the right, enter the read message into the displayed field, and click "Submit". Finally, students who participated in the research-filled in the questionnaire, answering questions about the application itself. In the given survey, students expressed their opinions on the application, but also answered questions that were related to satisfaction in solving each of the three questions asked.

#### A. Knowledge test results

The table shows the opinions of students related to the use of the extended reality application while solving the tasks set.

Regarding whether tasks were easier to solve by using the application, 71.43 percent of students said they fully agreed with the view that it was easier to solve the task with the application, while the other 28.57 percent of students replied that they could not decide.

No one answered that they partially or completely disagree that their tasks are easier to solve using the application.

**Table 1:** Questionnaire data

Question	% Strongly agree (score = 5)	% Agree (score = 4)	% Neutral (score = 3)	% Do not agree (score = 2)	% Strongly disagree (score = 1)	Mean score	Standard deviation
The task is easier to solve with using the application.	71.43	0.00	28.57	0.00	0.00	4.36	0.82
The task is easy to learn.	85.57	14.29	0.00	0.00	0.00	4.71	0.49
It's boring for me to solve this task like this.	14.29	14.29	28.57	14.29	28.57	2.64	1.29
I had the feeling of controlling the situation while solving the task.	42.86	57.14	0.00	0.00	0.00	4.36	0.54
Too bad that there were no more tasks of this type.	42.86	28.57	28.57	0.00	0.00	4.14	0.78
There was enough time to solve this task.	71.43	28.57	0.00	0.00	0.00	4.64	0.54
There was insufficient time to solve this task.	42.86	0.00	28.57	14.29	14.29	3.43	1.40
There was too much time to solve this task.	14.29	14.29	14.29	42.86	14.29	2.43	1.21
I prefer the classic test for solving this type of task.	14.29	14.29	14.29	28.57	28.57	2.43	1.33
The task is more fun to solve with the application	85.57	14.29	0.00	0.00	0.00	4.71	0.34

When asked if the tasks were easy to learn, 85.71 percent of students replied that they fully agreed, and one student partially agreed. Students in a percentage of 85.71 percent agree that it is more fun for them to solve tasks using the application, and as much as 42.86 percent think it is a pity that there were no more tasks of this type. When asked if they have a sense of controlling events while solving tasks, 57.14 percent of students agree in part and 42.86 percent of students fully agree. Students' indecisiveness is evident over time in solving tasks. We see that 42.86 percent think that there was insufficient time to solve the tasks, while in the same percentage; the students think that there was too much time to solve the tasks. It is believed that this way of solving tasks for students is new and, depending on their readiness and skills in the use of new technologies, their position on this issue varies. A certain number of students, 28.57 percent cannot decide and put their opinion in a large number of questions. This means that although they agreed that the given application was useful, they were not convinced that it fits their needs.

## B. Opinions about the application

After completing the coursework, students expressed their opinion on the most sensitive and most negative aspects of the application.

As the most positive aspects, they stated:

- Ease and simplicity,
- Interactivity,
- Interest,
- Facilitates learning and
- Virtualization.

According to the answers, the most negative aspects were:

- QR code is not being scanned,
- The application can crash,
- Slowness,
- Taking a lot of device storage space.

In the further stage of the research work, and the development of applications of expanded creativity for educational purposes, the answers of students who could not decide when it comes to needs and expectations, save time, easier tasks, in particular with the aim of improving the application as well as more successful and more efficient educational process.

## 5. CONCLUSION

The evaluation was conducted during practical lessons with undergraduate students in the course of the Internet of Things. Testing was done with a small group of students. The results showed that the application of augmented reality, used in conjunction with the game model, has the potential for implementation, that students considered it useful and fun, and that it contributes to their knowledge, as well as the quick and easy overcoming of the subject material. It also provided guidelines and suggestions for improving the application of augmented reality in widespread use in the educational process. In addition to improving the technical aspects of the system, the future work will be directed towards the development of a larger number of tasks, further integration with Moodle and complete technical and educational assessment of the system.

## ACKNOWLEDGMENT

Authors are thankful to the Ministry of education, science and technological development, grant no 174031.

\*Corresponding author, e-mail: tamaricatasagajic94@gmail.com

**Abstract:** *The analysis of contemporary systems for creating virtual simulations, difference between classical games and those supported by simulations, problems encountered by creators of scenarios, as well as the application of virtual simulations for the needs of military education are presented in this paper. The specific system for creating VBS3 virtual simulations shall be presented in the paper. Its comparing with commercial games has been done. Also, the advantages and disadvantages of these systems have been given. Its modular structure, as well as creating and using the user defined modules (script files) will be especially emphasized. The realization of the entire scenario with solving concrete problems will be discussed too. The end of the paper brings a brief description of the mode of system utilization, as well as the system evaluation, which is necessary for further implementation of this system in military training.*

**Keywords:** *virtual simulations, military education, VBS3, serious game, e-learning, edutainment*

### 1. INTRODUCTION

The Ministry of Defense and Serbian Army are trying to provide high-quality education and further advanced training for their members. Besides traditional education attention has been paid to electronic education and application of virtual simulations in the educational process.

During the last decades one of the biggest changes is an increasing use of computer games and virtual simulations (Hainey, Baxter, Boyle, Moreno-Ger, & Connolly, 2013). For this reason, it is necessary to perceive the benefits of learning compared to playing games and whether this complies with the theory of learning (Lindgren & Schwartz, 2009). In this paper we will present the specific system for creating virtual simulations VBS3. We will also present an evaluation of the proposed solution.

### 2. PRESENTATION OF VBS3 ARCHITECTURE AND DESIGN

Commercial games are primarily designed for entertainment. The value of applied or serious games is in the education and training (Minhua & Oikonomou, 2016). Playing games is not bad if they have been designed on the basis of simulations and when they contain educational value (Tobias, Fletcher, Wind, 2011). In this section we will explain the software use and classification of virtual simulations in the army environment.

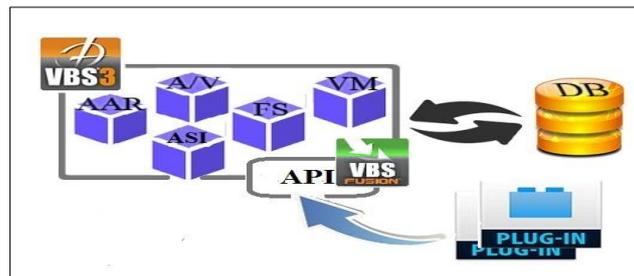

The classification based on complexity, methodology being used and objects level have been generally accepted in computer simulations, as follows (Šimić, 2012):

- Live Simulations – real environment, soldiers or blank ammunition.
- Virtual Simulations – developed and designed by programmers or a team of experts in complex software environment.
- Constructive Simulations – the most complicated, designed for the training, as well as for the training of personnel and commanders of integrated tactical structures.

VBS3 (Virtual Battlespace 3) is interactive, commercial-off-the-shelf (COST – software which is on sale), 3D training system providing the environment for creating an enormous number of the spectra of simulations for military training, can also serve for research purposes. It is based on modern 3D gaming technology. The emergence of VBS3 brings improved performances and multicast system is introduced, which enables the adapting of participants to the multiplayer operating mode, prevents delays occurring at server loading, improves performances in the local network. The commanding and managing system has been super structured by the ORBAT mode enabling a hierarchy in commanding (VBS3 v3.2 User Guide, 2014).

VBS3 is a flexible, open-platform simulation software providing programmers a broad spectrum of possibilities in creating the training scenario. Open-platform enables the link of the external applications with the VBS through API (Application Programming Interface) module. The architecture of the VBS system is

shown in Figure 1, where its modular structure can be seen precisely. The system itself is in connection with the database with which it performs data exchange and registration.

**Figure 1: VBS Architecture**

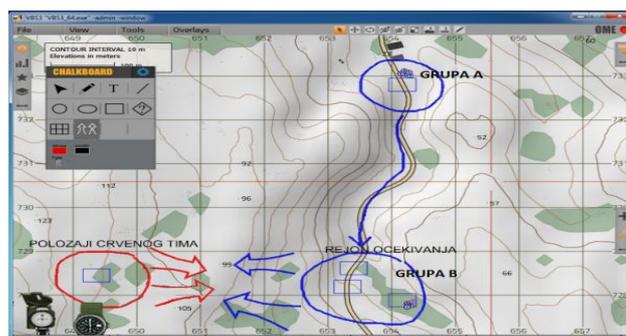

We shall demonstrate the differences between commercial games and virtual simulations on the example of the VBS software and one of the classics in the world of video games, Call of Duty (CoD). VBS brings the possibility of independent creating of the scenario. One of the essential characteristics of the VBS software is the possibility of analysis and evaluation of previously completed simulation exercise, while in the world of games this does not exist.

In addition to system defined there are also user defined modules represented by scripts (organized in the so-called sqf files) written in special VBS3 script language. Controls and data, written in the script, are converted into script files through the conversion module. Then, through conversion module, it is converted into the data type understandable to the user. When starting any scenario, the script file will be compiled each time. The number of user defined modules is not limited. Selecting other modules is carried out through initialized modules by using a special macro – controls execVM, call or preprocessFile. In the example, set forth in the paper, three user defined modules have been created in the scenario, the initializational and the module of synthetic units status (AI – Artificial intelligence) and real player control mode.

Starting of VBS3 can be carried out in two modules: user and administrator modules. Administrator module enables a complete access to audio, video and other advanced settings and has a complex interface. In the user mode the settings are very restricted, interface simplified, and RTE (Real Time Editor) is not available, because it is intended for simulation managing and control (VBS3 Manuals Version 17.1.0 , 2017).

### 3. PRESENTATION OF THE SCENARIO

The presented scenario is the research of the possibilities of training of the infantry squad in surmounting obstacles, coordination, management and commanding, as well as the implementation of the basic tactical training in the environment simulating reality. For the implementation of the scenario a terrain has been chosen, the geographical-topographical characteristics of which mostly corresponded to real characteristics the participants in the training can encounter. As far as time is concerned, the scenario can be divided in two parts: introductory and main part. In the introductory part of the scenario the participants have no control over their units, it serves to participants to be informed about the situation, concrete tasks, understand their roles in a team and that players who encountered such type of software for the first time get familiar with the controls serving for controlling the units. A special script has been made in the introductory part for creating and controlling objects, saved in a special file (blufor. sqf). The realization of the introductory part starts with creating two groups. The group located in the expectation region (Group B) and support groups (Group A). Figure 2 shows the view of the scenario map.

**Figure 2: View of the scenario map**

In the expectation region the task of Group B is to wait for the arrival of the support group. The central part of the introductory part is on Group A that should get on a combat vehicle and reach Group B in order that a squad is formed which would, from the expectation region, go in order to carry out tasks. After the arrival of Group A and forming of a squad, real participants take over control over their units and start performing the tasks. Practically, this is the transition phase in which human intelligence takes over partial control from the artificial intelligence. The main part of the scenario begins here, in which two tasks are carried out. The first task is destroying mine-explosive device (MED) located on a road, by means of a sniper rifle. The second task is occupying defined point on a map where fortified enemy forces are located. In the example, we created a mine-explosive device and a vehicle.

Practically, a trigger of defined type is created (empty detector), which is positioned on the corresponding coordinates on a map with determining the reaction zone. The function executed at its activation is in the last code line – in the concrete example, 5 soldiers are getting off a vehicle. From that moment players gain control over their units, and the text of the tasks, that a squad should perform, is written on the screen, and the titleText control is used for that. For creating enemy forces, a special module has been designed – script file opfor.sqf. For creating the units, the function createUnit is used. A unit can represent an individual soldier or their group. Furthermore, a unit can be controlled by participants, or by the VBS (AI Unit Control - Artificial Intelligence) and in that case, it is completely independent.

Besides creating units, it is necessary to adapt their conduct by using the control setCombatMode. There are five levels of training graded from the lowest to the highest, "blue", "green", "white", "yellow" and "red". Practically, it has been concluded, during the research, that for the enemy the level "white" is optimal for the conformation with the level of the participant of the simulation. The level "white" means that AI units will not open fire except in the case of an immediate danger and they will react defensively if attacked. Setting (adjusting) the level of training is performed individually for each unit, as presented in the paper, 7 enemy AI soldiers set on the "white" level. Combat mode "red" means the offensive responding of a unit – immediately after finding the enemy. This does not mean that the fire will be opened beyond weapon range, but the undertaken combat actions will be with the aim of destroying the enemy (concealed movement, taking cover, watching, aiming). Mode "yellow" enables a unit to attack the enemy if it is in the action zone, whereby units retain the disposition (formation). Mode "blue" means that units will never attack the enemy. From all stated, one can draw a conclusion concerning the "white" mode as the most convenient for the needs of unit training.

#### 4. EVALUATION OF THE SUGGESTED SOLUTION

An increasing use of simulations and games in the education and training puts a question to us as to what do we gain by that, and what do we lose (Roman & Brown, 2008)? We get the answer by developing the methods for evaluation of the software on which education is performed, in order to perceive its possibilities, limitations, as well as the effect on learning (Hainey, Baxter, Boyle, Moreno-Ger, & Connolly, 2013). The main idea in this section is to present our method for evaluation, by measuring time in different situations.

On the tactical level, in order to carry out the drill successfully, we must know the potentials of the units we have at disposal. The time required for a unit in the simulation to pass a defined distance depends on many factors, such as: terrain configuration, equipment carried, characteristics of a terrain, as well as on the endurance of units. Artificial intelligence, implemented in the VBS3 software, enables the control of these variables, their effect on the simulation, in order to approximate virtual behaviour to a real one as much as possible. Figure 3 shows the dependence of time on the way of movement and distance on a plain terrain. Measuring for movements has been performed: marching (normal walk), running and crawling. In the VBS3 this dependence is expressed by the fatigue variable. Fatigue is the least when walking (marching), while the greatest is when running.

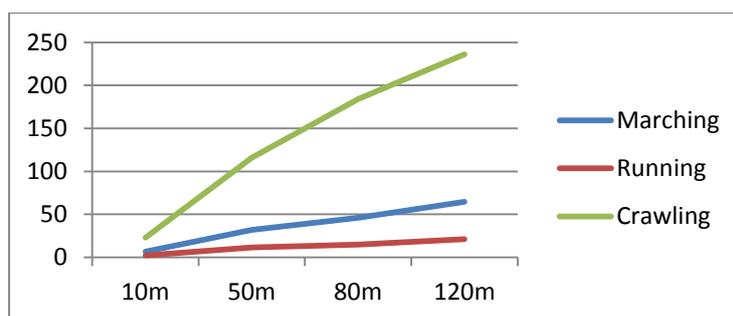

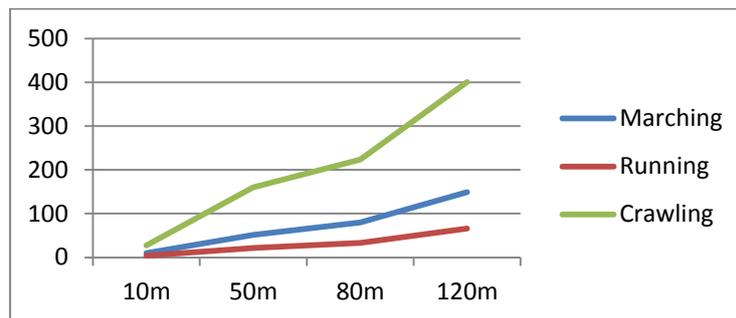

Figure 3: Movement of units on a plain terrain

Measuring has been also performed on a hill terrain. Results are shown on the following diagram (Figure 4), and based on them the effect of fatigue indicators on unit performances can be seen. As a section is increasing (becoming bigger), we can see the exponential increase in time, necessary to pass a section. A unit moving by running uphill has a drastic change of the fatigue indicator.

**Figure 4:** Movement of units on hill terrain

In addition to basic, there are also specific movements being modeled in the system. Table 1 shows the dependence of time for a crew, getting on a vehicle, on soldiers distance from a vehicle. The complete crew of a combat vehicle took part in measuring.

**Table 1:** Time of unit getting on a vehicle

	Directly in front of a vehicle	10m	100m
Time [sec.]	4,80	7,69	22,90

In the implementation of the scenario it is necessary to establish the time it takes AI units to react from different action zones to the participant (the so-called blue) team. This information is closely connected with the level of training of AI units. In high training states (red and yellow) the time that has passed from noticing a unit up to opening fire is very little and participants who are not trained sufficiently and have no experience in the use of software, have no chances against them. Downward trends for the blue and green level tells that on the distances of 250m, namely, 300m, AI units become completely passive relative to the enemy. Table 2 shows the time it takes, as from the moment of noticing, an average trained player to neutralize the enemy soldier on various distances. Comparing these data with the data for AI units, it is evident that the reaction of an average player is approximate to the "white" level of training.

**Table 2:** The time it takes a player to neutralize the enemy

	100m	200m	250m	300m
Time [sec.]	3,00	5,50	6,60	8,10

This means that either the participants' level of training should reach the level required for the given scenario (preparing for the drill – exercise), or when creating the scenario, one should realize the possibilities of change in the level of enemy training (AI units) in compliance with the current participants' level of training.

## 5. CONCLUSION

Efficient, modern and rational army presumes the employment of highly qualified and skilled personnel. Computer simulations enrich the educational process, stimulate the staff and train the personnel (Šimić, Gajić, & Vukadinović, 2018).

The use of the VBS platform in research and education enables the experimentation with minimum costs of resources, improvement of education quality by better application for the training on the terrain (transition of theoretical to practical knowledge by transfer of experience from the virtual to real environment). As an argumentation, only a part of a typical military scenario is presented in the paper. However, virtual simulations have not exclusively a military purpose, but they can be also applied in the training for preventing and control of extraordinary events (state of emergency) and natural disasters, anti-terrorist combat, conversion, negotiating in various cultural environments and situations, protection and supervision of entry and exit from security susceptible areas and similarly. Also, an advantage is that conditions, not occurring at all or seldom in the real world, can be simulated.

The Military Academy, in addition to theoretical knowledge, also provides practical knowledge to attendees. We must not disregard the traditional form of education. The opinion of many people is that this form of education should remain the basic and enrich the educational process by means of contemporary

technologies (Dillenbourg & Fischer, 2007). E-education opens new prospects and privileges for all participants in the education. E-learning means the development of a new educational system. In the conditions of fast technological possibilities and changeable market conditions, the educational system should provide better educational opportunities without increasing financial resources. The Ministry of Defense and Serbian Army aim at responding to this challenge by the development of various e-learning programs, including the possibility of application of virtual simulations in the educational process.

**Abstract:** *The purpose of this paper is to raise the level of knowledge and awareness on the importance of a systematic approach to planning and project management in a real business environment, regardless of the type of activity, or type of problem being solved. The real problem of regulating the Old Mlava riverbed is analyzed in the paper. The problem was solved and optimized, and a comparative analysis with real fieldwork was made, using the Network Planning Technique (NPT) in MS Project software package. The results obtained from the MS Project were compared with the results of already realized field work.*

**Keywords:** *Regulation of the Water Course, Floods, Network Planning Technique (NPT), Software Package MS Project*

### 1. INTRODUCTION

As the number of people continuously rises as well as their needs, the pressure on water and food resources in the environment is much stronger. Human activity is one of the main causes of water resources pollution. These activities lead to a fast increase of ecological problems, natural resources and an environment in which humans live and act (Andrić Gušavac et al., 2016).

Natural resources are raw materials that come from Earth and exist without any human actions. Water as a natural resource refers to the groundwater and surface water in the environment. Humans have the great need for fresh water which represents around 2.5% of all water on Earth (Postel et al., 1996). Part of fresh water is locked in glaciers and ice caps, and the rest is in lakes, rivers, atmosphere etc. Fresh water can be considered as a renewable resource when the usage, treatment and release of water are in a balance with its capacity, which is necessary for its regeneration. Its significance is reflected in the fact that water is the essential precondition for life of humans, animals, plants, etc. Because of that, it is important to continuously implement various measures to protect water quality which involves uncertain information, multiple and often conflicting objectives, and limited resources (Andrić Gušavac et al., 2016).

Floods are a constant threat to life and property. As increasing human activity downstream of rivers results in greater flood damage, the floods themselves, in turn, are also increasing in size and frequency due to human activities in the upstream section of the river system. An increasing trend in extreme flood events can be observed in many countries around the world (Dutta et al., 2006). The potentially flooded area in Serbia with a 100-year return period is 15,198.07 km<sup>2</sup> (17.2% of total area). Serbia is mostly threatened by the floods of small to medium-size torrential rivers mostly in late spring (from May to the end of June), a period characterized by intensive rainfalls of a few-hour duration (Dragičević et al. 2013).

To avoid flood hazards from leading to catastrophic disasters, a thorough risk analysis should be performed. Flood risk management is the process of managing an existing flood risk situation. It consists of the planning and development of a system to reduce the flood risk. Flood risk management takes place on three different levels of action:

- operational level, associated with operating an existing project system;
- project planning level, implemented when a new version or a revision of an existing project is planned;
- project design level, embedded into the second level, describes the process of reaching an optimal solution for the project (Plate, 2002).

To obtain optimal solutions for project planning, it is necessary to analyze the performance of alternative plans with regard to a reduction of risk for various possible scenarios (Dutta et al., 2006).

Among natural disasters, with serious risks for people and their activities, floods have been the most common in terms of frequency, their threat level and the damage they cause; accordingly, they deserve special attention. Even though in most of the cases, the floods are caused by natural factors, we can see that the human factor contributes more and more to the effects of the disasters (Ceobanu & Grozavu, 2009).

A major role in catastrophic floods in Serbia is played by cyclones in the Sava and Danube river valleys. Flood analyses show that inundation mostly occurs in late spring and early summer, i.e. in the periods when cyclones are the most frequent. Apart from the mentioned causes, it should be pointed out that the formation of floods in Serbia is also influenced by a rather high density of watercourses (747 m/km<sup>2</sup>), intense erosion processes and the presence of the lower courses of large international rivers in its territory. Torrent floods are rather frequent, particularly in the basin of the South Morava and they are caused by the unregulated water regimes of hill watercourses. The last two types of floods have also been recorded in the territory of Serbia; some of them had catastrophic consequences. The greatest floods in Serbia were those of 1965 and 2006 and they were the most severe ones in Serbia during the 1960 – 2010 period. At that time, water levels on many rivers reached the absolute maximum values (Gavrilović et al., 2012).

Project management is the application of skills, resources and techniques to plan, monitor and control the project to achieve its goals (Jovanović, 1999). It requires the balancing of contradictory requirements about time, price and quality. Project management is a process that implements: project planning; monitoring the realization of the project, with certain plan adjustments; analyzing, evaluating and reporting on results (Krčevinac et al, 2006). Planning is of key importance for project management. The project plan is a document that determines specific techniques, resources and series of activities needed to achieve the project objectives (Krčevinac et al, 2006). In addition to planning, activities of organizing, guiding and control planning are closely related. For project realization planning, a set of methods has been developed, known as Network Planning Techniques (NPTs). NPT is a set of methods used to plan, monitor and control project implementation (Krčevinac et al, 2006). Phases within the NPT are: structure analysis, time analysis, cost analysis and resource allocation (Martić et al, 2007).

In the late '50s and early '60s of the 20th century in the USA, methods for planning and tracking projects, called Critical Path Method - CPM and Program Evaluation and Review Technique - PERT, were independently developed. Based on techniques of these methods, the Precedence Diagramming Method - PDM was developed. Network Planning Technology (NPT) has found its application in all segments of planning.

This research paper presents the use of NPT to solve the vital problem that the city of Požarevac faced in 2014 due to the unregulated Mlava River bed, when floods occurred in some municipalities.

The planned approach required that problem had to be perceived, not only from the purely technical aspect, but also from the aspect of level of economic possibilities of local self-government and technological possibilities of the local construction company, i.e. that, from relatively modest sources of financing, the problem was solved in the optimal time frame and avoid further floods caused by autumn high water levels.

One of the major issues for knowledge management in a project environment is the poor project success analysis and the lack of proper documentation on the results of the previous projects. Knowledge management in a project environment is an insufficiently explored topic in project management (Todorović et al., 2015).

So far, some software has been developed that enable monitoring of activities and project control. Project Management software is a program that enables summarizing project data, data management, CPM analysis, multiple calendars, reports, networking, simultaneous monitoring of multiple projects, "what if" analysis, graphic presentation, planning and balancing of resources, and cost analysis (Kerzner, 2003). The common features of this kind of software are: support for project management; an environment that allows users to communicate, easy insight into the tasks and updating them; a large number of users; etc. (Jevtić, 2009).

For this work, Microsoft Project has been used to control the project activities, scheduling, costs, and communication of team members. MS Project also provides, in cooperation with other Office package programs, higher productivity, reporting, templates and user-oriented tools.

Using MS Project has enabled planning accuracy within one day. An insight was obtained on the necessary daily engagement of labor, mechanic equipment and materials for installation in control facilities. As it was a real world project, it was possible to visually get acquainted with the location and technology of performance, collect information about the contractor and gain insight into the significance of the project for the city of Požarevac and the local population. During the work on this project, the technology of carrying out the works, all working processes and technological units, as well as the complete planning system in solving the real world problem in the field of construction profession are all in detail familiarized with.

## 2. PROBLEM DESCRIPTION

By the '70s of the last century, two parallel water courses flowed through the municipalities of Požarevac and Malo Crniće:

1. "Mogila" as the main flow
2. "Old Mlava" as a secondary flow.

In the period between 1975. and 1978. defensive embankments were built, which controlled the Mlava River, i.e. the main flow of Mogila was regulated. The secondary flow of Old Mlava remains unregulated and, as such, at higher water levels, endangers, to a greater or lesser extent, the municipalities through which it flows.

In the municipality of Malo Crniće, the old Mlava riverbed is well-set and organised and represents a part of the drainage system all the way to the town of Salakovac, which borders with the municipality of Požarevac. From Salakovac to river conjunction, the secondary flow is unregulated and not capable of accepting and evacuating large amounts of water from the upstream part of the basin, i.e. from the drainage system. This practically means the flood of downstream riversides from Salakovac to conjunction, that is, any bigger quantity of water, and the Old Mlava riverbed can not take on without the spillway into the coastal area.

For the aforementioned reasons, the catastrophic floods that occurred in May 2014. have caused great material damage. After analyzing the current hydrological situation, it was concluded that the Old Mlava basin (in unfavorable events such as strong and long-lasting rain and snow melting at the end of winter) will present a permanent danger for flooding of land through which it flows through its upper stream. Due to the listed reasons, in 2015, JVP Srbijavode has elaborated a study entitled "Regulation of the old riverbed of the Mlava River", according to which the regulation would take place in two main phases (Elaborat, 2015):

- Phase I: Includes the work on the construction of protective and regulating facilities on the water stream of the 2nd line of Stara Mlava (cleaning of riverbeds, construction of hydro-technical structures, demolition of superfluous non-functional objects and bringing the system into functional state).
- Phase II: Includes works on securing the flow profile of the Stara Mlava watercourse between Djerdap embankment and the village of Bubušinac.

**Figure1:** Canal before the works have started (Elaborat, 2015)

## 3. PROBLEM SOLVING USING NPT

In the study "Regulation of the Mlava Old Riverbed ", the graphical and numerical data given is used in this paper as input elements for the application of the Network Planning Technique in solving specific problems. The project design and work calculations have been used to a greater extent for the creation of a list of activities with minor corrections (Elaborat, 2015).

Before the final listing of the activities, consultations were carried out with engineers from the company AD Vodoprivreda from Požarevac. This company won this job in public tender in December 2015 which, on behalf of the local authority of the City of Požarevac, was carried out by the Public Enterprise "Directorate for the Construction of the City of Požarevac", and the authors of this paper were given direct insight into the complete construction problem.

According to the experts' advice from the contractor and supervisory team, structure analysis was done. Based on the flow diagram of the technological process (Figure 3), a logical arrangement was established between the activities. Logical and technological dependencies were determined; first between the projected phases (I and II), and then the dependence between the individual stages of phase I. After this analysis, there has been significant displacement of certain phase stages about the design and the projection of works.

For the final starting analysis, the following concept was adopted:

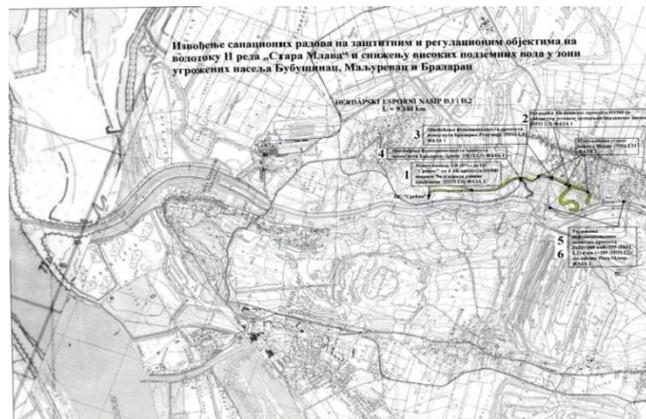

Phase I:

- Phase I preparatory work: 4 activities and 1 milestone activity
- The main works of phase I that consist of 6 stages in the new order:
  - I.6. Excavation of the canal and construction of an inflow building in the pumping station CS "Srečno" on the surface mine Drmno: 16 activities and 1 milestone activity
  - I.3. Seeding of the Djerdap embankment and construction of reinforced-concrete pipe drain(1500mm in diameter) with the floodgate: 10 activities and 1 milestone activity
  - I.4. Securing the functionality of a double pipe drain(1000mm in diameter each) on the relation Bradarac - Rukumija: 4 activities and 1 milestone activity
  - I.5. Securing the functionality of a double pipe drain(1000mm in diameter each) on the relation Bradarac - Drmno: 4 activities and 1 milestone activity
  - I.1. Removal of a non-functional doublepipe drain on the right embankment of the Mlava River (1000mm in diameter each) at a distance of km 0 + 035: 6 activities and 1 milestone activity
  - I.2. Removal of a non-functional double pipe drain on the right embankment of the Mlava River (1000mm in diameter each) at a distance of km 1 + 289: 6 activities and 1 milestone activity
  - Other works and phases: 2 activities and 1 milestone activity

Phase II:

- Phase II preparatory work: 4 activities and 1 milestone activity
- Main works of phase II
  - II.1. Extinction of the Mlava River: 3 activities and 1 milestone activity
  - Other Phase II works: 2 activities and 1 milestone activity

To define and analyze the activities more easily, Technological Process Maps (TPM) were made. Figure 3 shows the technological process map for AB drain on the relation Bradarac - Drmno and the dismantling of the drain on the left embankment of the Mlava River. Locations of the work phases are presented in figure 2.

**Figure 2:** Old Mlava - work locations of phase I and II (Elaborat, 2015)

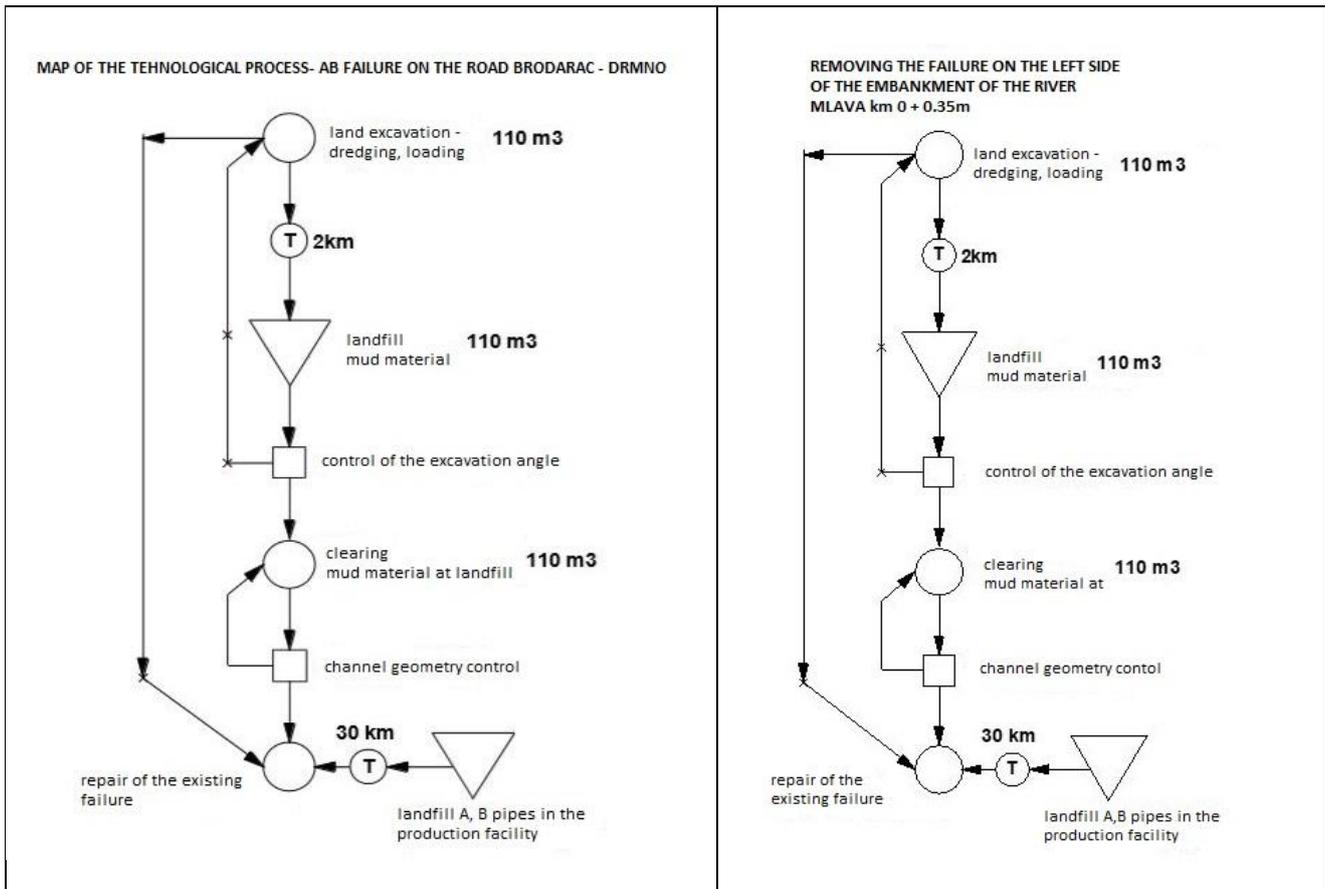

After defining all the activities and making the technological process maps, the analysis of each activity started. This analysis determined the following parameters: the required amount of work for each activity, the contracted cost of the works, the necessary resources for the execution of each activity, the practical performance of the construction machines, the number of machines that will be involved in the realization of the activity, and after that the minimum duration of the activity and duration of the activity is calculated.

To solve the problem, Microsoft Project 2010 was used. The working hour's calendar was adopted to work on one shift, lasting 10 hours. Working hours start from 7:00, and end at 17:00. All Saturdays are work days, only Sundays, state and religious holidays are adopted as non-working days. This ten-hour work is characteristic for the construction industry, with so-called redistribution of working time on an annual basis.

Outside the construction season (November - March period), the working hours are shortened to 8 hours and five work days a week. Works are completely stopped in the winter when weather conditions make it impossible to work outdoors.

A contract for the execution of works had been concluded between JP "Directorate for the Construction of the City of Požarevac" and AD "Vodoprivreda". The contracted construction period was 140 working days, and the works of both contracted phases had to be completed by the end of August 2016.

The realization of the project started on Monday, April 20th, 2016 according to the adopted calendar of working hours until the completion of the works. The analysis results were 105 working days and the closing date of 20.08.2016. (after optimization).

**Figure 3:** Technological Process Map

For each activity, the resources needed for its implementation are specified: material, mechanization and labour (workers) and its price. The price lists were taken from the price list of the contractor AD Vodoprivreda from Požarevac, and from the information provided by the Serbian Chamber of Commerce under the title "Recommendation on the performance of the Serbian operator on the foreign market".

The adopted price list used in the preparation of this project was created by a combination of:

- Recommendations of the Serbian Chamber of Commerce about the appearance of Serbian construction companies on the foreign market.
- Official price list of water company "Vodoprivreda" a.d. from Pozarevac.

#### 4. RESULTS

The application of Microsoft Project gives facility managers a clear and precise picture of the activities to be given special attention. Their realization should be without delay, so that the necessary resources would be on the construction site, according to the defined dates for the start of the activity. The required workforce and materials should be timely utilized to continuously carry out the activity without any waiting or delays.

During the development of this paper, an analysis was made for several different input parameters; the first variant had the following parameters:

- Beginning of works 15.03.2016.
- The construction time was 135 working days.
- Completion of works 20.08.2016.

These are the parameters by which the contractor based his business strategy for the realization of this project and based on them received a Gantt chart and a network diagram.

Network plan and Gantt chart for river Mlava water course are presented in figure 4. Activities that are on the critical path of the project are presented in red. Duration of each activity, start and finish, together with total and free slack are presented in the plan.

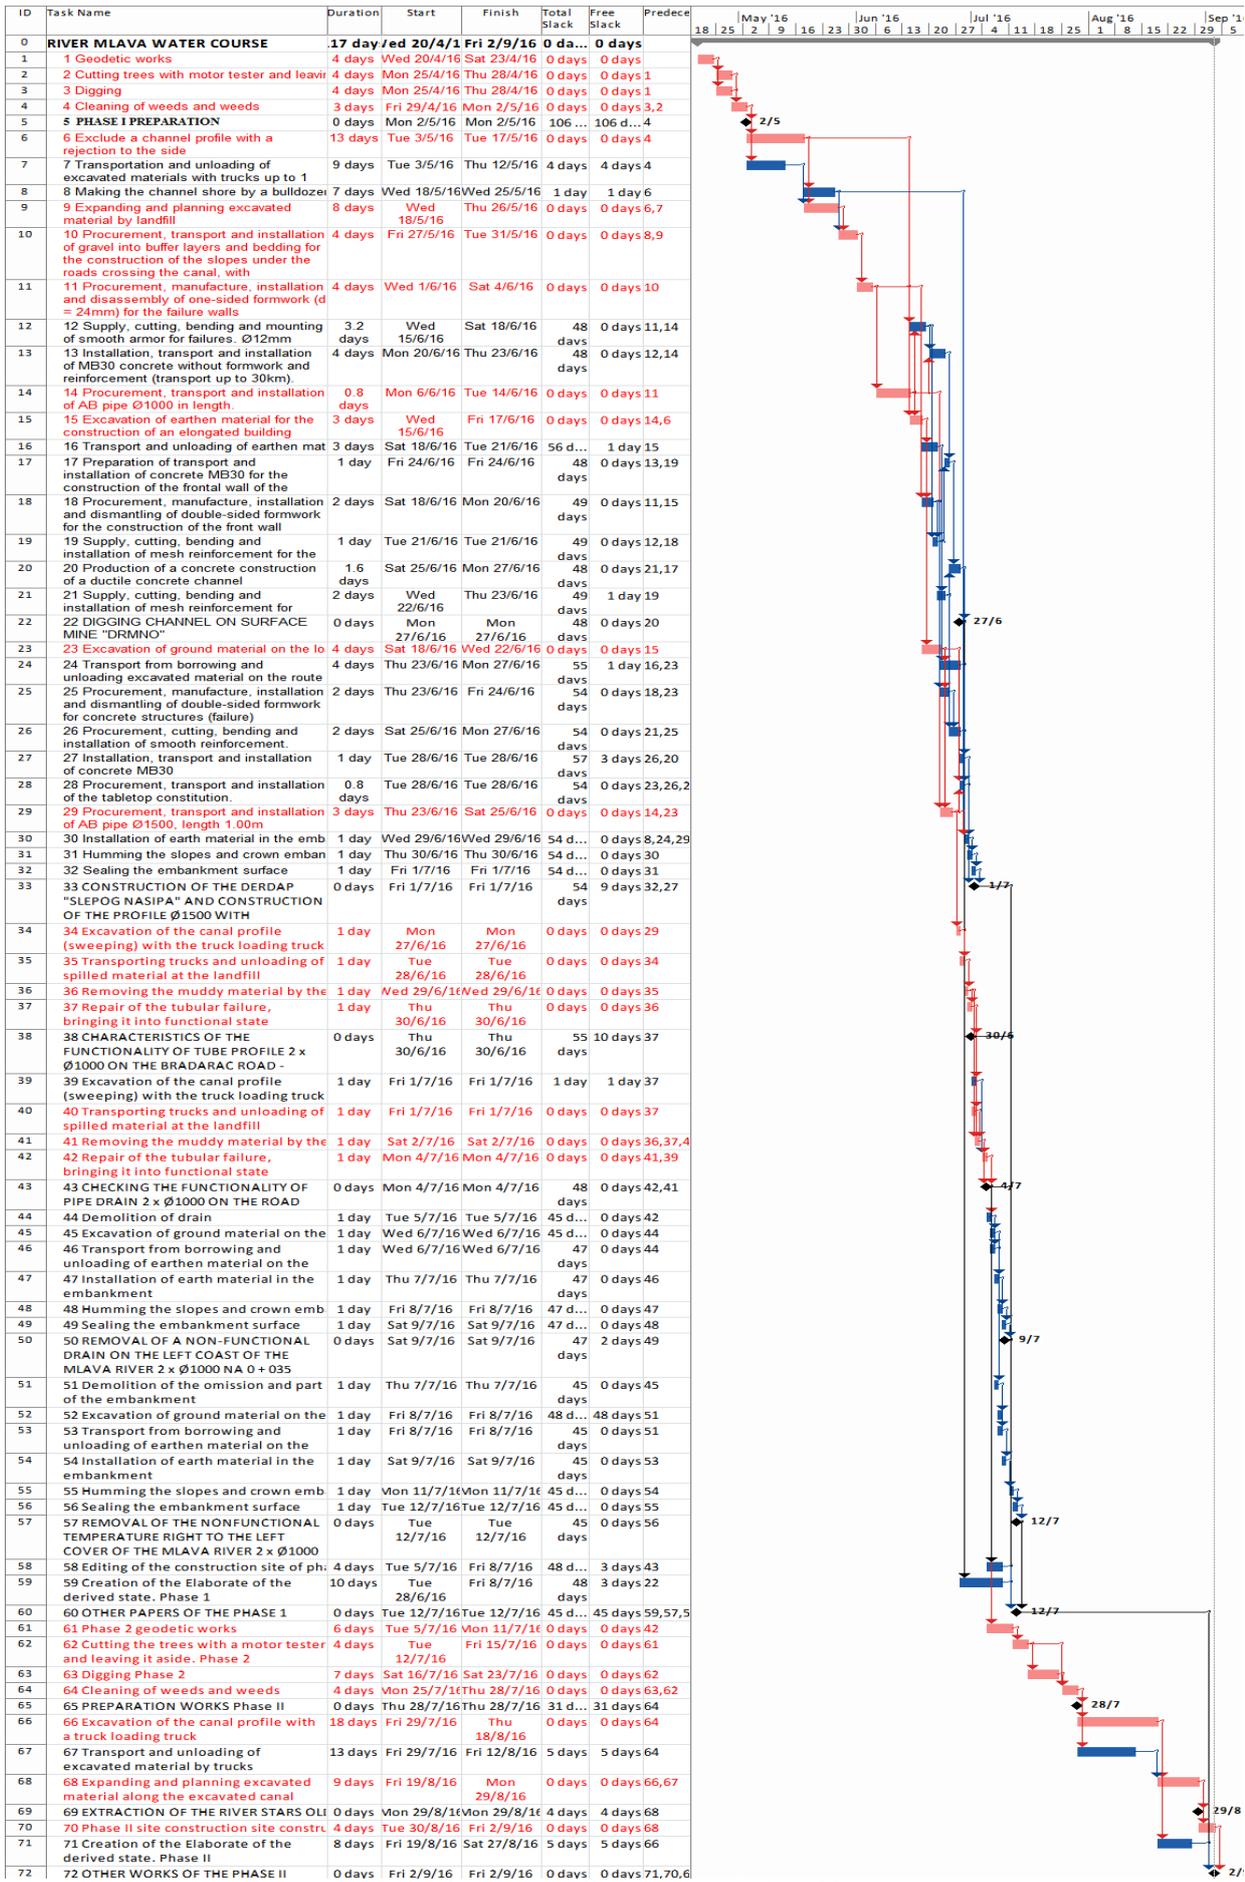

Figure 4: Network plan and Gantt chart for river Mlava water course

The first benefit from the application of network planning technique was already obtained in the analysis of the obtained Gantt chart and network diagram, where was realised that there were more possibilities for optimisation, that is, shortening the duration of the whole project. The parallelization of works has been intensified, and since the work route is geographically linear, simultaneous execution of works on several locations has been adopted, taking into account that none of the more crucial resources is exceeded.

The second benefit is seen in the resource analysis. The limiting condition for optimization was the maximum utilization of the resources of the contractor, that is, to avoid the additional recruitment of a subcontractor. Within the limits of existing resources, adopted building technologies and logical dependencies, the relationships between activities have been optimized, with the emphasis on maximum parallelization. This approach has provided a "more dynamic" mode of work execution, which manifests itself with a significant reduction in the duration of the project, from the initial 135 days to the new 117 days. By shortening the deadline, the contractor got the opportunity to postpone the beginning of works for April 20th, 2016. (30-day postpone). By moving the start of the works, earlier start of preparatory works in production facilities was made possible. March is the last winter month and belongs to climatically variable months, with more rainy days. By avoiding works in March, that is, by moving the beginning to April, the negative effects of working in the rain and the wet terrain were eliminated. This increases the performance of both machinery and workers and reduces the risk of stagnation due to rain, which ultimately increases the likelihood of completing the work within the planned time.

New project parameters received:

- The start of the project implementation is on Monday, April 20th, 2016.
- Completion of the project is 2.09.2016.
- Estimated working time 117 work days.
- The entire project has 72 (11 milestones) activities.
- No resources are exceeded.
- It was not necessary to perform additional dislocations of the resources used.

## 5. CONCLUSION

This paper shows the application of the network planning technique to solve the real construction problem of "Regulating the Old Mlava riverbed".

The technical aspect of the regulation of the Old Mlava riverbed was studied, the hydrological reasons for the occurrence of floods were explained and a list of technical measures, which had to be done on the terrain, was described. The technical characteristics of the new canal were given, as well as the cross-sectional drawings of the channels in variants with earth and concrete coating. In the shortest terms, the basic theoretical possibilities on the network planning technique are presented. Possible links between activities are described, the terms of the critical path and time reserves are explained, and the formulas for calculating the start and end of the activity are given. To better understand the method of calculating the time by the method back and forth, a short example of 8 activities was made in the paper.

The real problem of "Regulating the Old Mlava riverbed" was analyzed according to the NPT method. From the first to the last activity, the design work premise was subjected to precise analysis step by step. It should be noted that in the process of drafting this work, engineers from the company of the contractor were involved, and in cooperation with them, thanks to their experience and suggestions, an analysis of the structure was made. In parallel with the structure analysis, flow diagrams for the individual phases of the work were also analyzed. The duration of the activity was also calculated and the activities that preceded the observed activity were defined. The paper also defined how the MS Project software package was used, explaining the input of pre-prepared project and activity data.

From the above, it can be concluded that the application of the NPT method is possible in a wider range of diverse activities, and especially suitable for application in the field of construction. It was also concluded that NPT provides daily monitoring, control of project execution, as well as possible corrections in case of occurrence of some unforeseen circumstances that would cause a delay in realization.

This work has imposed a recommendation for all construction companies that NPT should be applied to any project of great importance. It may be necessary to launch an initiative to change the legislation, that is, in each project a section showing the NPT for that particular facility should also be included.

Field work was performed by company management experience, without taking into account more serious analysis of both technology and organization, without knowledge of the critical path and the accumulation of

certain resources. The company, both the contractor and the investor, need to improve the current understanding of planning and reduce it to the right frame, to avoid “spontaneous” planning. This type of planning often leads to exceeding the agreed deadline, increases the construction costs and reduces the profit of the contractor. Good planning identifies potential risks and takes measures to either neutralize or minimize them and propose optimization measures.

**Abstract:** *The purpose of this paper is to analyze various knowledge management factors in managing IT projects in order to achieve a higher level of organizational maturity. This paper presents an analysis of knowledge management processes according to CRISP-DM methodology by the clients, IT specialists and project managers of IT projects. The research presented in the paper was implemented in 154 different organizations in the Republic of Serbia. The internal and external perception of organizational maturity is taken into consideration. There are 6 clusters, specific for different contemplations of project contractors, project managers and IT specialists. The results of the study revealed that the knowledge management processes fluctuate from the initial to higher maturity stages. In addition, the agile approach and project management office establishing are immanent for higher levels of maturity. Theoretical and practical implications are discussed in the paper.*

**Keywords:** *IT, project, maturity, knowledge, process, cluster*

## 1. INTRODUCTION

In the last decade, maturity models have become a popular tool for analyzing the current state of organizations. Although on the one hand they are perceived as a promotional tool, on the other hand they are very useful in the process of lessons learned collection. The system for collecting and evaluating knowledge is certainly also important for reaching higher levels of maturity, and hence the main motive in this work is reflected through linking the field of knowledge management and project management maturity model. Niazi et al. (2016) analyzed global software development projects in order to map project management success factors to 10 project management knowledge areas according to PMBOK 5. The main conclusions from their research are related to human resource knowledge area. On the other hand, the generic application of knowledge and best practices does not fulfill the specific requirements of the projects (Sage et al, 2010). In previous releases of PMBOK, such as the fourth edition with nine functional areas, it has been noticed that knowledge in these areas is directly related to the success of project management (Abdul et al, 2014). Project practitioners recognized the link with the academic community in response to specific practices, in order to connect a systematic approach to knowledge acquisition on projects which is indirectly linked to a systemically and scientifically validated approach (Konstantinou, 2015).

Transferring knowledge from individual projects to the portfolio and programs occurs as a result of organizational project management and the achieved level of maturity (Görög, 2011). This situation is immanent for the IT industry, and therefore all the tendencies should be directed towards effective planning, collecting and sharing knowledge through projects, as well as through programs and portfolios. Kopečková & Máchal (2016) emphasize differentiation between knowledge and skills of project managers, which affects the utilization of full potential and capacity of the organization.

A large number of research on reaching higher levels of maturity highlighted by the knowledge management system directly outlines the role of the project management office. In this context, PMO appears as the main transmitter of knowledge in the field. However, in cluster analysis Müller et al. (2013) did not find a positive link between PMO members and project participants. There is an intent to explain the knowledge management process and identify important factors that affect the degree of maturity of an organization. Sohanvar et al. (2014) recognized that creating and collecting knowledge is more important than knowledge sharing and reusing. The knowledge distribution are mainly related with the transfer of individual and tacit knowledge focussing more on interpersonal and individual learning, than on organisational learning (Aerts et al, 2017). Project managers, or team leaders on software projects can learn from the agile effort and lessons learned, and therefore they have to find a method to use resources and processes, which are available at the moment (Bogojevic, 2017).

## 2. MATURITY ANALYSIS

The most common way to represent the level of maturity is reflected through five levels, which according to Carcary (2011) have the following characteristics:

1. Initial - At the first level of maturity there is a lack of formal efficiency of practices and processes in IT management structures. The effectiveness of the practice is based on ad hoc and informal successes of individuals;
2. Basic - At the second level of maturity, a formal management structure is established, with a basic understanding of the IT function, but without considering the entire business;
3. Medium - The third level of maturity implies that IT structures and management approaches are coordinated both in the company and with stakeholders, on the basis of which formal metrics and reporting system are set up;
4. Advanced - The fourth level of maturity is characterized by consistent and coordinated approaches that contribute to continual improvements above the industrial average;
5. Optimized - The fifth level of maturity includes the definition of policies, procedures and standards for achieving maximum possible efficiency, which is firmly linked to internal and external stakeholders. At this level, the organization is recognized as an industrial leader.

## 3. IT PROJECT MANAGEMENT MATURITY ORIENTED MODELS

### 3.1. Information Technology Capability Maturity Framework

IT-CMF (Information Technology Capability Maturity Framework) framework for assessing the maturity of key IT competencies was created in 2008 by the Institute for Innovation Evaluation. This framework consists of four integrated IT strategies and 34 competencies, which are grouped according to strategies. The assessment of maturity is based on a set of questionnaires or interviews carried out by an expert team (Innovation Value Institute, 2016).

Carcary and Zlydareva (2014) link IT-CMF with a strategic model of maturity of the organization, with the goal of recognizing strategic competencies in the field of IT in the organization. Curley and Kenneally (2011) point out that traditional metrics in the field of IT projects have a negative effect on business performance, while IT CMF components influence the correct definition of business value improvement.

### 3.2. COBIT Maturity Model

The IT Governance Institute (ITGI) was established in 1998 to promote international thinking and standards in the management and control of IT systems. ITGI has designed and created a publication called CobiT (Control Objectives for Information and Related Technology) 4.1. as an educational tool for senior management, IT management and controllers. Maturity level within the CobiT model have been created as a hierarchically structured set of levels with corresponding requirements for achieving maturity, where the fulfillment of requirements at lower levels goes to multiple levels of maturity.

CobiT model does not have a tendency to accurately measure the level of maturity or to certify an organization that has reached that level of maturity. With CobiT, the maturity of an organization is seen as a maturity profile within each level that has been reached, ie, it looks at the possible levels of maturity for IT processes at each level. For example, some processes can be well defined, even if they are incomplete. In this case, it can not be said that the processes given are not defined at all (Alfaraj & Qin, 2011). Using the maturity model developed for each of the 34 CobiT IT processes, the company's management can identify:

- Realized company performance - where the company is today;
- Current status of the branch - comparison with norms in the branch;
- Organizational goals for improvements - where the organization would like to be;
- Planned development path;

### 3.3. Project Maturity Model

In order to develop a framework for understanding, defining and planning improvements within the project management function, Consultant Interthink from Canada created in 1993 the PM2 maturity model (Project Maturity Model). It was originally used as a benchmarking tool for processes, structures and abilities in over 550 companies around the world. The development of the model itself was based on the CMM model and the Trillium model of estimation of maturity. In 1997, Interthink published a survey on organizational project management titled "Organizational Project Management - Basic Research".

The organization is evaluated within 12 areas divided into two groups. The first group consists of elements related to the life cycle of project management: program initiation, project initiation, project planning, scheduling and budgeting, project management, project monitoring and project reporting. The second group of elements refers to the structure, framework and environment of the organization: risk management, technology, organization, environment and resource management. The PM2 model of maturity uses a five-step maturity scale (Interthink Consulting, 2001).

### 3.4. PRINCE2 Maturity Model

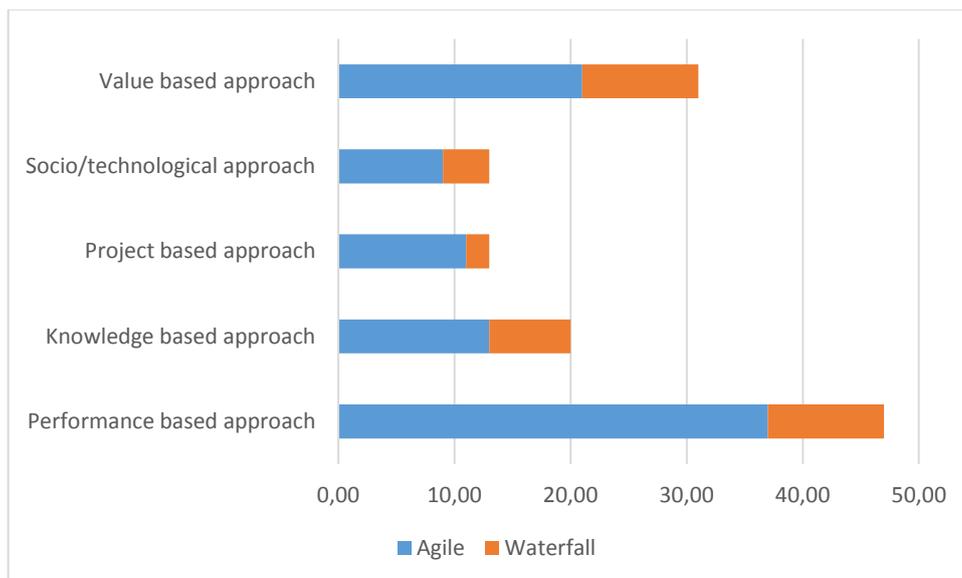

The PRINCE2 maturity model (P2MM) is based on the P3M3 and CMM maturity models. It is owned by Axelos. This model is used by organizations that are project management oriented and which use PRINCE2 methodology. P2MM uses the five-degree maturity framework previously explained. P2MM consists of three individual models:

- Portfolio Management Maturity
- Program Management Maturity
- Project Management Maturity Model

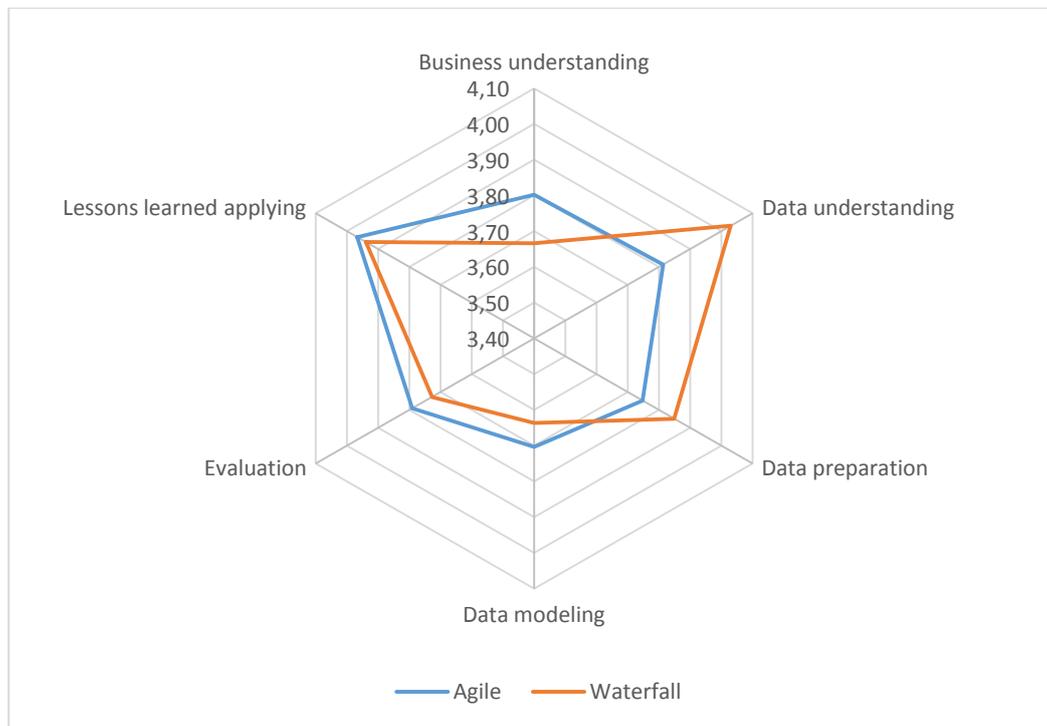

P2MM focuses on the seven key perspectives of the process, which include the models' analysis. The flexibility of this model lies in the fact that the application of this model can refer individually to a project, program, or portfolio. This can influence the better understanding of certain parameters in all aspects. For example, risk management or resource management can be seen from the point of view of the project, but also from the point of view of the program or portfolio. The level of maturity is sometimes not the same for these three aspects. The areas assessed within these three segments are: control, benefit management, financial management, stakeholder analysis, risk management, organizational management, resource management (Office of Government Commerce, 2009). The maturity analysis is done through the P2MM self-assessment questionnaire, in which they can participate (Axelos, 2013).

## 4. METHODOLOGY

The research involved 154 organizations in the Republic of Serbia, which have a defined IT component within the business strategy. In 75% of cases, organizations use an agile approach, where the greatest focus is on project performance (Figure 1). On the other hand, with comparative analysis of methodologies and knowledge management areas, it is noticeable that the hybrid approach yields the best results (Figure 2). The cluster analysis shows the characteristics of observations in relation to the dependent variable knowledge management, which includes the following subcomponents: understanding the general context of the business environment, understanding business data, preparing data for analysis, modeling, evaluating and applying knowledge and the lessons learned. Six clusters are presented, for 154 organizations, using the k-means algorithm.

**Figure 1.** IT project approach and methodology - comparative analysis

**Figure 2.** Knowledge management areas and methodology - comparative analysis

## 5. RESEARCH RESULTS

The first cluster is consisted of 34 organizations, of which 55.8% are at the at the first level, 5.88% at the second level, 11.76% at the third level, 20, 59% on the fourth level and 5.88% on the fifth level. The values of the dependent variables (understanding the general context of the business environment, understanding business data, preparing data for analysis, modeling, evaluating and applying knowledge, and the lessons learned) are unfavourably evaluated in comparison with other clusters. Organizations in this cluster mainly apply a traditional approach to IT projects, whose value is generally less than 50,000 euros and lasts up to six months. The number of end users, in most cases, is more than 20, and projects that are implemented in the public sector belong to the following categories: information systems, software and engineering, systems oriented to people and networks. Organizations in this cluster do not prefer the establishment of a project management office and mainly implement projects in education and IT.

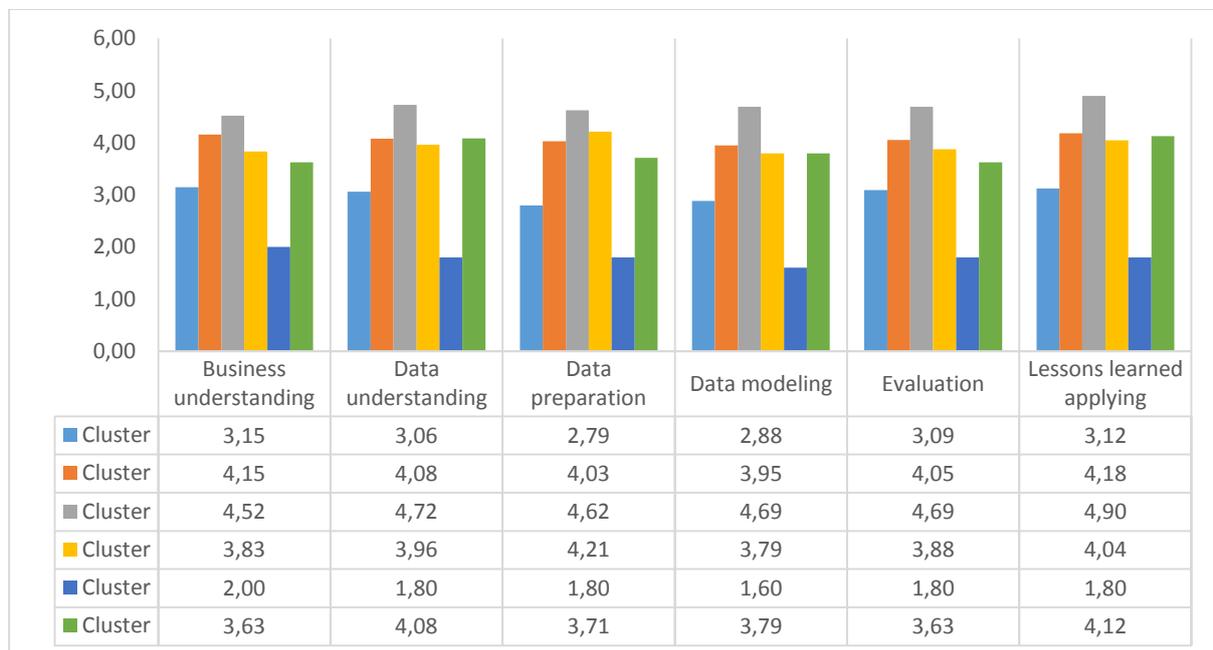

The second cluster consists of 39 organizations, of which 51.28% are at the at the first level, 15.38 at the second level, 12.82% at the third level, 17.95 % on the fourth level and 2.56% on the fifth level. Values of dependent variables (understanding the general context of the business environment, understanding business data, preparing data for analysis, modeling, evaluating and applying knowledge and keeping the lessons learned) are highly valued compared to other clusters. Organizations in this cluster mostly apply an agile approach to IT projects, whose value is generally less than 100,000 euros and the duration is up to 36 months. The number of end users, in most cases, is greater than 20, and projects that are implemented in the private sector belong to all categories of IT projects. Organizations in this cluster partially prefer the establishment of a project management unit and mainly implement projects in the following industries: creative industry, telecommunications, banking, insurance and investment services, trade and information technology.

The third cluster consists of 29 organizations, of which 62,07% are at the first maturity level, then respectively, 24,14% at the fourth level and 13,79% at the fifth level. Values of dependent variables (understanding of the general context of the business environment, understanding of business data, preparation of data for analysis, modeling, evaluation and application of knowledge and keeping the lessons learned) are highly evaluated compared to other clusters. Organizations in this cluster mainly apply agile approach to IT projects, whose value is generally less than 100,000 euros and the project duration is more than three months. The number of end users, in most cases, is more than 20, and projects implemented in the private sector belong to categories: information systems, software and engineering, systems oriented to people, applied computer systems and hardware. Organizations in this cluster do not prefer the establishment of a project management office and most often belong to organizations in the following industries: telecommunications and information technology.

The fourth cluster is consisted of 24 organizations, of which 50% are at the first maturity level, then respectively, 4,17% at the second level, 20,83% at the third level, 16,67% at the fourth level and 8,33% on the fifth level. Values of dependent variables (understanding the general context of the business environment, understanding business data, preparing data for analysis, modeling, evaluating and applying knowledge and keeping the lessons learned) are highly valued compared to other clusters. Organizations in this cluster predominantly apply agile approach to IT projects. The number of end users, in most cases, is greater than 20, and the projects that are implemented belong to the following categories: software and engineering, information systems, socially and professionally linked areas and applied computer systems.

The fifth cluster consists five organizations, of which 100% are at the first level of maturity. Values of dependent variables (understanding the general context of the business environment, understanding business data, preparing data for analysis, modeling, evaluating and applying knowledge and keeping the lessons learned) are low in comparison with other clusters. Organizations in this cluster mainly apply a hybrid approach to IT projects, whose value is generally less than 100,000 euros and the duration is shorter than 12 months. The number of end users, in most cases, is over 20, and the projects that are implemented belong to the categories: software and engineering, information systems and mathematical software and analyzes. Organizations in this cluster partially prefer the establishment of a project management office and mainly implement projects in banking, insurance and investment services and trade.

The sixth cluster consists 24 organizations, of which 37.15% are at the first level, 4.17% at the second level, 20.83% at the third level, 33, 33% on the fourth level and 4,17% on the fifth level. Values of dependent variables (understanding the general context of the business environment, understanding business data, preparing data for analysis, modeling, evaluating and applying knowledge and keeping the lessons learned) are highly valued compared to other clusters. Organizations in this cluster predominantly apply traditional approach to IT projects, the duration of which is up to 36 months. The number of end users, in most cases, is more than 20, and projects that are implemented in the private and public sectors belong to categories: software and engineering, information systems and computer systems of the organization - architecture and others. Organizations in this cluster prefer to establish a project management office and implement projects in all industrial branches (Figure 3).

**Figure 3:** Cluster analysis on sub-components of dependent variable - knowledge management

## 6. CONCLUSION

The significance of this research is supported by the fact that an increasing number of companies have defined IT component in their strategy. Also, IT industry is the largest export-oriented industry in Serbia, and therefore the application of knowledge management is justified. It often happens that higher level of knowledge and higher level of maturity are connected with the establishment of a project management office, which is a guide to organizations in the application of lessons learned and best practices implementation. At initial maturity level, the organizational focus is on understanding the general context of the business

environment, while at higher maturity level this aspect is implied in knowledge management. With the increase in maturity, there is a growing trend in understanding business data, as well as the importance of using the modeling and evaluation process. All levels of maturity include a high degree of application of knowledge and keeping the lessons learned because the development of the company is reflected in the number of mistakes it makes in relation to the previous period.

## ACKNOWLEDGEMENT

This paper is a result of the Project No. 179081 funded by Ministry of Education and Science of the Republic of Serbia: Researching Contemporary Tendencies of Strategic Management Using Specialized Management Disciplines in Function of Competitiveness of Serbian Economy.

## PLANNING PROCESS IMPROVEMENT IN RELATION TO BETTER RESOURCE MANAGEMENT

Milica Grujić<sup>\*</sup>1, Nemanja Minić<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

<sup>\*</sup>Corresponding author, e-mail: milicadjukic555@yahoo.com

**Abstract:** *Resource management requires incremental and occasionally radical improvements so as to maintain and increase the level of efficiency and effectiveness. There are a number of methods to improve the resource management process, and this paper analyzes the possibility of the improvement by means of better planning. Theoretically, various business and resource management planning improvement models have been developed, of which the one designed by the Deloitte consulting company can be singled out. The model is composed of a series of recommendations for the planning improvement grouped in two parts and represented in the form of a question: what an organization can do and what an organization can do better. The planning improvement and resource management ought to be considered as part of a wider organization improvement process. The aim of the paper is to present the basis and the advantages of the model as well as the possibilities for its improvement.*

**Keywords:** *business planning, resource management, organizational changes, organizational value.*

### 1. INTRODUCTION

Business planning includes the estimation of the future business conditions, the estimation of the effects of future conditions on an organization, the development and implementation of the strategies as a response to the changes of surrounding conditions, as well as the estimation of the outcome of the planned strategies. Since planning is basic for every business activity, we can state with certainty that efficient and effective resource management depends on good planning to a great degree. Significant acceleration of all business flows in modern conditions requires much more sophisticated planning methods, but on the other hand, modern information technologies make it possible for sometimes almost unimaginable things to become reality.

In recent years, companies from all branches of industry have begun introducing new digital technologies into business, by means of which they find new ways to solve various business challenges. By using digital platforms in the planning process, companies are provided with efficient and sustainable processes for problem solving, which means that improved data collecting, processing and visualization techniques are of a great benefit to employees dealing with business planning issues. Modern business planning techniques have become available owing to cloud technologies that enable new approaches to the planning process as well as faster and easier prediction of certain scenarios, which is not the case with conventional information systems of companies (Matt, Hess, & Benlian, 2015). Modern technologies significantly facilitate the business planning process, as well as the business strategy planning itself, which enables a company to remain competitive on the market (DalleMule & Davenport, 2017). The resources in modern conditions are becoming more and more digital, i.e. non-material resources are increasingly taking over primacy. Previously, data were a key resource in only some parts of the organization - for example, in finance and accounting, and today they have become the central part of each organization (Braganza, Brooks, Nepalski, Ali, & Moro, 2017).

In a study published in the *McKinsey Quarterly* magazine in which around 800 managers took part, only 45% percent of the participants claimed to have been satisfied with the strategic planning process within their organization, while 79% of the participants responded affirmatively to the question whether the process formalization leads to the strategic planning improvement. These data suggest that there are significant issues when planning in a number of organizations, but that there is also awareness of the necessity for the improvements. Theoretically, various models for planning improvement have been developed. For instance, if we take into consideration the approach that has been based on the increase of satisfaction among employees by means of strategic planning, we can single out the following recommendations: *to identify and analyze the key issues, to create the right teams (gather people who develop and realize a strategy), to adjust the planning circles to the needs of every organizational unit (it is not necessary to develop strategic plans every 12 or 18 months), to establish the system for strategic performance tracking and to integrate the human resource systems into a strategic planning (to link the managers' compensation to the new initiative progress) (Dye & Sibony, 2007).*

The paper will analyze the model for the company value increase developed by the *Deloitte*<sup>1</sup> consulting company, with the focus on the improvement of the process of planning in the resource management. The model represents a comprehensive demonstration of a number of ways in which the organization can be improved by the key fields (income, expense, resource, processes, etc.), with all directions being grouped into two fields: *what an organization can do* and *what an organization can do better*. The first part of the model refers to the activities that an organization is currently performing, and which can improve the planning process, while the second part refers to the activities that an organization can do better than with the existing method. Certain activities have been referred to individually within the model, but are represented together in the paper due to their connection, but also due to the limited space for analysis. The possibilities of planning process improvement according to certain fields are represented below.

## 2. WHAT AN ORGANIZATION CAN DO

There are a lot of ideas that can make an organization better and the key parts of the model will be presented below together with examples of successful implementation of proposed solutions with concrete benefits. The complete list of recommendations can be found on the link in the references section.

*Emphasize the planning based on a scenario* – The scenario-based planning is “a method for thinking creatively about uncertain future”. This approach is essentially based on considering more future variations that include plenty of uncertainties and risks in the system, i.e. focusing on the estimation of more than one possible outcome. According to the approach stated by Peterson, Cumming and Carpenter (2003), the key parts of the scenario-based planning are *the central problem identification, estimation, the identification of alternatives, scenario development, scenario testing and policy screening*. Certain scenarios have the goal to manage the uncertainties, while the goal of some is to discover them. The *Shell* Company used this method as early as in the 70s to deal successfully with the oil embargo and also realized the major investments in oil wells, but this method today has additionally been improved and popularized (Peterson, Cumming, & Carpenter, 2003). In most cases, in the business planning process, too much unnecessary data are used, where time is wasted on the data processing and the prediction of the outcomes of different scenarios, which means that management has no significant benefit from these activities. Modern information technologies enable digitization and automation of business planning processes, whereby planning is defined as a process that is in accordance with the requirements and needs of the company management, automated scenario planning systems and modern systems for modeling processes. Such an enhanced process can support various calculations, measurements, simulations, and predictions of different scenarios and their outcomes (Pollack, 2010; Matt, Hess, & Benlian, 2015; Phadnis, Caplice, & Sheffi, 2016).

*Harmonize the partial business strategies (consumer, product, marketing, sales, service, logistics and realization, HR, technology and other strategies)* – There are numerous problems that may arise in an organization, but also there are many examples of companies that managed to achieve significant results by means of the business strategy harmonization. For instance, in *Cisco Systems*, the annual sales have increased from 1.2 billion dollars in 1994 to 13 billion dollars in 1999, and within the same period the company realized 41 acquisitions. The secret to this success lies in a well-planned, flexible, harmonized and successfully implemented strategy, where the strategy for human resource management shall be emphasized in particular (Geer, 2003). Also, digitization as a modern trend requires organizational and technological adjustment. To survive on the market, organizations should develop a digital strategy aligned with other partial strategies. This is a prerequisite for digital competition with other organizations (Ross, Beath, & Seba, 2017). The need for partial strategy harmonization seems clear and sensible, but in practice, it is often omitted, i.e. there is the silo effect both in planning and in the realization, the business plans are merely copied from the previous year and alike. To harmonize business strategies means to establish their most important cause and effect relations (to establish the way in which minor changes in one element may cause the significant changes in another – similar to the *butterfly effect* in physics).

*Consider the possibility of a merger, an acquisition or disinvestment* – Both merging and separating organizations/organizational units lead to major changes in the structure of all kinds of resources. The companies with the same business activity, but also the companies which are related in the value chain, are merged. Mergers, acquisitions and disinvestment may, in certain situations, lead to similar, both positive and negative results – in some situations, disinvestment is by large a better option than additional investment, a merge or an acquisition (although in practice it is often treated as a defensive strategy), whereas in other situations, acquisitions or merges are a better solution. The example of one of the largest integrations as a consequence of successful planning is the acquisition of *Mannesmann* by *Vodafone Airtouch PLC* in 1999,

the value of which was 183 billion dollars (Carayan, Swenson, & Neff, 2002), whereas in Serbia it is the acquisition of *Mobtel* by *Telenor* for 1.53 billion dollars.

*Improve the integration of short-term and long-term planning* – In practice, more attention is often paid to short-term plans (a well-known saying "in the long run, we are all dead") rather than to long-term planning for a number of reasons: the future is difficult to be forecast, organizations lack in time to deal with all forecasts of uncertain future, insufficient knowledge of the strategic planning techniques and methods, etc. The future is certainly unpredictable, but as Peter Drucker stated: "the best way to forecast the future is to create it". These two planning methods are closely related and conditioned – short-term planning creates the basis for the realization of long-term goals, whereas the well-established long term goals facilitate the process of short-term planning. The external development is defined as the joining of businesses, most frequently in the form of strategic M&A (merge and acquisition) or strategic alliances. Research has shown that there is a significant correlation between the growth and diversification, based on the merge of companies, in terms of long-term business planning (Rajnoha, Štefko, Merková, & Dobrovič, 2016).

### 3. WHAT AN ORGANIZATON CAN DO BETTER

*Improve the process of identification and estimation of industrial and market trends* – This aspect implies the consideration of new needs, analysis of potential markets, analysis of required resources for satisfying the identified needs, chances, risks and methods for entering new markets etc. In the process of planning, the following must also be determined: the changes of consumers/users' needs on the existing markets and possible response of organizations in terms of non-profitable products withdrawal (the products that no longer satisfy the market needs), discovering new marketing and sales canals for the existing products and the placement of new products that will in near or remote future become the initiator for the organization growth and development (Paley, 2004; Porter & Heppelmann, 2015). The industrial and market trends are composed of certain *sub trends* whose relations and conditionality must also be taken into consideration. Apart from the trend and sub trend identification, it is also essential to determine what is, or what might be their effect on the organization profitability (Becker & Freeman, 2006). It is not easy to estimate and plan the response to the changes of industrial and market trends, but it needs to be done so that the organization may survive.

*Improve the identification of chances and threats* – *Strengths* and *weaknesses* are first of all the internal elements of analysis, whereas *possibilities* and *chances* are its external elements. The internal strengths and weaknesses include advantages and disadvantages in terms of business performance of a company, its current operations, available technology, relations among its organizational units, etc. The external chances and threats refer to the analysis of main competitors' performances, new technologies and legal regulations. Therefore, it ought to be determined what makes an organization or a product/service better or worse than the others and how these advantages shall be used, i.e. how the weaknesses shall be eliminated (Paley, 2004; Al-Turki, 2011).

*Improve the ability of the strategy development at the organizational and business unit levels* – The organizational strategy and resource management strategy planning and development ought to comprise the widest possible part of an organization, with the harmonization at all levels of planning being the most important issue. According to one approach, there are five strategy development styles – *command*, *symbolic*, *rational*, *transactive* and *generative*. *Command style* refers to the situation in which several top managers control the strategy development. The strategy development in accordance with the mission and vision represents *symbolic style*. *Transactive style* refers to additional improvement of employees and their bringing together with the aim of the best possible strategy development, i.e. it refers to the stimulation of the employees' engagement. *Generative style* implies experimenting, i.e. risk-taking by employees (White, Conant, & Echambadi, 2003). The strategy development at the organizational and business unit levels is the key step in the realization of higher goals and without the clear idea, the activities for business performance improvement, it may become a mere waste of time (Steiner, 2010).

*Improve the harmonization between budget and capital programs with strategic priorities* – *First, the strategic priorities need to be clearly determined, and then the resources shall be directed to their realization to the fullest possible extent. Planning is often being exclusively related to finances and budget of an organization, even though it refers to a much wider term. Efficient budgeting implies setting realistic goals, which motivate the management and other employees to act towards their realization. Simultaneously, budgeting, by its nature, implies relying on a standard expense concept. Furthermore, the conditions may be static, if the environment is stable, but more often than not, they should be flexible, i.e. adjustable to possible changes in business conditions (new goals, new technical-technological solutions, process improvement, etc.)* (Carayan, Swenson, & Neff, 2002).

*Improve the process of identification, estimation and realization of opportunities for disinvestment, mergers and acquisitions* – Certain rules that ought to be followed in the realization of the above-stated activities must be determined within the process of planning. Some of these rules are: proper selection of organizations or parts of organizations that will be the subject of the mentioned organizational changes, a thorough analysis of the target organization/organizational units (profitability, market share, product portfolio, competitiveness, etc.), consideration of the compatibility of the companies that are to be merged/split up (business, financial, social, organizational and other aspects following the merge/separation), the possibility of organizational structure harmonization, culture, the possibility of keeping the best quality staff and alike (Campbell, Stonehouse, & Houston, 2002). If the fact that a merge, an acquisition or disinvestments represent major organizational changes is taken into consideration, then it is evident that the role of business planning in their realization is also significant.

*Improve the process of transfer (communication) of strategic directions and priorities to all stakeholders* – A good plan shall successfully be communicated to all participants on whom its successful implementation depends. Poor communication or its complete absence frequently leads to failure to realize excellent business plans. All participants (employees and managers) need to have the idea about the goals and strategies of an organization, as well as about their individual role in their achievement (e.g. what are or what shall be the strategic resources of an organization, how the values are created, how they are managed, i.e. how they are used, improved and kept, etc.) (Paley, 2004). One example of a company that has achieved good business results by, inter alia, successfully communicating the strategic message to its employees is *Atlantic Grupa* from Croatia.

*Improve the ability of new business development and spin-off* – In order to remain competitive on the market, organizations must plan and develop new businesses. New business implies the development of new products or services that can be sold, rented or make profit through the sale of licenses (Carayan, Swenson, & Neff, 2002). It ought to be emphasized, though, that the innovations themselves are not a guarantee of success, but need to be sustained by adjusting other organizational units. *Business models* for which, without any thorough analysis, can be said to depict the value creation logic within an organization (the business models shall not be confused with strategies here) play a major role in the new business creation. Business models comprise and connect all most important elements of an organization that affect the value creation. Therefore, by new business planning, the business models that support innovations, create values and are difficult to be imitated ought also to be created (Teece, 2010). New business, including the one which has been created by using resources, can cause major changes – an organization may change the branch in which it operates, significantly increase its profitability, create entirely new markets, but also it may collapse.

*Direct resources to the priority projects* – The business venture priority hierarchy ought to be established by planning so that the major part of resources is invested in the most profitable projects independent of their type. The resources (apart from the free ones) may also be the ones that have been unlocked by, for instance, the sale of the excess equipment, land, the reduction of the number of employees and alike (Campbell, Stonehouse, & Houston, 2002). Also, resource management and especially strategic resource management and the application of its basic concepts can have a large and positive role in the project management process (Papke-Shields & Boyer-Wright, 2017). In Serbia, there are many companies that could unlock the locked resources and to invest them in the priority projects. For instance, the restructuring plan of the Public Enterprise *Srbijagas* provides the reduction of the number of employees through the so-called natural wastage (retirement or voluntary resignation, accompanied by the loss of these jobs without providing replacement) or through the stimulative termination of employment with severance payment. In practice, the plan has not yet been realized, but the savings that can thus be gained are not significant given the height and the structure of the income and expenses of this public enterprise. Following the reduction of expenses and the release of resources, the next step ought to be the development of new projects and the identification of priorities.

*Improve the monitoring of current and potential regulations/laws and lobbying effectiveness* – The monitoring and estimation of the impact of new and existing laws/regulations are the basis for the response planning and organization adjustment method. Certain “minor” articles in a law noticed and interpreted in the proper way may provide significant benefits to an organization and vice versa (e.g. in the area of tax law). Legal aspect is one of the key external factors that are to be taken into consideration when planning. For that purpose, numerous environment analysis techniques that also include the legal aspect (e.g. the BPLEST analysis) have been developed. *Lobbying* implies the engagement of specialized people responsible for the development of positive business relations between an organization and political or state-owned institutions and organizations. Lobbying can be both internal and external – internal refers to the connection with and the effect on the law creators, whereas external refers to the indirect effect by winning the influential individuals or by financial support. Mainly large enterprises deal with the planning of these activities due to enormous

funds they have available, the potential significant benefits they may obtain, but also the losses that may lead into a crisis or (in certain cases) the collapse of an organization. (Kelleher Richter & Samphantharak, 2009) Former politicians and diplomats are mainly the ones who are engaged in lobbying – e.g. Gerhard Schröder is lobbying for the gas line below the Baltic Sea, Joschka Fischer for the competing *Nabuko* gas line project from Turkey to Austria, *BMW*, *Siemens*, etc.

*Improve the estimation of internal and market organizational unit value*– In order to increase its value, an organization first needs to know the value of each of the resources it possesses and altogether and how that value will change in the future – if it is assumed that the value of one part will decrease in the future, the possibility of its sale might be taken into consideration. And vice versa, if it is estimated that the value will increase, the sale might be delayed. Provided that the market value is higher than the internal one, the organization is considered to be operating well and to have the future. And vice versa, in case that the market value is lower than the internal one, the organization is considered to be operating poorly. (Paley, 2004) The value of both certain organizational units and the organization as a whole needs to be determined as precisely as possible in the process of planning. A similar principle can also be applied here as in other business fields – the value of an organization and its parts shall be neither underestimated nor overestimated.

*Improve the analysis of internal and external risks in business planning* – The risk analysis is a systematic process for identification and estimation of events that might affect the goal realization. These events can be identified both in internal and the external environment of an organization. The risks exist but also arise when these events, for some reason, are not in harmony with the goals of an organization. The risk management analysis and planning imply their identification, the estimation of the effect volume and the response to each of the risks. When analyzing and estimating, it is essential to take two aspects into consideration: individual risks and their impact on the company goal realization as well as the general risk factors that might indicate a lower or a higher level of risk. For this purpose, different modeling methods are being used. For instance, the models based on the estimation of possibility measure the possibility and the volume of the impact on events, whereas the models which are not based on the estimation of possibility are used in case there are not sufficient available data (Atkinson & Jourdan, 2008; Brinckmann, Grichnik, & Kapsa, 2010).

*Improve the analysis and planning of tax benefits* – The tax planning and management is one of the possibilities to generate savings on the expenditure side – in case the company legally avoids paying a tax, it directly opens up the possibility of allocating those savings to other activities. It is understood that the resource structure, i.e. the participation of the resources subject to taxes and those that are tax-free, directly determine whether an organization will or will not obtain the tax benefits. The tax planning and management shall be integrated into the strategy of an organization and is by all means one of the most important elements in the analysis of competing advantage of an organization (Carayan, Swenson, & Neff, 2002).

*Improve the process of the recruitment, development and succession planning of managers* – Many organizations have major problems with developing leaders and massively losing talented people. Some of the recommendations for preventing such situations are: defining key competencies for leadership roles in the organization, rigorous assessment of a candidate's potentials, creating growth maps and giving real opportunities for employees' growth and development. It is important to emphasize that ideal candidates do not have to meet all conditions, but only those crucial (Fernández-Aráoz, Roscoe, & Aramaki, 2017). The improvement of these fields directly affects the possibility of crisis as the consequence of the departure of a manager for whom there is no adequate replacement ("successor"). Certain companies, e.g. *General Electric*, develop their educational centers for the training of managers, even though numerous universities have similar programs. Likewise, there are certain companies that directly cooperate with universities, that being the consequence (or the cause) of the development of programs that suit the specific needs of an organization, e.g. *Royal Air Force* and *Cranfield University* in Great Britain, *Ford Motor Company* and *University of Michigan* and *Cranfield School of Management* (Jackson, Farndal, & Kakabadse, 2003).

*Improve the leadership and management skills of the employees holding senior posts* – Companies indirectly invest in the increase of productivity and product and service quality, and thus in the development and the increase of the value of an organization as a whole by planning the development of managerial skills, i.e. by the training of managers. It ought to be emphasized that the key part of this process is the selection of right people (the identification of the employees with significant managerial and leadership capacity) as well as the right trainings (the identification of relevant or "tailor-made" programs) (Geer, 2003). This aspect of business planning improvement (closely related to the one stated above) is one of the most important aspects since people represent the most valuable resource of any organization.

## 4. CONCLUSION

Organizations ought to know which resources they possess, what their value is, whether they are strategic or not, how to create values, how to use and renew them, which new resources should be obtained, etc. Modern conditions complicate the process of resource management planning, but on the other hand, they also enable almost unimaginable situations. By summarizing all of the above theoretical aspects and examples, we can point out that the presented model leads to significant improvements:

- Harmonization of all parts of the planning process – short-term, long-term, planning through multiple scenarios, etc.
- Harmonization of strategies at all organizational levels
- Focusing on tracking significant market trends, chances, opportunities and threats
- Focusing on key parts of an organization in which better planning can generate significant benefits
- Better analysis and prioritization of projects
- Better communication of planning activities etc.

What can be noticed from all of the mentioned examples is that it is not necessary to apply all parts of the model, but only those that most closely correspond to a particular organization (logically, the organization that needs all of these improvements has serious issues). Parts of the model are related, and often the improvement of one automatically leads to the improvement of the other, although in some cases an organization has to opt for only one option. Another quality of this model is that it provides a great deal of the final list of possible improvements and represents a guideline for managers to overcome a crisis as well as to analyze the mentioned areas in regular circumstances. The result of all these efforts would be to increase the value of the organization in every sense of the word, in other words, to heal or to create a healthier organization. Each part of the model can be analyzed in detail as a separate entity which indicates the complexity of the model but also, on the other hand, the potential multiplied benefits it provides.

The paper includes only part of an integral model for the organization value improvement which its authors believe to consider the largest number of the planning process aspects. The key model parts can be singled out in one sentence: in order to plan and manage the resources successfully, it is most important to harmonize planning at all organizational levels, in all time frames (short-term and long-term), to track and, if possible, create trends, to set priorities and to sustain their realization by means of all resources available.

Following the description of possible improvements, it can be concluded that the success of all activities stated above depends on successful planning, while planning itself represents only the first, though possibly the most important, part of the resource management process. Planning improvement shall lead to the resource management process improvement, but also to the improvement of other related fields. The model shall be considered integrally and in the context of other organizational changes. The future research ought to include both quantitative and qualitative analyses of the success rate of the organization value increase model application, with special focus on the industrial branches in which the model generates the best results. We believe that In Serbia there is considerable space for the application of the described model. Applying the model to one or more of the domestic organizations and measuring results of its implementation will be the next step in the analysis of this area.

## IMPLEMENTATION OF DESI METHODOLOGY AND DIGITAL PERFORMANCES OF EUROPEAN UNION MEMBER STATES

Dragana Kragulj<sup>1</sup>, Sandra Jednak<sup>1</sup>, Miloš Parežanin\*<sup>1</sup>  
<sup>1</sup>Faculty of Organizational Sciences, University of Belgrade  
\*Corresponding author, e-mail: parezanin.milos@fon.bg.ac.rs

**Abstract:** *Implementation of DESI methodology for evaluation of the digital performances of the European Union member states is considered in the paper. DESI enables us to classify all the member states into three clusters. Denmark, Finland and Sweden are at the top regarding the DESI value. These states are leaders also at the global level regarding digital performances. Greece, Bulgaria and Romania have the lowest achievements. The results of implementing digitalization are modest at the level of the European Union as the whole and they should be improved. Digitalization may improve significantly the competitiveness of a country in the global market. However, this is valid only for countries that already have the well-established information-communication infrastructure. The composite index enables countries to understand weaknesses in the implementation of the digital economy according to individual indicators.*

**Keywords:** *Digital Economy, Digital Economy and Society Index – DESI, European Union, Economic Development, Competitiveness*

### 1. INTRODUCTION

Globalization, development and implementation of information-communication technologies (ICT) have changed the way of doing business and have caused transformation of economy and society. Digital economy studies how technologies influence the accomplishment of economic performances. It is based on information-communication, i.e. digital technologies. Economic activity is performed between different entities by ICT. ICTs have developed through time so that digital economy of the '90s was based on the Internet, intranets and private networks with additional value, computers, software and other aspects of ICT. Since 2010, it is based on the internet of things, mobile and smart telephones, tablets, laptops, cloud computing, digital platforms, big data, data analytics and robotics technologies (OECD, 2015). There are three definitions of the digital economy according to Bukht and Heeks (2017). The first one is that digital economy is generally digital sector, i.e. ICT sector that produces digital goods and services. The second one is that digital economy produces a part of the economic output that is accomplished by digital technologies with a business model based on digital goods and services. The third definition is the broadest and it refers to the implementation of ICT in all fields of the economy. The digital economy is growing seven times faster than other economies (European Commission, 2014), creates 5% of the global GDP and 3% of the global employment (Bukht & Heeks, 2017). The digital economy is closely connected with the knowledge-based economy where knowledge and innovation are the basis of the economic development, with the strong and necessary support of the ICT. Since the nineties of the 20<sup>th</sup> century until today, economists analyze countries that have revived their economies and have accomplished significant rates of development due to new technologies.

This paper discusses the application of the DESI methodology and the ranking of EU member states in the implementation of the digital economy. The following sections explain the strategies of the European Union that have contributed to the development of the digital economy. The third section of this paper examines the impact of the digital economy on economic development. The fourth section describes the DESI methodology. In the fifth section of this paper, countries ranking was done using the DESI methodology. The last section of this paper is a conclusion.

### 2. EUROPEAN UNION STRATEGIES IN DIGITAL ECONOMY DEVELOPMENT

During the nineties of the 20<sup>th</sup> century, the transformation of the American economy was based on the information-communication technologies (ICT). The ICTs were present in economic processes and influenced the economic efficiency in different ways and in different sectors. The American economy accomplished good economic performances by gradual adoption and their implementation, as well as structural changes. This trend of economic development, based on the influence of the ICT, attracted the attention of other economies. In order to accomplish the economic growth, greater competitiveness, economic performances and to reduce the existing gap between the European and the American economy, the European Union (EU) decided to transform own economy and increase the role of ICT in the

accomplishment of the goals. Therefore, the EU creates so-called electronic Europe (eEurope) and implements the Lisbon strategy.

The aim of the Lisbon Strategy (2000-2010) was to make the EU the most competitive economy and the knowledge-based economy. As a part of the Lisbon Strategy, so-called eEurope – an information society for all was launched. It was a political initiative to ensure that the EU benefits from the transformations to the information society, i.e. digital economy and knowledge-based economy (Europe 2020 Monitoring Platform, 2000). In December 1999, the European Commission initiated the creation of the eEurope. The Lisbon European Council approved it in March 2000. The conditions necessary for achievement of an information society are: 1) providing access to every citizen, home, school, company and administration to *online* services, creating the digital era; 2) creating digital literacy in Europe, supported by ICT and 3) providing information society for all social layers (eEurope Initiative, 2000). In order to achieve the objectives, the European Commission adopted the Action Plan – eEurope 2002. The basic actions of the Plan were stimulating a cheaper, faster and more secure Internet and its use, as well as promoting investments of humane and financial character. After eEurope 2002, the Plan eEurope 2005 was adopted. Targets of this Plan were the development of broadband access at competitive prices, providing more security and protection of networks and broader and better use of IT by state administration, i.e. eGovernment (EUR-Lex, 2005).

In June 2005, the new strategy i2010 was adopted – European information society for growth and employment in 2010. This strategy refers to the information society and media, with the following priorities: 1) to end establishing of a Single European Information Space, encouraging an open, competitive internal market for information society and media; 2) to promote innovation and investment in research into the ICT field; 3) to create the European information society that provides better public services and better quality of life (EUR-Lex, 2009). The EU managed to create 18 million new jobs with this strategy before the beginning of the economic crisis (European Commission, 2009).

In March 2010, the European Commission brought a *new strategy – the Europe 2020 strategy*, with the task to continue fulfillment of the Lisbon Strategy goals and the exit of the European economy from the economic crisis (Europe 2020, 2010). According to the strategy, the EU should exit from the crisis by a smart, sustainable and inclusive growth (European Commission, 2010). Seven pillars of the Europe 2020 support the Strategy goals. Achieving smart growth is set by the Digital Agenda, one of the seven pillars of the Strategy. The Digital Agenda proposes better using of the ICT in order to speed up innovation, economic growth and progress. The main objective of the Agenda is creating and development of the digital single market (Europe 2020, 2015). The Digital Single Market strategy was adopted in May 2015. The Digital Single Market should “ensure access to online activities for individuals and businesses under conditions of fair competition, consumer and data protection, removing geo-blocking and copyright issues” (Digital Single Market, 2018). The Strategy has three pillars: 1) Access – better access for consumers and businesses to digital goods and services across Europe; 2) Environment – creating conditions and planning levels for digital networks and innovative services; 3) Economy and Society – maximizing the growth of the digital economy. The Digital Single Market gives access to the market of over 500 million people. Completing the Strategy can contribute EUR 415 billion per year to the European economy, creating hundreds of thousands new jobs and transforming the public services (Digital Single Market, 2018). The EU digital economy grows at the annual rate of 12%, there are 7 million jobs in the European ICT sector, the expectation is that demand for jobs in the ICT sector will be 16 million (European Commission, 2014). In May 2017, the Commission published a mid-term review of the Digital Single Market Strategy. This publication has given the review and evaluation of the progress in the implementation of the Strategy. The achievements of the Digital Single Market are: reduction of price for electronic communication and abolishing roaming charges, better Internet connectivity, introducing more rigorous rules on data protection and privacy and the EU rules on cybersecurity that will be implemented from May 2018, creating conditions for digital networks and services, promoting digital skills and high-performance computing, digitalization of industry and services, as well as modernization of public services (European Parliament, 2018). In order to achieve the set goals, it is necessary to invest in artificial intelligence, blockchain, eHealth and innovation (European Commission, 2018). Value of the EU data economy was more than 285 billion Euros in 2015, which was 1.94% of the EU GDP. The value of the EU digital economy may increase to 739 billion Euro until 2020 and make 4% of the EU GDP (Digital Single Market, 2018). Due to the referred possibility, as well as in order to provide a fair, open and safe digital environment, future actions are directed to the EU data economy, cybersecurity for the property protection and online platforms.

### **3. INFLUENCE OF DIGITAL ECONOMY TO ECONOMIC DEVELOPMENT**

Digitalization changes the traditional business and has a great potential for increasing the economic development of countries and creation of a healthy social-economic environment. Primarily, some key advantages are in connecting individuals and companies, as well as increasing the internationalization of

business. High influence is also on reducing transaction costs and stock expenses. However, this may have a bad influence on competence, considering that there are companies with insufficient capacities to use these advantages. (Goldfarb et al., 2015; Arsic, 2018). Some authors emphasize the benefits of digitalization for environment protection. Implementation of new technologies and new production methods instead of the traditional industrial production result in positive effects on ecology and quality of life (Khan et al., 2015; Seele & Lock, 2017; Missalla et al., 2018). Special importance is given to the development of entrepreneurship, especially in the sector of services and software making. Low financial investments and highly skilled employees characterize such the type of entrepreneurship (Sussan & Acs, 2017). Likewise, it is considered also that innovations and diffusion of knowledge are introduced in this manner (Bilen-Katić & Radovanović, 2014; Nambisan, 2017).

The research conducted in the EU Member States has shown also the negative side of the implementation of the digital economy. Namely, the results have shown that there was a great difference between the member states in the digital infrastructure, especially in the states with a lower level of economic development. This results in the even greater gap in the economic development in the digital era. Linguistic barriers and distrust between business partners are also mentioned as limitations (Evangelista, et al., 2014).

The greatest controversy is about the topic how the digital economy influences the unemployment. Good and bad sides are often indicated. On one hand, new jobs are created, business in some fields is simplified considerably while productivity is increased (Brynjolfsson & McAfee, 2012). On the other hand, some jobs in new business models lose their significance. The need for certain skills is reduced and retraining for the new skills required by the digital economy is aggravated (Harrison & Budworth, 2015; Quinton et al., 2017).

#### 4. METHODOLOGY

Gross Domestic Product (GDP) and GDP *per capita* represent the traditional indicators of economic activity of a country and quality of life of its citizens. GDP enables monitoring of economy trends in a country in different periods. This macroeconomic aggregate enables distinguishing economic differences between regions and countries (Tvrdon & Skokan, 2011). Increase or decrease of total social production in a country is analyzed on basis periodic series, which is very important for economic planning and evaluation of the adequacy of economic policy measures of a country. However, there is a considerable number of disadvantages in using GDP as the measure of the welfare of a macroeconomics (Samuelson and Nordhaus, 2000; Mishaelson et al., 2009; Kragulj, 2016). GDP does not perceive the goals of production and the quality of economic growth. GDP does not inform on the quality of life, i.e. it does not provide the insight into the non-material needs, about the free time, about the quality of the environment, etc. A great shortage of GDP is that it provides no information on economic disparity (Kragulj, 2016; Jednak et al., 2018). Therefore, economists invest great efforts in finding a broader measure of economic activity. It is necessary regarding the complexity and multidimensionality of the development phenomenon that comprises different aspects of life: economic, technological, social, environmental, cultural, institutional, etc.

Evaluation of the level of economic and social development can be given by analytic observation of the development components and their decomposing to indicators. Since the key development components are at the same time just the first step in defining the level of development, it is necessary to establish determinable measures that will provide a quantitative picture of the development process. Economic, i.e. sustainable development is a complex social process. It has become clear that one indicator is not enough for the evaluation of the condition and the level of development of one economy in the contemporary economic conditions and the process of digitalization, but several indicators should be implemented. Just the complexity and the multidimensionality of the development phenomenon make the use of aggregate indexes, comprising of individual weighting indicators, especially attractive in this domain. Of course, there are still a great number of questions imposed. If several indicators are necessary, how these should be chosen? Which indicators should be chosen in order to get the adequate picture regarding the goal of the research? Are the chosen indicators analog to the measured phenomena? Can replacement of indicators, i.e. introducing the ones and eliminating the others, considerably change the picture of observation? (Kragulj, 2016). In addition, the series of other questions is possible to ask. Therefore, the methodology of research and analysis is of great importance for the achievement of the goal that we seek.

There are many different socio-economic indicators for measuring economic development formed by international institutions, as the United Nations, the World Bank, the European Commission, the Organization for Economic Cooperation and Development (OECD), etc. The modern age is a digital age. Expansion of the information-communication technologies has had the key impact on functioning and development of society, economy and business, as well as on macroeconomic and microeconomic performances. A digital economy based on digital technologies opens numerous possibilities, challenges, but also risks at macro and micro

plan. Therefore, a relatively new composite index will be presented in the paper, so-called Digital and Society Index (DESI).

The Digital Economy and Society Index – DESI was first published in 2014 by the European Commission with the basic goal to present and measure the results of the European Union Digital Agenda. The European Commission publishes this composite index, ranking the states of the European Union according to the achieved level of economic and social digitalization, once a year. Therefore, the indicators for this index exist for 2014, 2015, 2016 and 2017 and it is possible to monitor the progress of the EU states in the process of the economy and society digitalization in a period, but also of the European Union as the whole. Likewise, since it is a composite index, it is possible to identify the spheres and fields in which the EU Member States should accomplish better results. Regarding the structure of this index, it comprises of 5 dimensions, 12 sub-dimensions and 31 indicators, which is illustrated in Table 1 (DG CONNECT, DESI 2017).

*The Connectivity dimension*, with the weight coefficient  $w = 25\%$ , is composed of four sub-dimensions that are of key interest for connectivity with the Internet. *The Human Capital dimension*, with the weight coefficient also  $w = 25\%$ , is composed of two sub-dimensions that emphasize the necessity of developing digital skills, both basic and advanced, which would enable broader use of digital products and services, as well as their faster development. *The Use of Internet dimension*, with the weight coefficient  $w = 15\%$ , is composed of three sub-dimensions that show the possibilities and skills of citizens to be included in various online activities and using different online contents (from music to eCommerce). *The Integration of Digital Technology dimension*, with weight coefficient  $w = 20\%$ , is composed of two sub-dimensions that show in which extent the process of digitalization in the business sector has been implemented through the use of e.g. Cloud, Big Data or the Internet of Things, which significantly influence the improvement of the business efficiency and the increase of competitiveness. *The Digital Public Services dimension*, with weight coefficient  $w = 15\%$ , is composed of one single sub-dimension, showing the use of digital technology in public administration, i.e. the use of electronic systems in the interaction of business and citizens with the public sector. Weights are allocated for both sub-dimensions and individual indicators (DG CONNECT, DESI 2017).

**Table 1:** Structure of the Composite Index of Digital Economy and Society (DESI)

Dimension	Sub-dimension	Indicator
Connectivity	Fixed Broadband	Fixed Broadband Coverage Fixed Broadband Take-up
	Mobile Broadband	Mobile Broadband Take-up 4G Coverage Spectrum
	Speed	NGA Coverage Subscriptions to Fast Broadband
	Affordability	Fixed Broadband Price
Digital Skills	Basic Skills and Usage	Internet Users At Least Basic Digital Skills
	Advanced Skills and Development	ICT Specialists STEM Graduates
Use of Internet	Content	News Music, Videos and Games Video on Demand
	Communication	Video Call Social Networks
	Transactions	Banking Shopping
Integration of Digital Technology	Business Digitisation	Electronic Information Sharing RFID Social Media eInvoices Cloud
	eCommerce	SMEs Selling Online eCommerce Turnover Selling Online Cross-border
Digital Public Services	eGovernment	eGovernment Users Pre-filled Forms Online Services Completion Open Data

Source: DG CONNECT – DESI, 2017, p.6

With the aim to form DESI, normalization of indicators has been performed by an implementation of a min-max method with a linear projection on the scale between 0 and 1 (greater value on the scale is better) and with predefined values of minimal and maximal indicators. These values were introduced in order to make possible to compare indicators during the years, as well as in order to analyze their trend (Petrović and Bojković, 2017; DG CONNECT, DESI 2017).

## 5. RESULTS AND DISCUSSION

DESI enables also a comparative analysis of the member states within the achieved level of economy and society digitalization and their grouping into the most successful states and vice versa. DESI shows that the different EU Member States do not progress with the same speed. In 2017, Scandinavian states had the greatest DESI (Denmark, Finland, Sweden), while Bulgaria and Romania were at the rear. The average value of the index for the EU was 0.52. DESI in Denmark was 0.71, while in Romania its value was 0.29 (Figure 1).

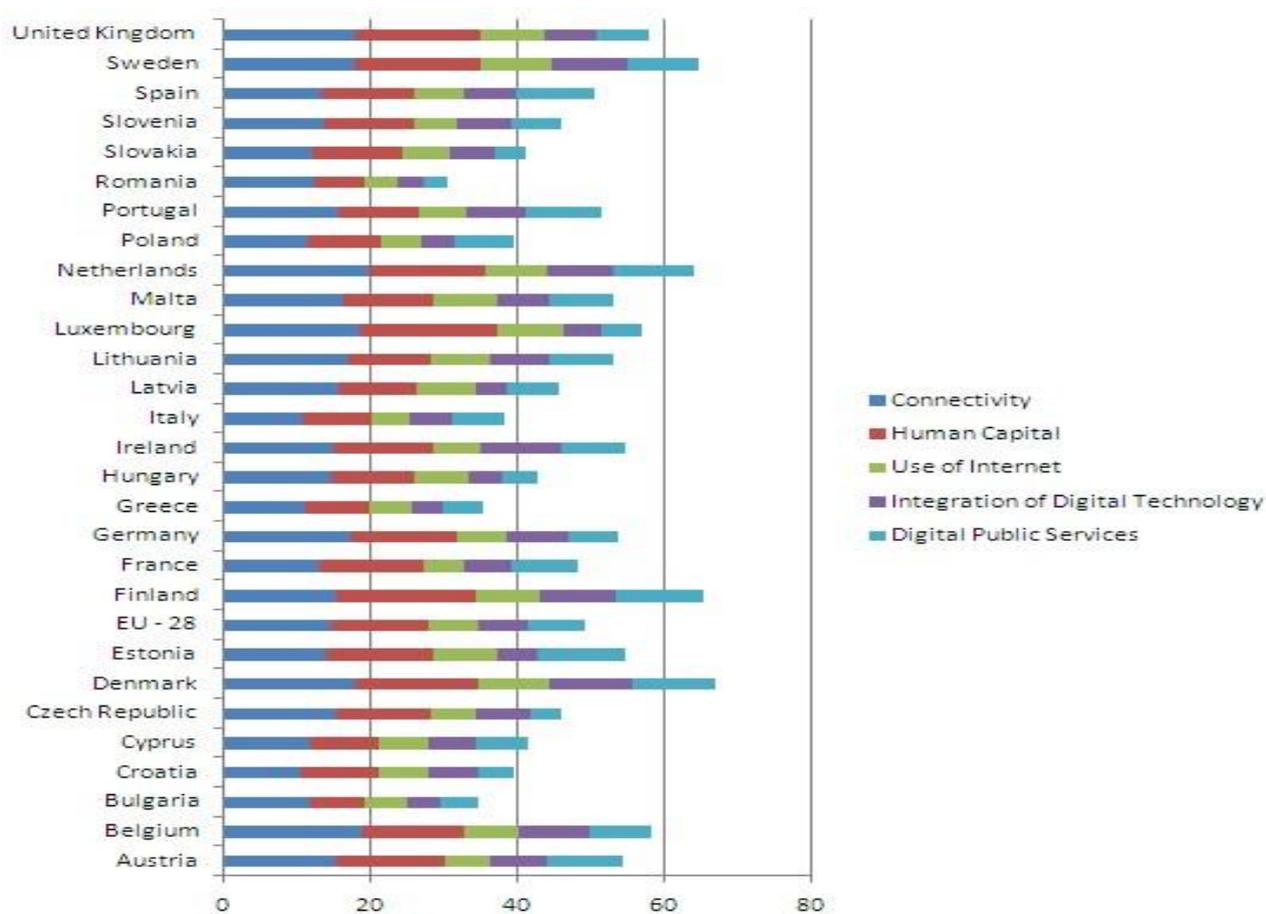

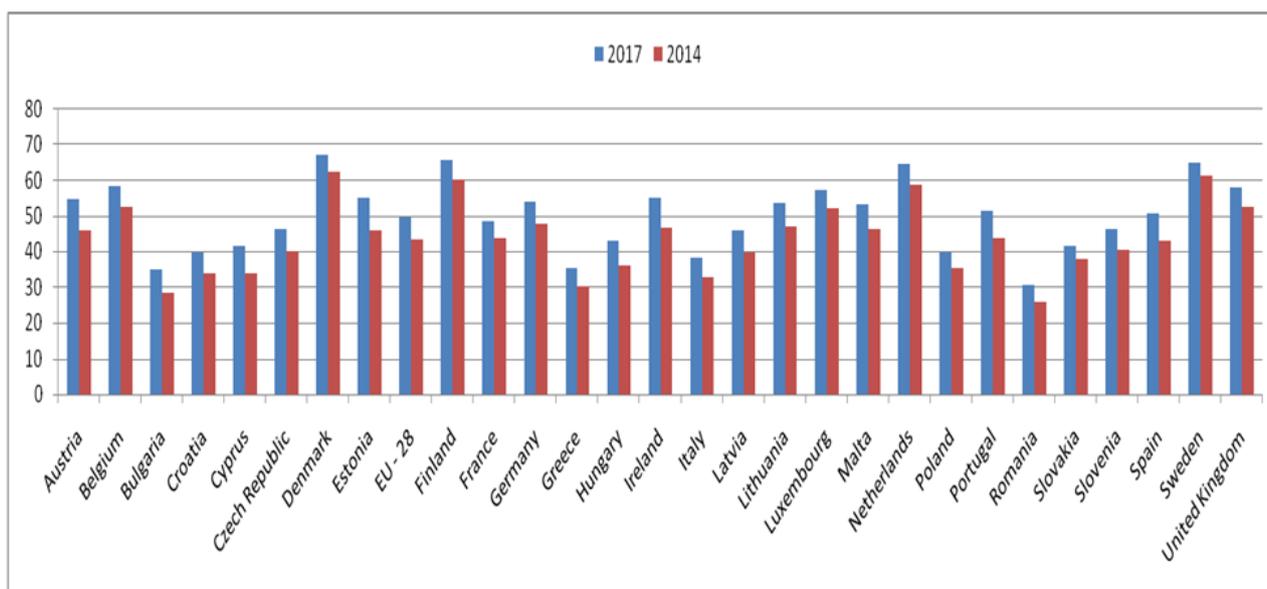

Figure 1: Digital Economy and Society Index, Source: European Commission, 2017

On basis of DESI value, it is possible to perform grouping into the three clusters. The first cluster comprises the states with high performances according to the DESI Value: Denmark, Finland, Sweden, Holland, Luxemburg, Belgium, Great Britain, Ireland and Estonia. The second cluster comprises of the states with middle performances. The value of DESI score for these states is similar to the average value for the whole EU. The second cluster comprises Austria, Germany, Malta, Lithuania, Spain, Portugal, France, Slovenia, Czech Republic and Latvia. The third cluster comprises the states with the worst DESI score: Slovakia, Hungary, Poland, Croatia, Italy, Greece, Bulgaria and Romania.

Figure 2 shows the growth of DESI in the period 2014-2017, where the year 2014 is taken as the base. On basis of this index, the European Union as the whole advances: DESI for 2014 was 0.43, for 2015 was 0.46, while in 2016 it was 0.49. In 2016, Slovakia and Slovenia advanced the most (more than 0.04, unlike the average for the EU of 0.028). On the other hand, low growth was recorded in Latvia, Germany and Portugal (below 0.02). The rank of states in the observed period changed very little, mostly for one position and only in case of some states. The states with the highest and the lowest DESI have kept their positions in the observed period.

**Figure 2:** Digital Economy and Society Index – growth 2014-2017, Source: European Commission, 2017

Observed by main dimensions DESI score gives a better insight into the rankings. On *Connectivity dimension*, the highest score in 2017 was obtained by the Netherlands (0.82) followed by Luxembourg (0.79), Belgium (0.78) and Denmark (0.76). Poland (0.52), Bulgaria (0.52), Greece (0.48) and Croatia (0.45) had the weakest performance regarding *Connectivity dimension*. For the observed period 2014-2017, these four countries are leaders by this dimension, while Italy and Cyprus were also at the forefront. Regarding the *Human Capital dimension* Finland (0.76), Luxembourg (0.73), United Kingdom (0.71), Sweden (0.69) and Denmark (0.67) obtained the highest scores in 2017, while Greece (0.35), Bulgaria (0.30) and Romania (0.28) got the lowest ones. These countries are at the top and bottom of the whole observed period 2014-2017. Regarding the *Use of Internet dimension* Denmark (0.72), Sweden (0.71), Luxembourg (0.64) and the Netherlands (0.62) obtained the highest scores in 2017. On this dimension, Poland (0.40), Bulgaria (0.38), Italy (0.36) and Romania (0.29) are at the bottom of the list. These countries are at the forefront for the entire observed period, while Denmark, Sweden and Finland are the leaders regarding the Use of Internet. As for *Integration of Digital Technology dimension* in 2017, businesses are the most advanced in Denmark (0.62), Ireland (0.56) and Finland (0.56), and the least developed in Latvia (0.23), Bulgaria (0.22), Poland (0.21) and Romania (0.19). Similar results were apparent for the whole period 2014-2017. European leaders in *Digital Public Services* are Estonia, Finland and the Netherlands, while Romania, Hungary and Croatia are lagging behind. In 2017, Estonia achieved 0.84 for this dimension, while in Romania it was 0.27. The average value for the EU was 0.55.

In order to provide an international compatibility, digital performances of the EU Member States have been compared with 15 states that were not the members. The International Digital Economy and Society Index (I-DESI) was created for that purpose in 2016. The referred index differs from DESI according to its components. The reason is that certain indicators are not available for the states outside the European Union. The following states have been taken for the comparison: Australia, Brazil, Canada, China, USA, Island, Israel, Japan, South Korea, Mexico, New Zealand, Norway, Russia, Turkey and Switzerland. The comparison was performed both with the EU Member States and with the average values for the complete EU. The leading states in the EU regarding the digital performances, Denmark, Sweden and Finland are global leaders also regarding the I-DESI score. These three states are followed by Japan, USA and South Korea. However, if the average values are taken for the EU as the whole, the values are below the average at global level measured by I-DESI methodology (European Commission, 2017).

## 6. CONCLUSION

DESI methodology has a great importance in monitoring digital performances of states. Its further development and harmonization of indicators through I-DESI might be in the future a global indicator for monitoring the level of digitalization development in certain states. The advantage of this composite index is that it comprises a broad spectrum of different indicators. In this way, states can get a clear insight in which spheres of the digital economy they are lagging.

It is noticeable that the leading industrial states of the European Union like Germany and France are lagging in implementation of digital economy behind the Scandinavian states. Italy is even in the last cluster

regarding the DESI. Due to the implementation of the digital economy, Baltic states have improved significantly their international competitive position. States candidates for the accession to the European Union are not included in DESI methodology. The problem is also that statistical offices of certain states do not monitor all the indicators that are the components of this index. It is necessary that these states improve their information-communication capacities in the next period in order to keep on successfully one day with other member states. Bulgaria, Romania and Croatia, as the last associated states, have not managed to do that, while the Baltic states based their competitive advantage just on the digital economy.

# GEOGRAPHIC INFORMATION SYSTEM – ONE STEP FORWARD IN THE DIGITAL AGE

Tatjana Kuzmić\*<sup>1</sup>, Marina Davidović<sup>1</sup>,

<sup>1</sup>Phd student at Faculty of Technical Sciences, University of Novi Sad

\*Corresponding author, e-mail: tatjana.kuzmic@uns.ac.rs

**Abstract:** *In recent years information technology has grown very rapidly. In the context of GIS, free/open source concept and three-dimensional implementation have also increasingly developed in recent years. The usage of these types of softwares is rapidly growing, so this paper describes the wide range of applications of GIS. It describes the major characteristics of GIS, as well as the reasons for the application of GIS in the analysis, modelling and display characteristics. The paper is focused on application of geoinformation technologies in mapping and managing in urban planning. Hence, in the paper are given examples of some GIS tools that can be used to manage data, no matter how big they are or what's their type.*

**Keywords:** *application, components, GIS, maps, data management*

## 1. INTRODUCTION

Geoinformation technologies are a new group of tools, methods, instruments and systems developed in recent decade to improve acquisition, processing, display and use of geoinformation technologies. Examples of such tools are GPS (Global Positioning System) receivers, GIS (Geographical Information System) tools, algorithms for spatial data modelling, remote sensing techniques, geostatistical tools etc. Geographical information system (GIS) technologies have been widely applied at all scientific fields and practical activities. These systems may be used as an aid to calculation of subsidies, serve as means of control and as support in decision making while following the latest technologies and standards.

GIS can be implemented as a comprehensive, multipurpose system (e.g. GRASS, ArcGIS), as a specialized, application oriented tool (e.g. GeoServer), or as a subsystem of a larger software package supporting handling of geospatial data needed in its applications (e.g. hydrologic modelling system, geostatistical analysis software, or a real estate services Web site). The multipurpose systems are often built from smaller components or modules which can be used independently in application oriented systems. GIS represents a set of related objects and activities that serve with their mutual relations the general purpose which is decision making of spatial activities. This system based on computer technology that enables archiving and manipulation of spatial data, is designed to provide answers and establish relationships between different data and enables us to make the right decision faster and safer. Also, GIS is very useful in marketing research, in geology and construction, as well as in all other areas using maps-related data.

## 2. MAIN GIS COMPONENTS

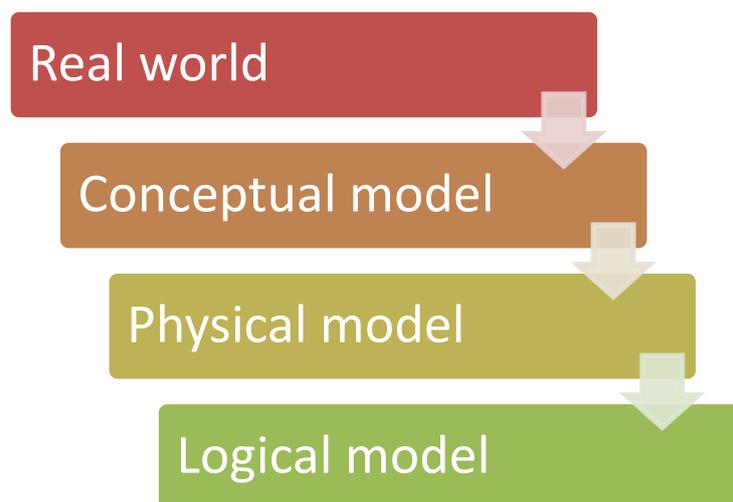

GIS is established on the basis of certain principles, of which the most important principle is integration, and this is the most important ability of GIS. There are not other system that can integrate, ie unify, spatial and non-spatial information in this way. Then, there is the principle of availability. The principle of data editing is achieved by the perfect combination of hardware components, software, experts and excellent database. Then, the principle of terminology and language definitions, which means that the GIS language has a formalized character defined by ISO standards. The last, but not less important, is the principle of visualization, so that the data is clearly displayed and understood by their users.

A GIS can be divided into five components: people, data, hardware, software, and methods (procedures), as showed in Figure 1. All of these components need to be in balance for the system to be successful. No one part can run without the other.

**Figure 1: GIS components**

Human resources represent the core of GIS, and make it functional by correcting the disadvantages of this system. Spatial data is a set of attributes (qualitative, quantitative, descriptive ...) that explain or define an element of GIS (object, event, activity ...). Information systems transform data into information. Data in GIS are organized from a human-oriented to computer-oriented: real world → conceptual model → physical model → logical model, as shown in Figure 2:

**Figure 2: GIS data organization**

Hardware affects the speed of the process, the way the system is formed, and the format of the output data. Software does not only include actual GIS software, but also various database software, drawing software, statistical software, software for analysis and photo processing, etc. Processes with different analyzes require well-coordinated methods to produce correct and required data.

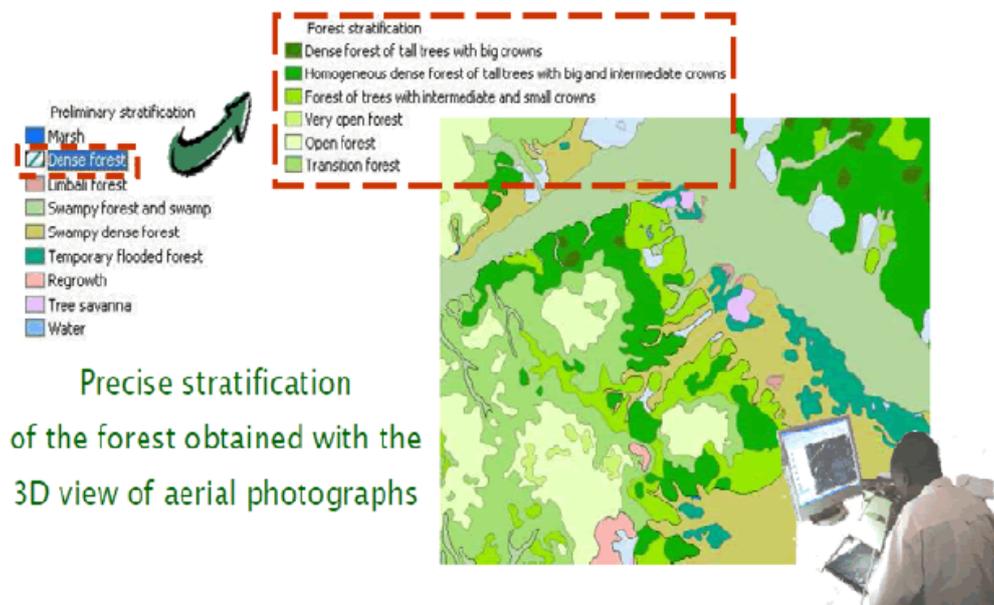

### 3. VARIOUS APPLICATION OF GIS

#### 3.1. GIS in forest inventory

GIS has shown as a good practice for forest management because it provides people with information that help better planning and making good development decisions. By creating maps in GIS tools it is possible to detect forest location, relations with the nearby places, and to find out what spatial patterns exist. Moreover, by surveying forest during longer period of time and creating maps, creation of overall difference map can be obtained. This map actually contains information about changes that happened during time of interest. The Forest Atlas is a dynamic tool that helps decision makers in the region to achieve sustainable management

of forest resources through strengthened land use planning and monitoring. Through a combination of interactive mapping applications, posters and analytical reports the Atlases provide users with timely, accurate, and synchronized information about land use allocation within national forest estates. With forest management becoming increasingly complex, due to greater environmental and social involvement and pressures, GIS is likely to play an increasingly central role. Application of GIS in forest inventory is shown in Figure 3.

## AERIAL PHOTOGRAPHS AND FOREST CHARACTERIZATION

**Figure 3:** GIS in forest inventory

### 3.2. GIS in flood protection

Most of the human casualties in the last few decades have been caused by floods. In addition, material damages that result from this natural disaster reach great intensities. This is due to climate change, urbanization and other natural and anthropogenic factors. It is precisely here that GIS systems play an important role in the analysis and forecasting of potential risks from the occurrence of floods, as well as their mapping and analysis of vulnerable areas. It is important to create a system that will provide early warning and allow evacuation of the population before the flood waters reach the houses. Flood risk mapping involves hydrologic and hydraulic analysis, damage and risk calculations, and mapping of the floodplain. The predicted water levels and floods for the next 24 and 48 hours can be displayed via dynamic web pages, and overlaid with maps of the transportation network, property boundaries, municipal infrastructure and water depth contour lines. This combination of technology and software can provide good flood prediction precision and strong support to the public evacuation if flood events happen. The basic inputs for automated floodplain delineation are the DTM and the water levels at the cross sections obtained from the water gauges. The floodplain depth datasets are generated by computing the elevation difference between the water surface TIN and the ground surface DTM data. Based on flood depth data, the floodplain extent and flood depth contour maps can be generated. The Web-GIS interface is designed to calculate and display the spatial extent of predicted flood plain (see Figure 4), enabling the visualization of the transportation network, property boundaries, municipal infrastructure, flood polygons and water depth contour lines.

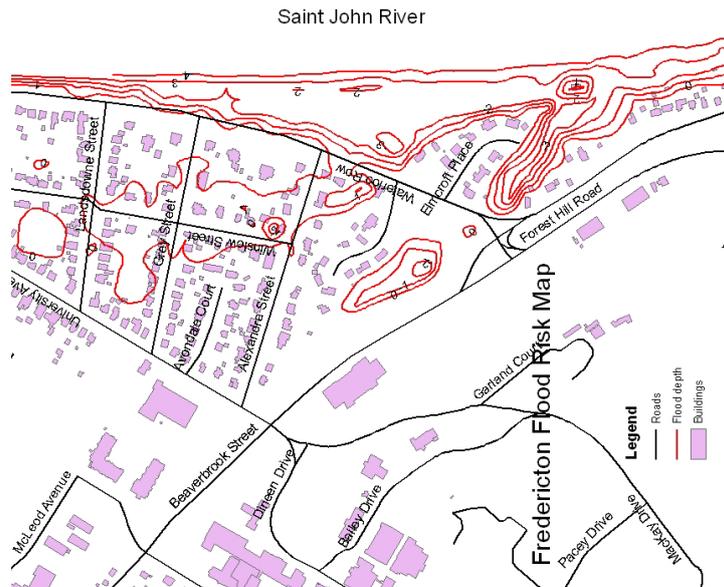

Figure 4: Flood risk map

### 3.3. GIS in tourism

Both tourism and IT increasingly provide strategic opportunities and powerful tools for economic growth, redistribution of wealth and development of equity around the globe. GIS technology offers great opportunities for the development of modern tourism applications using maps. This technology integrates common database operations such as query with the unique visualization and geographic analysis benefits offered by maps. GIS is used for bringing the georeferenced data (spatial and non-spatial) of geographic location Zlatibor and Zlatar into digital maps. Each object is assigned to a thematic layer. Each layer combines related objects like roads, building, protected areas or watercourses (Figure 5). GIS can be used in three types of applications such as inventory, analysis and evaluation of plan based on tourism development.

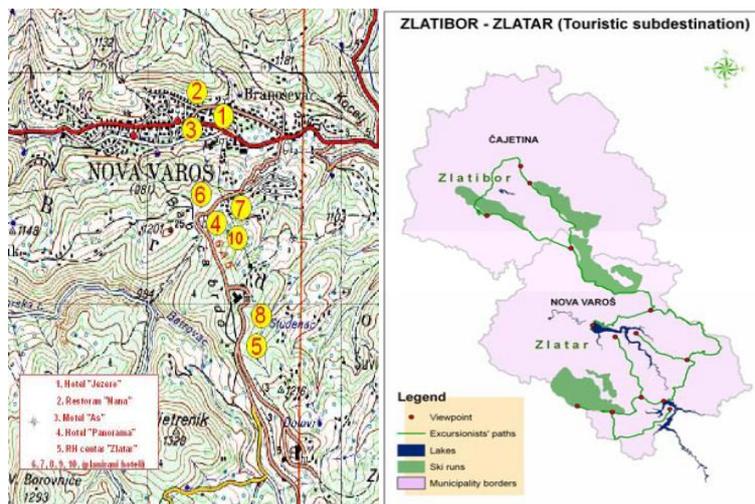

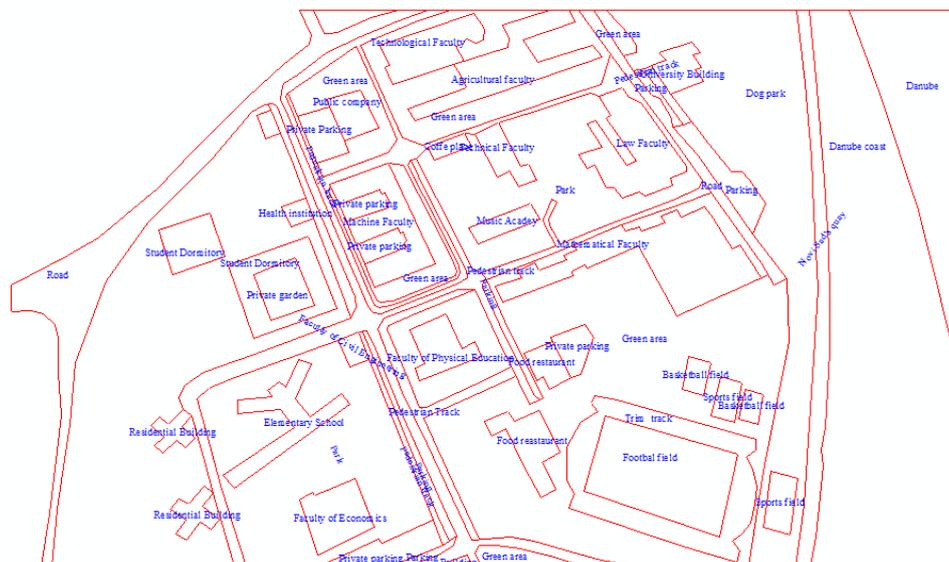

Figure 5: Maps with hotels at Zlatibor and Zlatar, tourist areas and main attractions

## 4. APPLICATION OF GIS IN URBAN PLANNING

Urban planning involves many functions, scales, sectors, and stages. In general, the functions of urban planning can be classified into general administration, development control, plan making, and strategic planning. Different functions, scales, sectors, and stages of urban planning make different uses of GIS. GIS tools are very important when considering making decision support systems for urban development, urban planning and usage ways of these areas, as well as making optimal solutions in terms of traffic regulation,

public transport and construction of various catering facilities. By using the GIS tool, you can create maps that graphically display current data of interest about an urban area. Based on the interpretation of these maps, planners and architects can make a decision where it would be the most rational to build facility, or how to regulate the green areas of the city or how to optimally manage traffic based on the analysis of the busiest parts of urban areas at different times of the day. GIS can also be used to model different development scenarios. It can show the modelling results in graphic form, making them easy to communicate with the decision-makers.

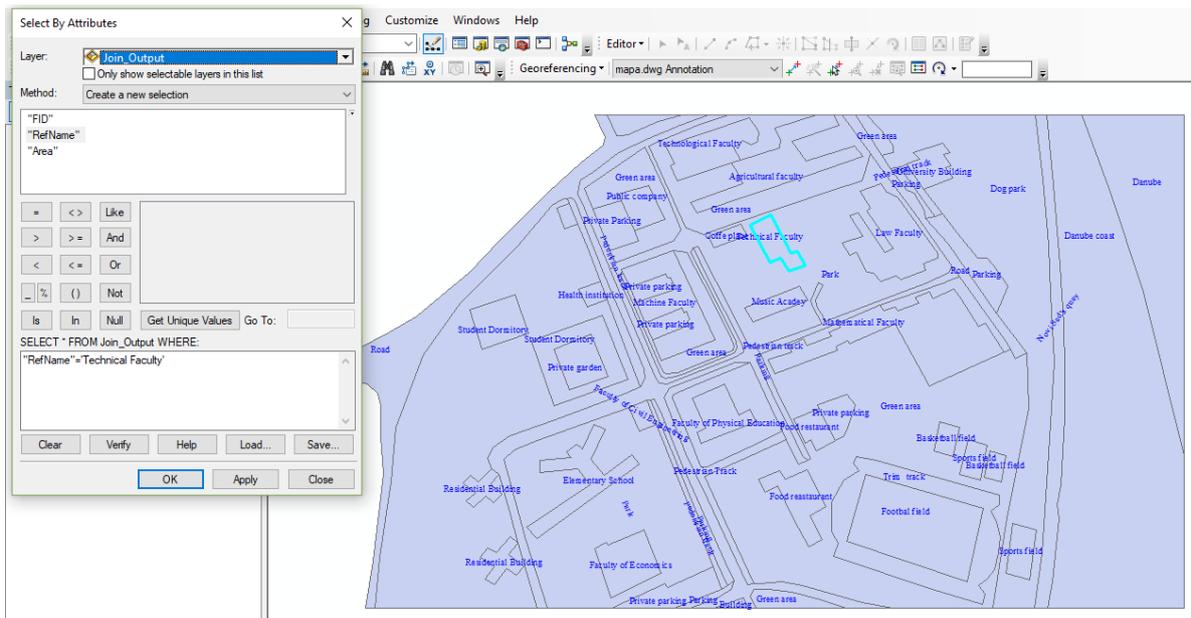

As an example of the application of data management for urban planning, one area of the city of Novi Sad-the Student campus, was chosen. In the case study, for representation of all above mentioned applications and for digital map creation, Google map is used. The aim of this paper is just to show various possibilities of GIS tools. In other circumstances, it should be used orthophoto or some other map with higher accuracy and better resolution. There are many programs that are used to create and visualize spatial data. Most professional programs are commercial, and they are free for some limited purposes. Commercial software usually comes in a combination of 3D display main elements, with additional features, such as GIS applications. They also allow working with geospatial data-on a large number of devices, as well as on the Internet search engine. The first step, using one of the programs, was digitization. Namely, the vectorization of scanned plans provides digital cadastral maps in vector form, which are presented in such a way and stored in digital form, represent a valuable database. Figure 6 shows the map of the Student campus in Novi Sad, and then the same digitized (on the left side the vectorization was done, all the streets, objects, parks were drawn, while on the left side are formed polygons- closed areas)

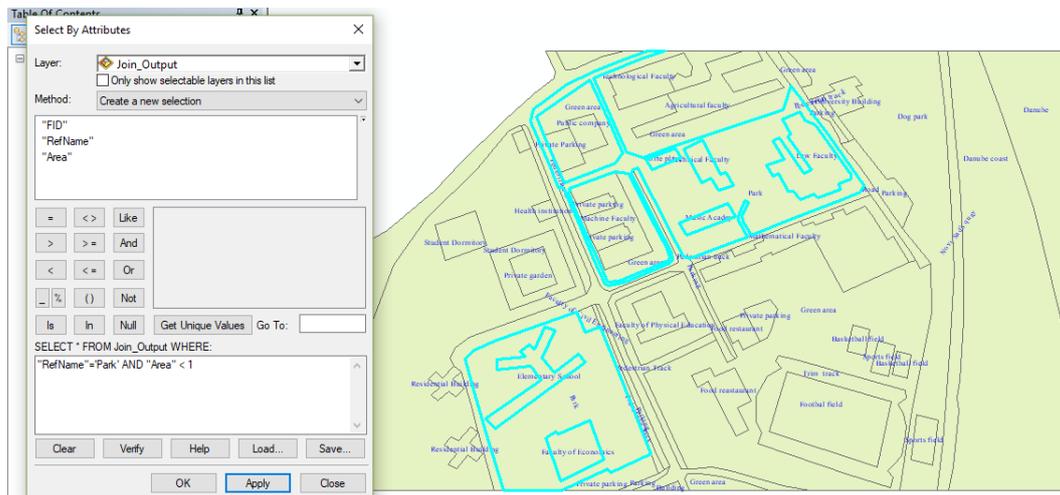

**Figure 6:** Map of case-study selected area and the same digitized map

After forming data in the appropriate form for manipulation, it is possible to use various queries, that make selection based on the given criterion. Figure 7 shows a simple query that selects a particular object. Namely, this query has a wide use for quickly finding of a particular object, in terms of navigating throughout the city, for navigation and orientation etc. It can also serve when creating applications for tourists, where tourists can easily find all objects and areas of interest.

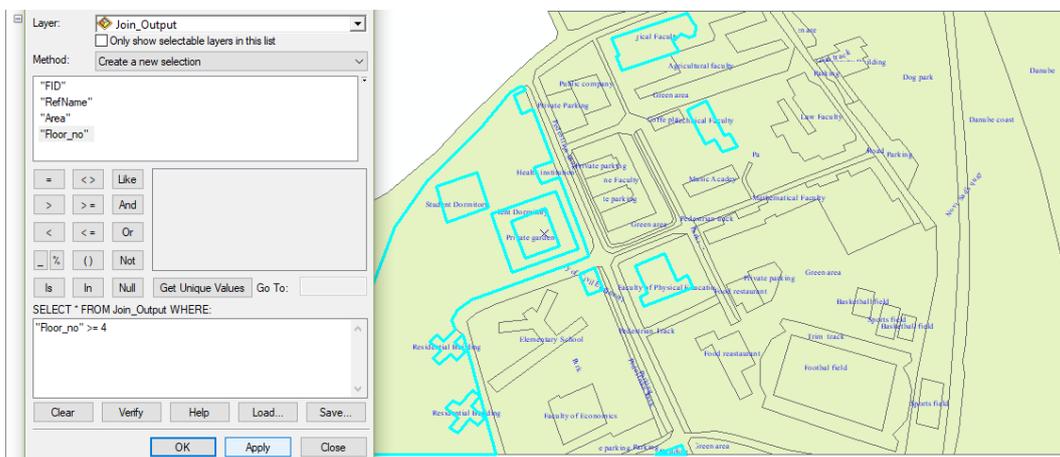

**Figure 7:** Selection of specified object

In addition, GIS allows an analysis of the distribution and representation of land types. It plays a great role in the expansion or regulation of parks and other green areas in accordance with urban plans. In the basis of selection, all parks with an area smaller than the given reference value (blue surfaces) are shown in Figure 8. This means that any polygons larger or smaller than some values can be selected, for updating or creation of maps, comparison with the situation in the Real Estate Cadastre or Land Cadastre and many other purposes.

**Figure 8:** Selection of all parks that have area smaller than predefined

Too high objects in some area can cause disturbances in terms of disrupting the harmony of the settlement. GIS technology is also used to check compatibility with the urban plan and to quickly find these facilities. Figure 9 shows the selected objects whose height is higher than the predefined value:

**Figure 9:** Selection of objects higher than predefined value

Figure 10 shows the application of geoinformation technologies for distance calculation, i.e. by marking the starting and ending points, and by defining a specific query, the shortest path is plotted, and its length is calculated:

**Figure 10:** Path from Health institution to Mathematical Faculty and Its distance

## 5. CONCLUSION

Most people think GIS is only about “making maps”. But governments, businesses and people harness the power of GIS because of the insights of spatial analysis. Before GIS, cartographers mapped out the land using paper maps. Over the years, people have witnessed a gradual shift away from paper maps. Instead, users build digital maps with computer-based spatial data.

Some of the largest problems of our planet are best understood spatially. For example, climate change, natural disasters and population dynamics are all geographic in nature. So, how to solve such problems in GIS? The answer is through spatial analysis which understand relationships between spatial and attribute data.

GIS is very important tool when it comes to natural hazards management and development planning. They can improve the quality and power of analysis and assist planners. This paper showed wide usage of GIS in data processing and management in the digital age, especially on example of urban management.

# DOING BUSINESS IN THE DIGITAL ECONOMY: SWOT MATRIX ENHANCEMENT FOR HIGHER ORGANIZATIONAL PERFORMANCE

Tanja Milić\*<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences

\*Corresponding author, e-mail: milic.tanja@fon.rs

**Abstract:** *The article covers an analysis of possibilities for enhancing the well-known SWOT analysis for the digital age. SWOT analysis is one of the most frequently exploited strategic business and marketing planning methods, commonly used for the formulation of business, and/or marketing strategy. However, its implementation is predominantly based on occasional, not so formalized, and well defined procedures, making it in a significant sense a victim of subjectivity. The proposal is to overcome this lack of SWOT analysis by basing it on contemporary strategic planning approaches and tools for determining the real facts concerning its internal and external elements appraisal, such as, the resource-based view of the firm, the core competence of the firm, contingency planning, competitive intelligence and, social media listening. The accuracy with which the SWOT analysis is being performed determines significantly the quality of developed strategies and hence the expected organizational performance.*

**Keywords:** *SWOT, digital economy, the resource based view of the firm, the core competence of the firm, contingency planning, competitive intelligence, social media listening*

## 1. INTRODUCTION

The development and increased usage of digital computing technologies in business purposes has brought to the development of the digital economy. The term *digital economy* was coined and popularized by Don Tapscott in his 1996 book *The Digital Economy*. It appeared with the advent of the Internet and World Wide Web, which enabled a new economy based on the networking of human intelligence. In this digital economy, individuals and enterprises create wealth by applying knowledge, networked human intelligence, and effort to manufacturing, agriculture, and services. Kling and Lamb (2000) identify four subsectors of a digital economy: (1) Highly digital goods and services - these are goods that are delivered digitally and services of which substantial portions are delivered digitally; (2) Mixed digital goods and services - these include the retail sale of tangible goods such as music, books, and flowers via the Internet, as well as services such as travel reservations; (3) IT-intensive services or goods production - these are services that depend critically on IT for their provision; (4) The segments of the IT industry that support these three segments of the digital economy. Nowadays, digital economy intertwines with the traditional economy in larger scale, abounding in the total revenue share across organizations in every industry. It reshapes the way of doing business and competition by interconnecting and including every individual stakeholder in the life of organization from the very beginning. In digitally interconnected world, defined with the global competition, fast and significant changes, increased business complexity, faster information and communication flow, organizations have to apply an appropriate way of doing business and new concepts in the process of strategy development in order to achieve business success and leadership. The dynamic environment of the digital economy and the necessity of organizations to respond to the opportunities in the environment in the fastest, the broadest, and the most profitable manner, requires dynamic business planning model, that will enable organizations to respond to newly developed changes in the environment in every moment, to seize the newly developed opportunities, as well as to create the new ones, and to position themselves above competitors (Milić, 2008). In terms of discontinuity it is necessary to constantly monitor the environment and study the changes, with the aim to establish how they will affect the position of the organization in the market and the results of its operations, in order to consider possible ways to react by changing the objectives, structure and strategy of the organization, in order to preserve the organization's ability to achieve its business objectives. Management who behaves responsibly towards customers adjusts the activities of the organization to changed conditions in the market of products and services (Ilić, 2001).

SWOT matrix appears nowadays as the most widely used tool for analysis of the business environment. Traditionally related to the old economy, SWOT analysis can be very beneficial in a digital business world as well. It acts as a source of information for strategic planning, builds organization's strengths and reverses its weaknesses, maximizes its response to opportunities, overcomes organization's threats. SWOT analysis provides information that helps in synchronizing the firm's resources and capabilities with the competitive environment in which the firm operates. (<https://www.managementstudyguide.com/swot-analysis.htm>)

Whether operating in traditional or digital business environment, SWOT analysis appears as a vital tool for strategy development. However, the subjectivity, the lack of trust and the lack of willing for facing the reality can make it difficult for organization to obtain a realistic image of itself and its environment (Andrews, 1980, seen in Milićević, 2011). Hence, its strategies can be misleading and costly. The main reasons for this issue can be determined in two sources: aspects which are not in control of management, such as price increase, inputs/raw materials, government legislation, economic environment, etc. (<https://www.managementstudyguide.com/swot-analysis.htm>), and the other source lies in the techniques commonly used to identify the strengths and weaknesses of organization, as well as opportunities and threats arising in its external environment. The paper first introduces SWOT matrix with specific elements related to the digital economy. The enhanced SWOT matrix follows, with concluding notes in the end.

## 2. SWOT MATRIX IN THE DIGITAL ECONOMY

SWOT matrix came from the research conducted at Stanford Research Institute from 1960-1970. The research was funded by the Fortune 500 companies to find out what had gone wrong with corporate planning and to create a new system for managing change. The Research Team were Marion Doshier, Dr Otis Benepe, Albert Humphrey, Robert Stewart, Birger Lie (Humphrey, 2005). Since then, it has become the unchangeable tool for strategic business and/or marketing planning. It precedes any functioning of the company, which makes it suitable in the following situations: (1) exploring the possibilities of new initiatives; (2) making decisions on the implementation strategy of the new policy; (3) identifying possible areas that need to be adjusted; (4) processing and redirecting plans. This analysis is an excellent tool for organizing information, presenting solutions, identifying barriers and highlighting opportunities.

SWOT matrix is a tool for planning strategies that faces internal strengths and weaknesses of the organization with external opportunities and threats over which the organization has no control (Certo, 2003, seen in Milićević, 2011). In the essence of the tool, the organization should activate the strengths, overcome weaknesses, seize the opportunities, and defend itself against the threats. At the beginning of the eighties, H. Weihrich (1982) developed the TOWS matrix, which analyzes the same factors as SWOT, only based on the result of external factors, in reverse order in relation to the methodological approach of SWOT (Figure 1).

External factors	Internal factors	STRENGTHS (S)	WEAKNESSES (W)
	OPPORTUNITIES (O)	SO: Maxi – maxi strategy	WO: Mini – maxi strategy
	THREATS (T)	ST: Maxi – mini strategy	WT: Mini – mini strategy

**Figure 1:** The TOWS matrix

The basic strategies that came out from this TOWS initiative are: (1) SO: Maxi-maxi strategy - SO strategy uses internal strengths of the company to take advantage of external opportunities. This is the best strategy (maxi-maxi), but many companies are not able to apply it. Companies often must first apply some of the remaining of the three strategies in order to be able to apply the aforementioned strategy. (2) WO: Mini-maxi strategy - WO strategy is used when sometimes the key opportunities from environment are present, but the company has internal weaknesses that prevent it to seize the opportunity. WO strategy aims to correct the weaknesses to take advantage of chances (mini-maxi). (3) ST: Maxi-mini strategy - ST strategy uses company strengths to avoid or minimize threats (maxi-mini). This does not mean that a strong organization should always avoid threats. It is essential that companies assess and measure the severity and immediacy of the threat before choosing this strategy. (4) WT: Mini-mini strategy - WT strategy is a strategy aimed to minimize weaknesses and avoid threats (mini-mini). The company faces a number of threats and its weaknesses can integrate, lead to bankruptcy or closing.

Since business and/or marketing strategy comes out as the result of this confrontation of internal and external factors, precise identification of internal and external variables is of the key importance for successful strategy development, and serves as the fundamental basis for successful strategic planning in

the case of SWOT analysis. Internal strengths and weaknesses of the organization operating in the digital economy cover three main components of the digital economy (Mesenbourg, 2001):

- E-business infrastructure, which relates to hardware, software, telecoms, networks, human capital, etc.
- E-business, which relates to how business is conducted, any process that an organization conducts over computer-mediated networks
- E-commerce, which relates to transfer of goods.

Identifying internal strengths and weaknesses in the digital economy is a demanding task that can be supported by the set of questions presented in Table 1. given in the Appendix of this paper.

The external appraisal of opportunities and threats includes the political, legal, economic, social, technological and competitive environment evaluation. The set of possible questions related to digital external opportunities and threats appraisal that can help in addressing this issue are presented in Table 2. given in the Appendix of this paper.

In its extension, SWOT analysis contains separated positive and negative factors which are related to a company and its competitors. In the process of strategy development, positive factors that include current strengths, future opportunities, and closely achieved success on the side of the organization, and weaknesses of its competitors are facing negative factors that contain current weaknesses, future threats, closely suffered failure on the side of the organization, and strengths of its competitors (Handscombe & Norman, 1989, seen in Milićević, 2011).

### **3. SWOT MATRIX ENHANCEMENT FOR HIGHER ORGANIZATIONAL PERFORMANCE**

The above mentioned subjectivity issue of the SWOT matrix is largely driven by the process of SWOT analysis implementation.

The procedure usually begins with the discussion related to mission statement, objectives, and characteristics of the organization to set the stage for the SWOT analysis. In the following step, key factors related to internal strengths and weaknesses of organization, as well as external opportunities and threats are identified. In the next step, each key factor receives its score in determined range by each team member. Generation of potential strategies responding to each determined key factor follows, adopting strategies that are driven by the highest rated key factors (Dyson, 2004).

A common technique used to identify the strengths and weaknesses of organization is a brainstorming session with the group of 10-12 members (Young, 1989, seen in Milićević, 2011). The same technique is used for external appraisal as well. Preferably SWOT analysis should be carried out by company managers, but in cooperation with the external consultants having special analytical skills and independent view. This is significant because in organizations is often present either too optimistic or pessimistic view that is more pronounced, and this is reflected in the managerial perception. Definition of strengths and weaknesses in practice is partly a question of facts, and partly a matter of judgment. Subjectivity, lack of confidence and the desire for confrontation with reality may complicate the organization to know itself (Andrews, 1980).

This subjectivity issue can be controlled using modern approaches and concepts in strategic planning, such as the resource-based view of the firm, the core competency of the firm, contingency planning (Dyson, 2004).

In the case of extended SWOT analysis implementation, it can be further enhanced by applying the concept of competitive intelligence in the segment of competitor strengths and weaknesses identification, and social media listening in the digital business world also in the segment of external appraisal.

These contemporary strategic planning approaches and concepts provide objective foundation for gaining facts and arguments, while identifying key factors related to all the wings of the extended SWOT matrix.

The resource-based view of the firm focuses on the internal resources as key to the superior organizational performance. It was developed in 1980s and 1990s with the major works of Wenerfelt (1984), and others. The essence of this approach is that it takes into account only internal company resources to find sources of competitive advantage instead of searching at external environment for it. The resource-based view relies on tangible and intangible resources that are heterogeneous and immobile. Intangible resources possess higher competitive advantage potential relating to tangible resources, which can be shortly supplied by other competitors of the company, which makes them to be considered as the main source of sustainable competitive advantage. Barney (1991) further developed the resource-based view by selecting specific

criteria, that a resource is to meet in order to be classified as a strategic one. The criteria refer to valuability measured by the resource capacity to increase the organisation's effectiveness and efficiency, rarity which means that resources are rare and in high demand, inimitability which means that resources are difficult to imitate, and substitutability which means that resources are not readily substituted.

The core competence of the corporation was developed by Prahalad and Hamel (1990). It is also internally turned identifying organisation's competencies as the foundation for strategy development. A company's competitiveness derives from its core competencies and core products - the tangible results of core competencies. The core competence is the collective learning in the organization, especially the capacity to coordinate diverse production skills and integrate streams of technologies. It is also a commitment to working across organizational boundaries. Organizing around core competencies requires a radical change in corporate organization. The first step requires identifying core competencies, which meet these three requirements: they provide potential access to a wide variety of markets, make a contribution to the customer benefits of the product, and are difficult for competitors to imitate. The next step is to redesign the architecture of the company and provide an impetus for learning from alliances and a focus for internal development. Management should ask: How long could we preserve our competitiveness if we did not control this core competence? How central is this core competence to customer benefits? What opportunities would be foreclosed if we lost this competence? As one can see, the core competence of the firm also focuses on internal environment in its search for competitive advantage source.

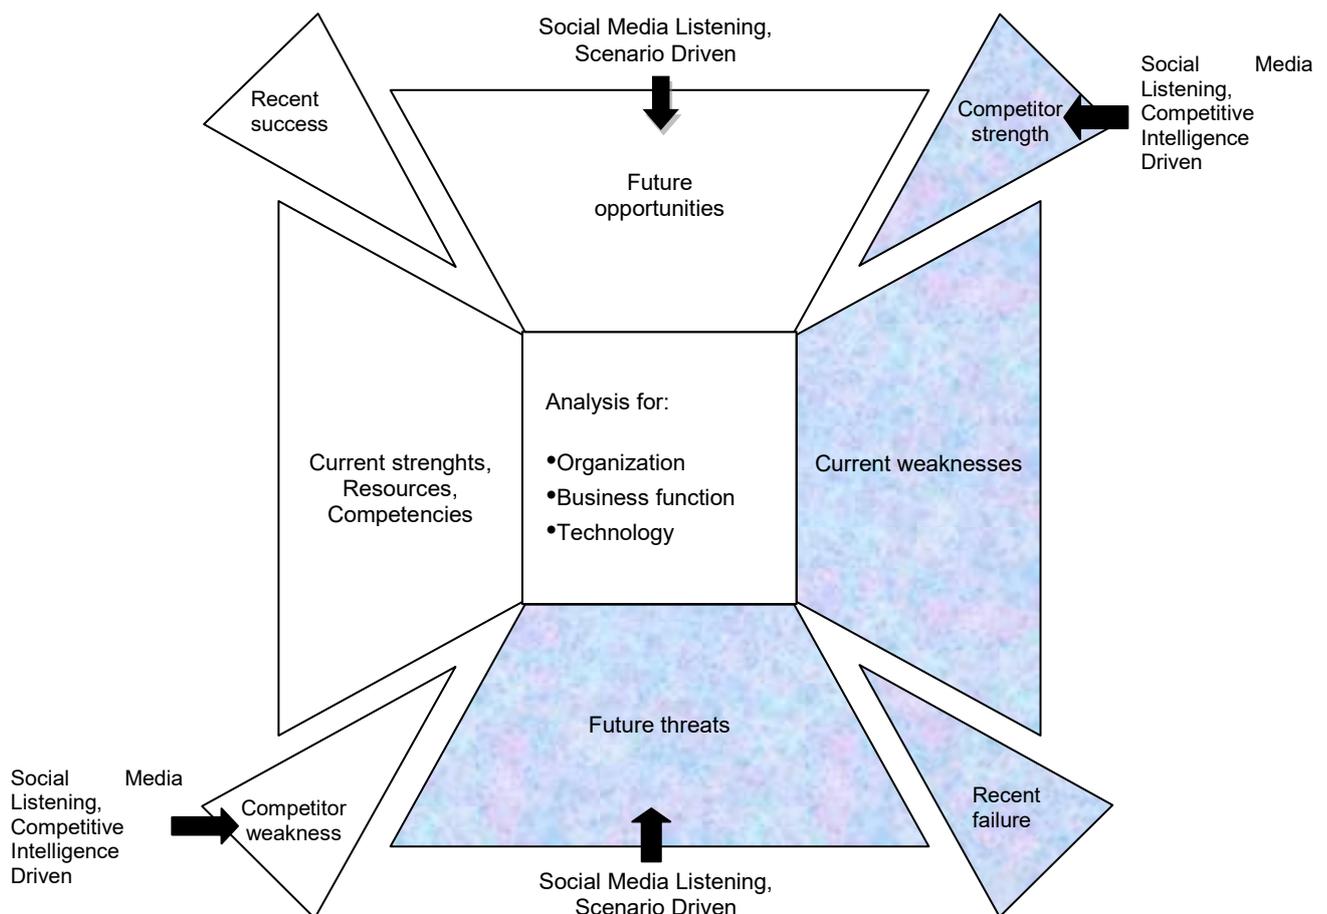

Dyson (2004) observes these more contemporary approaches to strategy formulation as developments of the internal appraisal of SWOT analysis, which can enhance SWOT analysis by serving as objective measures of internal organizational environment. The advantage of SWOT analysis is its attempt to connect internal and external factors to stimulate new strategies. Hence resource and competency-based planning can enrich SWOT analysis by developing the internal perspective whilst keeping internal and external perspectives in play simultaneously. Therefore it is possible to see it as a firm foundation for resource and competency-based planning. Similarly, contingency planning is superficially a rather different technique that is completely focused on the external environment and identifies key external factors in a similar way to the external appraisal of SWOT analysis. The contingency planning evaluates "if-then" relationships (Milićević, 2011) resulting in the development of scenarios, and can thus also enhance SWOT analysis (Dyson, 2004).

Further, funding on the above described rationalization, one can conclude that the extended SWOT analysis can additionally be enriched and made more objective with the introduction of the competitive intelligence approach. Competitive intelligence is a concept that provides organizations to know their competitors, allowing them to predict the next moves of competitors, devise strategies that will allow them to exploit their weaknesses, block their strengths and achieve victory. Competitive intelligence is the activity of observing the external environment of the company in order to obtain information relevant to the decision-making process in the company (Gilad & Gilad, 1988). It is an analytical process that transforms disaggregated competitive knowledge in relevant, accurate and useful strategic knowledge about competitors, position, performance, capabilities and intentions. It has a wide range of information, which, when harvested and analyzed, offers a fuller understanding of the organizational structure, culture, behavior, capacity and weaknesses of the competitor (Sammon et al., 1985). Competitive intelligence refers to the selection, collection, interpretation and distribution of publicly divulged information about competitors, which have strategic importance. Competitive intelligence uses public sources to locate and develop information into knowledge of the competition and the competitors (Mcgonagle & Vella, 1990). This knowledge includes the following: competitors, technology, regulatory and legal changes, suppliers, material, trends in the industry and market, political and economic changes. Competitive intelligence allows organizations to understand: how competitor rationalizes, what is his power, what is his weakness, where organizations can attack him, where the risk of attack is too big, etc. Competitive intelligence is used to: detect competitive threats, eliminate or reduce surprises, strengthen competitive advantage by reducing the reaction time to react, find new opportunities. It allows organizations to, by knowing their competitors, be able to anticipate their next moves, exploit their weaknesses, and block their strengths.

In the digital economy, given the importance of social communication and listening to every organization's future, social media listening seems to possibly appear as an approach that can also enhance the SWOT matrix objectivity, in the domain of external appraisal as well. Even though, social media listening model is not yet fully developed, and companies are still trying to find what suits them the best, organizations will derive more enterprise value from figuring out how to include listening into the business and its operations instead of merely treating it as a basic requirement. Social media listening can be done by organizations of all sizes, from small businesses to global enterprises. In the process, there are several steps that organizations should follow: (1) Organize for listening. There are three concepts for listening organizations: centralized listener, a person responsible for overseeing listening and, possibly, an organizational social media strategy; listening team, a group of people dedicated to listening, made up of individuals in the

company from either a single department or cross-functional; listening organization, this model is meant for companies where listening data is a resource utilized by multiple departments and functions. (2) Set the objectives in relation to business goals. Listening research needs to be anticipatory, innovative, action-oriented, and focused on making real business impact in order to make a valued contribution. (3) Define key performance indicators. Organizations that listen to social media conversations can compute metrics such as relating to business process improvements, which include quickening resolution time, increasing customer satisfaction levels, cost-efficiency gains, or profitability enhancement. (4) Determine the research subjects: the voices and conversation sources best suited to the listening program. Accessing the right conversations requires a number of steps: (a) choosing where to listen - online sources can be placed into one of two groups: brand backyard – company blogs, customer and private communities, discussion forums, e-mail, customer service logs, corporate Twitter accounts, and official presences on social networking sites like Facebook, or consumer backyard – publicly available online blogs, forums, ratings and review sites, Twitter and status update features, social networks like Facebook, or media-sharing sites like YouTube and Flickr, and offline word of mouth; (b) determining the footprint of sources where the topic of interest is talked about, locating the specific blogs, forums, social networks and other sites where conversations of interest take place; (c) vetting the sources, investigating the sources and choosing the most important ones based on topicality, focus, currency, and authority; (d) selecting sources to use for listening, from the search engines, social media monitoring, text analytics, private communities, full-service listening platform vendors (Rappaport, 2011). It allows organizations to develop and implement customer-centric programs, to reinvent sales, to identify where to promote products, and, to find customers before they find them.

An enhanced extended SWOT matrix in the digital economy based on the analyzed strategic planning approaches and concepts is proposed in Figure 2.

**Figure 2:** Enhanced extended SWOT matrix in the digital economy

## 4. CONCLUSION

SWOT matrix appears nowadays as the most widely used tool for analysis of the business environment. Traditionally related to the old economy, SWOT analysis can be very beneficial in a digital business world as well. However, the subjectivity, the lack of trust and the lack of willing for facing the reality can make it difficult for organization to obtain a realistic image of itself and its environment (Andrews, 1980, seen in Milićević, 2011). Hence, its strategies can be misleading and costly. In order to address this issue managers should turn to the contemporary strategic planning approaches and concepts, such as the resource-based view of the firm, the core competence of the firm, contingency planning, (and) competitive intelligence, and social media listening as tools, which have the potential to enhance the SWOT analysis objectivity, allowing it to play its role as a strategy development assistant securing higher organizational performance.

## STRATEGIC LEADERSHIP IMPACT ON NEW ORGANIZATIONAL CULTURE: EVIDENCE FROM A FAMILY-OWNED SME

Luli Miloš<sup>1\*</sup>, Dejan Petrović<sup>1</sup>, Marko Mihić<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, email: luli-milos@hotmail.com

**Abstract:** *This paper analyses strategic leadership impact on the formation of a new organizational culture. It reviews different leadership strategies and styles used in the change management process while trying to identify those variables which influence its adaptation to exigences of the situation in the corporate environment. Through a case study, a reorganization project in a family owned small and medium enterprise (SME) existing for more than 60 years, will be explained how a corporate reorganization as a change process, could be accelerated and efficiently executed when the adequate leadership approach is applied. The research shows that leaders' styles and strategy, should be adapted to different phases of the change process, while continuously considering internal and external environments. In that way interdependence of strategic leadership and corporate culture, and their mutual influence brings positive effects on the reorganization.*

**Keywords:** *strategic leadership, corporate culture, change management, leadership strategies, situational variables*

### 1. INTRODUCTION

The past decade was marked by significant changes in the business environment, determined by few major shifts in the global economy. Globalization, as social, cultural, political, and economic phenomena, influenced and supported by innovation and advancement of the technology, have structured a new world setting. The decrease in costs and improvements in transportation and communication infrastructure, followed by trade liberalization have created a larger interconnection between the participants in the world economy. The Internet connectivity and the larger application of digital technologies, as well as rise in prosperity reflected in the raising number of consumers, are considered by McKinsey Global Institute research two crucial elements which have the major impact on evolution and growth of global economic flows (McKinsey Global Institute , 2014).

According to International Telecommunications Union (ITU) the internet usage grew by 170% in the period from 2010 to 2016 (ITU, 2018). The same source reports the overall ICT development in mobile-cellular telephone subscriptions by 135,2%, individuals using internet by 166,4%, fixed-telephone subscriptions by 73,1%, active mobile broadband subscriptions by 489,1%, and fixed-broadband subscriptions by 172% in this period (ITU, 2018). McKinsey Global Institute analysis suggested that 1,8 billion people, above all from the emerging markets, will become part of the consuming class (McKinsey Global Institute , 2014). Furthermore, the growth of the knowledge-intensive goods is reaching 1,3 times the rate of labor-intensive goods, which indicates the shifts and need in the education and forming systems. The contemporary business environment has created other unique business strategies which give the opportunities to local entrepreneurs to become important players in the global value chain from the very beginning of their existence. Even if there are concrete limitations to this, with an innovative, proactive and risk-seeking behavior, entrepreneurs are no longer confined to a local market when developing a new business (Girard, 2013). The earlier in its life cycle companies internationalize, the faster they will establish their position in the global markets. Continuously changing market conditions supported by globalization are identified as some of the main drivers for the internationalization of born global firms, as they facilitate and enable global operations (Doh & Luthans, 2009). In such an environment, creating and keeping a competitive advantage, as well as differentiation from the international competitors become more difficult. Small and Medium Enterprises (SMEs) are particularly affected by this situation. The limitations of the human and financial resources, technology, and infrastructure they face could be compensated by the agile organizational structure and motivated leadership, crucial advantages in the contemporary business circumstances. The recent years have shown the shift in the consumers' and costumers' report to the brands. They show more interest in the ethical policies, values, and practices companies communicate. Global competition together with higher importance and visibility of corporate culture to the external stakeholders, force companies to reassess and synchronize cultural, operational, and strategical aspects. Competitive advantage and successful operations are dependent on the ever-augmenting number of factors, the ability of leaders to

anticipate stakeholders' requirements, to adapt corporate strategy to the environmental conditions, and to support its implementation, receives the significant weight.

## **2. THEORETICAL BACKGROUND AND LITERATURE REVIEW**

Hambrick and Pettigrew (2001) make the distinction between leadership and strategic leadership. Leadership can be referring to leaders of any level within the organization, whereas strategic leadership focuses on those at the highest levels within the organizational hierarchy. The authors point out that strategic leadership targets executive part, while not only considering the the relation between leaders and followers but focusing on both strategic and symbolic activities (Hambrick & Pettigrew, 2001).

The roles, functions, and behaviors of top managers differ from those of strategic leaders (Wideman, 2018). This will be described further in the case study, where we will point out the necessity of shifting the roles of managers and leaders during the reorganization, as well as adapting the leadership styles and strategies through different approaches during stages of the change process. The similarities could be found in the works of Bass, who applied the research on leadership, through transactional and transformational leadership framework, to a top-level management (Bass & Avolio, 1990). According to author, a leader can have transactional, transformational, both, or none of those dimensions (Bass & Bass, 2008). Transactional leaders have a role to set goals, motivate, assess, and reward the team members while protecting and reinforcing corporate strategy, structure, and culture. At the other hand, transformational leaders focus on the creative, charismatic, and emotional aspect by intellectually stimulating and inspiring the group. Empirical research has shown that both characteristics are present in the same individual at the different intensities (Bass, 1998).

The tight correlation between strategic leadership and organizational culture reviewed in the case study could be found in studies by Schein. According to him organizational culture evolves from its leadership at the same time it does impact the leadership's development (Schein, 1992). His further research shows how national, organizational, and occupational cultures impact performance of the organization (Schein, 2010). Aspects of culture and leadership were important in the following phase of this paper, where reorganization was analyzed through Kotter's Eight-step process for leading change (Kotter, 2018). The reorganization process was including transfer of knowledge, application of knowledge, and it identified also a characteristic of learning organization as described by Senge (2015) and Mikkelsen and Jarche (2015). During the reorganization process it was noticed that not all employees react in the same way. For this part of research, the theories of Maslow and McGregor were presented and used (Maslow, 1943; McGregor, 1957). The importance to adapt leadership styles in different situations were analyzed based on the Goleman's Six leadership styles (Goleman, 2000). Last sections of the case study are focused on review of leadership skills, through the model of Ancona (Ancona, 2018). As conclusion the interaction and interdependences between organizational culture, leadership, and organizational effectiveness are framed by the research of Parry and Proctor-Thomas (2002).

## **3. RESEARCH METHODOLOGY**

The methodology used in this paper is theoretical and empirical research. In the Literature review section, theories relevant for the reorganization project described in the case study will be reviewed. The empirical part will be presented in the separate chapter, through a case study, where the change management process will be analyzed, described, and supported by the theoretical data.

## **4. CASE STUDY**

### **4.1. Impact of organizational culture on strategic leadership**

StSp's corporate culture differentiated it from its competitors because it was a reflection of the founder's charisma, innovative technology, product knowledge, his informal management style, personal values and practices which were highly adopted and promoted by the employees, both internally and externally. The informal communication, reflected in the operational procedures which were "customized" to almost every single business partner, was at the same time a source of both high operational inefficiency and competitive advantage. However, the patterns of the corporate culture which directed the way how the strategy was integrated into the daily operations were not tailored to motivate departments' managers to support the appearance of any new leader who will be capable to identify and capitalize on opportunities and hazards in both internal and external environments. For the successful implementation of the changes on the organization's both strategic and operational levels, it was necessary to evolve the general manager's

position – from being a CEO who inherited the company from her family to a leader who will conduct and adapt the company to the new micro and macro environmental circumstances. It was also important to understand and keep the positive aspects of the existing corporate culture and to give it a new direction and structure which will be more appropriate for the future strategy. Similar to other SME-s where changes are introduced and directed by a very small team, it was necessary to create such a mind-set where the same persons were able to combine strategic leadership and managerial skills, to be able to create a strategic vision which will be based on a unique business model, well managed resources, technology, innovation, recognizable culture, and to support it by operational excellence, efficiency, and quality.

By following the process comparable to the phases described by Kotter, such an environment was created where the structural changes could be set and the changes in corporate strategy were starting to be reflected in the corporate culture. The result was a higher flow of information and interaction between the functional areas, which made a stronger network within the team, and a better understanding of the need for changes. In the first phase of the process it was useful to have a newly employed member of the team to support the company's general manager in a transition period, and who could have an objective view on the situation and explain the sense of urgency for changes. It required the alternation of their management and leadership skills through the project life cycle. In this initial phase, it was quite difficult to get the support of the employees, who emphasized, even more, the existing culture and corporate practices. The General Manager started to realize that a lot of operational practices which reflected the corporate strategy and culture must be analyzed, reviewed, systematized and taken under control to be able to advance and fulfill the new strategy.

The reactions to the newly set practices among the different groups of employees were different. Members of the management were opposed to changes, as a consequence of the fear of losing control on the existing practices, processes, and procedures. They couldn't understand the need to change, and as they were opponent to it, it was necessary to invest more time to make it clear and to try to motivate them to transmit their knowledge, experience, and practices. As time passed, the other employees become curious to learn more about the corporate's new mind set, which caused a more direct and open communication in the team. After the initial phase when the initiative came from the top, employees gave their constructive opinion, suggest a solution or propose the best practice using the existing tools for the system improvement at their working place. Top management team could analyze afterwards the data and create a system of procedures and processes which was based on BRC (food safety system) and focus on the operational efficiency and cost cutting which will add the value to every activity trough the value chain. Both positive and negative results started to be communicated – so the employees became more involved. By understanding their work environment and having direct information from the top management instead of information based on rumors which they were used to, the team was well prepared for new business demands and targets. Structural changes could be set and the changes in corporate strategy were starting to be reflected in the corporate culture. The result was a higher flow of information and interaction between the functional areas, which made a stronger network within the team, and better understanding of the need for changes. The new strategic direction included the goal to become a company which continuously learns. That included the participation in various management education programs and networking system by the leading team.

#### **4.2. Legal, current and emerging social concerns and expectations impacting on strategic leadership in the organization**

Ethical, legal, and regulatory requirements, specific to the organization and the industry where it operated, were crucial to:

- back-up change process leaders;
- raise awareness of the need for changes in the team;
- make the members of the team participate actively.

The goal of the reorganization process which had an impact on corporate culture was to reposition the company and save it from the failure. One of the key elements used to back-up changes was the BRC food safety standard. All the employees were aware of the importance of this certificate and they treated it as a part of the company's competitive advantage. The procedures and processes described and regulated by this food safety controlling system were used as a strict pattern upon which the automatized control of all operations within the value chain was introduced. In a time of changes, when many new practices in the operational part of the business were introduced almost on the weekly base, the necessity for an interaction and feedback of all the employees was on the highest level. They were expected to "materialize" their knowledge, practices etc. and transform them in the manuals which described the way business was conducted. Those data were processed by a custom-made operations controlling system and daily analytics and followed up by the change-leaders team. BRC regulations were a strong support to facilitate the

acceptance of the new rules. The leaders' strategic direction was focused above all on making the connection between the company and its environment with the goal to make its resources and operations more responsive to the opportunities which appeared during the process of reorganization.

There were several legal and regulatory issues which were affecting the decision-making concerning the pace of the restructuring and the members of the team. More than 50% of the employees had aged over 50 and worked at least for 25 years for the company. The most of the employees have used the possibility from the employment and social legislation to work 4/5 or 2.5/5 which caused problems in information flow on the operational level, which was reflected on the service. Those were also the members of the team which delivered the highest resistance to changes. These limitations motivated leaders to use another legislation, so-called bridge-retirement, which allowed the employees to retire earlier on the cost of both government's social fund and the company. The space for new more motivated and ambitious employees was made. The replacements and systematization of the processes and procedures were operationally intensive and demanding. However, while bringing the risk of operational inefficiency which could be reflected on the quality of service, they were as well great opportunity to re-examine the existing practices.

Current and emerging social concerns which influenced the strategic leadership demands are correlated with the BRC quality system and the business ethics. According to BRC standards, only those suppliers, who respond to the high-quality control demands and who own an evenly weighted certificate could be considered. As most of the raw materials used by the company are coming from the least economically developed areas around the world, the ethical requirements concerning the employment conditions, sustainable business conduction, and impact on the environment in general varied among the members of the supply chain. This fact is confronted with the business ethics, generically described as a direction the business is conducted to gain the public acceptance. It influenced the strategic leaders' decision to introduce sustainability in both corporate culture and strategy and in that way, try to compensate and propose a kind of remedy for the "damage" which they couldn't control directly. Some of the measures were as follows: shift to more ecological packing, optimization of a transportation system which decreased CO2 footprint, control of the energy usage in the plant, support to sheltered work communities by using their services as outsourcing, etc. As mentioned in the previous section the new legislation was introduced concerning usage and declaration of some ingredients. These regulations followed social concerns targeting the effect of widely used taste enhancer, which could cause serious health disorders. The new trends in the food industry, promotion of the healthier lifestyle, declaration of ingredients used, such as salt content, allergens etc. The abovementioned problems were used to act proactively to the rising demands of the retail customers (biggest supermarket chains) in reporting about company's effects on the environment and community (e.g. carbon foot print, and social issues such as child labour).

Due to the newly formed circumstances in the internal and external environment, the company StSp needed a complete reorganization of its strategy and operations. As the leadership strategy had to support strategic direction, the company engaged people with a broader view on the micro and macro environment, leaders who avoid hazards, use opportunities, and transform them into a strategy. Company StSp which already acted in international environment, needed professionals capable to adapt their styles to the diversified teams. They had to understand people they are leading, synchronize them in teams, and coordinate their skills, knowledge, talents, and capabilities to create a synergetic environment so they could reach the strategic goal of repositioning on the existing market with:

- an enhanced competitive advantage;
- newly determined product range;
- operational efficiency;
- automatization of the procedures and processes.

In that way, the company was capable to react in a more flexible way and benefit the changes. The general manager's shift from manager to leader was an important milestone in the change process. It was necessary to create such an environment where she could enhance her leadership skills. In the first phase, the roles were clearly divided: general manager was focused on the operational segment, trying to maintain the organizational structure, directing existing procedures, and trying to avoid any unnecessary risk. Her focus was on day-to-day goals and objectives. At the other hand, change leader was focused on creating a long-time vision to enhance the competitive advantage by putting the focus on human resources, highly developed technology, and innovation. In the process of corporate restructuring management skills of the general manager were continuously interacting and alternating with leadership skills of the change leader. In that way characteristic of leaders to capture the opportunities from the environment through taking the risk in innovative ways, could be synchronized with the characteristic of managers to control of the organizational structure, procedures, quality etc. This interactivity had a positive impact on the decision making in general. By understanding well both positions, ideas, and possibilities, the leader with her long-term, strategic focus, and manager, with her focus on operational goals and objectives, made decision-making process shorter,

more concrete, with more efficient and effective results. Introducing the changes was a well-coordinated process between strategic vision and operational capabilities to react optimally in various situations. It required alternation of leadership behaviours in different phases, as described in situational leadership and consistent managerial capacities to make it operationally effective. Along with group's or individuals' performance readiness level, as well as the task or project which was supposed to be accomplished, time (or timing) had an important role as well in this process. The right capabilities were developed to be able to learn those new skills faster and to apply them optimally.

### 4.3. Leadership styles impact on strategic decisions

During the change process, leadership styles were adapted to situation. The interactive exchange of ideas was stimulated with a goal to form, keep and manage innovative culture, operational excellence, efficiency, and highest quality standards. The feeling that the ideas were accepted and that feedback mattered, motivated employees as well as business partners (both customers and suppliers) to participate in reaching company's goals. Every organization has leaders with various styles. In the SMEs, the structural setting and the business environment require from the owners to be leaders which are capable to combine at least two styles. The timing of the strategic changes, the readiness of the group, type of project to be accomplished and the leader's vision were playing an important role in applying the style which would bring the best results on strategic decisions for the future direction for the company concerning:

**Table 1:** Leadership styles and their impact on strategic decisions (adapted from Goleman)

Strategic decision subject	Goal	Leadership style used	Focus on
Competitive advantage	<ul style="list-style-type: none"> <li>Identify C A</li> <li>How can we reinforce it, improve it and protect it?</li> </ul>	Commanding in the 1 <sup>st</sup> phase while the team was still not ready for the changes -> democratic later on when the team started to be responsive, creative, cooperative	Innovation, product range, operational efficiency, quality
Resources	<ul style="list-style-type: none"> <li>Define the most valuable resources</li> </ul>	Visionary -> making clear to everyone that employees, network, knowledge and skills are the most valuable asset	Employees, technology, raw materials
Operations	<ul style="list-style-type: none"> <li>Form processes and procedures</li> </ul>	Pacesetting by showing on own example the required standards in performing -> coaching later on as the employees were motivated and stimulated enough to perform highly	Systematization, control, best practices
Corporate culture	<ul style="list-style-type: none"> <li>HR</li> <li>Public image</li> </ul>	Commanding in the first phase -> affiliative later on	Introduction of the new company's culture internal and external
Hierarchy structure	<ul style="list-style-type: none"> <li>Decision making process</li> <li>Functional areas network</li> </ul>	Commanding -> visionary	Communication, information-flow optimisation, collaboration

The right balance between having a directing role which brings a structure in the execution of the tasks and supporting role which makes people feel positive about the role and relationship they are having within the team, gave extraordinary results.

Leadership style had to be adapted because of the different level and source of motivation. The fact that not all the employees were motivated at the same level, was one of the relenting factors in the time of changes, and difficult to accept above all from the point of view of the general manager. According to the Maslow's theory or hierarchy of needs, there are five levels of needs which each person strives to satisfy: basic needs, such as physiological and safety needs, psychological needs, such as love and belonging, and self-esteem needs, and the third group is self-actualization (Maslow, 1943). According to McGregor, there are two

different types of employees, the X, which should be strongly controlled and lead in all of their activities by the management, and the Y, which have satisfaction in doing their job (McGregor, 1957). We can compare these two theories and conclude that by the employees X, the source of motivation is based on the Maslow's lower levels of the hierarchy of needs, while for the employees Y the motivation results from the higher levels (need for self-esteem and self-actualization). By considering and understanding them, the leadership style can be adapted and successfully applied. However, in the time of radical changes within the company, certainly in the beginning phase, employees Y moved towards behaviour characteristic for employees X. This was caused by the lack of confidence in the new structure, uncertainty regarding the success of the reorganization and the fear of doing something wrong. By adapting leadership styles to the current demands of the environment, in accordance with the strategic decisions and vision set, the leader created such an environment where the other team-members could find the motivation on the other levels of their hierarchy of needs and found their purpose in achieving the strategic goals. Some of them showed the ambition and potential and become leaders themselves.

Leadership styles are reflected in the organization's culture and long-term strategy: a future vision created by following, understanding and reacting on the changes in external environment, its successful integration with the internal resources and operational capacities, and motivation of the employees and creation of the new leaders in order to reach the goals set. Different leadership styles have, accordingly, different effects on the organization. Leaders who continuously learn, as in the case of the company StSp, transfer the information and knowledge received to the company and apply them in the strategic management. They motivate other members based on their particular needs to follow the example and build up and share their knowledge, skills and practices in order to improve the overall organization structure in accordance with the strategy. We can resume different theories about leadership styles and synthesize them as follows through the process of changes in the company StSp. The strategic leaders were able to:

- Have a clear overview based on the multiple multi-level analyses of the company's internal and external environments. They were able to formulate the questions such as: Where are we now? Where we would like to be? Why do we have to change? What do we need to achieve it? What are our realistic capabilities? Do we have all the necessary resources to achieve our long-term vision? Why do we have to keep existing? What are the expectations of our stakeholders?
- Transmit the idea of need for changes to the employees; understand the group they will work with through this process; realize who will be the follower and who will be the opponent, and why; make an ever-spreading network across functional areas; motivate others to become leaders;
- Create a vision and strategy which will lead the company in a certain direction, but make it flexible enough to adapt to the opportunities, or avoid the hazards which they capture during the process;
- Create a structure to support the processes, finding the best practices, and synchronizing people you are leading: their capabilities, skills, knowledge, motivation, communication and interaction.

#### **4.4. Shift of the leadership strategies during the change process**

The autocratic leadership strategy was useful in the initial phase of the change process, because it gave a well determined frame and led the team with a system which provided them all basic resources and tools to optimally reach the strategic goals. This strategy took in consideration how could the employees participate in optimization of the overall business results, considering their full potential and readiness, an additional value and a source of the competitive advantage if they were systematized, managed and led in the right way. However, autocratic style was not optimal solution for the process: the lack of communication as well as the lack of the leaders across the functional areas which would look for the opportunities to improve the business, limited the implementation and the success of the new strategic goals set. Introducing the transformational leadership as a strategy was an optimal solution for the current situation. It was necessary to re-evaluate teams' structure, to focus on those team-members who had the willingness to participate, then to recruit new employees, who would support the changes. The individual assessment of the employees' capacities was useful, because they were more enthusiast to demonstrate them.

By communicating the ambitions and the reason why the changes were implemented, the leaders succeed to raise the level of motivation by inspiring the other members of the team. They committed in an easier way to the company's strategy and culture and appreciated that their presence matters. The innovation and creativity were stimulated by continuously cooperating on the optimization of the processes. The change leader and general manager were having a high impact on the group by doing many activities out of their own job description (Bass & Bass, 2008). The first purpose of that is to help the colleagues and create more tight bonds within the group. The second purpose was to get familiar with the procedures, processes and the team-members' comportment while doing their daily activities. The third purpose was to demonstrate that with well-structured manuals, directions, planning, and enthusiasm everyone could do the job in a satisfying way.

Situational variables played an important role in choosing a leadership strategy which would be optimal for the company. The questions to be answered were:

- Who are the leaders who will drive us through the process?
- How many of them we will need and in which functional areas?
- Are they capable to integrate their skills, behaviours, and ambitions in the organization's structure and long-term strategy?

The effects of the changes on the strategic level were visible through the correlation of organizational culture, leadership styles and organizational effectiveness. Organizational culture which changes according to the strategic goals, and influenced by strategic leader's and employees' behaviours, practices, values, as previously described, are reflected in the company's operations and image. Leader's style which is adapted to the circumstances: team's readiness, tasks' type, and structure, period of time, and the leader's source of authority and readiness to adapt to the new challenges, has an important role in shaping and promoting the culture. Along with the profit, sales volume, and production volume other indicators were added: production efficiency, number of employees and their contribution, number of customers, frequency of the orders of the purchasing department, quality standards as measured in number in customers' complaints. The follow-up of these factors has shown the real value and the influence of the employees on the results. Therefore, it was easier to make it clear why the effective leading of the team has to be one of the priorities for shaping a more successful future for the company.

## **5. RESEARCH RESULTS AND ANALYSIS OF FINDINGS**

StSp is being successful in adapting to the environmental challenges for more than 60 years. Although both company's management and employees were aware that there was a high necessity for change, corporate culture wasn't adequate and ready for reorganization. The right and systematic approach of the general manager supported the change leader to restructure company in efficient way. The ability to adapt leadership strategy and to combine several styles according to the environmental variables provided long-term sustainable effects. Corporate capabilities (know-how, technology, operational and quality excellence) transformed in distinctive competences (innovation, operational flexibility, and quality) to provide optimal technological solutions in a much shorter period of time than the competitors, have built the competitive advantage.

The finding based on the case study is that the strategic leadership played a crucial role in corporate reorganization in a specific environment characteristic for family owned SME. Corporate strategy, vision, and objectives became clear to all the employees. Change leaders created corporate culture which enables agility by using communication and interaction to improve and support procedures and processes;

- automatizing follow-up of all the operations;
- further developing relations with stakeholders, in particularly with vertical and horizontal forces.

In this way the whole corporate structure could promptly react to changes in the environment. The low hierarchy and a short decision-making process, which helped people from the different functional areas to cooperate in a more fluid way and build up an efficient network, stimulated forming of leaders in all the departments. Those people, even if they had different motivations for the success of corporate strategy, influenced and supported the changes in the culture. They were reassured that their participation will bring the difference, as the effects of both short-term achievements as well as negative results were communicated and explained. Leaders helped and motivated other team-members to accept the changes, to participate in the creating of a new culture, and implementation of the strategy.

The leader's approach applied in family owned SME, could be used in the bigger systems and organizations. The insight in all the activities within the company, as well as the capability to lead and manage them, stimulate formation of such culture capable to react to the changes in the environment. The low hierarchy and a short decision-making process, which helped people from the different functional areas to cooperate in a more fluid way and build up an efficient network, stimulated forming of leaders in all the departments.

## **6. CONCLUSION**

This paper has shown that strategic leadership, even if subjected to research for several decades, has become an important point of interest in organizational and management sciences. One of the reasons could be the fact that in the globalized market, where the flows of technology, resources, and information are more liberal than ever, creating low barriers to entry, human capabilities and skills are a driving force for differentiation and building of competitive advantage. The role of leaders is to create a flow of strategy, operations, and cultural aspect. That is: a clearly communicated strategy, based on the internal resources

and capabilities, forms operational excellence which enables companies to react to the environmental opportunities. This is feasible only if those concepts are incorporated in all the levels of the corporate culture. The interdependence of strategic, operational, and cultural aspects of the company and their effective synchronization have several advantages for building competitive advantage. The empirical research based on the case study has pointed out that the impact of strategic leadership, adapted to the situational variables, on organizational culture is significant during the change management process. Digitalization, customized ICT, and AI become essentials in helping companies to profile and preserve their competitive advantage. However, those new technologies should be seen as a tool which facilitates leaders and managers to better analyze the situation and to stimulate forming of cross-disciplinary teams capable of creating new approaches to change management. Education should play a crucial role in order to give a right direction to the processing of information, in overcoming the cultural differences and development and implementation of new technologies which should be focused on the problems of the present. Further research could be done on how neuroscience and artificial intelligence could be used to define and frame typical behaviors of the leaders and teams during change projects in order to shorten reorganization process.

**Abstract:** *Project management is developing field of academic study. Despite considerable diversity and richness, the current conceptual base continues to attract criticism on different accounts. The purpose of this paper is to review the conceptual base and current state of the project management research through two analytical frameworks: Nine schools of project management and Rethinking project management. Both analytical frameworks give valuable contributions to the development of project management knowledge and insights in current and future research. The paper concludes encouraging the development of the current body of knowledge and setting new research agenda. The paper could help both practitioners and academics to leverage their unique perspectives and have a holistic understanding of project management development.*

**Keywords:** *rethinking project management, project management schools, analytical frameworks, success, complexity, contextualization*

## 1. INTRODUCTION

Project management is one of the most important organizational developments in recent years (Winter, Smith, Morris, & Cicmil, 2006). In most organizations, management of projects has become an important way to structure work (Bakker, 2010) and implement strategy (Morris and Jamieson, 2004). A number of global trends influence the rise of importance of project management, such as the increased competitiveness of the global marketplace, emphasis on efficiency and growing customer expectations (Jugdev, Thomas, & Delisle, 2001). It is perceived that mobilization of projects, resources and competencies could bring strategic change, and thereby create competitive advantage and other sources of value for an organization (Turner, Anbari, & Bredillet, 2013).

The significant growth in project work across different sectors and industries resulted in the considerable economic importance of project management (Svejvig & Andersen, 2015). Over the past 50 years, project management grew exponentially to meet the demands of global competition (Jugdev et al., 2001). Turner et al. (2013) reported based on World Bank's report (2008) that more than 20 % of global economic activity takes place as projects, and in some emerging economies, it exceeds 30 %. With the exponential growth of project management and considerably poor performances of projects across different industrial sectors (Dalcher, 2014), management of projects become the important topic for both practitioners and academics.

Modern project management started as a sub-discipline of Operations Research. However, project management is now grown in the academic discipline in its own right. Despite this fact, the current conceptual base continues to attract criticism on different accounts. The purpose of this paper is to review the conceptual base and current state of the project management research through two analytical frameworks.

Paper is structured in four sections. In Section II nine schools of project management are discussed. In Section III concept of Rethinking project management is discussed. Finally, in Section IV some future directions for research and recommendations are presented.

## 2. NINE SCHOOLS OF PROJECT MANAGEMENT

Project management is a rather young academic discipline which dates back to early 1950's (Morris, 1997). As a research field project management has earned its place in the science of management as an organizational model and more generally as a system of anticipation and rationalization of temporary collective initiatives or even as a basis for a new theorization of the firm (Söderlund, 2004).

The categorisation of research traditions through the analytical framework based on "schools of thought" contributes to further development of existing theories and body of knowledge. First, it allows pluralism, which is important for scientific progress. Second, it avoids the traps of unification and fragmentation. And finally, it may contribute to the sophistication of existing body of knowledge and inspire new theories.

Building on previous work, there are several categorisations of project management schools. One of the first contributions in this field Anbari (1985) indicated that there are five schools of thought. Most recent, Turner et al. (2013) identified nine schools of project management. Also, important contributions in this field are those from Söderlund (2011), Bredillet (2004a) and Kwak and Anbari (2008). Despite the difference in the number, all nine schools were identified by the above-mentioned authors but differently grouped based on similarity in key concepts and issues, base discipline or research methodologies. Table 1 summarises origins research fields of project management and the key contributors.

**Table 1:** The Nine Schools of Project Management Research

School of Project Management	Field of study	Anbar (1985)	Bredillet (2004a)	Kwak and Anbari (2008)	Söderlund (2011)	Turner et al. (2013)
Optimization School	Operations Research	√	√	√	√	√
Modelling School	Management Science	√		√		√
Governance School	Functional School	√	√	√	√	√
Behaviour School	Organizational Behaviour and Human Resource Management	√	√	√	√	√
Success School	Strategy Management / Critical Success Factors		√	√	√	√
Decision School	Information Management	√	√	√	√	√
Process School	Operations Management	√		√		√
Contingency School	Contingency Theory	√	√		√	√
Marketing School	Marketing School		√		√	√

Main focus of optimization school is planning, scheduling, estimating, and efficiently carrying out the project task using optimization tools such as network scheduling techniques including the Critical Path Methods (CPM) and Program Evaluation and Review Technique (PERT), resource allocation and leveling heuristics, project crashing, resource-constrained scheduling, Graphical Evaluation and Review Technique (GERT), Critical Chain, Theory of Constraints, Monte Carlo Simulation of project networks and cost estimates, and variations of these methods (Turner et al., 2013). The future focus in this field is overcoming limitations of the tools and techniques to deal with growing complexity and speed of change (Söderlund, 2011).

The key idea of modelling school is to use system theory to model the project to deal with the increasing complexity of the projects. This school encompassed both hard and soft-systems methodology. The focus of hard system was modelling the project using techniques based on the System Dynamics approach. While "soft" system approach was based on dealing with inputs from organizational, behavioural, social and other effects from complex project environment (Williams, 2002). Research in this area will continue into modelling the total project management system, integrating hard systems and soft systems methodologies, including multiple constraints, and consideration of complex project environments.

The governance school is focused on the governance of relationship between project participants, investigating contractual aspects of the project. The majority of contributions include the application of agency theory, transaction cost theory and mechanisms of governance of the projects. Future research will include understanding the goal preferences among different actors and developing the governing mechanisms of projects with specific administrative problems and complex transaction.

The behavioural school originated from organization-theory. The research in this field includes organizational behaviour (OB) and human resource management (HRM). Research within this school typically addresses team building, conflict management, leadership, communication, time pressure and learning dimensions to contribute to the knowledge of the nature and process of the behaviour of projects. The focus in this field continues into virtual project teams, HRM in project-oriented organizations, cross-cultural issues and knowledge management.

Success school represents significant research area and the considerable body of project management research. The research is focused on success criteria (measures that will determine the success or failure of the project), and critical success factors (the most important areas of the project that, if successfully managed, will lead to better performances). The importance of this field is justified by the overwhelming

failure of the projects (Dalcher, 2014). Research can continue to further refine our understanding of the multidimensional construct of success, diversity of success factors and the relationship between project success factors and different dimensions of success.

Decision school research focuses primarily on the early stages of projects by investigating decisions made in this phase and the impact of those decisions on the project. Also, information management and information processing in projects constitute the second important field of research of this school. Studies within this tradition are built upon classic research within psychology and organization theory, in particular, decision-making theories (Söderlund, 2011). Future research agenda will address factors affecting initial estimates of cost and time, methods for handling deliberately optimistic estimates and improving such estimates, the relationship of the organization's portfolio to its strategy, as well as factors affecting the inclusion of projects and programs in the organization's portfolio (Turner et al., 2013).

In the process school, the main focus is to structure project as an algorithm that defines processes from the start to the end of the project to achieve the end objectives. "The project is like an algorithm that helps you solve the problem of how to get to that desired future state (Turner et al., 2013). One of the main contributions of this school is project life-cycle and project life-cycle management (Meredith and Mantel, 2006). The other focus of this school projects categorization (Crawford et al. 2005). Research may continue into the further investigation of categorization of projects, and alignment of project management process in different environments, as well as project audits and post-project reviews (Turner et al., 2013).

A considerable body of knowledge in project management reflects the contingency school of thought. The main premise is that there is a need to adopt a different approach to project management in consideration to different types of projects and project organizations, as well as different settings of the project environment. The school originates from organization theory, reflecting that there is a number of contingency elements affecting organizational design and processes. Research in this area could continue addressing uncertainty, complexity and deeper investigations into success factors and dimensions for different types of projects.

Marketing school or relationship school is a relatively young school of thought. The research within this school address project marketing (Cova and Hoskins, 1997) and stakeholder management (Welch, 2005). The main focus of the research in this field is investigating: 1) how companies sell and market their projects; 2) how clients buy projects; 3) how the early stages of a project can be seen as the management and organization of interactions between clients and the contractors; 4) how to overcome a lack of longterm relationships between stakeholders.

Despite distinction of different schools of project management, there is a certain level of overlapping, and further investigation of the interaction of different schools of thought should be one of the topics of the research agenda.

### 3. RETHINKING PROJECT MANAGEMENT

Rethinking project management (RPM) is a research field emerged in the 1980s to address the critic of technocratic and rationalistic viewpoint typical for classical project management. The purpose of RPM is to provide more holistic and pluralistic understanding of project management to enhance and expand the current knowledge and practice within the field (Svejvig & Andersen, 2015). Accordingly, several scholars have done a structured literature review to provide the new insights in contemporary trends in project management practice and compare it to the classical project management. Table 2 presents both classical project management and rethinking project management approaches.

**Table 2:** Classical project management vs Rethinking project management

<b>Classical project management</b>	<b>Rethinking project management</b>
<b>Author: (Jugdev et al., 2001)</b>	
Project management: a set of tool and techniques used to achieve project efficiency	Project management: a holistic discipline used to achieve project/program/ organizational efficiency, effectiveness and innovation.
Success: measured by efficiency performance measures	Success: a multidimensional construct measured by efficiency, effectiveness and innovation performance metrics
Practice project management: focus on the project details at an operational level and tactically	Sell practice project management: be an advocate and champion of project management by aligning its value to the firm's strategic business priorities

<b>Author: (Winter, Smith, Cooke-Davies, &amp; Cicmil, 2006)</b>	
The simple lifecycle-based model of a project, as the dominant model project and project management Projects as Instrumental Processes Concepts and methodologies which focus on product creation	Theories of the complexity of the projects and project management Project as a social processes Concepts and frameworks that focus on value creation as the prime focus of projects, programmes and portfolios
Narrow conceptualization of projects: projects in a single discipline with well-defined goals Practitioners as trained technicians	The broader conceptualization of projects: multidisciplinary projects with multiple purposes Practitioners as reflective practitioners
<b>Author: (Andersen, 2008)</b>	
Perspective: task perspective Project definition: a project is a temporary endeavour	Perspective: an organizational perspective Project definition: a project is a temporary organization
Main focus: execute the defined task	Main focus: value creation
<b>Author: (Svejvig &amp; Andersen, 2015)</b>	
Executability, simplicity, temporality, linearity, controllability and instrumentality	Learnability, multiplicity, temporarily, complexity, uncertainty and sociability

Using inductive analysis (Svejvig & Andersen, 2015) categorized the rethinking project management body of knowledge in following six categories: contextualization, social and political aspects, rethinking practice, complexity and uncertainty, the actuality of projects and broader conceptualization. Table 3 presents categories identified through the inductive analysis, the description and main contributors.

**Table 3:** Categories of rethinking project management research (Svejvig & Andersen, 2015)

<b>Categorization</b>	<b>Description</b>	<b>Contributors</b>
Contextualization	Expanding thinking about projects in a broader context by focusing on the management of multiple projects, the organizational strategy and the project environment.	Dille and Söderlund (2011) Alderman and Ivory (2010) Maylor et al. (2006)
Social and political aspects	Focus on social and political processes rather than the traditional focus on specific tools and procedures.	Leybourne (2007) Sense (2009)
Rethinking practice	Alternative methods, perspectives and approaches to rethinking how practitioners work with projects.	Berggren and Söderlund (2008) Thomas and Mengel (2008) Louw and Rwelamila (2012)
Complexity and uncertainty	Literature is dealing with the increasing uncertainty and complexity in project and project environment.	Atkinson et al. (2006) Cooke-Davies et al. (2007)
The actuality of projects	Need for empirical studies of projects that show how projects are actually carried out.	Cicmil et al. (2006)
Broader conceptualization	Alternative perspectives on, projects, project management and project success, outline how the field is broadening beyond its current limits or describe the existing perspectives within the field.	Turner et al. (2010) Koppenjan et al. (2011)

The overall challenge for rethinking project management research is to provide significant new insights in practice of project management and inputs for future development. This is partially achieved through the development of a body of knowledge in this field, but certainly, it still lacks wide distribution in practice. The above mentioned six categories are at the same time items on research agenda. It is up to future research to explain how to expand thinking about projects in a broader context and what are important factors of broader contextualization, as well as increasing uncertainty and complexity in project and project environment. The future research in this field should also address the questions of social and political aspects, especially in the light of projects as a social process. There is a need to expand research on alternative methods, perspectives and approaches to rethink how practitioners work with projects, but also to show how projects are actually carried out. Finally, broader conceptualization is the field which aims to contribute with alternative perspectives on, projects, project management and project success, and outline how the field is broadening beyond its current limits or describe the existing perspectives within the field.

## 4. CONCLUSION

This paper demonstrates that project management is relatively young, but rapidly developing research field. In last 70 years, project management evolved from sub field to academic discipline in its own right. Despite this fact, the current conceptual base continues to attract criticism on different accounts. This paper provided the review of project management body of knowledge using two streams of the literature review. As a result, both approaches provided important insights in the current state of project management research and inputs for defining new research agenda.

There is a certain level of overlapping between contributions within different project management schools. Accordingly, there is a need to investigate the interaction between these schools and reconsider the categorization. Next, review of optimization school revealed that there is a need to improve tools and techniques to deal with growing complexity and speed of change. Review of modelling school suggested that research in this area should continue into modelling the total project management system, integrating hard systems and soft systems methodologies, including multiple constraints, and consideration of complex project environments. The governance school directed future research into better understanding of the goal preferences among different actors and developing the governing mechanisms of projects with specific administrative problems and complex transaction. The focus in behavioural school will continue into virtual project teams, HRM in project-oriented organizations, cross-cultural issues and knowledge management.

Review of success school revealed that there is interest in refining understanding of the multidimensional construct of success, diversity of success factors and the relationship between project success factors and different dimensions of success. The future research agenda within decision school should address factors affecting initial estimates of cost and time, methods for handling deliberately optimistic estimates and improving such estimates, the relationship of the organization's portfolio to its strategy, as well as factors affecting the inclusion of projects and programs in the organization's portfolio. Process school research may continue into the further investigation of categorization of projects, and alignment of project management process in different environments, as well as project audits and post-project reviews. Research in the contingency school research field should continue addressing uncertainty, complexity and deeper investigations into success factors and dimensions for different types of projects. Finally, marketing school is the most recent of schools of thought and the main focus of the research in this field could be investigating: 1) how companies sell and market their projects; 2) how clients buy projects; 3) how the early stages of a project can be seen as the management and organization of interactions between clients and the contractors; 4) how to overcome a lack of long-term relationships between stakeholders.

Categorization of project management literature as either classical project management or rethinking project management helps the development of new insights needed for a pluralistic understanding of project management. Using inductive analysis (Svejvig & Andersen, 2015) categorized the rethinking project management body of knowledge in following six categories: contextualization, social and political aspects, rethinking practice, complexity and uncertainty, the actuality of projects and broader conceptualization. This six categories actually represents the future research agenda from rethinking point of view.

Finally, the overall challenge for both analytical frameworks is to provide significant new insights from the current project management knowledge base. Both analytical frameworks are enriching the body of knowledge and providing different topics for future agenda, but both suggest that there is lack of relevance to practice. Accordingly, further development of a body of knowledge should reflect the practice in a wider sense to help both practitioners and academics to leverage their unique perspectives and have a holistic understanding of project management development.

## ACKNOWLEDGEMENTS

This paper is a result of Strategic Project founded by Ministry of Education and Science of Republic Serbia: Exploring modern trends of strategic management of the application of specialized management disciplines in the function of the competitiveness of Serbian economy, No 179081.

**Abstract:** *Considering that one of the key priorities and needs of nowadays business organizations is to define knowledge, skills, abilities and personal characteristics that distinguish successful from less successful managers, the purpose of this paper is to explore and define list of key competences that enable them to achieve an exceptional level of performance in the workplace. The main goal of the research presented in the paper is the analysis of the specific attitudes of managers from both public and private sector in assessing the contribution of 49 individual competencies to their success. The research showed that opinion of both public and private sector managers is very balanced, given that the significant statistical differences exist in only five competencies, namely in dominance, helicopter approach, stress tolerance, flexibility and integrity and that the two sectors and managers working within them are equalizing, regardless of the particularities of public and private sector organization environment.*

**Keywords:** *competencies, public sector, private sector, competency management, research.*

### 1. INTRODUCTION

Today, every organization, either from public or private sector, having in mind the dynamics of the business environment in which it operates, has a strong need for successful managers. Thus, one of the key priorities and needs is defining knowledge, skills, abilities and personal characteristics that distinguish successful from less successful managers, allowing them to achieve exceptional performance level (Bhardwaj & Punia, 2013). Increasing competition, changing technologies and constant changes that characterize the external environment in which organizations operate, as well as the need to gain competitive advantage by increasing profitability and achieving a high level of performance, led to the creation of an approach based on competence management (Hondeghem et al., 2005). As many organizations have found that the key to their competitive advantage lies in human resources, more and more organizations are currently focusing on creating an adequate base of human resources and developing their capabilities, and the field of competencies and competency based management within organizations in expansion (Xuejun Qiao & Wang, 2009).

Although competency models have been used for more than 30 years for the purpose of selecting employees, a more recent trend is the definition of key competences as well as competency based approach integrated through other human resources processes, regarding evaluation and performance assessment, training of employees through various types of trainings and education based on competencies (Ennis, 2008). By defining the list of competences that contribute to the success of managers, the basis for defining the career path within the organization of each individual is created, then the development plan and the need for training of existing employees, as well as defining the profile of the newly employed, with the desired personal characteristics and competencies assessed based on an interview related to competencies and the entire selection and recruitment system that is in line with other human resource management processes. This connection and integration of the human resources management system within the organization allows for better results and achievement of competitive advantages on the market, since the organization in this case has the opportunity to shape its human resources and harmonize, develop and improve it in line with changing needs on the market (Donzelli et al., 2006). Also, such an integrated competencies based approach allows the organization to significantly reduce the costs of employee development (training realization according to specific needs of employees and effective training), easier organizational and individual analysis and assessment of each employee, adequate planning of workforce (according to the real organizational needs), faster adaptation to the external and internal changes that the organization faces,

\* This paper is a result of the project no. 179081 funded by the Ministry of Education, Science and Technological Development of the Republic of Serbia: Researching contemporary tendencies of strategic management using specialized management disciplines in function of competitiveness of Serbian economy.

achieving a higher level of performance (both at the individual and at the organizational level), adequate reward systems and basis for defining clear goals and career paths, higher levels of motivation and satisfaction as well as employee engagement, lower fluctuation costs, implementation of employee retention policy within an organization that represents one of the biggest challenges in today's business world, as well as a more adequate recruitment, selection and employment process (Gangani, et al., 2006).

Bearing in mind the above mentioned, the field selected for the purpose of this research presented in the paper is the field of competencies and competency based management approach, i.e. specificity of the contribution of individual competencies to the success of the managers according to the sector in which they are engaged –both in the private and public sector. The aim of this paper is to define and review the list of key competencies of successful managers in public and private sector organizations needed to achieve an outstanding performance in managerial positions. Certain similarities, differences, and specificities in terms of competencies that the managers consider to be key to success are determined through comparative analysis and analysis of public and private sector managers' attitudes. The theoretical review of literature, which is found in the first part of this paper, as well as the results of the research presented in the second part of the paper, provide the basis for understanding the factors that influence the success of managers and their performance in their workplace.

## **2. THEORETICAL BACKGROUND**

The literature on competency management and its impact on different aspects and functions of the business provides a large number of definitions for competency. Some authors, such as Prahalad and Hamel, observe and define competencies from the perspective of the organization, while other authors, including Collin, Burgoyne and Boyatzis, define competencies as employee characteristics rather than characteristics of organizations in which employees work (Abraham, S.E. et al., 2001).

The concept of competence was first introduced by David McClelland, defining competences as characteristics and traits of excellent workers, and then popularized by Boyatzis, who defines competences as basic traits of persons that imply "motives, characteristics, skills, self-confidence and the social role that an individual occupies, as well as the body language that one uses, and whose application results in superior performance "(Alexander et al., 2013).

In 1973, David McClelland introduced the concept of competence, emphasizing the preference of testing competence, not intelligence, when selecting potential employees. In his opinion, this term can best be described as an iceberg, where the summit of the iceberg represents knowledge and skills (visible), while the basic characteristics of the personality, their characteristics, motives and traits, such as empathy, orientation to achievements, self-confidence, the larger, invisible part of the iceberg, hidden "below the surface of the water" (Neagu et al., 2014). In his research and published papers, Woodruffe (1993) emphasizes that the definition presented by Boyatzis in his research and works leaves space for different interpretation of the notion of competence, and he defines this term as "a set of behavior, knowledge, skills and understanding which are key factors for the efficient and effective execution of tasks "within the managers' workplace. For Nordhaug and Gronhaug (2004), the notion of competence includes "knowledge and skills needed for work" and for Cardona & Garcia (2005) perceive it as "visible characteristics and behavioral patterns that enable managers to perform effectively" and achieving exceptional performance levels (Bosch & Cardona, 2010).

Westera (2001) defines competencies from two perspectives, theoretical and operational, where the theoretical perspective implies competence as a "cognitive structure that allows the realization of certain behaviors", and the operational, "spectrum of skills, knowledge and abilities that enable conscious and deliberate decision-making" by the inclusion of one's own attitudes in day-to-day business challenges (Merikas et al., 2006). Dianati and Erfani (2009) define competencies as "a set of knowledge, attitudes, abilities and skills that enable individuals to work and perform activities to achieve a certain level of performance based on expected standards of competence." Mashhoodi (2010) defines a similar definition in his work, where he defines competences as "personal attributes that enable individuals to successfully achieve their goals and perform their tasks", while competencies, according to Sparrow (1995), are "behaviors, that is, a set of patterns of behavior that is related to work performance and which sets it apart from average employees." Draganidis and Mentzas (2006) defined competencies as "a combination of tacit and explicit knowledge, behavior and skills that provide individuals with the basis and potential for efficient performance of tasks", and de Beeck and Hondeghem (2010) under the competences imply "visible characteristics of employees, which are expressed in the form of applied knowledge or certain behavior within the workplace, i.e. work they perform, which contribute to the successful functioning of managers in different functional areas of the organization." Furthermore, according to Neagu and others (2014), competencies represent the components of a job, which are reflected in the behavior that is visible within the

workplace where an employee works. They are represented by common elements such as knowledge, skills, abilities, attitudes, personality traits, behavior and impact on performance at work, but, as Campion et al. (2011) emphasized, competencies represent and imply more than a simple list of these components.

Furthermore, it can be concluded and as Petersen (2006) points out in his paper, that most of the definitions in the existing literature in the area of competence define this term in the following two ways:

- describing the work tasks and the expected outputs - related to the ability of managers to perform work tasks, make decisions in accordance with standards set in the job description and the expected level of output to be achieved.
- through a description of certain behaviors - they relate to competence as a set of knowledge and skills that are expressed by behavior that results in effective and / or superior performance in the workplace.

Also, the conclusion and summary from most of the author's definitions and available definitions is the setting of a clear correlation between the competences and performances that an individual reaches (Anvari et al., 2016).

The use of the concept of competencies in organizations is the basis for the emergence and definition of the concept of competency based management, that is, a managerial approach based on competences. This approach involves the use of competencies and results of competency analysis and their level of development in order to perform adequate recruitment, selection, employment, evaluation, development and improvement of employees, as well as an adequate process and defining reward system in accordance with the above mentioned elements (Armstrong, 2006). Thus, a comprehensive definition of a managerial approach based on competencies, that is competency management, implies the identification of competencies and those employees having and achieving incredible performance compared to those with average results in all areas of management, as well as the use and application of this system for all processes of human resources (workforce planning, job evaluation, recruitment, selection, employment, performance appraisal and evaluation, training and education, i.e. the development and improvement of employees, defining the reward system, career path and employee improvement) (de Beeck, & Hondeghem, 2010).

Therefore, in the scientific-research and practical sense, three eras of competence can be recognized. The first era, characterized by the work of scientists such as White, Boyatzis, McClelland, Schroder, Spencer-Spencer and Woodruffe, is the era of observing individual competences, while the other is focused on defining the competence model, as clearly shown in works by Mansfield, McLagan, RothwellLindholm and Lucia-Lepsinger (Skorková, 2016). The third, and also the last phase, is the era of defining key competences that are the basis of the competitive advantage of organizations and the success of managers, introduced in scientific and professional literature by Prahalad and Hamel, and which is the basis of the research that will be presented further in the paper.

### **3. RESEARCH METHODOLOGY**

The data collection method involved the use of a questionnaire, prepared according to the questionnaire that was previously validated and presented in the scientific work of Bakanauskienė and Martinkienė (2015). The questionnaire sent to professionals engaged in managerial positions consists of 13 questions, divided into 3 categories. The first group of questions is focused on the demographic data of respondents, such as gender, age structure, level of previous education, past professional experience, the sector of an organization where managers are employed, as well as the level of management. The second group of questions relates to assessing the contribution of individual types of competencies to the performance of managers and their success. Competencies are grouped into five categories: competencies in the area of information management, competence in communication, managerial competencies, interpersonal and personal competencies. Questions are fixed with the ability to select only one response or evaluate the contribution of each individual competency to the success of the manager using the Likert scale, with scales of grades from 1 to 5, where grade 1 implies that competencies do not contribute to the overall success of managers, and grade 5 meaning that they greatly contribute to their performance. The third group of questions relates to the type tasks and job that managers perform in their positions at different managerial levels. The results were analyzed using the SPSS statistical data processing package. For the purposes of the research, non-parametric tests is applied since the main objective of the research is the data analysis from the aspect of belonging to the public and private sector, and that there is a significantly higher number of surveyed managers working on one of the positions in the private sector, as well as that these two groups are unequal in the sample.. For this purpose, the difference between these two groups of managers was used by the non-parametric Mann-Whitney test to determine whether there are differences between groups in terms of assessing individual competencies.

#### 4. RESEARCH SAMPLE

For the research purposes, managers from the territory of the Republic of Serbia and Montenegro were examined. The total sample consists of 302 employees working on managerial positions within public and private sector organizations. Out of a total of 302 respondents, 60% are men, or 180 them, while a slightly lower percentage (122 (40%) out of 302) are women. The average years of age of the examined managers is 37.7. Most of the managers who participated in the research work on managerial positions within organizations belonging to the private sector (255 out of 302), i.e. 84% of them. On the other hand, 16% of the surveyed managers work within the organizations belonging to the public sector, or 47 of them. The average years of work experience of the respondents is 12.75, while the average years of work experience at managerial positions is 7.65. When it comes to managerial levels and positions on which surveyed managers are involved, even 38.1% of the respondents work within the positions belonging to the highest level of management, i.e. 115 of them work at top management level. The highest percentage of the sample consists of the middle-level management employees (148 (49%) of 302), while a smaller percentage of them are engaged in positions within the lower level of management (39 (12.9%) of 302). Analyzing the educational structure of the surveyed managers, it can be concluded that the highest percentage of them have completed master (154 (51%) of 302) and undergraduate (102 (34%) of 302) studies, while a slightly lower percentage of managers have completed MBA (25 (8%) of 302) and PhD (21 (7%) of 302) studies.

#### 5. RESULTS

The study analyzed 11 competencies in the field of information management, such as: decisiveness, information collection, problem solving skills and analysis, numerical interpretation of information, decision-making based on information (judgement), creativity, risk taking, business sense, helicopter approach, organizational awareness and sensitivity, as well as awareness of organization and external changes. By analyzing the group of competencies in the field of information management, it is concluded that, according to managers from the overall sample, the most important competence is "decisiveness". "Problem solving and problem analysis" holds the second place, according to the level of significance of the contribution of managers' success. "Numerical interpretation of information" is regraded as competence with the least significant contribution to the success of managers, according to managers who participated in the survey. By comparing the views of managers from the public and private sector, or using the non-parametric Mann-Whitney test, it was found that there is a difference between the responses of these two groups of managers in terms of competency assessment entitled "Helicopter approach". Bearing in mind that the statistical significance for the "helicopter approach" is  $p = 0.002 \leq 0.05$ , it is concluded that there is a statistically significant difference in the sample, between the answers of managers from the public and the private sector. By comparing the average ranking of the "helicopter approach" for the managers from the public (184.88) and private (145.35) sectors, it can be concluded that employees working within public sector organizations consider that the "helicopter approach" is more important and has a greater impact to the success of managers, compared to the opinion of private sector managers.

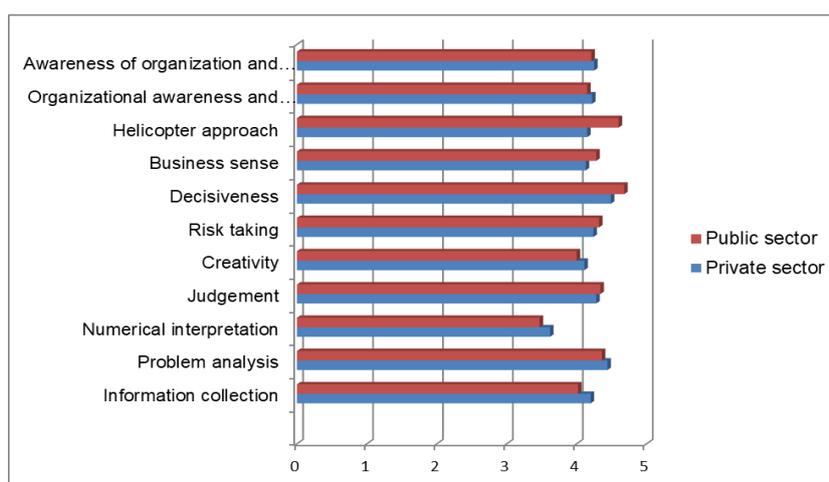

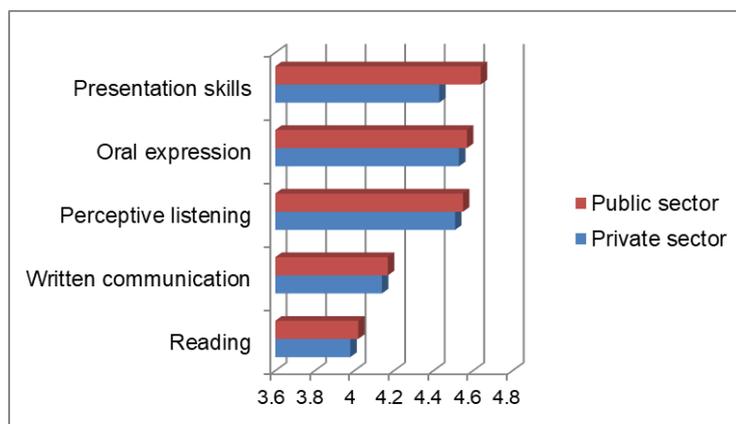

Figure 1: Competencies in the field of information management

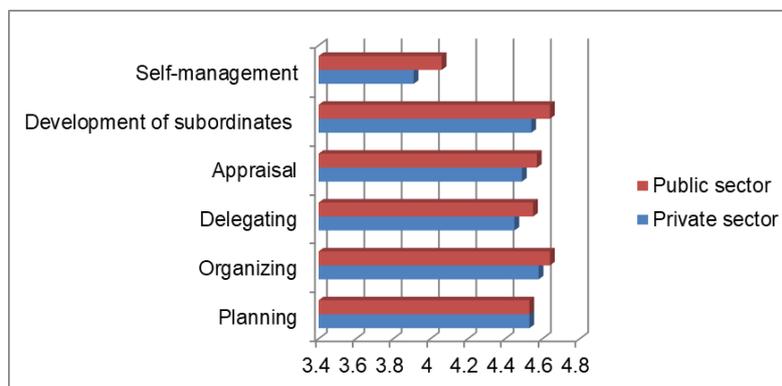

Another group of competencies whose contribution to success is analyzed in the research are competences in the field of communication such as presentational skills, oral expression, perceptive listening, written communication and reading. By analyzing the opinions of 302 managers from the overall sample, it is concluded that the most important competence in the field of communication is "oral expression". The second one, according to the level of significance of the contribution of managers' success, is "perceptive

listening". Reading has the least significant contribution to the success of managers, according to the interviewed managers. By analyzing the individual attitudes of the managers from the public and private sector, it can be concluded that there is no statistically significant difference between the answers of these two groups regarding the competences in the field of communication, bearing in mind that the statistical significance for all competences is greater than  $p \leq 0.05$ .

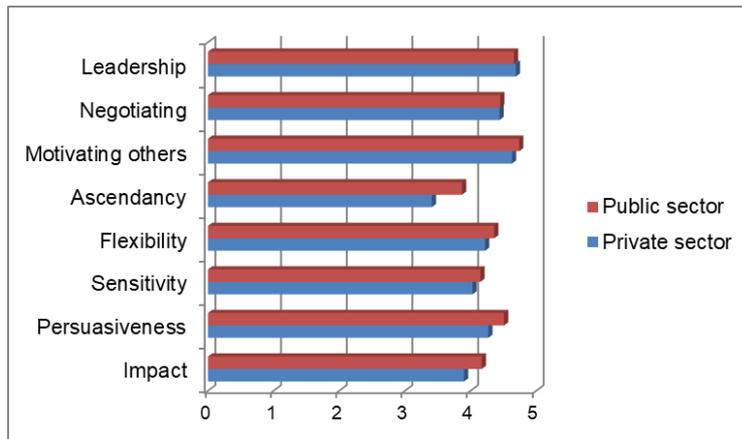

**Figure 2:** Competencies in the field of communication

The third group of competencies analyzed within the research is a group of managerial competencies such as planning, organizing, delegating, appraisal, development of subordinates and self-management. By analyzing the assessment of the contribution of a group of managerial competencies to the success, it can be concluded that "organizing" is the most important managerial competence, according to the managers who participated in the research. The second one, according to the level of significance to the contribution of managers' success, is "development of other employees, i.e. subordinates", followed by "planning" and "appraisal" and providing feedback. The competence of "self-management" has the least significant impact to the success of managers, according to managers who are interviewed. Using Mann-Whitney non-parametric test for testing the difference between the assessment of individual managerial competencies contribution to the success according to the opinion of public and private sector managers, it was found that there is no difference between the responses of these two groups of managers, bearing in mind that the statistical significance for all competences is greater from the limit  $p \leq 0.05$ .

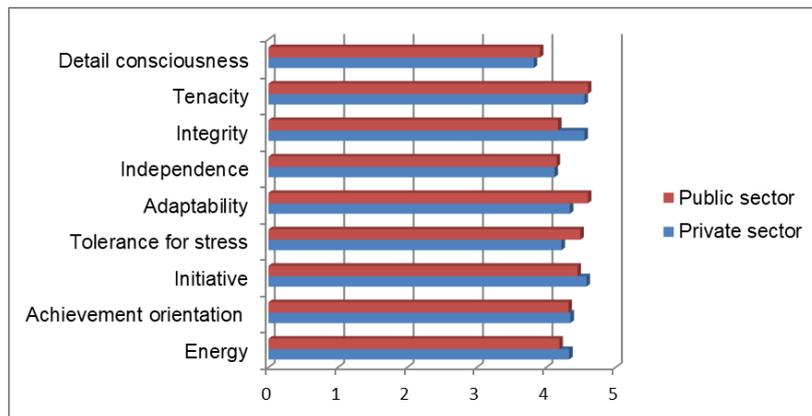

**Figure 3:** Managerial competencies

When it comes to interpersonal competencies, 8 interpersonal competencies have been analyzed in the research, such as: leadership, negotiating, motivating others, ascendancy, flexibility, sensitivity, persuasiveness and impact. By analyzing the fourth group of competences, i.e. interpersonal competences, it can be concluded that "leadership" is considered the most important interpersonal competence according to managers. Also, according to managers who participated in the research, "motivating others" significantly contributes to their success. On the other hand, in this group of competences, the surveyed managers rated "ascendancy" with the lowest average grade. Applying the Mann-Whitney test, it was found that there is a statistically significant difference between the responses of these two groups of managers in terms of an assessment of interpersonal competence called "ascendancy", since the statistical significance for "ascendancy" is  $p = 0.003 \leq 0.05$ . Comparing the middle ranking of interpersonal commerce, "dominance" for managers from the public (184.47) and private (145.42) sectors, it can be concluded that managers working within public sector organizations consider that "ascendancy" is more important competence and that it has greater impact on managerial success, compared to the opinion of private sector managers.

**Figure 4: Interpersonal competencies**

When it comes to the last group of competencies, managers evaluated the contribution of personal competencies such as: detail consciousness, tenacity, resilience, integrity, independence, adaptability, tolerance for stress, initiative, achievement orientation and energy. According to them, "initiative" and "tenacity" are the most significant personal competences, while "detail consciousness" contributes to their success to the least extent. Analyzing the impact of the individual personal competencies to the success according to the surveyed public and private sector managers, it can be concluded that there is a difference between the answers of these two groups of managers in terms of assessing personal competencies such as "tolerance for stress", "adaptability" and "integrity". By comparing the average ranking of the personal competence "tolerance for stress" for managers of public (176.80) and private (146.84) sectors, it can be concluded that the employees working within public sector organizations consider that "tolerance for stress" is more important competence and has a significant contribution to the managers success, compared to the opinion of their colleagues from private sector. Also, public sector managers (174.43) consider that personal competence "adaptability" significantly contributes to the performance of managers, compared to their private sector colleagues (147.27). On the other hand, private sector managers (156.46) consider that "integrity", as a personal competence, has a greater impact on the managerial success, than public sector managers (124.60).

**Figure 5: Personal competencies**

Therefore, for a manager who works in private sector organizations, today, it is important to be a leader, to motivate other employees and encourage them to give their best in the organization they work in, to have good organizational skills, business initiative and integrity, and to be persistent in the tasks and projects. Also, it is important to work on the development of other employees. They need to have strong communication skills, such as oral expression and perceptive listening, and, in addition to these, they plan tasks and their way of reaching in an adequate way. On the other hand, key competences that define the performance of managers working within public sector organizations include competences such as the ability to motivate other employees within the organization, as well as decision-making and leadership skills. They also consider important having good presentation and organizational skills, the ability to perceive the wider context of the situation, i.e. having a "helicopter approach" and working on the continued development of other employees. In the opinion of this group of managers, in addition to the above competences, adaptability, resilience, oral expression and continuous assessment of employees and providing feedback on the work of the employees they manage are also important. Furthermore, perceptive listening, the ability to

effectively delegate tasks, planning and persuasiveness, in their opinion, also represent competencies that determine the success of a manager working within public sector organizations.

## 6. CONCLUSION

Having in mind that human capital today represents the basis for creating and maintaining competitive advantage in the changing and dynamic environment in which organizations operate and that one of the key priorities is the need to define knowledge, skills, abilities and personal characteristics that distinguish successful from less successful managers, which enable them to achieve an exceptional level of performance within the work environment, this scientific paper presents the results of the research on the attitudes of public and private sector managers regarding the assessment of the contribution of individual competences to their success. Based on the research conducted among 302 managers of various managerial levels from public and private sector organizations, the list of competences that represents key competencies for the success of managers in today's public and private sector organizations has been defined.

In the opinion of managers who work in organizations belonging to the private sector, competences such as leadership, motivating others, organizational competencies, initiative, integrity, tenacity, development of other employees, oral expression, planning and perceptive listening are key competences that are a precondition and basis for success of a 21st century manager. On the other hand, when it comes to managers working in organizations within the public sector, the most important competencies that define successful managers of today are competencies such as motivating others, decisiveness, leadership, presentation skills, organizational skills, development of other employees, helicopter approach, flexibility, tenacity, oral expression, employee evaluation and feedback-appraisal, perceptive listening, delegating skills, planning and persuasiveness. As shown by the results of this research, the attitudes of managers of the public and private sector are very uniform, given that there are statistically significant differences in their attitudes for only five competencies - ascendancy, helicopter approach, tolerance for stress, adaptability and integrity. Public sector managers believe that competencies such as ascendancy, helicopter approach, stress tolerance and adaptability contribute to their performance at managerial positions, while private sector managers, in contrast to their public sector colleagues, have assessed the contribution of integrity as significant. Thus, as there are almost no key differences between public and private sector attitudes regarding competencies that define successful manager today, it can be concluded that there has been unification of these two sectors and employees working within them, despite the specific specifics that determine them.

The aforementioned specificities of public and private sector managers' attitudes regarding the assessment of the contribution of individual competences to them today are of strategic importance, especially from the aspect of human resources management, since human capital is the basis for creating and maintaining competitive advantage and high level of performance, and that the policies and practices that are defined for the purpose of retention of employees represent the biggest challenge of today's organizations. A set of key competencies defining a successful manager in today's business environment sets the basis for all human resource management processes and the development of employees within organizations in the public and private sectors.

**Abstract:** *At the time when Industrial revolution 4.0 is fundamentally changing the business environment, creating strategic capacities for a successful market positioning does not only presume a choice of relevant business strategies, but also a digital transformation of how companies do business. Unlike the traditional approach to doing business, which was based on an optimal combination of resources and a strategy of cost advantage or differentiation, open innovation has become the main driver of company growth and productivity in a digital environment, and innovativeness is one of the strategic factors that can help companies change the existing market limitations. This paper will focus, in particular, on an analysis of the impact information and communication technologies have on businesses today, and on the key challenges arising from the process of digitalisation.*

**Key words:** *Digital transformation, Industrial revolution 4.0, Innovation, Competitiveness*

### 1. INTRODUCTION

Ever since the industrial era and all the way through to the beginning of the digital period, the way companies did business was changing gradually, following the trends of the industrial revolutions. Natural resources and physical capital used to play the key role in company development, whereas in the modern environment, information and knowledge are the basis on which the competitive advantage is built. A company's added value is no longer generated from the company's physical assets, such as factories, equipment and machinery. Its value is now based on knowledge and intellectual property, which relies on the company's employees and their innovative ideas, technology, industrial and intellectual property rights, information systems, corporate and consumer brands, goodwill and other types of intangible assets, while intellectual capital is recognised as a company's key resource, Rakita (2013). Under these circumstances, innovation is recognised as the key driver of growth and productivity, while cooperation between companies becomes an imperative in order to maintain the competitive advantage in a global market, Onetti (2012).

Information and communication technology (ICT) is the basis of digital industrial revolution that today defines how modern companies operate and the global market functions. These technologies have essentially changed the way companies operate and create a competitive position for themselves in the market and have brought numerous advantages in terms of saving energy, space, money and time. ICTs have also facilitated management and improved flexibility of business systems, and provided for more reliable and secure operations. What will the fourth industrial revolution change in the way companies do business? The main effect of the Industrial revolution 4.0 is a creation of digital economy that combines the use of Internet with other advanced technologies that support companies' businesses and cause significant disruption in the business environment.

### 2. THE IMPACT OF INDUSTRIAL REVOLUTION 4.0 ON BUSINESS ENVIRONMENT

Many technical innovations are effectively changing the business environment today. The focus is on transition from industrial and traditional to a digital approach to business, and on creation of a digital economy based on knowledge. According to Schwab (2016), global businesses in Industrial revolution 4.0 will change not only the way companies operate, but also the way people live and communicate. Industrial revolution 4.0 according to Smokvina (2016), brings advanced industrial production, which relies partly on modern technologies for production automation, data processing and data exchange (p.30). This new industrial production framework merges two areas that used to be separate – robotics and e-business. In the core of the fourth industrial revolution lies the power of three technological innovations: automatisations, Internet of Things and artificial intelligence, Berger (2016). Industrial, economic and business models are changing fundamentally and humans are being removed from immediate production and monitoring of

manufacturing processes. In this way production can be accelerated and the number of halts and problems minimised.

According to Smokvina (2016), the fourth industrial revolution is based on six principles, which define the characteristics of the modern business environment (p.30-31):

- Interoperability – the ability of companies and people to connect and communicate in a cyber-physical system;
- Virtualisation – entails creation of a virtual copy of the physical world within a cyber-physical system in order to monitor and connect the system;
- Decentralisation – moving decision-making away from a few core people in a company. Product-related decisions have been transferred to consumers, who increasingly demand individualised products;
- Capacity to operate in real time – the data are collected and processed immediately. Production and conditions in manufacturing facilities are monitored constantly, and production is automatically shifted elsewhere in case of a disruption;
- Service-orientation – service architecture of companies is comprehensive and takes place via interconnected web services and Internet of Things;
- Modularity – thanks to standardised hardware and software systems, production can be flexibly adjusted to meet the manufacturer’s requirements.

The second wave of disruptive technological advances includes inter-dependence of mobility, cloud-based ICT services, penetration of social networks and rise of big data applications. Thanks to these technologies the use of ICT services grew significantly across all areas of business. In the near future we can expect to see a sudden expansion of connected devices (internet of things) and machine to machine communication. The latest research show that in 2017, the digital transformation in the Industry 4.0 concept focused on specific segments, such as a new geography of innovation, and moving the focus from the West to the East. The main emphasis is placed on the importance of an ethical approach in the use of technologies and on use of ICT platforms to improve the business models, as well as, on cyber security and crypto currencies, Davis, Engtoft-Larsen (2018).

**Table 1:** Five digital technologies

---

<b>Mobility and mobile applications:</b> Technologies that enable voice and data connections between people, and increasingly between objects, while on the move.
<b>Social media:</b> This primarily refers to the use of these media for business purposes. These tools include: social networks (e.g. Facebook, LinkedIn, etc), microblogging (e.g. Twitter), blogs, internal wikis and/or other enterprise collaborative software.
<b>Cloud:</b> Cloud computing is a model for enabling convenient, on-demand network access to a shared pool of computing resources (e.g. networks, servers, storage, software, applications and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction.
<b>Big data analytics:</b> Refers to the process of collecting, organising and analysing large sets of data (“big data”) from a variety of different sources to discover patterns and other useful information and use them as a basis for right business decisions.
<b>The Internet of Things (IoT):</b> Describes the network of physical objects that feature an IP address for internet connectivity, and the communication that occurs between these objects and other Internet-enabled devices and systems.

---

Source: EC, (2014). *Digital Transformation of European Industry and Enterprises*, Brussels.

Many authors believe that the industrial revolution 4.0 needs a group of industry leaders to spearhead the coming changes and create the conditions for a faster digital transformation of traditional business models into a new digital era, Mithas (2013). Transformation of the existing business concept may be expensive and take time, because some countries believe robotisation is reducing the number of jobs their citizens can have, and modifying the existing business programmes may also require additional investments. According to Berger (2014), to develop companies that will take the leadership position in the area of digitalisation, three key factors are required:

- Accelerated innovation, which necessitates continued investment in research and development;
- Cooperation with other companies (including cooperation with companies in different industries from one’s own);
- Creating a dynamic environment where key roles are given to cyber security, ecosystem and ICT, such as cloud computing.

Due to its complexity, it is still uncertain which direction the fourth industrial revolution will take. What is certain is the need for interconnection of all industrial sectors to work together in order to better understand the new trends. Governments, companies, academic communities and civil society have the responsibility

and the obligation to analyse changes brought about by the fourth industrial revolution, which has reshaped the functioning of economy and society, Schwab (2016). What must be considered is the social aspect of these changes and one cannot speak only about a new business environment, but about an entirely new social environment in which people live and work.

### 3. KEY CHALLENGES FOR BUSINESSES OPERATING IN THE INDUSTRY 4.0

Under the influence of fourth industrial revolution companies are facing with many challenges. In order to reach the successful market position in Industry 4.0 business environment they need to create strategic capabilities for the realisation of digital transformation. This transformation includes all the key segments of the business processes, and in particular, Schwab (2016):

- *Consumers* – consumer expectations are changing. Consumers are more demanding and more informed, because they have access to data;
- *Products and services* – quality of products and services is improving due to quick access to different data;
- *Partnerships* – new partnerships between companies are created, because mutual cooperation has become the key to maintaining a competitive advantage in the market;
- *Business models* – operational business models are transformed into new digital models.

Unlike the traditional business approach, the digitalisation process brings numerous challenges in managing demand. Companies must recognise what is important for their consumers and react timely to market changes and new market opportunities. By having easy and quick access to information, consumers can easily use different social networks to compare product prices and quality. Similarly, manufacturers can learn more efficiently what products and services their competitors offer or their potentials buyers want. All this information can be obtained in real time. Companies must join forces and change the way they operate in order to meet customer demands (become *customer-centric*) and must forecast which direction the market demands will take. With a careful analysis and observation of consumer portfolio, a relevant network between employees, suppliers, partners and investors can be created, who will develop the right proposal and idea for the new innovative enterprise. Furthermore, we must not forget that developing ideas requires leadership, an appropriate company culture and supporting human resources as the key means to realise the company goals.

The benefit brought about by digital technologies is greater interaction with the buyers and higher chances of meeting their expectations. This will definitely become a key element of competitiveness and maintaining the quality of products and services in the future. Unlike mass production and economies of scale, digital transformation shifts the focus to personalised and locally manufactured products, adjusted to the needs of individual users. Furthermore, the distribution of spare parts and simpler types of consumer goods is facilitated if only data is transferred remotely, while the production takes place locally. This is especially supported by application of 3D printing in factories which become less sensitive to labour costs, and are close enough to achieve product personalisation, Berger (2014).

The role of manufacturers, suppliers and consumers will change in the complex and intertwined network production by digital companies. In the new structure of the value chain industry leaders will have to face many new companies and have to support the concept of network manufacturing and the dynamics of manufacturing clusters, Popovčić-Avrić et al. (2017). The jobs are performed at dispersed locations, depending on the available workforce. One of the key opportunities is the phenomenon of “industrial democracy”, which means that the boundaries between physical and IT world are wiped out, and barriers to entry for small and specialised companies (SMEs) are lowered. The distribution of power is thus shifted between multinational companies, SMEs, or niche market players. In these conditions, the complexity of production and supply networks increases. This also leads to the concept of “mobile manufacturing units” – small autonomous production cells that may be positioned to produce for the local market, without the need to build a complete and complex factory system. This may change the flow of direct foreign investment by giving more importance to rapidly growing markets and local needs, Berger (2014).

One of the main characteristics of digital economy is the creation of virtual or digital companies (*dot.com*), who transfer a large part of their operations to virtual platforms and communicate with their suppliers and consumer electronically. Electronic transactions made via Internet or other electronic channels allow for a flexible and quick cooperation between entities, Sofronijević et al. (2015). This is how the digital economy leads to faster reorganisation of company resources, creation of new values and generation of business models that are relevant for consumers.

The company needs an educated workforce to achieve digital transformation of its business processes. In a digital company propelled by technological changes, training and education of the workforce are fundamentally important, as they enable the employees to use the modern techniques and tools in their day-to-day work. The dominant technologies in the Industrial revolution 4.0 will be information technologies, electronics and robotics, but other knowledge sectors, such as bio and nano technologies, will also be represented. It will be taken for granted that employees have both social and technical skills. Companies will remain competitive only if they introduce the necessary training and life-long learning for their employees into the corporate culture.

The experiences of companies that operate successfully in the new digital environment point to the importance of ICT education. ICT education for all citizens determine the success of ICT investments, more than technologies themselves. That is why the states must support training of all citizens to use IT tools and technologies. Training and education are necessary so that consumer and companies gain the knowledge and skills they need to use the new technology efficiently, Radenković et al. (2014). In these circumstances, improving and adjusting the ICT education and training system and creating opportunities for lifelong learning (LLL) become a priority. National innovation capacities supported by ICT define to a great extent a company's ability to cooperate and join global value networks and e-business networks.

In a changing digital environment, successfully managing of the growing global business risks gets in importance. These risks are related to the need to: move the traditional borders between industrial and other sectors, change the business models and favour cooperation between companies in order to create high-quality digital products and services. The focus is shifting to continuous innovation as the companies have the imperative to shorten product life cycle and to face with the informed demand and increasingly stronger competition. The challenges the modern companies are facing also include: fostering innovation, readiness to take risks to bring those innovative ideas to fruition and adapting to new technologies brought about by the fourth industrial revolution. Due to complexities of the innovation process, companies are unable to maximise the benefits from innovation if they innovate in isolation. There are very few companies that have all the necessary information and resources to put a profitable innovation on the market. According to Mocker et al. (2015), due to lack of internal resources, companies are increasingly turning to cooperation with external partners.

Combining different synergic advantages has seemed like a good way to create value for all parties involved and prompted creation of many strategic business alliances. According to Rakita (2013), strategic alliances include all forms of international partnership arrangements that are more than classical market transactions and long-distance transfers, but less than mergers and acquisitions of companies from different countries (p. 271-272). The flexibility of these interest-based alliances leaves enough opportunities, without changing ownership, to draw on new sources of innovation-based competitive advantage, to manage the global business risk more effectively and to reinforced a company's position in the market.

The fact that a company has started using digital technologies in its business, that does not necessarily mean the company has become a successful digital company. It will become so, when its repositioned organisational structure, strategies and the way the company operates, become the most important aspect of its agile operation. It is obvious that companies must incessantly adjust their business processes to increase productivity, flexibility and adaptability. According to Lovrić (2016), the key areas for digital transformation are digital business models (what the company should do), digital operational models (the way the company will do it) and digital talents and skills (who will do it).

A successful digital transformation of companies in Industry 4.0 assumes taking into consideration the following parameters, Marković (2016):

- *Creating value beyond the existing boundaries* and continuous redefining of the business to meet the consumer needs and the latest market trends. Digital companies must be ready to redefine completely the way they operate in search of new value sources for their buyers.
- *Creating value in the core business* – with new digital technologies (mostly ICT), companies can more easily connect their organisational parts and communication channels into an overarching value chain.
- *Raising the company's fundamental capacities* – with the help of modern technologies, companies can operate more quickly and be more agile, and with the help of open-source innovation, innovative products that have higher value can be created. Information technologies are expected to provide stable and reliable support for standard business processes, as well as for new products and services, or completely new business models (p.23-24).

#### **4. DIGITAL ENTREPRENEURSHIP AS THE BASIS FOR DIGITAL TRANSFORMATION OF BUSINESS – EU EXPERIENCE**

European Commission has been placing special emphasis on promoting smart use of digital technologies in European companies, with the aim to create new business opportunities and accelerate the transformation of the European business environment. The European Commission believes that the speed of adoption of digital technologies in the European economy will determine its future economic growth. Europe 2020 Strategy for growth and jobs is for that reason based on 4 key action areas, EC (2016): a) Digital Agenda for Europe, b) Digital Single Market Act, c) Industrial Policy for the Globalisation Era and d) The Entrepreneurship 2020 Action Plan.

The Entrepreneurship 2020 Action Plan stresses the potential of ICT to foster entrepreneurship, growth and job creation. The Commission puts the spotlight on digital entrepreneurship in particular, which encompasses all new jobs and transformation of the existing business enterprises through the use of digital technologies. Beside digital companies, the EU pays special attention to application of digital technologies in small and medium-sized enterprises, which are abundant in the European economy and are a significant factor in the growth dynamic of the entire European economy, EC (2016). To support the process of digitalisation of European companies, the European Fund for Strategic Investments has mobilised 315 billion EUR, EC (2015).

Digital Entrepreneurship Scoreboard 2015 indicates that many European countries are lagging behind in the creation of favourable conditions and environment for digital entrepreneurship. The countries that succeeded in creating a good enabling environment (UK, France and Germany) outperform the countries with weak enabling environments (Spain and Italy) in the process of digital transformation of their enterprises. There is still a large number of companies in Europe (around 40%) that do not use new technologies (cloud, mobile, social media and big data). These firms are typically SMEs operating in sectors such as mining, construction, manufacturing, transport and storage and utilities, EC (2015). On the other end of the spectrum are a group of companies whose operation is fully digital, by adopting all four technologies (cloud, mobile, social media and big data), but they account for less than 2% of the total number of companies. These are typically large companies operating in the sector of finance, IT and telecommunication, EC (2015).

The Commission confirmed that the transition into digital economy is the key precondition for improving competitiveness of the European economy by adopting the latest Declaration on the digital transformation in February 2016, which included seven recommendations for European companies to perform the transformation as quickly and as successfully as possible. The recommendations include accelerating the digital transformation process in order to create new business opportunities in the EU, mobilising investments and reskilling the workforce, who must also possess digital skills for a transformed European industry and economy, EC (2016). The entire process of digital transformation can only be performed by an educated workforce and companies whose corporate strategies place special focus on the issues of continued training and learning and make major investments in research and development, Vidas-Bubanja et al. (2017).

#### **5. CONCLUSION**

Intensive changes in the business environment brought by the fourth industrial revolution present numerous challenges for companies. Creating strategic capabilities for successful market positioning assumes digital transformation of the business and information and knowledge are recognised as key requirements for bolstering competitiveness. Digital transformation is a comprehensive change of the way modern companies do business, which is based on development and adoption of information and communication technologies and open innovation, which arise due to the interconnectedness of the global economy. Open innovation allows for better connectivity between all participants in the value chain in order to detect early the new technical possibilities and improve the business processes. Digital transformation of business processes can be observed in all the key areas of economy: industry and manufacturing, trade, banking, energy, transport, education, healthcare, as well as the media and publishing industry. Digital transformation leaders are companies that harmonise the social, financial and political framework to accelerate their innovation and improve their business.

Shifting the focus from a traditional to a digital approach to business means taking into consideration the changes in all the key segments of the business processes: from managing demand, through adopting digital business models and creating business alliances that will foster the innovation process and result in products and services of better quality. In the process of digital transformation, companies must start from raising awareness about changes in the overall business environment and the disruptive technologies brought by

the second digital wave. The basic motives that should move companies to adopt digital technologies include: the possibility to establish direct communication with consumers-users, global availability and expansion of the profit margins. Raising awareness about the need for digital transformation of businesses must take place at all levels, from the level of decision makers (who will initiate the reform process), to the level of local communities and enterprises (to help them recognise the new opportunities) Levi-Jakšić et al. (2014). Experiences in the EU show that activities that may especially contribute to digital transformation of businesses include: expanding the digital knowledge base, supporting a digital business environment, simplifying access to capital and finance, boosting digital abilities and talents, supporting a culture of digital entrepreneurship, EC (2016).

Companies can remain competitive only if they have a flexible and agile hierarchy, good strategies to attract and retain talent, real partners, and if they can combine different dimensions of their business (digital, physical and biological), Schwab (2016). Redefining completely the way companies operate in search of new value sources for their buyers is recognised as one of the key challenges of a successful digital transformation of companies. Digital transformation shifts the focus from mass production to personalised and locally manufactured products, adapted to the needs of individual users. Simultaneously, with the help of modern technologies, companies can operate more quickly and be more agile, and with the help of open innovation, higher-value innovative products can be created.

In the complex network production by digital companies, the role of manufacturers, suppliers and consumers will change, because the structure of the value chain will change. The business models of the modern digital companies are typically based on fragmentation of the value chain. Thanks to new digital technologies (mostly ICT), companies can more easily connect their organisational parts and communication channels into an overarching value chain, and thanks to lower barriers to entry, small players find it easier to enter markets and are in a position to offer products and services of increasingly higher quality.

## ACKNOWLEDGMENT

This Research Paper was a part of the Project "Advancing Serbia's Competitiveness in the Process of EU Accession", no. 47028, and of the Project "Modelling of Serbia's Development and Integration into Global Trends, in the Light of Economic, Social and Political Fluctuations", no.179038, financed by the Serbian Ministry of Education, Science and Technological Development.

**Abstract:** *This paper outlines and discusses a strategic and holistic approach to disaster management for nations worldwide. It notes the growing importance of investing funds in prevention but also rises awareness of consequences and causes of disasters. The paper then proposes a strategic approach to management from proactive pre-crisis planning through strategic implementation and finally evaluation and feedback. A discussion of crisis and disaster management literature and studies are also introduced. It notes that although crises and disasters cannot be stopped their impacts can be limited by both public and private sector managers. The paper concludes that the understanding and subsequent management of such incidents can be vastly improved through the extension and application of crisis and disaster management theory and concepts from other disciplines, coupled with the education of all the nations about behavior during and after the catastrophe. The paper offers five disaster trends, with brief overview in a view of planning the future actions based on analyses of stored data.*

**Keywords:** *disaster management, strategy, disaster trends, prevention*

## 1. INTRODUCTION

Certain infrastructures play a vital role in supporting our economy, safety and lifestyle. These complex and often interconnected systems have become essential for everyday life, but are frequently taken for granted. The moment when this attitude changes is when important services provided by such infrastructure are interrupted - when we lose easy access to electricity, healthcare, telecommunications, transportation or water supply, etc. It is at that moment that we become aware of our great dependence on these networks and the vulnerabilities that result from such dependence. In order to assess the vulnerability of those critical infrastructures (CIs), it is important to understand and define them, through the benefits they bring.

Projects for the construction of infrastructure facilities are characterized by initially high investments, non-commercial construction motives, hardly measurable benefits and abundant social direct and indirect benefits. It is precisely because of the high investment and the mentioned nature that these projects are estimated to be unjustified. Mechler (2005) points out that "Viability of such a project is tied very closely to the occurrence probability of disasters. For disasters happening relatively rarely (eg. earthquakes) it may be more difficult to secure investment funds than for more frequent events such as flooding. Furthermore, the problem of proper maintenance of installed infrastructure, a general problem with public investment projects, is an additional issue if there is little awareness that a severe disaster is a real possibility" (p. 12).

In the end, as a rule the investment motive is not profit but a positive impact on the quality of life of the wider community. If we look at these projects from another angle, the one that is provided by cost-benefit analysis, we will get a wider picture of the effects. During the application of this analysis, the problem that can be encountered is certainly the correct quantification of qualitative indicators as well as the capture of relevant data. Most often there are a lot of indirect effects on the community. It is important to pay attention to missed chances but also the savings. Only the achieved savings justify the investment of funds in the construction of infrastructure facilities. The relationship that needs to be reached concerns the amount of investment in remedying the consequences of catastrophic events as opposed to preventive investment at the moment when danger is just a prediction.

## 2. DISASTER MANAGEMENT

Disasters have negatively affected people since the very beginning of our existence. In response, individuals and societies have made many efforts to reduce their exposure to the consequences of these disasters by developing measures to address the initial impact, as well as the need for response and recovery after disasters. Regardless of the adopted approach, all these efforts have the same goal: disaster management.

Motivating concepts that lead to disaster management - reducing the risk to life, property and the environment - are mostly the same around the world.

However, Coppola (2015) points that the capacity to carry out this mission is not at all the same. Whether it's political, cultural, economic or other reasons, the unfortunate reality is that some countries and some regions are more capable than others to solve the problem. But no nation, irrespective of its wealth or influence, has made enough progress to be completely immune to the negative effects of disasters. Moreover, the existence of a global economy makes it difficult to keep the consequences of any disaster within the boundaries of a country (p.1).

## 2.1. Modern disaster management: A four-phase approach

When we talk about comprehensive disaster management, we have in mind four components also known as Coppola's (2015) four-phase approach - mitigation, preparedness, response and recovery, in the following way (p. 12):

- **Mitigation.** Also known as Disaster Risk Reduction (DRR), mitigation involves reducing or eliminating the probability or effect of the hazard, or both. Mitigation attempts to "treat" the danger so that it affects society to a lesser extent.
- **Preparedness.** This involves equipping people who may be affected by a disaster or who are able to help people with the tools to increase their chances of survival and to reduce their financial and other losses.
- **Response.** This involves undertaking actions to reduce or eliminate the impact of disasters that have occurred or are currently taking place in order to prevent further suffering, financial loss or a combination of both. Relief, a term commonly used in international disaster management, is one of the components.
- **Recovery.** This involves restoring the lives of victims to normal state after the impact of disasters. The recovery phase generally starts after the current response is completed and can last for months or years after that.

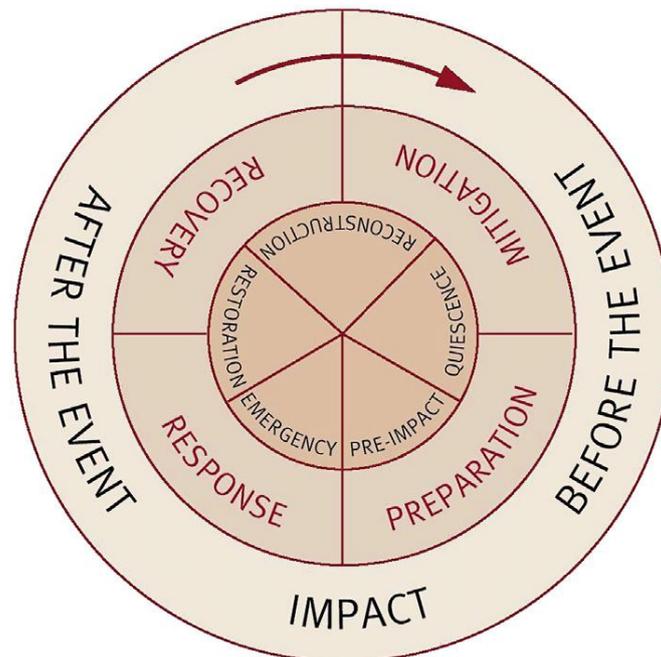

Figure 1: The disaster management cycle (Coppola, 2015)

We can notice the impact of strategic management on this approach. Strategic management creates a common vision that focuses on decisions, actions and people involved. The stages of the strategic management process form the core of the process itself and its main components. Thinking strategically, experts have a wider and longer-term view of the future, because without good-quality-plans management of a particular organization makes no sense (Obradović et al., 2012). This approach is exactly what is required in modern disaster management.

In the Table 1 Coppola (2015) gave us a parallel overview of two opposing approaches - on the one hand, a reactive response to the risks of catastrophic events, and on the other, investment in prevention and proactive regimes. (p. 17)

**Table 1:** Response and Recovery-Based Management versus Prevention and Risk Reduction-Based Management (Coppola, 2015)

<b>Response and Recovery-Based Efforts</b>	<b>Prevention and Risk Reduction-Based Efforts</b>
Primary focus on disaster events	Focus on vulnerability and risk issues
Single, event-based scenarios	Dynamic, multiple-risk issues and development scenarios
Basic responsibility to respond to an event	Fundamental need to assess, monitor, and update exposure to changing conditions
Often fixed, location-specific conditions	Extended, changing, shared or regional, local variations
Responsibility in single authority or agency	Involves multiple authorities, interests, actors
Command and control, directed operations	Situation-specific functions, free and open association and participation
Established hierarchical relationships	Shifting, fluid, and tangential relationships
Often focused on hardware and equipment	Dependent on related practices, abilities, and knowledge base
Dependent on specialized expertise	Focused on aligning specialized expertise with public views and priorities
Urgent, immediate, and short timeframes in outlook, planning, attention, and returns	Moderate and long timeframes in outlook, planning, values, and returns
Rapidly changing, dynamic information usage, which is often conflicting or sensitive in nature	Accumulated, historical, layered, updated, or comparative use of information
Primary, authorized, or singular information sources; need for definitive facts	Open or public in multiple, diverse, or changing sources; differing perspectives and points of view
In-out or vertical flows of information	Dispersed, lateral flows of information
Relates to matters of public security, safety	Matters of public interest, investment, and safety

### 3. DISASTERS CAUSED BY CLIMATE IN NUMBERS

According to data, the losses of global disasters have risen to the highest levels in the last four years.

Global natural disasters in 2016 caused economic losses of \$ 210 billion, a 21% rise over the 16-year average of \$ 174 billion. Losses were even more robust compared to the median (\$ 132 billion) - an increase of 59% was recorded. Economic losses were attributed to 315 events, compared to the average of 271. The disaster caused insured losses of \$ 54 billion, or 7% above the 16-year average of \$ 50 billion and 37% more than the median (\$ 39 billion). This is the largest amount of total insured losses since 2012, which ended the four-year downward trend. Significant events during the year were major earthquakes in Japan; hurricane Matthew in the United States and the Caribbean; catastrophic summer floods in China, Europe and the United States; several extreme weather outbreaks in the United States; wildfires in Canada and the United States; and drought in parts of Southeast Asia and Africa. The greatest three hazards - floods, earthquakes and severe weather - were accounted for 70% of all economic losses in 2016. While 72% of disaster losses occurred outside the United States, they still account for 56% of the global insured losses. This points to the gap in continuous protection in many areas around the world.

The deadliest event in 2016 was the April earthquake in Ecuador that killed at least 673 people. It is worth noting that the victims of the hurricane Metz were more than 600, and unofficial estimates of the number of casualties in Haiti were as high as 1,600. A total of 16 tropical cyclones (category 1+) were recorded in 2016; number equal to the average of 1980-2015. Fourteen cyclones occurred in the northern hemisphere, including two in the United States. Also, the year 2016 ended as the hottest year ever recorded since the global temperature of land and ocean (beginning of 1880). This is the third consecutive year of record making. April earthquakes in Japan were the most expensive single economic loss of the year. The Japanese government estimated that damage to the Prefecture of Kumamoto and neighboring prefectures

had an economic cost of more than \$ 38 billion. This was also the most expensive event for the insurance industry with \$ 5.5 billion.

The most expensive disaster in China occurred after annual floods along the Yangtze River Basin, causing a loss of \$ 28 billion. For insurance companies, Hurricane Matthew was the most expensive catastrophe caused by weather conditions, with an estimated loss of nearly \$ 5 billion.

The global economic losses in 2016 were ranked as the seventh recorded, and for the eighth time a record amount of \$ 200 billion was achieved. The secured losses are the sixth place in the industry and for the ninth time the annual value exceeded \$ 50 billion. (Aon Benifield, 2017)

#### 4. DISASTERS, POVERTY AND DEVELOPMENT

Research and practice support the theory that there is a strong correlation between disasters and poverty. It is well documented that developing countries, which are more prone to disasters, experience stagnant or even negative development rates over time.

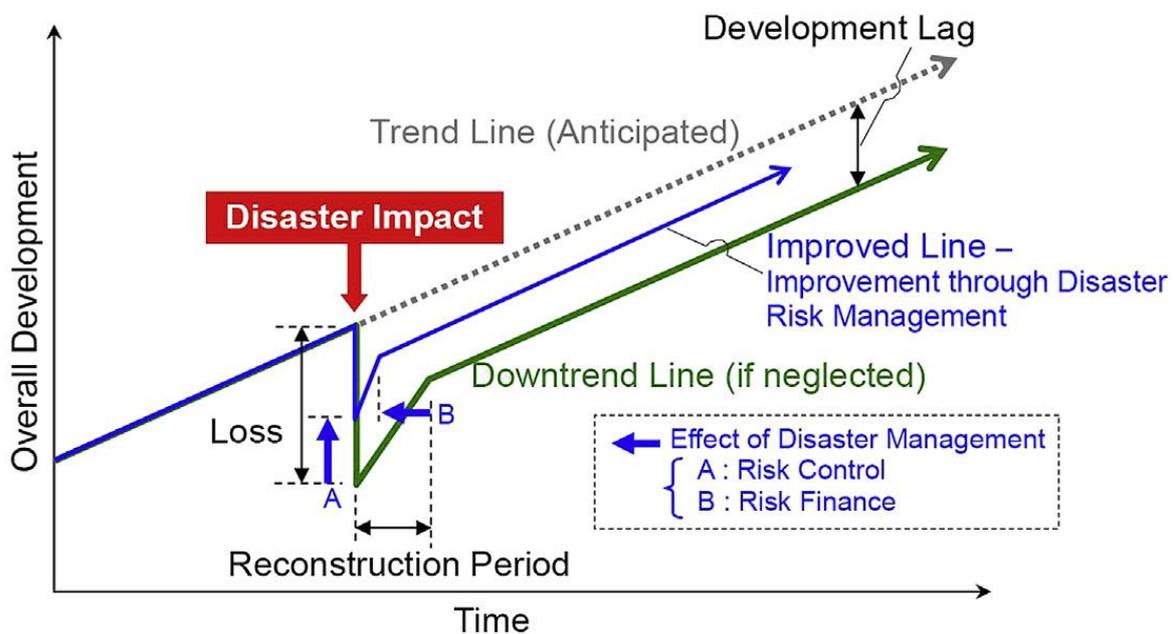

Figure 2: Impact of disasters on development (Coppola, 2015)

Throughout history, a natural disaster has led to significant changes in the functioning of the country. One of the spheres of influence could be the rate of development. For developing economies, the financial negative effect of these events can be devastating, in contrast to industrialized countries, where robust economies absorb such consequences. In 2001, for example, earthquakes occurred in both El Salvador and the United States (Seattle), each causing approximately \$2 billion in damages. While this amount had little or no noticeable impact on the US economy, the financial consequences in El Salvador amounted to 15 percent of that country's GDP. Developing countries have significant consequences and impact on disasters caused by disasters. Each disaster is unique in its consequences, so there is no unique formula that can be used to accurately predict how these problems will be played. (UNDP, 2004)

If we talk about ways in which disasters damage poor countries beyond obvious consequences such as death, injury, and destruction of property, Coppola (2015) have mentioned following (p. 18):

- National and international development efforts are stunted, erased, or even reversed.
- Sizable portions of GDP often must be diverted from development projects, social programs, or debt repayment to manage the disaster consequences and begin recovery efforts.
- Vital infrastructure is damaged or destroyed—including roads, bridges, airports, seaports, communications systems, power generation and distribution facilities, and water and sewage plants—requiring years to rebuild.
- Schools are damaged or destroyed, leaving students without an adequate source of education for months or even years.

- Hospitals and clinics are damaged or destroyed, resulting in an increase in vulnerability to disease of the affected population.
- Formal and informal businesses are destroyed, resulting in surges in unemployment and decreased economic stability and strength.
- Reconstruction efforts result in shortages of materials and labor, which in turn drive up construction costs, inflate salaries, and draw workers away from other sectors where they are needed.
- Residents are forced or impelled to leave the affected zone, often never to return, extracting institutional knowledge, cultural and social identity, and economic viability from areas that cannot afford to spare such resources.
- Desperation and poverty lead to a rapid upsurge in crime and insecurity.
- A general feeling of hopelessness afflicts the affected population, leading to increased rates of depression and a lack of motivation to regain independence from outside assistance.

Based on facts mentioned above, it can be concluded that it is extremely important that disaster management is incorporated into national strategic documents such as strategies and action plans.

#### **4.1. Example - Tsunami sets back development 20 years in Maldives**

Within minutes of the December 2004 tsunami in the Indian Ocean, much of the economic and social progress in the Maldives was washed away.

According to government officials, the tsunami caused a 20-year setback in the development of this small country, an island nation off the coast of India, which only six days before the disaster had been removed from the UN's list of least developed countries. In particular, the tsunami and its resulting floodwaters dealt a serious blow to the tourism sector, the country's main source of income. Nearly one-fourth of the 87 resorts in the Maldives were severely damaged and declared unable to operate. Tourism directly accounts for one-third of the country's economy, with the resorts alone providing between 25,000 and 30,000 jobs. When tourism-related tax and customs revenues are included, tourism contributes up to 70 percent of the economy, with the sector expanding each year. These earnings had helped to improve living standards in the Maldives, including increased school enrollment, lower unemployment, and more students seeking higher education abroad (UNDP, 2005).

### **5. DISASTER TRENDS**

In contemporary times, experts have become aware of the importance of accurate records and analysis of stored data in order to predict the future. As disaster data is becoming more and more accurate, scientists and managers have confirmed what has just been anticipated: the nature of the disaster is changing. The causative of these changes is mostly a human factor, and what is worrying is that disasters become more numerous year after year, affecting a larger number of people, either directly or indirectly. As disasters become deadlier and more influential, they also have impact on the finances of not only affected countries. This is exactly one of the negative sides of the global economy. Coppola (2015) points to the 5 latest trends (p. 20):

- The number of people affected by disasters is rising.
- In general, disasters become less deadly.
- All in all, disasters are becoming more expensive.
- Poor countries are disproportionately affected by the consequences of a disaster.
- The number of accidents is increasing every year.

People have always settled areas in order to meet needs such as the need for food, water, trade or even defense. In keeping with these needs, the risks of natural hazards are often neglected and understood as an "integral part of life" to be accepted. This has resulted in all risky settlements such as settlements along the river banks, seaside resorts, agricultural households on fertile slopes of active volcanoes, etc. As the number of settlers increases, the concentration of risk is also increased proportionally. Since 2000, it has been estimated that around 75% of the population is settled in disaster-prone areas. For this reason, it is logical that a large number of people per year are affected by disasters. (UNDP, 2005).

It is known that natural forces result in natural disasters from the emergence of the world - rivers have always swam, and earthquakes have occurred in every era of history. People only become victims of nature when they find themselves in it's path. Hence, as a species, we adjusted to the conditions of the location we inhabited and very often were successful in doing so. These results unfortunately failed to reach people when it comes to rare occurrences such as earthquakes or hurricanes. Modern science has made significant progress when it comes to protecting people from disasters developing new methods and technologies.

Globalization and increased international cooperation have helped the global community to effectively reduce risk and limit human-induced accidents. Although the number of accidents has tripled since the 1970s, the number of people around the world who have died has dropped by 50 percent.(UNISDR,2014) Experts have developed early warning systems, special protective structures for disasters, such as tornado security rooms, more effective management of the secondary consequences of catastrophes, such as hunger and disease, etc. which had an affected the fall of catastrophe fatalities.

If we talk about the costs of disasters, the situation is critical. At the end of the last century, the amount of economic cost of single event did not exceed 1 billion dollars, but after 2000 there are several cases where this amount is overcome. The new record was recorded in 2013 when 41 disasters surpassed \$ 1 billion and totaled \$ 125 billion. A year earlier there was a small number of catastrophes, but the cost was huge, 175 billion dollars. There are numerous reasons why disasters are more expensive - the number of people who inhabit sites at risk increases, there is a greater number of disasters, economies are much more dependent on technologies that can be canceled during disasters, secondary economic consequences are transmitted, etc. (World Post, 2014).

Natural disasters do not distinguish the poor from the rich countries, and affect all countries of the world. The difference arises when we talk about the consequences on the economy, and the speed of recovery after the disaster. The World Meteorological Organization of the United Nations (WMO) reported in 2011 that 95% of deaths from disasters occur in poor countries - a number that has been steadily growing for decades. About these statistics is worrying that UNDP has estimated only 11 percent of the world's "risky population" can be classified in the group of poor countries. In fact, on average, 90 percent of disaster-related deaths and deaths occur in countries with income levels below \$ 760 a year per capita. These facts stem from the fact that the poorer nations predominantly settle in disaster-prone and high-risk areas due to their affordable accessibility, in facilities which are below any standard, but also are less educated about actions when a disaster occurs. The budget for protection is low on the list of priorities in view of other social and economic problems that require expenditure (Coppola, 2015).

Furthermore, all the evidence suggests that despite the recent decline in the number of annual events in the past decade, the rising trend will only continue without significant changes in development patterns. We can find two main reasons for an increase in the number of catastrophes. The first is based on climate change (and subject to great debate) and the other is human impact on nature.

## **6. CONCLUSION**

Disaster management is a complex discipline. It involves actions that try to mitigate the effects of hazards, ensure that the population is prepared for catastrophes if they arrive, facilitate the response to disasters that occur, and help the recovery of society in months and years after the catastrophic events.

As it is presented through numerous papers, the consequences of disasters are becoming more expensive, reflecting not only the number of people affected, but the State as a whole; not only to the country in which they happened, but to the other countries connected through the global economy.

We also learned that the number of accidents has an upward trend, which should be our sign for change. Developing countries do not have the luxury of reactive strategies. As a rule, they are several times more expensive than prevention. In addition, long-term solutions are often not implemented in reactive strategies. The reason for this are most often limited resources.

Mobilizing resources for preventive strategies is a necessity. Not a single country is rich enough to ignore the savings achieved by the proper preparation for a catastrophic event. The hypothesis "Prevention requires high initial costs which has a negative impact on financial results in the short term, but the in the long-term period prevention results in multiple benefits that makes the investment of funds justified" is corroborated by many researches.

Corresponding author, e-mail:sandro.radovanovic@gmail.com

**Abstract:** *The significance of life insurance as the safest form of investment is reflected in the benefits to both the individual and society. The topic of this research includes creation and evaluation of a few different models for classification of potential and existing life insurance users into one of 8 possible risk categories. The dataset which was used to carry out the research has been downloaded from Kaggle.com competition, Prudential Life Insurance. The construction and evaluation of the aforementioned models have been conducted using CRISP-DM methodology. Due to the characteristics of the dataset, which included 128 attributes, and specific application area, attributes selection will be applied, as well as algorithm parameters optimization. The whole research has been conducted using open source web application Jupyter Notebook, which uses Python code language. It comes to the conclusion that XGBoost algorithm outperforms other algorithms used in this paper.*

**Keywords:** *Life insurance, multiclass classification, attribute selection, parameter optimization, principal component analysis*

### 1. INTRODUCTION

The problem of predictions in the field of life insurance lies in the fact that life insurance is a type of insurance that must be maximally adjusted to each user. This requires detailed analysis of all aspects of human life. In addition, it must be taken into account that the prediction is carried out for a very long period of time, which is an additional aggravating circumstance.

The dataset which will be analyzed is Prudential Life Insurance Assessment, one of the most famous life insurance companies. In America, only 40% of the households own a life insurance, and since life insurance payouts are quite big, and the repayment period long, it is clear why the insurance companies give great importance to previously conducted detailed research which also includes medical examinations. People refuse to take the medical exam which takes 30 days on average, while the classical insuring of life insurance is considered outdated.

Therefore, as a principal business problem, in the specific case of the Prudential Life Insurance Company, the selection of corresponding indicators so that the classification of potential users would be carried out significantly quicker while respecting user's privacy and personal data, is pointed out. The goal is to predict the value of the Response variable for each user Id that is to assign one of 8 values of the nominal Response variable to each Id value.

The complexity of this problem lies in the fact that it is a large dataset, and what is specific is that most of the data contain medical and financial information which represents a sensitive area of human life. Therefore, the selection of attributes as one of the approaches can contribute to a great saving of time and money.

In the following chapters, more will be said about the preparation and analysis of data as well as the modeling of the solution using a variety of different algorithms

### 2. LITERATURE REVIEW

According to the literature on this topic, we have come to the conclusion that data mining in the field of life insurance is used in four situations:

- Acquiring new customers.
- Retaining existing customers.
- Performing sophisticated classification
- Correlation between Policy designing and policy selection

Significant conclusions were made in Devale and Kulkarni article Applications of data mining techniques in life insurance (Devale,A.B, Kulkarni, Dr.R.V., 2012). They recommend KNN algorithm for performing

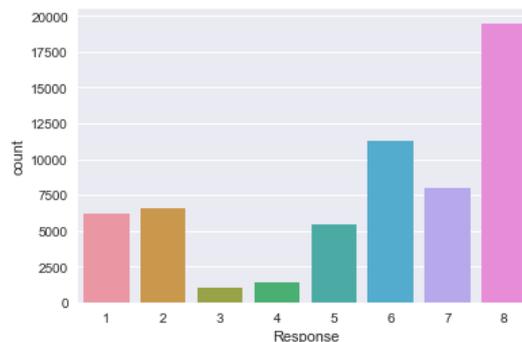

sophisticated classification. Also, they emphasize advantages of linear regression, which may be used to solve a problem because insurance industry regulators require easily interpretable models and model parameters.

Since the set of data contains a large number of attributes, the speed of execution of the algorithm is a very important component. Within his article on the potential for machine learning in the prediction of insurance policy sales, Adrian B.F. Ampt notes that the statistical analysis has two problems (Ampt, 2017). It is too slow and the analysis is prone to mistakes. Ultimately the Decision Tree algorithm and Logistic regression could generate model quickly enough and make accurate predictions. The results are not as accurate as statistical analysis in some cases, but the results were competitive and consistent. The models could also be generated much faster than the statistical analysis which takes weeks to set up for a new dataset, whereas machine learning could make predictions within the eight-hour window, although often within a minute and even seconds. Finally, machine learning was able to handle irrelevant features very well, which means that the data scientist does not necessarily have to comb through the data to pick relevant features.

## 2. METHODOLOGY

### 3.1. Data understanding and data preparation

The dataset was first imported into a Jupyter notebook (Kluyver, et al., 2016) and all the libraries which will be used in the project work were also imported.

**Figure 1: Distribution of classes of the output variable**

It can be deduced from the image that there is an imbalance of classes (Satyasree, K.P.N.V., Murthy J.V.R., 2013) and that classes 3 and 4 are significantly less represented than others, while class 8 counts the most.

A great number of missing values has been noted, which happens very often in real data sets and this presents a problem for algorithm application. In a Jupyter notebook, the presence of missing values can be checked by using the function *isnull()*.

The dataset contains following types of data:

- Categorical(nominal),
- Discrete and
- Continuous variables.

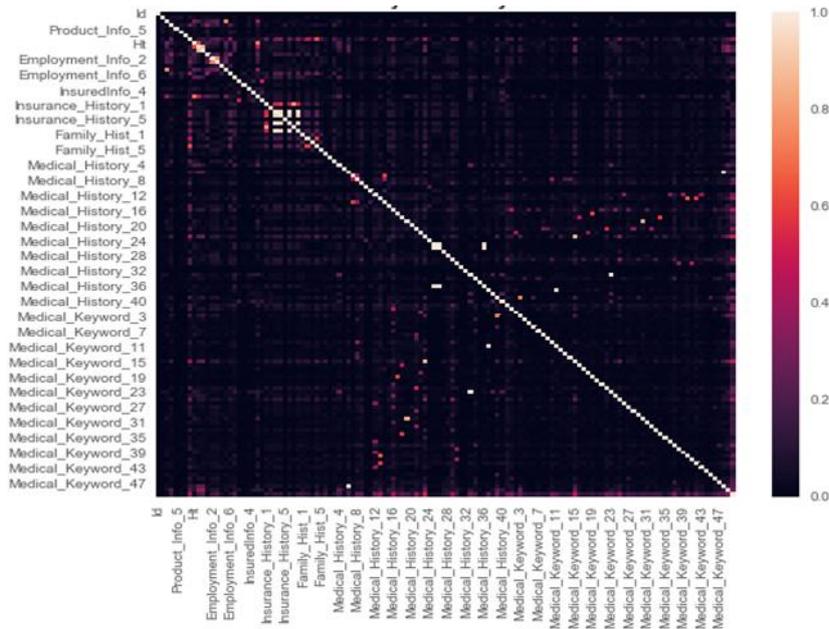

The variable which is predicted has an ordinal measure scale. This means that it is of a categorical type, with defined hierarchical relationship (ranked categories). Intervals between consecutive values are not necessarily the same.

So as to better understand the dataset, some of the variables will be presented and described:

- ID: key which uniquely identifies each line
- Product\_Info\_1-7: Normalized values pertaining to the type of product, that is, to the type of insurance
- Ins\_Age: Normalized values of the age of potential clients
- Ht: Normalized height
- Wt: Normalized weight

- BMI: Normalized body mass index
- Employment\_Info\_1-6: A set of normalized values which refer to the employment history of the logged client
- Insured\_Info\_1-6
- Insurance\_History\_1-9
- Family\_History\_1-5
- Medical\_History\_1-41
- Medical\_Keyword\_1-48
- Response

Using the heat map graph, the correlation between all of the attributes is shown, so as to note which pairs of attributes are more correlated. It strives towards the elimination of highly related attributes since they can provide an unrealistic image about the efficiency of the applied algorithm.

**Figure 2: Display of the correlation between attributes**

As expected, it is noted that there is a strong correlation between the pair of attributes Wt (weight) and BMI. Using analysis it has been determined that the three greatest correlations between pairs of attributes are:

- Medical\_History\_6, Medical\_Keyword\_48
- Medical\_History\_25, Medical\_History\_26
- Medical\_History\_33, Medical\_Keyword\_23

It can be concluded that the case of high correlation between attributes Medical History and Medical Keyword is probably about the medicinal state which is described using a specific term (Medical Keyword), therefore, about a kind of derived attributes. So as to better understand the above-mentioned correlation coefficients, it has been decided that the link between these attributes be shown in cross tables as well, which are shown in the images below.

Medical_Keyword_48	0	1					
Medical_History_6	1	37	3231				
	2	2	0				
	3	56106	5				

Medical_Keyword_23	0	1			
Medical_History_33	1	34	5767		
	3	53541	39		

Medical_History_26	1	2	3		
Medical_History_25	1	0	0	48040	
	2	3	11101	1	
	3	0	236	0	

**Figure 3: Crosstables**

Taking into consideration that the size of the dataset is 59,381, it is very significant that in most cases, as much as 56,106, the attribute `Medical_History_6` assumes value 3 when `Medical_Keyword_48` assumes value 0. The situation is similar to the rest of the attributes which have high correlation coefficients.

Mutual information was calculated. That is a measure which measures in what degree one attribute determines another attribute, specifically in this case, in what degree do the input variables determine the output variable (Witten, I. H., Frank, E., Hall, M. A., Pal, C. J., 2016). The mutual information concept is connected with the entropy of an accidental variable, a basic term in the information theory, which determines the quantity of information that is kept in an attribute. The attribute which carries the most information, of all the output attributes, is BMI. It is interesting that the next ranking is Weight, which is, according to a previously calculated coefficient, highly correlated with the attribute BMI. Next, to these two attributes, three more are shown:

	0	1
0	BMI	0.222455
0	Wt	0.151538
0	Medical_History_15	0.149882
0	Product_Info_4	0.081243
0	Medical_History_23	0.079088

**Figure 4: Mutual information**

As part of the data preparation phase, the following steps were implemented:

#### 1. Replacement of missing values

Since missing values (Kang, 2013) have been noticed inside of the dataset, the first step in the transformation phase is replacing missing values with some other values, other words, filling the lines. Since the occurrence of missing values can be a significant indicator too, here follow the attributes for which there is no data for all of the instances:

- `Medical_History_10` 99.061990
- `Medical_History_32` 98.135767
- `Medical_History_24` 93.598963
- `Medical_History_15` 75.101463
- `Family_Hist_5` 70.411411
- `Family_Hist_3` 57.663226
- `Family_Hist_2` 48.257860
- `Insurance_History_5` 42.767889
- `Family_Hist_4` 32.306630
- `Employment_Info_6` 18.278574
- `Medical_History_1` 14.969435
- `Employment_Info_4` 11.416110
- `Employment_Info_1` 0.031997

It is noticed that the missing values in a large number of cases occur with attributes which refer to data about the financial status of the subject, which could indicate wrong data collection methods or the sensitiveness of the subjects concerning this question group. Even though there are multiple methods to conduct the mentioned procedure, in this work, the method of filling the missing values with average values from the column in question was used. To that purpose, the `fillna()` method is used.

#### 2. Defining the input and output variable

Set of the variable will be divided between a rising variable X(all variables, except the variable we are predicting and Id which does not carry information which helps predict the output variable) and Y(variable for which the predicting is done).

### 3. Adding new, derived variables

Also, it has been noticed that the attribute `Product_Info_2` consists of a character part and a numerical part, therefore, two new columns will be created `Product_Info_2_number` and `Product_Info_2_char`, where categorical values will be placed in one column, and numerical in the other one, while the so-called dummy variables `Medical_Keyword_1 –48` will be placed in a new variable `Medical_keywords_sum`. Besides that, for each of the attribute categories, new dummy variables have been derived, which expands the data set to a total of 942 attributes.

### 4. Principal component analysis

After that, for each of the attribute categories, principal component analysis has been conducted. For the attribute group `InsuredInfo`, 7 principal components define more than 90% variance in data, for `MedicalKeyword` 34, for `MedicalHistory` 2, for `FamilyHistory` 1, for `EmploymentInfo` 5, for `InsuranceHistory` 2 and for `ProductInfo` 3. All the principal components are then merged into a new dataset which will be the subject of algorithms.

## 3.2. Experimental Setup

When the data preparation phase is over, we move over to the next phase – modeling the solution and cross-validation. Since the output variable was categorical, the classification problem is to be solved. For that reasons, algorithms which are used to solve classification problems will be used. Since the Response variable has 8 values, that are 8 classes to which the corresponding instances need to be sorted, we are dealing with multiclass classification. Based on the dataset, its characteristics and the characteristics of the mentioned algorithms for multiclass classification, seven algorithms which will be used and which are expected to provide relatively good results have been selected, whether in the case of performance, execution speed that is or in the case of successfulness of the classification. The mentioned algorithms are: Random Forest (Ho, 1995), Gradient Boosted Trees (Friedman, 2002), Extra Trees, Extreme Gradient Boosted Trees (Chen, T., He, T., Benesty, M., 2015), Logistic Regression, Ridge Logistic Regression and Lasso Logistic Regression (Tibshirani, 1996).

For the classification problem, the most commonly used measures of the classification of successfulness are:

- Confusion Matrix
- Accuracy
- Precision and Recall
- F measure

Since it has been determined that there is an imbalance between the classes, there measure F1 is selected (Powers, 2011), which combines precision and recall, with the same priority, is assigned to both. The usage of the accuracy measure is avoided since it can create a false image of the efficacy of the model and present it as better than it really is. The F1 score also enables for a simpler comparison of two or more algorithms.

$$F1 = 2 \frac{precision*recall}{precision+recall} \quad (1)$$

Since we are dealing with multiclass classification, so we could use the F1 score, it is needed to add the parameter average and calibrate it. Possible values of this parameter are:

- micro (calculates metrics on the global scale, counting the total number of TP, FN, FP)
- macro (calculates metrics for each output attribute while ignoring their imbalance)
- weighted (calculates metrics for each label and restores their average)

Of the above mentioned, a parameter has been applied with all three possible values, but only for Random Forest, while, for measuring successfulness of classification for other algorithms, the focus is on the F1 score with a micro parameter.

## 4. RESULTS

In the first phase, the mentioned algorithms have been applied on a new dataset which comprises of principal components of all groups of attributes, while the parameter default values have been left as they are. In the table below, shown are the resulting values of the F1 score for all seven algorithms with default parameters, as well as values of the F1 score derived from applying cross-validation. It can be seen that the Gradient Boosted Trees algorithm proved best, thus, in the next phase which includes parameter optimization, the most attention has been dedicated to this algorithm.

**Table 1: Algorithms before optimization**

Algorithms:	F1 score(micro)	F1 score(macro)	F1 score(weighted)	Cross validation(F1 micro, cv =5)
Random Forest	0.4526	0.3401	0.3830	0.4312
Gradient Boosted Trees	0.4777	0.3970	0.4258	0.4611
Logistic Regression	0.4314	0.3041	0.3614	0.4282
Ridge Logistic Regression	0.4042	0.1847	0.3157	0.4030
Extra Trees	0.4767	0.3323	0.4145	0.4107
Extreme Gradient Boosted Trees	0.4605	0.3613	0.3965	0.4535
Lasso Logistic Regression	0.4315	0.3041	0.3614	0.4285

Parameter optimization and attribute selection have been carried out only on the few selected algorithms, above all, so as to improve algorithm performance and reduce the overfitting problem of the training set. Specifically, with algorithms such as Random Forest, Extra Trees, Extreme Gradient Boosted Trees, calibration of the number of trees for the algorithms has been carried out. As for the attribute selection, it has been carried out for Ridge Logistic Regression (mainly for practical reasons, since this algorithm proved as the quickest one). Also, the selection of attributes on the basis of the mutual information measure has been tried out, where only those attributes which carry the most information have been selected.

Parameter optimization implied setting the number of estimators and the maximum depth of the tree. In addition, there is a grid search (Bergstra, J., Bengio, Y., 2012) for algorithms with internal cross-validation. It is significant that the algorithm as the optimum value for the parameter number of trees has taken the highest value from the offered, 140 while the optimal depth of the tree is 6.

Results after optimization:

**Table 2: Algorithms after optimization**

Score for fold	1.RandomForest	3. Logistic Regression	4.Ridge Logistic Regression	5.ExtraTrees	6.Extreme Gradient Boosted Trees	7.Lasso Logistic Regression
1	0.454	0.430	0.405	0.439	0.473	0.427
2	0.457	0.434	0.409	0.442	0.476	0.435
3	0.451	0.427	0.401	0.432	0.464	0.426
4	0.445	0.427	0.398	0.429	0.463	0.424
5	0.445	0.425	0.402	0.430	0.463	0.425
average	0.450	0.429	0.403	0.434	0.468	0.427

## 5. CONCLUSION

The main problem when working on a dataset was a large number of attributes that significantly slowed down the execution of most algorithms. That's why the focus was on attribute selection. In addition, an important role in improving performance is taken in the detailed preparation of data. An analysis of the principal components was performed, but it is important to emphasize that this analysis was performed on a group of attributes that related to the same aspect of the life of the respondents. The resulting main components for each of the 7 groups are then merged into a new set of data. This step has significantly contributed to improving the results, reducing the problem of overfitting and execution time.

As previously mentioned, in the scope of this research different algorithms have been applied, including ensemble algorithm, and it proved that they, in fact, gave the best results. Based on the results, it was concluded that the selection of attributes has a very large impact on the efficacy of applied algorithms;

therefore, further workings should pay more attention precisely to this phase of research. Besides principal component analysis, which has proved as a very good solution for reducing the number of attributes to which the algorithm is applied, it would be interesting to explore the possibilities of attribute selection based on mutual information indicators as well. Additionally, even though, due to technical reasons, it was not possible to conduct a more detailed optimization of parameters and define more values, significant improvements is possible concerning this aspect.

Although performance metrics, namely F1, seems very low with values less than 0.5 it is worth to notice that there were 8 different classes. Having this in mind, a naïve approach to solving would yield approximately 0.125 values. Therefore, obtained performances are indeed good. Additionally, it is worth to notice that best-performing algorithms were state-of-the-art ensemble algorithms such as Gradient Boosted Trees, Extreme Gradient Boosted Trees and Random Forest which is an indicator that problem we tried to solve is highly challenging and non-linear since the F1 score was lower for optimized Lasso Logistic Regression and Ridge Logistic Regression.

## PREFERENCES OF WINE CONSUMERS TOWARDS LOCAL WINE BRANDS: CASE OF SERBIA

Marija Kuzmanović\*<sup>1</sup>, Dragana Makajić-Nikolić<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, e-mail: marija.kuzmanovic@fon.bg.ac.rs

**Abstract:** *The wine market presents the consumer with a range of products and product attributes to consider when making a purchase decision. The study presented in this paper surveys the importance consumers in Serbia attach to both extrinsic and intrinsic attributes of the local wine brands. Five wine attributes were examined and tested through a discrete choice experiment. Two hundred forty wine consumers were asked to choose a wine they were most likely to purchase to have with friends and family. The results at the aggregate level indicate a high importance of the attributes brand and type of wine. Furthermore, preference-based segmentation based on individual respondents' utilities identified three distinct segments emerged from the overall sample.*

**Keywords:** *Wine, preferences, attributes, conjoint analysis, discrete choice experiment, segmentation.*

### 1. INTRODUCTION

In recent years, there is a growing interest in wine consumer behaviour. The dynamic nature of the wine sector increasingly attracts both practitioners and academics to undertake analysis of the different phases of the wine consumption process. This dynamics is reflected primarily in the growth and diversification of the offer, reduction of consumption in traditional countries, and emergence of new producer and consumer countries (Martínez, Mollá-Bauzá, Gomis, & Poveda, 2006). Moreover, in developed societies, consumer behaviour becomes diverse and creates continuous changes, both socio-economics and changes in modern lifestyles. These processes have led to a different patterns in the consumption of alcoholic beverages, especially wine (Caniglia, D'Amico, & Peri, 2006). Namely, while there has been a reduction in consumption of table wine, on the other hand there has been greater demand for quality wines and wines with regional specificity.

The consumer choice for wine is more complex than the choice for many other products, due to the large amount of different cues that may influence the purchase decision (Lockshin & Hall, 2003). The literature focusing on wine choice differentiates between two categories of choice attributes: extrinsic and intrinsic attributes (MacDonald, Saliba, & Bruwer, 2013). Intrinsic attributes are those associated with the vintage, type of grape, year and sensory characteristics of a wine (e.g. taste, flavour, sugar content and colour), and extrinsic cues refer to non-sensory characteristics such as price, region of origin, brand and packaging (Lu, Rahman, & Chi, 2017).

Previous studies have identified numerous factors that have been found to have an impact on the wine selection process (Gustafson, Lybbert, & Sumner, 2016). Moreover, the specificity of wine as a product affects the willingness of consumers to even try out a particular type of wine (Everett, Jensen, Boyer, & Hughes, 2018). Most of the researches have focused on the importance different product attributes have on consumers when purchasing wine in the retail stores (Goodman, 2009), although there are also studies researching factors that influence the wine choice in the on-premise purchasing (restaurants, bar, café), depending on the price or information provided on the menu (Corsi, Mueller, & Lockshin, 2012). Surveys have suggested that price and grape variety are often the most influential variables when choosing a wine in retail stores, whereas, packaging and label design have been reported to be of lesser importance (Thomas & Pickering, 2003). The region of origin was found to be the most important driver for an on-premises wine choice by Australian, French and Italian consumers (Corsi, Mueller, & Lockshin, 2012). However, Lockshin and Corsi (2012) argued that consumers seem to be less confident when purchasing wine in a restaurant than in a store.

The vast majority of studies on wine consumer behaviour are focused on red (Mehta & Bhanja, 2018) or white (Saliba, Wragg, & Richardson, 2009) wine. However, recent market and industry trends show a growing popularity of rosé wine among consumers around the world, and thus, an increase in its production, but also researches (Kolyesnikova, Dodd, & Duhan, 2008). Price has always been considered one of the most important drivers of consumer choice, and wine is no exception. In particular, price allows customers to

make inferences about the quality and value of a product (Gustafson, Lybbert, & Sumner, 2016; Chrea, et al., 2011). Lockshin, Rasmussen, and Cleary (Lockshin, Rasmussen, & Cleary, 2000) highlight the fact that the brand name acts a surrogate for a number of attributes including quality and acts as a short cut in dealing with risk and providing product cues. Bruwer, Li, and Reid (Bruwer, Li, & Reid, 2002) concluded that wine markets have been segmented based on nine major segmentation variables: quality, consumption, risk reduction, occasion based, cross-cultural, behavioural, involvement, geographic, wine-related lifestyles. Using Conjoint analysis, Mehta and Bhanja (2018) identified five factors (price, brand, taste, origin and type of the wine) as important in the choice of wine. Moreover, authors identify price as the most important factor, followed by the type of the wine whereby red was the most preferred type. Escobar, Kallas, and Gil (2018) used Generalised Multinomial Logit Model (GMNL) to determine the impact of the 2008 economic crisis on preferences of the citizens of Catalonia towards four wine attributes: wine origin, wine references, grape variety, and price. The research showed that the wine origin was the most important attribute before the crisis, while the price became the most important attribute during the crisis.

The purpose of this paper is to empirically determine the consumers' preferences towards both extrinsic and intrinsic attributes of local wines in Serbia, as well as to determine whether those preferences are heterogeneous. To our knowledge, several research related to wine consumers' preferences were conducted in Serbia. Different methods have been used to investigate the relative importance of cues on consumer wine choice and purchase behaviour. Vlahović, Potrebić, and Jeločnik (2012) implemented poll research survey on a sample of 150 respondents in Belgrade in 2011 with goal to perceive factors that influence on demand of wine; Radovanović, Đorđević, and Petrović (2017) used Descriptive statistics and Chi-test to analyse the data collected in 2015. In this paper, Conjoint analysis, the techniques commonly used to analyse consumer preferences will be used. Conjoint analysis implies that consumers have to show their preferences to a set of products or profiles created through a combination of product attributes and attribute levels. The growing wine market in Serbia presents a remarkable opportunity for marketers to formulate a strategy targeted at the Serbian consumers.

## **2. METHODOLOGY**

This study focuses on Serbian wine consumers' habits and preferences. An online discrete choice experiment was conducted on individuals who consumed wine at least once in the past 12 months.

### **2.1. Conceptual framework**

Conjoint analysis is one of the most widely used research techniques which helps uncover how people make choices and what they really value in products and services. It originated in mathematical psychology, and was first introduced in marketing research in the early 1970s to evaluate consumer preferences for hypothetical products and services. Nowadays, it is widely used to understand customers' preferences in various markets both service and manufactures (Kuzmanovic, Radosavljevic, & Vujošević, 2013; Vukic, Kuzmanovic, & Kostic-Stankovic, 2015). The foundation of conjoint analysis is breaking a product or service down into its components (attributes) and then testing combinations of these components in order to find out what customers prefer. It is then possible to estimate the value of each component in terms of its effect on customer decisions.

The most common type of conjoint analysis is Discrete Choice Analysis (often called choice modelling or choice-based conjoint analysis). Rather than merely asking respondents what they like in a product, or what features they find most important, discrete choice experiment employs the more realistic task of asking respondents to choose between potential product concepts (i.e. combinations of attributes and levels) carefully assembled into choice sets. Each respondent is typically presented with 8 to 12 choice sets (Samoylov, 2017).

The output from discrete choice analysis is measurement of utility or value. The utility scores are numerical values that measure how much each attribute and level influenced the customer's decision to make that choice.

### **2.2. Attributes used in the experiment**

The first step in Discrete Choice Analysis is identifying key product attributes and corresponding levels. As noted above, trying to model all the influences on wine purchase behaviour is complex and the total number of attributes could make the design of such an experiment much too large to be practical. The literature review highlighted that the most important wine attributes are price, region of origin, and brand name. In this paper, in accordance with the aim of the research, the following attributes were taken into account: Winery, Price, Type, Sweetness and Sparkling (see Table 1).

We developed the levels of the attribute Winery from available data on the market share of brands in the Serbian wine market. Namely, there is a considerable number of small family winery in Serbia, whose wine is considered to be of high quality and popular among the consumers. Therefore, in addition to an industrial winery with a tradition (Rubin), five more wineries has been taken into account. Prices on the Serbian wine market for these producers range from 400 RSD to 1600 RSD, thus the four price points were selected for the attribute Price. Depending on grape variety, three types of wine are distinguished. Thus, for an attribute Type we choose three levels: Red, White and Rosé. Wines can be made with a wide range of sweetness levels, from dry to sweet one. The subjective sweetness of a wine is determined by the interaction of several factors, including the amount of sugar in the wine, but also the relative levels of alcohol, acids, and tannins. According to EU regulation 753/2002 (eur-lex.europa, 2002), the following terms may be used on the labels both table and quality wines (depending of the sugar content): Dry, Medium dry, Medium and Sweet. Based on the amount of carbon dioxide in the wine, it can be sparkling or non-sparkling. Sparkling wine is a wine with significant levels of carbon dioxide in it, making it fizzy.

**Table 1:**Key attributes and corresponding levels

Attribute	Level 1	Level 2	Level 3	Level 4	Level 5	Level 6
Winery	Rubin	Kovačević	Radovanović	Aleksandrović	Zvonko Bogdan	Matelj
Type	Red	Rose	White			
Sweetness of wine	Dry	Medium dry	Medium	Sweet		
Sparkling	Sparkling	Non-sparkling				
Price	400 RSD	800 RSD	1200 RSD	1600 RSD		

### 2.3. The choice experiment design and survey technique

Based on the attribute and their levels, total of 576 (=6x3x4x2x4) virtual wine concepts could be constructed. However, it is unrealistic for respondents to compare and select from such a great number of tasks. In general, respondents will fatigue after comparing more than 15 concepts. Experimental design methods and conjoint.ly platform (Samoylov, 2017) were used to structure the presentation of the levels of the five attributes in the choice sets. An implemented algorithm is used to insure each level of each attribute appears nearly an equal number of times across all surveys, but does not repeat in the other product concepts in each choice task. Because the number of choice sets is excessive for one respondent, the experiment is split into seven blocks, each consisted of 10 different choice tasks, i.e. 10 different purchase decisions.

The participants were provided with three product concepts plus the “None of the above” in each choice task and were asked to select the bottle of wine they would choose to buy to have with friends and family. Each product concept had one level of each of the five attributes. Respondents were given a short survey along with the choice tasks. Socio-demographic data (age, gender, household income, level of education) and wine consumption habits (frequency of drinking, place, quantity, wine type) were also collected.

### 2.4. Analytical and segmentation method

Discrete choice models (DCM) can be derived from utility theory. A DCM specifies the probability that an individual chooses a particular (wine) concept, with the probability expressed as a function of observed variables that relate to the concepts and the individual. The assumption is that the behaviour of the individual is utility-maximizing: individual  $i$  chooses the concept that provides the highest utility. The choice of the person is designated by variables  $y_{ij}$  for each alternative:

$$y_{ij} = \begin{cases} 1, & U_{ij} > U_{ik}, \forall j \neq k \\ 0, & \text{otherwise} \end{cases} \quad (1)$$

$U_{ij}$  is the utility that person  $i$  obtains from choosing concept  $j$ :

$$U_{ij} = V_{ij} + \varepsilon_{ij} \quad (2)$$

$V_{ij}$ s the part of utility associated with the observed factors influencing it, whereas  $\varepsilon_{ij}$  represents the unobserved sources of utility. These unobservables can be characteristics of the individuals and/or attributes of the item, and they can stand for both variation in preferences among members of a population and measurement error (Hanemann & Kanninen, 2001). Then the probability of individual  $i$  choosing alternative  $j$  from a set of  $J$  mutually exclusive alternatives choice is given by:

$$P_{ij} = P(U_{ij} \geq U_{ik} | k \in J) \quad \forall k \neq j \quad (3)$$

To estimate the model parameters (part-worths), multinomial logit model or Hierarchical Bayes (HB) estimation can be used. Amongst other benefits of HB, this approach allows more parameters (attributes and levels) to be estimated with smaller amounts of data collected from each respondent (Samoylov, 2017). Estimated part-worths can be further used to assess the relative importance of each attribute for each respondent or group of respondents. These values are calculated by taking the utility range for each attribute separately, and then dividing it by the sum of the utility ranges for all of the attributes (Kuzmanovic, Savic, Popovic, & Martic, 2013).

Rather than use socio-demographic variables to define segments a priori and to test whether these groups differ in their preferences and behaviour, we thought the opposite approach, post hoc segmentation, would be more effective, because it derives segments from differences in their preferences. Segmenting on behavioural differences has been found to be more robust and stable over time. For choice experiments, segments that differ in their choice drivers can be found with K-means cluster analysis, which will be applied in this paper here to find consumer clusters that differ in their preferences.

### 3. RESULTS

#### 3.1. Sample characteristics

Data were collected online using Conjoint.ly platform in June 2017. In total, 256 individuals answered the survey. After the elimination of incomplete surveys and ineligible participants, 240 eligible surveys were collected. The sample characteristics as well as respondents' habits concerning wine consumption are presented in Table 2.

**Table 2:** Socio-demographics data and respondents' habits

Demographic	Category	Number of respondents	Percent
Gender	Male	123	51.25%
	Female	117	48.75%
Age	18-20	17	7.08%
	21-40	194	80.83%
	41-60	21	8.75%
	>61	8	3.33%
Level of education	Primary school	9	3.75%
	High school	43	17.92%
	Undergraduate	140	58.33%
	Master degree	45	18.75%
	PhD degree	3	1.25%
Employment status	Student	103	42.92%
	Unemployed	16	6.67%
	Employed	116	48.34%
	Retired	5	2.09%
Averaged monthly income	do 25000	34	14.17%
	25000-50000	80	33.33%
	50000-75000	58	24.17%
	>75000	68	28.33%
Frequency of wine consumption	Every day	5	2.08%
	Several times a week	30	12.50%
	Once a week	62	25.83%
	Once a month	82	34.17%
	Rarely	61	25.42%
Quantity	1 glass	45	18.75%
	2 glasses	90	37.50%
	3 glasses	42	17.50%
	at least 4 glasses	63	26.25%
Place of consumption	At home	56	23.33%
	At friends'/family place	55	22.92%
	In clubs/pubs	47	19.58%
	In restaurant	82	34.17%
Type of wine	White	109	45.42%
	Red	66	27.50%
	Rose	65	27.08%

With regard to the frequency of wine consumption, it has emerged that 34.17% respondents declared they drink wine "once a month" and 25.83% of them declared they drink wine "once a week" (25.83%), while only 12.5% % of consumers declared that they drink wine "several times a week" or even every day (2.08%). Respondents declare that most often consume wine in restaurants (34.17%), and most of them drink

white wine (45.42%). As much as 81.67% of respondents are willing to experiment with new brands and types of wine. Only one third of the respondents (32.5%) do not take into account the choice of the type of wine depending on the food they consume, while 31.65% of the respondents declare that the choice of the wine type affects the season. More than half of the respondents (60%) mostly buy domestic (Serbian) wine brands.

### 3.2. Aggregated preferences

Results from the analysis are shown in Figure 1 and Figure 2. Figure 1 is the graph description of the attributes importance. It can be seen that most important attribute to Serbian consumers is the Winery, and its average importance value at the aggregate level is even 59.43%. The attribute Type has shown to be second by importance (24.69%). The third ranked attribute is Sweetness, with a relative importance of 8.8%. The least important attributes are Sparkling and Price with importance values of just 4.92% and 2.16% respectively.

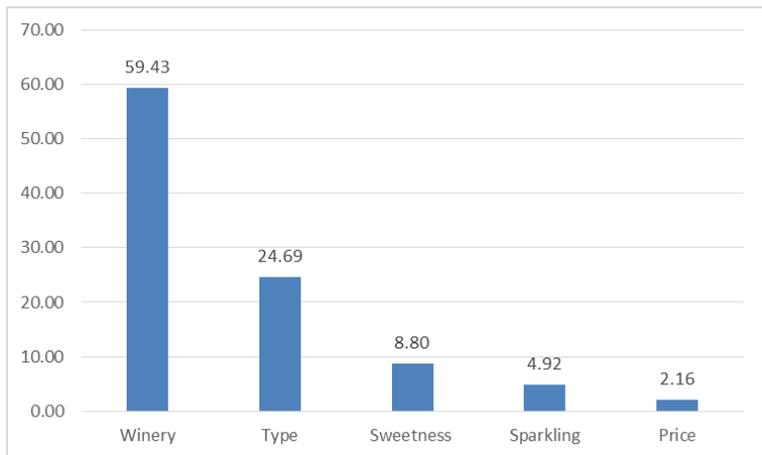

Figure 1: Relative importance of attributes (in %)

A more detailed insight into averaged preferences toward attribute levels (part-worths) is given in Figure 2. When it comes to the most significant attribute, Winery, respondents most prefer Kovačević, followed by Radovanović. The least desirable are Matalj and Rubin. On average, respondents almost equally prefer white and rose, and at least red wine, tilting with sweet wines, and most like medium and sparkling. When it comes to the attribute Price, at the aggregate level, there is no significant difference between the levels (price points), and at first glance the respondents are not price sensitive.

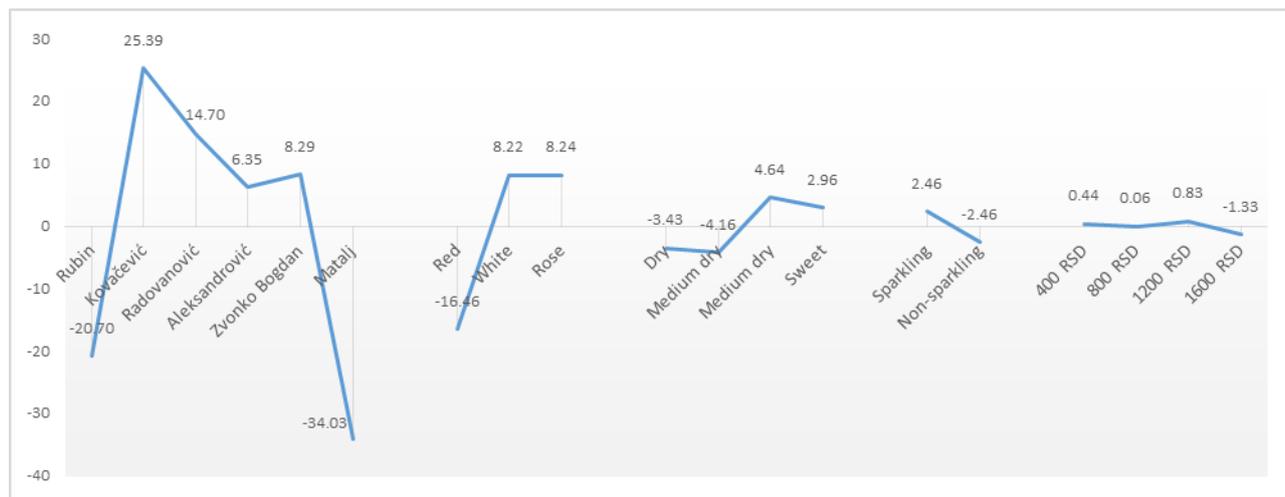

Figure 2: Averaged part-worth utilities

### 3.3. Post-hoc segmentation

A more detailed analysis of individual utilities revealed heterogeneity in consumer preferences, so three groups of consumers were isolated using *post hoc* segmentation (segmentation based on preferences). K-

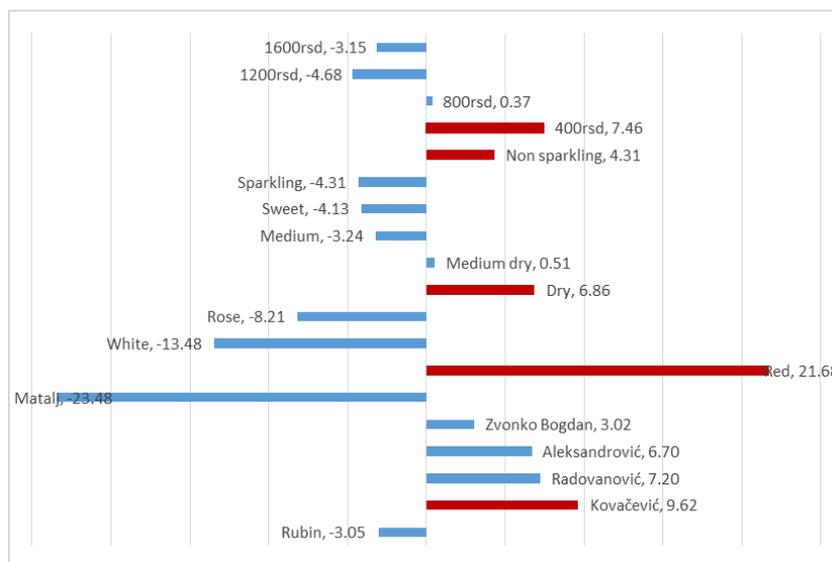

means cluster analysis was used for that purpose. Table 3 shows the importance of attributes for each of the isolated cluster.

**Table 3:** Relative importance of attributes (in %)

	Winery	Type	Sweetness	Sparkling	Price
<b>Cluster 1</b>	33.10	<b>35.16</b>	10.99	8.61	12.14
<b>Cluster 2</b>	22.17	<b>38.22</b>	17.78	4.40	17.43
<b>Cluster 3</b>	<b>39.57</b>	31.91	2.80	7.27	18.44

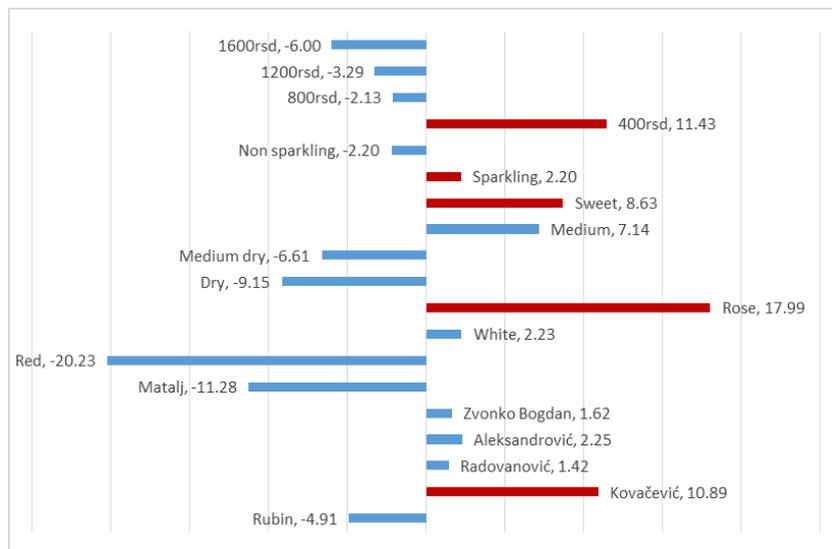

Although the price proved to be the least (negligible) important attribute on the whole sample, it can be noted that it is significantly more important at the segment level. This result indicates that averaging can cause loss of important information related to the actual preferences of the respondents, which may be reflected in the wrongly defined market strategy. Similar observations are made for other attributes as well. After the clusters were developed, socio-demographic data were used to further profile consumers.

The Cluster 1 covers 26.25% of the respondents and consists mostly of employed male respondents, who regularly drink wine, most often at home. This cluster includes respondents who especially prefer the red wine (which is in sharp contrast with the sample as a whole) and usually consume it (54%), so it is not surprising that they find the Type to be the most important attribute (35.16%). Somewhat less important is the attributes of Winery (33.10%), where respondents prefer Kovačević, Radovanović and Aleksandrović wine brands. The other three attributes are significantly less important to this cluster. However, they prefer non-sparkling dry wines, with the price of up to 800rsd (see Figure 3)

**Figure 3:** Preferences of Cluster 1

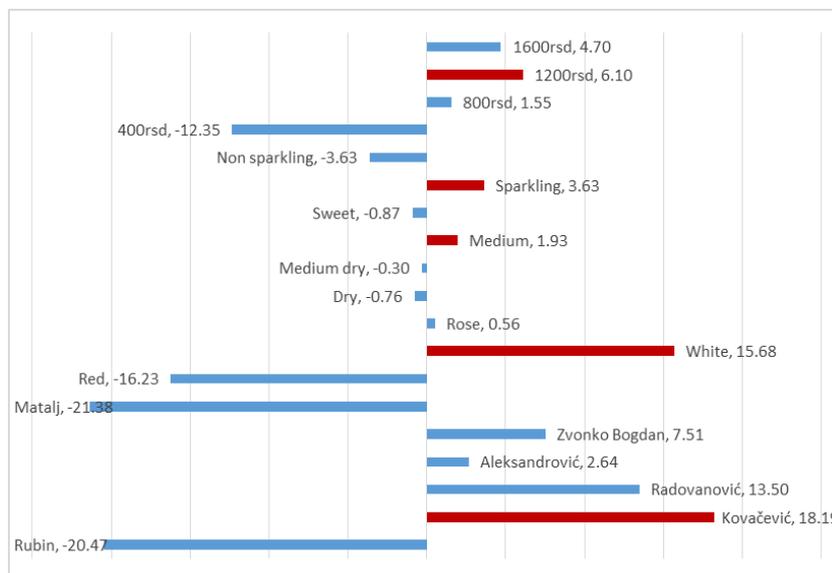

The second, somewhat larger cluster consists of 73 respondents (30.42%). The most important attribute for this segment is also Type (importance value = 38.22%), but respondents belonging to this cluster prefer rose wine, and to some extent white, while red wine is not preferred to them (see Figure 4). The Winery attribute is considerable less important for this cluster than for Cluster 1. In the same time, members of the Cluster 2 prefer the Kovačević brand wine by far more than the brands of other wineries. Sweetness and price are approximately equally important attributes (about 17%), whereby respondents prefer sweeter wines at a price of 400rsd. They are very price-sensitive, and expensive wines (from 800rsd) are negatively preferred. If they chose, they would rather choose sparkling wines.

**Figure 4: Preferences of Cluster 2**

The demographic data shows that the majority of the respondents in this segment are younger women, with lower earnings and education than the remaining two segments. Members of this segment are less likely to drink wine than members of the Cluster 1, and when they drink it, they do it in a restaurant or in friends' home, and rarely at their own place. They usually drink rose or white wine, while only 15% drink red.

Cluster 3 is the largest one (43.33% of total sample) with Winery as the most important attribute (39.57%). Members of this cluster prefer Kovačević and Radovanović brands, followed by Zvonko Bogdan. Again, Matalj and Rubin are the least popular wine brands (see Figure 4). Type of wine is the second by importance attribute, where the respondents prefer white wine, but do not like red. This cluster is price-sensitive, but the respondents' preferences to price levels are unexpected. Namely, respondents prefer more expensive wines, which can be due to the fact that they use price to make inferences about the quality and value of a wine. Moreover, the quality wines of the favourite Serbian producers are exactly in the price range that the respondents prefer. Although sweetness is negligible important attribute for this cluster (only 2.8%), respondents prefer semi-sweet sparkling wines.

**Figure 5: Preferences of Cluster 3**

#### 4. CONCLUSION

Wine is a difficult and confusing product for consumers to choose because of a large number of different cues that can influence purchasing decision. These cues are typically related to physical characteristics of wine as well as extrinsic attributes such as price and brand, labels and the like. Accordingly, understanding how consumers choose wine is a complex problem both for researchers and practitioners.

In this paper we have examined the importance consumers in Serbia attach to the key attributes of local wine brands. In addition to the brand, four attributes were also observed: price, type of wine, sweetness and whether it is sparkling or not. To elicit consumer preferences, we used conjoint analyses, i.e. one of its forms known as discrete choice experiment. The average results on the whole sample indicated the high importance of the attributes brand and type of wine. However, heterogeneity in preferences were noticed and three unique segments were identified. These segments differ primarily in the type of wine their favour, but also whether they like sweet and sparkling wine or not. It turned out that the price is a moderately significant attribute in all three clusters, while Kovačević is the most preferred brand.

The findings in this study represent first empirical insights that examine the preferences of consumers towards wine characteristics using discrete choice analysis in Serbia. However, since 40% of the sample drinks wine at most once a week, the question arises as to whether the preferences of the true wine connoisseurs are the same. The future directions of the research should be towards eliciting the preferences of the connoisseurs of fine wines.

**Abstract:** *Well-functioning legal and regulatory system is a prerequisite for creating an effective market economy. Therefore, it is in the interest of nations to improve their business regulation and stimulate business activity and growth. One of the means for measuring the ease of doing business is using the Doing Business Index (DBI) devised by the World Bank. In this paper, we examine the relationship among gross domestic product (GDP) per capita and DBI topics which measure the ease of conducting business processes. Our approach is two-fold. First, we apply a machine learning algorithm, a clustering approach to cluster the countries ranked by the DBI, and second, we employ the Potthoff analysis to compare the regression models of GDP per capita made on retained clusters. The results of the conducted analyses indicate there are differences in the effects of factors of doing business on GDP per capita between clusters. We believe our research could provide additional insights on the topic of factors which influence GDP, application of composite indicator data, and comparison of regression models between groups.*

**Keywords:** *Doing Business Index, Gross domestic product, Potthoff analysis, Machine learning*

### 1. INTRODUCTION

Legal and regulatory system is a prerequisite for creating an effective market (Corcoran & Gillanders, 2015). Research has shown that more complicated and more costly procedures have a negative effect on the business environment and on the number of new companies. Namely, Klapper, Laeven, and Rajan (2006) showed that higher entry regulations decrease the number of new companies created. Next, Djankov et al. (2002) found that economies with higher entry costs have more corruption and larger percentage of unofficial economy. Ciccone and Papaioannou (2007) showed that more complex procedures reduce job creation. The same authors draw the conclusion that therefore the simplification of time-consuming government procedures related to doing and starting new businesses should be high on policy agendas.

In the last few decades, additional efforts have been placed to provide a ranking of countries, regions, or even cities based on their openness to business (Brunetti, Kisunko, & Weder, 1997; Davis, Kingsbury, & Merry, 2012). Besides simple performance indicators which are commonly used for ranking, recently composite indicators stood out as a reliable source of information and ranking, especially in the public sector (Jacobs & Goddard, 2007). One of the earliest such ranking of countries based on doing business and economy dates from 1990's. Namely, Cavusgil (1997) proposed a ranking of emerging markets using seven dimensions: Market size, Market intensity–economic intensity, Market growth–future market potential, Commercial infrastructure, Freedom (economic and political) and risk, Market receptivity –market accessibility, Market construction capacity. Mullen and Sheng(2006) aimed to extend and modernise the original study conducted by Cavusgil (1997) by employing novel and more specific indicators in their framework. Besides academics, the international organisations also devise and publish composite indicators on the subject of ease of doing business. For this research, the most important one is the World Bank's Doing Business Index (DBI) published since 2003 (World Bank, 2017).

Gross domestic product (GDP) measures the monetary value of market production, of final goods and services produced for sale in a particular market and of nonmarket production, such as defence or education services provided by the government (International Monetary Fund, 2017). As such a metric, it provides information on the size of the economy and its performance. Therefore, it is used as an indicator of health of the economy whereas growth of the GDP implies the economy is doing good (International Monetary Fund, 2017). As the forecasting of future economic outcomes is a vital for decision-makers (Dritsaki, 2015), the question which arises is what influences the GDP and the growth of GDP. Different approaches have been taken to provide an answer. For example, time series analysis was used (Dritsaki, 2015). Schumacher & Breitung(2008) used expectation–maximization (EM) algorithm and principal component analysis (PCA) to forecast German GDP. Linear regression has also been used with success to model GDP. For example, Anghelache and coauthors(2015) aimed to regress final consumption and gross investment on GDP. Lakštutienė and Aušrinė(2015) modelled the GDP per capita using indicators of the capital market.

The academic community placed attention on the relationship between the GDP and the reform of business regulation and ease doing business. Namely, it is believed that the ease of doing business attracts foreign direct investments (FDI) which eventually have an impact on the GDP (World Bank, 2016). Many studies have been conducted to examine the relationship between FDI and gross domestic product (GDP) and showed positive relationship (Basu, Chakraborty, & Reagle, 2003; Hsiao & Shen, 2003; Nair-Reichert & Weinhold, 2001). Also, it has been shown that the ease of doing business and business regulation have an impact on the GDP. Namely, Djankov, McLiesh, & Ramalho(2006) in their model used as dependent variable the average GDP growth and as independent the normalized components of the World Bank's DBI. Also, Busse & Groizard(2008) used linear regression to model the GDP using FDI and the selected components of the World Bank's DBI. Their results indicate that the countries with lower level of regulation can stimulate growth by reforming. The two presented studies are important for the herein conducted research for two reasons. First, they show that there is relationship between GDP and ease of doing business which can be explored in more detail and second, that the values of World Bank's DBI

Our goal was to attempt to model the GDP per capita using the values of the DBI topics. However, our analysis aims to go a step further. Namely, we first propose the application of machine learning algorithm to divide countries ranked by the DBI. We collected the data on 187 countries, so our aim was to first group these countries into clusters and to compare the regression models built on each of the retained clusters. The proposed clustering approach is the Partition around medoid (PAM) algorithm (Kaufman & Rousseeuw, 1990) while the statistical analysis used to compare regression models is the Potthoff analysis (Potthoff, 1966). We believe that the obtained results can indicate whether there are differences between the regression models and which topics should policy makers from different clusters place more attention so as to increase their GDP.

The structure of the paper is as follows. Section 2 sees the introduction and a brief review of the DBI. The main concepts of the PAM clustering algorithm and the Potthoff analysis used to compare regression models are given in Section 3. Next, the research results are elaborated, while the discussion and the concluding remarks are given in the final section.

## **2. DOING BUSINESS INDEX (DBI)**

Doing Business Index (DBI) is a complex composite indicator consisted of 10 topics made of 41 indicators in total. In our research, we focused solely on topic data. Herein, we will present the basics of each topic.

The first topic, *Starting a business*, is intended to measure the number of procedures, time, cost, and paid-in minimum capital to start a limited liability company. Next topic, *Dealing with construction permits* measures the number of procedures, time, and cost to complete all formalities to build a warehouse and the quality control and safety mechanisms in the construction permitting system. *Getting electricity*, quantifies procedures, time, and cost to get connected to the electrical grid, the reliability of the electricity supply and the transparency of tariffs. *Registering property* is related to procedures, time, and cost to transfer a property and the quality of the land administration system. The following topic, *Getting credit* measures movable collateral laws and credit information systems. *Protecting minority investors* deals with minority shareholders' rights in related-party transactions and in corporate governance. Payments, time and total tax and contribution rate for a firm to comply with all tax regulations as well as post-filing processes are quantified by the topic *Paying taxes*. Time and cost to export the product of comparative advantage and import auto parts are measured in the topic *Trading a cross borders*. Succeeding topic, *Enforcing contracts*, measures how commercial disputes are resolved and the quality of judicial processes. The final topic, *Resolving insolvency*, deals with time, cost, outcome and recovery rate for commercial insolvency and the strength of the legal framework for insolvency(World Bank, 2017). So, to make the presentation of the results more clear (see Section 4), the topics have been coded from T1 to T10, in the order in which they have been briefly explained here.

The data collection process is based on a detailed reading of domestic laws and regulations as well as administrative requirements. The process itself is guided and overlooked by the World Bank experts. A signal that the data collected for the DBI is precise and of interest is the fact that there are 17 different data projects or indexes that use Doing Business Index data as one of their data sources (World Bank, 2017). For example, in a similar study, Morris and Aziz (2011) aimed to measure the relationship between the DBI topics and the FDI using the Pearson's correlation coefficient based on the results of Sub-Saharan Africa. Nevertheless, Arruñada (2007) argues that the procedure of indicator and topic data collection could be itered so as to better represent the actual policies.

### 3. METHODOLOGY

#### 3.1 PAM algorithm

Partitioning Around Medoids (PAM) is an implementation of the K-medoids algorithm. The algorithm partitions the entities into clusters and aims to minimise the distance between the entities assigned to a cluster and its centre, in this case, an entity (Kaufman & Rousseeuw, 1990). PAM has several favourable properties as it performs clustering with respect to any specified distance metric and it identifies clusters by the medoids. Thus, each element is considered as a potential medoid, while the other K-1 medoids are fixed (Van der Laan, Pollard, & Bryan, 2003). Nevertheless, the PAM algorithm has a slight drawback: it works inefficiently with large data set due to time complexity (Han, Kamber, & Tung, 2001). Namely, one of the advantages of the PAM method is the silhouette plot that shows how well cluster members are positioned within their respective clusters. Besides the calculation of the predefined number of clusters, it is possible to use the silhouette average widths for assessing the best number of clusters.

The silhouette plot shows how well cluster members are positioned within their clusters, and average silhouette widths enable us to assess the quality of the cluster structures. The silhouette width has a range [-1,1]. Values near +1 indicate that the entity is far away from any neighbouring clusters. A value of 0 indicates that the entity could be in the current cluster or in the neighbouring clusters and negative values indicate that the entity might be assigned to the wrong cluster. On the other hand, a value of the average silhouette below 0.5 shows a rather weak clustering structure, between 0.5 and 0.7 shows a reasonable cluster structure, and above 0.7 shows a strong structure (Kaufman & Rousseeuw, 1990).

#### 3.2 Potthoff analysis

Multiple books and research articles aimed at introducing methods and tests to compare coefficients from ordinary least squares regression models (Howell, 2013; Potthoff, 1966). The Potthoff analysis stands out as a simple way of comparing linear regression models. Namely, so far it has been used with success in the fields of social psychology (Lawson & Lips, 2014), medicine (Akolekar, Syngelaki, Gallo, Poon, & Nicolaides, 2015), innovation management (Truong, Klink, Fort-Rioche, & Athaide, 2014), and others. Another evidence that the idea of comparing linear regression models is still developing, especially the Potthoff analysis, is the recently published SAS and SPSS code for related tests (Weaver & Wuensch, 2013).

In the simplest case, a Potthoff analysis is multiple regression analysis of the following model CGI:  $Y = a + b_1C + b_2G + b_3C*G$ , where Y is the criterion variable, C is the continuously distributed predictor variable, G is the dichotomous grouping variable, and C\*G is the interaction between C and G. Grouping variables are commonly “dummy-coded” with  $l-1$  dichotomous variables, where  $l$  is the number of groups (Wuensch, 2016). The same form would be made if there were more continuously distributed predictor variables. Namely, then there would be added  $j$  interaction variables, where  $j$  is the number of continuously distributed predictor variables.

Essentially, the Potthoff analysis consists of three tests: test of coincidence, test of intercepts, and test of parallelism. To conduct all three tests, four regression models should be made. Namely, the analysis is done as a series of multiple regressions with comparisons among the various models (Wuensch, 2016). The first model, named CGI, consists of the dependent variable explained through the continuous variable, grouping variable, and the interaction variable. The second model, C, models the dependent variable using only the continuous variable. The next model, CG, is formed using the continuous and grouping variable to explain the dependent variable. Finally, the fourth model is CI, where the explanatory variables are the continuous variable and the interaction variable. The model CGI is then compared to each of the three remained models using the partial F-test:

$$F = \frac{SS_{full} - SS_{reduced}}{(f - r)MSE_{full}} : F(m, n - k - 1) \quad (1)$$

Where  $SS_{full}$  is the sum of squares of the model CGI,  $SS_{reduced}$  is the sum of squares of the reduced model, which is C, CI, or CG depending on the test,  $f$  is the number of degrees of freedom of the full model,  $r$  is the number of degrees of freedom of the reduced model, while the  $MSE_{full}$  is the mean square error of the CGI model. The test has Fisher's distribution with  $m$  and  $n-k-1$  degrees of freedom, where  $m$  is the difference in the number of variables between the full and the reduced model,  $n$  is the number of observations, and  $k$  is the number of variables in the full model.

Test of coincidence compares CGI with the C model as it aims to explore whether there is difference between the intercept, slope or both between the observed groups. Namely, the null hypothesis that the regression line for predicting Y from C is the same at all levels of some grouping variable (Wuensch, 2016).

Further, the test of intercepts compares CGI with the CI model to test whether the intercepts are identical across groups. Finally, the test of parallelism compares CGI with the CG model. The null hypothesis states that the slope for predicting Y from G is the same for all observed groups of G.

The three presented tests can provide a detailed comparison of the two or more regression models created using the same variables on different groups. If there is a significant F result in the test of coincidence slopes and intercepts may then be assessed separately to determine whether they differ (Reynolds & Gutkin, 1980). So, the first test when conducting the Potthoff analysis is the test of coincidence, followed by the test of intercepts and test of parallelism if needed. However, before the Potthoff analysis, the grouping variable must be recoded meaningfully (West, Aiken, & Krull, 1996). In the conducted case study the grouping variable is the cluster the country belongs to.

#### 4. RESULTS AND FINDINGS

The dataset on which the analysis was performed contained all ten topic values for 187 countries which are ranked by the DBI for the year 2016. The World Bank defines GDP per capita as the gross domestic product divided by midyear population (World Bank, 2018). The values of the GDP per capita have been collected from the World Bank database (World Bank, 2018) and normalised using *Min-Max* normalization. Afterwards, the first step in our analysis was to apply the clustering method, the PAM algorithm.

For our case study (187 entities, PAM algorithm, Euclidean distance), the “NbClust” package was able to obtain the results of 24 indices out of 30. The number of clusters suggested by the highest number of indexes was retained. In our case, seven indices proposed to retain two clusters. The most commonly used metric to evaluate PAM, the average silhouette width for the two retained clusters is 0.279, whereas the average silhouette width of each cluster is 0.190 and 0.451, respectively. Although the average silhouette of the first cluster is low, it is still positive. Countries which represent the cluster centres are Lebanon and Latvia.

Next, the descriptive statistics of the two retained clusters is presented in Table 2. The first column indicates the size of the clusters. We can observe that the clusters are not of similar size, 123 and 64 countries. Some of the countries which make cluster 1 are: Argentina, Brazil, China, India, Malta, Saudi Arabia, and South Africa. On the other side, some of the countries which make cluster 2 are: Australia, Belgium, Germany, Norway, United Kingdom, and the USA. As the clusters are large, the list of countries which make each cluster will not be listed completely, but it is available on demand. The next column indicates the mean value of topics in the specific cluster. According to the mean values in the first cluster, it can be observed that these countries underperform when it comes to certain topics and could reform to attract more FDI and investors. The topic with the lowest mean value in this cluster is T10, *Resolving insolvency*. On the other hand, the second cluster can be identified as a cluster of countries which perform well according to the DBI topics and whose laws aim to facilitate and stimulate doing business. It is also interesting to observe the minimum and maximum values of topics per cluster. In the first cluster, the lowest values of all topics expect T1 *Starting a business* and T9 *Enforcing contracts*, is 0, while in cluster 2, the situation is completely different. Namely, there is only one topic with the minimum value of 0, T2 *Dealing with construction permits*. What can also be observed from Table 2 is that the standard deviation (StD) of topics per cluster is high. This could lead to the conclusion that although the countries have been grouped in two clusters and that the majority of indices suggested such a structure, the obtained clustering structure might not be that coherent.

**Table 2** Basic descriptive statistics of clusters created using the PAM clustering method

Cluster 1	Size	Mean	Min	Max	StD	Cluster 2	Size	Mean	Min	Max	StD
T1	123	76.27	33.53	94.51	13.25	T1	64	89.94	63.60	99.96	5.81
T2	123	59.77	0.00	83.79	16.13	T2	64	70.77	0.00	86.30	12.20
T3	123	56.68	0.00	90.63	19.63	T3	64	78.83	43.42	99.88	12.13
T4	123	52.86	0.00	90.59	15.96	T4	64	75.64	49.62	94.46	11.00
T5	123	36.50	0.00	85.00	19.78	T5	64	66.72	35.00	100.00	15.02
T6	123	44.68	0.00	76.67	11.97	T6	64	63.46	38.33	81.67	8.79
T7	123	64.37	0.00	99.44	18.38	T7	64	79.89	48.60	99.44	10.13
T8	123	58.44	0.00	100.00	20.56	T8	64	88.77	59.61	100.00	11.21
T9	123	49.89	6.13	78.23	11.76	T9	64	65.20	32.43	84.15	9.51
T10	123	30.67	0.00	69.59	17.36	T10	64	66.32	20.30	93.81	16.79

To additionally inspect the clustering structure cluster means were compared using t-test as used by Russell and coauthors(2017) to compare means of clusters of countries. The results are presented in Table 3. As it can be observed, there is statistically significant difference in group means for all ten topics. This could lead to the conclusion that the clusters differ and that they are well separated. The absolute mean difference

varies from 10.99 (T2) to 35.65 (T10). The high absolute mean difference can also be acknowledged for T5 (30.22) and T8 (30.33).

**Table 3** Results of the cluster means comparison t-test

\*\*p<0.01

Prior to conducting the Potthoff analysis we modelled the GDP per capita for all observed countries (Table 4). The obtained adjusted  $R^2$  is 0.466 and the model is statistically significant ( $F(10,176)=17.255$ ,  $p<0.01$ ). Taking a closer look on the values of the obtained coefficients and their significance, we conclude that the intercept, *Getting electricity*, *Getting credit*, *Paying taxes*, *Enforcing contracts*, and *Resolving insolvency* are statistically significant for modelling the GDP per capita. The model created on all of the observed countries is statistically significant and of a good quality, indicating that the GDP per capita could be modelled using 10 DBI topics.

**Table 4** Regression model of GDP for all the observed countries

Topics	Intercept	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10
$\hat{\beta}_i$	-33.022	-0.038	0.124	0.170	0.014	-0.151	-0.083	0.202	0.019	0.221	0.292
t	-5.053**	-0.398	1.65	2.479*	0.192	-2.894**	-0.861	2.888**	0.328	2.340*	5.166**

\*p<0.05, \*\*p<0.01

The next step in the analysis was the application of the regression analysis on the retained clusters. The models for Cluster 1 and Cluster 2 are presented in Table 5. The obtained adjusted  $R^2$  is 0.274 for Cluster 1 and 0.508 for Cluster 2. The model created for the Cluster 1 is of a bit lower quality as 27.4% variability of GDP per capita is explained, while the model created for Cluster 2 is of a better quality as it explains 50.8% variability of GDP per capita. Both models are statistically significant ( $F_{cluster1}(10,112)=5.595$ ,  $p<0.01$ ;  $F_{cluster2}(10,53)=7.506$ ,  $p<0.01$ ).

**Table 5** Regression models of GDP for the two retained clusters

	Topics	Intercept	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10
Cluster 1	$\hat{\beta}_i$	-21.583	-0.039	0.114	0.126	0.008	-0.145	-0.096	0.165	0.031	0.211	0.100
	t	-3.232**	-0.466	1.631	1.994*	0.109	-2.747**	-1.06	2.708**	0.558	2.284*	1.655
Cluster 2	$\hat{\beta}_i$	-131.39	0.430	-0.039	0.564	0.078	0.039	-0.199	0.423	0.17	-0.089	0.543
	t	-3.846**	1.196	-0.182	2.749**	0.397	0.301	-0.788	1.539*	0.914	-0.386	4.233**

\*p<0.05, \*\*p<0.01

When it comes to the model made for the countries in the first cluster, the intercept, *Getting electricity*, *Getting credit*, *Paying taxes*, and *Enforcing contracts* are statistically significant (Table 5). For *Getting electricity*, *Paying taxes*, and *Enforcing contracts* there is a positive relationship with the values of GDP per capita, while the ease of *Getting credit* decreases the value of GDP per capita. Topics which proved to be significant in Cluster 1 which attract attention are *Getting credit* and *Enforcing contracts*. The negative coefficient for *Getting credit* can be explained as that the credits given by banks in these countries might not generate enough positive return on investment (ROI). The negative impact of some indices seems to be logical (Messoud & Teheni, 2014). When it comes to *Enforcing contracts*, the obtained coefficient can be explained as the more the country is prepared to enforce contracts, the foreign and domestic investors are more secure to invest knowing their investment can be timely solved in a quality and unbiased judicial process.

In the created model for Cluster 2, there are differences. Namely, the intercept is statistically significant, alongside *Getting electricity*, *Paying taxes* and *Resolving insolvency* (Table 5). All three topics have a positive relationship with the values of GDP per capita. Topic which proved to be positive and significant in

Cluster 2 which attracts attention is *Resolving insolvency*. The importance of this topics can be explained that if the investors know there is a legal framework for insolvency and that the commercial insolvency can be dealt in time and with a high recovery rate, they will invest more, which will eventually have an impact on growth.

Finally, we conduct the Potthoff analysis to inspect is there statistically significant difference between the two models. The analysis can provide valuable insights as if there is a difference in the regression models, it means that there is a difference in the importance of topics of doing business for the growth of GDP and GDP per capita. Therefore, the decision makers could be informed to use different approaches to increase the GDP per capita depending on the cluster they belong to.

The Potthoff analysis showed significant difference between the two models, ( $F(10,165)=4.000$ ,  $p<0.01$ ), whereas that difference is in the slopes ( $F(10,165)=4.2264$ ,  $p<0.01$ ), and in the intercept ( $F(1,377)=13.925$ ,  $p<0.01$ ). This result indicates that the models significantly differ, and that both intercept and coefficients differ. Topics which are statistically significant for both models are *Getting electricity* and *Paying taxes*. Nevertheless, in the model for Cluster 1, *Getting credit* and *Enforcing contracts* are statistically significant, while in model for Cluster 2 *Resolving insolvency* has statistically significant impact on the GDP per capita.

These results indicate that government representatives in all analysed countries should place more effort to ease the procedures and cost of getting electricity and to create a reasonable total tax and contribution rate. The representatives in developing countries which are mostly in Cluster 1 should be stricter regarding the ease of allowing credit, while they should improve their laws on enforcing contracts. On the other hand, the more developed country, mostly in Cluster 2, should think of improving their laws regarding insolvency.

## 5. CONCLUSION

Extensive research was done on the subject of the effects of nations' political, legal, economic and social reforms on wealth and long-term growth(for example Acemoglu, Johnson, & Robinson, 2001; Knack & Keefer, 1995). Messaoud and Teheni (2014) went a step further and tried to model the relationship between business regulations and growth. Their results are also coherent with the results of Djankov, McLiesh, and Ramalho (2006) who stated that "good" business regulations lead to higher economic growth. Our paper is an attempt to extend the current literature on the topic.

The taken research approach was two-fold. We first clustered the countries ranked by the DBI. We retained two clusters, which are well separated. The first cluster is made of countries in which underperform when it comes to certain topics and could reform so as to attract more FDI and investors. On the other hand, the second cluster can be identified as a cluster of countries which perform well according to the DBI. In the next step, we performed the regression analysis of the GDP per capita and the Potthoff analysis. The chosen analysis has been used previously to compare regression models between groups (Lawson & Lips, 2014). Therefore, its results could indicate whether there is a difference in the models and should the decision makers use different approaches to increase the GDP per capita. The obtained results showed that the GDP per capita can be modelled using the DBI topics, that there is statistically significant difference between the two models. The observed difference indicates that policy makers in countries form different cluster should undertake different reforms to increase the GDP.

During our research we could identify two possible future directions of the study. One would be towards reducing the number of observed topics which make the DBI. For example, post-hoc I-distance could be implemented(Savic, Jeremic, & Petrovic, 2016). The second direction would be towards implementing hierarchical clustering methods (Miyamoto, 2012) or more advanced clustering methods, such as biclustering (Busygin, Prokopyev, & Pardalos, 2008) as the clustering results indicate that the currently suggested clustering scheme could be modified.

We believe our research could provide additional insights on the topic of modelling GDP, application of composite indicator data, and comparison of regression models between groups.

# CONFIDENCE INTERVALS FOR THE POPULATION STANDARD DEVIATION: SIMPLE RANDOM SAMPLING VS. RANKED SET SAMPLING

Ivana Ivković<sup>\*1</sup>, Vesna Rajić<sup>1</sup>

<sup>1</sup> University of Belgrade, Faculty of Economics, Serbia

\*Corresponding author, email: ivanaivkovic@ekof.bg.ac.rs

**Abstract.** Ranked set sampling (RSS) is the cost-efficient sampling procedure. This procedure gives more efficient estimators of the population parameters than the procedure based on simple random sampling (SRS), with the same sample size. In this paper, we compare the coverage probabilities of confidence intervals for the population standard deviation using the simple random sampling and the ranked set sampling. The following confidence intervals are considered: the exact, the Bonett, the Steve large sample normal approximations, the log asymptotic approximation and the adjusted degrees of freedom. The results for the Gamma, Log-normal and Exponential distributions and for the real data set are presented. The simulation study shows that the results obtained using the ranked set sampling are better than those using the simple random sampling.

**Keywords:** population standard deviation; confidence interval; coverage accuracy; ranked set sampling; simple random sampling

## 1. INTRODUCTION

In this paper, we construct the confidence intervals for the population standard deviation. The population standard deviation is the most common scale parameter. The existing confidence interval for the estimation of the population standard deviation is the exact confidence interval, based on the statistic which has  $\chi^2$  distribution. This interval is appropriate if the distribution of the data is normal with no outliers. We are interested in confidence intervals which are appropriate if the data are not from the normal distribution, but from skewed distribution or have heavy tails. There are some alternatives to the exact confidence interval which can be used in such situations. There are no many authors who dealt with the confidence intervals that were less sensitive to the departure from normality and/or presence of outliers. Bonett (2006) proposed an approximate confidence interval for the population standard deviation which results were close to the exact confidence interval under the normality and had very good small-sample properties under the moderate non-normality. Cojbasic and Loncar (2011) and Cojbasic and Tomovic (2007) used the resampling methods for construction of confidence intervals for the population variance (taking the square root of the endpoints of that intervals gave the confidence intervals for the population standard deviation). Abu-Shawiesh et al. (2011) and Banik et al. (2014) conducted the large simulation studies in which compared the performances of the different confidence intervals for the standard deviation under the symmetric and skewed conditions. Hummel et al. (2005) proposed two alternative methods for finding the confidence interval for the standard deviation.

Ranked set sampling (or shortly RSS) is an alternative method of data collection and presents the cost-effective sampling procedure. The RSS is used for improving the estimators in the situations where the ranking of the units can be done easily compared to the effort required for the actual measurement of the variable of interest. This method was first proposed by McIntyre (1952). He estimated the mean of the population using the RSS instead of simple random sampling (or shortly SRS). Dell and Clutter (1972) showed that the ranked set sampling provided more precise estimates of the mean when the ranking of the units in the sample was easy. Using the RSS, Stokes (1980) concluded that an estimator of variance was asymptotically unbiased regardless of the errors that could occur during the ranking and that asymptotic efficiency of that estimator was better relative to the estimator based on the same number of the measured units from the random sample. Chen (2007) gave the review of the several variants of the ranked set sampling and presented some recent applications of that method. Samawi (1999) showed that the performance of the Monte Carlo methods, such as an importance or control variate sampling, were improved a lot using the ranked set sampling. Wolfe (2012) wrote the review article about the impact of the ranked set sampling on the statistical inference. Ganeslingam and Ganesh (2006) applied the ranked set sampling procedure on the estimation of the population mean and ratio using the real data set on the body measurements. Husby et al. (2005) used the crop production dataset from the United States Department of Agriculture to show the advantages of the RSS relative to the frequently used simple random sampling in the estimation of the mean and median of the population. Terpstra and Wang (2008) examined the several

methods for construction of confidence intervals for the population proportion based on the RSS. Albatineh et al. (2014) performed the simulation study in which evaluated the performance of the several confidence intervals for the population coefficient of variation, using the coverage probabilities and the width of the intervals. Albatineh et al. (2017) constructed the confidence intervals for the Signal-to-Noise ratio using the RSS. More about the ranked set sampling methodology and its application can be found in Ozturk (2018), Zamanzade and Mahdizadeh (2017), Zamanzade and Vock (2015), Zhang et al. (2016), etc.

In this paper, we examine the confidence intervals for the population standard deviation which are more adequate to use when the data do not follow the normal distribution. We construct the confidence intervals using the simple random sampling and the ranked set sampling. The examined intervals are implemented using the R programming language. We generate random data from the Gamma, Log-normal and Exponential distributions, respectively and compare the coverage probabilities of the presented confidence intervals. Then, we apply the considered intervals to the measure of the systematic risk data.

The goal of this paper is to present the ranked set sampling procedure for construction of confidence intervals for the population standard deviation. The contribution of this paper is to emphasize the advantages of the ranked set sampling procedure over the simple random sampling procedure. The paper is organized as follows: in Section 2, we describe the ranked set sampling methodology; in Section 3, we present the confidence intervals for the population standard deviation; in Section 4, we conduct the simulation study for the data from the Gamma, Log-normal and Exponential distributions and for the real data set; in Section 5, we summarize results and draw the conclusions.

## 2. RANKED SET SAMPLING METHODOLOGY

The ranked set sampling procedures can be balanced or unbalanced. Each procedure can be with the perfect or imperfect ranking process. In this paper, we consider the balanced RSS with the perfect ranking process (see Ganeslingam and Ganesh (2006), Wolfe (2012), Albatineh et al. (2014)). The process of generating the balanced RSS involves drawing  $k^2$  units at random from the population. After that, these units are randomly divided into  $k$  sets of  $k$  units each (we get  $k$  simple random samples of the size  $k$ ). Within each set, the units are ranked according to the variable of interest. The perfect ranking process implies that actual measurements of the variable of interest on the selected units are done and that ranking is based on them. Opposite to the perfect ranking process, the imperfect ranking process includes visual comparisons of the units or the use of the auxiliary variables. After the ranking process, from the first set we select the unit with the smallest rank  $X_{(1)}$  (if the ranking is perfect or  $X_{[1]}$ , if the ranking is imperfect). The remaining  $k-1$  units are not considered further. Then, from the second set we select the unit with the second smallest rank  $X_{(2)}$ , and so on, until we select the unit with the largest rank from the  $k$ -th set,  $X_{(k)}$ . This procedure results in  $k$  observations  $X_{(1)}, X_{(2)}, \dots, X_{(k)}$  and is called the cycle. The number of the units in each simple random sample,  $k$ , is called the set size. If we want to obtain the balanced ranked set sample of size  $n = mk$ , we repeat the cycle  $m$  times (see Table 1). The complete balanced RSS with set size  $k$  and  $m$  cycles is given by  $\{X_{(j)i} : j = 1, 2, \dots, k; i = 1, 2, \dots, m\}$ . The term  $X_{(j)i}$  is called the  $j$ -th order statistic from the  $i$ -th cycle.

**Table 1:** The balanced RSS with  $m$  cycles and set size  $k$

Cycle 1	$X_{(1)1}$	$X_{(2)1}$	...	$X_{(k)1}$
Cycle 2	$X_{(1)2}$	$X_{(2)2}$	...	$X_{(k)2}$
...	...	...	...	...
Cycle $m$	$X_{(1)m}$	$X_{(2)m}$	...	$X_{(k)m}$

Source: Wolfe (2012)

The estimators of the mean and the variance of the population, based on the RSS, are given with the following formulas (see Stokes, 1980):

$$\bar{X}_{RSS} = \frac{1}{km} \sum_{j=1}^k \sum_{i=1}^m X_{(j)i}, \quad (1)$$

$$S^2_{RSS} = \frac{1}{km-1} \sum_{j=1}^k \sum_{i=1}^m (X_{(j)i} - \bar{X}_{RSS})^2. \quad (2)$$

### 3. CONFIDENCE INTERVALS FOR THE POPULATION STANDARD DEVIATION

In this section, we report five confidence intervals for the population standard deviation.

- The exact confidence interval

Let  $X_1, \dots, X_n$  be independent and identically distributed random variables from the normal distribution, i.e.  $X_i \sim N(\mu, \sigma^2)$ . Let  $S^2 = (1/(n-1)) \sum_{i=1}^n (X_i - \bar{X})^2$  be a sample variance. The statistic  $(n-1)S^2 / \sigma^2$  has  $\chi^2$  distribution with  $n-1$  degrees of freedom. The exact  $(1-\alpha) \cdot 100\%$  confidence interval for the population standard deviation, based on the previous statistic, is of the form:

$$\sqrt{\frac{(n-1)S^2}{\chi^2_{\alpha/2, (n-1)}}} \leq \sigma \leq \sqrt{\frac{(n-1)S^2}{\chi^2_{1-\alpha/2, (n-1)}}}, \quad (3)$$

Where  $\chi^2_{\alpha/2}$  and  $\chi^2_{1-\alpha/2}$  are the  $\alpha/2$  and  $1-\alpha/2$  percentiles of the  $\chi^2$  distribution with  $n-1$  degrees of freedom.

The exact confidence interval (3) is very sensitive to minor violations of the normality assumption. In the cases of violations of the normality assumption, there are the confidence intervals which present the alternatives to the exact confidence interval. In remain of the section, we consider that confidence intervals.

- The Bonett confidence interval

Let  $X_1, \dots, X_n$  be continuous, independent and identically distributed random variables with  $E(X_i) = \mu$ ,  $\text{var}(X_i) = \sigma^2$  and the finite fourth moment. Bonett (2006) proposed the following estimator of the kurtosis,  $\gamma_4$ , which is asymptotically equivalent to the Pearson's estimator:

$$\bar{\gamma}_4 = n \cdot \sum_{i=1}^n (X_i - m)^4 / \left( \sum_{i=1}^n (X_i - \bar{X})^2 \right)^2,$$

Where  $m$  is a trimmed mean with trim-proportion equal to  $1 / \{2 \cdot (n-4)^{1/2}\}$ . This estimator tends to have less negative bias and smaller coefficient of variability than Pearson's estimator in the symmetric and skewed leptokurtic distributions. The  $(1-\alpha) \cdot 100\%$  confidence interval for the population standard deviation can be written in the following form (see Bonett, 2006):

$$\sqrt{\exp[\ln(cS^2) - Z_{1-\alpha/2} se]} \leq \sigma \leq \sqrt{\exp[\ln(cS^2) + Z_{1-\alpha/2} se]}, \quad (4)$$

Where  $c = n / (n - Z_{1-\alpha/2})$ ,  $S^2$  is the sample variance,  $Z_{1-\alpha/2}$  is the  $1-\alpha/2$  percentile of the  $Z$  distribution and  $se = c \cdot \left[ \{\bar{\gamma}_4 \cdot (n-3) / n\} / (n-1) \right]^{1/2}$ .

- The Steve large sample normal approximations confidence interval

Steve proposed the following  $(1-\alpha) \cdot 100\%$  confidence interval for the population standard deviation (see Banik et al., 2014):

$$\sqrt{\frac{S^2}{1 - Z_{\alpha/2} \sqrt{\frac{\hat{\gamma} - 1}{n}}}} \leq \sigma \leq \sqrt{\frac{S^2}{1 + Z_{\alpha/2} \sqrt{\frac{\hat{\gamma} - 1}{n}}}}, \quad (5)$$

where  $S^2$  is the sample variance,  $Z_{\alpha/2}$  is the  $\alpha/2$  percentile of the standardized normal distribution and  $\hat{\gamma} = n \cdot \sum_{i=1}^n (X_i - \bar{X})^4 / \left( \sum_{i=1}^n (X_i - \bar{X})^2 \right)^2$  is the kurtosis estimator.

- The log asymptotic approximation confidence interval (LOG CI)

The distribution of the sample variance,  $S^2$ , has the high skewness for small  $n$ . In order to reduce the skewness, Hummel et al. (2005) applied natural log to the sample variance in (5) and proposed the  $(1 - \alpha) \cdot 100\%$  confidence interval for the population standard deviation:

$$\sqrt{\left[ S^2 \exp\left( Z_{\alpha/2} \sqrt{\frac{\hat{\gamma} - 1}{n}} \right) \right]} \leq \sigma \leq \sqrt{\left[ S^2 \exp\left( -Z_{\alpha/2} \sqrt{\frac{\hat{\gamma} - 1}{n}} \right) \right]}, \quad (6)$$

Where  $Z_{\alpha/2}$  is the  $\alpha/2$  percentile of the  $Z$  distribution and  $\hat{\gamma}$  is the kurtosis estimator.

- The adjusted degrees of freedom confidence interval (ADF CI)

Hummel et al. (2005) adjusted the degrees of freedom of the exact confidence interval (3) and proposed the following  $(1 - \alpha) \cdot 100\%$  confidence interval for the population standard deviation:

$$\sqrt{\frac{\hat{r}S^2}{\chi^2_{\alpha/2, \hat{r}}}} \leq \sigma \leq \sqrt{\frac{\hat{r}S^2}{\chi^2_{1-\alpha/2, \hat{r}}}}, \quad (7)$$

Where  $\hat{r} = \frac{2n}{\hat{\gamma}_e + \left( \frac{2n}{n-1} \right)}$  and  $\hat{\gamma}_e$  is the estimate of the kurtosis excess, which is defined as

$\hat{\gamma}_e = \frac{n(n+1)}{(n-1)(n-2)(n-3)} \sum_{i=1}^n \frac{(X_i - \bar{X})^4}{S^4} - \frac{3(n-1)^2}{(n-2)(n-3)}$ . If the random sample is generated from the normal distribution, then  $r = n - 1$  and (7) reduces to (3).

The performance of all presented intervals will be considered using the SRS and the RSS. In order to get the estimators of the mean and variance of the population we will use the regular formulas for the SRS and Equations (1) and (2) for the RSS.

#### 4. CASE STUDY

In this part of the paper, we present the results of applying the proposed methods on the simulated data and real-economic data.

##### 4.1 Simulation study

In this part of our work we examine the coverage accuracy of two-sided confidence intervals for the standard deviation introduced in the Section 3. Our objective is to compare the performance of the confidence intervals for estimating the standard deviation using the SRS and the RSS. The nominal confidence level is set to 95% and we want to determine which of the proposed intervals will give the coverage probability that is the closest to 95%. For that purpose, we consider three scenarios. In the first scenario we deal with the Gamma distribution, while in the second scenario the subject of the consideration is the Log-normal distribution. In the third scenario we investigate the Exponential distribution. It is important to emphasize that we can deal with any other scenario with the other skewed distribution.

In the first scenario, we consider the Gamma distribution with the shape parameter 2 and with the scaling parameters 0.5, 1.6 and 3.2. For each combination of the parameter setting and the sample size (15, 20, 50, 80), we performed 1000 simulations. All examined intervals are implemented using the *R* programming language. In Table 2 we present the results of the coverage accuracy of 95% confidence intervals for the standard deviation of the Gamma distribution. It can be seen that for the small samples (size 15), the RSS Bonett interval gives the best results, i.e. the coverage probabilities that are the closest to 0.95 (the coverage greater than 0.932). For the moderate samples (size 20), the RSS Bonett interval gives the best coverage (below 0.961). In the case of big samples (size 50), depending on the scaling parameter of the Gamma distribution, the best coverage probabilities are obtained using the Bonett and the RSS Log intervals (the coverage greater than 0.939). For the samples of size 80, the Bonett interval and the RSS ADF interval give the best coverage accuracy (above 0.943).

**Table 2:** The coverage of 95% two-sided confidence intervals for the standard deviation of the Gamma distribution

		50	0.765	0.856	0.936	0.982	0.901	0.923	0.885	0.939	0.919	0.932
		80	0.758	0.840	0.952	0.965	0.907	0.941	0.905	0.938	0.922	0.936

In the second scenario, we deal with the Log-normal distribution with the shape parameter 2 and with the scaling parameters 0.25, 0.5 and 0.6. For each combination of the parameter setting and the sample size (15, 20, 50, 80), we generated 1000 samples. All considered intervals are implemented using the *R* programming language. In Table 3 we present the results of the coverage accuracy of 95% intervals for the standard deviation of the Log-normal distribution. For the small samples, the RSS  $\chi^2$  and the RSS Bonett intervals give the coverage probabilities that are the closest to 0.95 (above 0.924). In the case of the moderate samples, depending on the scaling parameter of the Log-normal distribution, the RSS  $\chi^2$  interval and the RSS Bonett interval give the best results (the coverage greater than 0.933). For the big samples (size 50) the best results are obtained with the Steve interval and the RSS Bonett interval (above 0.940). For the samples of size 80, the Steve, the RSS ADF, the Bonett and the RSS Bonett intervals give the coverage probabilities that are the closest to 0.95.

In the third scenario, we investigate the Exponential distribution with the rate parameters 0.5, 1.5 and 2.2. For each parameter setting and each sample size (15, 20, 50, 80), we performed 1000 simulations. All considered intervals are implemented using the *R* programming language. In Table 4 we present the results of the coverage accuracy of 95% confidence intervals for the standard deviation of the Exponential distribution. It can be seen that for the small samples, the RSS Bonett interval gives the best results (above 0.923). For the moderate samples, the RSS Bonett interval gives the best coverage (greater than 0.938). In the case of big samples (size 50) the best coverage probabilities are obtained using the RSS Bonett interval (above 0.945). For the samples of size 80, depending on the rate parameter of the Exponential distribution, the Bonett and the RSS Bonett intervals give the best coverage accuracy (above 0.942).

#### 4.2. Application to the real data

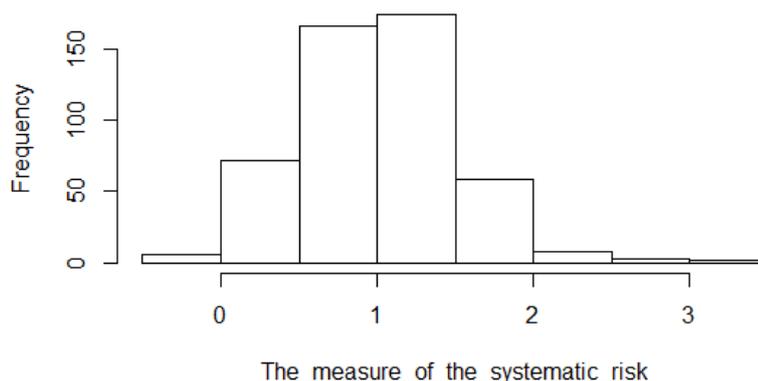

In this part of the paper, we analyze the measure of the systematic risk data in 490 companies (it is about S&P500, but there are no data for some companies) on the 5<sup>th</sup> July 2017. The data are from the website <http://finance.yahoo.com/>.

In analysis of securities, the measure of the systematic risk (beta) takes a central place. The measure of the systematic risk represents the measure of the sensitivity of the yield of the securities to the changes in the yield on the market. Beta shows that if the yield on the market changes by one percent, by how many percentage points the yield of the securities will change.

Descriptive statistics for the analyzed data are given in Table 5. Figure 1 represents the histogram of the analyzed variable. We can see that the measure of the systematic risk is not normally distributed. Also, we used the Shapiro-Wilk normality test to examine whether the beta was normally distributed. The test showed the same result as the histogram ( $p$ -value is approximately 0).

**Table 5:** Descriptive statistics for the data set

Variable	N	Mean	Std. deviation	Skewness coef.
The measure of the systematic risk	490	1.02	0.52	0.43

**Figure 1:** Histogram of the measure of the systematic risk

Results of the coverage accuracy of 95% confidence intervals for the standard deviation of the data set are given in Table 6. It can be seen that for the small samples, the RSS  $\chi^2$  interval gives the best coverage (0.945). For the moderate samples, the RSS ADF interval gives the coverage that is the closest to 0.95. For the samples of size 50, the RSS Steve interval is the best choice and in the case of the samples of size 80, the ADF interval gives the best coverage accuracy (0.946).

**Table 6:** The coverage of 95% two-sided confidence intervals for the standard deviation: the data set

$n$	$\chi^2$	RSS $\chi^2$	Bonett	RSS Bonett	Steve	RSS Steve	Log	RSS Log	ADF	RSS ADF
15	0.934	0.945	0.962	0.975	0.811	0.833	0.839	0.879	0.907	0.919
20	0.918	0.924	0.972	0.977	0.878	0.893	0.873	0.898	0.926	0.935
50	0.921	0.943	0.976	0.986	0.919	0.955	0.904	0.920	0.921	0.943
80	0.911	0.921	0.971	0.968	0.938	0.931	0.913	0.915	0.946	0.938

## 5. CONCLUSIONS

In this paper, we used the simple random sampling and the ranked set sampling to compare the coverage probabilities of confidence intervals for the population standard deviation. The exact confidence interval, the Bonett, the Steve large sample normal approximations, the log asymptotic approximation and the adjusted degrees of freedom confidence intervals were examined.

In the first scenario, we investigated the Gamma distribution. For the small and moderate samples, the RSS Bonett interval gave the coverage probabilities that were the closest to 0.95, whereas for the big samples the Bonett, the RSS Log and the RSS ADF intervals gave the best results. In the second scenario, we dealt with the Log-normal distribution. For the small and moderate samples, the best results were obtained using the RSS  $\chi^2$  and the RSS Bonett intervals. In most cases, for the big samples, the Steve interval and the RSS Bonett interval gave the best coverage. In the third scenario, we considered the Exponential distribution. For the small and moderate samples, the RSS Bonett interval was the best choice, whereas for the big samples, the Bonett and the RSS Bonett intervals gave the best results.

The analysis of the real data showed that for the small samples, the RSS  $\chi^2$  interval gave the best coverage accuracy, while for the moderate samples the best choice was the RSS ADF interval. For the big samples, the RSS Steve and the ADF interval gave the best results. We can see that using the RSS gives much better coverage probabilities, so we recommend using it when construct the confidence intervals for the population standard deviation.

\*Corresponding author, e-mail: cvetkovic.nikola@fon.bg.ac.rs

**Abstract:** *As the human population is growing day by day, need for food is growing. However, possibilities for arable land are limited; it is necessary to improve the process of food production on the arable surfaces and use its full potential. With the development of remote sensing, it is possible to obtain information about agriculture surface without physical contact. Attention is devoted to monitoring the condition of crops and making different decisions based on the obtained data information in the electromagnetic spectrum. This paper presents an algorithm for detection of crop stress in the field using remote sensing. The algorithm is based on the extraction of vegetation indices from the image and comparing histogram of vegetation indices values of a healthy crop with all segments of the image. In this way, it is possible to notice the difference in vegetation indices between the healthy crop and stressed area.*

**Keywords:** *remote sensing, stress detection, agriculture, vegetation index, the algorithm*

### 1. INTRODUCTION

We live in the world where the current situation of global food security is one of the main issues. The balance between constantly growing food demand of the world population and global food production is alarming. From year to year, it is necessary to produce more food and raw materials which will be used in the further process of production, to feed growing population. As the climatic changes have a major impact on the production process, more efficient and acceptable production methods should be used. Given that the arable land has less, we must use their potential in the best possible way. Authors (Strange & Scott, 2005) explained that plant protection in general and the protection of crops against plant diseases in particular, have an obvious role to play in meeting the growing demand for food quality and quantity. Oerke, E.C., (2006) discovered that pathogens, animals and weeds, as direct yield losses are altogether responsible for losses between 20 and 40 % of global agricultural productivity. Zadoks, J. C., (1967) explained that crop losses due to pests and pathogens are direct, as well as indirect and they have some facets, some with short-term, and others with long-term consequences. Since the agricultural areas are very large, usually it is not possible to survey the whole field and detect all plant diseases. With the development and expansion of remote sensing in agriculture and using Unmanned Aerial Vehicles (UAVs) as part of it, this problem is overcome. Since every object on the earth, due to solar radiation, radiates the energy of a part of the electromagnetic spectrum, using remote sensing it is possible to obtain information of the observed part of the field that carries part of the electromagnetic spectrum. Analyzing changes in the spectrum are noticed. By measuring these changes and studying their relationships, information on plant health is obtained.

The literature about the use of remote sensing is extensive. It is used in various fields to obtain images without physical contact to object. Suresh, S. et al. (2018) explained how to improve remote sensing process by collecting better quality images from the satellite. Remote sensing found the application in different areas like geology, hazard assessment, oceanography, construction etc. In one paper, Rathje and Franke, (2016) found the use of remote sensing in geotechnical earthquake reconnaissance to document damage patterns and measure ground movements. Thus, the most important application was found in agriculture. The benefits of using remote sensing in agriculture over traditional were described on nitrogen stress detection in wheat by Wright Jr., D. L. et al. (2005). With the appearance of Unmanned Aerial Vehicles, use of remote sensing has experienced an expansion. Many authors (Konar & Iken, 2017; Omar et al., 2017; Xue et al., 2016) presented various possible areas of UAV's application and their benefits, such as intertidal monitoring, concrete bridge decks surveying and development of automatic aerial spraying systems. Remote sensing application in agriculture was found thanks to multispectral images used for extraction of vegetation indices. Berni, J. et al. (2009) explained how to extract information about vegetation and plant stress using multispectral images. McDonald, A. J. et al. (1998) evaluated different vegetation indices obtained with multispectral images on coniferous forests. Combination of the multispectral image and variable rate technology in remote sensing was used to detect tree health problems and application of a pesticide in the citrus production, as described by Du., Q. et al. (2008).

In agriculture, remote sensing is used for a variety of purposes. Ballesteros, R. et al. (2014) noticed that remote sensing high-resolution images with proper treatment might be considered as a useful tool for precision in monitoring crop growth and development, water requirements, yield production, weed and insect infestations, among others. Vegetation indices, there are a lot of possibilities for monitoring condition of the field. Gitelson and Merzlyak (1998) used vegetation indices to determine the concentration of chlorophyll in higher plant leaves. Zhuang, S. et al. (2017) also used them to determine water stress in early phases. For stress detection in the field, in many papers, k-means is used for classification. Badnakhe and Deshmukh (2011) applied k-means clustering with AI to detect crop diseases. Also, Cheng, H. et al. (2013) presented k-means for image segmentation in their paper. Further research has found that there are many algorithms for stress detection, usually specialised for a particular type of stress.

Paper is organised as follows. After the introduction, Section 2 is devoted to the methodology and algorithm used for stress detection. Section 3 refers to the application of the stress detection algorithm on a wheat field. In Section 4, there is a conclusion and directions for further research.

## **2. METHODOLOGY**

Remote sensing is the process of collecting information about an object or phenomenon without making physical contact with the observed phenomenon or object. It is a phenomenon that has numerous applications including photography, surveying, geology, forestry and other. Also, because of its ability to collect information about the huge area for less time and without physical contact, the remote sensing has found significant use in agriculture. There are very many applications of remote sensing in a field of agriculture like crop production forecasting, crop detection, identification all types of stress. In the field of agriculture, using unmanned aircraft sensor, the object is recorded, which is, in this case, the earth's surface with the plant cultures. It is possible to determine plant stress using changes of the electromagnetic spectrum.

Plant stress is manifested as any state of the biological system that deviates from the optimum. Different intensity and length of negative effects affect the severity of stress, which always leads directly to a decrease in yield and quality of crops below the genetic potential. Stress causes a large number of natural and factors that are caused by man's actions. Some of the types of stress that are most commonly represented are stress from low temperature, stress from excess water, city and storms, stress from pesticides, whiskey mites, insects and plant diseases. It is thought that 90% of plant production worldwide is endangered by stress and that it has an increasing impact.

The algorithm for field stress detection using remote sensing shown in this paper consists of three main parts. First part includes the preparation of data, an image acquiring using unmanned aerial vehicles (UAV). The second part is pre-processing, which consists of selecting samples from the acquired image, selection of vegetation indices and extracting them, and input values for clusters. The last phase is processing of the image by comparing vegetation indices values of each image segment with the vegetation indices values obtained from samples and put it in the appropriate cluster defined in part two. Each part of the algorithm is explained below in more detail.

### **2.1. Preparation phase**

The data preparation phase involves the process of collecting images from the air. One of the most advanced remote sensing technologies today is the use of UAVs equipped with a camera. This way, in a very quick and easy way, images of a certain surface are suitable for precision agriculture. Gathering images from the air is one of the essential steps of the entire image analysis process. When taking a certain surface, it is necessary to take care of more details to obtain a picture that is appropriate for the further analysis process. Image quality depends on several factors such as camera specifications, weather conditions and flying altitude.

In remote sensing in agriculture, several types of cameras are used to capture fields such as thermal camera, RGB and NIR cameras. Thermal technology is not so often used to getting images from the air because of low spatial and temporal resolution, low shooting and high price. Color RGB (Red, Green, Blue) present images that most closely represent how human eye would see a field from a plane. The advantage of this image type is that RGB is available from most aerial imaginary platforms. Thus, it has certain limitations. Generally, the crop needs to be significantly stressed to see a visual difference that can be identified in a colour image. Also, colour imaginary provides little opportunity to distinguish small differences in areas of high yield. RGB images are suitable for extraction of VARI and ExG vegetation indices. Near-infrared (NIR) imagery provides a greater assessment of plant health than traditional photos by visualising colour bands outside of what the human eye can see. It uses a false colour composite to display information that would normally be invisible to the human eye. The NIR map shows areas of highly vigorous crops in

bright red and weak crops or bare soil in grey. The most used image type in agriculture is Normalized Difference Vegetative Index (NDVI). This image type is often obtained using BNDVI filter, and the present calculated index used to monitor crop health and photosynthetic activity.

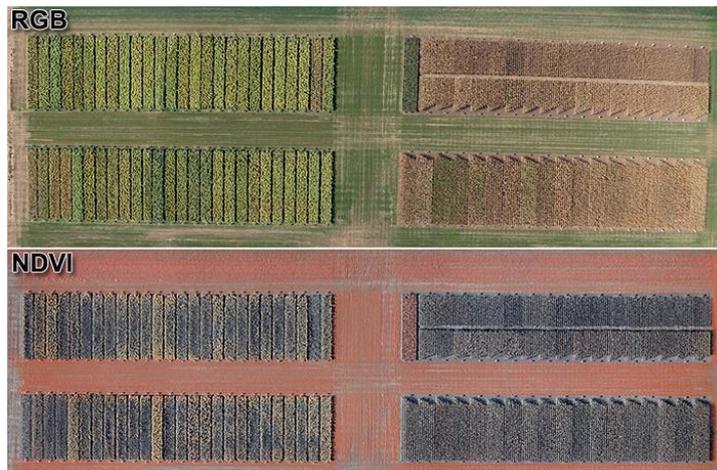

Figure 1: RGB and NDVI images of the field

## 2.2. Pre-processing phase

After image acquiring, it is necessary to select samples from the image of the field. The samples should be selected that represent a healthy plant crop. To achieve the efficiency of the algorithm, it needs to select at least ten samples.

Vegetation interacts with solar radiation in a different way than other natural materials. The vegetation spectrum typically absorbs in the red and blue wavelengths, reflects in the green wavelength, strongly reflects in the near-infrared (NIR) wavelength, and displays strong absorption features in wavelengths where atmospheric water is present. Different plant materials, water content, pigment, carbon content, nitrogen content, and other properties cause further variation across the spectrum. Measuring these variations and studying their relationship to one another can provide meaningful information about plant health, water content, environmental stress, and other important characteristics. These relationships are often described as vegetation indices.

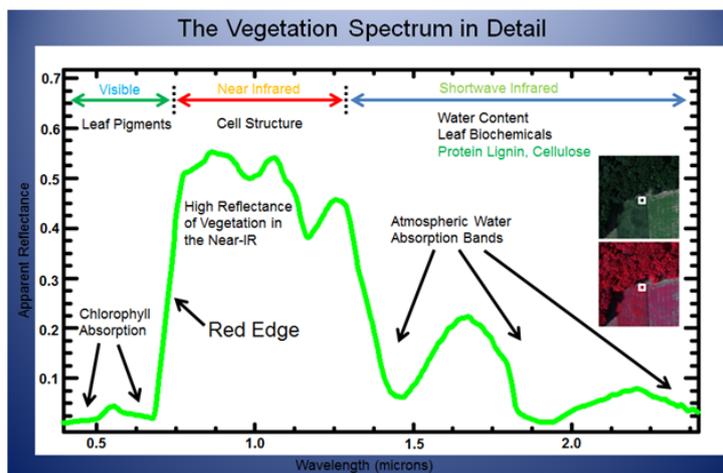

Figure 2: Vegetation Spectrum

The Normalized Difference Vegetation Index (NDVI) is perhaps the most well-known and often used vegetation index. It is a simple, but effective VI for quantifying green vegetation. The NDVI normalises green leaf scattering in the near-infrared wavelength and chlorophyll absorption in the red wavelength. The value range of an NDVI is -1 to 1 where healthy vegetation falls between values of 0.20 to 0.80. The vegetation atmospherically resistant index (VARIGreen) is based on the Atmospherically Resistant Vegetation Index (ARVI) and is used to estimate the fraction of vegetation in a scene with low sensitivity to atmospheric effects. The Excess Green Index (ExG) provides a near-binary intensity image outlying a plant region of interest, from which a segmentation can be accomplished with a suitable threshold.

Depending on the type of image (RGB or NDVI, plant species and type of possible stress, the appropriate vegetation index is selected to be extracted from each sample. The process of vegetation index extraction is following: every sample is divided into a certain number of segments (depending on the spatial resolution of the image), and vegetation index value is calculated. After that, for each sample, a histogram of segment vegetation indices is made. Passing through all the samples and calculating vegetation index histograms, one histogram which represents their average is calculated, and it will be used as a benchmark for the healthy plant for processing phase.

K-means is a widely used clustering algorithm in remote sensing for segmentation. The K-means clustering algorithm tries to classify objects based on a set of features into K number of classes. The classification is done by minimising the sum of squares of distances between the objects and the corresponding cluster or class centroid. Experimental results demonstrate that improved k-means clustering algorithm can reduce the computation amounts and enhance precision and accuracy of clustering (Ballesteros, R. et al., 2014). Thus, using k-means in many cases, it is not able to clearly distinguish a healthy plant from all types of stress in the field. The algorithm overcomes this problem explained in this paper. In the last step of pre-processing phase, the range of values of each cluster is entered. The algorithm is using three predefined clusters which represent: healthy plant, potential stress and stress in the field. Entered values should include a range of 0-100 which represents the percentage of overlapping histograms, so they do not match.

Example of cluster range:

- Healthy plant: 80-100% overlap
- Potential stress: 60-80% overlap
- Stress: 0-60% overlap

With vegetation index benchmark histogram calculated and entered cluster range values, the last phase of the algorithm is accessed.

### **2.3. Processing phase**

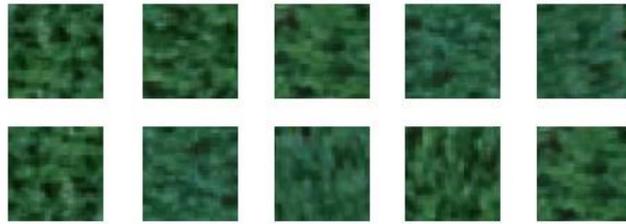

Image processing phase is the finishing step of an algorithm for stress detection. Segments of the image are compared with it and depend on the percent of overlapping, clustered in one of the predefined clusters using benchmark vegetation index histogram.

In this phase, the whole image is divided into equal size segments (usually size  $1\text{m}^2$ ). Then, passing through each image segment, the histogram value of extracted vegetation index is calculated. By comparing the resulting histogram with the benchmark histogram, the percentage of the overlap is determined. Depending on this percentage, the segment will be classified to a particular cluster which includes an overlapping percentage. After classification of all image segments process of stress, detection is finished, and every segment of the image contains information to which cluster belongs. In this way, stress detection has been determined, and the data is ready for further processing and decision making.

## **3. CASE STUDY**

Wheat is one of the most important plants used in the everyday nutrition of people. As the world is harvesting more than 218 million hectares, it is very important that crops are healthy to meet the people needs. Since it is a highly sensitive plant, various insect species can very often harm her. Also, black rust and ash are some of the diseases that can affect the crop due to the action of various insects and microorganisms. All of this points to the importance of monitoring these changes that affect the plant itself. Stress detection algorithm described in the previous section will be applied to the wheat field.

Image acquiring process was carried out by passing and 8.9 ha field of wheat located in the Sutton Bridge, United Kingdom. Aerial images are collected flying 70m from the ground, using DJI's drone, Phantom 4 Advanced. It is equipped with integrated still visible-light camera (RGB) with 20 megapixels objective and 3-axis gimbal stabilisation. After collection of images, stitching software is used to format picture of the whole field.

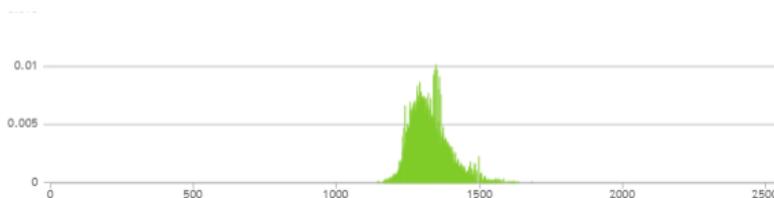

**Figure 3:** Healthy wheat sample images

After image stitching, next step is a selection of samples which represent a healthy plant. Ten samples size of 1m<sup>2</sup> is selected from the field image, and shown in Figure 3. For each sample, vegetation indices will be extracted. Since the image was collected using an RGB camera, the most appropriate vegetation index for stress detection of wheat is The Excess Green Index (ExG) which is calculated in the following manner:

$$ExG = 2g - r - b \quad (1)$$

$$r = \frac{R}{R + G + B} \quad g = \frac{G}{R + G + B} \quad b = \frac{B}{R + G + B} \quad (2)$$

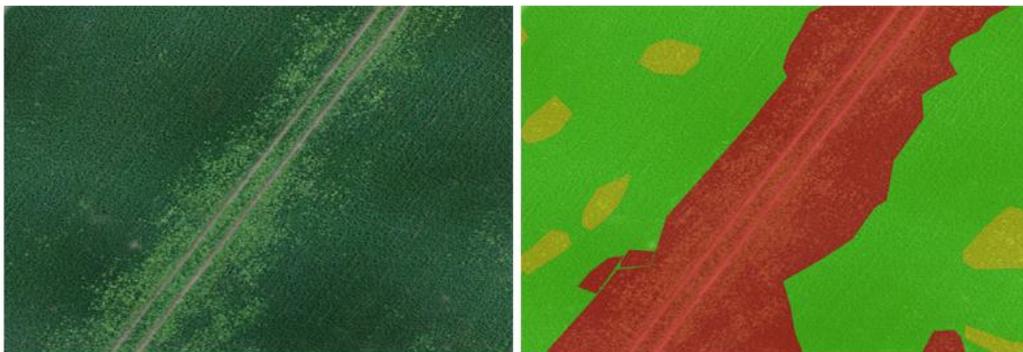

Each sample is then split into 10x10 segments, and ExG vegetation index is calculated for all of them. After creating histograms of vegetation index values for all samples, an average histogram was obtained which will be used as a benchmark in the processing phase.

**Figure 4:** Benchmark vegetation index histogram

Before accessing image processing, cluster range values should be entered for percentages of overlapping. The empirical research found that the algorithm gives the best results for cluster values: Good (80-100% overlap of the histogram), Potential stress (50-80%) and Stress (0-50%).

When the cluster range values are defined, and benchmark histogram is calculated, the image processing step is accessed. Using software for image processing, by passing through each segment of the image, vegetation index histogram is calculated and then compared to benchmark histogram. Depend on the overlapping percent; the segment is classified to the appropriate cluster. In Figure 5, the original image, and image with classified segment are displayed by cluster colours. In the right picture, healthy plant is displayed with green colour, potential stress with a yellow and stressed area with red.

**Figure 5:** Original image and image with a clustered area

The stress detection algorithm has identified the areas that are affected by stress and need to be rehabilitated, as well as areas with potential stress to which attention should be paid.

## 4. CONCLUSION

It is possible to influence the health of the plants and yield significantly using and improving various algorithms for stress detection in the field with remote sensing. The algorithm shown in this paper is very convenient to display generalised stress in the field. With geographic information system (GIS), used to capture, store, manipulate, and present geographic data, it is possible to extract georeferenced data for each segment of the field. From these data, in a very easy way, exact coordinates of areas that are under stress should be extracted, and then healed appropriately. In the future, emphasis should be placed on comparing this algorithm with existing ones, with the aim of improving it. Also, the focus should be on possibilities of integration the data obtained with this algorithm with GPS based technologies.

# CRYPTOCURRENCY PRICE FORECASTING USING TIME SERIES AND MONTE CARLO MODELING AND SIMULATION

Nikola Zornić\*<sup>1</sup>, Aleksandar Marković<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, e-mail: Nikola Zornić, nikola.zornic@fon.bg.ac.rs

**Abstract:** *Over the recent years cryptocurrencies have attracted a significant amount of attention. Everything started with Bitcoin and built up to the situation where we have over 1500 cryptocurrencies. Cryptocurrency market is the new stock market. Highly volatile, decentralised, open, widely accessible market. In this paper we will employ time series analyses together with Monte Carlo simulation to build financial simulation model for forecasting the price, analysing profitability and risk for some of the most popular cryptocurrencies. Although the cryptocurrency market has massive oscillations, any contribution to modeling its value increases the awareness of potential profits and losses.*

**Keywords:** *cryptocurrency, time series, simulation, model, Monte Carlo, profitability*

## 1. INTRODUCTION

Cryptocurrencies can be defined as digital, computer currencies whose implementation stands on the principles of cryptography, both to validate the realised transactions and to enlarge the currency in circulation (Cocco, Concas, & Marchesi, 2017).

The most well-known and widely used cryptocurrency is Bitcoin (BTC). At the same time, this cryptocurrency has the highest market valuation, usage, merchant acceptance and popularity (Hayes, 2015). Bitcoin was introduced in 2009, as the first decentralised digital currency platform, a currency which does not have a central authority to regulate its usage, validate, and settle transactions (Gandal & Halaburda, 2016).

Following Bitcoin's footsteps, other cryptocurrencies were launched (Iwamura, Kitamura, & Matsumoto, 2014). Everyone can create its own cryptocurrency in minutes (Long, 2018). All cryptocurrencies formed after Bitcoin are called altcoins. Some of the most popular altcoins are Ethereum (ETH), Litecoin (LTC), Ripple (XRP), Zcash (ZEC), and Monero (XMR).

Bitcoin is one of the most studied cryptocurrencies, many authors analysed its pros and cons. Barber, Boyen, Shi, and Uzun (2012) pointed to several problems with Bitcoin, such as technical vulnerability, potential deflationary spiral, accidental loss of bitcoins, and malware attacks. Yermack (2013) analysed Bitcoin price against fiat currencies and showed that its volatility undermines its usefulness as a currency. Baek and Elbeck (2015) presented strong evidence to suggest that Bitcoin volatility is internally (buyer and seller) driven – leading to the conclusion that the Bitcoin market is highly speculative. Urquhart (2016) showed that Bitcoin market returns are significantly inefficient if observed at once, on the whole sample, but when sample is split into two subsample periods, test indicate that Bitcoin is efficient in the latter period. Bitcoin showed vast success and popularity since its creation (more in the recent years), thanks to its added value. Namely, some of the most important pros of Bitcoin are anonymity, decentralised nature, enhanced revenue, and use of proof-of-work mechanisms (Moore & Christin, 2013).

Cryptocurrencies have not been a topic of great interest for scientific papers until recently. Namely, only 193 articles have been published by the end of 2017 in journals indexed on Clarivate Analytics Web of Science Social Sciences Citation Index (SSCI) and Science Citation Index Expanded (SCIE) with the topic "cryptocurrency" OR "bitcoin" (Clarivate Analytics, 2018). Most of the authors tried to determine which factors influence the cryptocurrency price, trade volume, and volatility. Kristoufek (2013), for example, showed that there is a connection between the search queries and the Bitcoin price. Glaser, Zimmermann, Haferkorn, Weber, and Siering (2014) studied whether the reason for interest in cryptocurrencies on Wikipedia is looking for the new investment asset or the usage as currency itself. The result of the study showed that most of the interest is due to the asset aspect. It will be interesting to investigate their value if they ever become usable for their primary purpose – as medium of exchange for goods and services. Although concept of digital currency would highly increase efficiency of payments in digital world, it currently involves high risk for both consumers and businesses, due to its value instability.

This paper presents steps in modelling the cryptocurrency price and trying to forecast it. The first step was to apply time series analyses for fitting the cryptocurrency historical price data using specific time series model. Afterwards, the resulting function is used for forecasting the price with the help of Monte Carlo simulation.

After defining cryptocurrency and short literature review, in section two, the process of collecting data and building the model is presented. In the same section, the example of investment profitability analyses is demonstrated using the developed model as a framework and running simulation experiments. The results are analysed afterwards. Finally, in section three, conclusion and some future directions of the research are provided.

## 2. CRYPTOCURRENCY INVESTMENT SIMULATION MODEL

Three most popular cryptocurrencies have been chosen for building the model for forecasting cryptocurrency price: Bitcoin, Ethereum, and Litecoin. Data has been collected for the daily closing price in USD (\$) for each of them. Bitcoin data covers the period from 17.07.2010 to 29.04.2018 (CryptoCompare, 2018a), Ethereum from 07.08.2015 to 29.04.2018 (CryptoCompare, 2018b) and Litecoin from 24.10.2013 to 29.04.2018 (CryptoCompare, 2018c). There are a lot of online cryptocurrency historical price databases, but CryptoCompare is selected as the one that has prices for all the mentioned cryptocurrencies. Simple descriptive overview of the data is presented in Table 1.

We can see that Bitcoin price has grown from an average of \$0,14 in 2010 to \$9.883,01 in 2018. The rate has been even higher for some periods of time, reaching the maximum value of \$19.345,49 on 16.12.2017. Ethereum and Litecoin saw excessive growth in value, too.

**Table 1:** Cryptocurrency prices

Year		Bitcoin price [\$]	Ethereum price [\$]	Litecoin price [\$]
2010	Days	168		
	<b>Mean</b>	<b>0,14</b>		
	Std. Dev.	0,09		
2011	Days	365		
	<b>Mean</b>	<b>5,64</b>		
	Std. Dev.	5,62		
2012	Days	366		
	<b>Mean</b>	<b>8,29</b>		
	Std. Dev.	3,21		
2013	Days	365		69
	<b>Mean</b>	<b>200,15</b>		<b>16,75</b>
	Std. Dev.	260,77		12,96

Eleven time series algorithms have been employed on cryptocurrencies prices using Palisade @RISK 7.5.2 plug-in software for Microsoft Office Excel 2016. @RISK features automatic detection of required transformations to achieve stationarity. Each algorithm used logarithmic data transformation and first-order detrend. There have not been need to de-seasonalize the data. Akaike Fit (Akaike information criterion – AIC) and Bayesian Fit (Bayesian information criterion – BIC) are used as quality measures for time series fit. Results for the best ranked algorithms for each cryptocurrency are presented in **Error! Reference source not found.**

AR2 – the autoregressive model showed the best result for representing Bitcoin price, and it will be used for creating the financial model for cryptocurrency profit analyses. This fit is presented in Figure 1, together with parameters for AR2 @RISK function.

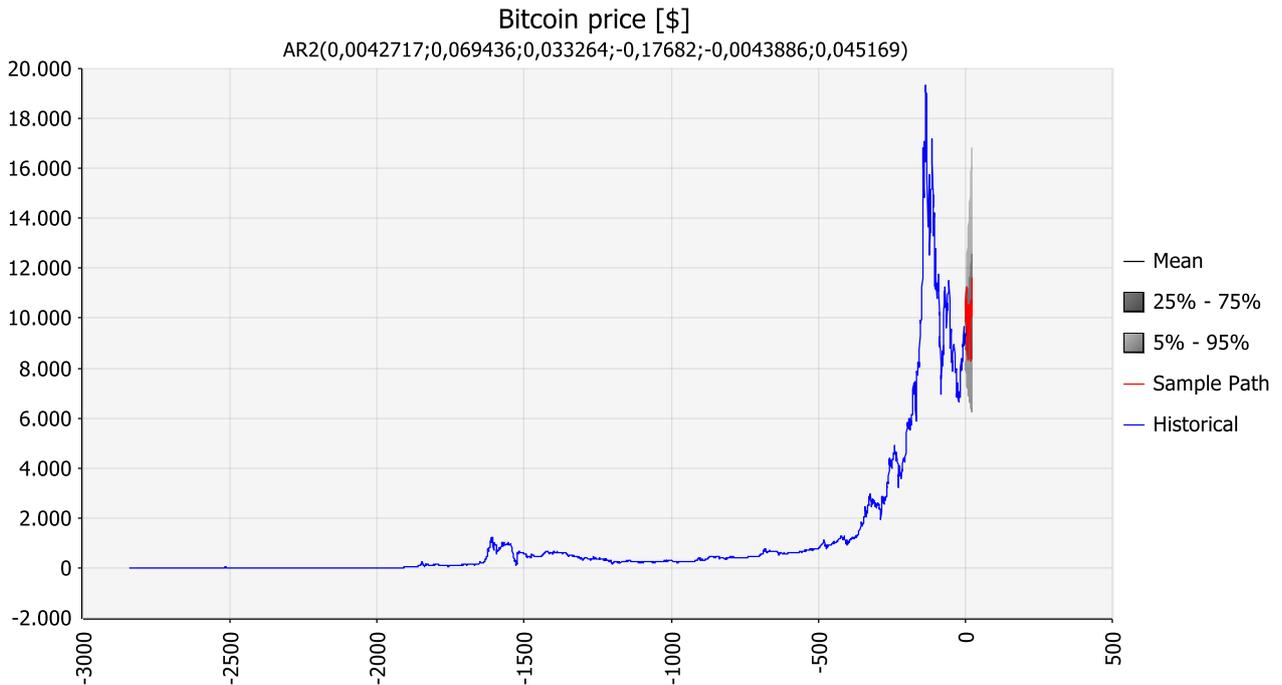

Figure 1: AR2 time series for Bitcoin price

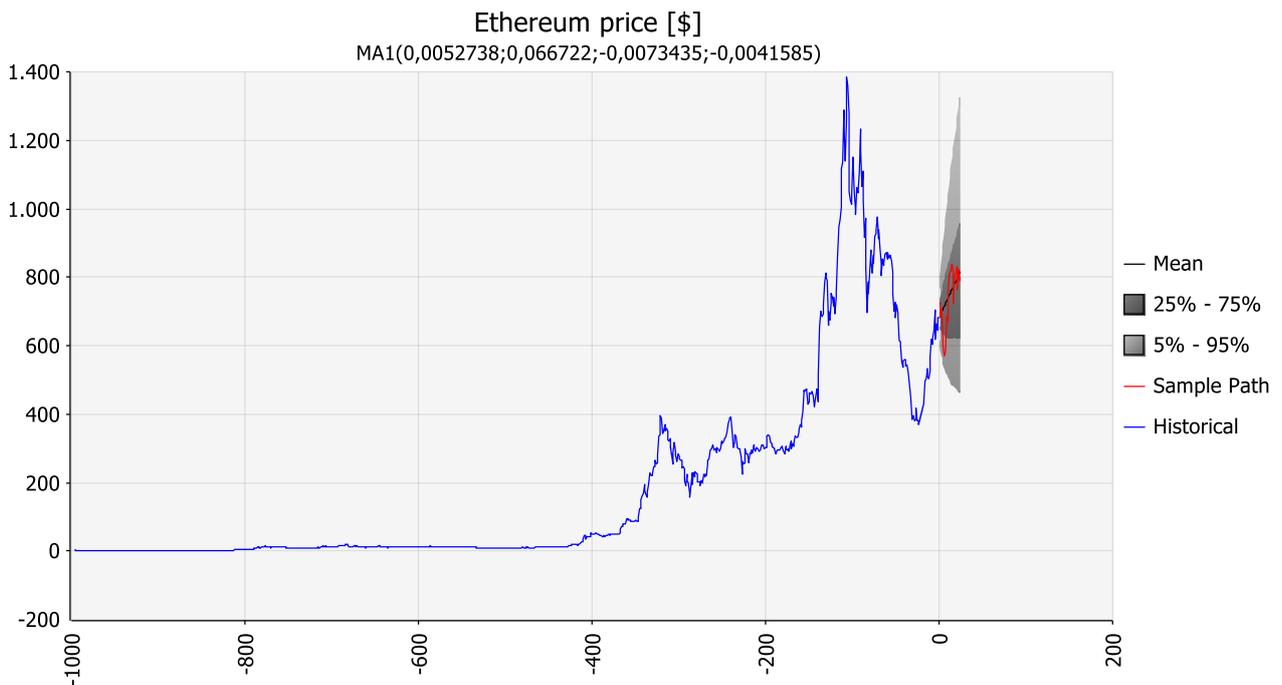

Figure 2: MA1 time series for Ethereum price

MA1 – moving average model showed the best results for representing Ethereum price according to both quality measures, and it will be used for simulating price in the financial model. This fit is presented in Figure 2, including parameters for MA1 @RISK function.

GARCH – generalised autoregressive conditional heteroskedasticity model is selected for representing Litecoin price trend. It has been ranked as the best one according to both quality measures, and it will be used for simulating price in the financial model. This fit is presented in Figure 3, as well as parameters for GARCH @RISK function.

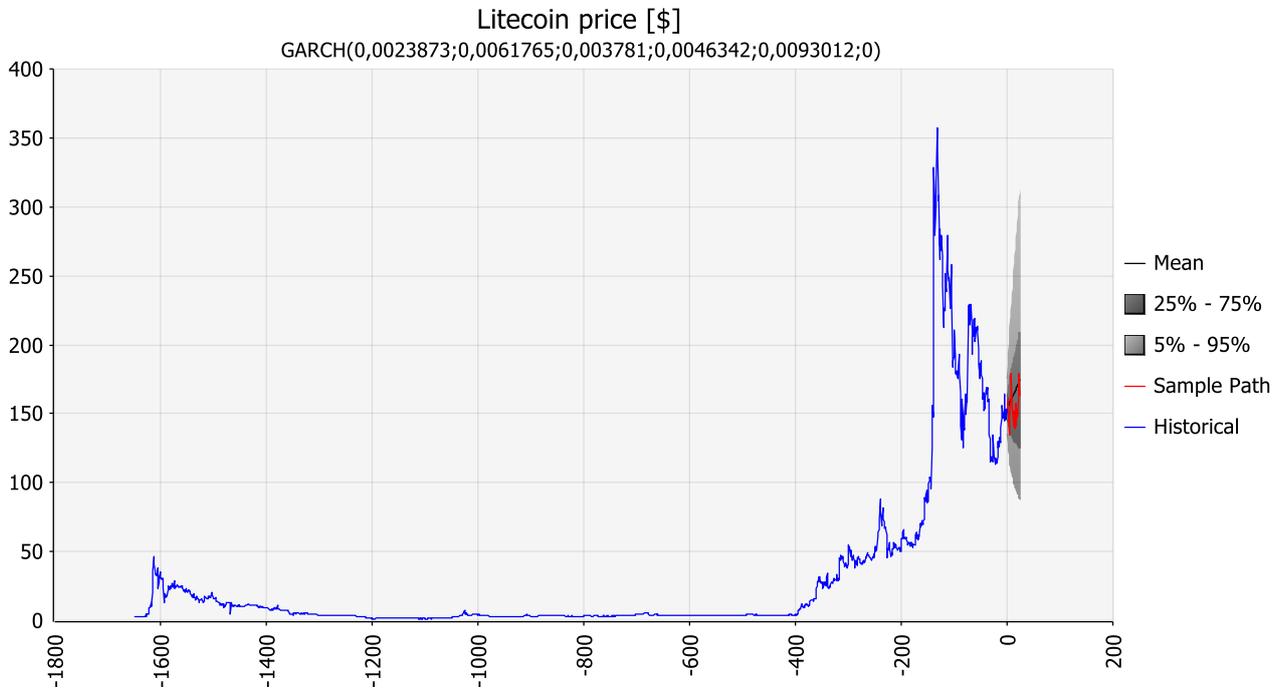

Figure 3: GARCH time series for Litecoin price

We will analyse a hypothetical situation where \$10.000 is invested in each observed cryptocurrency on 29.04.2018 (Figure 4 – yellow fields are for input variables, blue for calculation steps, and green for output). Based on the investment, quantity of each cryptocurrency bought is calculated. In the next step, three time series fit functions are used for generating market price on 29.05.2018. Afterwards, the new cryptocurrency value and profit are calculated. Note that RiskOutput() is used for setting the profit as simulation output variable.

	A	B	C	D	E	F	G	H
1	Cryptocurrency	Price [29.04.2018]	Quantity	Investment [29.04.2018]	Price [29.05.2018]	Value [29.05.2018]	Profit	Profit [%]
2	Bitcoin	\$ 9.310,52	1,07	\$ 10.000,00	\$ 11.139,58	\$ 11.964,51	\$ 1.964,51	19,65%

Figure 4: Predicted cryptocurrency profit

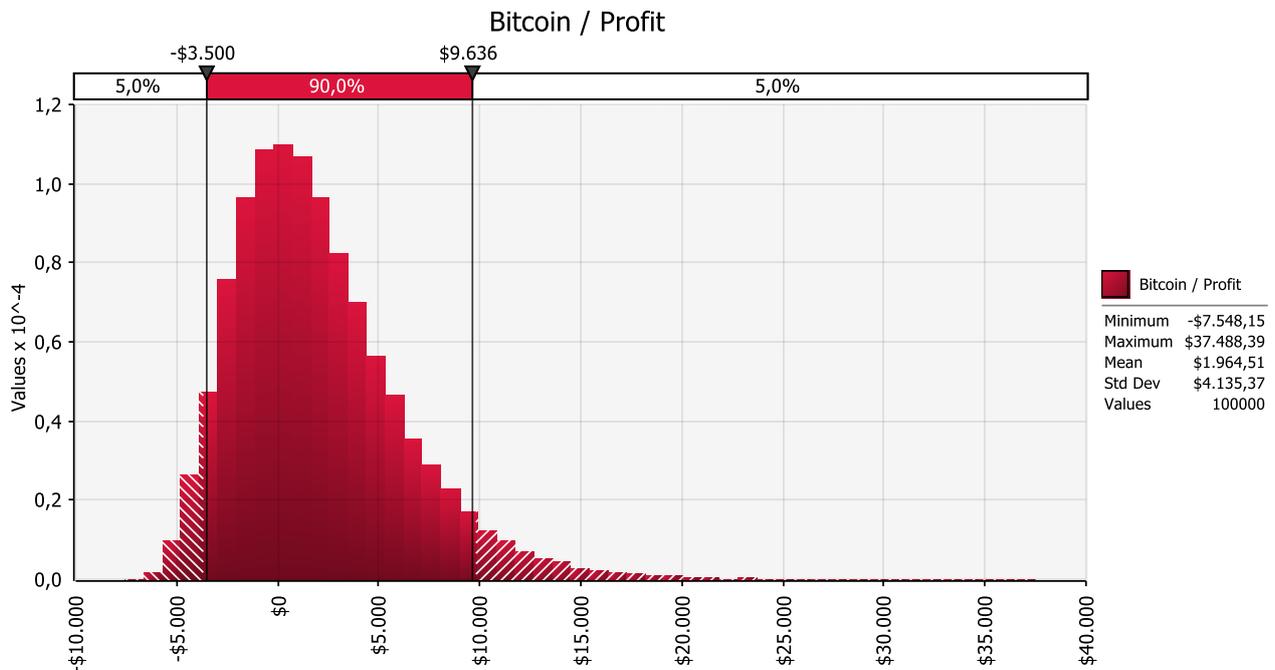

After building the model, simulation is conducted using @RISK software with 100.000 iterations (Figure 5).

In each iteration, the cryptocurrency price on 29.05.2018 is generated using the selected time series model, other values are calculated and results are saved in database. When the simulation is finished, results are presented in form of probability distributions with extensive statistical indicators.

**Figure 5:** @RISK Monte Carlo simulation

We can say that investment into any cryptocurrency involves high risk, as the market is highly volatile (Yermack, 2013). Our results showed that the average profit on Bitcoin investment on 29.05.2018 should be \$1.964,51, with a standard deviation of \$4.135,37. Highest losses are set at \$7.548,15 and the highest profit at \$37.488,39. If we take a look at Figure 6, we can see that the profit will be between -\$3.500 and \$9.616 with 90% chance. Results for Ethereum and Litecoin are analysed in a similar manner.

**Figure 6:** Bitcoin profit

Based on the current market situation and our predictions, Ethereum shows the highest potential for growth and profitability (Figure 7). Namely, mean profit on an investment of \$10.000 into Ethereum is \$2.524,90, and the maximum possible profit is \$46.346,79.

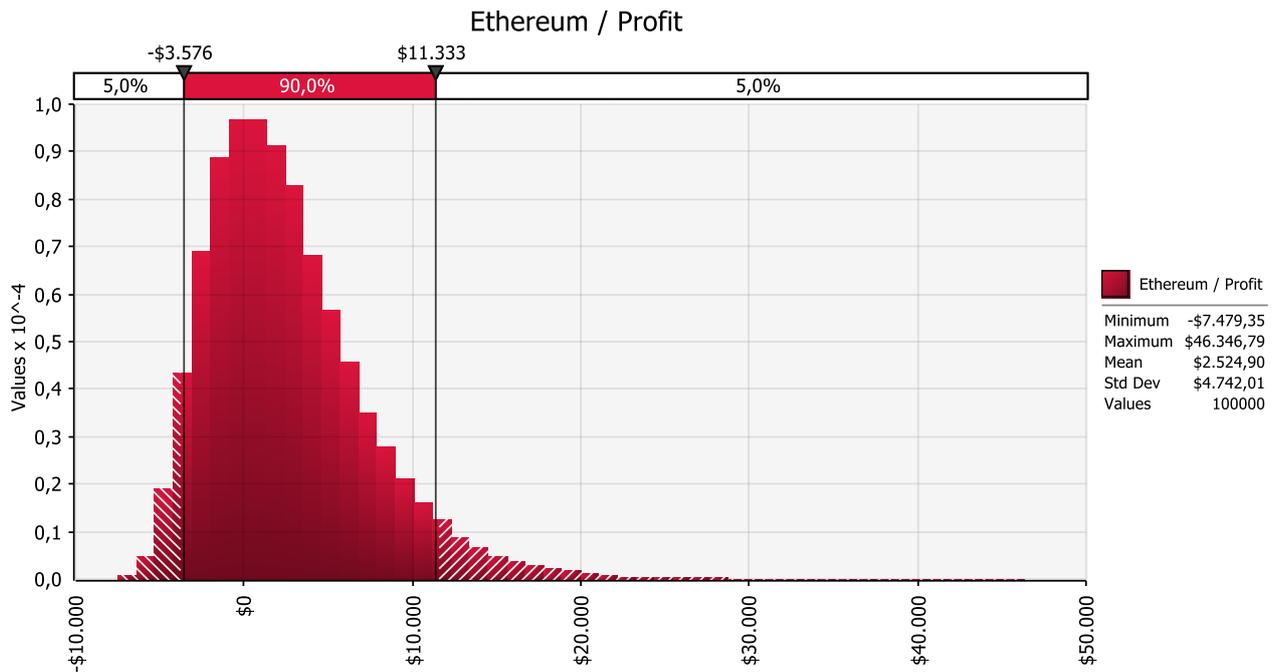

Figure 7: Ethereum profit

Litecoin carries the highest risk (Figure 8), with highest standard deviation and highest possible losses, but also it has the highest potential profit of \$71.228,63.

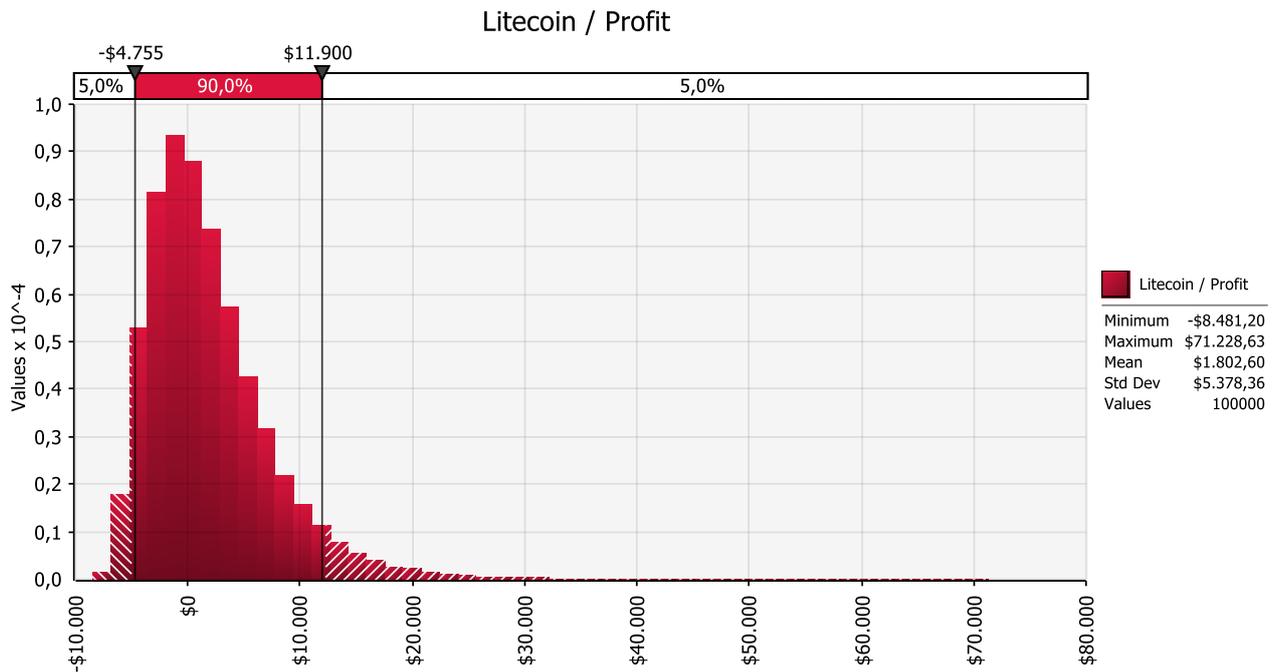

Figure 8: Litecoin profit

### 3. CONCLUSION

Cryptocurrency popularity is inevitably rising (Cheah & Fry, 2015). Our aim in this paper was to make a step towards equipping individual investors with a model for cryptocurrency price analyses using well-known time series analyses and Monte Carlo simulation.

To encourage other researchers on modelling and forecasting cryptocurrency price, the data sources and widely accessible tools for analyses are suggested. Afterwards, the model is created using the mentioned methodologies. Additionally, the model is employed on the example of investment and results are analysed.

Bitcoin price is prone to speculative bubbles and the bubble component contained within Bitcoin price is substantial (Cheah & Fry, 2015; Fry & Cheah, 2016). The market is highly volatile, but any kind of information gathering and analyses are giving higher insight into the possible price trends. Combination of time series with Monte Carlo simulation gives the investor possibility to analyse potential price in terms of probabilities and statistical indicators.

Monte Carlo simulation results for the three observed cryptocurrencies show high investment risks, but also high potential profits. Ethereum emerged as the cryptocurrency with highest mean and potential maximum profit, while Litecoin has the lowest mean profit and highest maximum losses. Bitcoin is in the middle, with lowest standard deviation, and solid mean profit.

During the research, we identified several future directions of the study. Firstly, the built model can be enabled with portfolio optimisation features. This would significantly reduce potential investors' risk and make investing more tempting. The other direction is regarding the number of cryptocurrencies analysed. The model can be simply expanded to involve a higher number of cryptocurrencies, especially the new and rising ones.

# STATISTICAL AND SOFT COMPUTING TECHNIQUES IN AIRLINE INDUSTRY – A LITERATURE REVIEW

Nikola Vojtek<sup>\*1</sup>, Ana Poledica<sup>2</sup>, Bratislav Petrovic<sup>3</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

<sup>\*</sup>Corresponding author, e-mail: vojtekn@gmail.com

**Abstract:** *Statistical and soft computing techniques are widely used in airline industry for processing a large amount of data and assisting in the decision making process, since they are capable to capture both internal and external factors. Depending on the data, presence of vagueness, uncertainty and model existence, statistical and soft computing techniques could be applied in various processes. Aim of this paper is to provide the analysis of the literature covering the usage of these techniques in airline industry. We reflect on 44 papers published in a period 1961-2018. It consisted of 3 stages: initial analysis (publishing year), brief analysis of proposed methods and identification of operations/business processes. Results are indicating an extensive usage of statistical techniques. However, due to the ability to tolerate imprecision and uncertainty, there is a lot of opportunity for the application of soft computing techniques, especially for the passenger demand, overbooking and no-show forecasting.*

**Keywords:** *soft computing techniques, statistical techniques, airline, forecasting, no show*

## 1. INTRODUCTION

Nowadays, processing a large amount of data in airline industry is much easier than in previous few decades. Development of computational technologies allowed carriers to process data much faster and to make real time decision (Min & Joo, 2016; Pineda, Liou, Hsu & Chuang, 2018). Numerous techniques based on mathematics theory are applied in this complex process, and depending on the nature of the problem, there are - statistical or soft computing techniques. As pointed out by Lim and Balas (2013), the main difference is that statistical techniques (ST) are based on principles of precision and certainty, and soft computing techniques (SCT) tolerate imprecision and uncertainty. When it comes to the big data processing, ST need more time and a precisely formulated analytical model for computation. On the other hand, when observing vagueness and inconsistency in data, application of SCT could offer required and much needed solutions.

Two most commonly used SCT are fuzzy logic (FL) and neural networks (NN). As pointed out by Zadeh (1994), FL could be used to a highly extent in solving problems related to the vagueness and NN could be applied in situation in which uncertainty is highly present. When it comes to the ST, time series and statistical analyses are frequently used approaches. Both could be very efficient in capturing trends among data, seasonal components and could be a strong predictive tool with a precisely formulated analytical model. In airline industry, there are several fields in which both SCT and ST could be applied and contribute to the great extent. Fuzzy logic is mostly applied to measure quality of airline service (Li, Yu, Pei, Zhao & Tian, 2017) and neural networks are proposed for various predictions – aircraft maintenance operations (Luxhoj, Williams & Shyur, 1997), seat inventory management (Sun, Brauner & Hornby, 1998) and forecasting passenger demand (Chikr-El-Mezouar & Mohamed Hassan Gabr, 2011). Time Series analysis technique is used for building ARIMA models for forecasting passenger trends (Riddington, 1987) and statistical analysis is applied for building a model that is calculating the overbooking level (Amaruchkul & Sae-Lim, 2011). One of the overlapping area for both techniques is forecasting passenger demand. As highlighted by Cheng and Mengting (2018), various methods and their combinations could be found on this topic. Good example could be Faraway and Chatfield (1998) who combined neural networks and time series to create forecasting model. Aim of this paper is to provide the analysis of the literature covering the usage of both statistical and soft computing techniques for solving issues and challenges in airline industry. The analysis is covering 44 papers published in a 1961-2018 period. Next two sections contain the analysis of papers in which SCT and ST are used respectively. Focus of the analysis is to highlight proposed solutions and applied methods, and to link them to the carrier's business processes and operation areas in which they are used. Section four contains numerical analysis. Section five concludes the paper.

## 2. APPLICATION OF SOFT COMPUTING TECHNIQUES IN AIRLINE INDUSTRY

Due to the complexity and frequency of changes in the airline industry, carriers are often forced to take into account the uncertainty and ambiguity in the decision making process. Depending on the type and subject of

the decision, SCT could be used to embrace uncertainty and deal with the incomplete and inaccurate information. Fuzzy logic could be applied to measure airline service quality, in new routes selection and supplier evaluation. Neural networks are finding their application in forecasting passenger demand, as a standalone technique or with the combination of other SCT and ST. Beside the FL and NN, other SCT were also considered as a part of this research - genetic algorithms and case based reasoning approach. In the following subsections, 17 papers dealing with the application of SCT in airline industry were analyzed.

## 2.1. Fuzzy logic

One of the key contribution of the fuzzy logic could be seen through the treatment of linguistic variables (Sugeno & Tanaka, 1991) and by applying fuzzy rules and fuzzy graphs (Zhu & Xu, 2014). With respect to the airline industry, an extensive usage of FL is recorded in measuring carrier's service quality. Chou, Liu, Huang, Yih and Han (2011) proposed weighted SERVQUAL method. Since human judgments are often vague, they stated that it is more adequate to use linguistic approach for describing the expectation value, perception value and important weight of evaluation criteria. Proposed method was applied on the Taiwanese airline and in the conclusion, recommendations were made for the carrier to improve current service quality. Li, Yu, Pei, Zhao and Tian (2017) developed a hybrid approach based on fuzzy analytic hierarchy process (AHP) and 2-tuple fuzzy linguistic method. The performance of the proposed three-stage model was measured on a three airlines' in-flight service quality in China. As stated by Perçin (2017), evaluation of the service quality in airline industry has become one of the most challenging tasks that could influence carriers' success on a long term basis. Using the combined fuzzy decision-making approach, Perçin proposed a method for evaluation of the service quality performance of airlines in Turkey. Combined approach, included fuzzy DEMATEL for dealing with the interactions among the evaluation criteria, fuzzy analytic network process for considering the interdependence and calculate the relative importance of each criterion and fuzzy VIKOR for evaluation and ranking.

Similar to addressed carriers' service quality, methods for evaluating service quality of an airport towards carriers were proposed. Pabedinskaitė and Akstinaitė (2014) also used SERVQUAL method, to assess the quality of airport services that has been provided to the carriers. Their method resulted in a set of criteria that are taking into account the changes in consumer needs. Evaluation of the service quality provided by the airports was also a subject of a research conducted by Pandey (2016). Author conducted investigation of service quality using the fuzzy multi criteria decision making method in order to identify the scope of improvements. Two airports in Thailand were assessed, and results indicated that the service quality of both airports is satisfactory, and some areas are marked for improvement.

In addition to the service quality evaluations, FL were also applied in other areas. Atli and Kahraman (2012) developed an aircraft maintenance planning system, in which for minimizing aircraft maintenance planning time, they proposed fuzzy critical path algorithm. Schedule planning was covered by Deveci, Demirel and Ahmetoğlu (2017). They proposed the interval type-2 fuzzy TOPSIS multi-criteria decision-making method for identifying the aspects and selecting the new routes. Rezaei, Fahim and Tavasszy (2014) analyzed suppliers within airline retail industry and emphasized the importance of selecting the most suitable supplier(s) that will meet a carrier's specific needs. Since this is a complex process characterized with the involvement of many, sometimes conflicting, qualitative and quantitative criteria, authors proposed a fuzzy AHP.

## 2.2. Neural Networks

A significant organizational and technological advantages are offered by neural networks within the decision making process (Aiken & Bsat, 1999). NN could be very useful with the imprecise and data with nonlinear relationship, and when exact model don't exist or it is poorly defined. When it comes to the airline industry, an extensive usage of NN is present in forecasting passenger flight demand. One of the earliest application in this field is proposed by Nam and Schaefer (1995). They highlighted forecasting passenger demand as crucial and necessary for carrier when making decision regarding seats allocation, hiring additional staff during the summer months, or even when ordering materials that have long delivery lead times. Authors also expressed their suspicion that the appropriate statistical technique will provide the best results. Thus, they proposed NN to be applied and included in the forecasting process. Chikr-El-Mezouar and Mohamed Hassan Gabr (2011) proposed iterated neural network models for time series analysis and performed validation on the two time series datasets - airline data and sunspot data. Comparing with the Box-Jenkins ARIMA model, NN gave slightly better results. Similar, Weatherford, Gentry and Wilamowski (2003) proposed NN for forecasting passenger demand and compared results with the traditional forecasting techniques - moving averages, exponential smoothing and regression. Results indicated that even basic NN structures provided better forecasts results.

The application of NN in the forecasting passenger flight demand is evident, but it is not limited to only that field. Luxhoj, Williams and Shyur (1997) developed NN model for prediction of the inspection profiles for aging aircrafts issue. The aim of the NN was to provide the number of abnormal and potentially unsafe conditions in aircraft and/or aircraft components/equipment that carrier could expect. Performance of the proposed NN model was tested against the performance of regression based model, and both models provided good prediction results. A more complex neural network model was applied by Sun, Brauner and Hornby (1998) to help in the decision making process within the carrier's revenue management system. Their findings implied that a significant improvement in accuracy can be achieved by applying NN.

### **2.3. Genetic algorithms and case based reasoning**

A recent research conducted by Demirel and Deveci (2017) is proposing the application of genetic algorithm (GA) variants in the crew pairing process. Main objective of the GA is to generate a combination of crew pairings that will have minimal cost, will cover all flight legs and meet legal criteria. Similar, Kotecha, Sanghani and Gambhava (2004) proposed GA for solving the carriers' crew pairing problem. They added new cost-based uniform crossover (CUC) to the GA in order to solve set partitioning problem efficiently. Combined GA and CUC model was tested using the 28 real-world airline crew scheduling problems and promising results were obtained. Chiu, Chiu and Hsu (2004) proposed the usage of GA in the combination of case based reasoning (CBR) in the aircraft maintenance process. Objective of the proposed machine learning method is to retrieve similar cases for Boeing 747-400, and GA was applied for determining the dynamic weights and to introduce much needed non-similarity functions. In order to enhance the performance of the seat inventory management system, Chang, Hsieh, Yeh and Liu (2006) proposed a CBR seat allocation system in the combination with the dynamic probability method. Using the large carrier data, new combined system provided better results from the first-come first-served method that was currently applied.

## **3. APPLICATION OF STATISTICAL TECHNIQUES IN AIRLINE INDUSTRY**

Processing a large amounts of data, using one of the ST require a significant amount of time and a precisely formulated analytical model. Considering a problem in which these conditions are met, ST could provide excellent results in various decision making processes. Among many techniques that could be categorized here, it can be said that time series and statistical analyses are frequently used approaches within the airline industry. In addition, other ST were also considered - operational research, stochastic programming and others. In the following subsections, 25 papers dealing with the application of ST in airline industry were analyzed.

### **3.1. Time series analysis**

Time series analysis is widely applied ST in airline industry for forecasting passenger flight demand. One of the earliest research was conducted by Riddington (1987), who emphasized the financial benefits that carrier will achieve if forecasting accuracy is increased. Riddington proposed ARIMA model with the combination of cash management process in order to increase accuracy in predicting passenger flight demand. Research examined the effect of forecasting accuracy using the 'safety stock' approach and cash-management policy. Based on the obtained results, Riddington concluded that "*far greater returns can be achieved by adopting, in financial areas, approaches common in planning physical inventories*".

Forecasting method that combines time series analysis with additional approach was proposed by Benitez, Paredes, Lodewijks and Nabais (2013). With the modified Grey model authors introduced new aspect of time-varying coefficients which enabled recent data within database to be more influential. Solution has been tested on approximately 18000 routes from airport origin to airport destination, which is equal to 5857 routes, operated by different airlines, from city origin to city destination. Results indicated that modified Grey model worked properly for all airports and connections. To identify passengers demand trend, Tsui, Balli, Gilbey and Gow (2014) proposed a combination of two ARIMA models - the Box-Jenkins seasonal ARIMA (SARIMA) and the ARIMAX. Proposed solution was tested using the data of the Hong Kong airport. Different monthly time series were used for testing. SARIMA models were tested using the monthly time series between January 1993 and November 2010 and ARIMAX models were applied on the periods of January 2001 to November 2010. As concluded, even for different forecasting periods, both models provided accurate forecasting results with low MAPE and RMSE values.

### **3.2. Statistical analysis**

Statistical analysis found its place within the revenue management area in airline industry. Various methods and solutions were created with the aim to optimize inventory, minimize the worst case regret, and forecast number of seats that carrier should allow to be overbooked. As explained by Somboon and Amaruchkul

(2017), maximization of profit could be achieved by seat inventory control and overbooking (accept number of reservations greater than plain capacity to compensate late cancellations and no-shows). Authors developed two-class overbooking model using the show-up probability, and conduct testing on a real life data. Based on the findings, they concluded that the profit is higher if overbooking limits are included.

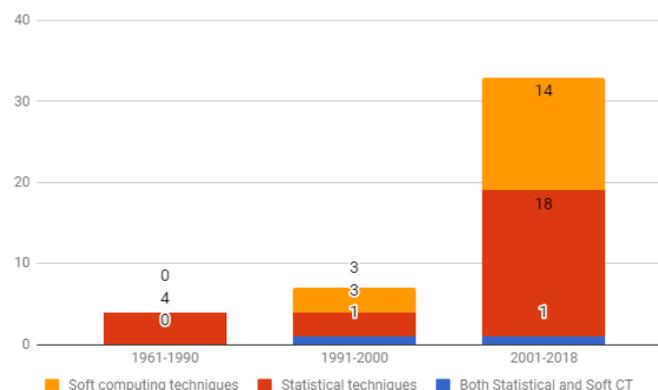

To optimize inventory capacity, Chen, Günther and Johnson (2003) proposed optimal yield management policies that are considering statistical learning approach. As emphasized, a good yield management policy could be crucial to the carrier, since it allocates airplane seat capacity to various fare classes and maximizes revenue. Another capacity optimization method was proposed by Amaruchkul and Sae-Lim (2011). Their overbooking models comprised of three show-up rate distributions - normal, beta and deterministic. For testing and comparison purposes, binomial model was used as a benchmark. Based on the obtained results, model with beta show-up rate performed best. Lan, Ball, Karaesmen, Zhang and Liu (2015) developed a simultaneous overbooking model that minimizes the worst case regret. As important factor in airline network management area, Grammig, Hujer and Scheidler (2005) highlighted forecasting passenger demand. Thus, they introduced a multinomial probit specification model for forecasting number of passengers and tested it on a real airline booking data.

### 3.3. Other statistical techniques

One of the earliest researches of the booking problem with multiple fare classes was conducted by Thompson (1961). Later, Rothstein (1984) analyzed the same problem in order to emphasize the operational research techniques that carriers applied. After 60's and early 80's, this field gets more "deserved" attention from a both researchers and practitioners. Belobaba (1989) proposed a probabilistic decision model to be implemented as a part of carrier's automated booking limit system. Smith, Leimkuhler and Darrow (1992) analyzed multiple models for revenue management in airline industry, and Robinson (1995) proposed probabilistic decision making model to set booking limits on future flights (seat inventory utilization). Van Ryzin and McGill (2000) recommended a simple approach based on adaptive algorithm and stochastic approximation theory to tackle the same problem - seat utilization. Similarly, other researchers proposed solutions with stochastic programming technique (Ahmed & Poojari, 2008; Gu & Zhu, 2016). All efforts towards the seat utilization should lead towards financial results. To measure airline financial performance, Weatherford and Belobaba (2002) proposed simulation analysis based on heuristic decision rule model. The same effort was made by Boyd and Bilegan (2003) who concluded that seat inventory utilization mechanisms are arguably the most important factors for carrier for achieving revenue. Fan and Wang (2013) even included risk and discount in the seat control model using the Markov decision process. To maximize revenue, another group of authors (Huang, Ge, Zhang & Xu, 2013) also used Markov decision process approach and applied on parallel flights with transference. As demand for flights increased progressively, focus slightly shifted from seat optimization to forecasting passenger flight demand. Under the limited demand information, Lan, Gao, Ball and Karaesmen (2008) proposed a new static and dynamic booking control policies. Filder, Wei and Ismail (2011) observed existing forecasting econometric models and evaluated their forecasting performance using multiple error measures. Zeng and Li (2015) analyzed passenger seat choice behavior and suggested overbooking policies to be applied. To determine the level of overbooking, the efficient way is to forecast no show, as suggested by several authors (Fildes, Nikolopoulos, Crone & Syntetos, 2008; Kunnumkal, Talluri & Topaloglu, 2012).

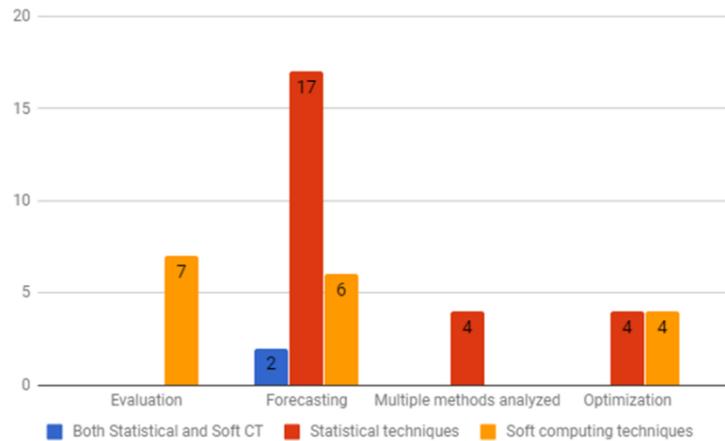

## 4. NUMERICAL ANALYSIS

This section represents the numerical analysis of the literature review. Next figures represent analyzed papers by year and technique group.

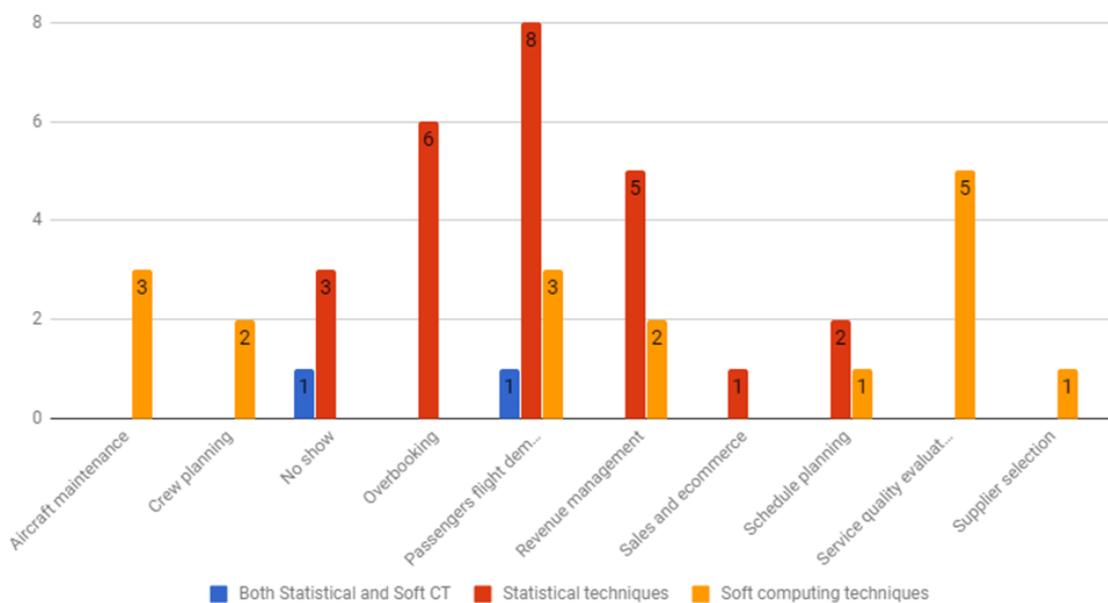

**Figure 1:** Analyzed papers by year and technique group

Among the total of 44 papers, 17 (38,6%) are covering SCT, 25 (56,8%) are covering ST and 2 (4,5%) are covering combination of both. Publishing years are grouped into three periods, based on the interests in the application of various techniques within the airline industry: (1) 1961-1990, early start; (2) 1991-2000, slow expansion; and (3) 2001-2018, progressive increase of interest. This can also be confirmed by observing the number of papers found and analyzed in those periods. This is not a finite number of papers, but it can definitely serve as a representative example how application of various techniques in solving airline industry issues moved through time. Next figure shows the methods proposed and analyzed in papers.

**Figure 2:** Analyzed papers by methods covered and technique group

Majority of papers are proposing a forecasting method (25) with an extensive usage of ST. In terms of the evaluation methods, a primary role of SCT is evident (7), which is opposite when it comes to papers that analysed multiple methods (4). For the optimization, equal number of statistical and soft computing techniques is captured. Next figure shows the business processes/operations within airline industry that are covered in papers.

**Figure 3:** Analyzed papers by business processes/operations covered and technique group

The majority of analyzed papers are considering passenger flight demand forecasting (12), and among others, next business processes/operations are highlighted: seat utilization as a part of revenue management (7), overbooking (6), Service quality evaluation (5) and no show (4).

## 5. CONCLUSION

Complexity of business processes and operations, and the need for processing large amounts of data, made airline companies an interesting field for the application of computer techniques. Depending on the data, presence of vagueness, uncertainty and model existence, statistical and soft computing techniques could be applied in various decision making processes within airline industry.

Aim of this paper is to provide the analysis of the literature covering the usage of both statistical and soft computing techniques for solving issues and challenges in airline industry. For the purpose of this literature review, papers from various scientific journals were used. Analysis covered three stages: initial analysis (focus on publishing year and techniques), brief analysis of the proposed methods and identification of operations/business processes. Based on the initial analysis, it can be said that the airline industry is receiving a lot of attention nowadays when it comes to the application of SCT. A majority of founded and analyzed papers are covering a period of 2001-2018, and just few of them could be found in earlier periods. More than half of the papers are proposing a forecasting method (25) with an extensive usage of statistical techniques. Passenger flight demand forecasting is still one of the most interesting topics (12), as well as inventory seat utilization as a part of revenue management (7).

Based on the analysis, it can be concluded that there is still a lot of opportunity for the application of SCT, especially when it comes to the passenger demand, overbooking and no show forecasting. Although this research is not final and certainly not covering all papers that are dealing with the application of SCT and ST in airline industry, it could be used as a guide for additional researches and reviews.

**Abstract:** *The introduction of low cost model into long-haul service has been a challenging task which is proved to be successful for several carriers across the globe. Norwegian Air Shuttle has been the pioneering carrier in Europe that adopted the low-cost model in long-haul market mainly focusing its network on high density transatlantic routes from Scandinavian cities as well as from United Kingdom. This paper performs analysis on some aspects of competition in the route that connects two metropolitan cities London and New York. By employing descriptive statistics, the comprehensive analysis on certain competition indices such as market share, market concentration index (HHI) and price comparison of fares has been performed in this paper. The findings approve that Norwegian expansion at London Gatwick has become a serious threat to well established carrier on this route, particularly British Airways that put substantial effort to create counter strategy to efficiently combat the rival.*

**Keywords:** *Low cost long haul model, Norwegian Air Shuttle, transatlantic route, British Airways, secondary airport*

### 1. INTRODUCTION

The Deregulation Act stipulated in 1978 in United States has become a milestone for revolutionary changes bringing the number of innovations. The most important among them are regulatory changes that certainly shape the market structure allowing the entrance of new players on the market and providing the level playing field for all participants. The wave of changes was riding at phenomenal speed serving as an impetus to other regions, specifically Europe, to liberalize its market across national borders. The emergence of low-cost business model can be perceived as a “pure fruit” of market liberalization (Francis et al., 2006) in Europe that permanently alter the landscape of competition. In such new circumstances, the full-service network carriers (FSNCs) initially protected by the state, coped the severe competitive pressure induced by low-cost carriers (LCC) and their business model that aims at keeping the costs as lower as possible. Although the LCCs organize their network as point-to-point system opposed to FSNCs that highly rely on hub-and-spoke network concept, they still have a large portion of overlapping market in which a fierce battle is evident among them.

Thanked to its simple operating model with no-frill product (Cento, 2009) and their network focused on connecting intra-European destinations, the LCCs successfully survived the crisis occurred as an outcome of terrorist attack in 2001. Moreover, the emergence of LCCs with their flights operated from secondary, less congested airport (in the vicinity of primary airports) become a serious threat to FSNCs that operate their flights from primary (hub) airports. In that sense, the competition must be light at a broader context taking into account not only competition among competitors on specific airport pairs, but also between city pairs or even region levels.

According to Dobruszkes (2006) who used exhaustive data from 2004, the LCCs contained 18% of regular intra-European seats at the time, and that these seats were limited almost exclusively to Western Europe (98%). In the following years, the LCCs put substantial effort to diversify its networks towards markets of Central and Eastern Europe (Dobruszkes, 2009). Finally, in recent years some European carriers have attempted to incorporate the low-cost business concept into long-haul markets mainly by connecting large European cities with large metropolis in North America. The aim of this paper is to investigate some aspects of competition on long-haul route where low-cost carrier offer its service in addition to several full-service carriers that are traditionally dominant in these markets.

The paper is divided as follows. After a brief Introduction, the Section 2 provides literature review on long-haul low cost business model. Section 3 outlines some essential information on long-haul low cost model that emerge as a new business concept by exploring Norwegian Air Shuttle as a representative of the airline group that successfully applies this business model. The Section 4 highlights some aspects of competition between on the route between London and New York characterized by the presence of both LCC and FSNCs. In this section, several measures that represent some aspect of competition will be calculated such

as market share and HHI index. Additionally, the price competitiveness of airlines on this route will be given through comparison of air fares obtained by Internet search. Finally, Section 5 concludes the paper.

## 2. LITERATURE REVIEW

The long-haul low cost business model has been relatively novel in airline industry. In recent few years, abundant of literature investigate the viability of such concept that require the radical enhancement in order to be profitable. Bearing in mind that large number of airlines adhered to this model in recent past, the investigation of cost and revenue aspect of their business model become essential factor for their sustainability on the dynamic competitive market. Low cost business model has been reserved for short and medium-haul routes for years with 50-60% cost savings compared to FSNCs, the advantage that is impossible to achieve on long-haul routes.

The viability of low cost business concept into long-haul service has raised the fierce debate among scholars and airline experts who broadly investigated the financial aspects of such model. Morrell (2008) was among the first who examined the applicability of well-established LCC business model advantages into long-haul service. The author took a rather pessimistic approach and questioned the problem of generating demand (due to the lack of connecting passengers) to support the existence of hub by-pass service. The author also claimed that lowering long-haul fares significantly from current fares is not feasible for LCCs. On the other hand, Daft and Albers (2012) held optimistic side emphasizing the importance of revenue consideration as a key factor of feasible existence of LCC long-haul service. The authors found that ancillary revenues can significantly contribute to airline's profitability. The recent study conducted by De Poret et al. (2015) who performed a detailed financial assessment of low-cost operation on the transatlantic market leads to similar conclusions. Namely, the authors revealed that higher seating densities, higher cargo revenues and additional ancillary revenues can ensure the economic viability of long-haul LCC operation

Despite previous work that focused on revenue side of long-haul low cost model, Soyk et al. (2017) focused solely on evaluation of cost differences between 37 airlines that operates transatlantic routes, among which there are those who adopt low-cost business model. The authors found that emerging long-haul LCC carriers within derived cluster achieved 33% lower unit costs compared to legacy hub carriers, of which 24 percentage points were evaluated as sustainable. Finally, in the contrast to the previous researches, Soyk et al. (2018) found that the emerging North Atlantic long-haul LCCs do not have a revenue disadvantage compared to FSNCs particularly on dense routes approved by the application of new metric proposed.

In addition to already well-established European long-haul carriers, one can anticipate that prominent LCCs such as Ryanair could pave the way for successful acquiring of long-haul operation in the future, the idea which is thoroughly investigated in van den Hoek (2017). Having in mind that there is a potential of between 20 and 113 out of 442 routes of up to 12,000 km that do not have non-stop flight to and from Europe (Wilken et al., 2016) combined to the tendency of LCCs to enter the charter airline long-haul territory (Rodríguez and O'Connell, 2017), the development of future network of LCC long-haul carriers will be challenging task.

## 3. THE EVOLUTION OF NORWEGIAN LONG HAUL LOW COST BUSINESS MODEL

As stated in Wensveen and Leick (2009), the concept of low-cost long haul flying dated back to 1977 when Skytrain, the company founded by Freddie Laker, operated between New York and London offering airfares substantially lower than its legacy competitors. However, it took several decades that this concept becomes well established in airline industry. The current iteration of the long haul low cost model has been around for a decade, with Jetstar (2006) and AirAsia X (2007) the initial pioneers (CAPA, 2017). Concerning European floor, Norwegian Airlines was the pioneering company that launched its first long haul flight in 2013 between Oslo and New York and shortly after between Stockholm and New York. In addition to these transatlantic flights from Scandinavia (including Copenhagen), the carrier introduced long-haul links from three large European cities: London (2014), Paris (2016) and Barcelona (2017). By the end of October 2017, the airline long haul network encompassed 26 destinations and 28 routes that place it as a largest long haul low cost operator in terms of network size and in the second place in terms of weekly seats (Table 1).

However, this network expansion is supported by the strategy of exploit new Boeing 787-9 with 294 seats onboard. The long-haul strategy for the 787 fleet currently highly relies on dense routes into popular leisure markets that can easily be stimulated by low-fares. These routes include New York (via JFK and now Newark), Los Angeles, San Francisco (via Oakland) and Miami (via Fort Lauderdale).

As abovementioned, Norwegian put substantial effort to position itself on U.K. market since 2014 by operating its transatlantic flights from the less congested airport in London airports system, London Gatwick (LGW), which provides more flexibility in terms of airport charges as well as slots allocations. Table 2

outlines the characteristics of six competing routes between Norwegian and legacy carriers British Airways which traditionally been dominant in these markets. On the other hand, British Airways flights are mainly concentrated at London Heathrow (LHR), although it directly competes with Norwegian on San Francisco and Orlando routes from London Gatwick.

**Table 1:** Long haul low cost operations ranked by weekly seat capacity (2<sup>nd</sup> -8<sup>th</sup> October 2017)

Rank	Airline	Weekly seats	Number of routes
1.	AirAsiaX	133458	21
2.	Norwegian	87337	48
3.	Scot	69144	18
4.	Jetstar Airways	46900	14
5.	Air Canada rouge	37923	20
6.	Thai AirAsia X	31668	4
7.	NekScoot	24070	6
8.	Cebu Pacific	13080	5
9.	Azul	12466	4
10.	Eurowings	11780	12

Source: CAPA (2017)

However, not all routes presented are characterized by the same level of competition between those two airlines. It is evident that competition will be intensified when there is overlapping characteristics of service offered. However, the market share on specific routes will be highly affected by passenger's personal preferential towards. The competition will be certainly intensified when both carriers offer their flights with similar schedule (the same day and approximately the similar departure times) such as the case with New York and Los Angeles routes. On the other hand, Norwegian operates Miami route only twice a week, while the same route with one stopover is served by British Airways in the code share with its partner American Airlines every day with high frequency accounting up to ten daily flights. Since direct flight is not offered by British Airways, it is reasonable to expect that certain amount of passengers will be attracted by Norwegian direct flight if the timetable fits specific passenger's requirement.

**Table 2:** The characteristics of the competing transatlantic routes between Norwegian Air Shuttle (DY) and British Airways (BA) in 2017/2018 winter timetable

Destination airport	Origin airport	Days of operation	Frequency	Schedule departure
<i>New York (JFK Airport)</i>				
DY	London Gatwick	1234567	2 daily flights	06:00; 17:10
BA	London Heathrow	1234567	13 daily flights	From 08:25 to 19:50
BA	London Gatwick	1234567	1 daily flight	16:45
<i>Los Angeles (LAX Airport)</i>				
DY	London Gatwick	1234567	1 daily flight	12:50
BA	London Heathrow	1234567	5 daily flights	From 10:35 to 15:30
<i>Boston (BOS Airport)</i>				
DY	London Gatwick	1234567	1 daily flight	16:00 (4, 7); 16:20 (1,3); 16:50 (5)
BA	London Heathrow	1234567	4 daily flights	From 11:15 to 19:10
<i>Fort Lauderdale-Miami (FLL Airport)</i>				
DY	London Gatwick	1234567	1 daily flight	16:20 (1); 14:55 (3,5); 14:50 (7)
BA	London Gatwick	1234567	1 daily flight	09:05 (1, 4); 09:10 (6)
<i>Florida Orlando (MCO Airport)</i>				
DY	London Gatwick	1234567	1 daily flight	14:05
BA	London Gatwick	1234567	1 daily flight	11:35 (1,2,3); 11:00 (7)
		1234567	2 daily flights	11:35; 13:20
<i>San Francisco – Oakland (OAK Airport)</i>				
DY	London Gatwick	1234567	1 daily flight	12:55 (2, 6); 12:45 (4); 14:20 (7)
BA	London Gatwick	1234567	1 daily flight	08:45 (1); 10:10 (3); 11:00 (6)

It is evident that Norwegian's less-price based strategy aims at diverting the portion of those price sensitive passengers away from legacy carriers, and to secure some portion of business traffic in order to increase its yield. For example, on New York routes, traditionally perceived as the most popular touristic market, the Norwegian's average fare is approximately 30% less than its rival British Airways price. However, British Airways offers fourteen daily flights spread across entire day at LHR compared to one daily flight offered by

Norwegian. With its well-established flights to New York, British Airways can capture the portion of passengers that highly regards early departure times. With its late afternoon flight, Norwegian could count on the price sensitive segment of passengers who are willing to arrive late afternoon in New York and it is likely that certain portion of these passengers previously used the legacy carrier's flight. Afternoon departure times are generally characteristics for all Norwegian transatlantic routes from London Gatwick, as it is probably seen as a good strategy that provides the balance between different passenger segments' requirements.

The next section provides the comprehensive assessment of different aspects of competition that exists or has existed in the high-density market such as those that connects two metropolitan cities London and New York. The influence of Norwegian on legacy carriers, specifically British Airways as a dominant player in London-New York market, will be thoroughly discussed through traffic and capacity statistics.

#### 4. THE OUTLOOK OF LONDON – NEW YORK ROUTE

The London New York route has always been perceived as one of the high density route in the world. Two metropolises have historically had important links that catalyze the mobility of people, trade and service. Moreover, London stands out as an important gateway that consolidates a large portion of traffic from different part of Europe, Africa and Asia that terminate in New York area. Both London and New York are served by multiple airport system, which allow the large number of possible connections between two cities Table 3 provides the list of airports that serves these two metropolitan cities along with their respective number of passengers.

**Table 3:** Airports serving the metropolitan areas of London and New York (Port Authority, 2015)

City	Airports	IATA code	Number of passengers in 2015 (mil.)
London Airport System	London Heathrow	LHR	74.9
	London Gatwick	LGW	40.3
	London Stansted	STN	22.5
	London Luton	LTN	12.3
	London City	LCY	4.3
New York metropolitan area	John F. Kennedy International	JFK	56.8
	Newark Liberty International	EWR	37.5
	LaGuardia Airport	LGA	28.4

For example, London is served by five airports among which London Heathrow is the largest one and serves as a hub of full-service carrier British Airways. On the other hand, New York metropolitan area is served by three airports, among which JFK is the largest and most important one from which large number of intercontinental flights have been performed. In other words, the same city pair (i.e. London-New York) can be realized throughout different airport pairs offering the potential passengers possibility to make selection between different airports as well as between different airlines.

##### 4.1. Number of passengers and airlines' market share

In order to have better insight into the different degree of competition, Table 4 outlines the characteristics of three routes (airport pairs) that serve these two metropolitan areas in 2016. The data on the number of passengers have been retrieved from U.S. DoT's T-100 database provided by Bureau of Transportation Statistics that allows the free access.

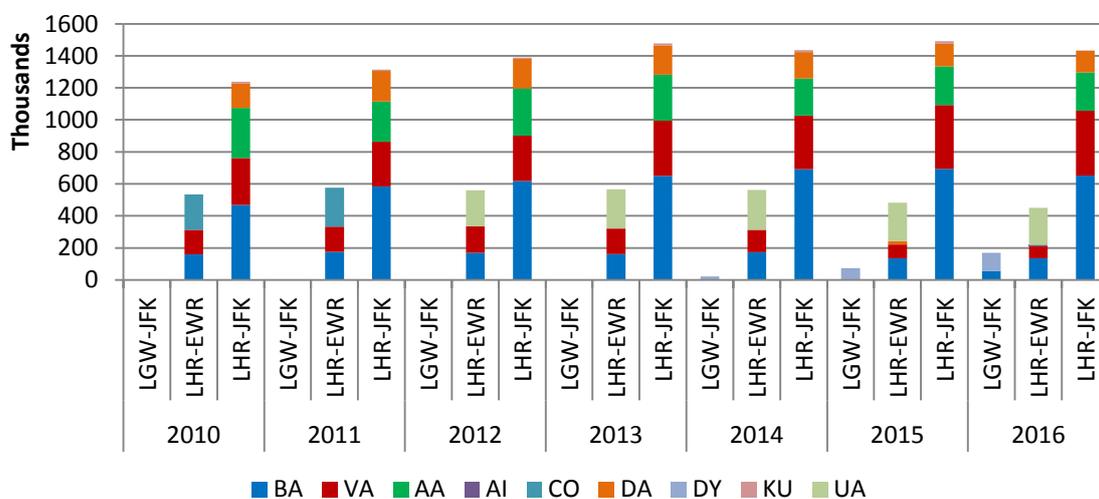

**Table 4:** Some characteristics of London –New York route in 2016

Airport pairs	Airlines operated	Number of passengers	Total number of passengers (% of all pax)	Market share per route per airline
LHR-JFK	British Airways (BA)	651 397	1 434 051 (69.9%)	45.4%
	Virgin Atlantic (VS)	406 229		28.3%
	American Airlines (AA)	238 756		16.6%
	Delta Air Lines (DL)	135 282		9.4%
	Kuwait Airways (KU)	2 387		0.2%
LGW-JFK	Norwegian Air Shuttle (DY)	112 469	168 480 (8.2%)	66.8%
	British Airways (BA)	56 011		33.2%
LHR-EWR	United Airlines (UA)	232 118	449 963 (21.9%)	51.6%
	British Airways (BA)	134 599		29.9%
	Virgin Atlantic (VS)	74 050		16.5%
	Air India (AI)	9 176		2.0%

Source: Bureau of Transportation Statistics (2018)

As seen from Table 4, London – New York route was operated by two European carriers (BA and DY), four American carriers (VS, AA, UA, DL), one Middle Eastern carrier (KU) and one Asian carrier (AI). The high density route among these three options is certainly one that connects two major airports (LHR and JFK) within the cities. This route encompassed the market share of 69.9% in terms of passengers that commenced their trip at London. BA is dominant carrier on this route accounting for 45.4% of all passengers transported and followed by three American carriers – VS, AA and DL which market share accounts for 28.3%, 16.6% and 9.4% respectively. The second dense route is one that connects LHR with EWR, the second largest airport in New York area, with market share of almost 22%. Similar to LHR-JFK route, this route is operated by BA as a dominant player (51.6%), two American carriers that combined have a market share of almost 50% and Air India with only 2% of share. Finally, the route that connects second largest airport (LGW) and major airport in New York (JFK) is characterized by the presence of low-cost carrier DY that started its operation in the third quarter of 2014. In order to reduce the competitive pressure induced by low fares offered by DY, BA has recently announced its flights to JFK from LGW. However, the market share of BA is significantly lower compared to DY that held almost 70% of share and transported more than hundred thousand passengers in 2016.

Fig. 1 depicts the historical trends in terms of number of passengers on the route London New York including the traffic on all three possible airport cities pairs. It was felt that 2010 was an appropriate start year because this period coincides with recovery of airline industry after the severe world economic crisis occurred in 2008.

**Figure 1:** Number of passengers at three routes connecting London and New York

As observed from Fig. 1, the number of passengers from London Heathrow to New York JFK had seen the steady growth in the period from 2010 to 2013. Afterwards, the number of passengers fluctuated around 1.45 million reaching its peak in 2015 when almost 1.5 million people were transported between these two points. Among five airlines operated these routes, it is evident that BA has the highest market share. BA is currently the most dominant carrier on this route with market share encompassing approximately 45% of total passengers carried, followed by three American carriers: VA, AA and DA. However, not all of them have been the real competitors. For example, AA offers some portion of its flight in the cooperation with BA through code-share agreements, while other portion operates independently. Over the time horizon, VA has radically increased its market from 23.7% in 2010 to 28.3%, whereas AA reduced its share from 25.2% in 2010 to 16.6% in 2016. Finally, Kuwait Airways has been present on this route during the observed period, but its market share is not significant (less than 1%). On the other hand, the number of passengers at LHR-EWR was stable during the period from 2010 to 2014 accounting for around half million passengers with slight decrease in 2015 and 2016. Continental Airlines (CO) was present at this route with significant market share in the past, but it withdrew the market in 2012. Finally, the flights to New York have been introduced from LGW for the first time in 2014 when DY offered its service by affordable prices. Since then, this carrier records the rapid expansion with number of passengers exceeding one hundred thousand in 2016.

#### 4.2. The market concentration of London – New York route

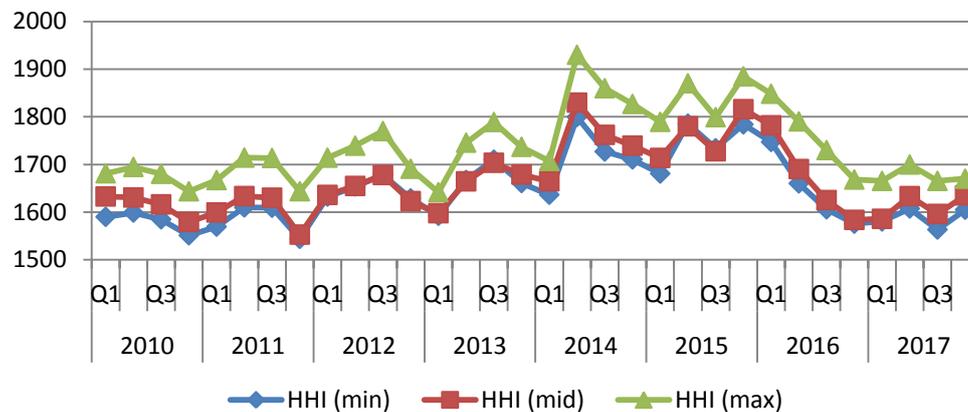

The Herfindahl–Hirschman index (HHI) is defined as the sum of squared market shares of airlines in a market and thereby provides an easily interpretable measure of concentration (Lijesen, 2004). The HHI for specific route can slightly vary depending on the measure used to express the market share and thus it can be calculated by either capacity offered or number of passengers transported. The HHI ranges from the value close to zero, indicating nearly perfect competition to ten thousand, indicating a monopoly. For the purpose of this paper we calculated the value of HHI based on market share expressed through number of

seats (i.e. capacity of aircraft) offered by specific airline. It is worth mentioning that depending on the configuration of the aircraft operated, the values of HHI can slightly differ. As a carrier with the most carried passengers, BA's configuration of two most dominant aircraft type B777 (two version – V1 and V2) and B747 (three versions – V1, V2 and V3) (Table 5) can have impact on the value of HHI. Fig. 2 shows the different value of HHI based on maximum, medium and minimum configuration of aircraft operated this route.

**Table 5:** British Airways B777 and B747 configuration

	B777			B747		
	B777-200 (V1)	B777-200 (V2)	B777-300	B747-400 (V1)	B747-400 (V2)	B747-400 (V3)
Standard seats	203	122	185	243	185	145
Recliner seats	24	40	44	36	30	30
Flat bed seats	48	48	56	52	70	86
Open suites	-	14	14	14	14	14
<b>Total</b>	<b>275</b>	<b>224</b>	<b>299</b>	<b>345</b>	<b>299</b>	<b>275</b>

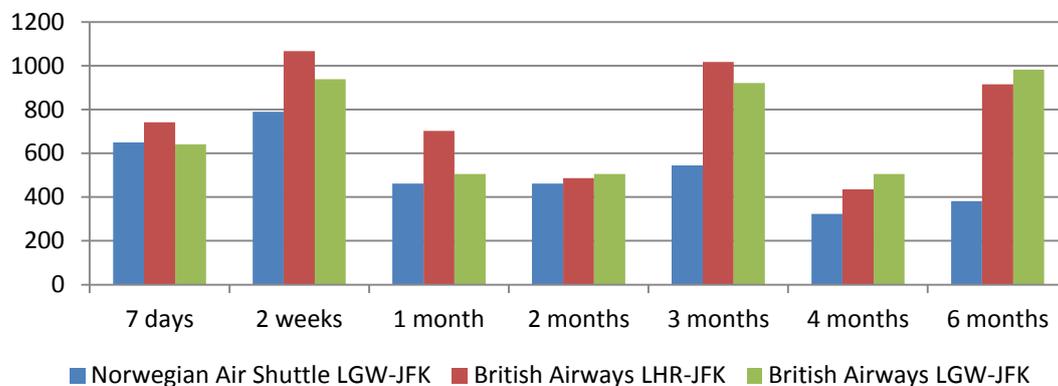

The U.S. Department of Justice considers a market with an HHI of less than 1,500 to be a competitive marketplace, an HHI of 1,500 to 2,500 to be a moderately concentrated marketplace, and an HHI of 2,500 or greater to be a highly concentrated marketplace (Investopedia, 2018). As observed from Fig. 2 the market concentration index ranges from less than 1,600 in 2010 to more than 1,800 in the case of moderate capacity. Thus, the London New York route can be characterized as a route with medium level competition, which is certainly benefit for potential passengers perceived through lower fares and higher level of service.

**Figure 2:** HHI index for different aircraft configuration for London New York route

### 4.3. Price competitiveness between BA and DY

In order to investigate the price competitiveness of two major rival BA and NY, the fares from both carriers are collected throughout time-horizon starting from fixed points in the time (2<sup>nd</sup> October) encompassing twelve points in time ranging from 7 days before departures to 6 months (7 observations in total). For each of time point, the average value in economy travel class (the lowest tariff) are calculated and presented in Fig 3.

**Figure 3:** Average fares of BA and DY on routes connecting London and New York (in EUR)

DY average ticket price is even two times lower for this route than that offered by its major competitor BA. This makes the LGW-JFK route appealing to price sensitive passengers. Moreover, the differences in price is

significant enough to seriously harm BA market position, although it still can count on its well established hub-and-spoke network that serves as a “feeder” to these long-haul flights. The evidence of rising competition can be found in British Airways strategy that has been recently announced through “squeezing” 52 seats on its Boeing 777 flights from Gatwick by shrinking seating space (Telegraph, 2016). The configuration of British B777 counts 275 seats in 3 classes, and with additional seats BA services will be more in accordance with Norwegian’s B787 with 294 seats onboard. In this way, the airline attempts to reduce its unit cost and to offer even more low fare in order to retain its market position on competitive routes. According to comparative analysis of fares provided by BA from LGW provided in Fig. 3, it seems that BA successfully applied the mentioned strategy.

## 5. CONCLUSION

The long haul routes have been traditionally reserved for full-service carriers that successfully manage to collect a large number of passengers over their hub-and-spoke network system. However, in recent few years, the situation has been radically changed with several low-cost carriers that started to efficiently operate long-haul routes. One of the most successful one among them in Europe was certainly Scandinavian carrier, Norwegian Air Shuttle with its aggressive strategies that aims at diverting a large portion of passengers, particularly those price sensitive, from well-established airlines. The Norwegian routes are still focused on touristic destinations that characterized the high demand during the entire year.

The paper investigates some aspects of competition on London New York route as one of the highest density route in the world. Norwegian initially used the opportunity to solely operate from London Gatwick, less congested airport in London Airport System offering one daily flight and offering the fares which are almost double lower than its major competitor British Airways from London Heathrow. In order to efficiently combat the fierce competition imposed by low-cost rival, British Airways started to operate the flights from the London Gatwick implying the strategy of “squeezing extra seats”. In such way, British Airway succeeded to offer lower fares which are highly in line with those offered by Norwegian. However, the introduction of low-cost service in this market stimulating the demand generating the new growth in market that is well matured.

# MULTIVARIATE APPROACH TO MAKING SPONSORSHIP DECISIONS: THE CASE OF EUROPEAN FOOTBALL LEAGUES

Strahinja Radaković<sup>\*1</sup>, Milan Radojičić<sup>1</sup>, Milica Maričić<sup>1</sup>,  
<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia  
<sup>\*</sup>Corresponding author, e-mail: radakovic.strahinja@gmail.com

**Abstract:** *Sponsorship, as a communication activity, has significantly developed in the last several decades. Although the budgets that the companies are willing to allocate for sponsorship are growing, the sponsor's attitude towards sponsorship and sponsoring events is changing. The decision on which athlete, sports club or competition to sponsor is nowadays a highly important decision which can have a significant impact on the brand image, brand awareness, brand preference, and attitude towards the brand. Therefore, analytical approach should be taken. Herein we suggest a multivariate approach to making sponsorship decisions. The proposed approach was employed on the case of European football leagues: Premier League (United Kingdom), La Liga (Spain), and Ligue 1 (France). We hope the presented research will provide additional insights on differences between the three European football leagues and on the application of multivariate analysis in decision making in sport sponsorship.*

**Keywords:** *Sport sponsorship, Football, Data analysis, Clustering, Decision making*

## 1. INTRODUCTION

Sponsorship can be defined as an investment, in cash or products or services, in return for exploitable commercial rights (Smith, Graetz, & Westerbeek, 2008). The possibility of displaying advertisement messages to wider public has attracted the attention of marketing managers to turn to sponsorship as the mean of marketing communication. Sponsorship of sport, arts, and entertainment-related events and competitions has slowly, but surely, become an important part of the marketing mix (Jensen & Cornwell, 2017). According to the International Events Group (2017), companies spent \$60.1 billion on sponsorship in 2016, whereas the most common type of sponsorship is sport sponsorship.

With the development of information systems and technology it became possible to use distinct methods of tracking and collecting data from the sport matches. The collected data could later be used by various interest groups: team managers, journalists, data analysts, and of course, the fans (Radojičić, Djokovic, & Jeremić, 2016). The application of statistical and mathematical methods, data visualization, and data mining to the collected data from the pitch to gain information on previous play and predict future results is considered sports analytics (Alamar, 2013). Experts in sport marketing are taking the advantage of the acquired data and the results provided by sports analytics to assess their current marketing activities, but also to predict new ones (Fried & Mumcu, 2017). Namely, the obtained results can help the experts to make the decision which event or talented individual to sponsor.

The big five of the European football are the English Premier League, Spanish La Liga, German Bundesliga, Italian Serie A, and French Ligue 1. In the last several years the Serie A has witness a decline in both results and attendance (Kate Langshaw, 2017; UEFA, 2016), leaving Premier League and La Liga to dominate. In the last four years of the last 15 major European and International major club titles, Spanish clubs have won 14 and English clubs just one. In our analysis, we chose the Premier League, La Liga and Ligue 1. Bundesliga was listed out of the analysis as their league consists of 18 clubs compared to 20 in the chosen three and Serie A was ruled out due to the current decline of the League.

The aim of this paper is to try to assist marketing and brand managers in the process of deciding which football league and football club to sponsor. Namely, using statistical multivariate analysis, we strive to inspect the differences between three leading European football leagues based on seasonal post-match data. The research hypothesis is that there are differences in the football style that these clubs play within their leagues, and that the clubs although from three different leagues can be grouped. The analysis could assist the decision makers to choose the football clubs which play similar style when making their sponsorship mix of clubs and leagues in which they will be present.

The structure of the paper is as follows. Section 2 sees a brief literature review of sport sponsorship and decision making in sponsorship. The research results are elaborated in the next section while we finish the paper with the discussion and the concluding remarks.

## **2. LITERATURE REVIEW**

In the following two subsections we will place our attention on the role of sport sponsorship in the integrated marketing communications of a company and the possible benefits the sponsoring company might gain from such activities. Accordingly, we give an overview of the process of decision making in sponsorship.

### **2.1. Sport sponsorship**

Sport events attract the attention of a large number of spectators and thus are increasingly being broadcast worldwide. As a result of this high media coverage, sport sponsorship takes on an international character, and the budgets allocated for becoming an official sponsor of a global sports event are rising and have no tendency to decline (O'Reilly, Lyberger, McCarthy, Séguin, & Nadeau, 2008). For many world acknowledged brands, sponsorship of sports event plays a central role in their integrated marketing communication (Santomier, 2008).

Sport sponsorship has become the most common form of sponsorship (Quester, 1997). Sports events and sporting competitions have traditionally been given significant support by the sponsors (McCarville & Copeland, 1994). However, the popularity of sport sponsorship has grown significantly in the past century thanks to drastic social changes, i.e. the development of information technologies, the Internet, social media, media, and transport. Namely, the marketing experts saw the possibility to use the attention of spectators during sports events to show them their sponsorship messages. Therefore, sport sponsorship has become a long-term marketing strategy which is used to communicate with a large external and internal audience to gain competitive advantage (Papadimitriou & Apostolopoulou, 2009).

Another major benefit of sponsorship sport events is the presence of heightened emotions. Namely, visitors and viewers of sport competitions are emotionally involved with the game, their club, favourite athlete, or national team (Biscaia, Correia, Rosado, Ross, & Maroco, 2013). Global brands are aware of the emotional impact of sport and utilize it to connect with the consumers (Santomier, 2008). Namely, the best world-class athletes and teams are sponsored by the largest companies in the world under the motto "the best with the best" (Šurbatović, 2014). In this way, companies want their brand to be identified with athletes and teams and want to transfer the positive sports results to their products and services. Therefore, sport sponsorship has become an effective marketing strategy for companies, but at the same time it is an important source of revenue for sports organizations.

### **2.2. Decision making in sponsorship**

Decision making in sponsorship is a topic which is slowly, but surely gaining importance. As the decision on sponsorship activities can impact the brand, the question "whom to sponsor" still remains a challenging practical and academic question (Lee & Ross, 2012).

There are several studies which have employed statistical, data mining, and decision-making techniques in the field of sponsorship. Lee & Ross (2012) employed Analytic Hierarchy Process (AHP) to identify the decision-making factors of sport sponsorship. Their analysis covers sponsors of clubs competing in different sports, therefore providing insights on the importance of factors from different perspectives. Research also shows that AHP could be easily combined with other multiple attribute decision making (MADM) methods such as TOPSIS (Isik, Ozaydin, Burnaz, & Topcu, 2016).

Another interesting approach, although not yet applied in the sphere of sponsorship, is the application of Data envelopment analysis (DEA) and efficiency analysis the efficiency of sports teams. According to the received results of efficiency analysis, managers can choose whether a player should be given more play time or not, the board can decide to decrease or increase player's salary, or sponsors can make a decision which player or team to sponsor. For example, an interesting distance-based approach to efficiency initially suggested by Jeremic et al. (2012) was applied to evaluating efficiency of basketball players (Radovanović, Radojičić, Jeremić, & Savić, 2013).

Multivariate statistical analyses were also employed to assess the effectiveness of sponsorship, which can be used in decision making in sponsorship. For example, linear regression was employed to model the accuracy and certainty of brand recognition (Olson & Mathias Thjømøe, 2009). On the other side, multivariate statistical analyses were used in sports analytics. Multiple linear regression was used to calculate the efficiency of football players in the UEFA Champions League (Radojičić, Djokovic & Jemremić,

2016), while cluster analysis and Principal component analysis (PCA) were used to assess players of Real Madrid and Barcelona (Radojičić, Milenković, Totić, Bijelić, Djoković, 2013).

The presented literature review shows that the field of application of statistical and mathematical methods on data related to sport is developing and that the obtained results can be of use for decision making in sponsorship.

### 3. RESEARCH RESULTS

In the proposed research we collected the data on the Premier League, La Liga, and Ligue 1 for the season 2016/17. The data was collected from the official web sites of the three leagues which provide aggregate statistics (Soccer Stats, 2018). The chosen indicators which we observed in the analysis can be grouped as follows:

- Attractiveness of the game – Measured through indicators *Goals for, Number of assists, Total shots, Shots on goal, Goals scored from direct play*
- Roughness of the game – Measured through indicators *Number of yellow cards, Number of Red cards, Number of fouls against.*

We chose the indicators of attractiveness and roughness of the game as we believe these features of the game can attract or turn away football fans and spectators. Accordingly, we consider that these features might be of interest for sponsors, so as they could choose the league and/or club which will attract the most viewers.

#### 3.1. Comparison of the three football leagues

In this part of our analysis we aimed to inspect whether there is statistically significant difference between the values of the chosen eight indicators within the three leagues. The first step was to determine whether the observed indicators are normally distributed or not. The Kolmogorov-Smirnov test showed that none of the indicators is Normally distributed, therefore, in the next steps of the analysis we used nonparametric tests.

When it comes to the comparison of attractiveness indicators between the three leagues the Kruskal-Wallis test indicates that there is no statistically significant difference. This means that the spectator or viewer of the French League can expect to enjoy the same attractiveness of the game as the spectator or viewer of the Spanish or English league. There is no statistically significant difference between the total number of goals for (KW=2.483,  $p>0.05$ ) and for the number of assists (KW=0.346,  $p>0.05$ ). Also, goals are scored after a similar number of shots on goal (KW=4.159,  $p>0.05$ ) and total shots (KW=2.946,  $p>0.05$ ). In the three observed leagues, there is no difference in the number of goals scored from direct play (KW=4.601,  $p>0.05$ ). All this could lead to an important conclusion that the French league, which might not be financially and marketing supported as English or the Spanish League, is not missing out on-field excitement. Namely, Premier League clubs' revenue in 2016 was €110m per club, compared to €44m in La Liga, and €21m in Ligue 1 (UEFA, 2016).

Analysis of the roughness indicators shows there is difference between the leagues. It has been established that there is statistically significant difference: *Number of yellow cards* (KW=32.256,  $p<0.01$ ), *Number of Red cards* (KW=16.559,  $p<0.01$ ), and *Number of fouls against* (KW=26.051,  $p<0.01$ ). All indicators are related to the subjective factor reflected through referees, because they are the ones who assess whether a particular start or duel will be defined as a foul and whether it will be sanctioned by a card. As there has been noted that there is difference between the three leagues in terms of roughness, we examined more closely the Medians of the three indicators per league. The results are given in Table 1.

**Table 1:** Median of the chosen three indicators of roughness per three observed leagues

<b>League</b>	<b>Number of yellow cards</b>	<b>Number of red cards</b>	<b>Number of fouls</b>
Premier League	71.5	2.0	430.5
La Liga	97.5	4.0	537.5
Ligue 1	65.0	4.0	470.0

According to the median, the most yellow cards are awarded in the Spanish league. However, the situation is different when the number of red cards is observed. In La Liga the red cards are awarded more often, and the same accounts for France. The results of French League have the lowest median of *Number of yellow cards* and the highest median of *Number of red cards*. This could indicate that style of the League 1 is rougher with more tackles which are sanctioned. On the other hand, this could indicate that the referees in the league do not allow rough play. As far as the number of fouls is concerned, they are most often awarded in the Spanish league, which has the median of 537.5. This result could be interpreted as that the referee

organization in Spain suggests their referees to protect the players from possible injury and stop any signs of dangerous play. It is presumed, that such a decision has been made because La Liga, especially Real Madrid and Barcelona, has the best and the most expensive players of today's. Namely, their injury and absence from the field would mean a drawback for the team. On the other hand, it would also be a financial loss for the entire league reflected through marketing activities and sponsorship contracts, and primarily by selling broadcast rights. The least fouls are awarded in Premier League, which means that their referees allow a rougher game. It can also be concluded that the Premier League is therefore the most dynamic of the three leagues as it has the least stoppage time during matches.

To additionally inspect the relationship between the chosen three indicators, we conducted the correlation analysis per league (Table 2). It can be observed that there is high positive correlation between fouls and yellow cards over all leagues, which ranges from 0.702 (Premier League) to 0.619 (La Liga). Such a result indicates that a large number of fouls is accompanied by a larger number of yellow cards. Interestingly, the correlation between the number of yellow and red cards is only observed in the Spanish league. The relationship is such that a greater number of yellow cards leads to a greater possibility of obtaining red card. This indicates that in the French and the English league there is a greater possibility of getting a direct red card. The Pearson's correlation coefficients show that there is no statistically significant relationship between number of fouls and red cards, which may indicate that most red cards are not received after two fouls, whereas that players after the objection or inappropriate tackles often earn the most severe warning.

**Table 2:** Correlation analysis between the chosen three indicators of roughness per three leagues

<i>League</i>		<b>Number of yellow cards</b>	<b>Number of red cards</b>	<b>Number of fouls</b>
Premier League	<b>Number of yellow cards</b>	1	0.226	0.702**
	<b>Number of red cards</b>	0.226	1	-0.026
La Liga	<b>Number of yellow cards</b>	1	0.506*	0.619**
	<b>Number of red cards</b>	0.506*	1	0.168
Ligue 1	<b>Number of yellow cards</b>	1	0.382	0.646**
	<b>Number of red cards</b>	0.382	1	-0.045

Note: \*p<0.05, \*\*p<0.01

### 3.2. Clustering clubs from the three football leagues

The second direction of our research was to cluster clubs of the three observed leagues according to "roughness" and "attractiveness". To conduct the analysis, we performed the K-means clustering (Hartigan & Wong, 1979). K-means clustering algorithm partitions n observations into k predetermined number of clusters in which each observation belongs to the cluster with the nearest mean, serving as the centre of the cluster. Therefore, on our analysis, the cluster centre is a fictive club. To cluster clubs according to "roughness" we used *Number of yellow cards*, *Number of red cards*, and *Number of fouls*. We retained three clusters which we named Rough, Medium rough, and Soft clubs.

The distance between the cluster Rough clubs and Medium rough clubs is 74.682, between Rough clubs and Soft clubs 151.281, and between Medium rough and Soft clubs 77.336. The cluster centres are presented in Table 3. It can be observed that the clubs in the cluster Rough clubs tend to receive more yellow cards, red cards, and commit more fouls. Interestingly, the Medium rough clubs almost receive the same number of red cards as the Rough clubs. According to the cluster centre of the third cluster, the clubs in cluster tend to play "clean" and avoid making fouls.

**Table 3:** Cluster centres of the three retained clusters of clubs based on "roughness"

<i>Cluster</i>	<b>Number of yellow cards</b>	<b>Number of red cards</b>	<b>Number of fouls</b>
<i>Rough clubs</i>	102.3	4.4	564.7
<i>Medium rough clubs</i>	77.2	4.2	494.3
<i>Soft clubs</i>	66.0	3.2	417.8

The analysis which would be of interest for the decision-makers is to observe how many clubs from each league is in each of the retained clusters and to provide additional information on the retained clusters. Table

4 provides valuable insights. The cluster Rough clubs consists of 12 clubs of which 11 are from Spanish league, and only one from French league (Toulouse). Interestingly, there is no club which plays in the Premier league that is characterized as rough. For the European football it is a good result that this is the smallest cluster, meaning that the clubs from the first leagues of these three countries primarily practice “fair play”. When it comes to the cluster Medium rough clubs, the clubs in this cluster have a similar average of red cards as Rough clubs, but they have considerably fewer fouls made and yellow cards obtained. This cluster is mostly made of French clubs (10), followed by Spanish (7) and English clubs (5). The last cluster includes 15 clubs from Premier League, nine from Ligue 1 and only two clubs from La Liga. Interestingly, the two clubs from La Liga are the two best Spanish clubs, Real Madrid and Barcelona. Therefore, according to the number of fouls that their players make, the number of red and yellow cards received, Real Madrid and Barcelona are more similar to English than Spanish clubs.

**Table 4:** Cluster centres of the three retained clusters of clubs based on “roughness”

Cluster	League			Total
	Premier League	La Liga	Ligue 1	
<i>Rough clubs</i>	0	11	1	<b>12</b>
<i>Medium rough clubs</i>	5	7	10	<b>22</b>
<i>Soft clubs</i>	15	2	9	<b>26</b>

However, since the previously conducted Kruskal-Wallis test indicated that there might be difference in the referees’ criteria between the observed leagues, these assigned cluster names should be taken with caution. Namely, the “soft” clubs do not have to play without contact yet that referees hesitate to give their players red or yellow cards. One thing is certain, Real Madrid and Barcelona in the Spanish league have a similar treatment from the referees as clubs from the English League.

For potential further, in-depth analysis, we provide the list of clubs within each cluster (Table 5).

**Table 5:** Clubs which make each of the three retained clusters on based on roughness indicators

Rough teams	Medium rough teams		Soft teams	
Sevilla (ESP)	Middlesbrough (UK)	Watford (UK)	Chelsea (UK)	Hull City (UK)
Espanyol (ESP)	Everton (UK)	Monaco (FRA)	Tottenham (UK)	Sunderland (UK)
Alaves (ESP)	Real Sociedad (ESP)	Olympique Lyonnais (FRA)	Stade Malherbe Caen (FRA)	Montpellier (FRA)
Malaga (ESP)	Las Palmas (ESP)	Olympique de Marseille (FRA)	West Ham United (UK)	Barcelona (ESP)
Valencia (ESP)	Manchester United (UK)	Nantes (FRA)	Arsenal (UK)	Paris Saint Germain (FRA)
Real Betis (ESP)	Villarreal (ESP)	Saint-Etienne (FRA)	Southampton (UK)	Nice (FRA)
Deportivo La Coruna (ESP)	Atletico Madrid (ESP)	Avant de Guingamp (FRA)	West Bromwich Albion (UK)	Girondins Bordeaux (FRA)
Leganes (ESP)	Crystal Palace (UK)	Lille (FRA)	Bournemouth (UK)	Rennes (FRA)
Sporting Gijón (ESP)	Athletic Bilbao (ESP)	Metz (FRA)	Liverpool (UK)	Angers (FRA)
Osasuna (ESP)	Eibar (ESP)	Dijon (FRA)	Leicester City (UK)	Real Madrid (ESP)
Granada (ESP)	Celta Vigo (ESP)	Nancy (FRA)	Stoke City (UK)	Manchester City (UK)
Toulouse (FRA)			Swansea City (UK)	Lorient (FRA)
			Burnley (UK)	Bastia (FRA)

To cluster clubs according to “attractiveness” we used *Goals for*, *Number of assists*, *Total shots*, *Shots on goal*, and *Goals scored from direct play*. We again retained three clusters which we named Attractive, Watchable, and Boring clubs.

The distance between the clusters Attractive and Watchable clubs is 144.595, between Attractive and Boring clubs 237.800, and between Watchable and Boring clubs 93.869. Comparing the distances between clusters retained in case of “roughness” and “attractiveness”, it can be observed that in the case of “attractiveness” the clusters are more separated. The cluster centres are presented in Table 6. According to the cluster centres it can easily be concluded that there is difference in the values of attractiveness indicators which achieve the clubs in the three clusters. Attractive clubs dominate within all five attractiveness indicators.

**Table 6:** Cluster centres of the three retained clusters of clubs based on “attractiveness”

Cluster	Goals for	Number of assists	Total shots	Shots on goal	Goals scored from direct play
<i>Attractive clubs</i>	86.3	57.1	601.3	238.4	67.2
<i>Watchable clubs</i>	53.9	37.1	479.3	176.9	38.8
<i>Boring clubs</i>	41.8	27.5	399.9	130.3	28.7

Additional analysis of the three retained clusters is presented in Table 7. Among the 60 observed football clubs, more than half of them can be classified as Boring clubs. Namely, the play of 34 clubs is mostly oriented to defence and actions to save their goal. The league with most Boring clubs is the French league, where 43.33% of them practices such tactic, followed by Spanish league (36.67%), and English league (33.33%). Interestingly, the least boring and the most attractive clubs come from the English league. The six attractive clubs from the Premier league are the clubs which finished the season 2016/17 on the top six places (Arsenal, Liverpool, Manchester United, Manchester City, Tottenham, Chelsea). Expectedly, the two attractive clubs from the Spanish league are Barcelona and Real Madrid. However, the analysis of the attractive clubs from the French league provides interesting insights. Olympique Lyonnais has been grouped as an attractive club, while Nice was not. However, Nice completed the championship as third, and Olympique Lyonnais as fourth. Therefore, although Olympique Lyonnais played more attractive football, Nice had better defence which eventually led to its better rank. The provided clustering structure indicates that the Premier League is the most attractive league, where the spectators could expect more goals and more shots on target.

**Table 7:** Cluster centres of the three retained clusters of clubs based on “attractiveness”

Cluster	League			Total
	Premier League	La Liga	Ligue 1	
<i>Attractive clubs</i>	6	2	3	<b>11</b>
<i>Watchable clubs</i>	4	7	4	<b>15</b>
<i>Boring clubs</i>	10	11	13	<b>34</b>

For potential further, in-depth analysis, we provide the list of clubs within each cluster (Table 8).

**Table 8:** Teams which make each of the three retained clusters based on attractiveness indicators

Attractive teams	Watchable teams	Boring teams		
Arsenal (UK)	Southampton (UK)	Leicester City (UK)	Stoke City (UK)	Hull City (UK)
Chelsea (UK)	Everton (UK)	Swansea City (UK)	Burnley (UK)	Sunderland (UK)
Tottenham (UK)	Bournemouth (UK)	Middlesbrough (UK)	Crystal Palace (UK)	Watford (UK)
Paris Saint Germain (FRA)	West Ham United (UK)	Las Palmas (ESP)	Deportivo La Coruna (ESP)	Leganes (ESP)
Real Madrid (ESP)	Sevilla (ESP)	Alaves (ESP)	Eibar (ESP)	Celta Vigo (ESP)
Manchester City (UK)	Villarreal (ESP)	Real Betis (ESP)	Sporting Gijón (ESP)	Nice (FRA)
Olympique Lyonnais (FRA)	Atletico Madrid (ESP)	Stade Malherbe Caen (FRA)	West Bromwich Albion (UK)	Girondins Bordeaux (FRA)
Manchester United (UK)	Real Sociedad (ESP)	Espanyol (ESP)	Saint-Etienne (FRA)	Rennes (FRA)
Monaco (FRA)	Athletic Bilbao (ESP)	Granada (ESP)	Metz (FRA)	Lorient (FRA)
Barcelona (ESP)	Malaga (ESP)	Bastia (FRA)	Toulouse (FRA)	Nancy (FRA)
Liverpool (UK)	Valencia (ESP)	Lille (FRA)	Osasuna (ESP)	Nantes (FRA)
	Olympique de Marseille (FRA)			Dijon (FRA)
	Angers (FRA)			
	Montpellier (FRA)			
	Avant de Guingamp (FRA)			

## 4. CONCLUSION

The field of study of application of statistical, mathematical, and data-mining techniques in sponsorship and in sports analytics is developing (Radojičić, Djoković & Jeremić, 2016). In this paper, we aimed to enlarge the current literature on the topic of decision making in marketing, particularly in sport sponsorship. Herein, we applied statistical multivariate analyses to ease the sponsors' decision making when choosing which league or club from the Premier League, La Liga or Ligue 1 to sponsor.

Our results show that there is no statistically significant difference between the three observed leagues when it comes to attractiveness, meaning the matches in all three leagues are of same quality. However, difference was spotted when it comes to roughness. Maybe there really is the difference in the style of play, but maybe there is difference in the referees' approach to what a *foul is* and what is not. This result might indicate that the game in La Liga might be a little bit slower and with more stoppage time due to referees' decisions. The results of clustering showed that Real Madrid and Barcelona are more similar to English than Spanish clubs and that most of the clubs from the three leagues are oriented to defence and actions to save their goal.

Several future directions of the study could be determined. One direction could be towards the introduction indicators of popularity of football clubs on social media. Namely, football clubs have large, committed communities of fans who can easily be communicated with via sponsorship. The second direction of the analysis could be the application of Structural Equation Measurement (SEM) analysis. Namely, SEM has been used with success in the analysis of data related to football. For example, it was used to examine the linkages between financial performance, sporting performance and stock market performance of English football clubs (Samagaio, Couto, & Caiado, 2009). Also, other statistical multivariate analysis such as Principal Component Analysis could be employed (Moura, Martins, & Cunha, 2014).

We hope the presented research will provide additional insights on differences between the three European football leagues and on application of multivariate analysis in decision making in sport sponsorship.

## MEASURES OF DIGITALIZATION IN EUROPEAN ENTERPRISES: LINEAR REGRESSION MODEL

Marko Prodanović<sup>\*1</sup>, Damjan Rovinac<sup>1</sup>, Stefan Radibratović<sup>1</sup>  
<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia  
<sup>\*</sup>Corresponding author, e-mail: marcusdee012@gmail.com

**Abstract:** *The main idea of this research is to show how digital world expansion that is ubiquitous nowadays affects the economies. We observed the financial measures of digitalization, as total turnover from e-commerce in enterprises, and nonfinancial indicators such as percentage of enterprises that are purchasing or selling online, that own a website and advertise through the internet, that employ ICT specialists, as well as the percentage of employees that use a computer or mobile internet connections. In this paper, we mainly focused on countries in EU. A backward linear regression model was employed in the analysis. Our findings show that the total turnover from e-commerce is mostly affected by Internet advertising, number of ICT specialists employed and the percentage of enterprises that are selling online. The obtained model accounts for 73% of the variability. The presented research might provide insights on the factors which influence digitalization of enterprises.*

**Keywords:** *European Union, digitalization, enterprises, e-commerce, the linear regression model*

### 1. INTRODUCTION

Economic growth, as a very important feature for every country, depends on many factors such as natural resources, implemented laws, available technology, human capital. The digitalization is one of them, especially important nowadays. Because of this, the whole world, including European Union (EU), started to measure digitalization and to collect data for analysis in order to increase its positive effects. The term digitalization could be defined as a process of creating new value through the aspects of digital technology (Schallmo & Williams, 2018a). It focuses on capabilities which support the whole business idea, and with the fast development in the field of ICT, countries, industries, and companies compete and create value in completely new ways (Schallmo & Williams, 2018b).

World institutions are continually reporting on how to stimulate the digital transformation of European economies and enterprises, and proposing short and long-term strategies on digital entrepreneurship to maximize its impact (Ardolino et al., 2017). Before any new processes implemented, it is important that we have a clear picture of how the new process affect other parts of the industry. More particularly, EU has noticed that digitalization can affect massively on traditional businesses and industries, by creating and destroying jobs (European Economic and Social Committee, 2017). Logically, by implementing new methods of work and new technologies, not all the people in the industry, especially older generations, can follow up new trends and be ready to change their work routine. Accordingly, it is clear that implementing digitalization can have a positive effect, but it is also really important to be aware of the downsides and to find a reasonable solution to minimize the possible negative effect.

It is also important to mention that not all EU countries are developed, and according to that, digitalization is not the main focus for all. Research showed that in developing countries population age and urban population are positively associated with the ICT adoption (Billon, Marco, & Lera-Lopez, 2009). Additional research showed that in developing countries Internet costs are negatively associated with ICT adoption (Chen, Jaw, & Wu, 2016). However, a number of researches argue that ICT and the Internet decrease production costs, enhance the creation and spread of new ideas, support knowledge, sharing, and improve R&D processes (Kamalipour & Friedrichsen, 2017; Matt, Hess, & Benlian, 2015; Meijers, 2014). The main belief of these authors is that ICT is tightly linked to higher economic growth (Czernich, Falck, Kretschmer, & Woessmann, 2011; Degryse, 2016; Heeks, 2010). Therefore, countries should create strategies in order to use the potential that the digitalization has (O'Donnell, 2016).

The Digital Economy is a global phenomenon, and in order to see the whole potential of the digital economy, it is important to review EU on a global level. In order to do that, European Commission has introduced Digital Economy and Society Index - DESI (European Commission, 2018), which evaluates the performance of both the individual EU countries and EU as a whole in comparison to 15 other countries: Australia, Brazil,

Canada, China, Iceland, Israel, Japan, Korea (Rep.), Mexico, New Zealand, Norway, Russia, Switzerland, Turkey, and the United States.

When we discuss about digitalization, NRI index is something worth to mention. NRI represents a key tool in assessing countries' preparedness to reap the benefits of emerging technologies and capitalize on the opportunities presented by the digital transformation and beyond. More particularly, the World Economic Forum experts assess the factors, policies, and institutions that enable a country to fully leverage information and communication technologies (ICTs) for increased prosperity and crystallizes them into a global ranking of networked readiness at the country level in the form of the NRI (The Global Information Technology Report , 2016).

The research conducted in this paper aims to find the connections between different digitalization indicators. Connection between indicators could be very useful for society in global, especially for companies and counties in developing stage. We observed the financial measures of digitalization, as total turnover from e-commerce in enterprises, and nonfinancial indicators such as percentage of enterprises that are purchasing or selling online, that own a website and advertise through the internet, that employ ICT specialists, as well as the percentage of employees that use a computer or mobile internet connections. In this paper, we mainly focused on countries in Europe, specifically the 28 countries that are the members of the EU, EU-28.

The paper is organized as follows. The next section gives the list of indicators that are used in this study, as well as the employed methodology. The third section presents the results and discusses the findings of the research. The final section gives some concluding remarks on the presented topic.

## 2. METHODOLOGY

This paper focuses on investigating and modelling the relationship among different measures of digitalization in the enterprises in Europe. The data for this analysis are collected from Eurostat and are publicly available (Eurostat, 2017). The data are collected for 28 European countries (EU-28). We observed a set of eight variables that measure the digitalization of the enterprises in the economies of European Union countries:

- *Value of E-Commerce Sales of Enterprises* – This indicator measures enterprises' total turnover from e-commerce. It is given as a percentage of total turnover and includes all the enterprises, without financial sector (ten persons employed or more).
- *E-commerce Purchases of Enterprises* – The percentage of enterprises that have ever made any purchase through computer-mediated networks.
- *E-commerce Sales of Enterprises* – The percentage of enterprises that are selling their products online (which covers at least 1% of their turnover).
- *Internet Advertising of Enterprises* – The percentage of enterprises that use any social media for advertising over the internet.
- *Computer Internet Connections used by the Employees in Enterprises* – Persons employed that are using computers with access to World Wide Web; a percentage of total employment.
- *Mobile Internet Connections used by the Employees in Enterprises* – This indicator counts persons employed in a company (a percentage of total employment), which were provided with a portable device that allows a mobile connection to the internet for business use.
- *Enterprises that have a Website* – Percentage of enterprises that own a website, enterprises without financial sector (ten persons employed or more).
- *Enterprises that Employ ICT Specialists* – A percentage of enterprises that employ ICT specialists, without financial sector.

In order to investigate and model the relationship among digitalization indicators in enterprises in EU, we observed the variable *Value of E-Commerce Sales of Enterprises* as a dependent variable. We have chosen this specific variable because it can be defined as a financial indicator that describes the current turnover from digital commercialization. We aimed to investigate whether the set of seven other variables, which could be defined as the explanatory variables, significantly influence the e-commerce sales in Europe.

We used backwards multiple least squares linear regression (Narula & Wellington, 1982; Rencher & Christensen, 2012; Seal, 1967) to create a model, which would automatically exclude non-significant variables from the observation (Gujarati, 2002). The original multivariate regression model is given by the following formula:

$$Y_i = \beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \dots + \beta_k X_{ki} + \varepsilon_i \quad (1)$$

where  $Y_i$  is an  $i$ -th observation of the dependent variable  $Y$ ,  $\beta_j$  is a  $j$ -th regression coefficient ( $j=1, \dots, k$ ),  $X_{ji}$  is an  $i$ -th observation for the  $j$ -th independent variable, and  $\varepsilon$  is a residual.

### 3. RESULTS AND DISCUSSION

Table 1 gives the descriptive statistic of the variables used in the research. As described in Section 2, variables are mainly given as the percentage of turnover/enterprises/employment/etc. Thus, all the variables are normalized. Among the observed variables, the variables *E-commerce Purchases of Enterprises* and *Enterprises that have a Website* have the widest range. The largest mean value is for the *Enterprises that have a Website*, 76.11%, which tells us that this is the mostly spread digitalization indicator in the countries of EU. Other two digitalization indicators that are spread across Europe are *Internet Advertising of Enterprises*, with the mean value 49.96%, and *Computer Internet Connections used by the Employees in Enterprises*, with the mean value 48.86%. The largest standard deviation is noticed with the variable *E-commerce Purchases of Enterprises*, SD=16.41%, followed by *Internet Advertising of Enterprises*, SD=13.13%.

**Table 1:** The descriptive properties of variables defined in Section 2

Employment rates of recent graduates	Minimum	Maximum	Mean	Std. Deviation
Value of E-Commerce Sales of Enterprises	4	33	16.360	7.445
E-commerce Purchases of Enterprises	11	75	38.571	16.419
E-commerce Sales of Enterprises	7	30	17.250	6.598
Internet Advertising of Enterprises	27	74	49.960	13.128
Computer Internet Connections used by the Employees in Enterprises	27	75	48.860	11.891
Mobile Internet Connections used by the Employees in Enterprises	10	51	25.071	10.846
Enterprises that have a Website	45	96	76.110	11.955
Enterprises that Employ ICT Specialists	10	33	20.960	5.175

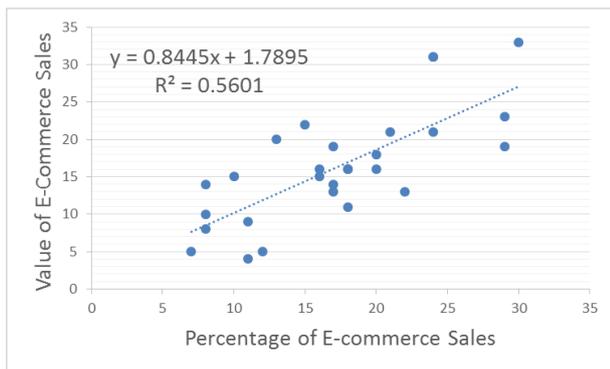

The basic objective of this study was to determine the relationships between *Value of E-Commerce Sales of Enterprises* and the overall digitalization performance. For this purpose, we calculated Pearson correlation coefficients that are given in Table 2.

**Table 2:** Pearson's correlation coefficients between variables

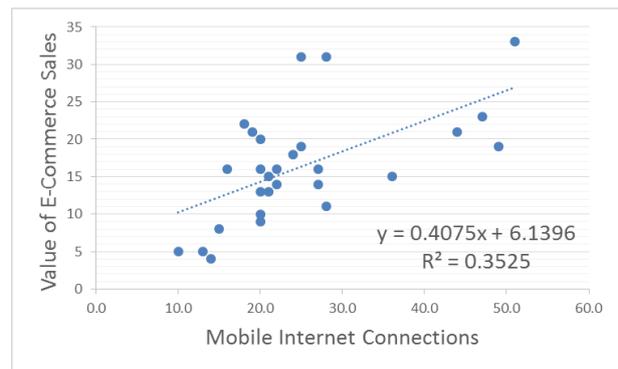

Employment rates of recent graduates	Value of E-Commerce Sales	E-commerce Purchases	E-commerce Sales	Internet Adv.	Computer Internet Conn.	Mobile Internet Conn.	Enterprises with a Website
E-commerce Purchases	0.556**						
E-commerce Sales	0.748**	0.603**					
Internet Advertising	0.205	0.454*	0.516**				
Computer Internet Connections by Employees	0.444*	0.785**	0.666**	0.648**			
Mobile Internet Connection by Employees	0.594**	0.669**	0.747**	0.575**	0.822**		
Enterprises that have a Website	0.525**	0.720**	0.661**	0.618**	0.821**	0.618**	
Enterprises that Employ ICT Specialists	0.495**	0.420*	0.469*	0.733**	0.401*	0.495**	0.503**

\*p<0.05, \*\*p<0.01

From Table 2, we can see that the variable *Value of E-Commerce Sales (percentage of turnover)* is strongly correlated with *E-commerce Sales (percentage of enterprises that are selling online)* and *Mobile Internet Connections used by the Employees in Enterprises*. These relationships are graphically presented in Figure 1, a and b. Pearson's correlation coefficient ranges from 0.205 to 0.822 and we have only one coefficient which is not statistically significant, the correlation coefficient between *Internet advertising* and *Value of E-Commerce sale* ( $r=0.205$ ,  $p>0.05$ ).

(a)

(b)

**Figure 1:** Relationship between *Value of E-Commerce Sales* and (a) *Percentage of E-commerce sales* and (b) *Mobile Internet Connection used by the Employees in Enterprises*

From Figure 1a and Table 2, it can be seen that the Pearson's correlation coefficient between *Value of E-Commerce Sales (percentage of turnover)* and *E-commerce Sales (percentage of enterprises that are selling online)* is  $r=0.748$  ( $p<0.001$ ). The coefficient of determination is  $R^2=0.5601$ , indicating that the percentage of enterprises that are selling online alone explains 56.01% of the variability in the percentage of total turnover for e-commerce. In Figure 1b and Table 2, we see that the Pearson's correlation coefficient between *Value of E-Commerce Sales (percentage of turnover)* and *Mobile Internet Connections used by the Employees in Enterprises* is  $r=0.594$  ( $p=0.001$ ). The coefficient of determination  $R^2=0.3525$ , which means that 35.25% of total turnover for e-commerce is explained solely by mobile internet connections.

In order to model the presented relationships, we have built the linear regression model. As mentioned previously, we used backwards multiple least squares linear regression model. The original regression model is presented in Table 3.

**Table 3:** The original multiple linear regression model for the dependent variable *Value of E-Commerce Sales of Enterprises*

Explanatory variables	B	SE	Beta	t	95%CI B	
Intercept	-2.174	5.785		-0.376	-14.241	9.894
E-commerce Purchases of Enterprises	0.055	0.082	0.121	0.670	-0.116	0.225
E-commerce Sales of Enterprises	0.687	0.191	0.609	3.598**	0.289	1.086
Internet Advertising of Enterprises	-0.396	0.111	-0.698	-3.555**	-0.628	-0.164
Computer Internet Connections used by the Employees in Enterprises	-0.067	0.204	-0.107	-0.327	-0.493	0.359
Mobile Internet Connections used by the Employees in Enterprises	0.117	0.161	0.171	0.730	-0.218	0.452
Enterprises that have a Website	0.110	0.134	0.177	0.822	-0.170	0.391
Enterprises that Employ ICT Specialists	0.775	0.260	0.539	2.978**	0.232	1.318
F	10.974**					
R <sup>2</sup>	0.793					
Adjusted R <sup>2</sup>	0.721					

\* $p<0.05$ , \*\* $p<0.01$

In the original linear regression model, all of the variables defined for this research were included in the analysis. From Table 3 it can be seen that, among all of the listed variables included in the model, only *E-commerce Sales of Enterprises*, *Internet Advertising of Enterprises*, and *Enterprises that Employ ICT Specialists* influence the dependent variable *Value of E-Commerce Sales of Enterprises*. All other variables' influences are not significant ( $p>0.05$ ). With the adjusted coefficient of determination  $R^2=0.7210$ , the model reveals that 72.1% of the variability of total turnover for e-commerce is explained by the given combination of explanatory variables. The whole model is significant at 0.01 level of significance ( $F=10.974$ ,  $p<0.001$ ). The model also exhibits a large level of multicollinearity among explanatory variables.

Table 4 presents the reduced backwards multiple linear regression model. This model was used to exclude the non-significant variables from the model, step by step automatically, and thus to create the model that would better fit the given data.

**Table 4:** The reduced multiple linear regression model for the dependent variable *Value of E-Commerce Sales of Enterprises*

Explanatory variables	B	SE	Beta	t	95%CI B	
Intercept	1.144	3.255		0.352	-5.573	7.862
E-commerce Sales of Enterprises	0.906	0.133	0.803	6.796**	0.631	1.181
Internet Advertising of Enterprises	-0.363	0.087	-0.639	-4.165**	-0.542	-0.183
Enterprises that Employ ICT Specialists	0.844	0.214	0.587	3.941**	0.402	1.286
F	25.335**					
R <sup>2</sup>	0.760					
Adjusted R <sup>2</sup>	0.730					

\*p<0.05, \*\*p<0.01

From Table 4, it can be seen that the reduced model includes only three, of initially seven explanatory variables. As indicated by the original model, only *E-commerce Sales of Enterprises*, *Internet Advertising of Enterprises*, and *Enterprises that Employ ICT Specialists* significantly influence *Value of E-Commerce Sales of Enterprises*. The most influential indicator is *E-commerce Sales of Enterprises* (percentage of enterprises that are selling online). What is interesting to see from result is that the values of *Internet Advertising of Enterprises* have a negative impact on the dependent variable. This result could be interpreted as that the use social networks for advertising does not automatically mean the sales are going to rise.

The estimated model is presented as follows in the given formula:

$$\hat{Y} = 1.144 + 0.906X_1 - 0.363X_2 + 0.844X_3 \quad (2)$$

where *Y* is the dependent variable *Value of E-Commerce Sales of Enterprises*, *X*<sub>1</sub> is *E-commerce Sales of Enterprises*, *X*<sub>2</sub> is *Internet Advertising of Enterprises*, and *X*<sub>3</sub> is *Enterprises that Employ ICT Specialists*. With the adjusted coefficient of determination R<sup>2</sup>=0.730, the model reveals that 73% of the variability of the total turnover of e-commerce in European enterprises is explained by the given combination of explanatory variables. The whole model is significant at 0.01 level of significance (F=25.335).

#### 4. CONCLUSION

This research focused on creating a model that would analyze the dependence of a total turnover of e-commerce in European enterprises, as a financial indicator, from a set of indicators that measure the state of digitalization transformation.

After four iterations in a backwards linear regression model analysis, the final model shows that the dependent variable *Value of E-Commerce Sales of Enterprises* depends on *E-commerce Sales of Enterprises*, *Internet Advertising of Enterprises*, and *Enterprises that Employ ICT Specialists*. Other four variables (*E-commerce Purchases of Enterprises*, *Computer Internet Connections used by the Employees in Enterprises*, *Mobile Internet Connections used by the Employees in Enterprises*, and *Enterprises that have a Website*) are not statistically significant in creating the model. The final model, presented in table 4, has the coefficient of determination R<sup>2</sup>=0.73, which means that 73% of the variability of total turnover for e-commerce is explained by the given combination of explanatory variables.

This analysis could be useful for researchers and companies which have implemented digitalization or have a plan to do so in a future. According to this data, all the enterprises can focus only on three variables and consequently, reduce costs in the process of digital transformation. Besides companies, research can be helpful for policy makers and governments as it provides insights that ICT specialists are needed in companies so as to increase the value of e-commerce sale and thus increase the level of economic activity. For example, policy makers could promote higher education in the ICT field.

As a direction of future research, it would be interesting to analyze the same regression model, using the same variables, but on different groups of countries (divided for example according to different life standards). It is possible to get certain changes in scores because of the market diversity and different people priorities according to their living standards (developed countries, developing countries, or undeveloped countries).

**Abstract:** *In modern business it is a challenge to find possibilities to improve business decision-making of managers. Managers' decisions directly affect the profit and success of companies at the market. As very complex process that should result with right managers' decisions, there is need to improve methods and techniques of modern decision-making. In the paper the significance and application of association rules will be analysed on the example of car sales. Research will be dealing with data in large databases of car sales by use of data mining software Orange. Main results provide recommendation to create suitable promotional activities according to existing and potential buyers, with car offers and additional equipment that are bought together. One of advantages of this model, when compared to others, is that it could also be applied in other industries. Associations have been used in order to make convenient and interesting product offer for the market.*

**Key words:** *decision-making, data mining, association rules.*

## 1. INTRODUCTION

Business decision-making is choosing the best solution of all available alternatives, according to (Suknović and Delibašić 2010). According to (Agrawal et al, 1993), Agrawal first established the association rules with the purpose of analysis the market basket.

Although the market basket is mostly being used in sales, it is important to highlight that there are also other segments where its application is significant: analysis of finances, medical analysis, then analysis of insurance companies or telecommunications services.

The example of company Catalogue sales is one of the examples of successful application of method of association rules in marketing, especially on improvement of sales (Verhoef et al, 2010). The most important result of the application of association rules is oriented towards the need to create thematic catalogues that will contain certain items of products that will adapt to market segments.

In order to solve the problem of company Colorful world of colors the method of association rules had been used (Verhoef et al, 2010). Company recognized the fall of sales of certain products. The goal was to find out if these are products that are sold together with some other products or on their own. Analysis was designed so that it was analysed the preferences of buying non-popular set of products in combination with the main set of products. In main set of products are the ones that bring the biggest sales profit. Research showed that the buyers continued to buy products from the main set, and the sales of non-popular products stayed at the same level.

Another example of application of method of association rules has been described in the frame of searching the web (Verhoef et al, 2007). Searching the association rules were used to reveal the web pages that are jointly used. For instance, information that users who approach to pages A and B also do it for page C, can be used to create certain links (i.e. from A to C), which would result for further analysis of e-business.

Extensive research on association rules mining has been conducted in (Martin et al, 2014). This research extends evolutionary algorithm based on decomposition to perform learning of the intervals of the attributes and a condition selection for each rule. Application of association rules on market basket analysis had been described in (Omondi, A. O., and Mbugua, A. W., 2017). The methodology used contain minimum spanning trees. According to (Jain, S. et al, 2018), the importance of data mining and business strategy have been described with patterns that emerged as results. In (Griva, A. et al, 2018) there is business analytics approach that describes customer visit segments from basket sales data.

Researchers were dealing with the extensive application of method of association rules in business decision-making. This method has been proved to be the most successful in the field of market basket. This paper presents the application of association rules with the purpose of discovering patterns of the customers' buying habits in the car industry.

## 2. RESEARCH

Data mining is mostly oriented towards the model creation. Under right circumstances, model can provide the explanations how output elements of certain interest, such as precise order or unsuccessful payment of bills, are connected and can be predicted by available facts.

Association rules determine the items that are bought together. According to (Grabmeier, J., and Lambe, L., 2007), the term of association rules was firstly used by Agrawal. The task of association is to find out rules that exist between the cases in the dataset. According to (Grabich, M., 1997), knowledge is accumulation of the facts and information, whilst wisdom is the synthesis of knowledge and experience that deepen our understanding of the connections between different entities and eventual some hidden message in their existing. We can say that knowledge is tool, while wisdom is set of skills where we use knowledge as the tool. Cases for association rules are grouping the items that are bought together in shopping in supermarket – the field of market basket is dedicated to this issue (Fernando, B., and Susanto, B., 2011).

The importance of rules, that is the quality of rules discovered by the association, is determined based on the markers of support and confidence. Support is the procentual part from the sample that applies to certain rule, that is the number of instances that satisfy a rule. Confidence tells what percentage of cases possess attribute A, also possess attribute B. The biggest fault of the association rules is that in most cases of analysis on large databases many rules are not interlinked, so their simplicity can go to inconsistency (Doko A., 2010). There are numerous approaches that can be used for revealing certain rules, and the most basic one is the Apriori algorithm. This algorithm works on the preassumption that if certain number of items is present in the dataset, than each item is also present (Grabmeier, J., and Lambe, L., 2007).

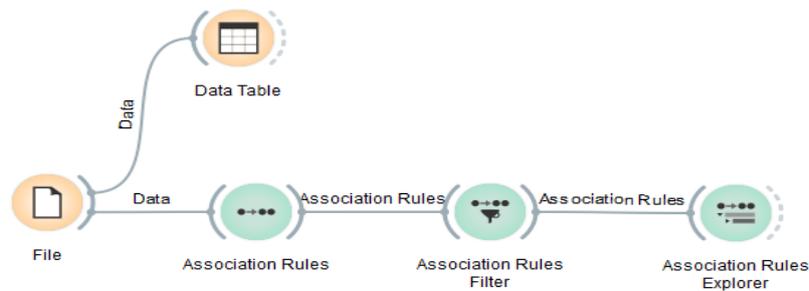

This paper shows the structure of data, the evaluation process and the application of association rules. Based on the structure of research data, as well as the use of tools of business intelligence, the end-result will be the model of business decision-making and knowledge discovery.

According to (AL-Zawaidah and 2011), there are three dimensions that determine the complete development of modern decision-making. Those are: qualitative aspect, quantitative aspect and information-communication aspect. In this paper the multidisciplinary approach will be described. Data will be shown in quantitative way and will be processed by numerical values. Methods and techniques of business intelligence will be applied. Attributes will be described in order to ensure the qualitative aspect of modern decision-making.

Description of the result will ensure qualitative aspect. Use of software architecture and visual overview of data will ensure information-communication aspect of modern decision-making. Data that was used in research is connected to car sales. Total of 1728 transactions are being processed. Attributes are connected to buying (very high rate of transactions, high, medium and low), maintenance of cars (very high rate, high, medium, low), number of car doors (two, three, four, five), number of persons (two, three, four), seating space (small, medium, large) and safety (low, medium, high).

All data are divided into four classes: accurate, unaccurate, good and very good. Orange has options for each phase of CRISP-DM methodology. From large database of car sales transactions, data will be processed in software Orange Canvas (Figure 1), in order to find the association rules. Associations could help buyers with provided knowledge about the best car offer. Buyers help the process of association rules in the selection of cars, based on relevant sales data.

This paper describes the model of application of business intelligence on business problem, with the use of modern software architecture. Orange, as very suitable and user-friendly software, contains numerous options for data mining, such as model creation, testing, data visualization, application of model, etc. One of the popular technologies for data mining is CRISP-DM methodology.

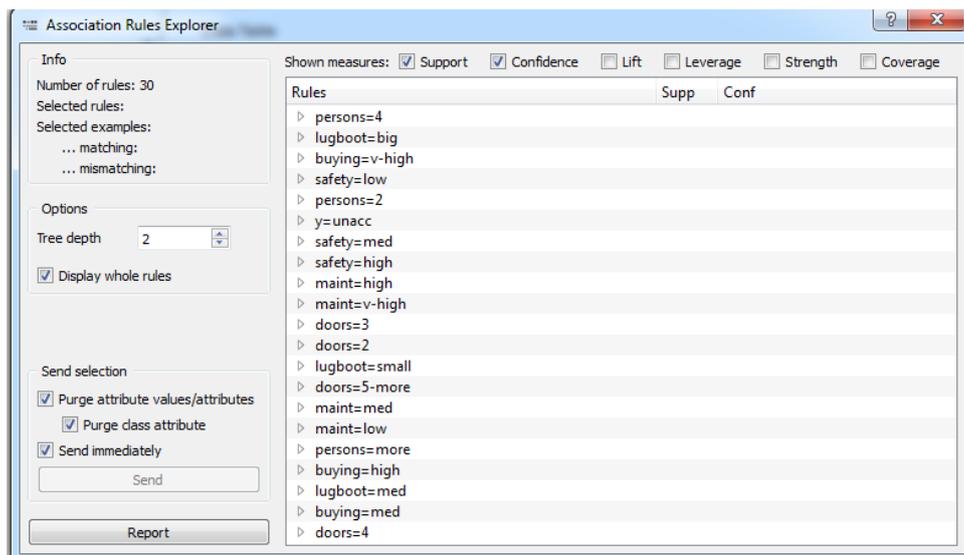

**Figure 1:** Model of association rules created in software Orange Canvas

### 3. DISCUSSION

The parameters for support and confidence are being defined. In this case minimal support is defined at 30%, and minimal confidence is 50%. In further research this parameters were changed in order to show how their change affect the end-result of finding the association rules.

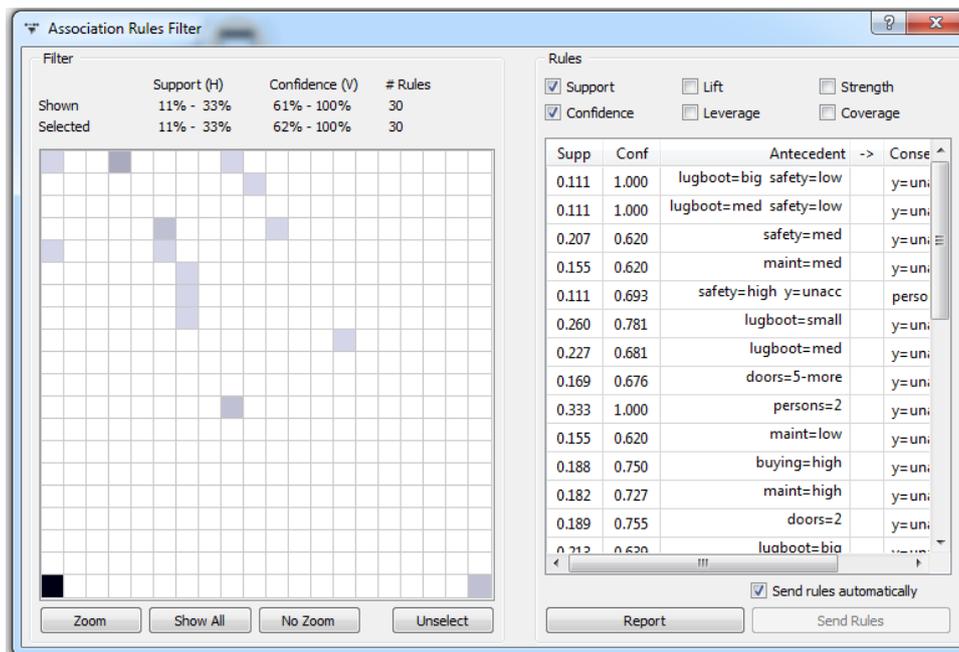

Considering that the minimal support is set at 30%, there are only two association rules derived. First association with provided parameters is that car for two persons belongs to class that is called unaccurate. Moreover, 30% of all car sale transactions for two persons were from the class unaccurate. Support of 50% means that when customers buy from the class unaccurate, there is 50% probability that they will buy cars for two persons. It is predicted that in all future transactions, cars from this class would be offered to customers. Second association rule is that when safety is defined as low, then it follows that the most often car is from class unaccurate. These changes of parameters show the strength of created association rules. The higher the parameters are, the stronger association rules are (with highest probability to show).

Orange is convenient for goods visual overview of gained results. Report shows the number of gained association rules, as well as their description (Figure 2).

**Figure 2:** Association rules

By reducing minimal support from 30% to 10 %, and increasing minimal confidence from 50% to 60% different results are achieved. The number of revealed association rules has increased. There are thirty new association rules with support rate from 11% until 33% and confidence rate from 62% until 100%. Further explanations show patterns that are used to create best set of products for sales which results with highest degree of sales and customer satisfaction. On the left-hand side of the graphicon (Figure 3) there is overview of gained association rules. More details in (Istrat, 2017).

**Figure 3:** Overview of obtained association rules

From the obtained association rules one was highlighted with biggest support of 0.333 and biggest confidence of 1. It is the rule when customers buy car for two persons they most often decide to buy from the class that is defined as unaccurate. Analysis of each association rule show precise patterns of buyers' behaviour. Another association rule that is distinguished by importance is the one with support of 0.260 and confidence of 0.781 which shows that when smaller space inside the car is needed, then buyers most often buy from class unaccurate. Nonstandard data (outliers) can cause problems in creating the model. Outliers represent rare events that are exemptions from the ruled in data. They can affect that the model applied on all data won't be with high quality, because it is difficult for algorithms to find the regularities in the presence of exemption. There are no outliers in this research. More details in (Istrat and Lalić, 2017).

Putting data through Apriori algorithm provided association rules that are then checked and only the most important are chosen to show and create meta rules, in order to get the most acceptable solution. This solution is applicable not only in finding the original universal rule for improvement of car sales, but for other items as well. Recommendation is creating the marketing campaigns based on knowledge that was revealed by use of tools of business intelligence. It is recommended that customers are provided by questionnaire that would search for what car characteristics are the most important.

In the case there are car characteristics (attributes): price, maintenance costs, number of doors, number of seats, size of the truck and safety. Gained association rule showed that buyers that buy car for two persons and which find safety at low level, they most often do it from the class unaccurate.. It is recommended to create promotional activities according to existing and potential buyers, with car offers and additional equipment that are bought together. Advantage of application of this model when comparing to others is that it could be applied also in other different sectors (banking sector, education, etc.). The topic of research is very interesting and provides extensive space for further elaboration of association rules application. Real-term settings and practical implication of research provide advantage when compared to other similar research. Experienced business intelligence analytics were used to define the results of the research.

#### 4. CONCLUSION

It is challenge for researchers to provide significant scientific and expert contribution. Innovation of research of application of business intelligence is shaped with knowledge and creativity, as well as the use of modern software architectures from the field of data mining. Gained associations were used with purpose to make the best products' offer at the market. The process of improvement of model was shown with the help of knowledge that managers get through association rules about habits and buyers' behaviour in shopping. Better choice of the product offer for launching at the market was improved by efficiency of management of sales with the help of business intelligence. Developed model points out at the significance of methods and techniques of business intelligence for support of management of business systems in creating maximization

of profit. The goal of further research would be creating the model of business decision making that is applicable to market in business systems of different areas and with commercial purpose.

# SKI LIFT TRANSPORTATIONS AS PREDICTORS FOR INJURY OCCURRENCE

Boris Delibašić\*<sup>1</sup>, Sandro Radovanović<sup>1</sup>, Miloš Jovanović<sup>1</sup>  
<sup>1</sup>University of Belgrade – Faculty of Organizational Sciences  
\*boris.delibasic@fon.bg.ac.rs:

**Abstract:** *Ski lift transportation data is readily available in ski resorts, still heavily underused. There are many ways this data can be used, but in this paper, we study the applicability of this data for injury occurrence prediction on the data from ski resort Kopaonik. We propose a decision tree model for studying injury occurrence. We find that the most relevant predictor for injury occurrence is the number of ski lift transportations. While the number of ski lift transportations is below a certain threshold we can predict the number of injuries on a day almost linearly with the number of ski lift transportations. When the number of ski lift transportation increases, i.e. when the ski resort gets congested, the occurrence of injuries depends on the level of satisfaction skiers achieve. If skiers have an above average or even a below average level of satisfaction, the injury occurrence risk is high. If skiers experience average level of experience then the risk of injury is average or low.*

**Keywords:** *Ski injury occurrence, data mining, ski lift transportation data, Ski resort Kopaonik*

## 1. INTRODUCTION

The problem studied in this paper is the daily occurrence of ski injuries based on ski lift transportation data, a readily available resource in ski resorts. Studying this problem is important as ski injuries pose a major public healthcare problem with significant medical costs worldwide. Ski resorts are interested to accurately predict the daily level of injury occurrence. This is important for allocation of medical resources in ski resorts. Insurance companies are also interested to know more accurate statistics for ski injury occurrence for defining ski insurance prices. The problem of predicting injuries has usually been assessed by assessing the number of skiers in the resort and knowing the injury rate of ski injury occurrence which is usually 0.2% (Ruedl et al. 2013). Bohanec and Delibašić (2015) have proposed several models for daily ski injury occurrence based on ski lift transportation data. Their models were concerned whether injuries will occur on a certain day or not, and whether an above average number of injuries will occur. This paper extends the problem defined in the paper from Bohanec and Delibašić (2015) by predicting whether injuries will occur at an expected level (within one standard deviation of the normalized residual between expected injury occurrence and real injury occurrence) or injuries will occur at a higher or lower level. Our results suggest that the number of ski lift transportations is a great predictor for situations when there is a specific amount of skiers in the ski resort. Above this amount of skiers, i.e. when assumably congestion in ski resort occurs, ski lift transportation number are not a reliable predictor of ski injury occurrence. To understand the behaviour of skiers better we introduce a skiers satisfaction measure which gives better insight whether injuries will occur at lower, higher, or expected values.

The remainder of the paper is structured as follows. In Section 2 we provide background on ski injury research based on ski lift transportation data. In Section 3 we explain the data and the methods used in this research. In Section 4 we present the obtained results. We make the conclusion in Section 5.

## 2. BACKGROUND

The study of ski injury based on ski lift transportation data is recently getting more attention (e.g. Dallagiaco, M. 2017). Ski lift transportation data is a resource kept within ski resorts and usually only used for simple reporting for ski resort management. Delibašić, et al. (2017a) have proposed spatial and temporal clustering models based on ski lift transportation data. The identified clusters provide motivation for the marketing team of ski resorts to enable more intelligent ski ticket formats to their users. Delibašić et al. (2017c) have extended the previous work of skiing clusters by investigating hidden factors that motivate skiers to choose a specific path.

Ski injury is a well-studied area (e.g. Dalipi, F., & Yayilgan, S. Y. 2015), however, the data from ski lift transportation has only been recently started to be used for studying ski injury.

Delibasic, B., & Obradovic, (2012) proposed a decision support system prototype for early warning for ski injuries. The same authors also suggested (Delibašić, B., & Obradović, Z. 2015) that skiing in groups has a significant influence on ski injury occurrence. Bohanec, M., & Delibašić, B. (2015) proposed several data-mining and expert models for predicting daily injury risk for a ski resort. Dobrota, et al. (2016) clustered skiing trajectories and found clusters with varying levels of injury risk. Delibašić, et al. (2017b) have proposed a ski injury assessment model for individual skiers. This study suggested ski injuries to be early failure events, i.e. it was shown that the first couple of hours of skiing are more critical to get injured than the later hours.

### 3. DATA AND METHODS

The data for this research stems from the ski resort Kopaonik, Serbia, which is Serbia's largest and most significant ski resort bordering its southern province Kosovo & Metohija. The data is from the period 2006 to 2011 and belongs to the company Ski resorts of Serbia. The injury data is provided with courtesy of the Mountaineer rescue service of Serbia which covers the ski resort of Kopaonik with its ski patrol. In this research also data from the Serbian hydrometeorological service was used.

The basic format of the ski lift transportation data is:

- Date and time of ski lift gate entrance
- Location of ski lift gate
- Skier ID

The complete dataset for this research had the following attributes:

- Average daily temperature
- Average wind speed
- Average cloudiness
- Daily number of ski lift transportations in the ski resort
- The total daily sum of vertical meters of all skiers in the ski resort
- Total number of skiers

The output attribute was the risk level which could have been:

- Low injury occurrence
- Expected injury occurrence
- High injury occurrence

The output attribute was calculated as a normalized residual. For each skier day, the expected level of injury was calculated based on the number of ski lift transportations, as ski lift transportations showed a better correlation to the number of injuries than the vastly used measure which is the number of skiers.

Then the residual was calculated as the difference between the expected injury occurrence and the observed injury occurrence. As it was not the same if there was a difference when there is a small number of ski lift transportations in the ski resort or a huge number of ski lift transportations, the residual was normalized taking into account the largest number of ski lift transportations.

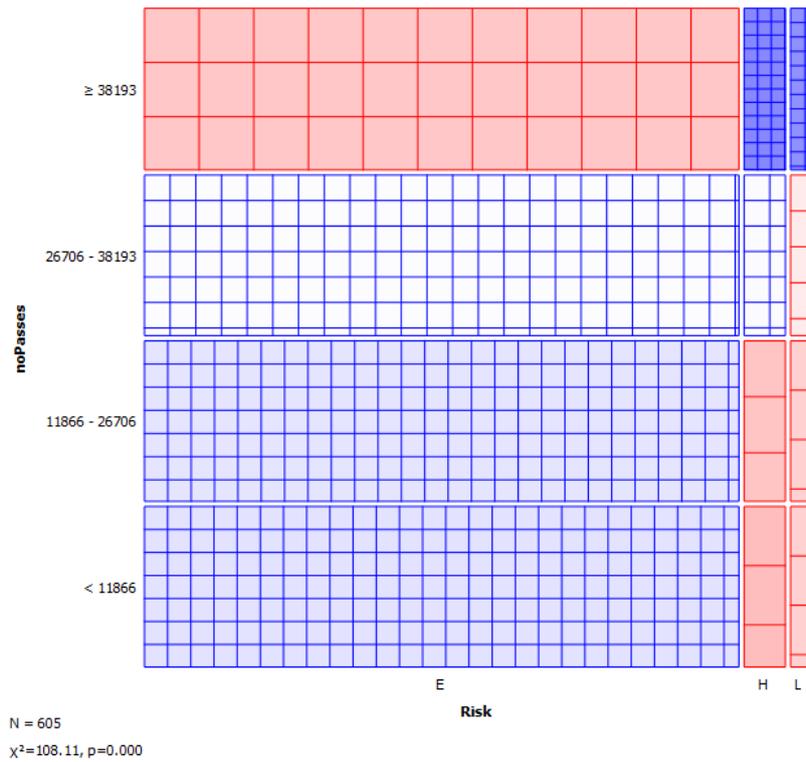

For the analysis in this paper, we used the data mining software Orange from the University of Ljubljana (Demšar et al 2013). We used Sieve diagrams which find a correlation between attributes based on the strength of the chi-square statistics. We also applied decision trees and other popular data mining algorithms to test the strength of our results.

### 4. RESULTS

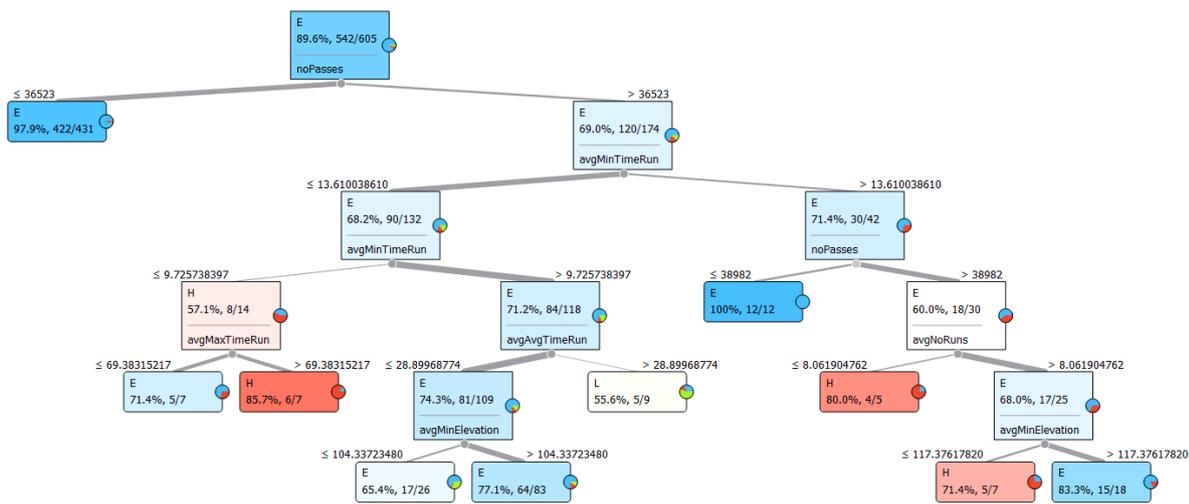

We found a strong correlation between the number of ski lift transportations and the risk level. In Figure 1 this relationship can be seen. This relationship indicates that while the number of ski lift transportations is below 38,193 then mostly the expected level of injury risk can be noticed, i.e. we can safely use the number of ski lift transportations to predict ski injury. However, if the number of ski lift transportation is higher than this number then either a low or above average number of injuries can be expected.

On the decision tree on Figure 2, this point is made clearer. The most important indicator of risk injury prediction is the number of ski lift transportations (the root of the tree). If the number of ski lift transportations is 36,523 or below then an expected level of injuries will occur. We are confident of this finding with 97.9% percent at the training set. However, when there is a larger number of ski lift transportations it is much more difficult to get an overall good prediction. The decision tree on Figure 2 has an overall classification accuracy at the test set 88.9% while the majority class prediction (which is the expected value) has an occurrence of 89.6% which means that the decision tree makes a worse prediction than if using only the expected value as the forecast. Although accuracy is low, it is more important to identify injury behavior. In other words, false

positive (predicting injury that did not occurred) prediction is of less cost compared to false negative predictions (predicting that injury will not occur, but it occurred). Therefore, recall of prediction model is more important.

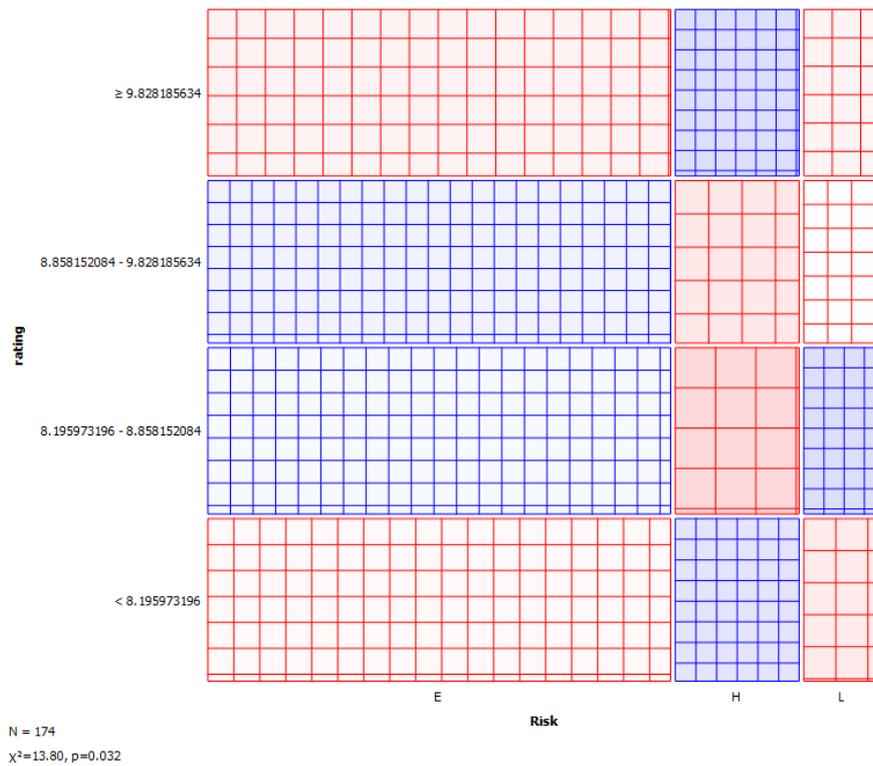

**Figure 1:** Sieve diagram showing a correlation between the number of ski lift transportations (noPasses) and the risk level (E-expected, H-high, L-low)

**Figure 2:** Basic decision tree model

In order to understand what is happening when there are a lot of transportations in the ski resort (the ski resort has a lot of skiers in the system) we propose a measure for quantifying success in the ski resort. We assume that each skier's goal is to achieve as much skiing in the resort as possible. We measured this success with achieved vertical meters (the sum of height above sea level between ski lift exit points and ski lift entrances) within a certain time period.

**Figure 3:** The relationship between the rating of the success of skiers and the risk level

The rate of success is shown in (1). It is calculated for each day, and is the ratio of the total amount of vertical meters (vm) skiers have achieved and the total time (t) skiers have spent in the ski resort:

$$SR(d) = \frac{\sum vm}{\sum t} \quad (1)$$

From Figure 3 it can be noticed that if the rating of success is below 8.19 or above 9.83 (vertical meters per minute) an above average level of risk can be expected. If this level is between 8.86 and 9.83 an average level of injury can be expected. If this level is between 8.19 and 8.86 either an average or low level of ski injuries can be expected.

This finding is interesting as it suggests that a smaller, but also greater, a rating of success influences high risk of injury. This can be explained as follows. If skiers' population have a high rate of success, they ski at faster speeds. Faster speeds induce greater levels of risk, which is a well-known result known from road traffic injuries. On the other hand, if the rate of success is below a certain threshold either the conditions of skiing are not optimal (low visibility, bad conditions of slopes) or the ski resort is overcrowded. This way injury due to collisions is more likely to occur. In any case, it worth noticing that safer skiing can be expected when this ratio is between 8.2 and 9.8 vertical meters per minutes.

We have also analyzed the performance of several data mining algorithms on the dataset that only included days with ski lift transportations above 36,523. The results are shown in Table 1.

**Table 1:** Data mining algorithm performance is shown in percentages

Algorithms	Accuracy	Recall (Expected Risk)	Recall (High Risk)	Recall (Low Risk)
AdaBoost	56.9	70.8	30.3	4.8
Logistic Regression	69.5	100	3	0
Naïve Bayes	54	71.7	15.2	1.43
Random Forest	59.8	85.8	3	0
Tree	61.5	79.2	33.3	1.43

It can be noticed that algorithms have it overall difficult to predict the occurrence of the low-risk level. On the other hand, algorithms don't achieve a better accuracy of prediction over 69.5% which is the majority class

predictor (Logistic regression models uses this method for prediction). However, if we inspect recall of the models we can observe that lower accuracy models had better recall for high risk of injury. For predicting high-risk occurrence two algorithms showed to be the best, AdaBoost and the Decision tree where the decision tree had a slight advantage of 3%.

## 5. CONCLUSION

This paper has studied the occurrence of ski injury based on ski lift transportation data. It was shown that this data can only be used a good predictor until a certain amount of ski lift transportation happens in the ski resort. After this level, the injury risk can vary significantly. We, therefore, introduced a success measure of skiers which showed to be significantly correlated ( $p=0.032$  from Figure 3) to the risk level occurrence. From data, it can be noticed that the safest skiing occurs when skiers have a balanced success score. If this score is above or below the average values high risk of injuries could occur. Ski resorts could influence the safety of the ski resorts by controlling that skiers achieve the optimal success scores. This could be either done by intelligently slowing down the ski lifts if skiers speed too much. Ski lift speeds could be also better adjusted to achieve faster transportations when there is congestion in the ski resorts. Of course, better warnings of skiers to ski safely could also be of great help.

This paper suggested some first insights into studying the daily level of injury occurrence in ski resorts. Further efforts should be made in understanding what is happening in ski resorts which are congested and how this influences the level of injury. We propose to introduce new features which could probably be better predictors, such as quality of snow or other quality of success measures, for data mining models, but also to test these findings on other ski resorts to prove the validity of these findings.

# DECISION TREE-BASED ALGORITHM FOR THE CLASSIFICATION OF MUSICAL INSTRUMENTS

Anja Bjelotomić<sup>\*1</sup>, Aleksandar Rakićević<sup>1</sup>, Ivana Dragović<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences

\*Corresponding author, e-mail: anjinimejl@gmail.com

**Abstract:** *This paper examines the use of binary decision tree for classification of musical instruments, using mel-frequency cepstral coefficients as timbre features. We analyze 4094 samples of bass clarinet, contrabassoon, flute, oboe, trumpet and violin to get their timbre coefficients. The dimensions of these coefficients are reduced using principal component analysis. A binary tree is created and optimized to predict the instrument classes based on these timbre coefficients.*

**Keywords:** *Binary decision trees, musical instrument classification, mel-frequency cepstral coefficients*

## 1. INTRODUCTION

The human capability to perceive differences between musical instruments is a subject of research for a number of years. Even with minimal musical knowledge, most people can easily make distinction between familiar musical instruments, even played at the same loudness and pitch. By definition of American National Standards Institute (1951) the quality of auditory sensation by which a listener can distinguish between two sounds of equal loudness, duration and pitch are known as timbre. Hence it could be said that musical instrument recognition is strongly dependent on timbre. Unfortunately, unlike pitch and loudness, timbre has proven to be somewhat difficult to measure or quantify (Loughran, Walker, O'Neil & O' Farrell, 2000).

Over the last decade, numerous studies have been investigating the nature of speech and speaker recognition research. Progress has been made on the analysis of speech waveforms, in its perception by humans, and in the use of different statistical methods for classification. On the other hand, the topic of instrument classification and recognition has been studied less. In this paper, we will be relying on knowledge gained in speech research, such as the *mel-frequency cepstral coefficients*.

This paper focuses on the automatic recognition of musical instruments, where the idea is to build a binary decision tree that can "listen" to the musical sounds and recognize which instrument is playing. The experimental material consists of 4094 single notes, the timbre of which has been studied comprehensively. Combined with the state-of-the-art automatic sound source recognition systems, these form the foundation for the most important part of this work: the extraction of perceptually relevant features of acoustic musical signals and their classification into instrument groups.

Binary trees are one of most common and powerful data structures in the computer science. The computational cost of making a tree is fairly low, but the cost of using it is even lower -  $O(\log N)$  (Castan, Ortega & Lleida, 2010). Binary trees are used as a cornerstone of classification analysis, which is the main reason it is discussed in this work.

The literature review and motivation part of this paper introduces the studies of the sound timbre and classification methods used for their recognition. Following, Section 3 reflects the method used in the experiment and explains the core idea of the work, while details on implementation of binary tree are given in Section 4. Finally, results are concluded in Section 5.

## 2. LITERATURE REVIEW

As mentioned, the field of speech/music classification was studied by many researchers. Firstly, there are numerous studies that analyze the behavior of different classification algorithms used for music and speech other than binary trees. In the Tables 1 and 2, a brief overview is given on general studies already done in the field of music recognition.

Large amount of data is in the audio format, from several resources such as broadcasting channels, databases, Internet streams and commercial CDs. This has made space for a new field of research, audio content analysis (ACA), or machine listening, whose purpose is to analyze the audio data and extract the

content information directly from the acoustic signal (Burred & Lerch, 2004). Speech and music classification is also useful in other forms of applications, for example, content-based audio coding or indexing other data, such as classification of video content through the accompanying audio. Spurred by the growth of annotated datasets and the democratization of high-performance computing, feature learning has enjoyed a renewed interest in recent years within the MIR community, both in supervised and unsupervised settings (MATLAB, 2015).

**Table 1:** Summary of studies in the field of audio classification

Authors	Classification method	Main application	Audio materials	Results
Saunders (1996)	Multivariate Gaussian classifier	Automatic real-time FM radio monitoring	Different types of music, commercials, talk	95-96% of accuracy
Footer (1997)	MFCCs, short-time energy	Using acoustic similarity to retrieve audio documents.	409 sounds and 255 (7sec long) clips of music	High rate of success, although no specific accuracy rate provided
Burred and Leech (2004)	KNN classifier, 3 component GMM classifier, MFCC	Classification of music into genres and audio classification	Speech, 13 genres of music, background noise	94,6% hierarchical approach and 96,3% direct approach
Marques and Moreno (1999)	Gaussian mixture model, Support Vector Machines, mel-frequency feature set	Automatic annotation system	Bagpipes, clarinet, flute, harpsichord, organ, piano, trombone and violin	GMM had an 75% accuracy rate, SVM 70% accuracy
Eronen (2001)	Distance-based algorithms, probabilistic classifiers	Listen and recognize the instrument playing	29 instruments	35% accuracy between 29 instruments, 77% accuracy between six instrument families
Toghiani-Rizi and Windmark (2017)	Multilayer perceptron	Musical instrument recognition	Feature vector of length 50, containing a normalized frequency spectrum of the audio signal	Average accuracy of 93,5%

Numerous studies have been done in the field using binary decision trees (Table 2).

**Table 2:** Summary of studies in the field of audio classification using binary decision trees

Authors	Main application	Audio materials	Results
Wold, Blum and Wheaton (1996)	Building a system to distinguish between sound classes	laughter, bells, synthesizer, different instruments	98,6% accuracy
Han, Pen, Jeon, Lee and Ha (1998)	Genre classification	Songs from three genres: jazz, classical and popular music.	55% accuracy
Lavner and Ruinsky (2009)	Segmentation of audio signals into speech and music	12 hours of speech, 22 hours of music	99,4% accuracy for speech, 97,8% for music, quick adjustment to altering speech/music sections
Castan, Ortega and Lleda (2010)	Classification of audio frames into speech or music	20 tracks, that alternate segments of music, speech or both	99,56-99,94% accuracy

Nowadays, many Internet search sites, such as AltaVista and Lycos, evolved from purely textual indexing to multimedia indexing. It is estimated that there are approximately thirty million multimedia files on the Internet with no effective method available for searching their audio content (Swain, 1998). If every sound file had a corresponding text file that accurately described human perceptions of the given audio content, audio files

could be easily searched. For example, in an audio file containing only speech, the text file could include spoken text, names, most frequent words etc. In a music file, the annotations could include instruments recognized in the file or parts of the songs used. There is an uncountable amount of audio data stored off and online with no adequate classification technique based on its content, so the interest of creating computer systems and algorithms to classify instruments is evident. In that manner, automatic methods able to effectively index multimedia files are key.

With a goal of gaining broader knowledge about audio information retrieval, we chose binary decision trees as the cornerstone of our analysis, as it is easy to use, but also provides a lot of useful information. Binary trees are closely related to information theory. The idea behind trees is to choose the most informative feature at each step. The principle is to quantify how much information is provided by knowing certain facts. Additionally, binary trees usually give highly accurate classification rates, which is the reason they will be used in this work. The goal is to provide basic classification insight in order to carry out our analysis further.

### 3. THE PROPOSED MODEL

In this study, we investigate a problem of classifying samples of six instruments: bass clarinet, contrabassoon, flute, oboe, trumpet and violin. The first part of the experiment is focused on extraction of relevant timbre features from original input dataset. The second one regards the construction of a binary decision tree, which will be used to classify input data into instrument groups.

#### 3.1. Feature extraction

The original data is represented as a set of tones played on different instruments. Instruments used in the experiment are bass clarinet, contrabassoon, flute, oboe, trumpet and violin. Each instrument covers a range of different dynamics and scales, ranging from pianissimo to fortissimo, from second to eighth octave, respectively.

Since the goal of this paper is to determine the timbre similarity between tones of the same instruments, first we must extract and explicitly represent timber features of the sound. This is done using **Mel-Frequency Cepstral Coefficients (MFCCs)**. It is well known that the MFCCs are a compact and efficient representation of speech (Castan *et al.*, 2010). Each coefficient has a value for each frame of the sound. We examine the changes of these coefficients across the range of the sound. In order to obtain MFCCs we must:

1. Divide signals into frames,
2. Get the amplitude spectrum of each frame,
3. Take the log of these spectrums,
4. Convert to mel-scale,
5. Apply the discrete cosine transform (DCT).

First, we divide signals into frames. This is done using a windowing technique. In most applications, the audio signal is analyzed by means of *short term* or *short-time* processing technique, according to which the signal is broken into, in our case, overlapping windows (frames) and the analysis is carried out on a frame bases (Giannakopoulos & Pikrakis, 2014). The reason we use windowing is because sound signals aren't stationary and their properties vary usually very dynamically over time. So in order to catch the switch in time between the frames, we use overlapping by some percent (25%, 50%, 75% etc.). In this experiment, the overlapping step is set to 50%.

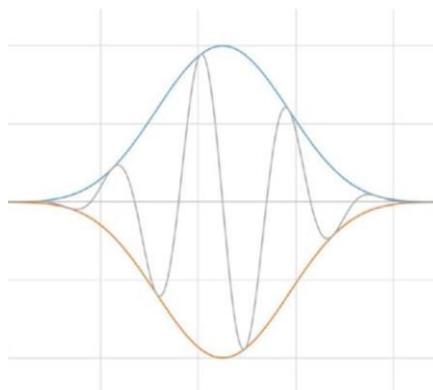

Figure 1. Windowed sample (Marsland, 2009)

Mel-scale is a perceptual scale of pitches judged by listeners to be equal in distance from one another (Stevens, Volkman, & Newman, 1937). We project our signals onto mel-scale in order to represent the computed sounds in a way that's similar to human perception of the tones.

Sampled, these tones were split into windows, or frames. Windowing reduces the amplitude of the discontinuities at the boundaries of each point of the sampled signal. This makes the endpoints of the waveform meet and, therefore, results in a continuous waveform without sharp transitions. Applying a window minimizes the effect of spectral leakage (National Instruments, 2015).

This way, we are able to catch changes between the signal frames and apply the discrete Fourier transform (DFT), which is kind of a cornerstone of digital signal processing. Discrete Fourier transform gives us a frequency-domain (spectral) representation of the signal:

$$X[k] = \sum_{n=0}^N x[n] e^{-\frac{2j\pi kn}{N}}. \quad (1)$$

Or, if we rewrite it:

$$x(n) = \frac{1}{N} \sum_{k=0}^{N-1} X(k) y_k(n), \quad (2)$$

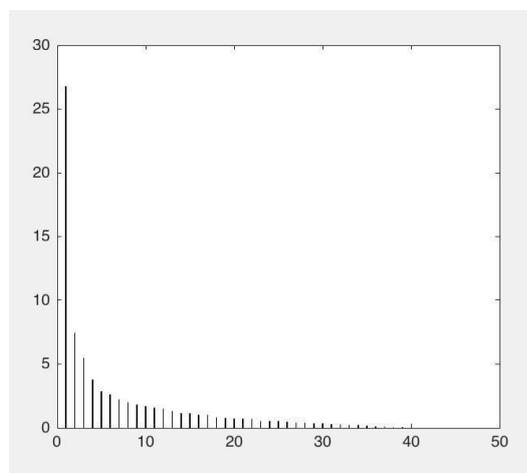

where  $y_k(n) = \frac{-2j\pi kn}{N}$ ,  $n = 0, \dots, N-1$ .

It can be seen that the original signal can be represented as a weighted average of a family of fundamental signals (basis functions), where each signal,  $y_k(n)$  is a complex exponential and its weight is equal to the  $k$ th DFT coefficient (Giannakopoulos & Pikrakis, 2014).

After these transformations our data is represented in frequency or spectral domain, where we get the most of our timbre information from. Most commonly used and very efficient algorithm for the computation of DFT coefficients is fast Fourier transform. We are particularly interested in the magnitude of the  $k$ th DFT coefficient, since it represents a measure of intensity with which the respective frequency participates in the signal  $x(n)$  (Giannakopoulos & Pikrakis, 2014).

Discrete Cosine Transform is used to reduce the data. DCT represents our input as a sum of cosine waves oscillating at each frequency of the signal. Discrete Cosine Transform can be expressed as:

$$y(k) = a(k) \sum_{n=0}^{N-1} x(n) \cos\left(\frac{\pi(2n+1)k}{2n}\right), \quad k = 0, 1, \dots, N-1. \quad (3)$$

**Figure 2.** Eigen spectrum of the violin tone A3 (*forte*)

After this algorithm has been applied, we have got a matrix of values for each sample sound. That is, every sound is represented with the *number of coefficients observed*, in this case **40**, by the *number of frames* in size. Since we must represent our data in a more compact way, we are using **Principal Component**

**Analysis (PCA).** We apply PCA to the calculated coefficient data. PCA provides a roadmap for how to reduce a complex data set to a lower dimension to reveal the sometimes hidden, simplified dynamics that often underlie it (Wold, Blum, Keislar & Wheaton, 1996). This way, we get our final matrix of input data. It shows that one principal component is enough to describe the data needed for this model.

In Figure 2 we represent the eigenspectrum of a tone A from the third octave, played with forte dynamics on the violin. We can see, that the first principal component out of 40 describes the most of the signal. Three, or four at most, principal components are enough to describe the data in most efficient way. In this experiment, we are using one principal component. Finally, we apply binary decision tree to our set of signals.

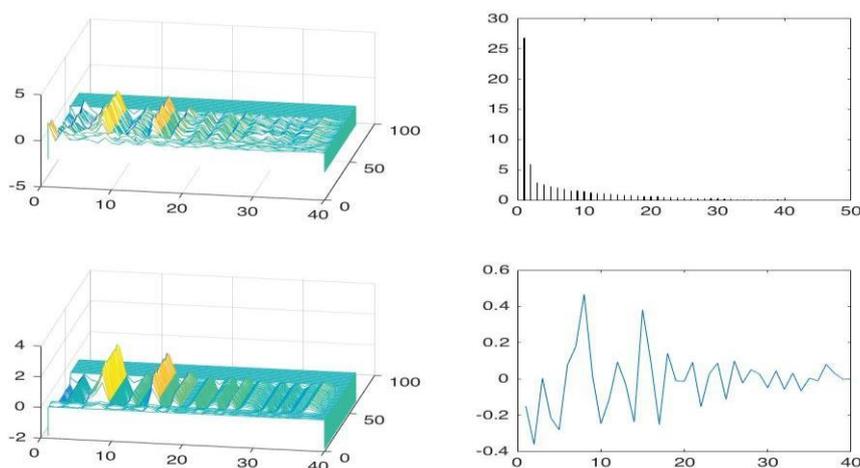

### 3.2. Decision tree

Tree-based algorithm used in this study is **Classification and Regression Trees (CART)** algorithm. As the name indicates, it can be used both for classification and regression (Saunders, 1996). CART uses **Gini impurity** as information measure. The 'impurity' in the name suggests that the aim of the decision tree is to have each leaf node represent a set of data points that are in the same class, so that there are no mismatches. This is known as purity (Marsland, 2009).

The CART classification method is implemented using MATLAB *fitctree* function. Once *fitctree* function returned classified tree, there are a number of parameters which can be used in order to optimize the tree in the best manner. In this experiment, we focused on getting the best values for name-value arguments *Maximum number of categories (MaxNumCategories)* and *Minimum Leaf Size (MinLeafSize)*. After setting up these arguments, another method for optimizing the decision tree is used, called pruning. Pruning optimizes tree depth (leafiness) by merging leaves on the same tree branch (Marsland, 2009). Now that the tree is improved it can be used to classify and predict outputs of our test dataset.

### 3.3. Classification details

Since the feature extraction is a big and complex process and isn't quite the focus of the work, we are not going to overview that part of the experiment. We are using the output matrix of the feature extraction process as our input matrix. It is represented as a set of 4094 sound signals and 40 cepstral coefficients describing the timbre for each of them.

**Figure 3:** Representation of tone A4, *mezzo forte*, played on the oboe

Figure 3 is a representation of the oboe tone A, from the fourth octave, played in mezzo forte dynamics. In the upper left corner, we can see the spectral envelope of the sound, in its original form. Figure from the lower left corner shows the same tone, but with dimensions reduced using Singular Value Decomposition. We can see from the similarity of two left figures, that even with reduced dimensionality we still get a good approximation of the analog music signal. On the right part of the picture, in the upper corner is eigen spectrum of the tone. It allows us to see that two or three principal components are enough to describe the whole signal, while even with one we get all the information needed. Lower left graph is a 2-D representation of the signal with reduced dimensions.

In order to construct the tree, we first separated the data into training and testing sets. We are going to optimize our binary tree to fit our problem adjusting parameters *minimum leaf size* and *maximum number of*

*categories*. In order to grow an efficient tree, we must consider its simplicity and predictive power. Usually, a deep tree with many leaves is highly accurate on the training data. On the other hand, the tree is not guaranteed to show a comparable accuracy on an independent test set. This leafy tree tends to overfit, or overtrain, and test accuracy is often far less than its training (resubstitution) accuracy. A shallow tree does not attain high training accuracy. But it can turn out more robust – meaning, its training accuracy could be close to that of a representative test set and shallow tree is easy to interpret.

The argument that we used to control the depth of decision trees in MATLAB is *MinLeafSize*. Function *fitctree* splits a categorical predictor using the exact search algorithm, if the predictor has at most *MaxNumCategories* levels in the split node. Passing a small value can lead to loss of accuracy and passing a large value can increase computation time and memory overload (Marsland, 2009). Commonly used method for optimization is called pruning which is commonly used in construction of binary decision trees. Pruning optimizes tree depth or leafiness by merging leaves on the same tree branch. Pruning is implemented with MATLAB function *prune*. Now our tree is final, optimized, depth-adjusted binary decision tree that we can now use to classify our test, using MATLAB function *predict*.

#### 4. RESULT ANALYSIS

There are several possible uses of a learning tree. Creating tree to classify unknown sounds is the first one. Others include the analysis of the tree: which questions, or we could say attribute, splits the data? In our case: which coefficient has the biggest informative value? Furthermore, the tree can be used to improve the analysis, by finding out what's wrong with the misplaced data (Marques & Moreno, 1999). The main focus of this paper is to classify the sounds using binary decision tree. In addition, we will analyze which timbre attribute split the data into instrument classes.

The argument that we used to control the depth of decision trees in MATLAB is *MinLeafSize*. Function *fitctree* splits a categorical predictor using the exact search algorithm in case the predictor has at most *MaxNumCategories* levels in the split node. Otherwise, *fitctree* finds the best categorical split using one of the inexact algorithms. Passing a small value can lead to loss of accuracy and passing a large value can increase computation.

In order to test our tree, we will feed it with test data. As we mentioned, this is done using predict function in MATLAB. Function returns predicted class labels for our classification tree and predictor, in our case testing dataset. This vector is crucial in understanding how well our tree classified data. Output argument LABEL is a vector of the same type as the response data used in training tree, *ctree*. Each entry of LABEL corresponds to the class with minimal expected cost for the corresponding row of testing input features. We used two measures to calculate the error rate of the tree: resubstitution loss and cross-validation error. Both values are fairly low, where resubstitution loss is 0,065% and cross-validation error 0,13%.

**Table 3:** Confusion matrix for binary tree classifier

	Bass clarinet	Contra-bassoon	Flute	Oboe	Trumpet	Mandolin
Bass clarinet	163	0	0	0	0	0
Contra-bassoon	0	166	0	0	0	0
Flute	0	0	147	0	0	0
Oboe	0	0	0	130	0	0
Trumpet	0	0	0	0	99	0
Mandolin	0	0	0	0	0	316

With respect to our low classification error, we can see that tree predicted only 2 samples out of class. As confusion matrix shows us, tree misclassified two flute samples as the violin tones. This makes sense, because the flute and violin are two instruments that can reach to the highest tones. Also, this confirms the rules our binary tree defined for this problem. As we can see in the figure 4 below, the first question our tree asks is: Does our input signal's 40th cepstral coefficient hold a value that's larger than -0,0344922? If it does have a value larger than -0,0344922 it is directed to the class six, which is enumeration for the violin, and further classified. On the other hand, if it doesn't, then it is classified as class three, in our case the flute.

This is also an example of another use of binary trees – analyzing the factors influencing classification. Unlike neural networks, binary trees offer the possibility of insight in our system, which can give us a lot of useful information for method improvement.

**Spectral component** is any of the waves that range outside the interval of frequencies assigned to a signal. By extracting these spectral features, meaning each spectral component of the tone, and calculating their

amplitude, we are presented with the occurring frequency of each spectral component in a single tone. In other words, we are able to see how much of each non-fundamental frequencies of the tone are represented in the signal. Differences in these frequencies define what we call timbre of a tone.

**Figure 4:** Representation of classification binary decision tree for our problem

We log these frequencies, actually mel-scale it, and by doing it we adjust it to human perception of the sound, since we perceive it logarithmically. Human ear perceives frequencies lower than 1 kHz on a linear scale, after which it switches to log scale. Meaning, we perceive less the difference between higher tones, ones over 1 kHz, then we do with the lower ones.

Analyzing the tree to see which attributes it used to split the data, we can see in which range of the frequencies bears the most information. We can see that the lower indexed filters are more present than the higher ones, but the *highest indexed* one is the most informative one. This makes sense, since the lower filters present lower non-fundamental frequencies, and together they represent a lot of spectral information, but the amount of highest frequencies is what makes the big difference. The bass clarinet could never get the high notes of the violin. It is important to notice, that the first 13 filters stand for lower frequencies, while the rest 27 stand for higher frequencies, in log space.

## 5. CONCLUSION

This paper has presented the classification of musical sounds in instrument families using binary decision trees with the accuracy of 99,87%. The automatic tree construction, using *fitctree* function, has created well-balanced, efficient trees. Binary decision trees are easy to use and usually give accurate results for classification and regression, so we often use them as a cornerstone of classification analysis.

As we can see, binary decision trees give a high accuracy in musical signal classification, not just for our problem type. We notice that in all of the mentioned studies in the field accuracy is rarely lower than 90%. Since the data is represented in a compact manner, with most important features represented directly and our data vectors are decorrelated, it makes it much easier for our tree classifier to segment the data. This is a good sign for our information retrieval method. In addition, optimization of the tree parameters benefits the high accuracy. Optimal parameters have been set for this specific problem.

We used cross-validation error and resubstitution error to measure the accuracy of classification tree. These measures were also used for evaluating the efficiency of the tree supplied with different-valued parameters

MinLeafSize and MaxNumCategories. We have created a high accuracy tree, with our features extracted from unified audio data, with dimensions reduced. Analyzing the tree, we can see that a major part of timbral information lies in the lower frequency range, but the filter bearing most valuable information is the highest indexed one, meaning the first question and the crucial information is the amount of the highest frequencies presented in a single tone.

There are a lot of questions and space for future work. Analyses should be done on how cepstral coefficients behave in the same instrument family, as well as changes in cepstrals just for one instrument. The effect of playing techniques could also be taken into account. These analyses would bring us closer to understanding and using timbre of a sound with more clarity.

Further work should also check accuracy of binary tree with different parameterization, more instrument families, and different sound representation and see the effect on the result and accuracy. Using different filter shapes within the first layer seems crucial for an efficient learning with spectrogram-based CNNs (Shlens, 2003), which is another direction for research.

**Abstract:** *The evaluation of dishes represents basic activity in the structuring of the menu, which allows the optimal use of resources in order to fully satisfy the expectations of users and restaurant management. Models for menu analysis allow systematic evaluation, by comparing individual dishes according to previously selected criteria. This paper presents a new approach for determining the weights of criteria in menu evaluation using Best-Worst Method (BWM) which objectivize the inconsistencies in expert judgment. The model was successfully tested on the menu of a collective nutrition restaurant, where nine relevant experts have influenced on forming the weight coefficients of three groups of criteria.*

**Keywords:** *menu evaluation, collective nutrition, restaurant management, BWM, MCDM, expert judgment*

### 1. INTRODUCTION

A high-quality menu allows optimal utilization of capacity and resources of a restaurant in order to fully satisfy the expectations of users and restaurant management. The menu represents a worthwhile synthesis of needs of the target group of users, on one hand, and the ability of a restaurant to prepare a dish in a cost-effective way according to the defined standards, on the other. The menu is structured based on the production capacities of a restaurant (technical, technological and organizational), available resources and preferences of restaurant service users.

In the process of menu optimization, the evaluation of dishes constitutes a basic activity by which the dishes with lesser performance and a smaller contribution to the set goals, are innovated or substituted with better ones. All business decisions of restaurants related to production and placement are derived from the menu. (Taylor, J., Brown, D., 2007). The menu interprets to the guest restaurant's offer, kindness, and a type of service and influences the creation of a unique experience in dining (McCall, M., Lyn., A., 2008). For this reason, researchers in many studies are working to create a model for optimizing menus to increase efficiency, customer satisfaction and profit (Taylor, J., Reynolds, D., Brown, D., 2009).

An early attempt to menu analysis, as first introduced by Miller (1980), employed a four quadrant matrix with vectors associated with sales and popularity, measured as sales velocities. Kasawana and Smith (1982), later, using the Boston Consulting Group Portfolio Analysis as the basis for the Menu Engineering Matrix approach, incorporated contribution margin defined as the difference between the sales price of an item and the cost of food product to produce that item. They considered high gross profit and low food cost as mutually exclusive. Pavesic (1983), used weighted gross profit/contribution margin to replace the individual menu item gross profit and included "popularity" as an indirect third variable. Hayes and Huffman (1985) developed an individual profit and loss statement for all menu components in an attempt to allocate all costs including labor and fixed costs to individually menu items. Bayou and Bennet (1992) developed a profitability analysis model to evaluate the financial strength of menu items in an attempt to allocate variable costs such as labor. Horton (2001) proposed different approach and modified Kasawana and Smith's Menu Engineering Model by including estimated labor into the contribution margin (gross profit).

Tom and Annaraud (2017) applied fuzzy multi-criteria decision making techniques to Kasawana and Smith model in order to reduce inaccuracies in the evaluation of alternatives presented by linguistic expressions and providing more relevant information to the decision makers.

Previous researchs did not advantage multi criteria decision making methods based on non-matrix access, wich disable aggregation of wide range relevant criteria for evaluation menu items, both quantitative and qualitative, in a peculiar comparable figure. A new approach, presented in this paper exceeds specified limits and allows for more accurate menu evaluation and an optimization of menu assortment by elimination or substitution of weak ranked menu items with a new better ones.

In this study, the authors have chosen to apply BWM for determining the weight coefficients of criteria due to following advantages (Rezaei, 2015): (1) A smaller number of comparisons in pairs, e.g. The Analytical Hierarchy Process (AHP) method (Satty, 1980) requires  $n(n-1) / 2$  comparisons, while BWM requires  $2n-3$  comparisons; (2) The weight coefficients obtained by using BWM are more reliable - comparisons are made

with a higher degree of consistency; (3) In most models for multi-criteria decision-making (MCDM), e.g. AHP method, the degree of consistency represents a check whether the comparison of criteria is consistent or not; in BWM degree of consistency is used to determine the level of reliability since BWM outputs are always consistent; (4) When comparing in criterion pairs BWM uses only integer values, unlike AHP which also requires the use of fractional values.

## 2. BEST-WORST METHOD

This section shows BWM algorithm that includes the following steps:

Step 1. Identification of the evaluation criteria set  $C = \{c_1, c_2, \dots, c_n\}$ , where  $n$  represents the total number of criteria.

Step 2. Identification of a single criterion with the most dominant and most inferior impact provided that if there are two or more criteria of the same importance only one is arbitrarily chosen.

Step 3. Determining the dominance of the most important criteria from the set  $C$  in relation to other criteria of the same set, this is measured on the scale of numbers 1-9. The measurement result is represented by vector "best in relation to others" (BO):

$$A_B = (a_{B1}, a_{B2}, \dots, a_{Bn}) \quad (1)$$

where  $a_{Bj}$  represents the advantage of the most dominant criterion B in relation to criterion j, where  $a_{BB} = 1$ .

Step 4. Determining the dominance of all the criteria from the set  $C$  in relation to the most inferior criterion of the set, expressed by a number on scale 1-9. The result of measurement is represented by vector "others compared to the worst" (OW):

$$A_W = (a_{1W}, a_{2W}, \dots, a_{nW}) \quad (2)$$

where  $a_{jW}$  represents the dominance of criterion j in relation to the worst criterion W, where  $a_{WW} = 1$ .

Step 5. Calculation of optimal values of weight coefficients of the criteria from set  $C$ ,  $(w_1^*, w_2^*, \dots, w_n^*)$ , whereby the condition should be satisfied that maximum absolute values of differences (3)

$$\left| \frac{w_B}{w_j} - a_{Bj} \right| \text{ and } \left| \frac{w_j}{w_w} - a_{jW} \right| \quad (3)$$

for all values of  $j$  be minimized. This condition can be represented by the following minimax model:

$$\begin{aligned} & \min \max_j \left\{ \left| \frac{w_B}{w_j} - a_{Bj} \right|, \left| \frac{w_j}{w_w} - a_{jW} \right| \right\} \\ & \text{s.t.} \\ & \sum_{j=1}^n w_j = 1 \\ & w_j \geq 0 \quad \forall j \end{aligned} \quad (4)$$

The previous model (4) can be represented by an equivalent model in the following way:

$$\begin{aligned} & \min \xi \\ & \text{s.t.} \\ & \left| \frac{w_B}{w_j} - a_{Bj} \right| \leq \xi, \forall j \\ & \left| \frac{w_j}{w_w} - a_{jW} \right| \leq \xi, \forall j \\ & \sum_{j=1}^n w_j = 1 \\ & w_j \geq 0 \quad \forall j \end{aligned} \quad (5)$$

By solving the system of equations and inequations of the model (5), optimal values of the evaluation weight coefficients  $(w_1^*, w_2^*, \dots, w_n^*)$  and  $\xi^*$  are obtained.

For each value  $a_{BW} \in \{1, 2, \dots, 9\}$  the values of consistency index are calculated  $CI(\max \xi)$ , (Rezaei, 2015), Table 1

**Table 1:** Consistency index values

$a_{BW}$	1	2	3	4	5	6	7	8	9
$CI(\max \xi)$	0.00	0.44	1.00	1.63	2.30	3.00	3.73	4.47	5.23

By solving the system of equations and inequations of the model (13), we get the optimal values of evaluation weight coefficients ( $w_1^*, w_2^*, \dots, w_n^*$ ) and  $\xi^*$ .

It is considered that the values of evaluation weight coefficients are reliable if the condition represented by the expression (6), (Rezaei, 2015) is satisfied,

$$CR = \frac{\xi^*}{CI} \leq 0,25 \quad (6)$$

$$CR \in [0,1]$$

where  $CR$  is the degree of consistency. From the expression (6) it can be noticed that as the value  $\xi^*$  increases, the value of  $CR$  increases, that is, the reliability of comparison results of the defined criteria by experts is decreased. If the condition represented by expression (6) is not satisfied, the optimal weight coefficients of criteria are calculated in the form of interval numbers by solving the model (7)

$$\begin{array}{ll}
 \min w_j & \max w_j \\
 s.t. & s.t. \\
 \left| \frac{w_B}{w_j} - a_{Bj} \right| \leq \xi^*, \forall j & \left| \frac{w_B}{w_j} - a_{Bj} \right| \leq \xi^*, \forall j \\
 \left| \frac{w_j}{w_w} - a_{jw} \right| \leq \xi^*, \forall j & \left| \frac{w_j}{w_w} - a_{jw} \right| \leq \xi^*, \forall j \\
 \sum_{j=1}^n w_j = 1 & \sum_{j=1}^n w_j = 1 \\
 w_j \geq 0 \quad \forall j & w_j \geq 0 \quad \forall j
 \end{array} \quad (7)$$

For each interval value, the center of the interval is determined, which is used to rank the criteria of alternatives (Rezaei, 2016).

### 3. DETERMINING THE WEIGHTS OF CRITERIA USING BWM

In the first step, based on the expert experience, nine relevant criteria for menu evaluation have been identified: Time required for preparation, Technical-technological and organizational requirements (TTOR) for storage of meal components, TTOR for meal preparation, Price, Energy value, Digestibility, Sensory properties, Elan for work and Possibility of preparation in unforeseen circumstances, for which the labels and explanations are given in Table 2

**Table 2:** Evaluation Criteria

Criterion label	Criterion name	Explanation
C1	Time needed for preparation	The duration of technological process
C2	TTOR storage of meal components	Space, appliances and storage facilities
C3	TTOR for meal preparation	Space, machines, appliances, accessories, recipes, qualifications of people
C4	Price	Cost of fresh foods
C5	Energy value	Caloric value of a meal
C6	Digestibility	A subjective feeling in the body after consuming a meal
C7	Sensory properties	Appearance, smell, taste, texture
C8	Elan for work	Mental and physical work after the meal
C9	The possibility of preparation in unforeseen circumstances	In case of TTOR dysfunctionality

In the second step, BWM (Rezaei, 2015) was applied and a comparison of the best criterion with the others was made using the nine-degree scale [1.9], where 1 is the same significance, and 9 is a distinct dominance. The survey included nine reference experts with a minimum of ten years experience who carried out a comparison and the obtained results were presented with nine BO vectors, (Table 3)

**Table 3:** BO vector of compared criteria

	Criterion	E1	E2	E3	E4	E5	E6	E7	E8	E9	GM	Rank
BO	C1	4	6	7	4	8	9	4	5	5	5,53	8
	C2	2	2	8	8	7	8	1	9	9	4,72	6
	C3	1	1	5	7	2	2	2	6	8	2,88	2
	C4	3	7	3	9	3	6	3	8	7	4,93	7
	C5	7	3	1	2	1	5	7	1	1	2,25	1 (B)
	C6	8	4	4	6	4	3	9	2	3	4,30	4
	C7	5	5	2	3	9	7	6	3	6	4,65	5
	C8	9	8	9	1	5	1	8	4	2	3,90	3
	C9	6	9	6	5	6	4	5	7	4	5,60	9 (W)

In the next step, the experts compared the worst criteria with the others and the results were presented with nine OW vectors, (Table 4)

**Table 4:** OW vector of compared criteria

	Criterion	E1	E2	E3	E4	E5	E6	E7	E8	E9	GM	Rank
OW	C1	6	4	3	6	2	1	6	5	5	3,70	2
	C2	8	8	2	2	3	2	9	1	1	2,88	4
	C3	9	9	5	3	8	8	8	4	2	5,55	8
	C4	7	3	7	1	7	4	7	2	3	3,82	3
	C5	3	7	9	8	9	5	3	9	9	6,34	9 (B)
	C6	2	6	6	4	6	7	1	8	7	4,44	6
	C7	5	5	8	7	1	3	4	7	4	4,27	5
	C8	1	2	1	9	5	9	2	6	8	3,49	7
	C9	4	1	4	5	4	6	5	3	6	3,82	1 (W)

The values of BO and OW vectors were aggregated using the expression for geometric mean (GM) calculation, and then they were assigned the ranks which were used to form the model (5). Thus, for BO vector in table 3 for criterion C1, averaging was carried out as follows

$$GM_1 = \sqrt[9]{E_1 \cdot E_2 \cdot \dots \cdot E_9} = \sqrt[9]{6 \cdot 4 \cdot 3 \cdot 6 \cdot 2 \cdot 1 \cdot 6 \cdot 5 \cdot 5} = 3.70$$

In the same way, the ranks of remaining criteria in Tables 3 and 4 were obtained. Based on the acquired values of criteria ranks, the model was set (5)

$$\begin{aligned} & \min w_j \\ & s.t. \\ & \left\{ \begin{array}{l} \left| \frac{w_5}{w_1} - 8 \right| \leq \xi ; \\ \left| \frac{w_5}{w_2} - 6 \right| \leq \xi ; \\ \left| \frac{w_5}{w_3} - 2 \right| \leq \xi ; \left| \frac{w_5}{w_4} - 7 \right| \leq \xi ; \\ \left| \frac{w_5}{w_6} - 4 \right| \leq \xi ; \\ \left| \frac{w_5}{w_7} - 5 \right| \leq \xi ; \left| \frac{w_5}{w_8} - 3 \right| \leq \xi ; \\ \left| \frac{w_5}{w_9} - 9 \right| \leq \xi ; \\ \sum_{j=1}^9 w_j = 1 \\ w_j \geq 0, \quad \forall j = 1, 2, \dots, 9 \end{array} \right. \quad \left\{ \begin{array}{l} \left| \frac{w_1}{w_9} - 2 \right| \leq \xi ; \\ \left| \frac{w_2}{w_9} - 4 \right| \leq \xi ; \\ \left| \frac{w_3}{w_9} - 8 \right| \leq \xi ; \left| \frac{w_4}{w_9} - 3 \right| \leq \xi ; \\ \left| \frac{w_6}{w_9} - 6 \right| \leq \xi ; \left| \frac{w_7}{w_9} - 5 \right| \leq \xi ; \\ \left| \frac{w_8}{w_9} - 7 \right| \leq \xi ; \\ \sum_{j=1}^9 w_j = 1 \\ w_j \geq 0, \quad \forall j = 1, 2, \dots, 9 \end{array} \right. \end{aligned}$$

The model shown is solved using the Lingo 17.0 software. By solving this model, the final values of weight coefficients were acquired

$$\begin{aligned}
 w_1 &= 0.03687; \\
 w_2 &= 0.06155; \\
 w_3 &= 0.19627; \\
 w_4 &= 0.04988; \\
 w_5 &= 0.26313; \\
 w_6 &= 0.11567; \\
 w_7 &= 0.08035; \\
 w_8 &= 0.17174; \\
 w_9 &= 0.02453.
 \end{aligned}$$

Using the expression (6), the value of consistency degree ( $CR$ ) is calculated,

$$CR = \frac{\xi^*}{CI} = \frac{1,725083}{5,23} = 0.3298$$

Since the minimum consistency condition is not satisfied ( $CR > 0.25$ ), the optimal weight coefficients of criteria are calculated in the form of interval values by solving the model (7). In the following section a model for obtaining the interval values of weight coefficient of the first criterion is shown.

$$\begin{array}{ccc}
 \min w_1 & & \max w_1 \\
 s.t. & & s.t. \\
 \left\{ \begin{array}{l} \left| \frac{w_5}{w_1} - 8 \right| \leq \xi^*; \\ \left| \frac{w_5}{w_2} - 6 \right| \leq \xi^*; \\ \left| \frac{w_5}{w_3} - 2 \right| \leq \xi^*; \quad \left| \frac{w_5}{w_4} - 7 \right| \leq \xi^*; \\ \left| \frac{w_5}{w_6} - 4 \right| \leq \xi^*; \\ \left| \frac{w_5}{w_7} - 5 \right| \leq \xi^*; \quad \left| \frac{w_5}{w_8} - 3 \right| \leq \xi^*; \\ \left| \frac{w_5}{w_9} - 9 \right| \leq \xi^*; \\ \sum_{j=1}^9 w_j = 1 \\ w_j \geq 0, \quad \forall j = 1, 2, \dots, 9 \end{array} \right. & & \left\{ \begin{array}{l} \left| \frac{w_1}{w_9} - 2 \right| \leq \xi^*; \\ \left| \frac{w_2}{w_9} - 4 \right| \leq \xi^*; \\ \left| \frac{w_3}{w_9} - 8 \right| \leq \xi^*; \quad \left| \frac{w_4}{w_9} - 3 \right| \leq \xi^*; \\ \left| \frac{w_6}{w_9} - 6 \right| \leq \xi^*; \quad \left| \frac{w_7}{w_9} - 5 \right| \leq \xi^*; \\ \left| \frac{w_8}{w_9} - 7 \right| \leq \xi^*; \\ \sum_{j=1}^9 w_j = 1 \\ w_j \geq 0, \quad \forall j = 1, 2, \dots, 9 \end{array} \right. & & \left\{ \begin{array}{l} \left| \frac{w_5}{w_1} - 8 \right| \leq \xi^*; \\ \left| \frac{w_5}{w_2} - 6 \right| \leq \xi^*; \\ \left| \frac{w_5}{w_3} - 2 \right| \leq \xi^*; \quad \left| \frac{w_5}{w_4} - 7 \right| \leq \xi^*; \\ \left| \frac{w_5}{w_6} - 4 \right| \leq \xi^*; \\ \left| \frac{w_5}{w_7} - 5 \right| \leq \xi^*; \quad \left| \frac{w_5}{w_8} - 3 \right| \leq \xi^*; \\ \left| \frac{w_5}{w_9} - 9 \right| \leq \xi^*; \\ \sum_{j=1}^9 w_j = 1 \\ w_j \geq 0, \quad \forall j = 1, 2, \dots, 9 \end{array} \right. & & \left\{ \begin{array}{l} \left| \frac{w_1}{w_9} - 2 \right| \leq \xi^*; \\ \left| \frac{w_2}{w_9} - 4 \right| \leq \xi^*; \\ \left| \frac{w_3}{w_9} - 8 \right| \leq \xi^*; \quad \left| \frac{w_4}{w_9} - 3 \right| \leq \xi^*; \\ \left| \frac{w_6}{w_9} - 6 \right| \leq \xi^*; \quad \left| \frac{w_7}{w_9} - 5 \right| \leq \xi^*; \\ \left| \frac{w_8}{w_9} - 7 \right| \leq \xi^*; \\ \sum_{j=1}^9 w_j = 1 \\ w_j \geq 0, \quad \forall j = 1, 2, \dots, 9 \end{array} \right.
 \end{array}$$

In the same way, non-linear mathematical models for the remaining criteria (C2-C9) are constructed, with limitations. By solving these limitations interval values of weight coefficients of the remaining criteria are acquired. The obtained intervals, the lower boundary (LB) and the higher boundary (HB), are shown in Table 5

**Table 5:** Boundary values of weight coefficient intervals

$w_j$	LB	HB
$w_1$	0.02535418	0.04736751
$w_2$	0.05185670	0.07025333
$w_3$	0.15435290	0.24982500
$w_4$	0.02941330	0.05611102
$w_5$	0.24318140	0.30230740
$w_6$	0.09790565	0.13126080
$w_7$	0.07425574	0.09230993
$w_8$	0.12876410	0.21785330
$w_9$	0.02267408	0.02818695

Since evaluation of menu dishes (alternative) could be done in the next stage using the selected MCDM model, the obtained interval values of weight coefficients will be considered as interval or rough numbers.

The concept of rough numbers introduced by Zhai (Zhai et al., 2008) was derived from the theory of rough (Pawlak, 1982).

#### 4. CONCLUSION

The evaluation of menu is based on an objective and precise understanding of relevant factors that affect the satisfaction of users and restaurant employees.

User satisfaction is reflected in sensory perception and subjective feeling during and after the meal, while employee satisfaction reflects the synthesis of various impressions such as personal income, working conditions, working atmosphere and other feedback effects that imply user satisfaction. In a stimulating working environment, users and employees in the restaurant stimulate each other by raising the aspiration level over a longer period of time (Arsic, S., 2014).

BWM based approach allows the elimination of uncertainty of subjective assessment about importance of criteria of experts (Pamucar, D., et al., 2018) in various areas related to nutrition (nutrition, food technology, nutrition organization, quality of life) and precise positioning of dishes according to value rank which was acquired by evaluation. During the testing of the introduced approach 9 relevant experts have influenced on forming the weight coefficients of three groups of criteria: 1.group of criteria related to the subscribers (C6-C8) was evaluated by 35 users; 2.group of criteria related to food preparation (C1-C3 and C9) was evaluated by 15 experts involved in the food preparation process; 3.group consists of criteria related to the price of fresh foods required for food preparation (C4) acquired from market analysis and the caloric value of a ready meal (C5) measured in a renowned state institution.

The model is adequate for analysis and predictions in the following time period for the purpose of quality business decision-making by top management (Suknović, M., et al., 2012). The approach can be very effectively applied when it is necessary to form a menu based on the defined effects that nutrition should manifest on the target group of subscribers (favoring the quantity of nutrients and their digestibility, elan for physical work after the meal, preparation in unforeseen circumstances, etc.) especially in restaurants for collective nutrition of students, athletes, security forces and rekonvalescents, so future research should be aimed in that direction. In educational terms, the approach helps decision makers to better understand the complexity of process of identifying relevant criteria, dish evaluation and creating an optimal menu in given time, space, social, economic and other circumstances.

# ANALYSIS AND PREDICTION OF VIEWS IN YOUTUBE INTERVIEWS

Stefan Vujović<sup>1\*</sup>, Danijel Mišulić<sup>1</sup>, Sofija Krneta<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences

\*Corresponding author, e-mail: stefanvujovic93@gmail.com

**Abstract:** *YouTube videos carry great number of data about the viewers habits, topics of interest and attention catchers. Several YouTube channels in Serbia stream specialized content in form of interviews. By analyzing channel content, it can be seen that there are some impacts that lead to popularity of a certain video. This paper is written in order to show correlation between video guests popularity on Wikipedia and view count on YouTube, as well as a connection between the words used in the title of the video and view count.*

**Keywords:** *YouTube, Wikipedia, interviews, correlation, popularity, analysis*

## 1. INTRODUCTION

In the last few years, YouTube as a video streaming service gained more television channel formed content. According to YouTube fact sheet, there are over 300 hours of content being uploaded every minute, many of them being interviews, weekly shows that are only available on YouTube. There are many channels in Serbia with specialized content, such as one to one interviews. These videos carry a large number of data within which gives the opportunity to understand content popularity, trends in online marketing and change of habits of the targeted audience.

Analyzing the content of Serbia's most popular YouTube interview focused channel, the purpose of this paper is to answer following questions: Is the view count influenced by the guest interview and/or the title of the video? Are there any "trigger" words that influence the popularity of a video and are there any trends in selection of guests? The questions will be answered through detailed analysis of statistics collected from YouTube API, information about guests obtained from Wikipedia and by exploring information about guests in DBpedia.

First part of the analysis will cover pure statistics and try to mine the correlations between popularity of the video on the characteristics of the guest, such as guest's gender and profession. Second part of the analysis will focus on the topic of the interview, keywords that are mentioned in the title and to correlate it with the video's popularity. Finally, information about the guests, the topic and the popularity of the video will be put into clustering algorithm in order to generate clusters of guests that might implicate the popularity of future videos.

The main goal of the analysis should lead to concrete advice to YouTube channel owners on how to improve their statistics and popularity.

## 2. RELATED WORK

Several papers in the last 5 years have written about impact on popularity of YouTube videos. Mekouar, Zrura and Bouyakhf (2017) had used two simple regression models for applying machine learning in predicting the popularity of videos based on videos parameters and they proposed a popularity function with good performance over the tested set of videos. Shuxina, Chenyu and Xueming (2017) applied more in depth techniques for analysis of similar video service provider, Youku, where they defined popularity patterns based on initial popularity of the video. Similar approach was taken in Pinto, Almeida and Goncalves (2013) where authors created models to advise users on actions needed for reaching a greater number of views. Initially, idea of defining popularity patterns of videos over time was used in Figueriedo, Benevenuto and Almeida (2011) for the first time. Slightly different approach was taken in Brodersen Scellato and Wattenhofer (2012) by analyzing content of the video, its geographical origin and geographical popularity.

Slightly different goal, but the same means was used recently in Woo, BKP, & Chung, JOP (2018). The authors used YouTube statistics to create a model for evaluation of an educational video. In Tackett et al. (2018) YouTube statistics was used for predicting viewing pattern for popular medical YouTube videos.

Over the years, targeted audiences had grew, but also had changed. The need to have personal relationship with a viewer, to target specific needs resulted in appearance of a great number of vlogs - video blogging

channels, interview specialized channels and similar content. It is now more than the view count in preceding days that impacts the popularity of the video. In Cheng, Dale and Liu (2008) similar statements from the overall YouTube statistics were taken out, but even though the approach to analyzing content to find the connections between videos and popular content is great idea, over the 10 years period the statistics had changed, and so did the statements concluded. 10 years later, in Bärtil, M (2018), decent analysis of YouTube videos was done, but the paper was solely focused on analysis, without creating any conclusions about the connection between popularity and the content.

### 3. DATA EXPLORATION

#### 3.1. Data structure

The initial data was obtained by using YouTube API from Balkan Info channel. Titles of videos on this channel are well structured and it was easy to collect guest names from the interviews. This way, it was possible to collect the main characteristics of a published video clip such as video title, number of views, number of comments, number of likes and other.

Some columns of the dataset obtained in this way are the following: title, published, tags, comments, likes, dislikes, favourites, views, guest\_name, quote and page\_name. The gender of interviewed guests was extracted using an automated approach combining name-based and image-based gender inference methods, as done in Karimi, Wagner, Lemmerich, Jadidi, & Strohmaier (2016).

The existing data set was then expanded with data from the Wikipedia api. For each guest, a number of reviews of their wiki pages have been collected, if their page exists, for 2018, 2017. and 2016. from Serbian wikipedia and English as well. It was necessary to collect this data to find out more about the popularity of the guest and thus compare it with the number of views of his clip. In order to get more information about guests, their professions were collected for a later analysis of the impact of what they do on number of views of their videos. Eleven different profession groupings were identified, and data were obtained from dbpedia, writing Sparql queries. The collection of the entire data set is done using the Python programming language due to easy manipulation of the data and corresponding libraries that it offers, and all data values are saved in the CSV (comma separated file) after collection. Data was collected for every published video clip in the period from July 15, 2015. to March 6, 2018.

#### 3.2. Guest statistics

The number of unique guests is 284 of the total number of interviews collected - 474, and the total number of different data columns is 38. Further analysis of data shows that women appear much less frequently as speakers in the show, only 11 of them were guests, and they appeared in total 24 times in the observed period. Furthermore, it can be argued that their interviews are significantly less frequently reviewed, on average 60 449 times per video clip, and that same average for men is 80 716. On average, male guests average 91 likes more than female per video clip. Clips in which men appear on average have more dislikes and comments, but those differences are much less compared to the number of views. Men have 152 dislikes per clip, and women 139, on average. The number of comments where the guest is a male is an average of 235, and for women 225. It is interesting to visualize some of these data that is available after the initial collection phase. Comparison of male and female guests is shown in the Figure 1.

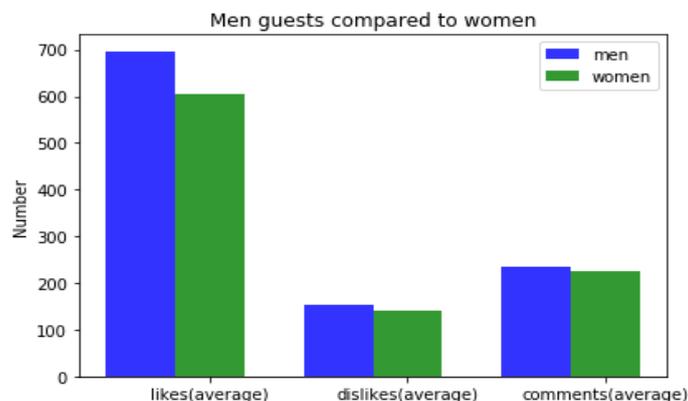

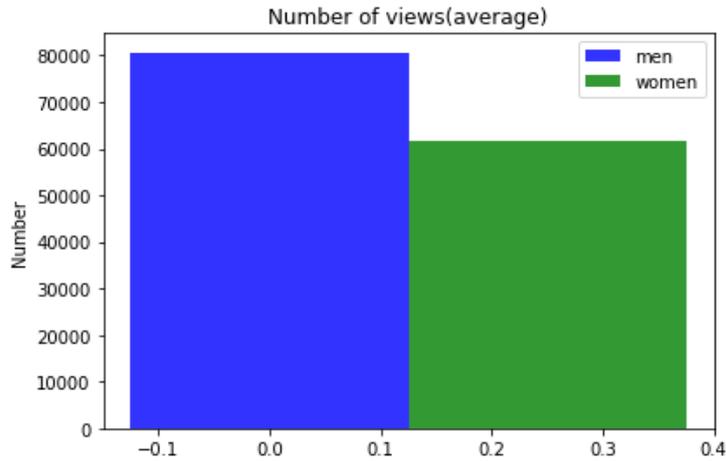

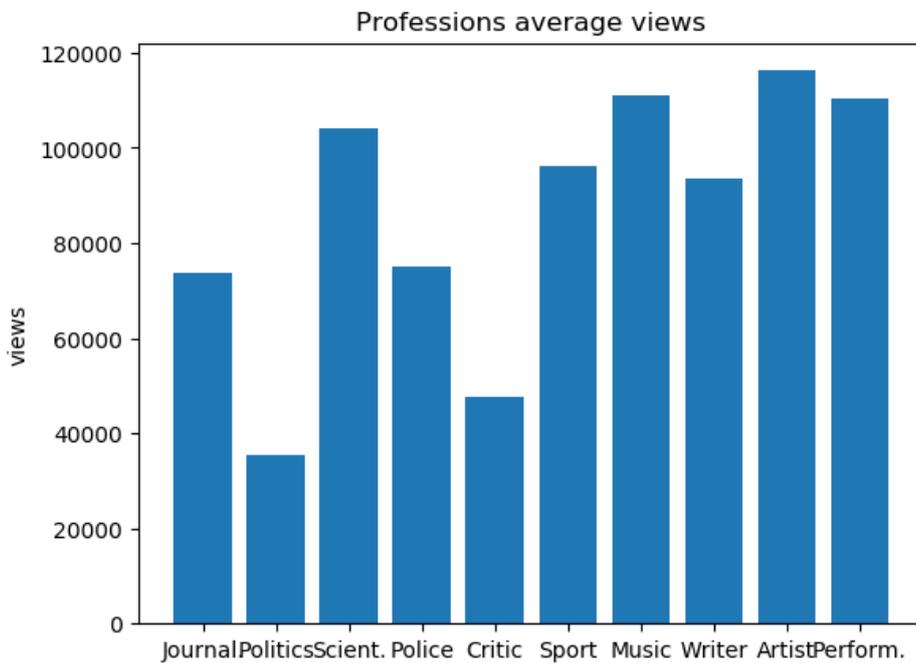

Figure 1: Female and male guests compared

Comparison of average views by gender is shown in the Figure 2.

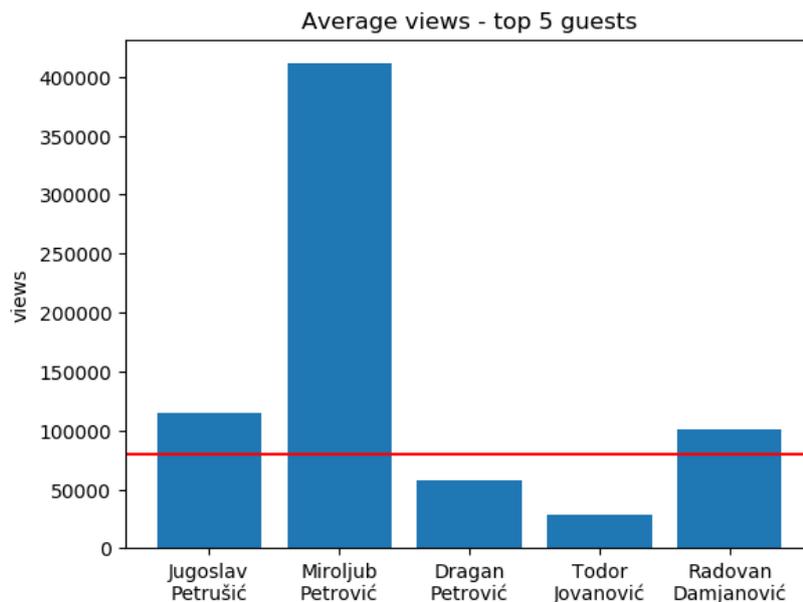

**Figure 2:** Views compared by gender

As for the professions differentiation of guests, The largest part of guests comes from scientists and politics. Profession with most views per video clip on average is Artist, and Music and Performer professions are positioned high also. Politics is the profession with least number of views on average. It is interesting to note that guests from the sphere of politics are the second most often welcomed to the show despite of the lack of people viewing their clips. On the other side, there is a small number of guests that are artists by profession despite to the fact that their clips are viewed the most.

**Figure 3:** Average views by professions

The guest who is most often invited to the show in the observed period is Jugoslav Petrušić and this number is 14 times. The average number of views of his interviews is 115 054 per clip. In Figure 4 you can see how many views on average have five guests who were most often invited to give interview.

**Figure 4:** Average views of five most often guests

Red line in Figure 4 represents average views of all video clips collected in the observed period - 79 744. Three of five most frequent guests are above the average views line, and other two are significantly below. A person who certainly justifies a large number of invites to the show is Miroljub Petrovic with an average number of views with over 300 000 above average. This guest also has the most cumulated views - 5 007 144, more than next four guests combined together.

Of the total number of guests, only 89 of them have a page on en.wikipedia in all three observed years 2016, 2017, and 2018. The number of views of these guests interviews is above average - 73 902 which is in contrast to the assumption that guests who have wiki pages are more popular and will have more views on their show appearances. The number of guest pages is considerably smaller when looking at sr.wikipedia where only 19 guests have their own wiki pages in the observed years. There is only 10 different guests that have wiki pages both on en.wikipedia as well as on sr.wikipedia through these 3 years. The average number of views that these guests get is 45 790 per video. Also, guests that are not present in wikipedia pages, do not have any SparQL knots, which made profession based analysis unreliable from this source. That is why our profession based classification of guest was made solely on YouTube data.

In the Figure 5 is shown correlation between guest pages yearly searches on Wikipedia and views of their videos. Guests that do not have wiki page are excluded from consideration. There is a strong correlation between the number of views on Youtube and sr.wikipedia searches and very little between en.wikipedia and video clip views. This is a good indicator that en.wikipedia can be excluded in some future work for our particular case.

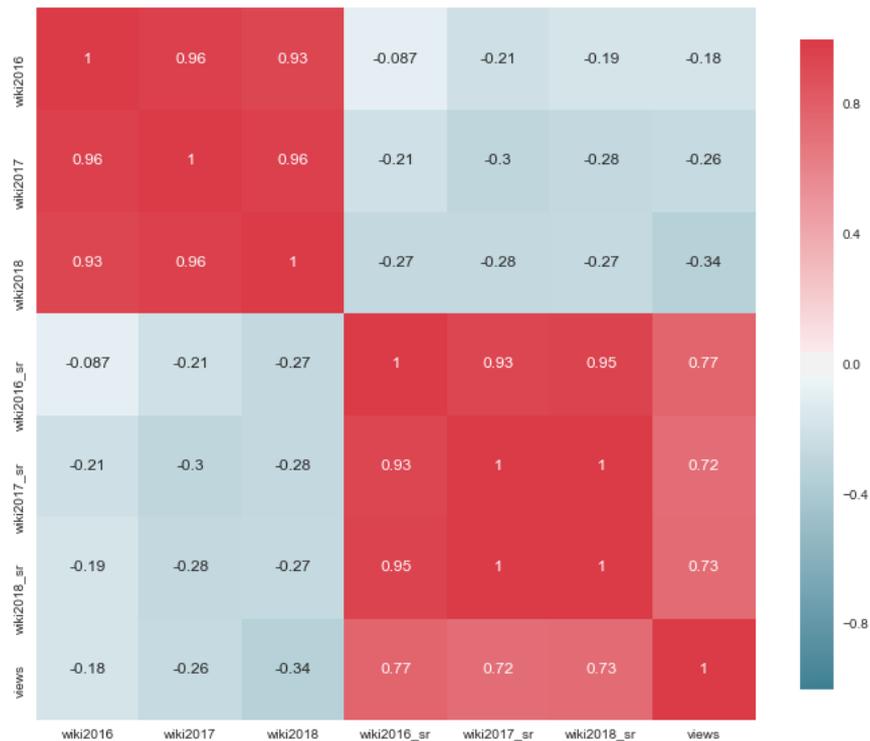

Figure 5: Correlation between views and wiki searches

### 3.3. Title statistics

Text processing focused on title of videos and tags, related to each of the video. Using text processing libraries in Python and extensions in RapidMiner, a set of most used words and phrases was created. Analysing most popular words, it can be concluded which are the most popular words and phrases in videos (Figure 6 and 7).

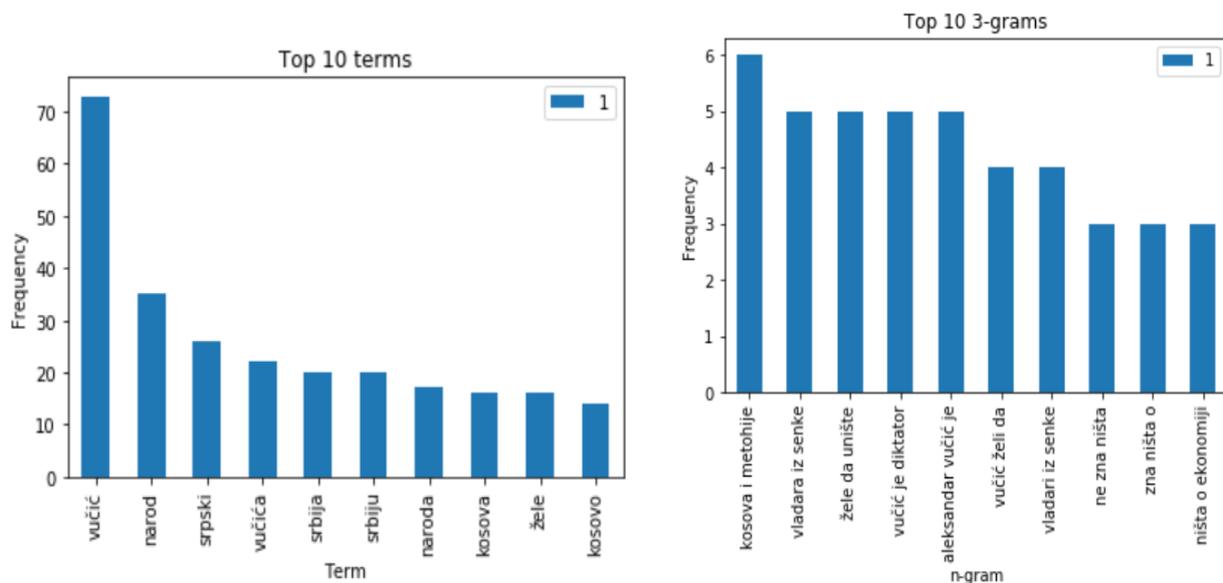

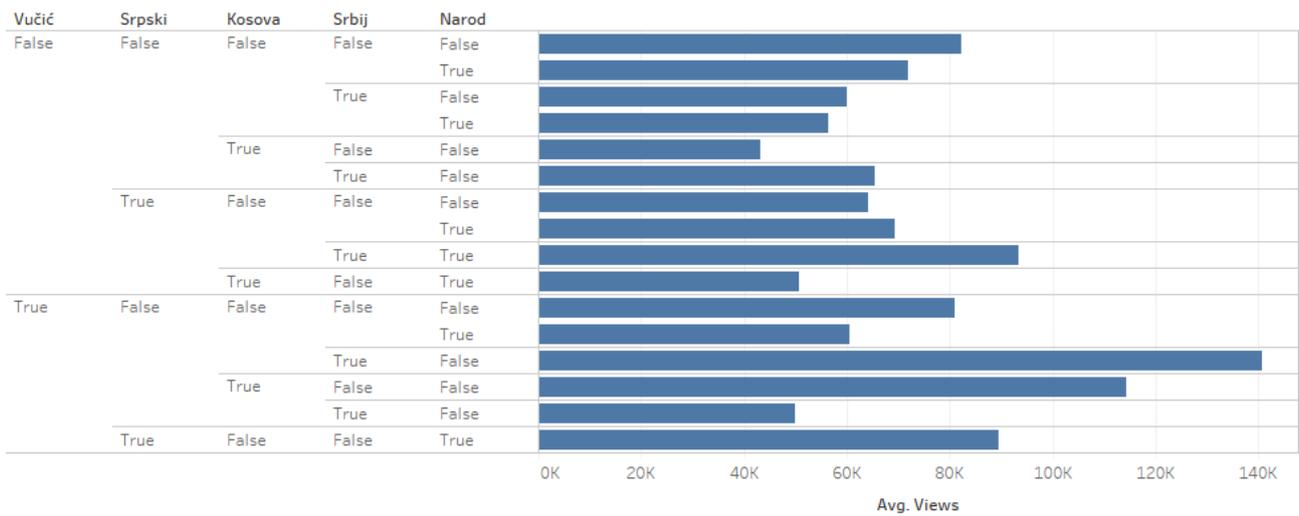

Figure 6: Top 10 terms (left) and Figure 7: Top 10 phrases (right)

Above mentioned words are connected to the popularity of videos, which is shown on the following figure:

**Figure 8:** Correlation between views and use of keywords

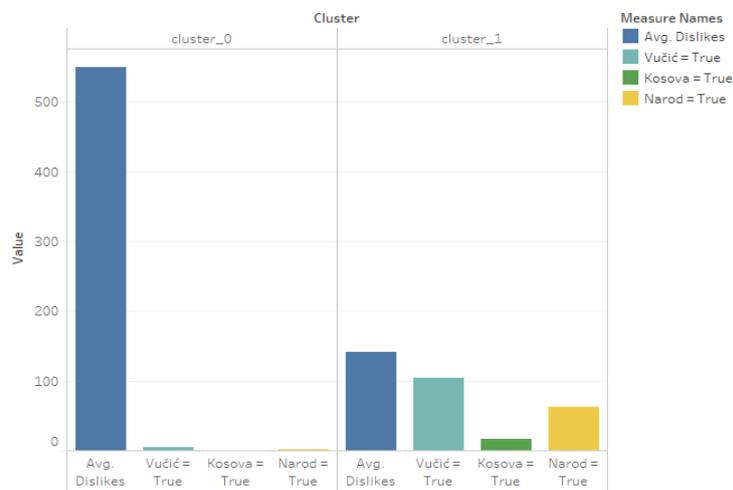

It can be concluded that use of words “Vučić” and “Srbija” in the video title attract more attention than use of other words. Also, “Vučić” and “Kosovo” have the same influence on the reach of the video.

### 3.4. Clustering Guests

As claimed in the channel description, “Balkan Info strives to provide unbiased reporting and has opened its doors to all guests and all political parties”. As presented above (Figure 3), the interviewed guests come from different professional backgrounds and they discuss about different topics. However, some guests could be considered more ‘serious’ than others, as some guests tend to share information that could be described as conspiracy theories. An interest application of clustering would be to divide guests into the ‘serious’ ones and the ‘conspiracy theorists’. Having assumed that this could save time for the viewers when making the decision to watch the video or not (as they tend to be between 1 and 3 hours long), an attempt for clustering was made.

As features for clustering, we used the following predictors, out of the earlier mentioned set attributes: comments, likes, dislikes, favourites, views, wiki2016, wiki2017, wiki2018 and the name of the guest. We used k-means algorithm to train the clustering model. However, just around 8 percent of them were assigned to the ‘conspiracy’ cluster, which we do not consider as a proper distribution. It is worth mentioning that a higher number of dislikes could be considered as a signal of a guest being a ‘conspiracy theorist’, but there are exceptions where the guest is perceived negatively by the audience even though being ‘serious’.

In the following figure, it can be seen that the characteristics of the first cluster is high number of dislikes, while the second cluster has a high number of popular words with a lower number of dislikes.

**Figure 9:** Main characteristics of the clusters

## 4. CONCLUSIONS AND FUTURE WORK

From the explorative analysis done, several conclusions can be outlined. First, guest from the sphere of politics are not interesting content for viewers. On the other hand, performers and artists are interesting and attractive content. Taking into consideration that people without any information on wikipedia pages are more view than others, lead to conclusion that locally familiar people that do not have the chance to appear on other media do have greater popularity online, on YouTube. Certain guests in Serbia have great popularity and can bring a lot of popularity to the channel if invited.

As for the timing, it can be recommended to publish video clips on Sundays, since that is the day with the largest number of views cumulative.

Topics which need to be covered in the interview need to contain several of the popular words such as: vučić, kosovo, srbija, žele, narod etc. in order to attract viewers and it needs to be mentioned in the title of the video.

We have seen that en.wikipedia gives very small correlation with views of published video and can be excluded from consideration. Sr.wikipedia gives strong correlation and in some future work data searches will be collected not only for the past 3 years, but also for years before 2016.

For the purpose of this research it was only taken into consideration title of the video in the part of text processing. Next step would be to dig deeper into semantics of the whole conversation. Another idea for future work is to include other sources for data collecting, besides dbpedia and wikipedia.

# NEURAL NETWORKS IN MARKET SENTIMENT ANALYSIS FOR AUTOMATED TRADING: THE CASE OF BITCOIN

Matija Milekić<sup>\*1</sup>, Aleksandar Rakićević<sup>1</sup>, Pavle Milošević<sup>1</sup>  
<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia  
<sup>\*</sup>Corresponding author, e-mail: matija.milekic@outlook.com

**Abstract:** *Cryptocurrency mining and trading have attracted much attention lately. There are numerous studies and experiments performed to predict the future prices of cryptocurrencies and identify factors that influence the cryptocurrencies' price movement. The aim of this research is to investigate the potential relationship between market sentiment and Bitcoin price movement. The market sentiment analysis is performed on Reddit social network using neural networks. Furthermore, we propose an intelligent system for automated cryptocurrency trading based on neural network outputs. The proposed intelligent trading system is tested over a 4-month period (December 2017 – April 2018), with daily records. The trading simulations are performed multiple times in order to obtain credible results. It is shown that the proposed system achieves a positive average profit that significantly outperforms Bitcoin performance. The results may be seen as a confirmation of the assumption that market psychology is an important factor in the still emerging cryptocurrency market.*

**Keywords:** *neural networks, automated trading, market sentiment, cryptocurrency, Bitcoin, Reddit.*

## 1. INTRODUCTION

The price movements of cryptocurrencies have attracted much attention in the year 2017 and 2018 from both practitioners and academia. The problem of prompt estimation whether the prices will go up or down, i.e. should investors buy or sell assets from their portfolio, has been in the spotlight. These kinds of researches have been conducted for a very long time in different markets. Numerous studies have been done in order to predict movements of the stock or foreign exchange markets. These markets are characterized with relatively low volatility compared to the cryptocurrency market where the price can either suddenly go down or rapidly rise by more than 100 percent on a weekly or even daily basis. Being this unpredictable, the factor that has been added to the formation of the prices and has become one of the most dominant is the factor of faith of investors. Bearing this in mind, the aim of this paper was to show how investors' approval and interaction within the social network can affect the future price movements of cryptocurrencies.

Cryptocurrency trading is currently a hot topic. Numerous researches have been conducting experiments to predict the future prices of cryptocurrencies. Brauneis and Mestel (2018) showed that cryptocurrency prices become less predictable as liquidity increases. Gandal, Hamrick, Moore and Oberman (2018) dealt with the problem of suspicious trading activities identification, and the estimation of their impact on the price. Gangwal and Longin (2018) examine oscillations of Bitcoin prices based on extreme value theory. Dynamic investment strategies based on the rational expectations bubble model of prices were proposed by Kreuser and Sornette (2018). Detzel, Liu, Strauss, Zhou, and Zhu (2018) documented that Bitcoin returns are predictable by moving the average technical indicator. On the other hand, the influence of the social media on cryptocurrencies' price movements was thoroughly analyzed by Bollen, Mao and Zeng (2011), Garcia, Tessone, Mavrodiev, and Perony (2014) and Garcia and Schweitzer (2015). Their results imposed a new perspective on researchers and practitioners. Further, Kim, Kim, Kim, Im, Kim, Kang and Kim (2016) estimated the fluctuations in the prices and the number of transactions of cryptocurrencies based on user comments in online cryptocurrency communities. Phillips and Gorse (2017) proposed a class of novel online social media indicators to deal with the price prediction problem.

In this paper, we used social media data generated on the Reddit network. The Reddit network has a large number of subscribers who generate an even larger number of posts and comments each day about many subjects. This network has become especially popular among investors as a place for discussing the cryptocurrency market. We saw a potential in analyzing posts and comments from Reddit network to extract trading signals for Bitcoin. Similarly, this was done by Garcia and Schweitzer (2015) who presented a framework to derive general knowledge from social network data. To do this, they combined economic signals related to market growth, trading volume, and the use of Bitcoin as a means of exchange, with social signals (including search volumes), word-of-mouth levels, emotional valence and opinion polarization.

In order to predict trends in the cryptocurrency price movement, we used an artificial neural network. For the purpose of this paper, we used a standard one-layered feed-forward neural network with back-propagation learning algorithm and the inputs that describe the sentiment of the Reddit network and technical indicators of price movement. In fact, the sentiment of the Reddit network is depicted using the daily difference of ups and downs and the number of posts on Reddit. On the other hand, daily Relative Strength Index and Volume-to-Market-Capitalization are technical indicators used in the experiment. The trading signal obtained from neural network is further extracted using another technical indicator, i.e. ZigZag. The experiment is performed on the dataset of daily records collected during the period of 4 months.

The paper is arranged as follows. In Section 2 we provide a detailed overview of the literature. In Section 3 we present the research methodology. Results are presented in Section 4. Finally, Section 5 concludes the paper and gives a brief discussion of future research direction.

## **2. LITERATURE REVIEW**

This section briefly explains the components relevant to this research, including basic terms related to Bitcoin trading, the problem of Bitcoin price predicting and the predictions based on sentiment tracking.

### **2.1. Bitcoin**

In 2008 a mysterious person, whose identity has yet to be discovered, named Satoshi Nakamoto released a paper "A Peer-to-Peer Electronic Cash System". In addition, he also implemented open source blockchain software ushering in a cryptocurrency by the name of Bitcoin. The blockchain technology, on which the Bitcoin is based, has enabled a flow of money through online payments directly from one side to another without using a third party, in this case a financial institution (Nakamoto, 2008). This may be considered revolutionary, and it has had a great influence on the current financial system.

Since then, numerous cryptocurrencies and blockchain platforms have emerged. They brought a different perspective to financial markets, despite raising many questions and doubts. Numerous debates and discussions sprang up about the validity of cryptocurrencies and whether they should be banned or even criminalized and how the government could regulate them. Even though the rise of cryptocurrencies was followed by many negative effects and frauds, there are also a lot of benefits that they have brought. Some of them are:

- a faster settlement process,
- lower transaction fees,
- decentralization.

Nowadays, there are more than 1600 known cryptocurrencies. Even though they are different in nature and purpose and independently priced on the crypto market, their prices are mostly correlated to the price of Bitcoin. This fact allows the market to be easily influenced by the effects of "the herd" and "big players". Gandal et al. (2018) analyzed the impact of suspicious trading activity on price manipulations in the Bitcoin market. The herd effect and market bubble creation were the subject covered by Gangwal and Longin (2018) and Kreuser and Sornette (2018).

### **2.2. Predictability and profitability**

If one had invested in Bitcoin back in the 2010 it would have generated an astonishing return of more than 15.000.000% by the end of the year 2017. At the same time, investment in S&P500 stock index would have grown by a rate of 130% over the same period of time. Being this volatile is the main reason why people decide to either invest in Bitcoin or steer clear from it. Without the fundamental information (such as interest payments, book values, dividends etc.) investors are relying solely on price charts when it comes to investment decision making.

Numerous researches have been done to try to predict the Bitcoin price and to make those predictions profitable. Brauneis and Mestel (2018) tried to investigate the predictability and efficiency of several cryptocurrencies using the statistical testing methodology. They concluded the Bitcoin is the least predictable and most efficient in terms of the efficient market hypothesis. Prediction of fluctuations in cryptocurrencies has been researched by Kim et al. (2016) and Phillips and Gorse (2017), who showed great results and provided excellent trading guidelines. However, this topic needs to be further revised in the shortest possible time span because changes are occurring on an hourly/daily/weekly level.

### 2.3. Market sentiment analysis based on social media data

Using social media, people are generating a huge amount of information on a daily basis. If handled in a proper way, this information may be used to determine and understand the public opinion about a certain topic. One such topic is the price movement of cryptocurrencies. This topic can either be discussed directly by saying that the price is going to rise/fall for a certain reason; or indirectly by mentioning that you are going to invest in the near future, ask around about the cryptocurrency itself or show any kind of interest in it. All of the aforementioned can give us an indication of how the observed price could move in the future, which was underlined by Garcia et al. (2014).

Price predictions for Bitcoin cannot be obtained in an easy way. Contrary to the stock price predictions, which are based on company's business insights, the price of a certain cryptocurrency is formed based on the level of its usage in society, the level of the faith community has built, the mood of the people such as their skepticism, risk awareness and other feelings/emotions. By using these subjective factors, one can try to predict the future price movement like Bollen et al. (2011) did for American stock market using Twitter data.

## 3. METHODOLOGY

In this section, we introduce the methodology used to construct and test the proposed trading system based on artificial neural networks.

### 3.1. Trading system

In this paper, we build and test an automated trading system (ATS) for cryptocurrency trading using artificial neural networks as a machine learning component within the system. The proposed trading system is a continuation of the previous work by Rakićević, Milovanović and Aničić (2016), who build a similar ATS for stock market trading. The proposed system consists of two components (Figure 1): the pre-processing component and trading logic component. In pre-processing component there are three modules that work in parallel. Market analysis module gathers cryptocurrency market data and calculates different technical indicators. The second module is for social network data analysis. It crawls data from Reddit service and quantifies it using different indicators. Finally, there is a trading signal extraction module that uses the price data to extract trading signals used as target data for training neural networks. The second part of the system is reserved for trading logic. It consists of the learning part (implemented as a neural network) and a trading algorithm that uses neural network forecasts to decide whether to buy, sell or hold Bitcoin.

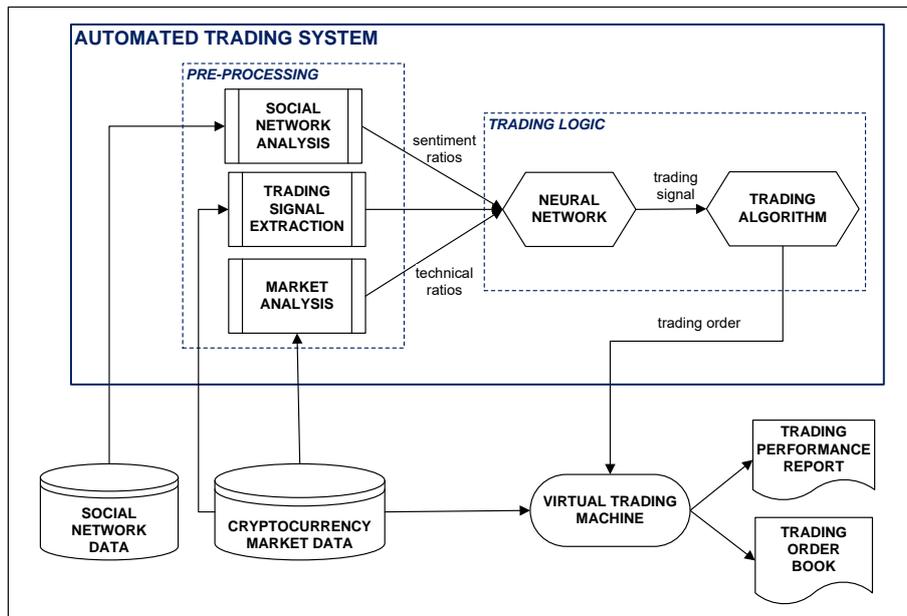

Figure 1: The structure of the proposed ATS

### 3.2. Artificial neural network

Our system uses a standard feed-forward neural network (FFNN) as a learning component to obtain intelligent system design. In this type of network, each network node aggregates all input variables as a

weighted sum and then uses an activation function to obtain nonlinear output from the node. Our network model has three layers:

- input layer with four input variables,
- one hidden layer with 15 nodes,
- an output layer with one output variable.

The proposed FFNN is trained using aback-propagation algorithm. Further, log-sigmoid function is used as an activation function in all network nodes:

$$\sigma(x) = \frac{1}{1 + e^{-x}}. \quad (1)$$

When the ATS starts operating, the first time periods of data  $t$  are used for training FFNN. The neural network uses technical and market sentiment indicators as input variables to learn how to predict the trading signal (extracted using a special pre-processing component). When the underlying model in the data is discovered, trading starts from the  $t+1$  time period. In this operating segment, the system is using a neural network to predict the trading signal based on input variables. Afterwards, the obtained trading signal prediction is used in a trading algorithm for the decision making process and creating the corresponding trading orders. Trading is done until the stopping criterion is met (the end of data series or another condition). If a stopping criterion is met, the ATS stops trading and starts training the neural network again (from the beginning of dataset until the stopping point). After the learning process is done, trading is resumed again (until the stopping criterion is met again).

### 3.3. Input variables

Our trading system uses four input variables obtained with two pre-processing modules. The market analysis module is based on technical analysis and uses market data to calculate indicator values. In this paper, we use two indicators: Relative Strength Index (RSI) and Volume-to-Market-Capitalization (Vol2MCap) indicator. The RSI indicator is one of the most common indicators in technical analysis used to analyze trend momentum. It is derived from the market price in the following way:

$$RSI = 100 - \frac{100}{1 + RS}, \quad (2)$$

where RS is the ratio of average gain of up periods during the specified time frame to the average loss of down periods during the specified time frame.

The Vol2MCap indicator is used for market volume analysis, to provide us with an easy interpretation whether the current trading volume is high, low or average. We calculate this indicator with the following formula:

$$Vol2MCap = \frac{tradingVolume \cdot marketPrice}{marketCapilatization}. \quad (3)$$

To analyze the market sentiment through social networks, we use two additional indicators. The first one we call Sentiment Score (SS). It is calculated as a simple difference between positive reactions on the Reddit social network (ups) and negative reactions (downs) calculated on a daily basis:

$$SS = ups - downs. \quad (4)$$

The SS indicator should track investors' feelings and give us an insight into psychology of cryptocurrency market. Another indicator that was used as an indicator of behavior on the social network is the number of comments on a daily basis. This indicator is aimed to detect "herd behavior" in the market. We assume that when the irrational euphoria hits the market, investors are tempted to talk more about markets on the web. These four indicators are input variables that are used by neural network to learn trading.

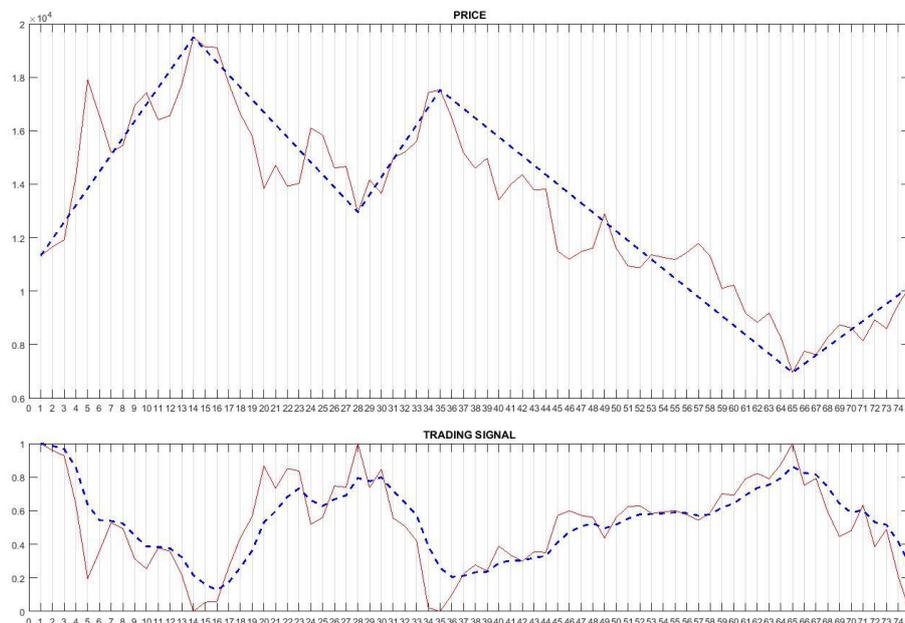

### 3.4. Trading signal extraction

In order to learn our system to trade on the market, we use FFNN as a learning mechanism. The output/target variable for completing that task is a trading signal. Trading signal is a value in  $[0,1]$  range that can be easily interpreted in the trading action (buy, sell, hold/do nothing). We use the well-known ZigZag technical indicator to extract values from price data.

The ZigZag indicator uses a general definition of a trend, a tendency in the data that creates a positive or a negative change in data level over a certain period of time, to construct the lines on charts that represent

trends in data. The indicator tracks the change in price from the previous maximum/minimum value changes its direction should the current return cross the set threshold indicator. The smaller the threshold value is, the more sensitive the ZigZag indicator is to changes in price. In Figure 2 we show an example of trend identification and trading signal extraction.

To extract the trading signal from the ZigZag indicator we use a simple linear transformation which transforms ZigZag trend data into  $[0,1]$  value range. The values of 0 and 1 are assigned to be the reversal points in the trend. When the trading signal takes a value 0 it signals the market bottom to our system, while the value of 1 signals the market top.

**Figure 2:** An example of trend identification and trading signal extraction

### 3.5. Trading algorithm and virtual trading machine

To enable automated trading based on neural network's trading signal prediction we build a simple trading algorithm. We build three simple rules in order to convert trading signal into the corresponding trading action:

1. IF  $\text{trading\_signal} > \text{threshold\_value}$  THEN  $\text{trading\_action} = \text{buy}$
2. IF  $\text{trading\_signal} < (1 - \text{threshold\_value})$  THEN  $\text{trading\_action} = \text{sell}$
3. IF  $(1 - \text{threshold\_value}) < \text{trading\_signal} < \text{threshold\_value}$  THEN  $\text{trading\_action} = \text{hold}$

Furthermore, the trading algorithm splits the investment funds into trading lots, which are calculated as the certain percentage of the current account balance. Whenever the trading algorithm receives buy/sell trading signal it keeps purchasing/selling Bitcoin until all the investment funds are spent.

Finally, to make trading simulation possible, we built a simple virtual trading machine (VTM) that uses real Bitcoin prices from the market. VTM manages trading orders, records transactions and does all the necessary accounting on trading accounts. It also delivers the trading report when the trading simulation is done.

## 4. RESULTS

In this section we present trading simulation results followed by the corresponding discussion. Before results are shown, we describe our dataset, present specific parameter settings for our trading system and list the measures that we used to evaluate trading system performances.

### 4.1. Data

For this research, we collected data from two sources: cryptocurrency market and the social network Reddit. The market data includes standard prices (open, high, low and close), volume and market capitalization data. Social network data includes posts and comments on the subject of Bitcoin collected on the Reddit network. We chose this data source for two reasons: easily accessible data which we gained by scraping the "Daily discussion" posts about Bitcoin and because of almost one million subscribers of this network. We

collected this data on a daily basis within the four-month time period (from December 2017 to April 2018) including 137 observations.

## 4.2. Parameter settings and performance measures

In Section 3 we presented a general methodology used for building our ATS. Here, we give detailed parameter specification which is used to obtain results presented in Section 4.3.

In Table 1 we summarize specific system parameters used in this study:

**Table 1: Automated trading system parameters**

Parameter	Value
Initial investment funds	\$ 1.000.000
Lot size (as a percentage of current investment funds)	33%
ZigZag threshold	±10%
Trading signal threshold	0,7
Stopping criterion (for position)	5% loss
Stopping criterion (for trading)	3 consecutive losing trades

To measure the system performance, we use several standard performance measures: percentage of winning trades, return on investment (ROI), profit factor (PF) and maximal drawdown. To obtain a more detailed look at ATS results, we also calculate some of these measures for long and short positions separately.

The percentage of winning trades is often utilized to assess the performance of trading strategy. This indicator is focused only on the number of winning transactions and it does not take into account the amount that was earned/lost. ROI and PF are the most common indicators used to evaluate the efficiency of an investment. ROI is a ratio of the amount of return on an investment to the investment's cost, while PF indicates the number of monetary units earned over units lost. On the other hand, maximal drawdown is an indicator of the downside risk over a certain time period. It represents the relative difference between the highest and lowest account balance values.

## 4.3. Results and discussion

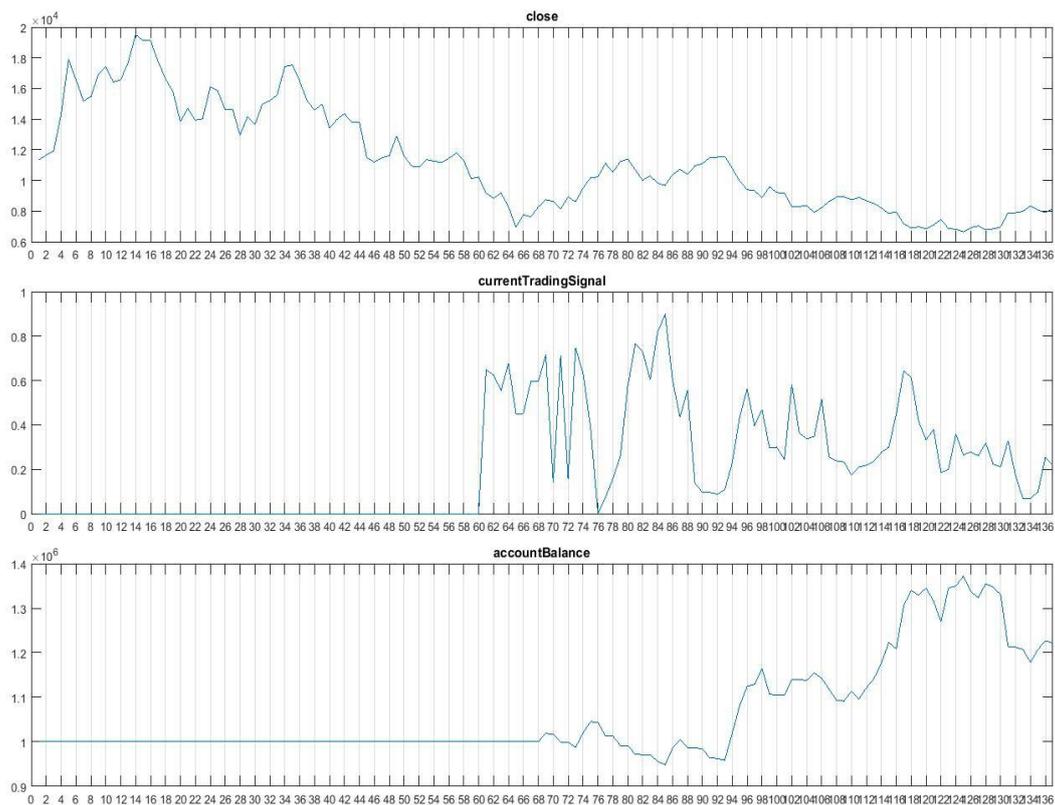

Experiments with neural networks showed that forecasting results of network can differ significantly when the experiment is repeated several times under the same conditions. This phenomenon is a direct consequence of how a neural network works. In order to obtain as accurate as possible approximations of network performances, researches repeat experiments several times and then calculate the average results. In this study, we did 10 simulations of trading with the same initial conditions. Simulation results are presented in Table 2.

As we can see from the results, our trading system proved to be quite a dynamic one. Considering all 10 simulations, it makes 13 daily trades on average during the four month period. Furthermore, the system was able to achieve an average ROI of 6% and average PF of 1,52 even though it has less than 50% of winning trades. It is worth noting that during the same period of time Bitcoin has lost 26% of its value. This can be used as a benchmark result to determine whether the proposed system is successful or not. Having all this in mind, we can conclude that we successfully beat the market.

If we look deeper and analyze long and short trades separately, we obtain interesting results. The results show that the proposed ATS performs much better when shorting (selling without previously buying the currency). This is probably the consequence of the predominant downward Bitcoin trend that happened after the market bubble burst in December of 2017. The following Figure 3 presents one of the simulated trading scenarios with the profit performance trajectory.

**Table 2: Summary results**

PERFORMANCE MEASURE	SIMULATIONS										AVG
	1	2	3	4	5	6	7	8	9	10	
Total trades	11	17	16	13	11	12	16	10	9	16	<b>13</b>
Percentage of win	45%	29%	44%	31%	27%	50%	25%	60%	44%	44%	<b>40%</b>

**Figure 3: An example of trend identification and trading signal extraction**

## 5. CONCLUSION

In this research, we presented an intelligent system for automated cryptocurrency trading based on neural networks. The system uses a neural network to analyze the market sentiment and learn to trade Bitcoin. For that purpose, it uses two technical indicators (Relative Strength Index and Volume-to-Market-Capitalization) in combination with two social network indicators (Sentiment Score and number of comments on the Reddit network). Another important aspect of the system is the way it extracts price trends from raw market data. In

this paper, we use the well-known ZigZag indicator to extract trends. We then used a simple linear transformation to convert the obtained trend values into trading signals. Based on the trading signals, we trained the neural network to learn how to trade.

To obtain and verify results, we performed multiple trading simulations. Summary results show positive average profit performance that significantly outperforms Bitcoin performance. These results may be perceived as a confirmation of the assumption that market psychology is an important factor in still emerging cryptocurrency market. This assumption is embedded in our system indirectly, i.e. through the choice of input variables. Another interesting fact is that our system performs significantly better when trading short position, which is in accordance with the downward trend that has dominated the Bitcoin market since the euphoria bubble burst in the middle of December 2017. These encouraging results give us a motivation to further improve the proposed methodology and to continue to investigate intelligent systems for automated trading in cryptocurrency markets. Some possible further improvements would involve the implementation of some other type of neural network (such as NARX), the development of some intelligent classifier to accurately separate between positive and negative comments on the Reddit network, and the development of a more complex trading algorithm to improve the investment decision making process within our system.

# EXPERIMENTAL COMPARISON OF MULTI-LABEL LEARNING METHODS

Dušica Stepić

Faculty of Organizational Sciences, University of Belgrade

e-mail: dusica.stepic@gmail.com

**Abstract:** Multi-label learning has gotten noteworthy consideration in the research community over the recent years. This has led to the enhancement of diverse multi-label classification methods. This paper presented an experimental comparison of 5 multi-label classification techniques using 10 evaluation measures over 4 benchmark datasets from different application domains. Furthermore, additional efficiency analysis of the methods, in terms of time necessary to learn a classifier and time expected to predict a set of labels for an unseen example, was conducted to determine the most beneficial ones. The results of the analysis show that the best-performing multi-label learning methods are distinct RANdom k-labELsets (RAkELd) and Label power-set (LP).

**Keywords:** machine learning, classification, predictive modeling, multi-label, multi-label learning methods

## 1. INTRODUCTION

In plenty application domains where single-label classification failed to solve a problem, multi-label classification succeeded. For example, single-label classification can classify a song as either “rap” or “pop” and not both, where in fact it could belong to both genres simultaneously. (Alazaidah & Ahmad, 2016). Similarly, in text classification issue, an article can belong to more than one conceptual class at the same time, for instance, a news article can be labeled with both “Politics” and “International Relations” (Nayak et al., 2013).

In the traditional single-label classification method, training instances are associated with a single label  $\lambda$  from a set of disjoint labels  $L$ ,  $|L| > 1$ , where  $|L|$  represents the number of possible values of a label. However, genuinely more complex classification issues exist in the real world, where an instance can belong to more than one class at the same time. If  $|L| = 2$ , then the learning issue is called a binary classification issue, while if  $|L| > 2$  it is called a multi-class classification issue. If the instances are associated with a previously predefined set of labels  $Y \subseteq L$ , then the issue is called multi-label classification. If it is possible that multiple target labels can be assigned to an example from the test set then it is concerning a multi-label classification issue, unlike the multi-class classification where only one label is assigned to each instance (Tsoumakas & Katakis, 2007).

The number of techniques accessible for solving the multi-label data issues is constantly on the rise. (Read & Hollmén, 2017). Latest application areas involve text, image and e-mail classification, functional genomics, music categorization into emotions and others (Madjarov et al., 2012). Many different approaches that were developed in order to solve multi-label problems can be grouped into three methods. On the one hand, existing methods, which attempt to adapt multi-class algorithms, in such manner to directly solve the multi-label issue, are called algorithm adaptation methods. On the other hand, exist problem transformation methods, which attempt to transform the problem of multi-label classification. They can transform it into multiple binary problems or multi-class classification issues (Probst et al., 2017). Furthermore, there are ensemble methods for multi-label learning. Ensembles are being used in this set of methods to make predictions, whereby classifiers they work with are part of problem transformation or algorithm adaptation techniques.

In this paper, five methods for multi-label learning were compared and evaluated. The multi-label methods comprise three different problem transformation methods, one algorithm adaptation and one ensemble method. Namely, those methods are Binary Relevance (BR), Classifier Chain (CC), Label power-set (LP), Multi-Label k-Nearest Neighbor (MLkNN) and RANdom k-labELsets (RAkEL), respectively. The main aim of the research is to compare these methods and give an estimation of their performance. By making a conclusion which method has achieved better performance it would be easier to decide which one to use in some future research. Without having any previous knowledge about utilized algorithms in the process of solving multi-label issues it would be possible to choose the best proven method or technique similar to it, just by using the results of this research as a guideline.

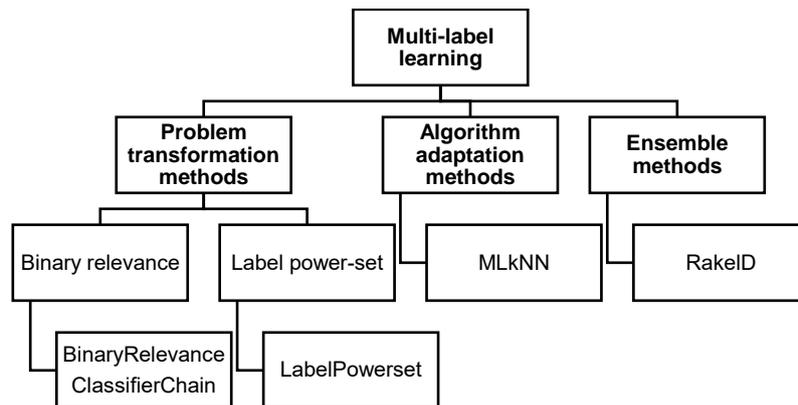

The remainder of the paper is organized as follows. Section 2 defines the main objective of multi-label classification and presents methods that were tested and evaluated in this study. Section 3 analyses research methodology and section 4 presents the results of the experiment. Finally, conclusion and future work are described in Section 5.

## 2. MULTI-LABEL LEARNING METHODS

Multi-label learning is instance-based, whereby each instance is associated with a subset of labels, which belong to an already predefined set of labels. The main objective of multi-label classification is to build a predictive model based on the training data. Next step is testing if the model is adequate. The result of this phase will be a list of labels that are relevant for a given, previously unseen instance (Madjarov et al., 2012).

Multi-label learning methods are divided into three categories: problem transformation, algorithm adaptation and ensemble methods. In the first category, whose methods are algorithm independent, any single-label learning algorithm can be used to solve multi-label classification issue. It consists of methods which transform the multi-label classification problem into either a few binary classification problems, such as the BR approach, or one multi-class classification issue, such as the LP approach. The second category is algorithm adaptation methods that consist of methods which extend existing learning algorithms to deal with multi-label data directly. The MLkNN algorithm used in this work belongs to this category (Spolaôr et al., 2013). The third group of methods is called ensemble methods. This group consists of methods that use ensembles to make multi-label predictions and their base classifiers belong to either problem transformation or algorithm adaptation methods, such as the RAKEL, which uses LP as a base classifier.

The multi-label learning methods used and evaluated in this experimental study are shown in Figure 1.

**Figure 1:** The multi-label learning methods used in this study

In this study five multi-label learning methods were used:

- Binary Relevance (BR) is the notable one-against-all strategy. It addresses the multi-label learning issue by learning one classifier for each class, using every one of the examples labeled with that class as positive cases and all remaining examples as negative. In order to make a set of labels that are relevant for a previously unseen example, each of the binary classifiers, when making a prediction, has to predict whether its label is important or not for that given example. BR technique has been actively analyzed and criticized because of its insufficiency of dealing with label dependency. In fact, the BR technique makes an assumption that every single label is independent of the others, which makes it easy to implement and generally effective, although unequipped of handling any sort of label relationship. (Cherman et al., 2011). During its transformation process, BR completely overlooks label relationships that exist in the training data. (Read et al., 2009)
- Classifier Chain (CC) is a technique firmly identified with the BR strategy. The fundamental idea of this algorithm is to transform the multi-label learning issue into a chain of binary classification issues, where consecutive binary classifiers in the chain are built upon the predictions of preceding ones (Zhang and Zhou, 2014). The CC model includes  $|L|$  binary classifiers as in BR, where  $|L|$  is the total number of labels. Classifiers are connected along a chain where every classifier handles the BR issue related with label  $l_j \in L, j = \{1, \dots, L\}$ . (Read et al., 2009)
- Label power-set (LP) belongs to the group of the label power-set methods. The LP approach directly transforms the multi-label dataset into one single-label dataset, whereby each label is a unique combination of labels appearing on the training set, which was previously transformed to a single-label dataset, in which any method for the multi-class issue can be directly applied to. Moreover, this approach implicitly considers label dependence (Spolaôr et al., 2013). However, problem is that the space of

possible label subsets can be very large. If the number of meta-classes is large that can be an extremely difficult issue to resolve because it makes probability estimation challenging. Additionally, most LP-based method implementations essentially overlook label combinations that are not present in the training set. (Dembszynski et al., 2010)

- Multi-Label k-Nearest Neighbor (MLkNN) is the multi-label version of the well-known kNN algorithm. First, for each instance from the test set, the MLkNN determines its k nearest neighbors in the training set. At that point, according to statistical information gathered from the label sets of these nearest neighbors, namely the number of neighboring instances belonging to each of the possible labels, the maximum a posteriori principle is used to determine the relevant set of labels for an unseen instance from the test set. (Zhang & Zhou, 2007)
- Distinct RANdom k-labELsets multi-label classifier (RAkELd) is an ensemble technique for multi-label learning developed on top of the common problem transformation method (LP). RAkEL, as its name would suggest, constructs an ensemble of LP classifiers. It performs LP methods on M different, random subsets of size k, whereby  $subsets \subset \{1, \dots, L\}$ , and k is a small number,  $k < L$ . Those chosen subsets are called k-label sets. Each performed LP method, trains an LP classifier by using randomly chosen subsets. (Modi & Panchal, 2012). Thus, RAkEL takes in consideration label relationships and avoids the disadvantage of the LP method by applying single-label classifiers on k-label subsets with a satisfactory number of labels and a sufficient number of instances per label (Tsoumakas et al., 2011). Predictive power enhances by using ensembles of LP algorithms, in comparison to using only LP method.

### 3. RESEARCH METHODOLOGY

The basic idea of this research is to compare tested multi-label learning methods and identify the best ones based on their predictive performance and time complexity. The experiment was implemented in the Jupyter Notebook.

In this paper, an experimental assessment of methods for multi-label learning is presented. Five of the most popular methods for multi-label learning were evaluated using a wide range of evaluation measures. Datasets used in the experiment were acquired from UCI Machine Learning repository (Dua & Karra, 2017) and MULAN (Tsoumakas et al., 2011). List of datasets with basic details is shown in Table 1.

**Table 1:** Benchmark datasets from UCI repository and MULAN used in this study

Dataset	Classes	Attributes	Size
student performance	6	53	382
yeast	14	117	2417
emotions	6	78	593
scene	6	300	2407

First, five of the most popular multi-label methods that were recently proposed in the literature were selected. The chosen methods are divided into three main groups: problem transformation (three methods), algorithm adaptation (one method) and ensembles (one method). The methods use two types of basic algorithms for machine learning: SVM (problem transformation methods), random forest (an ensemble method) and k-nearest neighbors (an algorithm adaptation method). Moreover, 10 different evaluation measures that are typically used in the context of multi-label learning were considered. A better and more detailed view of the algorithm performance can be shown by using a variety of evaluation measures.

The evaluation measures are divided into three groups: example-based (Accuracy and Hamming loss), label-based (Macro-precision, Micro-precision, Macro-recall, Micro-recall, Macro-F1, Micro-F1 and Roc AUC score) and ranking-based (One error). Every multi-label method was trained on 70% of the data. Final testing and evaluation were performed on 30% of the data. Furthermore, the efficiency of the methods is evaluated by measuring the time necessary to learn the classifier and the time needed to create a prediction for an unseen example. Additionally, the methods were evaluated on four multi-label benchmark datasets from different application domains: social science, protein, image and music classification.

As far as the BR, LP and RAkEL techniques, they can use any learning algorithm for classifier training. The chosen methods were using two kinds of base classifiers for resolving the partial binary classification issues in all problem transformation methods and the ensemble method: support vector machines (SVM) and Random Forest (RF), respectively. The SVM with the Radial Basis Function kernel was used for training in all problem transformation methods and RF classifier was used for an ensemble method.

### 4. RESULTS

Evaluation measures (Accuracy, Macro-Precision, Micro-Precision, Macro-Recall, Micro-Recall, Macro-F1, Micro-F1, 0/1 Loss, Hamming Loss, Roc auc score) and efficiency measures of the tested methods (Train

and Test time) are shown in Table 2 and Table 3. The best performance was bolded for each dataset, and the second best was presented in italic.

Further analyzing the predictive method performance across all ten evaluation measures and two efficiency measures: the very best performing methods on all measures are either RAKELd or LP. RAKELd is the best performing method, closely followed by LP. Performance of the BR was inferior over all evaluation measures, aside from precision, meaning that the labels predicted as relevant were truly relevant in the original examples (small number of false positives results in high precision). However, BR is leaving out some of the relevant labels when making predictions (larger number of false negatives results in low recall).

**Table 2:** Evaluation and efficiency measures for Student performance and Yeast dataset

Measures	Student performance					Yeast

**Table 4:** Best and second-best performances of multi-label learning methods

	BR	CC	LP	MLkNN	RAKELd
<b>First</b>	4	5	13	6	22
<b>Second</b>	3	11	15	8	13

Table 4 shows number of best and second-best performances of each multi-label learning method through all four datasets. The best multi-label learning method was RAKELd, which performed best 22 times, and was second 13 times. LP has also shown great performances and BR performed worst of tested multi-label learning methods. It was first 4 times, and second only for 3 times. BR is the simplest problem transformation method. However, lately, it is sidelined on the grounds of assuming label independence. BR disregards label relationships that exist in the training data.

LP-based methods directly consider the label correlations. However, the main problem is the size of the set, which consists of possible label subsets, because that set can be quite large in LP. RAKELd is a tactic that creates a group of LP classifiers, or in other words an ensemble of them. During the classifier training process, each LP classifier is being trained on a different and random subset of the labels. This approach aims at considering label correlations and at the same time avoiding the problems of LP. Results of performance comparison against the BR and LP methods are in favor of the LP-based methods (RakELd and LP).

**Figure 2:** Multi-label learning methods - Train time (seconds)

**Figure 3:** Multi-label learning methods - Test time (seconds)

As mentioned earlier, each dataset was randomly split into two sets: 70% for training and 30% for a test. For comparison, the charts in Fig. 2 and Fig. 3 show the efficiency of five tested methods, in terms of time complexity (test and train time of the classifiers). Considering efficiency, RAKELd (using the tree-based method as a base classifier) was generally faster to train a classifier and make a prediction for an unseen example than the SVM-based methods. The results show that RAKELd is faster than LP on testing time (on average 2.8 times) and on training time (on average 7.11 times). Furthermore, RAKELd is faster than MLkNN on testing time (on average 6.5 times) and on training time (on average 13 times).

When comparing only problem transformation methods among each other, LP performed better than BR and CC. The multi-label variant of k-nearest neighbors (ML-kNN) performed poor and had the worst train and test time. MLkNN is the most time-consuming algorithm.

## 5. CONCLUSION

This paper presented results of five different methods for multi-label classification. The goal was to show comparative experimental results of certain multi-label classification methods that were previously chosen from various research papers and to determine the greatest ones. This work also gave an organized presentation of those methods and provided empirical evaluation over four different multi-label datasets with a variety of evaluation and efficiency metrics.

All in all, considering the performance and the efficiency of the evaluated methods RAKELd, an ensemble method used in this paper, proved superior among other tested methods. Empirical evaluation demonstrates the competitiveness of RAKELd against other multi-label learning methods, which were tested, both in terms of predictive performance and time complexity.

Furthermore, RAKELd and LP proved to be the best in terms of predictive performance and demonstrated better competence than the remaining methods. Both of this method are LP-based, which prove that label dependency is important when it comes to predictive modeling in multi-label classification problems. On the other hand, it depends upon the concrete objective of the learning issue whether label dependencies can be used to enhance predictive performance (Dembszynski et al., 2010). Researchers have been working on the plan of designing multi-label methods competent for handling the diverse relationships between labels, particularly label dependency, correlation and co-occurrence. For example, in the LP method, inter-relationships between labels are mapped straightforwardly from the data, since all the existing combinations of single-labels present in the training examples are used as one of the possible labels in the given multi-class classification issue (Cherman et al., 2011).

Future work will include performing more extensive experiments with more datasets and extending this experimental study by including more multi-label learning methods, especially ensemble and algorithm adaptation methods. Moreover, including Grid search for hyperparameter optimization and investigating the issue of selecting appropriate parameters for all multi-label classifiers to improve performances.

## DATA MINING USING ORACLE DATA MINER AND ANALYTIC FUNCTIONS WITH HADOOP

Ivan Rakić<sup>\*1</sup>, Željana Milošević<sup>1</sup>, Slađan Babarogić<sup>1</sup>  
<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia  
<sup>\*</sup>Corresponding author, e-mail: ivan.rakic@fon.bg.ac.rs

**Abstract:** In this paper we have described how a large amount of data can be processed in Oracle Database using different algorithms and functions. After training data mining algorithms, their performance on new datasets can be measured and examined. We have focused on the comparison of specific algorithms in order to decide which of them gives more reliable data processing results. To make sure that more efficient algorithm is chosen, Oracle analytic functions can be used for data preparation before using the algorithms and for processing the results obtained after the execution of the algorithms. Hadoop framework and Hive, as part of it, have been used to improve access to data being processed.

**Keywords:** Data Mining, Oracle, Hadoop, classification, clustering, analytic functions

### 1. INTRODUCTION

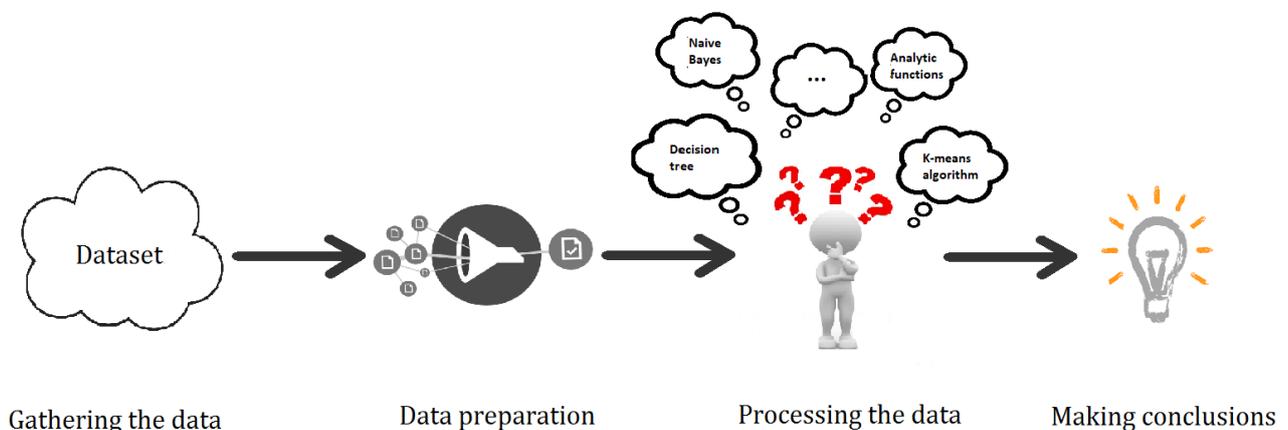

One of the biggest challenges that people who deal with information technology today face is how to handle large amount of data generated by users of different systems every day. (Thearling, 2017)

Lately, Data Mining is very important part of computer science that investigates data in order to discover and describe patterns. Because we live in a world where huge amounts of data are generated every day, it is imperative to find a way to extract useful information from this data, to classify it and to make certain conclusions (Thearling, 2017).

At the beginning, in the second chapter we described the problem of data analysis that we tried to solve in this paper.

In the third chapter is given a brief overview of what a Big Data and Data Mining represents, and after that is described the model which is usually used in Big data processing techniques as well as technologies and tools used for the realization of the demonstration case studies. Also, we make some review about the most useful Data Mining algorithms for classification and clustering, such as Decision tree, Naive Bayes, Hierarchical clustering and K-means algorithms. And finally, we present some of the most frequently used analytical functions, in this case used for data preparation and analysis of results of Data Mining algorithms. An example of using these algorithms and functions in Oracle Database is shown in the fourth chapter. In the end, in the fifth chapter we give our vision of further application of Data Mining algorithms.

### 2. PROBLEM STATEMENT

**Figure 1:** Problem statement

Nowadays, large amounts of data are piling up from various sources and the amount of this data has a constant tendency of growth. New ways to analyze this data need to be discovered, in order to find the best way to extract important information from it. Data in the original form represents only the noisy data that needs to be prepared for the application of various techniques and algorithms. Various techniques and algorithms can be applied to the data which is obtained as a result of prior data cleansing. In order to make a certain conclusion which of these techniques give the most reliable results depending on the context of the problem, it is necessary to apply several techniques separately or a combination of several techniques, functions and algorithms. If combination of techniques is applied, it is important to plan the sequence in which they will be used. Out of all these steps, choosing appropriate algorithm for given domain is still mostly unspecified, since there is no universal approach to this problem, and solutions vary from case to case.

### 3. THEORETICAL BACKGROUND

In this chapter are given main theoretical concepts concerning Big Data, Data Mining and corresponding algorithms, as well as required Oracle functionalities, such as analytic functions.

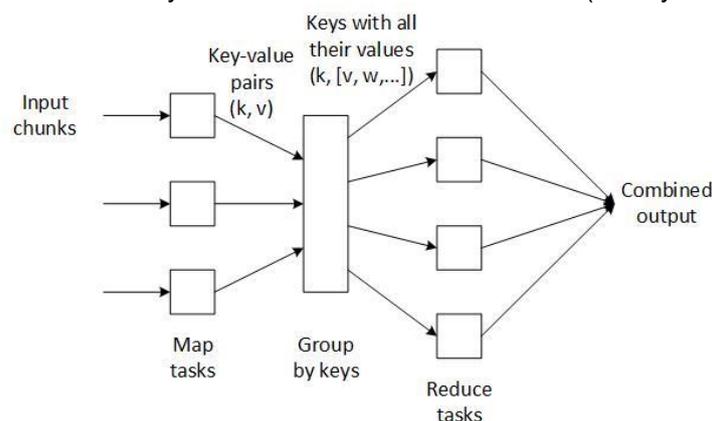

#### 3.1. Big Data

Big data can be defined as “The storage and analysis of large and/or complex data sets using a series of techniques including, but not limited to, NoSQL, MapReduce and machine learning”. (De Mauro, 2016) The term “Big Data” is used to identify amounts of data which size is bigger than software capacity that is usually used for storage, processing and data management. (Elgendy & Elragal, 2016)

##### 3.1.1. Hadoop

**MapReduce** is one of the earliest and most popular programming models created by Google in 2004 and based on C++ language. This model is used for parallel processing and generating Big Data sets. (Yahya, Hegazy, & Ezat, 2012)

The MapReduce model is based on two basic functions: **Map** and **Reduce**. At first, the **Map function** is used to process the input records into a sequence of key-value pairs, and then generate a set of intermediate key-value pairs. The method key-value pairs, which are derived from the input data is defined by user for the Map function. The **Reduce function** merges all the key-value pairs with the same key into the same Reduce task. Reduce task processes one key at the time and combine all values associated with that key. The mode of combination of values is determined by the user for the Reduce function. (Jeffrey Dean, 2008)

**Figure 2:** Schematic of MapReduce computation (Leskovec, Rajaraman, & Ullman, 2014)

There are many implementations of MapReduce model, but the most commonly used is a **Hadoop framework**. (Venner, 2009)

The big companies like Facebook, Google, Amazon and Yahoo were first to face rapid increase in the amount of data. They have to execute terabytes and petabytes of data by the day, in order to interpret the requirements, they receive from users and respond to them. The problem of handling and processing all of this data is resolved by Hadoop which has replaced scarce, existing tools. (Ghazi & Gangodkar, 2015)

### 3.1.2. Hive

One of the most common problems that Hadoop users encounter is creating queries over data with Hadoop as in traditional RDBMS infrastructure. **Hadoop Hive** is an open source SQL-based shared warehouse system which is suggested to solve mentioned problem by supplying an SQL-like abstraction above the Hadoop framework. Hive is translator which represents a combination of SQL language and MapReduce model. It uses HiveQL, in order to create queries over data stored in a cluster. Hive is used to bridge barriers between traditional applications which are implemented using SQL-based RDBMSs and Hadoop framework. (Dokeroglu, Ozal, Bayir, Cinar, & Cosar, 2014)

### 3.2. Data Mining and Data Mining algorithms

“**Data Mining** is a collection of techniques for efficient automated discovery of previously unknown, valid, novel, useful and understandable patterns in large databases. The patterns must be actionable so they may be used in an enterprise’s decision making.” (Gupta, 2014)

Some of techniques which are used for Data Mining are very similar to the machine learning techniques, but on the other hand, a lot of them are closely related to techniques that are deployed for statistical analysis. (Gupta, 2014)

Data Mining uses advanced mathematical algorithms for automatically searching data warehouse in order to predict some future events based on past events. Although being a powerful tool, it is very important to remember that it is not able to recognize the value of the information which is derived from the data. (Data Mining Concepts, 2018)

**Data Mining algorithms** have various purposes today, ranging from fraud detection and bankruptcy prediction to target marketing and customer retention as, perhaps, its most commonly used purpose. However, results of such techniques depend largely on complex nature of data to be processed and choice of adequate Data Mining algorithm, since there is no established practice related to use of specific algorithm on specific problem domain. More traditional approach is represented by statistical algorithms, which rely heavily on mathematical models and assumptions such as data normality. Opposed to them, machine learning algorithms are assumption free, and tend to outperform above mentioned algorithms when mining business datasets. (Becker, 2001)

#### 3.2.1. Classification

The aim of **classification** is to develop a classification rule, which can later be used to categorize given objects based only on their vector of features. Training dataset is necessary for classification, and it contains collection of object, their vector of features, as well as their correct classes. Most reliable way to determine correct classes is by consulting domain expert. In other words, the goal of classification is to distribute given objects into  $m$  distinct categories, with highest precision as possible. (Alpaydin, 2014) Classification is part of supervised learning scenario, in which “the learner receives a set of labeled examples as training data and makes predictions for all unseen points”. (Mohri, Rostamizadeh, & Talwalkar, 2012) Some of the most used classification algorithms are:

- **Decision Tree** - a decision tree represents a binary tree in which leaves render decisions (classes) and interior nodes conditions on the object being classified. The classification process starts at the root of the tree where predicate is evaluated, and algorithm moves to one of the children based on the result of the evaluation. These steps are repeated for each interior node, until one of the leaves is reached. Reached leave represents object's class. Important task in this process is the choice of predicates for each of the interior nodes. (Leskovec, Rajaraman, & Ullman, 2014)
- **Naive Bayes** classifier is used to assign most likely class to a given object which is described by its feature vectors, with the assumption that given features are independent given class. The base of this classifier is Bayes’ theorem, which describes probability of an event, based on conditions related to that event with “naive” assumptions about feature independency. These assumptions are not realistic, but despite that, Naive Bayes has shown exceptionally good results in practice. (Rish, 2001)

### 3.2.2. Clustering

**Clustering** is defined as process of examining a collection of certain “points” and grouping them into “clusters” according to some distance measure, in such manner that the distance between points in the same cluster is small and the distance between points in different clusters is large. The distance between two points can be defined in various ways, and most often it is traditional Euclidian distance. (Leskovec, Rajaraman, & Ullman, 2014)

Clustering is part of unsupervised learning scenario, where, based on an unlabeled dataset, learner makes predictions for all unseen points. Due to this, it is hard to evaluate the performance of a learner. (Leskovec, Rajaraman, & Ullman, 2014) Mostly used clustering algorithms are:

- **Hierarchical clustering** - each point starts as separate cluster, and in every iteration, new, larger clusters are built by merging two smaller clusters. The most common way to represent a cluster is by using centroids, and centroids to be merged are usually ones which have the shortest distance between each other. (Leskovec, Rajaraman, & Ullman, 2014)
- **K-means algorithms** require that the final number of clusters,  $k$ , is known in advance. In initial step  $k$  points which will represent clusters are selected. After that, each point, other than  $k$  selected points, are considered and assigned to the closest cluster. The distance between a point and a cluster is usually measured by distance between a point and the centroid of a cluster. There are several options for determining initial points, such as picking the points that are as far away from another as possible, clustering a sample of the data using some other algorithm, etc. (Leskovec, Rajaraman, & Ullman, 2014)

### 3.3. Oracle database support for data processing

**Oracle Data Mining** represents a powerful ability to analyze data inside of Oracle Database. It can be used for developing predictive Data Mining applications, adding smart possibilities in existing applications, or generating predictive queries to research data. Oracle Data Mining is a component of the Oracle Advanced Analytics Option of Oracle Database Enterprise Edition. One of the essential features of this component is the ability to work with Big Data sets in different forms. (Data Mining Concepts, 2018)

A development environment that can be used to execute Data Mining algorithms in Oracle databases is Oracle SQL Developer which has the appropriate extension called **Oracle Data Miner**. This tool is based on workflow paradigm which allows catching, documenting and automating the process of building, evaluating and using Data Mining algorithms. Inside of a workflow, it is possible to specify data transformations, build and evaluate more algorithms, and score more data sets. It is possible to create predictive models in Oracle Data Miner, which developers can integrate into applications to automate the discovery new business intelligence-predictions, patterns and discoveries-throughout the enterprise. (Data Mining Concepts, 2018)

#### 3.3.1. Oracle analytic and aggregate functions

Data Miner can operate on data stored in tables and views in database, and results of tested algorithms can also be stored in such manner, which gives a lot of flexibility and potentiality by combining Data Mining process and big relational database, such as Oracle database. One of such advantages is the opportunity of using aggregate and analytic functions on datasets and results of Data Mining algorithms.

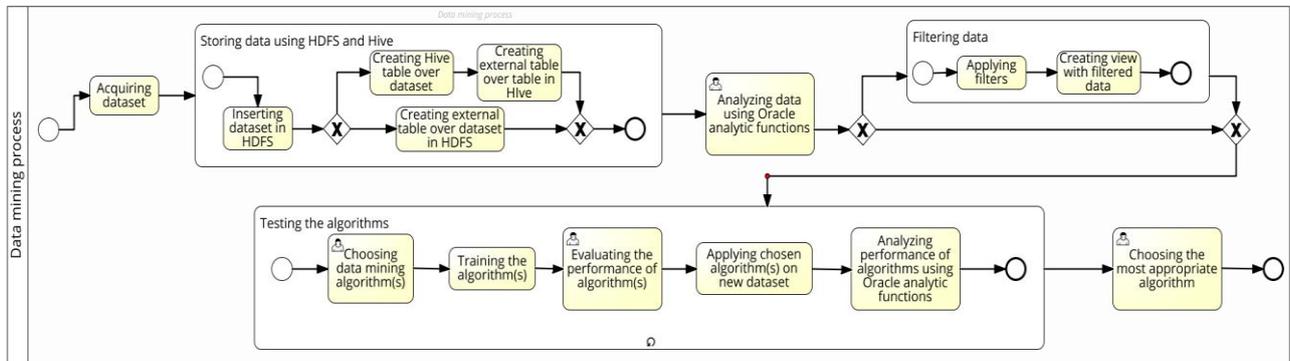

An aggregate function is used for aggregating data from several rows into a single result row. Analytic functions also operate on subsets of rows, but they do not decrease the number of rows returned by the query. Analytic functions calculate an aggregate value based on a group of rows. They differ from aggregate functions in that they return multiple rows for each group. (Analytic Functions, 2018)

Some of the most used aggregate and analytic functions are **MAX**, **MIN**, **VARIANCE**, **STDDEV**, etc. (Analytic Functions, 2018)

## 4. SELECTING DATA MINING ALGORITHMS USING ORACLE DATA MINER, HADOOP AND ORACLE ANALYTIC FUNCTIONS

In this chapter will be described the example of using Oracle Data Miner extension and Oracle analytic functions for classification and clustering of datasets stored in Hadoop file system. This example was implemented using Oracle Big Data Appliance, which contains all necessary services and software.

The process of selecting the most appropriate data mining algorithm for given dataset is described using following BPMN 2.0 diagram.

**Figure 3:** BPMN diagram describing the selection of data mining algorithm

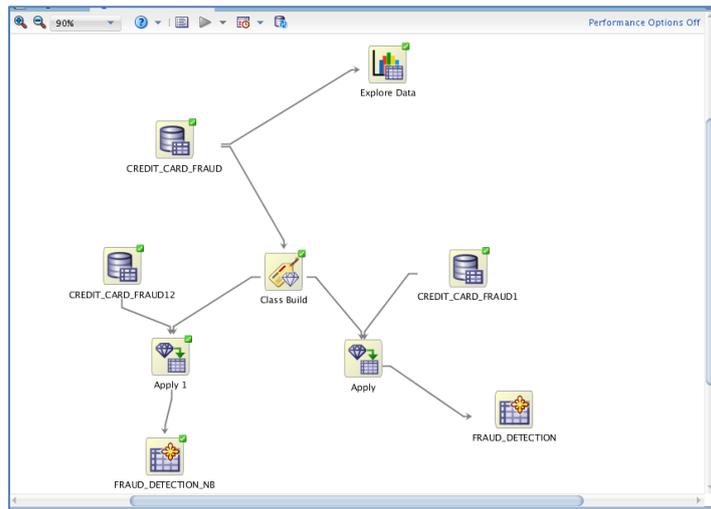

Process shown in diagram above starts with finding suitable dataset for desired mining area. After that it is necessary to store acquired dataset in some manner. One of the most popular ways to do that today is by using Hadoop and HDFS. After inserting dataset in HDFS, Hive can be used to access imported data, or data can be accessed directly in HDFS. Since this example shows data mining in Oracle database, this step also includes creating external tables over previously imported data. This is followed by data analysis, which includes detecting and eliminating inconsistent and “dirty” data, possibly done with Oracle analytic functions. If inconsistencies are found, data should be filtered and result of that filtering should be stored in some way, possibly by creating a view. Next step is about testing data mining algorithms, and this includes choosing algorithms to be tested, training as well as evaluating results of that training. After that, chosen algorithms can be applied on new dataset and their performance on this dataset can be analyzed, again with Oracle analytic functions. Last few steps are repeated until a decision can be made, choosing the right algorithm.

### 4.1. CLASSIFICATION EXAMPLE

Dataset used for classification is about detection of credit card frauds. First step described in Figure 3 is acquiring dataset and **storing it using HDFS and Hive**. After starting all necessary services, dataset file is imported in Hadoop file system via terminal commands. Since the format in which the files are stored is .csv format, it is stated that all fields are separated by comma. Next step is about creating external table in Oracle database over the previously created Hive table.

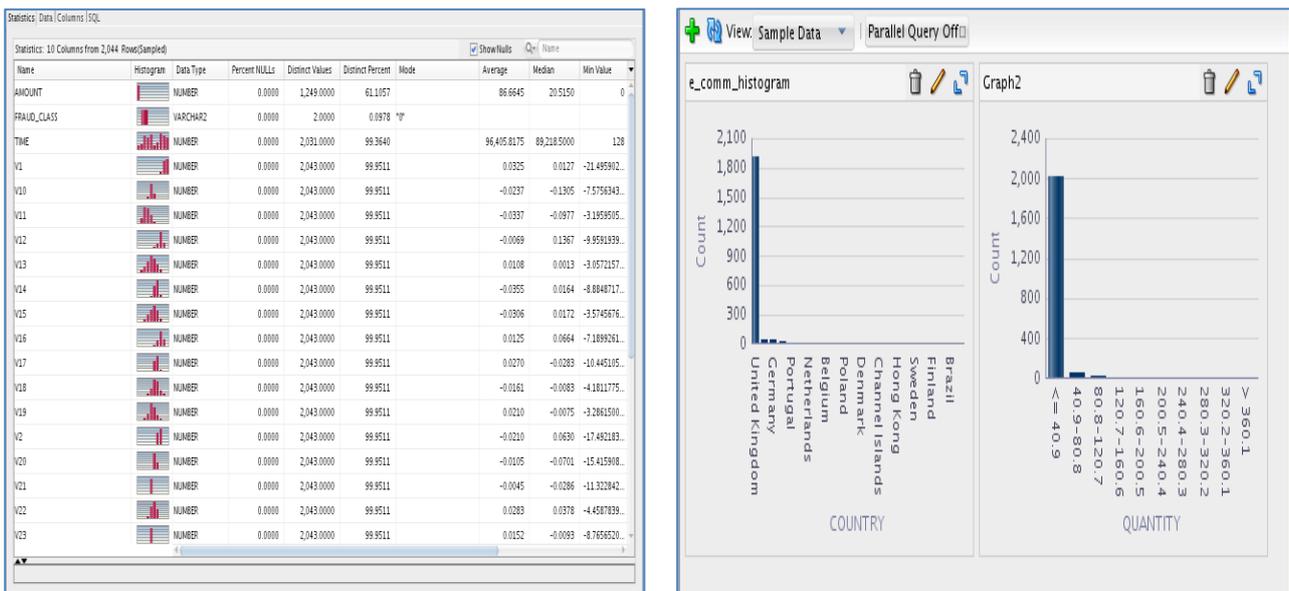

No missing or “dirty” data were found after **analyzing the data**, so there is no need for **filtering**.

Next step is about **testing and evaluating algorithms**. Before all, Data Miner connection must be created, and that connection must be created over the same schema that was used for creating external tables in previous steps. After that, workflows can be added.

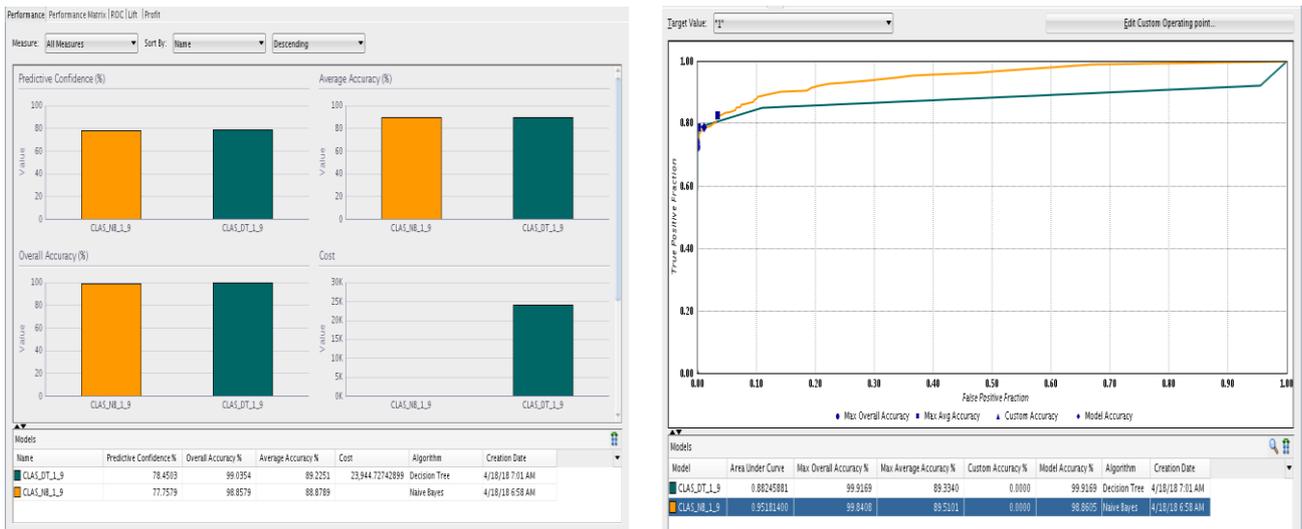

**Figure 4:** Workflow for classification in Data Miner

After adding node that represents data source and connecting it with appropriate table, different operations can be performed with it. Wide range of statistics is at disposal, such as minimum and maximum value, median, variance, standard deviation, etc. Data can be also visualized, using many different graphs, as shown in pictures below.

**Figure 5:** An example of statistical functions and graphs applied on data sets

Four classification algorithms are available: Decision Tree, Naive Bayes, Generalized Linear Model and Support Vector Machine. After the selection of the algorithms (in this example Decision Tree and Naive Bayes algorithms are used), connecting classification node with data source and setup of parameters (such as percent of dataset to be used for training and testing), classification process can be started. When this is complete, performance of chosen algorithm can be examined, and different algorithms can be compared using many criteria, such as predictive confidence, average accuracy, overall accuracy, cost, or using visual representation, as shown on pictures below.

**Figure 6:** Compared performances of algorithms and ROC curve

In this example, Naive Bayes algorithm (orange bar) and Decision Tree algorithm (green bar) are almost equally precise, with less than a percent of difference. Because of that, it is hard to tell which of these two algorithms will fare better in classification of new data. This is where Oracle analytic functions come in handy. Each of trained algorithms can be separately applied on test data set (as shown in Figure 3), and results of each appliance can be stored in Oracle tables. These tables by default contain information about predicted class for each row and probability with which the algorithm designated class for a given row. Now, wide range of queries can be applied on created tables. For example, we can compare variance and standard deviation for prediction probabilities of both of algorithms, and minimal and maximal probability can also be of interest.

In last step described in Figure 3, a **choice** must be made which algorithm suits better for a given problem. After using VARIANCE, STDDEV, MIN and MAX functions to examine mentioned probabilities, we can conclude that that Naive Bayes algorithm, although a percent less accurate than Decision Tree algorithm, has significantly less variance and standard deviation when it comes to predicting positive fraud cases (class with label "1"). We can also note that Naive Bayes algorithm have minimal probability of approximately 0.5 against approximately 0.007 for Decision Tree algorithm. Based on these analyses, conclusion can be made that Naive Bayes algorithm is far more confident when it comes to credit card fraud detection.

	CLAS_DT_1_9_PRED	VARIANCE(CLAS_DT_1_9_PROB)	STDDEV(CLAS_DT_1_9_PROB)	MIN(CLAS_DT_1_9_PROB)	MAX(CLAS_DT_1_9_PROB)
1 "1"		0.08236722401694024	0.2869969059361795	0.007309941520467836	0.8859649122807017

**Figure 8:** Analyses of prediction probability for Naive Bayes algorithm

## 4.2. CLUSTERING EXAMPLE

Among other models, Data Miner also supports clustering. In this section will be described process of **filtering the data**, since the rest of the steps are the same as in classification example.

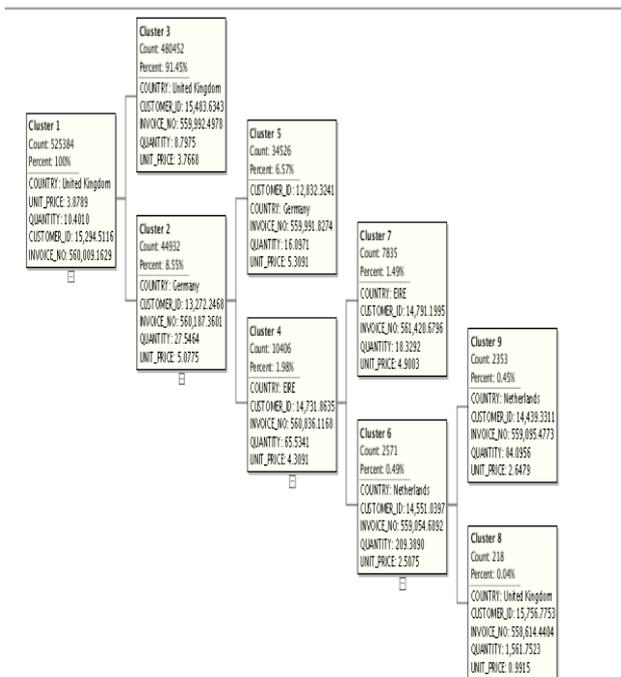

Acquired datasets usually contain inconsistent data, which should be eliminated before data mining algorithms are trained on them. Examples of inconsistent data include negative quantities of products, negative prices, missing values for identifiers and other important fields and so on. This is where Oracle analytic functions might become useful again. Using these functions, anomalies in datasets can be easily identified and eliminated. Another advantage of using Oracle relational database management system is that there is no need to delete inconsistent rows from the original table. Simply, a view can be created with filtered data, and this view will be later used for clustering. That way, original data can be kept, and data mining algorithms can be applied on filtered data.

Dataset used for clustering contains e-commerce data, such as data about products bought, their prices, quantity of bought products, date of purchase, and so on. Analyzing the data with MIN and MAX functions, we can detect negative values for quantity and price of purchased products and also missing values for description of products. Since these rows make only a small percentage of the entire dataset (about 0.03%), they can be eliminated without fear that this will jeopardize the training process. Now, a view can be created that will contain only valid data, and it will be used for clustering algorithms.

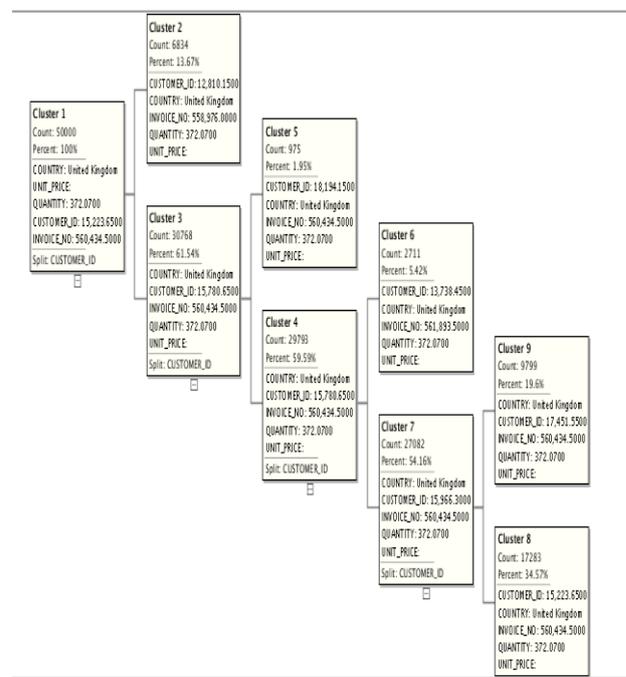

```
CREATE OR REPLACE VIEW E_COMMERCE_VIEW
("INVOICE_NO", "STOCK_CODE", "DESCRIPTION", "QUANTITY", "INVOICE_DATE", "UNIT_PRICE", "CUSTOMER_ID", "COUNTRY") AS
select invoice_no, stock_code, description,
quantity, invoice_date, unit_price, customer_id, country
from e_commerce
where quantity > 0 and unit_price != 0 and description is not null;
```

**Figure 9:** A view containing filtered data

Clustering node also requires data source for its execution, and three algorithms are available: Expectation Maximization, K-Means and O-Cluster, an Oracle proprietary algorithm similar to hierarchical clustering. In this example K-Means and O-Cluster will be compared. After the selection of algorithms, desired number of clusters and other parameters, clustering process can be started. When it is done, received clusters from both algorithms can be examined with information such as number of instances in each cluster, information about centroid, percent of all instances in given cluster, etc. Both algorithms divided rows in five clusters, as can be seen in pictures.

**Figure 11:** Clusters obtained using O-Cluster algorithm

**Figure 10:** Clusters obtained using K-Means algorithm

One of, or both algorithms, can be used for clustering of a new data source, and results of that operation can be saved in separate table as described in classification.

## 5. CONCLUSION

There has been a rapid growth in Data Mining usage in different areas like business, education, medicine, science, etc. It is not possible to examine all the data that users generate through various applications in these areas, therefore it is crucial to use different algorithms and techniques for their processing and making certain conclusions from them.

In this paper, the accent was on the very process of Data Mining and selection of the most appropriate algorithm for given domain. Being one of the most rapidly developing disciplines, Data Mining has been integrated in all aspects of IT world, using their advantages to produce more effective solutions, generated faster. One of such examples is using Data Mining algorithms in combination with relational databases and

all the benefits they provide. These benefits can be used to complement and aid mentioned algorithms and eliminate eventual flaws. There are numerous ways, perhaps yet undiscovered, to achieve this, and using analytic functions to additionally analyze Data Mining algorithms is just one of them.

The process of applying certain algorithm on dataset can be divided in steps, and largest part of these steps is independent of the type of algorithm applied. This implies that it can be abstracted to some degree, which could lead to its automation. This could further lead to acceleration of Data Mining process, and its standardization. This also represent course of further development of the subject depicted in this paper.

## BIG DATA ANALYSIS IN SOCIAL MEDIA

Jelena Ljubenović\*, Ognjen Pantelić, Ana Pajić Simović<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of organizational sciences, Serbia

\*Corresponding author, e-mail: [jelena.ljubenovic@fon.bg.ac.rs](mailto:jelena.ljubenovic@fon.bg.ac.rs)

**Abstract:** *The Internet community has changed a lot in the past few years. Social media has changed the way of communication and connected millions of people. With the increase of information that is being generated in these communication channels, there is a new problem: storing all the data. Relational databases are no longer most suitable storage for social media data. Two technical entities have come together. First is big data for massive amounts of data. Second, there's advanced analytics, which is a collection of different tool types for getting meaningful information from the data. Together they make big data analytics, a new practice in BI today.*

*This paper presents big data, social media, and social media data infrastructure. It also shows tools for analyzing big data. The contribution of this paper is to provide an overview of tools and techniques for analyzing social media data either for research or business purposes.*

**Keywords:** *big data, big data analysis, social media, social media data, social media data infrastructure*

### 1. INTRODUCTION

Information overload and the limits of human cognition in dealing with information are much older than new technologies and Internet network. As hardware technology has improved, software technology has improved as well. It's never been that easy to communicate and stay connected with other people. But, the information and data overload have also increased. A brand new way of communication and new technologies have brought massive amounts of various data and a new problem: How to store it? The answer is big data. It is not regular, structured data and can be explained through three dimensions: volumes, variety, and velocity.

Companies are recognizing the potential value of this data and they are putting great efforts in order to extract some useful and meaningful information from it. The only way to derive value from big data is the use of analytics. It must be analyzed and the results should be used by decision makers and organizational processes in order to generate value. The type of information extracted from social media is constantly in motion. Analyzing social media data can contribute to better understanding people's behavior, their needs and habits. New data sources bring new challenges and new challenging questions.

### 2. BIG DATA

Big data is a very popular buzzword used by IT companies to increase their sales. However, it is more than just a word. It is real and extremely important technology trend with huge business potential. Big data can often be associated with social media. Rather, it is a combination of data-management technologies that have evolved over time. Big data enables organizations to store, manage and manipulate vast amounts of data. Over time, size and type of data that needs to be stored have changed and new ways of storing data appeared. Big data does not represent regular, structured data. It can be explained through three dimensions: volumes, velocity, and variety, so-called three Vs (Xiang, Du, Ma, and Fan, 2017).

Volume is also known as the big part. It represents the amount of data that is being generated in everyday use. As we generate more and more data, this point of big data will keep growing. Some experts consider that the size of memory that is used for storing data is measured in Petabytes.

Velocity represents the speed of generating new data or the frequency of delivering data. It shows how fast that data is processed. Big data improves real-time data analyzing and enables fast access to a large amount of data.

Variety is about the different type of data and file types available in everyday use. For example there are tweets (500 million per day), video files on YouTube (3.25 billion hours of watching video each month), posts on Facebook (510,000 per second), profiles on LinkedIn (over 5 millions) and then there are also all the different log files and other data produced by any computer system we use. So the explanation of big data could be that it is dealing with high-velocity and high-volume data streams while data types are highly diverse.

Big data requires methods and tools that can be used for analyzing and extracting patterns from large-scale data. The large Volume of data poses a challenge to conventional computing environments. It requires scalable storage and a strategy to data querying and analysis (Choi, Chan, and Yue, 2017). The Volume of data is also a major advantage of big data. Dealing with the Variety among different data is a unique challenge for Big Data, which requires preprocessing of unstructured data in order to extract structured information. The importance of dealing with Velocity in big data is the quickness of the feedback, translating data input into usable information (Bello-Orgaz, Jung, and Camacho, 2016).

### **3. SOCIAL MEDIA**

Social media was originally intended for people who want to interact with friends and family but later many companies started using it as a very powerful tool for communication with customers. Now we can define it as a technology based on computers and Internet that is meant for facilitating the sharing of information and ideas. A huge advantage that social media has is the ability to connect with anyone and share information as long as they also use social media. Some of the most popular social media services are Facebook, Twitter, LinkedIn, Instagram, Pinterest, YouTube etc.

Twitter is a real-time service that allows users to post short messages of 140 or fewer characters. Messages posted on Twitter are called tweets. The network infrastructure of “friends” and “followers” on Twitter is asymmetric. User’s friends are the accounts that user is following and user’s followers are the accounts that are following the user. Very important dimension of Twitter is the ability to analyze and track user activity. Retweet function is a form of data sharing. It is a way for Twitter users to participate in discussion without starting it. Twitter offers Apps for various mobile phones and tablets. Interactions or integrations with Twitter are done using the Twitter APIs (Newman, 2017).

Facebook is social networking site. Originally it was designed by Mark Zuckerberg for college students at Harvard University. Today, Facebook is the largest social network with more than 1 billion users all over the world. Facebook allows users to send messages, post pictures, videos, links, share information and like content posted by other users.

LinkedIn is a social network for business people. LinkedIn started in 2003 and had only 2,700 members the first week. Today, it has more than 350 million members. It provides a way to connect with other professionals. LinkedIn is used for exchanging knowledge, ideas, as well as finding a job.

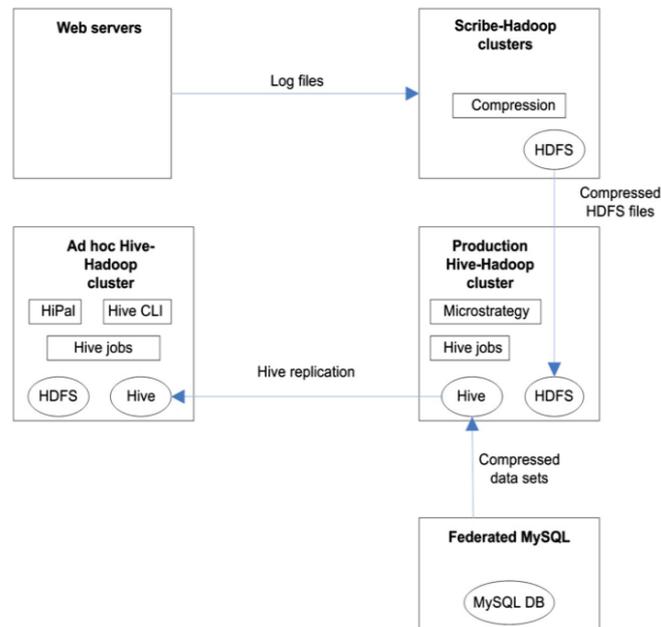

### **4. SOCIAL MEDIA DATA INFRASTRUCTURE**

Next three chapters show data analytics infrastructure at Facebook, LinkedIn, and Twitter.

#### **4.1. DATA INFRASTRUCTURE AT FACEBOOK**

There are two sources that Facebook collects data from. These are federated MySQL tier and web servers tier. Web servers generate event-based log data and the data is collected to Scribe servers which are executed in Hadoop clusters. The Scribe servers aggregate log data, which is written to Hadoop Distributed File System (HDFS) (Kamar Sahu, 2015). Data from HDFS is compressed and transferred to Production Hive-Hadoop clusters for processing. Federated MySQL tier contains user data.

There are two different clusters for data analysis. Tasks that have a higher priority are executed in the Production Hive-Hadoop cluster. Tasks with lower priority and ad hoc analysis tasks are executed in Ad-hoc Hive-Hadoop cluster. Data from Production cluster is replicated to the Ad hoc cluster. Data analysis results are saved in Hive-Hadoop cluster or to MySQL tier. The graphical user interface (HiPal) or Hive command-line interface (Hive CLI) are used for specifying queries for Ad hoc analysis.

**Figure 1.** Data analytics infrastructure at Facebook  
 (Source: Pääkkönen, P., & Pakkala, D. (2015). Reference architecture and classification of technologies, products and services for big data systems)

## 4.2. DATA INFRASTRUCTURE AT LINKEDIN

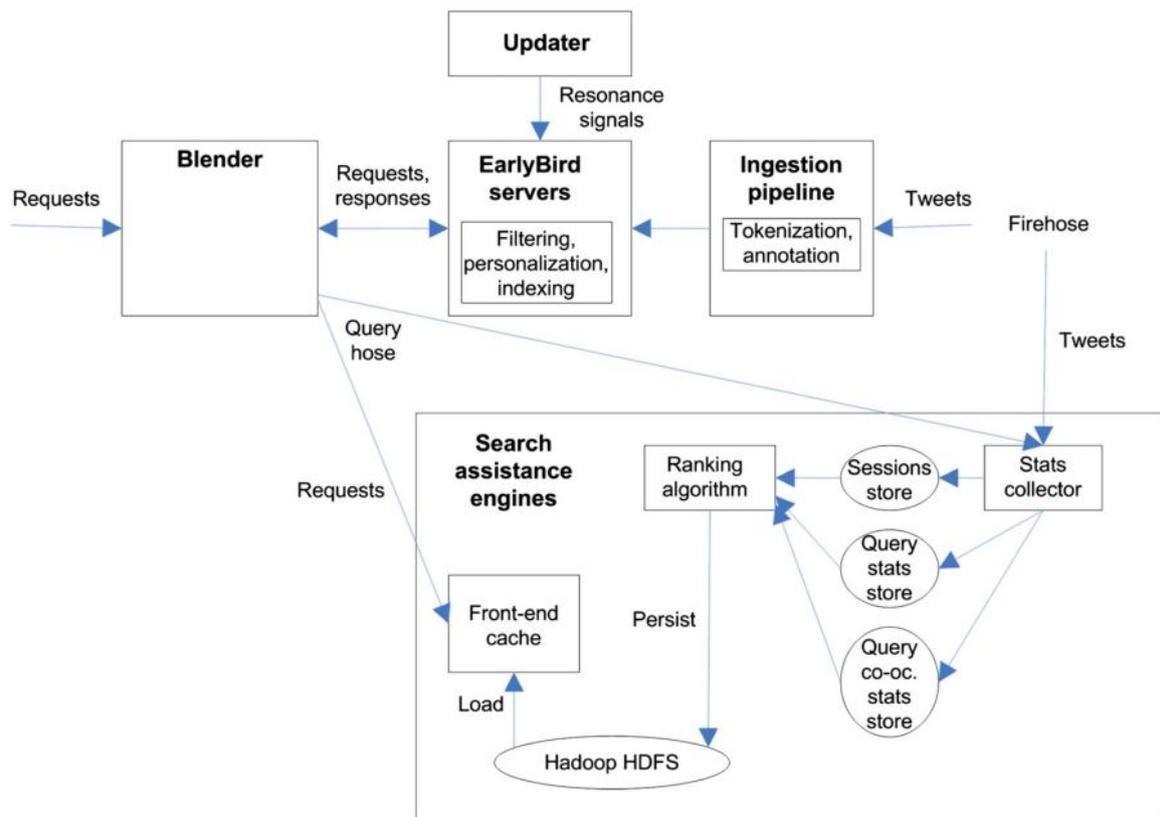

LinkedIn started as a single monolithic application called Leo. As the site began to grow, it was necessary to “Kill Leo” and break it up into many services. As the amount of data that needed to be collected also grew, LinkedIn developed many custom data pipelines for streaming and querying data. The site needed to scale and each pipeline needed to scale. The result was the development of Kafka, distributed messaging platform which is used for collection of streaming events.

Data is collected from two sources: activity data that includes streaming events based on usage of LinkedIn’s services and database snapshots. Kafka producers report events to topics at a Kafka broker, and Kafka consumers read data at their own pace. Kafka’s event data is transferred to Hadoop ETL cluster for further processing. Data from the ETL cluster is copied into production cluster and development cluster.

Azkaban is a workload scheduler for supporting various types of tasks. It is realized as MapReduce, Pig, Hive jobs or shell script. Workloads are tested in the development cluster and transferred to production after testing. Analysis results are moved to an offline debugging database or to an online database. It can also be back to Kafka cluster.

Avatara is used for the preparation of OLAP data. Analysed data is read from the Voldemort database, pre-processed, and aggregated for OLAP, and saved to another Voldemort read-only database (Clemm J. 2015).

**Figure 3.** Data analytics infrastructure on Twitter

(Source: Pääkkönen, P., & Pakkala, D. (2015). Reference architecture and classification of technologies, products and services for big data systems)

## 5. ANALYSING BIG DATA IN SOCIAL MEDIA

Social media store a great amount of data. Underneath the surface of a Facebook profile, Facebook page, Instagram business profile or just tweets on Twitter, there is a huge information potential that is still just mostly unstructured data. Social media analysis is the analysis of structured and unstructured data from its channels.

At the moment, data in social media is available either via simple routines or require analysis in some research programs that use programming languages such as MATLAB, Java or Python. Researchers require:

- **Analytics dashboards** — non-programming interfaces for ‘deep’ access to ‘raw’ data.
- **Holistic data analysis** — tools required for combining multiple social media and other data sets.
- **Data visualization**—researchers also require visualization tools so information can be visualized in some schematic form.

There is a number of tools for big data text analyzing that can be used for analyzing social media data. Attensity’s software is one of them. Attensity is one of the original text analytics companies. It uses a Hadoop framework (MapReduce, HDFS, and HBase) to store data. Another text analytics vendor is Calarbridge. Clarabridge CX Social is its tool specialized for exploring social media data. IBM offers several solutions such as Watson, SPSS, IBM Content Analytics with Enterprise Search (ICAES). IBM BigInsights for Apache Hadoop is an industry standard Hadoop. It is a data management platform. SAS is also solving big data problems. The SAS High Performance Analytics Server is an in-memory solution that allows a user to analyze complete data. It uses Hadoop Distributed File System (HDFS).

There are also custom applications for big data analysis. The purpose of these applications is to increase the speed of decision making or action taking. For example, the “R” environment is based on the “S” statistics and analysis language. It is an integrated suite of software tools and technologies designed to create applications that are used to ease data manipulation and analysis. It supports effective data-handling, operations for arrays and other ordered data types and tools to a wide variety of data analyses.

The Google Prediction API is an example of an emerging class of big data analysis application tools. It functions by looking for patterns and matching proscriptive, prescriptive or the other existing patterns. While

doing this matching, it also learns. The source can be postings from Facebook, Twitter, Amazon, LinkedIn and the goal finding specific patterns of behavior. That can be very useful in business for a consumer products company. Based on the gathered information, the company might launch a new product or upgrade the old one. It is implemented as a RESTful API and supports .NET, Java, PHP, JavaScript, Python, Ruby, and many other programming languages. It also provides scripts for accessing the API as well as a client library for R.

Hadoop is an open source framework which is designed to solve problems associated with distributed data storage, analysis, and retrieval of big data. A distributed file system (HDFS) stores data and replicates it so it is always available. MapReduce is a distributed processing system for parallelizable problems. The idea is to design map functions that are used for generating a set of key/value pairs after which the reduce function will merge all the values associated with the same key. In the first step (Map), a problem is divided into many small problems and sent to servers for processing. In the second step (Reduce) the results of the previous step are combined to create the final results of the problem. Reduce can't begin until all the mapping is done, and it isn't finished until all instances are complete. The output of mapping and reduce are key-value pairs. Hive is a data warehouse system in which the user can specify instructions convert them to MapReduce tasks. Pig is another member of Hadoop family. It has similar functions like Hive, but it uses a programming language called Pig Latin, which is more oriented to data flows. HBase is another component of the Hadoop ecosystem, which implements Google's BigTable data store. Bigtable is a multidimensional sorted map. Elements in the map are an array of bytes. They are indexed by a row key, a column key, and a timestamp. The official Hadoop project is Apache. Hadoop solutions are also offered by companies such as Cloudera and Hortonworks. There is also a company MapR. It offers a commercial implementation of Hadoop (Zadrozny and Kodali, 2013).

## 6. COMPARISON OF SOCIAL MEDIA DATA INFRASTRUCTURE

With large incoming data and the fact that more and more data needs to be properly stored in order to allow data analysis, many social media platforms use Hadoop tools. Hive-Hadoop is an ad hoc cluster. It is a data warehousing framework built on Hadoop. It was created by Facebook and then given to Hadoop as a subproject of Hadoop ecosystem. Hive allows users to query and analyze data using SQL which makes data processing easier. In LinkedIn event data from Kafka cluster is transferred to Hadoop ELT (Extract – Transform - Load). ELT on Hadoop is a data integration process that provides flexibility in data processing environment. Also, Azkaban, a workload scheduler for supporting various types of tasks, is realized as MapReduce, Pig, Hive jobs or shell script. All the three social media networks, Facebook, Twitter and LinkedIn use Hadoop HDFS typically for storing structured data or storing the results of the analysis.

LinkedIn data is collected from two sources: activity data and database snapshots. Facebook also collects data from two sources. From federated MySQL tier it collects structured and stream-based user data. From web servers tier it generates event-based log data. The data is applied for batch-based data analysis. Every time user sends a Facebook message, add a contact on LinkedIn or tweets on Twitter digital data is being generated. These platforms are able to gather real-time data. All these events are captured, streamed and processed in digital form as they occur (Pigni, Piccoli, and Watson, 2016). Twitter uses a new stream processing system called Heron. It provides significant performance improvements and other advantages such as debugging-ability, manageability, and scalability. If something goes wrong, the design of Heron makes it transparent as to which part is failing. Each Heron Instance is executing a single task, so it is easier to debug that instance (Kulkarni, Bhagat, Fu, Kedigehalli, Kellogg, Mittal, and Taneja, 2015).

Relational databases are still applied for storing important user data as MySQL for Facebook and Oracle for LinkedIn. For storing data analysis results NoSQL databases or in-memory stores are used (LinkedIn's Voldemort). Log facilities are used for storing stream-based data. For Facebook it is Scribe, For LinkedIn Kafka. Technologies for data processing can be classified as a batch and stream processing. Real-time jobs require special technologies and algorithms (Twitter's ranking algorithm and the EarlyBird architecture). Batch processing is used for jobs with less strict timing requirements (Facebook's and LinkedIn's MapReduce, Hive and Pig scripts). Jobs for batch processing in LinkedIn are scheduled with Azkaban, in Facebook's with Databee. Processed data can also be presented with commercial Business Intelligence tools. Facebook uses MicroStrategy (Pääkkönen and Pakkala, 2015).

## 7. CONCLUSION

Big data analysis is a very powerful way to get right insights, information, and meaningful data from a huge volume of various data on social media platforms. It is now easier to collect data than it has ever been before. But extracting and utilizing useful information is not easy at all. From the business viewpoint, online reviews, photos, and the reviewer's personal information are very important in order to understand and influence user behavior. Social media isn't just used by marketers to find out about the position of their brand on the market or about customers opinion. It is used by healthcare institutions to discover health threats all around the world. The government is using it to predict terrorist attacks. Business intelligence can benefit from big data analytics. Social media data hides great informational potential. With the right tools and the right techniques, data can be transformed into valuable information. As big data evolves, software vendors are competing to make the best tool for all sorts of analysis. There are numbers of programs designed to meet the needs of data analyzing. It's up to analyzer to choose the one that is most suitable for the given problem.

In this paper, various definitions of big data and social networks have been presented. A primary focus has been on big data analytics tools and social media data infrastructure for three different social media platforms: Facebook, LinkedIn, and Twitter. The paper can be a good starting point for further social media data exploring.

## QUERY PROCESSING ASPECT IN HETEROGENEOUS DBMS

Sofija Prokić\*, Jelena Ljubenović<sup>1</sup>  
Univerzitet u Beogradu, Fakultet organizacionih nauka<sup>1</sup>  
\*Corresponding author, e-mail: sofija.prokic@fon.bg.ac.rs

**Abstract:** This paper presents the method of realization of query processing in two heterogeneous database management systems. There is NoSQL and SQL query processing aspect that are integrated into different ways depending on the architecture. Integrated results are displayed to the user. In HQPS, Resource Description Framework (RDF) is used for data integration from heterogeneous databases. The CloudMdsQL uses a functional SQL-language, capable of querying multiple heterogeneous data stores.

**Keywords:** NoSQL database, relational database, HQPS system, CloudMdsQL system

### 1. INTRODUCTION

Until a few years ago relational databases played a leading role in storing data. They provide great precision, consistency, and availability of data. Relational databases store data using SQL query language (Bergamaschi, Guerra, Interlandi, Trillo-Lado, & Velegrakis, 2016). Characteristic for the SQL database is that they are based on ACID properties (Đurđevac, 2012). The ACID properties are the acronym for:

- Atomicity
- Consistency
- Isolation
- Durability

The ACID model is in the database layer, which means that all operations that are performed must be executed in one transaction and all operations are performed at the database level. However, relational databases are not the best solution for storing a large amount of data or when it is necessary to manipulate data at high speed. Then NoSQL databases appeared. NoSQL do not use the SQL query language, but support it. NoSQL databases are much more flexible than relational because they do not have a strictly defined schema in data storage and consume much fewer resources. Also, the NoSQL databases sacrifice the consistency that is the property of ACID in order to provide better research performance. NoSQL is short for Not Only SQL (Oluwafemi, Sahalu, & Abdullahi, 2016).

These databases support a set of BASE features that are the acronym for:

- Basically Available
- Soft state
- Eventually consistent

The BASE property model is in the application layer and it is good for use in storing data on the web, where it is necessary not to block transactions, while others are still not executed. NoSQL databases work with structured, semi-structured and unstructured data (Nikolaus, 2015). Eric Brewer (Brewer, 2012) has devised CAP theorem in response to the fact that there is a conflict in the availability of data in distributed systems. The CAP theorem shows that in distributed systems cannot be simultaneously available more than two of the following properties: (Nayak, Poriya, & Poojary, 2013)

- Consistency
- Availability
- Partition tolerance

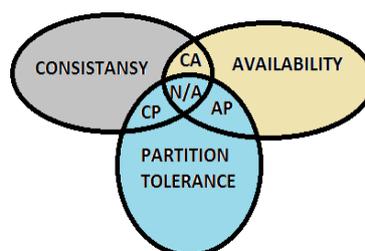

Figure 1: CAP theorem

The second chapter gives a brief overview of the types of NoSQL databases. The third chapter deals with the integration of SQL and NoSQL data; the architecture view shows how the data is transformed from one form to another and through which layers they pass through the transformation. The fourth chapter presents two HQPS and CloudMdsQL architectures that analyze the query and give a plan for its execution. Mapping functions between different data formats are also given. In the fifth chapter, we give our vision for further research on heterogeneous systems, in order to improve and maximize their performance.

## 2. TYPES OF NOSQL DATABASES

### 1. Key/value database

The key/value do not have a strictly defined schema. This model can be presented as a single table in a relational model with two columns, where one column represents a key and the other value. Three operations that can be performed over the database are: PUT, GET and DELETE (Luković, 2015).

### 2. Document oriented databases

The central part of these databases is a document. With such databases, each JSON document represents a separate object.

### 3. Column oriented database

With this database, the data is arranged by columns, unlike RDBMS, where data is stored in rows. Such warehouses do not require a complete schema, but pre-defined column families, which are mutually independent. Apart from the concept of a family of columns, there is a notion of super columns. A super column may contain other columns, but not other super columns.

### 4. Graphic databases

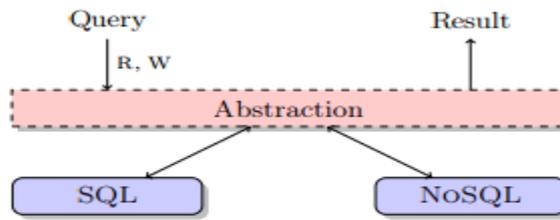

Graphic databases are based on graph theory, using graphic structures with nodes (entities), branches (connecting nodes), and properties (attributes) for displaying and storing data. Each node can have an unlimited number of attributes that describe nodes (Veljković, 2013).

## 3. PROBLEM OF INTEGRATION OF RELATIONAL AND NOSQL DATABASES

Although in recent years there is rapid growth and development, as well as the popularization of NoSQL databases, there are still situations when it is more convenient to use relational databases. For example, when it is necessary to provide ACID properties that reduce anomalies and protect the integrity of the database by defining the way in which transactions communicate with the database. NoSQL databases sacrifice these properties for flexibility and speed of execution. In NoSQL databases, there is also no inner join or transaction (Varughese & Rajeswari, 2009).

NoSQL databases prevent the occurrence of bottlenecks or congestion due to volume. They also reduce storage costs and easily deploy data to multiple servers, allowing simultaneous access to a large number of different users. The big problem is the selection of relational databases that ensure consistency and usefulness in combination with NoSQL databases that provide benefits in terms of scalability and partition tolerance. The problem occurs when one software product needs to provide data storage, where one part is ideally stored in the NoSQL database, while the other data is ideally stored in a relational database (Adeyi, Abdullahi, & Junaidu, 2013). Indian scientist Ali (Ali, 2009) proposed a solution that creates a global scheme instead of multiple local schemes. One access to all components of a heterogeneous database, or heterogeneous system, is formed. Ali believes that in this way there is an integration of several different local systems, and it can be called MDBS (Multidatabase system). To the end user, this system is presented as a single database that they can use, while on the lower layers it consists of several local databases (Haber, et al., 2015).

The problem that occurs when storing data is that one part is stored in the SQL database, while the other is stored in the NoSQL database, so the user needs to extract data from different sources. To avoid writing a different code for each type of database in which the data is located, the Roijackers suggested using a hybrid database. It requires the construction of an abstraction layer at the top of SQL and the NoSQL database. The abstraction layer is responsible for translating data from NoSQL into a triple format and incorporating the resulting format into an SQL database as a virtual relationship. In this way, using one query language, data can be downloaded regardless of the database, because this layer is responsible for collecting relevant data, but also combining received data in one query (Katsov, 2012).

**Figure 2:** An example of the architecture of the hybrid base proposed by Roijdzakers (Roijackers & Fletcher, 2012).

To virtualize data from different databases (MySQL and MongoDB), RDF is used as a data format for relational and NoSQL data. RDF (*Resource Description Framework*) is a language for displaying resource information and metadata on the World Wide Web. The RDF is designed to store and model information as well as to provide interoperability between applications that exchange information that is understandable for machines on the web. Distributed NoSQL data is in the form of a triple format in the RDF (subject, predicate, object), so that they can be embedded in the SQL database (Thant & Naing, 2014). Triple notation represents arbitrary data that facilitate the work of the hybrid base. The problem that arises with NoSQL data is that there is no standard that can be compared with SQL data from a relational database. All SQL databases use the same SQL query language, while in the NoSQL database, there are different NoSQL query languages that can be used (Roijackers & Fletcher, 2012).

The picture shows that the triple format is represented by F (id, key, value), where different data can be described in triple format. The data to be found in the F relation are derived from the outside world, or from the NoSQL database. All nodes that actually represent NoSQL data must have a unique ID value according to a set of key/value pairs. All keys at the same level of nesting, with the same "parent", must be unique. The combination of id and key is unique, so it refers to one value of NoSQL data (Roijackers & Fletcher, 2012).

**Table 1:** Relational representation

ID	Name	Age
1	Ana	18
2	Boba	35

**Table 2:** Representation of triple format

ID	Name	Value
i1	id	1
i2	Name	Ana
i3	Age	18
i4	Id	2
i5	Name	Boba
i6	age	35

**Table 3:** Nested data

ID	Name	Value
i1	name	Boba
i1	grades	i2
i2	0	8
i2	1	6

If NoSQL data is nested within another NoSQL data, a transformation function must be performed so that all nested elements in the triple format can have the same id value. SPARQL is used to represent the NoSQL query. It is the W3C standardized query language for RDF. The most important part of the SPARQL query is the basic graphic representation (Roijackers & Fletcher, 2012). The picture shows the nesting object, the SQL query and the nested NoSQL query within it. The process of translating NoSQL into the corresponding

SQL fragment is shown in the section of the architecture in the following image, which is colored in yellow. The translation should be executed automatically, before executing the query itself, but this transformation still does not represent a final SQL query, it is yet to come (Mijalkovic, 2013).

```

1 SELECT
2   r.name
3 FROM
4   NoSQL(
5     name: ?name,
6     grades: (
7       0: ?f,
8       1: ?s
9     )
10  ) AS r
11 WHERE
12   r.f = 8
  
```

Figure 3: SQL query and nested NoSQL query within it.

Each transformation is unique depending on the type of the NoSQL database, which means that for different NoSQL solutions it is necessary to make new transformations in triple RDF formats. This part of the architecture is shown in the green part of the image. Only after this transformation, the obtained RDF triple format is embedded in the SQL base and is merged with the SQL query set by the user, if the user wrote the SQL query at all. The last blue section represents SQL query that is a result of user's query and NoSQL query which was previously transformed into a triple format. In the end, this new query is sent to the relational database and executed as a normal SQL query. The result is an output made from SQL query as a response to a user's request.

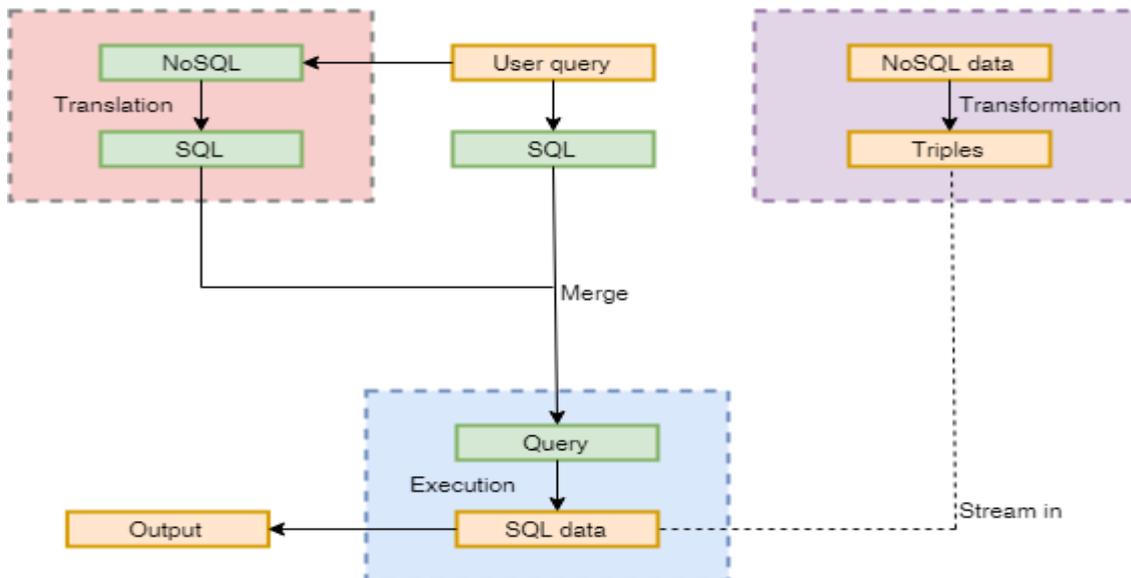

Figure 4: Architecture that illustrates execution and query transformation (Rojackers & Fletcher, 2012).

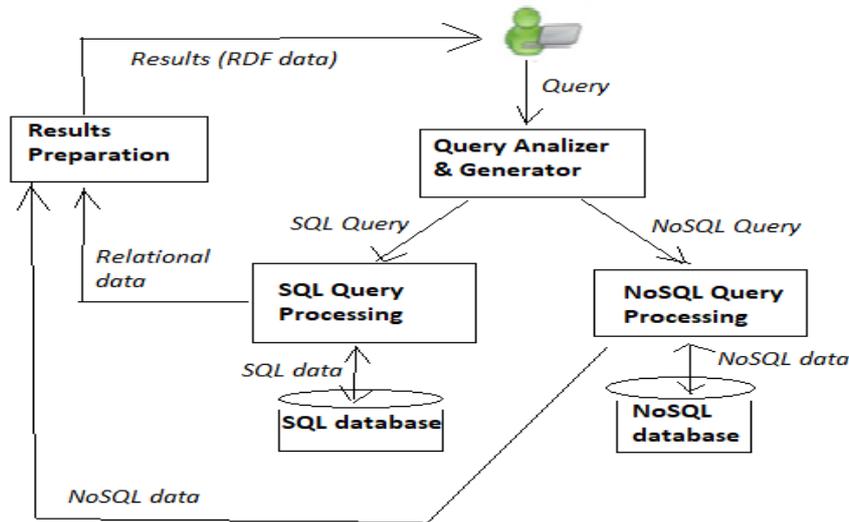

## 4. ARCHITECTURE OF INTEGRATED SOLUTION

### 4.1. Hybrid Query Processing System ( HQPS )

Hybrid Query Processing System–HQPS was created to use and manage data from the SQL database, as well as data from the NoSQL database, or to handle both types of user queries. HQPS consists of two components, which are:

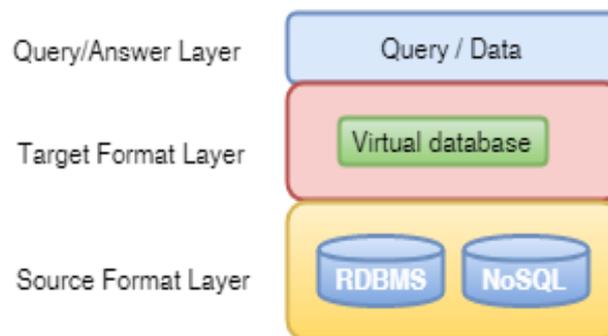

- 1) Query Analyzer & Generator (Control SQL and NoSQL Queries)
- 2) Result Preparation (Preparation of results where results are prepared and presented to users)

In the picture below is given a graphical representation of the HQPS system. The user writes a query in Query Analyzer & Generator, then the same query is sent to the SQL or NoSQL query processing unit, depending on the type of query. In query processing units, queries are executed with the help of the database the query belongs to (SQL or NoSQL), and in the end the result is sent to Result Preparation. In Result Preparation integration of data from heterogeneous databases, SQL or NoSQL is performed. Integration is done using the RDF format, and if the data is from the NoSQL database it is translated into a triple RDF format. Then the data is integrated with the data from the SQL database, and the result of integration is sent to the user as a response to a user's query. (Thant & Naing, 2014).

**Figure 5:** Architecture of the HQPS system

When a query is sent to Result Preparation, it first enters the query layer and then into the virtual database that is in the target layer. From a virtual database, the data is sent to a Relational or NoSQL database depending on the type of query. Sending the response backward goes through the same layers only in the opposite order. In the picture below is given a summary of the Result Preparation architecture.

**Figure 6:** Architecture of Result Preparation (Thant & Naing, 2014).

To integrate data, NoSQL data must be transformed into an RDF triple format, which is easy when the NoSQL data is normalized. However, when the data is nested one within another, a more complex mapping is required. In order to transform the nested key-value structure into a triple format, it is important that all nested elements have the same ID value that will define them and which will be found in triple format.

**4.1.1. Mapping between NoSQL and RDF triple format is given in the following lines:**

*Let*

$\alpha$  = transformation function for a key value pair

$\delta$  = transformation function for set of key value pairs

$i$  = subscript for given equal id values

$$\alpha_i(N) = \begin{cases} \{(i, N_k, N_v)\}, & \text{if } N_v \text{ is not a set} \\ \{(i, N_k, j) \cup \delta_j(N_v), & \text{if } N_v \text{ is a set} \end{cases}$$

$$\delta_i(S) = \bigcup_{n \in S} \alpha_i(N)$$

```

{
  "bookid" : "100100A",
  "subject" : "Distributed Database Systems",
  "title" : "Principles of Distributed Database Systems",
  "autor" : [
    "Tamer Ozsu",
    "Patrick Valduriez"
  ]
}

```

$$\begin{aligned} \delta_i(S) &= \bigcup_{n \in S} \alpha_i(N) \\ &= \{(i1, BookId, 1000100A)\} \cup \{(i1, Subject, Distributed Database Systems)\} \\ &\quad \cup \{(i1, Title, Principles of Distributed Database Systems)\} \\ &\quad \cup \{(i1, Author, i2)\} \\ &\quad \cup \{(i2, 0, M. Tamer Ozsu)\} \cup \{(i2, 1, Patrick Valduriez)\} \end{aligned}$$

**Figure 7:** An example of a transformation function from NoSQL to a RFD triple format with a nesting document Author (Thant & Naing, 2014).

#### 4.1.2. Mapping between Relation Model and RDF Triple Format:

Let

$\beta$  = transformation function for a relational record

$\varphi$  = transformation function for relational records

$i$  = subscript for given equal id values

$$\beta_i(R) = \{(i, A_k, V_j) \mid \forall j, V_j \in N_j\} \quad \delta_i(S) = \bigcup \beta_i(R)$$

**Table 4:** Example of mapping between Relation Model and RDF triple format

Member ID	Name	Password	Email	Major
000001	MonMon	345mon	mon@gmail.com	Computer Science

$$\begin{aligned}
\emptyset_i(S) &= \cup_{r \in s} \beta_i(R) \\
&= \beta_i2(MemberID, 000001) \cup \beta_i1(Name, Mon Mon) \\
&\cup \beta_i1(Password, 345mon) \cup \beta_i1(Email, mon@gmail.com) \\
&\cup \beta_i1(Major, Computer Science) \\
&= \{(i1, MemberID, 000001)\} \cup \{(i1, Name, Mon Mon)\} \\
&\cup \{(i1, Password, 345mon)\} \cup \{(i1, Email, mon@gmail.com)\} \\
&\cup \{(i1, Major, Computer Science)\}
\end{aligned}$$

**Figure 8:** An example of a transformation function from SQL to an RFD triple format. (Source: Hybrid Query Processing System (HQPS) for Heterogeneous Database (Relational and NoSQL))

#### 4.1.3. Mapping algorithm from NoSQL to RDF and from SQL to RDF format

Using the mapping algorithm, you can see what the inputs are and what is the outcome, as well as all the steps that are executed until an RDF format is obtained. The mapping algorithm from NoSQL to RDF receives the query and db properties as inputs, and as the output has an RDF format. In the first step, a database is loaded, then a query is executed as long as the cursor reports that there are still queries or entities for execution and converting to objects. Converting is done in RDF format (key, name, value) and in the end, the RDF format is obtained.

The mapping algorithm from the relational database to the RDF format is similar. The data from the database is loaded, the query executed and a set of results is obtained. As long as there are results or data in the list, the data from the relational base is converted to RDF format (key, name, value) and the result in RDF format is printed. When it is necessary to return to the user the results of a query from two databases, one relational (MySQL) and one non-relational (MongoDB), the system itself integrates data from MySQL and JSON data from MongoDB and then shows integrated data to the user. The implementation of relational data in RDF mapping is done using a free database called Sakila, a product of MySQL Corporation. For mapping operations, the HQPS system needs to provide SQL expression, while the result will be displayed in the RDF format (Thant & Naing, 2014).

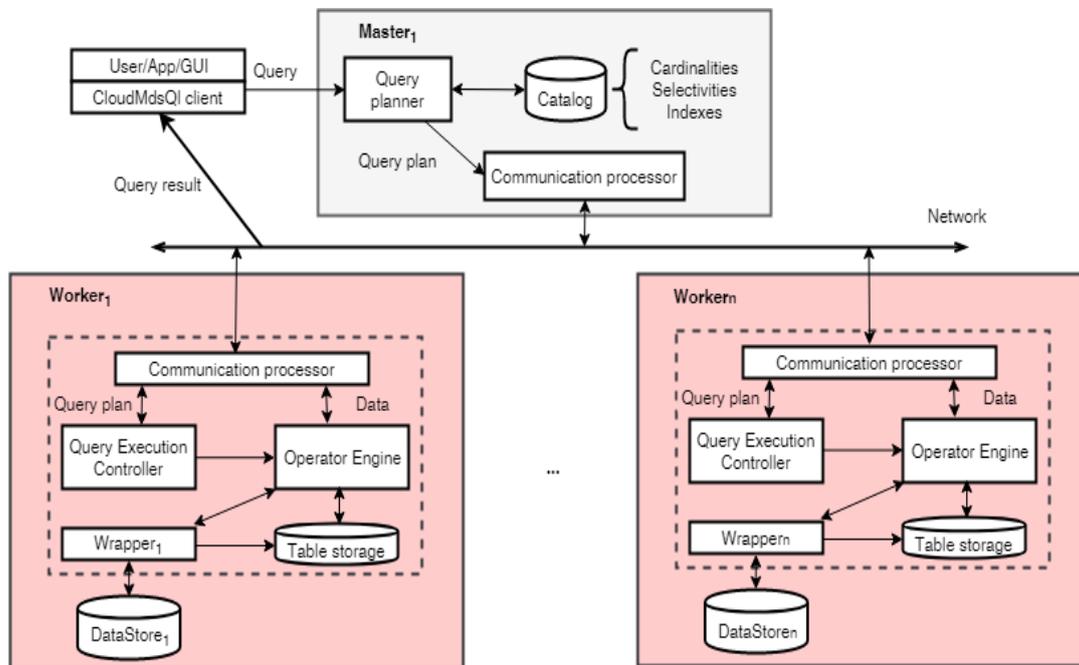

## 4.2. CloudMdsQL System

CloudMdsQL is a specific DBMS that is categorized as web-based data. CloudMdsQL uses different sizes for displaying different data and databases. It uses relational properties for data exchange, such as ACID, transaction independence, SQL query language. It provides scalability, schemaless databases, and good performance. CloudMdsQL has provided a solution to the problem of data storage in three different databases. It is necessary to write a program that will have access to three different databases through their APIs and which will integrate their solutions.

The query engine is part of the platform that allows deployment over one or more data centers. The picture below shows the architecture of a single data center. The architecture of the query engine is fully distributed, so that query engine nodes can directly communicate with each other. The query engine does not follow the traditional mediator/wrapper architectural model where mediator and wrappers are centralized. Each query node consists of two parts of the master and the workers, and they are located on each data hub in a computer cluster. Every master or worker has a communication processor that supports the sending and receiving of data exchange operators and commands between nodes.

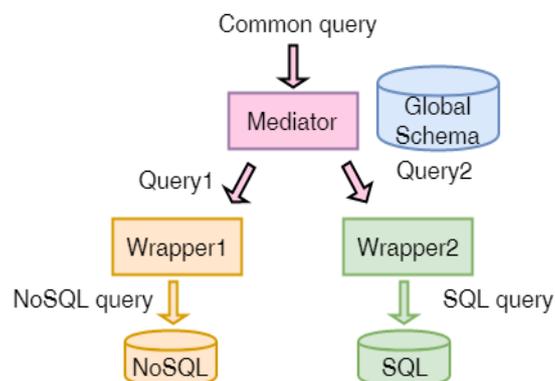

If there are multiple masters, the client chooses one of them to send a query to. A master takes as input a query and produces a query plan, which it sends to one chosen query engine node for execution. The query planner performs query analysis and optimization and produces a query plan serialized in a JSON form. All operations in the plan have the identifier of the query engine node that is in charge of performing it. The operation determines the first worker, which the master should send the query plan to. Query execution controller controls the execution of a query plan by interacting with the operator engine for local execution with one or more workers. The query execution controller will synchronize the execution of the operators that require the intermediate results produced by the distant workers, once they are received back.

Operator engine executes the query plan operators on data retrieved from the wrapper, from another worker, or from the table storage. These operators include CloudMdsQL operators to execute table expressions in the query and communication operators to exchange data with other workers. Table storage provides efficient, uniform storage for result data in the form of tables. Wrapper with its data store interacts through its API to retrieve data, transforms the result in the form of a table, and writes the result in table storage or delivers it to the operator engine.

**Figure 9:** Architecture of the query engine (Kolev, Valduriez, Bondiombouy, Jiménez, Pau, & Pereira, 2016).

The architecture that uses the CloudMdsQL language consists of a mediator and a wrapper and it is given in the picture below (Kolev, Valduriez, Bondiombouy, Jiménez, Pau, & Pereira, 2016). The mediator collects the information found in the global schema. Transforms queries set in common language for the wrapper and integrates query results. The wrapper displays information about source schemes and provides mapping functions that translate data between source schemas and schema mediators. The wrapper transforms queries written in a common language into queries for different DBs. Transforms query results into a common data model. The characteristic of this architecture is that one query that represents output from one database can be input to another database (Kolev, Valduriez, Bondiombouy, Jiménez, Pau, & Pereira, 2016).

**Figure 10:** Mediator/wrapper Architecture (Kolev, Valduriez, Bondiombouy, Jiménez, Pau, & Pereira, 2016).

CloudMdsQL is not built to integrate web data. CloudMdsQL sticks to the relational data model for data representation, integration of data and the benefits of relational algebras operations.

Below are examples of relational, non-relational and common queries:

*1\*\*/ show from document db all reviews made in 2018*

```
reviews_2018 ( pub_id int, reviewer string )@DB2 = {*
  db.reviews.find( {'date': {'$gte': '2018-01-01', '$lte': '2018-12-31'} }, {'pub_id': 1, 'reviewer': 1, '_id': 0} )
  }
```

2\*\*/ show from relational db the publications of scientists from Africa

```
pubs_Africa ( id int, title string, author string )@DB1 = (
  SELECT pubs.id, pubs.title, pubs.author
  FROM pubs JOIN scientists ON (pubs.author = scientists.name)
  WHERE scientists.affiliation = 'AFRICA' )
```

3\*\*/ joining the previous two queries

```
SELECT pubs_Africa.id, pubs_Africa.title, pubs_Africa.author, reviews_2018.reviewer
FROM pubs_Africa JOIN reviews_2018 ON (pubs_Africa.id = reviews_2018.pub_id) ;
```

**Table 5:** Joining the previous two queries

ID	Title	Author	Reviewer
6	Principles...	Mark	Peter
6	Principles...	Mark	Rui

## 5. CONCLUSION

Researching and analyzing HQPS system and CloudMdsQL system reveals some differences between them, as differences in data transformation. In the HQPS system, a user prints a query that is sent to the Query Analyzer&Generator, which checks if the last query is relational or not, and sends it to the corresponding database (SQL or NoSQL). When a query is executed in the database, it is sent in the Result Preparation for the integration of the results from different databases. In the Result Preparation, the transformation of the NoSQL data into the RDF triple format is executed and that result is shown to the user.

In CloudMdsQL architectures that are fully distributed, nodes can communicate with each other, which enables optimization, or minimization of data transfer between nodes. CloudMdsQL sticks to the relational data model, because of its intuitive data representation and integration datasets by applying joins, unions and other relational algebra operations (Kolev, Valduries, Bondiombouy, Jiménez, Pau, & Pereira, 2016). In CloudMdsQL System nesting is allowed in both SQL and native expressions. CloudMdsQL allows for optimizing the query execution by rewriting queries according to bind joins and, planning optimal join execution orders, and the delivery of intermediate data is optimal. CloudMdsQL query can exploit the full power of local data stores.

Architecture based on CloudMdsQL has little advantage over HQPS architecture if the criteria of comparison are the speed of transforming data. The conclusion is based on the CloudMdsQL architecture which allows nodes to communicate with each other which makes transforming data faster. We examine factors that influence query result performance, including databases with different sizes and different table sizes. The results show size affects the time of executing queries. In the future, other criteria for comparing different databases should be considered, in order to better identify the benefits of both with the optimization of query execution.

# RESTRUCTURING THE COMPANIES BY IMPLEMENTING PROCESS OF DIGITALIZATION

Dušan Mežnar\*<sup>1</sup>

<sup>1</sup>JOP d.o.o., Slovenia

\*Corresponding author, e-mail: dusan.meznar@gmail.com

**Abstract:** *Digital era is not just a great opportunity for the companies, but also brings some threats by its implementation. One of the greatest challenges of digital transformation is the internal transformation of the company. The problems that are usually facing the companies are redundant business and technological processes, bad responsiveness, inadequate managerial skills and rigid human resources management. The basic purpose of this article is to present the model of digitalization process of the company, which can be used for transforming the company structure to increase productivity and flexibility. The model is primarily based on process optimization which consists of the implementation of lean management, human resources management, employee competence management and the implementation of new more flexible organizational forms.*

**Keywords:** *digitalization, restructuring, lean management, process optimization*

## 1. INTRODUCTION

Business problems and presence of crisis are often a good opportunity for a complete business restructuring and successful growth of a company (Mežnar, 2015). The major problem that companies now face is how to sustain their competitive advantage. Becoming digital may be a complex undertaking due to the magnitude and the complex nature of the systems. Digital transformation should be designed to establish a profitable and sustainable position against the forces that determine industry competition.

Digital transformation brings new business opportunities enabled by technology and technological innovation, which triggers and stimulates business innovation, innovation in business processes, business models. The biggest opportunities for digital transformation are in particular internal company transformations.

To be a digital master, companies must excel in two dimensions: digital capability and leadership capability. Becoming digital depends on the ability of leaders to get everyone on board and moving in the same direction. "The what" needed to succeed at becoming digital requires significant investment in three key strategic priorities: customer experience, operational processes, and business model innovation (Westerman G., Bonnet D., McAfee, 2014).

Most of the economy is still represented by traditional industry sectors that can use digital transformation for faster work, lower costs, innovation, better customer relations. The described approach and model in this article is one of the options how to become digital.

## 2. DIGITALIZATION AND RESTRUCTURING OF BUSINESS PROCESSES

The technological and information revolution undoubtedly brings an enormous number of new opportunities and potential. Digitalization is also changing the economic sector because it enables companies to operate more easily on a global scale, while others pose a path to ruin. The introduction of digitalization certainly does not eliminate jobs, but it creates new jobs. Production is increasingly moving back to rich countries, not because salaries in less developed regions of the world are growing, but due to the fact that companies want to be closer to their customers to be able to respond faster to changes in demand.

The inevitable fact is that certain industries experience a drastic decline in revenues, while the flow of money is slightly redirected and opens up space for new business models. The companies should not be worried about this fact, but they should see new opportunities. Opportunities for restructuring and adjusting business processes.

The main purpose of business processes digitalization is integration and cooperation with partners, optimization, lowering the costs of processes, increasing the competitiveness of products and services, faster responsiveness and easier access to the customers and integration with business partners. This makes companies more efficient, they achieve better business results and higher profits. Easier access to information also affects the final customer who, when flooding advertisements of various products and services, very difficult separate grain from weeds. At the same time, the availability of information and a wide range of offers represent a new challenge for companies that they should be even more innovative and responsive if they want to keep customers. Business partners, either buyers or suppliers, do not just expect, but also require fast and impeccable service. The consequence is, that companies will have to adapt, be in step with time, should constantly analyze the market and adapt to it effectively. Digitalization means a very effective response to all of these requirements.

### **3. THREATS OF DIGITALIZATION**

With digitalization, however, certain dangers occur. The greatest danger is the protection of sensitive information, espionage, and manipulation of them. Particular attention must, therefore, have to be put on security and potential hazards. It could happen that the benefits of redesigning business processes through digitalization can quickly outgrow and leave a devastation that can seriously jeopardize the existence and development of a company or organization.

Consumers will quickly adapt to the changes. A major problem will be the establishment of an appropriate infrastructure, which is a prerequisite for digitalization. For this, the state is responsible, which will also have to provide better schools for skilled labor, clear rules and a level playing field for companies of all kinds.

If there is no digitalization, you are simply not on the market. Trends are as they are. The companies simply need to adapt to the situation, otherwise, they will simply disappear from the market after a while. The problem that arises here is the dependence on communication tools, the dependence on the monopoly positions of the developers of the digitalization equipment, and the possibility of their interference within the structure of the company. In the process of digitalization, we can not avoid the surprising growth of the data quantity, computational power, and connectivity. New forms of human-machine interaction appear, such as touch interfaces; improvements in the transmission of digital content to the physical world, which, in certain circumstances, can also represent unimaginable disruptions.

Like all revolutions, this will be disruptive as well (Whitehurst, 2014). Many people feel fear of the factories of the future. There will be any more classic machines, production facilities. Most of the jobs will not be in factories, but in offices where designers, engineers, IT professionals, logistics experts and other experts will work. Digitalization means that the culture and climate of a company have to change.

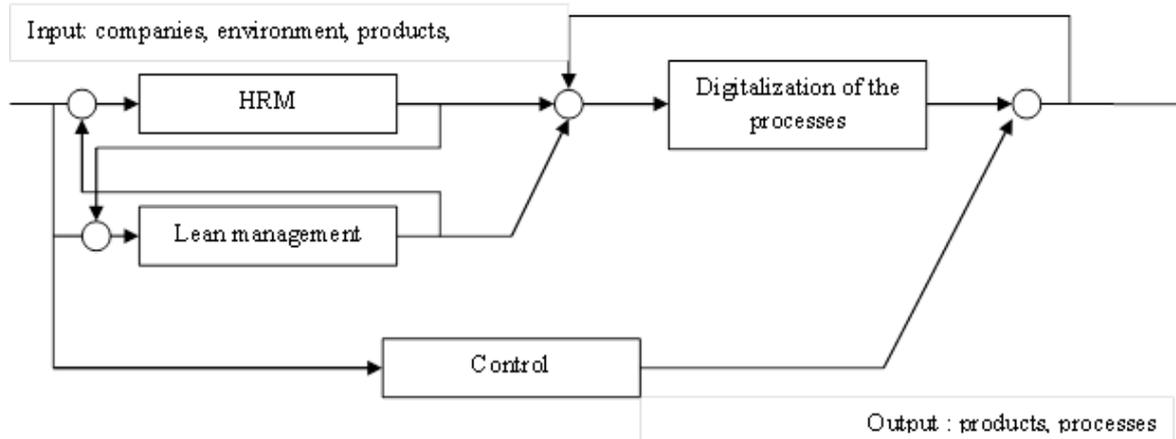

The fact that we encounter in the process of digitizing the company is the management of different generations, at least three in the organization;

- (1945-1960) baby boom generation,
- (1960-1978) generation X,
- (1978-1995) generation Y,
- (1995- ) generation Z

### **4. DIGITALIZATION OF THE COMPANY AS A RESTRUCTURING TOOL**

The digital age in the industry is best represented by the massive use of the Internet in the industrial and at the same time in the entire social environment. The industrial internet provides a digital information link between automated machines, development, sales, purchasing, financial, marketing departments in companies, the situation on the market, financial institutions, etc. Digitalization is a process that forces the management teams to rethink some basic structures. Progress in technology causes that companies need to restructure their organizational structure, transform their departments, and develop new management models. Most of these changes start as a result of the implementation of new basic software, which, however, must be followed by preparations for organizational renovation. The model is based on and takes into account the essential factors to achieve a better return on assets, namely:

- employees
- business processes
- optimization of processes and processes (customer expectations, product improvement, ...)
- database management.

**Figure 1:** Digitization model as a restructuring tool

The model of restructuring is based on lean management (lean management) and human resource management (human resources management). Parallel to this, it is necessary to develop existing ones and to implement new innovative business models:

- to know exactly the processes and to introduce them into all the processes of the lean concept;
- exploit new technologies for after-sales activities and the launch of new services;
- introduce the concepts of autonomy in production and use;
- robotise and automate machines;
- adjust production lines to maximize flexibility and enable the production of small and large batches of different products with similar operations.

An essential guideline is: digitalization needs to be implemented comprehensively.

The most common mistakes that need to be avoided by the successful digitalization of business processes are:

- bottom-up digitalization,
- the management of the project is entrusted to someone who restructuring by digitalization do not understand,
- allow the existing culture of the organization and the attitude of the management to prevent a quality and profound implementation of the digitalization process,
- too narrow definition of the scope of restructuring,
- very quick finishing of the project, digitalization is a continuous and continuous process,
- neglecting the values and beliefs of people in the company,
- design strategies while project implementation is a problem,
- try to restructure so that no one is affected.

The basic restructuring guide is to create new digitally supported systems without the parallel use of the old non-digitalized system.

The process of redesign means finding highly effective solutions to reducing ballast in business and improving production cycles and the capacity of the process has forced manufacturers to adopt the principles of lean manufacturing. By increasing the number of business solutions, companies can automate tasks related to effective production management, while managing the quality process and gaining a better overview of capabilities, design, and demand. The principle of lean management has become the guiding principle throughout the entire production network (Mežnar, 2017).

The company's focus on cost reduction is reflected in the following main points:

- Reduction of the necessary resources for the existing business volume,
- increasing the volume of business for the existing volume of necessary resources,
- the speed of internal and external response in the purchasing and sales markets,
- connectivity with the business environment.

## 5. MANAGEMENT AND HRM IN THE PROCESS OF DIGITALIZATION

Leadership and managing have an important role to play in achieving company goals, working with customers and meeting their demands. Depending on the requirements of the market, the management styles and adaptation of production processes are changing.

Digitalization, using new concepts, models, and technologies, enables faster and more efficient work, and on the other hand, helps managers to better and more intelligent leadership.

One of the essential conditions for a successful digitalization of the company is that managers understand the strategic opportunities and dangers of the digital age. Digital leadership starts at the top (Whitehurst, 2014). The problem that most often occurs is that they are weak in digital leadership, that is, in the construction and enthusiasm of employees in the implementation of the business vision in the digital age. The vision of digitizing the company must become a daily reality in achieving the goals of each employee. Vision and engagement are just part of the story of leadership capabilities. An energized workforce, believing strongly in a shared vision, may still proceed in many directions. Governance provides the guardrails and steering wheel to keep the transformation on the right track. (Westerman G., Bonnet D., McAfee, 2014):

Management is no different than it was a few years ago. IT is not everyone's job. Functional leaders do not need to become IT, experts. Rather, they need to know how to use the technology and what it can do for the company (Whitehurst, 2014). The only change is that leadership in the digital age is taking on topical changes, such as globalization, connectivity, innovative technologies, mobility, autonomy, and personalization. A dynamic combination of thoughts, behaviors, and skills required for change or improvement through technology is required.

Digitalization, deployment of digital technologies and increasing demand for digitalization force organizations to re-evaluate and study a number of established strategies, business models. Instead of employing the most formally educated person for a specific task, many companies now put more emphasis on cultural skills and flexibility, as they know that individual functions will need to be developed along with the implementation of digitalization. On one hand, there is a need to count on existing staff, and on the other hand, companies must prepare for digital transformation. Demand will decrease for workers who perform simple, repetitive tasks because these activities can be standardized and performed by machines. Most of the job losses will result from the introduction of robotics on the shop floor and the computerization of routine jobs (Lorenz, M., Rusmann, M., Rainer, S., Lasse L., Knudd., Bolle, 2015) One of the main tasks is that at the same time thinking about how to set up their digital organization, they start hunting for the best digital talents.

The coming digital age also brings a lot of labor shortages. The new business models brought by digitalization are based on the fact that employees will have to develop in particular efficiency and productivity. As a result, employees will need to be properly guided and motivated, which means that all organizations need professionally qualified leaders who will be able to achieve the goals of the organization and can connect different generations. The main potential uncertainty that we encounter in the process of digitizing the company is the management of at least three different generations in the organization.

## 6. CHANGE IN ORGANIZATIONAL STRUCTURES

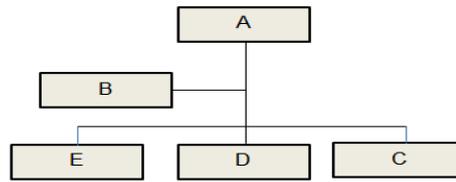

Due to the specifics of digitalization, a hierarchical organization in a global and rapidly changing digital economy is no longer optimal. Successful companies succeed in the cultural shift from "Mad Men" to "Math Men", where decision-making is based more on data rather than on - the wrong ones - management's opinions (<https://www.i-scoop.eu/digitalization-digital-transformation-disruption>, 2017).

In the digitalization of the company, a transition from a classical hierarchical business-functional organizational structure (Figure 2) to a network organizational structure and a decentralized performance of business functions is necessary (Figure 3) or in a virtual organizational structure (Figure 4) depends on the nature of the industry in which the company operates, its size and intensity of presence in the global market.

### 6.1. The hierarchical structure

The characteristics of the business-functional organizational structure are the division of the second hierarchical level based on business functions and the centralization of decisions with the help of line type management. The business-functional organizational structure is suitable for small and medium-sized enterprises that have one product or program of similar products, predominantly routine technology and

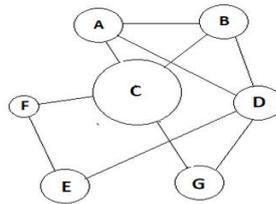

operate in a stable and not too complex environment. This type of organizational structure is totally unsuitable for the digitized company because it is insufficiently flexible and because of the high level of employee specialization it is difficult to adapt to changes, communication is slow, decisions are taken extremely slowly.

**Figure 2:** Hierarchical business functionality of business functions

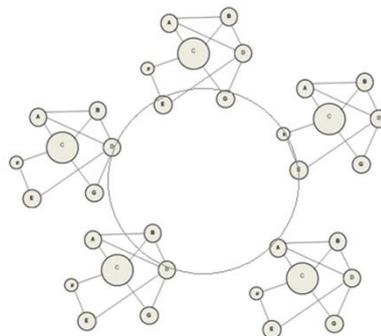

**6.2. Network decentralized organizational structure**

Network organizational structure and decentralized performance of business functions is a much more appropriate organizational form for a company that is digitized and in some ways illustrates the principle of outsourcing. Management in the company chooses to carry out only that part of the activity, which represents the key advantages, but everything else is put into the implementation of external experts. The advantage of this type of organizational structure is high flexibility, the use of human resources, greater efficiency, lower costs, allowing the restructuring of fixed costs into variable and increased product quality. The main disadvantage is dependence on other network partners

**Figure 3:** Decentralized management of business functions

**6.3. VIRTUAL organizational STRUCTURE OF BUSINESS FUNCTIONS**

**Figure 4:** Virtual organizational structure and flexible decentralization of business functions

Looking at the possibilities offered by digitalization, the virtual organizational structure that represents the form of a constantly evolving network of independent organizations is the most suitable for the company, with the purpose of sharing the capabilities, costs, and access to common markets. Every company that

connects with other companies to a virtual network organization must determine its key capabilities and connections with the key capabilities of other companies. It is a form of connecting specific joint knowledge of different companies to a common task. The creation of virtual organizational structures enables modern information technology, communication is carried out through a computer network, including suppliers and customers, which enables the provision of deliveries at the right time and the participation of customers in the development of the desired product. The advantages of a virtual organizational structure are flexibility and dynamism, risk diversification, specialization by key competencies of individual members, lower operating costs and quality service. Weaknesses are too much specialization, which can lead to rigidity, the possibility of abusing business secrets and excessive centralization around the affiliate.

## 7. CONCLUSION

The main purpose of this paper is to demonstrate that the digitalization process can be very usefully used as a tool for the renewal and restructuring of enterprises. In the context of crisis management, it can be very useful for the organizational renovation of the company. The organization's crisis and business problems often turn out to be opportunities for comprehensive business refurbishment and successful organization growth.

The presented model of digitalization of the company does not provide an absolute algorithm for increasing the competitiveness of companies and their survival, but it is certainly a fairly good response to the emerging situation and provides a good basis for organizational renovation, the existence and further development of companies that are facing the impact of globalization and increasing pressure on the competitiveness and flexibility of the company.

## POSTAL OPERATORS IN A DIGITAL WORLD

Bojan Jovanović<sup>\*1</sup>, Momčilo Kujačić<sup>1</sup>, Nikola Trubint<sup>1</sup>  
<sup>1</sup>Faculty of Technical Sciences, University of Novi Sad, Serbia  
<sup>\*</sup>Corresponding author, e-mail: bojanjov@uns.ac.rs

**Abstract.** *The development of digital technologies brings forth the rise of digital communications, which causes continual decline of mail volumes. This creates numerous changes in the use of postal traffic as a means of communication, package delivery, as well as pricing. In the time of digitalization, postal operators face a lot of challenges, which opens new possibilities for digital transformation of the postal sector, that is, creating postal services suitable for future generations of users. Of course, there is no unique solution for all postal operators, but they have to adjust their solutions to this problem according to their business environment.*

**Keywords:** postal operators, digitalization, e-commerce, customers

### 1. INTRODUCTION

Postal services are the cornerstone for numerous economic activities. Their development is influenced by the development of technology and customers' behavior. The evolution of customers' behavior, characterized by customers' growing expectations, is an outcome of all-around digitalization, as well as market changes that have appeared with the processes of liberalization and privatization in the postal sector. The field of postal sector has extended over the areas of once marginal activities of national postal operators, such as logistics and finances (UPU, 2014). Basic segments of the postal sector today are: letters, packages and logistics, financial and other services. In all these segments postal operators have intensive competition. Nevertheless, comparative advantage of national postal operators lies in the fact that in most countries they are viewed as highly trustworthy, which allows them to perform a wide range of services necessary in the age of e-commerce (from placing orders to shipping to payment).

Basic customers' requirements are: choosing a place and time of delivery, with the possibility of changing both parameters during shipping, monitoring package status using different applications, and returning a package in the most convenient way.

### 2. MARKET CONDITION

In the last few years there have been major changes in the postal sector. The development of new technologies has brought about significant progress in the domain of e-commerce (prerequisites for its easier utilization have been created). The growth of e-commerce has led to a greater number of parcels handled by postal operators. A continual decline of letter volumes, caused by new technologies development, is compensated by a stable increase of parcels (Figure 1). This situation on the postal market calls for adjustment of postal operators' infrastructure, different employees' skills, as well as different forms of employment.

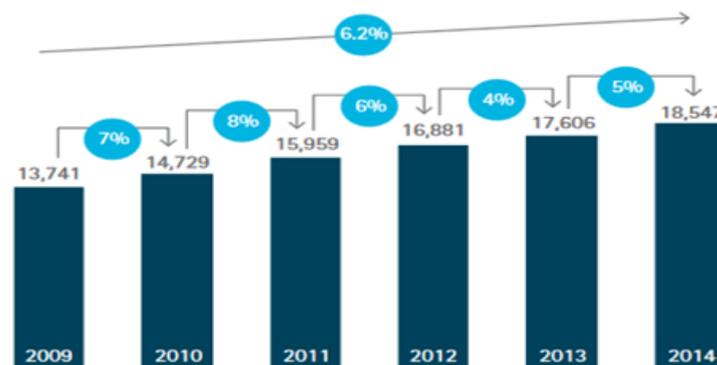

Figure 1: Growth of parcel market (Accenture Consulting, 2016)

Entities on the parcel market are cost-driven, with flexible models of employment, especially in the delivery phase. On the other hand, customers are demanding flexible, innovative and adjusted delivery, as well as parcel returning options. In order to meet customers' needs and survive on the highly competitive market, postal operators have to make adjustments (which, apart from meeting customers' needs, means providing adequate working conditions).

### 3. DIGITALIZATION

The interaction between customers and economy has been drastically changed with the development of digital technologies and mobile access (especially notable in buying goods and services). This resulted in a rapid increase of online shopping. Globally, online retail commerce has been growing 20% per year since 2005, coming to €901,6 billion in 2015 (IPC, 2016). Digitalization has a crucial influence on every domain of the postal sector, from changes in customers' needs and behaviour to last mile changes. With the rise of digital technologies, the number of letters is dropping (Crew and Brennan, 2014).

Postal operators have been transformed through optimization, diversification and redistribution of employees' duties. Modifying the main business activity was done in order to lessen the decline of letter volumes. Some postal operators managed to come up with solutions to increase the number of letters items using digital platforms (Asher, Callan and Marsh, 2012). Still being trusted, postal operators can improve various digital applications which successfully deal with safety issues.

Factors that shape the postal sector are (IPC, 2017): economic conditions, urbanization and digitalization. Due to enhanced migration from rural to urban areas, urbanization will be facing new challenges (infrastructure, environment and social matters). With regard to digital connections, it is expected that by 2021 more than half of the world will be using the Internet (IPC, 2017). By 2012, m-commerce is expected to account for more than 50% of total online commerce. (Figure 2).

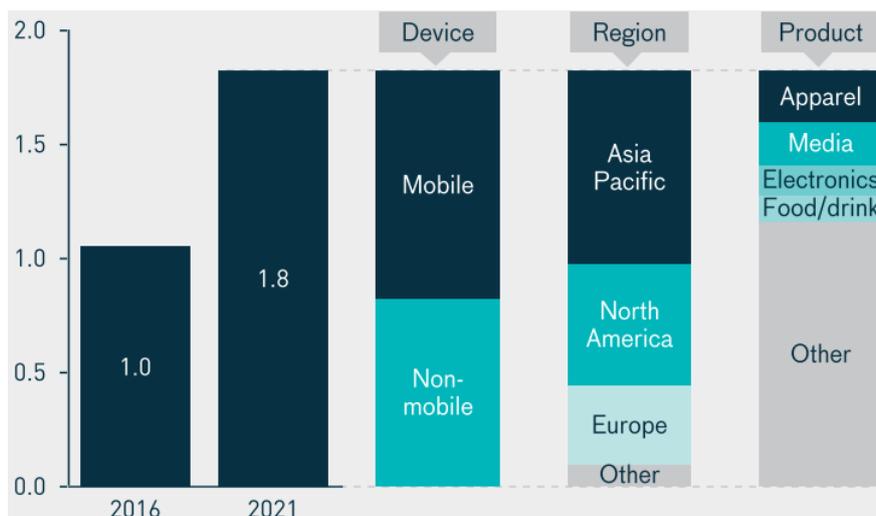

Figure 2: E-commerce growth in billions of euros (IPC, 2017)

In its evolution, parcel market is facing various challenges (demands for greater productivity, automatization, etc.). In some cases, diversification and innovation processes brought forth advanced solutions in the field of digital services, such as a digital signature. Creation of digital business models and platforms provides the base for establishing a closer relationship with customers. The importance of implementing digital platforms is not easily measured, since customers consider digital improvements as an integral part of entry level postal services (from advanced options for e-commerce to digital identity for products).

### 4. FUTURE DEVELOPMENT

The significant growth of e-commerce is an outcome of increased internet access (Lawrence and Tar, 2010). As a result of a greater number of goods bought online, parcel marketing started expanding. Further expansion of the market can be expected due to a wider choice of goods and lower prices comparing to traditional commerce. Due to ever more intense competition in e-commerce, vendors are challenged to find more efficient business solutions. Technologies used for collecting data can be of great importance (analysis of collected data is used for optimizing supply chains, optimizing the number of employees, etc.). In order to

reach its full potential, it is necessary to build an adequate network infrastructure, as well as sophisticated analytical tools.

For improving the existing and introducing new postal services, postal operators are relying on new technologies (as a result of customers' demand for a faster and more convenient parcel delivery). Technologies which have already been used in the postal sector are: sensors, RFID chips, personal digital assistants, GPS technologies. Some of the technologies, like 3D printing, big data, Internet of Things are yet expected to have a significant role in the postal sector. A review of sensor technologies is given in Table 1.

**Table 1: Sensor technologies (OIG, 2015)**

Technology	Key Features
<b>RFID</b>	<ul style="list-style-type: none"> <li>▪ A sensor technology that uses electromagnetic fields to transfer data</li> <li>▪ Allows unique identification of moving objects</li> <li>▪ RFID tags can be either passive or active</li> <li>▪ Is a widely accepted standard, used in a variety of industries</li> <li>▪ Has read distances of 1-60 feet (for passive tags) or up to 1600 feet (for active tags)</li> <li>▪ Fairly inexpensive, although active RFID tags cost more than passive ones (\$20-80 vs. ten cents per tag, respectively)</li> </ul>
<b>Beacons</b>	<ul style="list-style-type: none"> <li>▪ A low-powered sensor that communicates with mobile devices, notifying a mobile app</li> <li>▪ when it is within a specified radius</li> <li>▪ Beacons tend to be larger than other technologies: current size and weight are similar to a computer mouse, but future beacons could be much smaller</li> <li>▪ Beacons can transmit signals as far as 200 feet away, but signal strength is reduced</li> <li>▪ when traveling through objects (such as walls)</li> <li>▪ Beacons range in cost from \$10-150, depending on the size and strength, but beacons</li> <li>▪ are currently dropping in cost</li> </ul>
<b>Wi-Fi</b>	<ul style="list-style-type: none"> <li>▪ A standard for wireless connectivity through radio bands</li> <li>▪ Wi-Fi is perhaps the most pervasive type of connectivity, in use in many people's homes</li> <li>▪ Read distance is about 60 feet</li> </ul>
<b>Bluetooth</b>	<ul style="list-style-type: none"> <li>▪ A wireless connective technology for exchanging information over short distances</li> <li>▪ Read distance is about 150 feet</li> <li>▪ Can connect and synchronize multiple devices</li> <li>▪ Lower-power consumption</li> </ul>
<b>ZigBee</b>	<ul style="list-style-type: none"> <li>▪ A high-level communication protocol that uses low-power digital radios</li> <li>▪ Communications through ZigBee are able to pass through intermediary devices, but must</li> <li>▪ be within the mesh network to be read</li> <li>▪ Connectivity ranges up to about 300 feet</li> <li>▪ Offers low power consumption because the device is not "on" all the time</li> <li>▪ A ZigBee chip costs about \$30-70 per tag</li> </ul>
<b>Near Field Communication (NFC)</b>	<ul style="list-style-type: none"> <li>▪ NFC allows data to be communicated by touching together two NFC-enabled data collection devices, or bringing them into close proximity</li> <li>▪ As such, read distances are only a couple of inches</li> <li>▪ Utilizes electromagnetic radio fields</li> <li>▪ Similar to RFID, NFC tags can be active or passive</li> </ul>

The development of technology brings forth some changes regarding parcel transfer, in the way that services are adapting to customers' needs and behaviour. Smart phones and accompanying applications offer the customers a possibility of personalizing delivery time and place. This way, the parcel delivery is improved and there is a lower risk of an unsuccessful delivery attempt in the case that the receiver is not at the address of delivery.

One of the key logistic elements is ensuring data visibility. This concept can be fully realized by innovatively using the available data. Although the option of parcel tracking is set as a standard, the parcel status is updated at a certain period of time. Using sensors that have the Internet connection, with an adequate

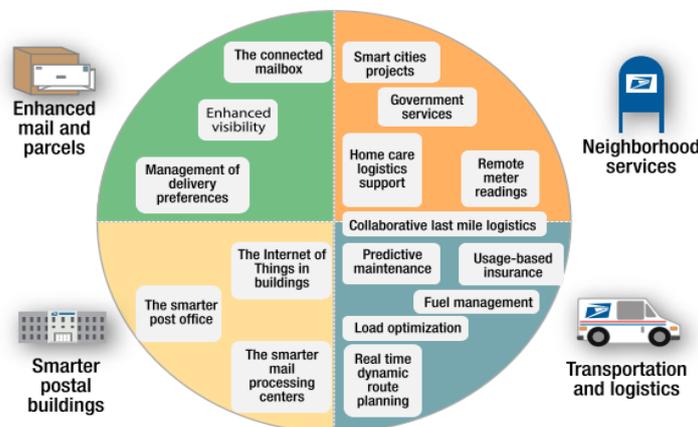

technology (such as GPS), it is possible to provide a continual data transfer (thus, the receiver can track the parcel in real time, which offers him new possibilities, such as subsequent change of the delivery address). This degree of data availability enables the optimization of each stage of parcel delivery (collecting, sorting, transport and delivery).

Possible strategic solutions as a reaction to digitalization are (Jaag and Finger, 2017):

1. post as a provider of physical infrastructure: can sell the access to its network to various forms of service providers; as such, a postal operator usually holds a strong market position; in this way, a postal operator is restricted to defending its main business;
2. post as a hybrid mediator: in this way, a postal operator manages the discontinuity between the physical and digital domain; the access to digital services can be allowed through physical infrastructure;
3. post as a purely digital services provider: a postal operator redirects its activities into the digital domain, providing services such as e-government or e-health; this approach can be developed due to gained reputation for its physical infrastructure and physical presence; this leads to gradual transition from physical to digital networks.

Customers' expectations are on a constant increase. Whether it be physical or legal entities, they expect to get the goods as soon as possible, and a flexible delivery with low or no costs at all. There is a trend of product personalization (to meet the needs of an individual), which is very appealing for customers, but causes multiple logistic problems. On the other hand, there is a constant pressure in the postal sector to provide the best possible service at the lowest possible price. Introducing innovations is often a real challenge in big organizations. This is especially emphasized in organizations such as national postal operators, which have historically been associated with the government. However, a lot of postal operators manage to successfully steer their companies so that some of them even set standards for innovations and meeting the needs of customers.

One of the technologies that can be significant for the improvement of the postal sector is the Internet of Things. The Internet of Postal Things (Figure 3) adjusts a postal infrastructure with low cost sensors, enabling a wide range of data, and thus offering support for improving operative efficiency, customer experience, evolution of new services and business models (OIG, 2015). Various interconnections and data collection is enabled by postal infrastructure. Based on the analysis of collected data, postal operators can reduce costs, optimize processes and meet growing customers' demands (improving the main business, generating new revenue and developing new business models).

**Figure 3:** Areas of application of the Internet of Things (OIG, 2015)

The evolution of e-commerce has led to significant changes in customers' behaviour and demands (Morganti et al., 2014). On the other hand, work environment has also changed, requiring employees to adapt to new circumstances. In this situation, postal operators try to get a synergistic effect from network reintegration, with a special attention on quality and improving automatic sorting. Circumstances on the parcel market bring new challenges before postal operators. This is manifested in the organization trying to move from static towards dynamic organization models. Parcel services are characterized by distinct variations regarding the volume, and as such open up a question of hiring two part-time employees in order to manage peaks.

National postal operators, as members of the UPU (Universal Postal Union), form a global postal network which allows them to take part in international postal traffic and have a certain competitive advantage in the postal sector. Furthermore, since national postal operators are often state institutions or companies, they are somewhat privileged in exploitation of domestic markets (specific regulation, financial support, a different

tax system, etc.). Considering that they have control over resources and processes on the domestic market, they get more freedom to come up with solutions for e-commerce that meet the needs of local economy. Key features of e-commerce which are necessary for better understanding and recognizing opportunities for postal operators are (UPU, 2016):

- web hosting: elements associated with stores on web sites, including technical tools and support, content management, search and price comparison engines;
- payments: money flow model and payment options;
- logistics: main business activity of postal operators, which includes basic services and tools related to postage, delivery and information;
- CRM: elements of the customer relationship (vendors and buyers);
- Promotion channels: for increased visibility of vendors and sales, including direct marketing, web advertising, traditional media;
- Data exchange: standards and tools for exchange data about products, customs and taxes, customers, orders and other data shared by parties in e-commerce;
- Elements of support: safe identification and message exchange, market evolution and secure framework.

## 5. EXPERIENCES

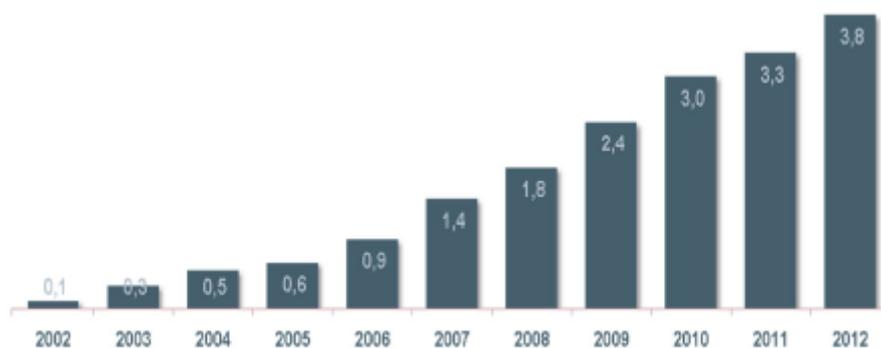

By bringing together physical and digital services, postal operators create prerequisites for comparative advantages on the market. The success in digital services development is tightly connected with the level of trust that customers have for postal operators. As global market is changing quickly, postal operators need to adapt quickly to customers' requirements. Therefore, their business is shifting towards a greater volume of parcel mail generated in e-commerce and towards the development of digital services.

*Posti Group Corporation* (the national postal operator in Finland) developed a concept of secure digital mailboxes – NetPosti. Physical mail is opened, scanned and sent as a PDF file in secure digital mailboxes. Citizens have accounts with their social security numbers and e-mail addresses. Recipients receive an e-mail or a text message notification of an incoming mail item. NetPosti enables its customers to use the invoice option and get receipts for their online purchases directly to their secure NetPosti account.

*Post Danmark* (Denmark) managed to make up for a radical decline in letter-post volume by developing digital services. Post Danmark is still holding its position of the leading sender-receiver interface in Denmark. This is a result of the government's approach to actively encourage progressive digital strategy, a high level of digitalization in the financial sector and a high level of digital take-up (Post Danmark, 2016). In order to adapt to new circumstances, Post Danmark had to do the following:

1. reduce costs, as a reflection of a dramatic decline in volume and revenue,
2. introduce a three-day parcel delivery outside the USO,
3. invest in digital services,
4. use the government resolution to encourage digital communication channels

These activities resulted in developing digital services including B2C & B2B e-Invoices and e-Archiving, Hybrid Mail, remote printing and scanning services. The most significant service is e-Boks, electronic mail box (Figure 4).

**Figure 4:** Citizens receiving digital mail using e-Boks (Post Danmark, 2016)

*Poste Italiane* has invested greatly in technology and thus made the gap between physical and digital domain smaller (Poste Italiane, 2017). It has developed an advanced infrastructure which, regarding technological operations, sorts out a large amount of parcels using automated systems. Poste Italiane has

also upgraded already existing and introduced new services, using various channels: scanning and electronic archives, electronic invoicing for state contractors, mobile virtual network operators, etc.

*Swiss Post* emphasizes a high level of trust from customers, which is crucial for new possibilities in the domain of digital services. A successful example of the development of digital services is "My Consignments", which automatically, via an e-mail or a text message, informs a customer of an incoming registered mail (this way, the customers can control the place and the time of delivery). *Swiss Post* has also engaged in the process of electronic voting infrastructure. E-voting allows voters to vote using computers, tablets or smartphones (*Swiss Post*, 2018).

*SingPost* is one of the leaders in Asia-Pacific region. The main reason for its high ranking is high quality and a wide range of its services. Services related to e-commerce stand out. Their network of parcel lockers (POPStations), where customers pick up their own mail, is also very significant. A relatively new service called Rent-A-POP allows customers to drop off their mail directly in a rented locker (*SingPost*, 2016).

## 6. CONCLUSION

Postal operators, whether it be public or private companies, face a big pressure in trying to ensure new revenues and offer cost efficient services. Considering that postal operators generate a big amount of data (regarding the number of employees, the number of postal units, processing a large amount of mail, postal network structure, etc.), there is an opportunity for using certain digital technologies in order to overcome existing problems.

It is necessary that postal operators put their customers in the center, and model their activities to meet customers' demands (a closer relationship with customers is needed in order to understand their requirements). This calls for an upgrade of existing services, as well as creating new ones. Therefore, innovations are very important for postal operators. Keeping up with the digital technologies evolution is an imperative for the survival and successful development of postal operators, as is for utilizing the available resources effectively.

# LINKING PROCESS COMPLEXITY INDICATORS AND PROCESS PERFORMANCE INDICATORS

Matjaz Roblek\*<sup>1</sup>, Benjamin Urh<sup>1</sup>

<sup>1</sup>University of Maribor, Faculty of Organizational Sciences

\*Corresponding author, e-mail: matjaz.roblek@um.si

**Abstract:** *Purpose - We are presenting research in progress about how changes of process complexity indicators in models relate to changes of process performance indicators in real business processes. Commonly we use process models to model planned changes and anticipate their impact on the company's operations. We try to find process complexity indicators that are more important to subject of improving process performance indicators. Research method - In this article, we present first findings. We researched the literature, and summarized all available measurable process complexity indicators. Then we consolidated them into a single set with the use of comparative method. Hereafter we present the idea of survey with which we will research the link between both types of indicators. Important findings - We contribute to the theory of process model structural analysis with a comprehensive overview of useful process complexity indicators.*

**Keywords:** *business processes, process complexity indicators, process performance indicators*

## 1. INTRODUCTION

Companies operate exclusively on the basis of their business processes. Apart from a few actions that are carried out by a single employee, the company consists mainly of larger or smaller processes. Each process has defined flow and a sequence of activities. The defined sequence of activities must be understood and guided as a whole (Vila, 1999). Business processes are composed of employees, information technology, business rules and organizational activities. The development and rapid expansion of the use of information technology, leads to an ever-increasing and more frequent change of business processes (Cheng, 2008). Some changes can significantly improve the efficiency and effectiveness of the business process. Others can increase the complexity of process, reduce the flexibility and cause problems of interconnected processes (Bose, 2002; Jarrar, Al-Mudimigh & Zairi, 2000; Davis, 2002).

### 1.1. Business processes and business process models

We describe business systems with different models. With computer-based models, we examine the effects of process changes in the virtual environment in advance (Indulska et al., 2009). Models are more or less precise, depending on the purpose of the model, the available time and the desired information (Pavlović, Kern, Miklavčič, 2009). With models, we can anticipate, prevent and minimize the risks of incorrect changes in the business environment (Škrinjar et al., 2008). We describe the operation of business system with business process models. Their purpose is to document the business due to standards, change management, information support. In the business environment, graphic techniques of modelling business processes are popular, with which we visualize the process and make it understandable to the large number of interested users (Johannsen et al., 2014).

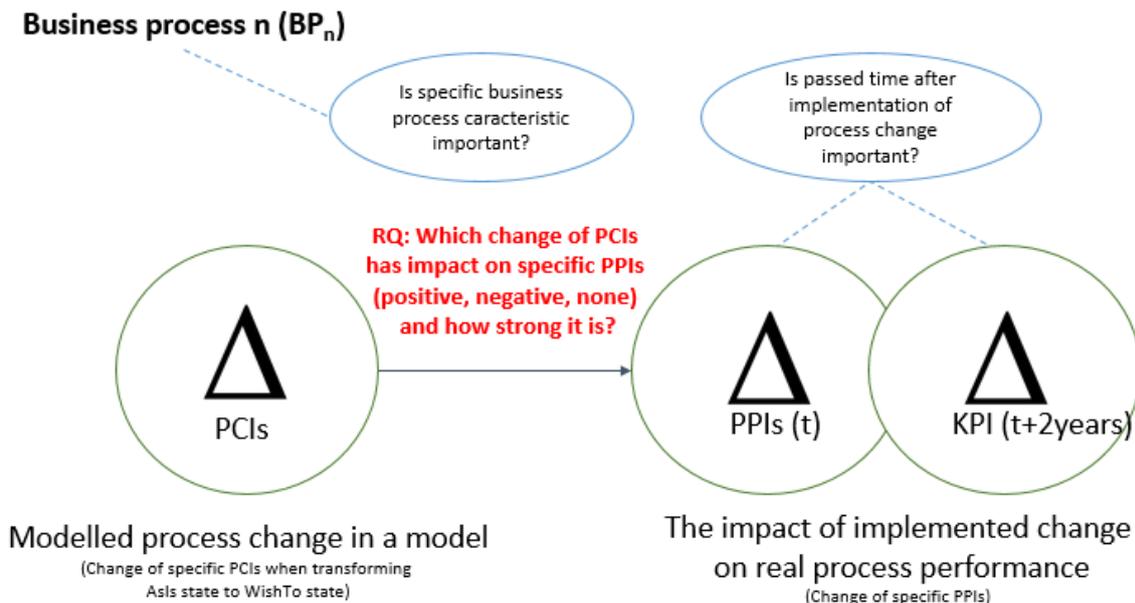

### 1.2. Process complexity indicator (PCI) and process performance indicator (PPI)

We can analyse business process models numerically and structurally. Numerical analyses can be static calculations or dynamic simulations. They require time and business data to perform measurements or estimates. Otherwise, we are trying to predict the effects of changes in business system only from the structure of the model (Charette, 2005). Each process modelling technique has a set of design elements that reflect certain elements of the real business process. The links between different elements form the structure of process model. The structure of business process model can be analysed in various ways and measured through process complexity indicators (PCIs), e.g. we can count elements and relationships between elements of the process models (Cardoso, 2006). Based on the values of PCI of each process model, it is possible to compare the models of processes structurally (Aguilar, et al., 2006). We found out, that there are different PCIs in the literature for structural analysis of process models. Various authors propose a different set of PCIs (Aguilar, et al., 2006; Cardoso, 2006; Mendling, 2008). Analyse of specific PCIs depends on the

existence of referring element in a modelling technique. Therefore, the modelling technique has important influence on availability and on selection of the specific PCIs. When the process is implemented, we measure its operational capabilities with process performance indicators (PPI). They are of different types: financial, operational etc. We define planned values and measure real values of PPIs of specific process and perform control activities on this basis (APICS, 2017).

### 1.3. Research gap: the impact of PCIs on process performance indicators (PPIs)

The effect of complex business changes (output of digitization project or reengineering project) is that the benefits occur sometime after completion of the project. In order to solve the problem of anticipating the effect of complex business changes, we first need to establish the connection between PCIs and PPIs (Figure 1). With this preliminary research, we want to obtain information which change of PCIs in certain business process of a particular industry gives the highest impact on PPIs.

**Figure 1:** Research model of measuring the impact of PCIs on PPIs

## 2. METHOD

Urh (2011) described findings of the relationship between the PCIs and PPIs with descriptive statistical methods. He found groups of PCIs (clusters) that affect specific PPIs. In a detailed analysis of his results, we found that all representatives of a particular PCI group are of the same type (e.g. personnel PCIs only, or logical PCIs only, or information PCIs only). We assume that real situation groups should be formed differently. There are likely to be groups of more or less important PCIs and in each group there should be representatives of different PCI types. To answer this dilemma, we carried out next steps in this research:

1. First, we developed a set of process characteristics. We used them to assess different business processes whether they have similarities between PCI change and PPI change.
2. We prepared a set of process performance indicators (PPIs), which represent the success of the implemented changes in real processes. To determine the PPIs set, we decided to take the top level of PPIs according to the SCOR model (APICS, 2017). They are independent from the type of business process and are broadly recognizable. We have verified their suitability and existence in balance score cards (Kaplan, & Norton, 2008) and APQC (APQC, 2017).
3. We found that it is difficult to define the effects of PCIs on PPIs with the technique of performing measurements of real processes. Therefore, we decided to perform the survey. We found that process managers and process owners are the best target groups of respondents, because they know best the process characteristics and the influence of specific change in their processes (Pavlović, Kern, Miklavčič, 2009).
4. In the literature, we researched known PPIs. Then we prepared a set of absolute PPIs for survey (that we can count). We excluded all relative PPIs that we can derive from the absolute PPIs.
5. For absolute PPIs, we prepared for process owners understandable questions and a simple description of a real business change that has connection to the change of a particular PPI in the background (translation table).

6. Then we asked process owners to evaluate how a specific process change effects specific PPI: what impact it has immediately and after 2 years (Mc Afee, 2002). This research phase is still running.
7. After the survey will terminate, the answers will be statistically analysed with comparative and correspondence analyses. We will try to prove which PCI change of specific process model has the main impact on a change of specific PPI in the real process, according to answers of process owners.

### 3. RESULTS

#### 3.1. Explored set of process characteristics

Based on the APQC model (American Productivity & Quality Centre), we developed a set of generalized business process characteristics that apply to all business processes. That means that according to these characteristics it is possible to evaluate any process independently of the business area and the industry. We classified characteristics into groups according to APQC process areas (Table 1).

**Table 1:** APQC process areas (groups) and belonging characteristics

Num.	Process characteristic group	Business process characteristics
1	General aspect of the process	Frequency Structuring Standardization
2	Operational aspect of the process	Automation Creativity Analytics Technological uniqueness
3	Developmental aspect of the process	The uniqueness of the output The complexity of the output
4	Customer aspect of the process	Determination of demands Dislocated execution Exclusivity for customer
5	Supply aspect of the process	The specialty of the inputs Changing of the inputs
6	Financial aspect of the process	Operating costs
7	Risky aspect of the process	Impact on organizational performance Difficulty of implementing process changes
8	Current excellence of the process	Reliability Responsiveness Agility Cost Asset Management Efficiency

For each process that will be the subject of the survey, we also need its initial excellence (Table 1, num. 8). We found that is important to exclude or to confirm the influence of this factor in the search for the impact of PCIs change on PPIs change.

#### 3.2. Explored set of process performance indicators (PPIs)

We used PPIs categories of evaluation from the SCOR model (Table 2). These categories represent the top level of process performance indicators, to which we will compare their impact of a PCI change.

**Table 2:** Process performance indicators and their definition SCOR (APICS, 2017)

Num.	PPI	Definition
1	Reliability	The ability to perform tasks of a process as expected. Reliability focuses on the predictability of the outcome of a process. Typical metrics for the reliability attribute include: on-time, the right quantity, the right quality
2	Responsiveness	The speed at which tasks of a process are performed. The speed at which a process provides outcome to the customer. Examples include cycle-time metrics.
3	Agility	The ability to respond to external influences, the ability to respond to changes in the process environment to gain or maintain competitive advantage. Agility metrics include adaptability and overall value at risk
4	Costs	The cost of operating the process. This includes labour costs, material costs, and management and/or transportation costs. A typical cost metric is cost of goods sold.
5	Asset Management Efficiency (Assets)	The ability to utilize assets. Asset management strategies in a process include inventory reduction and insourcing vs. outsourcing. Metrics include Inventory days of supply and capacity utilization.

### 3.2. Explored set of process complexity indicators (PCIs)

In Table 3, we introduce explored PCIs, which were derived from the literature review (Aguilar, et al., 2006; Cardoso, 2006; Mendling, 2008). We grouped PCIs into individual sets according to the element of modelling. It is important if new element of modelling a specific process change is an exclusively new element in relation to other elements in the process (definition copy – def.), or it is a known element in relation to other processes (occurrence copy – occ.).

**Table 3:** Process complexity indicators

Num.	PCI set	PCI
1	New events in the process	Number of events or. states (occ.) Number of start or entry events (occ.) Number of end or closing events (occ.)
2	New activities in the process	Number of different activities in the process (def.) Number of activities that do not add value
3	New elements of process logic in the process	Number of AND switches (def.) Number of AND mergers (def.) Number of OR switches (def.) Number of OR mergers (def.) Number of XOR switches (def.) Number of XOR mergers (def.)
4	New connections in the process	Number of alternate parallel paths in the process Minimum number of transitions between process activities (occ.) Maximum number of transitions between process activities (occ.) Number of feedback loops within process (occ.) Number of feedback loops back to the previous processes Number of connection types Must execute (occ.) Number of connection types Must be informed (occ.) Number of connection types Must participate (occ.)
5	New jobs / work roles in the process	Number of job positions (occ.) Number of transitions between different organizational units Number of transitions between different hierarchical levels
6	New information carriers in the process	Number of documents or information carriers (occ.) Number of different documents or information carriers (def.)
7	New ICT (information & communication technologies) solutions in the process	Number of supported activities with at least one ICT system Number of ICT solutions (occ.) Number of different ICT solutions (def.)
8	New links to other processes	Number of input processes Number of output processes

## 4. DISCUSSION

Based on the explored sources, we found that the presented set of PCIs is sufficiently independent according to modelling technique (e.g., EPC, BPMN, ISO flowchart). We also found that the differences in sets of PCIs between the different authors (Aguilar, et al., 2006; Cardoso, 2006; Mendling, 2008) are mainly due to the purpose of the represented process model: reorganization of the process, IKT support of the process, ISO documentation of the process, process simulation. Our choice is the union of those modelling elements that are common to all purposes. We emphasized those PCIs, the change of which is understandable by the process owners. In Figure 2, we present an example of a question that is part of prepared survey. It shows how we retrieved data to prove PCIs impact on PPIs change. In the literature, we did not find this comprehensive review. Therefore, these sets of PCIs are our contribution to the area of process management and analytics.

23. If process change requires that we automate with information&communication technology (ICT) additional, currently un-supported activity (the type of ICT does not matter)?

*Related PCI: Number of supported activities with at least one ICT system /*

The change has impact on PPI:	Immediately after implementation					2 years after implementation				
	very negative	negative	no impact	positive	very positive	very negative	negative	no impact	positive	very positive
Reliability of the process	1	2	3	4	5	1	2	3	4	5
Responsiveness of the process	1	2	3	4	5	1	2	3	4	5
Agility procesa	1	2	3	4	5	1	2	3	4	5
Reduction of operational costs	1	2	3	4	5	1	2	3	4	5
Asset Management Efficiency	1	2	3	4	5	1	2	3	4	5

**Figure 2:** An example of the descriptive question

## 5. CONCLUSION

This research is currently in phase, where we are testing the questionnaire with randomly selected process owners in the form of guided interviews. Based on the experience, comments and suggestions of process owners, we will adjust the questionnaire and proceed with the final survey.

When we prove the importance of specific PCIs, we will measure the change of selected key PCIs and the change of PPIs in real processes of companies. We will follow which purpose initiated the change of the process and how successfully this change is implemented in the real process. In this way, we will be able to ensure calculation of the benefits and reduce the risks of performing different types of changes in advance. After that, we will be able to demonstrate to companies on basis of current PCIs how much potential is hidden in the process for possible improvements.

This research is set to avoid most possible constraints: it is not limited to the type of business, type of business process, modelling technique and is not limited to the cause of changing the process. In the first part of this research, we do not expect problems. We will obtain those PCIs (key PCIs), which are important from view of process owners. It will be interesting to see whether PCIs from a particular area (informatics, organization, personnel) dominate against other areas.

## THE ROLE OF FACEBOOK IN BUSINESS MODELS AND INCREASING COMPETITIVENESS OF HIGHER EDUCATION INSTITUTIONS

Nina Đurica\*<sup>1</sup>, Maja Đurica<sup>1</sup>, Ivan Todorović<sup>2</sup>

<sup>1</sup>Belgrade Business School – Higher Education Institution for Applied Studies

<sup>2</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, e-mail: nina.djurica@bbs.edu.rs

**Abstract:** *In recent years, many studies concerning the use of social networks among students indicate that social networks promote educational communication and cooperation between faculties and students. The trend of using social networks in higher education is relatively new, but it points to their numerous advantages, acceptance and use in education. The aim of the study is to examine the purpose of using Facebook among students, as well as their observations, benefits and attitudes about educational use. The research was conducted among students of the Belgrade Business School - Higher Education Institution for Applied Studies and 430 students at bachelor and master studies were surveyed in October 2017. In the analysis of the obtained data the following methods were used: t-test and factor analysis. The results show that students use Facebook for educational purposes to exchange materials and information from lectures, communication with colleagues, and the creation of academic groups, and that higher education institutions should adopt their business models to the changed communication trends and include e-learning platforms and social networks in their official channels towards students, potential candidates and alumni in order to increase their competitiveness.*

**Keywords:** *educational use, Facebook, social networks, digitalization, e-learning, student, higher education*

### 1. INTRODUCTION

The popularity of social networks and their global presence in the everyday life of students is growing, who use them not only as a means of networking, but also for educational purposes. The research on social and educational institutions is trying to answer a series of questions – how is social media used in education, what are the goals of social media, what are the experiences, what are the barriers to effective use and what is the future of social media in education (Hebrang, Grgić, Mučnjak, 2015: 234). Students have different learning styles (Marič, Penger, Todorović & Đurica, 2015) and the use of social networks provides the basis for social, emotional and cognitive development of young people who spend most of their time on the Internet (Hayes, Van Stolk-Cooke, Muench, 2015: 508).

Numerous studies have shown that social networks have led to significant changes in communication and interaction between students and professors, as well as learning methods. The use of social media in the university classroom is gaining in its popularity and is transforming learning and teaching in significant ways (Foster, Farshid, Juena, Wallström, 2016: 789). Social networks provide students with more opportunities to communicate, learn, discuss, exchange information, reflect, judge and rate downloaded materials, give feedback and acquire new knowledge on the Internet (Volungevičienė, Teresevičienė, Mejerytė-Narkevičienė, 2015: 19).

The existence of the Web has changed the nature of the educational process, and modern network technology has improved the ability to communicate of people around the world and become a necessary educational tool (Soleša, Rajsman, Juričić, 2014: 1403). Today, higher education institutions have recognized the potential benefits of social networks and use them to improve their own business, communication and promotion. Students are offered with a variety of useful tools for easier sharing of teaching materials and interaction with colleagues and professors. Because of the increasing number of Facebook users among students, educational research shows that Facebook can be used to provide educational content and can be used as a successful learning tool (Buragga, Dhir, Boreqqah, 2013: 21).

Numerous studies deal with Facebook as the most popular social network from various aspects. Facebook is well-known for the purpose of daily entertainment and getting information: playing games, watching videos, expressing opinion, sharing files, tracking events in someone's social circles, dating, etc. (Kabilan, Ahmad, Abidin, 2010: 180; Sharma, Joshi, Sharma, 2016: 342). Although it was originally created for social use, according to some studies (Bosch 2009, Mazman & Usluel, 2010; Sharma, Joshi, & Sharma, 2016) Facebook is also successfully used for educational purposes. According to a study conducted by McCarthy

(McCarthy, 2012), students consider Facebook an important tool for studying that improves the development of academic links and promotes academic criticism, discussions and networking (McCarthy, 2012: 760).

According to the study conducted by Latib, Bolong and Ghazali, the purpose of using Facebook is divided into seven functional areas: the creation of personal identity; distribution of content; communication with friends; creating personal reputation; the creation of groups of people with similar interests; constant tracking of new information and the development of personal, friendly and business relations (Latib, Bolong, Ghazali, 2014: 290). Social networks provide the opportunity to create same-interest groups. Professors create *online* groups on the topic of their subject and upload teaching materials and important information for the exam. Students join groups on social networks and in that way they can establish contact with colleagues and professors, exchange opinions, comments and information.

It has been found that most students use social networks for educational purposes to perform group projects and assignments. Furthermore, research has showed that social networks are very useful in conducting group work (Zanamwe, Rupere, Kufandirimbwa, 2013: 15). Therefore, the use of social networks for educational purposes is recommended to overcome problems, such as the feeling of isolation from the group, which often occurs in learning processes and has a negative impact on learning and "inability to express themselves in public" due to shyness (Ozturk, 2015:22).

Universities as educational institutions are concerned about the growing lack of interest of university students toward the traditional way of learning (Manasijević, Živković, Arsić, Milošević, 2016: 443). Professors should, through attractive teaching content, innovative and interactive models of work, involve students to participate in lectures and make education more effective. Facebook provides a social environment, enabling the student to interact with instructors and peers and facilitates the process of knowledge construction (Çoklar, 2012: 49). Resource and material sharing consists of activities such as exchanging multimedia resources, videos, audio materials, animated videos, resources and documents (Manasijević, Živković, Arsić, Milošević, 2016: 443).

## 2. METHODOLOGY OF RESEARCH

Higher education institutions have realized that the implementation of new technologies and the following of trends significantly influence the achievement of competitive advantage and adaptation to changing market conditions. Nowadays, higher education institutions are focused on being present on each platform and updating information at any time.

The basic research instrument is a structured questionnaire, which consists of two parts. The first part of the questionnaire refers to control variables (whether you use Facebook, how long you have a profile on Facebook and how often you access Facebook). The second part of the questionnaire consists of 14 items for testing the purpose of using Facebook, using Likert's five-point scale, and special attention is paid to examining the educational use of Facebook. Today's student population uses social networks, in addition to entertainment and communication, also for the exchange of relevant information about their studies. A high percentage of students use Facebook, about 97.2% of them. Most students have a profile on Facebook for more than 5 years, 67.4%, and 20% of students have a profile for a period of between 3 and 5 years. When it comes to the frequency of accessing Facebook, 60% of students approach several times during the day and 18% of students once a day.

The collected data, obtained by student questionnaires, were processed and analyzed using software for statistical analysis SPSS 22.0 (Statistical Package for Social Science). In the analysis of the obtained data the following methods were used: t-test and factor analysis.

## 3. RESULTS OF RESEARCH

Table 1 presents descriptive statistical dimensions for the second part of the questionnaire. Based on the obtained results, *the Purpose of Using Facebook* contains two main factors defined as *Social Relations and Everyday Activities* and *Educational Use of Facebook*. The assumed model of two factors *The Purpose of Using Facebook* was examined on an existing sample of students using factor analysis.

**Table 1:** Descriptive statistics for items related to Social Relationships and Everyday Activities on Facebook and Educational Use of Facebook (n=430)

<b><i>Social Relationships and Everyday Activities on Facebook</i></b>	Mean	Median	Std. deviation
I use <i>Facebook</i> to establish and maintain contact with friends I have not been in contact with for some time.	4,06	4	1,052
I use <i>Facebook</i> for acquiring new friends.	2,67	2	1,407
I use <i>Facebook</i> to communicate and share information with my friends.	4,19	4	,950
<i>Facebook</i> allows me to create and access groups of people with whom I have the same interests and needs.	3,99	4	1,169
I use <i>Facebook</i> to track the latest information, news and events of my friends.	3,84	4	1,122
I use <i>Facebook</i> to track innovation.	3,55	4	1,255
<b><i>Educational Use of Facebook</i></b>	Mean	Median	Std. deviation
I use <i>Facebook</i> to communicate with my friends from the faculty regarding test tasks, group projects, recommendations and experiences.	4,25	5	1,004
<i>Facebook</i> improves communication with professors and facilitates receiving all the necessary information about teaching content, all issues essential for passing exams, designing projects and final papers.	3,10	3	1,364
The use of <i>Facebook</i> makes it easy to transfer information, teaching content and notifications about classes, lessons, exams, and extra-curricular activities.	3,90	4	1,149
<i>Facebook</i> allows creating and accessing academic groups of people with the same interests and needs.	3,89	4	1,021
The use of Facebook enhances the team work of students.	3,84	4	1,151
I use <i>Facebook</i> as a means to increase the performance on the lectures.	3,14	3	1,348
<i>Facebook</i> enables the exchange of different materials from lectures between professors and students and students among themselves.	3,54	4	1,277
<i>Facebook</i> provides me with multimedia contents (videos, audio materials, documents, etc.) that are relevant to learning.	3,53	4	1,293

As for the first factor, *Social Relationships and Everyday Activities* give the students put the utmost importance on items "I use *Facebook* to communicate and share information with my friends" (M = 4,19; SD = 0,95) and "I use *Facebook* to establish and maintain contact with friends I have not been in contact with for some time" (M = 4, 06; SD = 1,052). The results indicate that students consider *Facebook* an important means of social networking because the items have a high score, or a mean value above 3. The item "I use *Facebook* for acquiring new friends" has a very low mean value (M = 2,67; SD = 1,407) and the lowest for the whole dimension *Social Relations and Everyday Activities*. This result shows that students attach little importance to using Facebook for gain new friends.

All items related to *Educational Use of Facebook* have mean values greater than 3, which show that students understand the importance of Facebook for educational purposes. The highest mean value has the phrase "I use *Facebook* to communicate with my friends from the faculty in relation to test tasks, group projects, recommendations and experiences" (M = 4,25; SD = 1,004), "The use of *Facebook* makes it easy to transfer information, teaching content and notifications about classes, lessons, exams, and extra-curricular activities" (M = 3,90; SD = 1,021), and "*Facebook* allows creating and accessing academic groups of people with the same interests and needs" (M = 3,89; SD = 1,021) and enhances the team work of students"(M = 3,84; SD = 1,151). The results show that the main advantages of using Facebook for educational purposes are quick and easy communication between students regarding test tasks, passing recommendations, experiences, information and notifications regarding teaching and extra-curricular activities. Also, the results show that students understand the importance of accessing academic groups, as well as the significance of social networks in the realization of group projects and teamwork.

The results of factor analysis are presented in Table 2.

**Table 2:** Results of factor analysis of 14 items and 2 separate factors

	Characteristic value	Factor loadings	Variance (%)	Cumulative variance (%)
<b><i>Educational Use of Facebook</i></b> (Cronbach alfa=0.889)	6,130		31,05	31,05
<i>Facebook</i> enables the exchange of different materials from lectures between professors and students and students among themselves.		,815		
I use <i>Facebook</i> as a means to increase the performance on the lectures.		,758		
<i>Facebook</i> provides me with multimedia contents (videos, audio materials, documents, etc.) that are relevant to learning.		,752		
<i>Facebook</i> improves communication with professors and facilitates receiving all the necessary information about teaching content, all issues essential for passing exams, designing projects and final papers.		,746		
The use of <i>Facebook</i> makes it easy to transfer information, teaching content and notifications about classes, lessons, exams, and extra-curricular activities.		,728		
The use of <i>Facebook</i> enhances the team work of students.		,658		
<i>Facebook</i> allows creating and accessing academic groups of people with the same interests and needs.		,632		
I use <i>Facebook</i> to communicate with my friends from the faculty regarding test tasks, group projects, recommendations and experiences.		,507		
<b><i>Social Relationships and Everyday Activities on Facebook</i></b> (Cronbach alfa=0.781)	1,390		22,66	53,71
I use <i>Facebook</i> to track the latest information, news and events of my friends.		,811		
I use <i>Facebook</i> to track innovation.		,745		
I use <i>Facebook</i> to establish and maintain contact with friends I have not been in contact with for some time		,606		
I use <i>Facebook</i> for acquiring new friends.		,599		
I use <i>Facebook</i> to communicate and share information with my friends.		,560		
<i>Facebook</i> allows me to create and access groups of people with whom I have the same interests and needs.		,552		

The sampling adequacy for factor analysis was verified by the value of the Kaiser-Meyer-Olkin index of 0,914 and exceeds the recommended (critical) value of 0,6. Also, Bartlett's spherical test has reached statistical significance ( $p < 0,001$ ). In the further analysis, the factors whose characteristic value was greater than 1 (Kaiser's criterion) were retained and thus retained two factors. These two retained factors explain 53,71% variance, with the first factor contributing 31,05% and the second 22,66%. In order to facilitate the explanation of the factors Varimax rotation was carried out, and in the further analysis only those variables whose factor loadings increased by an absolute value of 0,5 were retained.

By using the factor analysis in this survey, 14 observed variables (questions) were reduced to two dimensions, or two factors of *the Purpose of Using Facebook*. These two dimensions correspond to the following factors: *Social Relationships and Everyday Activities* and *Educational use of Facebook*, whose names have emerged as a common denominator of a set of correlated variables (questions) within them.

The overall alpha-coefficient of reliability analysis is 0,899 and the results of the reliability test for the two resulting sub-clusters are as follows: *Social Relations and Everyday Activities*- Cronbach alpha = 0,781; *Educational use of Facebook* - Cronbach alpha = 0,889. In the relevant literature it is considered that the confidence coefficient greater than 0,7 confirms the hypothesis that the questions that make up each dimension (factor) are interconnected.

The total number of retained factors is significantly lower than the number of observed variables (questions), thus justifying one of the basic objectives of the factor analysis that the initial set consisting of a large number of original, interconnected variables (questions in the questionnaire), which measure similar characteristics, reduce to a smaller number of new, mutually unreleased variables - factors (the principle of dimensional reduction). These factors summarize the essential concepts behind the use of *Facebook*.

#### **4. DISCUSSION**

Many studies investigate the phenomenon of social networks and their impact in many areas of life. Facebook, as the most popular social network, has found great application among higher education institutions and students. The results show that students mostly use Facebook for social purposes. As for the use for educational purposes, Facebook is the most valuable platform for sharing materials and information from lectures, communication with colleagues and the creation of academic groups. The phenomenon of Facebook has influenced the changing way of communication among students and others, the exchange of information and the broadening of knowledge (Volungevičienė, Teresevičienė, Mejerytė-Narkevičienė, 2015: 2).

The results show that the greatest importance regarding the use of Facebook for educational purposes, students see in easier communication with their friends from the faculty in relation to test tasks, group projects, recommendations and experiences. Also, Facebook facilitates the transmission of information, teaching content and notifications about teaching, classes, exams, and extracurricular activities (Hamid, Waycott, Kurnia, and Chang, 2015) have found that students using social technologies show more interaction with other students at lectures. The results of this study greatly support the involvement of students in academic groups, collaboration through academic groups and the improvement of group work (Hamid, Waycott, Kurnia, Chang, 2015).

Higher education institutions use social networks in order to provide information about students, improve communication and learning methods. Also, social networks can also be used as part of a corporate strategy for managing and maintaining lasting relationships with students. In the latest academic programs, networking technology has become an essential educational tool (Soleša, Mateljan, Juričić, 2012: 1562).

#### **5. CONCLUSION**

Higher education institutions have realized that the implementation of new technologies and the monitoring of trends significantly influence the achievement of competitive advantage and adaptation to changing market conditions. Nowadays, higher education institutions are focused on being present on each platform and updating information at any time. Employees and students have recognized the numerous advantages of adopting and using social networks for educational purposes. Facebook, as the most popular social network, has found great application among higher education institutions and students.

The results of this study show that students mainly use Facebook for social purposes, but that this social network has a significant application for educational purposes. Compared to other social networks, Facebook is the most valuable platform for sharing materials and information from lectures, communication with colleagues and the creation of academic groups. The results of this research also show that the greatest importance of using Facebook for educational purposes is that it facilitates students' communication with colleagues in relation to test tasks, group projects, recommendations and experiences. Also, Facebook facilitates the transmission of information, teaching content and notifications about classes, lessons, exams, and extra-curricular activities.

Higher education institutions should use social networks to provide information on students, improving communication and learning methods. Also, social networks can also be used as part of a corporate strategy for managing and maintaining lasting relationships with students. The results also indicate that higher education institution ought to accept digitalization and incorporate modern technologies in teaching methods by including e-learning platforms and enabling the usage and share of learning materials in digital form.

Main limitation of this research is the sample, which covered only one higher education institution from Serbia, so further research should test the use of social networks for educational purposes in various academic fields, and different universities from Serbia. Another direction for further research in this area might be a comparative analysis of multiple countries regarding the use of social networks by students, but also about the level of implementation of digital platforms in business models of higher education institutions.

## ACKNOWLEDGEMENT

Authors' engagement on this research was partially supported by the Ministry of Education and Science of the Republic of Serbia through the Project No. 179081: Researching Contemporary Tendencies of Strategic Management Using Specialized Management Disciplines in Function of Competitiveness of Serbian Economy.

**Abstract:** *This paper analyses organizational structure and business model appropriate for a digital marketing agency. Our goal is to help facilitate development and the maintenance of the Digital Agencies business through the successful implementation of corporate culture, business organization model and organization structure. We have presented business model of the organization through the canvas scheme and structure by the organizational chart. Our theoretical framework was Mintzberg's approach of three hypotheses of configuration, congruence and extended configuration. We have used his partial assumptions and qualitative approach to determine if our structure and business model is aligned with internal and external factors in this particular business context.*

**Keywords:** *digital marketing, business model, matrix organization, organization structure, organization culture*

### 1. INTRODUCTION

Digital marketing includes the process of use of modern digital technology to place goods and services on the market through the system of traffic increase using web sites and social networks. e.g., (Lamberton & Stephen, 2016). Main focus in a digital marketing is placed on creating quality content that will draw attention and encourage the readers to share it through their social platforms. Additionally, the stated digital marketing is a general term used for promoting products or services using digital technology platforms, mostly through the Internet. Their placement is performed via computers, mobile phones, tablets or other digital devices. One of the main advantages of using social platforms in marketing is the option of placing content to a narrow target market which is an inevitable advantage compared to other marketing channels. Business systems of the digital marketing are usually called Digital Agencies, Marketing Agencies or Advertising Agencies that include digital departments. Activities of digital agencies cover: creating marketing content and its placement online, SEO of web sites, SEM optimization, influencer marketing, creating marketing campaigns, managing social network pages, e-mail marketing, social network ads, Google ads, SMS ads, re-marketing, banners, preparing SEO friendly articles for digital media, etc.

Lower budgeting is among main advantages of digital marketing compared to the traditional marketing mix. This is why a growing number of companies focuses their promotions on using modern technology and platforms such as Google, Facebook, Twitter, Youtube, Instagram, LinkedIn etc. The growth of demand dictates the increase of providing services. The industry of digital agencies grows rapidly and is very large (Ibisworld, 2018). "Statistics show that only in the United States of America in 2018 year, digital agencies employ 68,059 employees and whose industry collects \$ 12 billion a year with a projected annual growth rate of 14.4%". This trend is visible in the western Europe, but, for the last couple of years, the east of Europe, as well.

Digital marketing enables the advertiser to exit the local and regional communication with consumers and customers and to enter the global market and promote its goods or services all around the world for a relatively low budget. This chance is equally given to service providers, i.e. digital agencies that can operate from a local level to national and international markets with minimum capital investments. In this manner, an agency located in Serbia can operate on the market of United Arab Emirates, Serbia and China, at the same time. As of 01 April 2018, a new law comes into effect proposed by the Ministry of Finance of the Republic of Serbia related to the income tax of non-resident legal entities, that is, Withholding Tax. A Rulebook was adopted on the type of services based on which a non-resident may acquire income that is subject to withholding tax. According to this Rulebook the services of marketing, propaganda, and advertising are not subject to taxation. e.g., (Official Gazette of the Republic of Serbia 113/2017, 2017). "Accurate list of non-taxable services is: marketing, media setting, advertising on the Internet and over social networks, in public media, lease of media space, development and videos and advertising, event organization regardless of the location, provision or use. The activity codes are 7311 and 7312 – Advertising agencies activities." Digital

agencies in Serbia operate under this code. This new law enables invoicing the service of managing digital channels for a foreign client without VAT, thus making this invoiced amount not subject of further taxation by the Ministry of Finance of the Republic of Serbia. This certainly facilitates the work with clients that are not Serbia residents and stimulates the development of digital agencies in the region. Namely, the price and quality ratio of domestic digital agencies compared to foreign competition is certainly promoted in this manner, for the benefit of domestic agencies.

As the technology and the development of different platforms, software and tools grow, it is increasingly easier to monitor the consumer demographics, behavior and measuring the amount of income per user. This promotes the development of digital marketing industry and shows us that it will significantly grow in the following five years. The prediction for technological development certainly impacts the development of digital agencies and the service they provide. The interaction between the advertiser and consumer is now, owing to social media platforms, much more transparent motivating the improvement of such communication, causing opening of new positions within the digital agency organizational structure. As synthesized in the review by Marquis and Tilcsik (2013) under the influence of the idea of relations between social structures and organization (Stinchcombe 1965), wider social context can imprint its form into the structure of the organizations. Our research question is if there are modern forms of organizational structures and business models which are fit for the digital marketing agencies. We focus on the analysis of fit between digital marketing business on one side and matrix organizational structure, as well as multi-sided platform as the business model, on the other. To do that, we have formulated following hypothesis:

H1: Matrix organizational structure and multi-sided platform are appropriate solutions for the digital marketing agency business

Our main hypothesis will be elaborated according to Mintzberg's (1995) framework, where effective structuring of organization is bounded by configuration, congruence and extended configuration, presented in the following hypotheses:

- H 1.1. Matrix organizational structure and multi-sided platform are aligned with the Mintzberg's configuration hypothesis
- H 1.2. Matrix organizational structure and multi-sided platform are aligned with the Mintzberg's congruence hypothesis
- H 1.3. Matrix organizational structure and multi-sided platform are aligned with the Mintzberg's extended configuration hypothesis

## **2. METHODS AND LITERATURE REVIEW**

For our research we have used qualitative business analysis methods, common in the business research (Saunders, Thornhill and Lewis 2009). Organizational structure and business model are complex phenomena (Jaško, Čudanov, Jevtić and Krivokapić, 2017), with large number of non-numerical attributes and characteristics, and thus are not subject to complete or even significant quantification. Analysis is thus aimed at coding themes and assigning meaning to the data, which are usually words or images, according to the Gliner, Morgan and Leech (2011). Our results will not be illustrated by the statistical analysis, but instead by the study of individual cases and traits of the observed phenomena. According to the Healey and Rawlinson (1994), our approach is based on meanings expressed through words, collected data is not standardized and is classified into categories, as well as conceptualization of observed phenomena.

### **2.1. Changing organizational context for digital marketing**

Technological changes are bringing disruptive innovation (Christensen, Raynor and McDonald, 2015) into established industries. Digital disruption is already present in publishing (Gilbert, 2015; Karimi and Walter 2015), banking (Tornjanski, Marinković, Šavoiu & Čudanov 2015), education (Dellarocas & Van Alstyne, 2013) and entertainment (Rombes 2017), but our focus is on marketing changes in a digital age (Ahonen and Moore, 2005; Ryan, 2016; Begum, 2017; Jovanović, Vlastelica, & Cicvarić Kostić, 2017; McCosker, 2017). As stated by Bolman and Deal (2008) "Business models, management models and organizations that were successful in the last two decades are outdated now. This period is called the organizational big bang. Information revolution, globalization of economies, immediate information sharing on global events, collapse of big ideology, establishment of large media companies that turn the world into a huge planetary village promote the acceptance of general culture values that results in new business models and new organization structures, turning the yesterday ones into antiquities." This brought along business models that include the industry of digital marketing.

## 2.2. Corporate culture in digital age organizations

As a groundwork for a successful business model and sound organization structure we should take a look at another important success factor for digital agencies – corporate culture. The culture in the context of the organization is defined as mutual presumption, values, beliefs, language, symbols and systems of meaning that are an integral part of an organization. When the cultures are strong employees in the entire organization on all levels share the same goals, have the same type of feeling on the organization and interpretation of its culture in the same manner (Gottlieb, 2007). Services provided by digital agencies require identification with clients and their values in the form of best and more relative content creating that will present the client to the market, followed by the continuous communication with consumers for and in the name of the client. Considering the diversity of activities performed and identified with for a longer period, for digital agencies, there is a danger of employee service quality drop due to losing focus from the culture and adopted values of the original employer.

Also, considering the option of managing digital channels of a global client from a local level, acceptance of global culture and maintenance of local subculture is a must. When we are a part of a business system culture we become codependent to other members of this business system, we manage stress better and have better productivity. It is very important to maintain the motivation of employees and provide the conditions of work that support creativity. The essence of activities of digital agencies is seen in the creativity of its employees. To achieve this Galbraith (2009) states: “the task is challenging, since you need the best leaders in the company for motivating employees and maintaining corporate culture, and what the Council for Corporate Leadership identified as the key role in the matrix is a strong communication skill of the leader, the way of motivating for teamwork, adjustability and calling for mutual goal and introducing the reward system.” We will present a successful example of the organization culture of Google, from author e.g., (Smithson, 2017) “Google organizational culture is not a typical one, partly due to the effect of the organization structure of the company. In principle, the structure and culture interact to impact the capacity of the organization. Openness is achieved through the matrix organization structure. Within the Google context of organization structure, employees are free to share their ideas and opinions”.

On the domestic market, the company that develops a successful culture of a business system is surely the Serbian technological company Nordeus. The success of Nordeus was initiated by a pioneer cross-platform gaming concept including online games you can play from any platform and device at any moment. Nordeus operates since 2010 and successfully nurtures the startup culture of its organization to this day. Also, similar to Google, it applies the matrix organizational structure.

The examples of Google and Nordeus organizational culture and satisfaction of the employees that give maximum in these conditions and do not lose focus from company values gives us enough valuable information on the importance of maintaining this aspect in the essence of existence of a digital agency. For the mere essence of operations of a digital agency is similar to Google platform. It connects two sides providing content. Google uses its platform for placement as well as Nordeus, while the digital agency uses others. This leads to a conclusion that a business model of a digital agency in a lower volume but with similar description could be defined as multi-sided business model.

## 3. BUSINESS SYSTEM BUSINESS MODEL IN DIGITAL MARKETING

Osterwalder & Pigneur (2010) define business model by “how an organization creates, delivers and maintains value” and describe patterns of unbundled, long tail, free, open business models, as well as multi-sided platforms model. Synthesis of how the research on business models shows that it can also be perceived as the statement, description, architecture, conceptual tool, structural template, method, framework, pattern and set (Zott, Amit and Massa, 2011). In order to generate all information and define under which business model a digital agency operates we will review the definition of the multi-sided platforms model from e.g., (Osterwalder&Pigneur, 2010): “Multi-sided platform business model collects several different but mutually dependent groups of buyers. Such platforms are valuable for one group of buyers only if other groups of buyers are present. The platform creates value by facilitating interactions between these two groups. Multi-sided platform grows in the sense it draws more users, which is a phenomenon known as the network.” Using the canvas provided by Osterwalder and Pigneur (2010), we can describe business of the average digital marketing agency through the figure 1.

Multi-sided platforms existed in the past but have developed in the last two decades with the significant development of informational technologies. In addition to Google, Facebook, we can also include Microsoft Windows as an example of successful multi-sided platform business models. Since digital agencies connect the client with end users of such a platform engaging the third parties in the form of lease of ad space online we can say that digital agencies operate on the multi-sided platform business model as well. The task of a

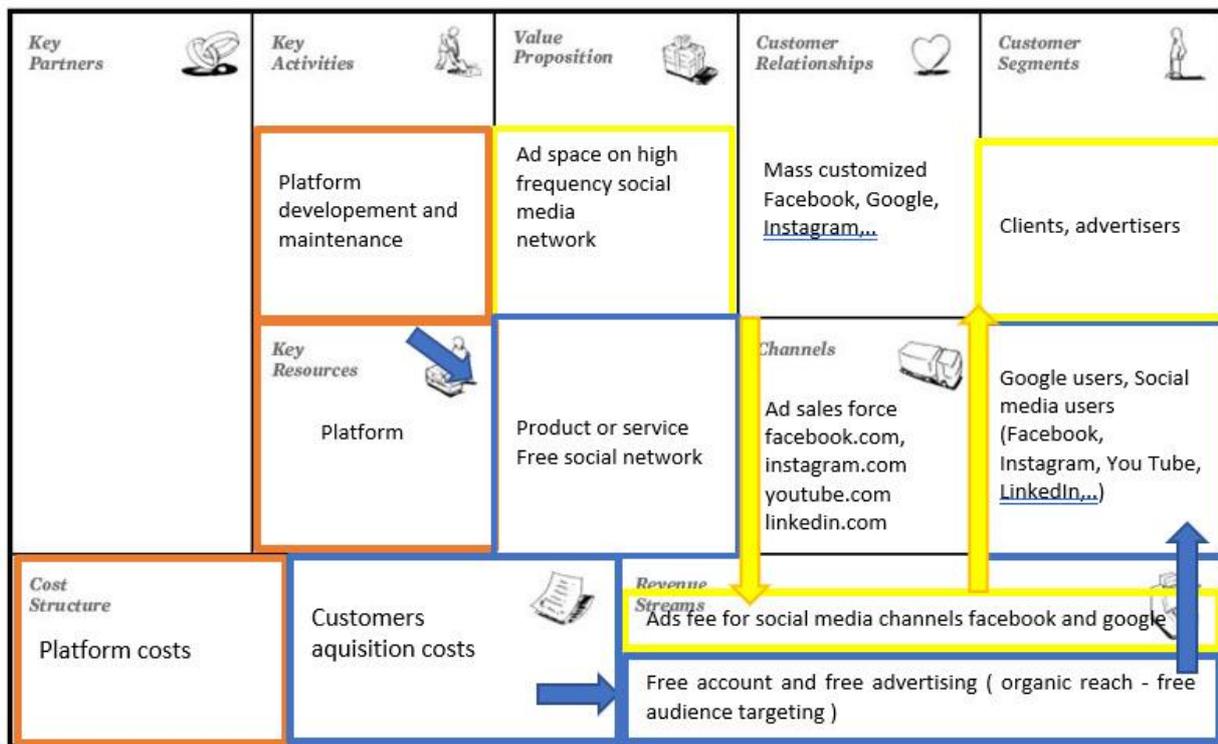

digital agency is to attract and serve all these groups at the same time to create value through creating quality content. The success of the project that the digital agency is leading is seen in the number of users on the “other side” of the platform and their activities. Namely, to manage and retain a client the digital agency must engage one of the platforms to place the marketing content that will attract visitors and followers. To do that, it will have to allocate certain budget for a better promotion on a given platform. Since the company investing the budget expects a fast return on invested funds (ROI) as well as profit, digital agency has the task of envisaging sufficiently interesting and quality marketing content to motivate a customer group for the given subject. Using different marketing tools in the form of good design, text, slogans, vlogs and activations the task of a digital agency is to create a buyer from a user. This model includes some of the free business model as well.

<b>Key partners</b>	<b>Key activities</b>	<b>Value proposition</b>	<b>Customer relationships</b>	<b>Customer segments</b>
Project associates, free lancers Social networks (Google, FB, Youtube) Influencers, bloggers	Development of digital strategies and plans Development of campaigns on digital networks Development of web and mobile applications	Providing services from digital marketing (SEO, SEM, Google optimization) Providing IT Services, support	Managing projects for clients Maintaining good relationships with target groups – community management	Big and small companies Companies Marketing agencies
	<b>Key resources</b>		<b>Channels</b>	
	Designer, creatives Digital account managers Media planners Developers		Social networks Platforms – Google, Facebook Web sites	
<b>Cost structure</b>		<b>Revenue streams</b>		
Salaries, space lease Material costs for the company		Agency fee – compensation for services Discounts		

**Figure 1:** Generic business model of a digital marketing agency

Namely, the free business model enables free offer pattern. It includes the option of continuous usage of a free offer by at least one segment of buyers. Financing in this case comes from another segment of the business model or another segment of buyers. One side of the platform is designed to attract users free of charge to follow content, see products and services while the platform itself generates income from selling advertising space and the advertiser created profit from sales of products to this segment of buyers that uses the platform for free. All three groups are organized and managed by the digital agency.

One of the most popular multi-sided business models is certainly Google. The core of its business model is the value proposal, ad or text Google provides to a very targeted group on a global level, over Internet. Through the service the advertisers publish sponsored announcements that appear on the Google browser along with other non-sponsored announcements but not at the top of the page. The service is attractive for advertisers since it enables filtered demographic categories of target groups. However, the model is successful only if a lot of people use the Google browser. The more people use it, the more ads it can show. In addition to aforementioned, the value of the Google browser lies in the dependence of clients from Google, where their web page appears. The advantage is given to those that optimize their site, but certainly to those that use Google Web Tools such as Google Map, Gmail, etc. Additionally, Google introduced a new service, AdSense, that is called re-marketing also, enabling presentation of the Google ad on other Google web locations, that is, sites, portals, etc. of others. This service is useful for third parties, that is, owners of these web pages and portals, resulting in income from advertising of Google clients.

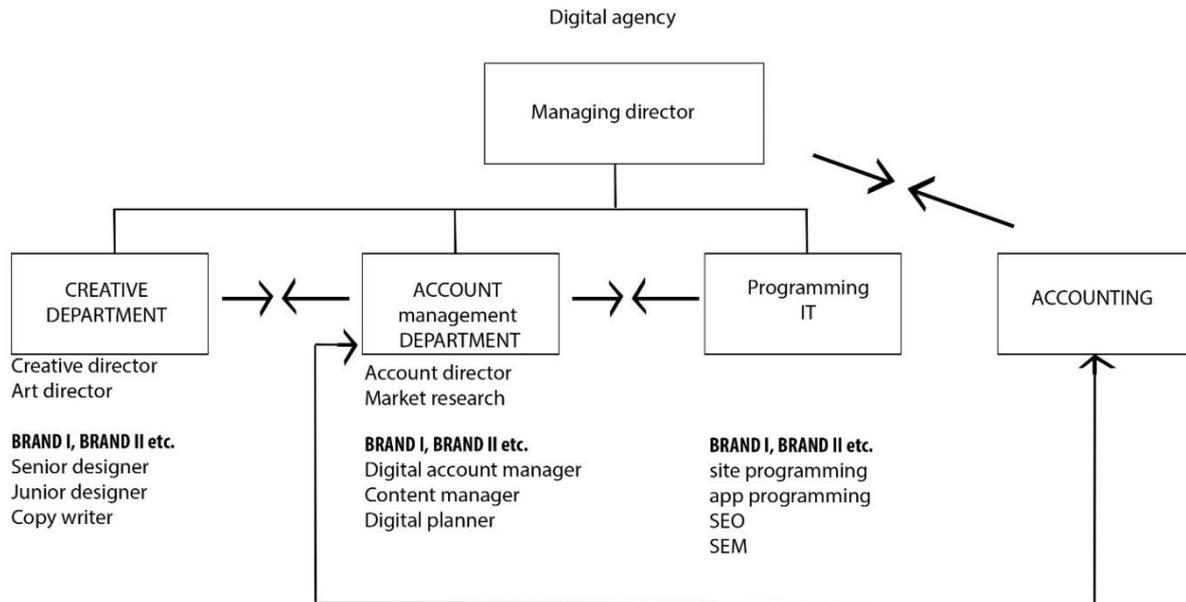

**Figure 2:** Free advertising pattern of multisided platforms - business model - digital advertising agency

#### 4. ORGANIZATIONAL STRUCTURE IN THE DIGITAL MARKETING

As it is important to clearly define the business model, culture of the organization, the business system organizational structure is of equal importance. Business system includes a group of people organized for the performance of tasks. Thus, it is necessary for them to be efficient, flexible and dynamic. These conditions can be met only through appropriate organization structure. Each structure is managed by management. The role of the management is to plan and execute activities, therefore, organization is a process of envisaging activities, rules for conducting such activities, execution and performance measurement. Organization and organizing do not mean the same, organization is a group of people that execute certain tasks led by the management while the organization is a process as the word organization can represent entity, attribute, process or scientific discipline (Jaško, Čudanov, Jevtić and Krivokapić 2013).

When designing organization, top management must align several key factors, such as: well envisaged hierarchy structure, clear function diversification, standardization of behavior in task performance, decision adoption on function level, etc. Better or worse organizational solution depends on the design and the structure of the organization that includes: division of jobs performed, division by departments, coordination mechanisms, dispersion of formal authority and control mechanisms, among other factors. As a basis for structuring we can have functions, processes, products/services, location, matrix of collaboration, project model, innovation centres or strategic business units

Tasks of digital marketing agencies are primarily organized per functions and on the second level per products, that is, brands it manages. Combination of the two results in the general matrix organizational form. Basic functions that need to be covered include creative department, account department, IT department and Accounting Department. Second line of job division, as well as authority is related to the brand that is managed by the dedicated team. So, for example, Coca Cola that is a client of a digital agency within such agency may have its own creative, account and IT team. Such organization enables teams to be directly responsible for the project they lead and in direct communication with the director of the functional department.

**Figure 3:** Job division and departmentalization basis of the digital marketing agency organizational structure

Each department of the digital agency has its clearly defined role as well as the responsibility for the part of the project it manages. Creative Department is in charge of envisaging creative campaigns and their visual and textual shaping. Creative Director is at the top of the hierarchy of the creative department, which is responsible for setting main creative concept, which is, afterwards, delivered to Art Director that will shape the idea visually through given communication channels and then supervise Graphical Designers whether the given brief is in accordance with visual elements. Graphical Designers create key visuals of the campaign and their implementation to given format while Copy Writers create slogans, and all required key words and texts necessary for campaign launch. Within the creative department organization of business is divided to projects, that is, brands that require so, through the volume of other requirements, so, large clients, within the Creative Department, may have their own Art Director, Graphical Designer and their own Copy Writer. This is repeated in all other departments of the digital agency. For example, Account Management Department is responsible for communication with clients, market analysis preparation, proposal of financial investments by the clients, performance analysis as well as delegating jobs to the creative and programming department. Account Director is responsible for the work of Digital Account Managers, whose clear responsibility is visible in daily communication with clients, managing their tasks and organization of them within the digital agency. Digital Account Managers have close cooperation and perform delegation with Content Managers that envisage daily content that is part of the comprehensive campaign but that must be communicated daily with new information by social networks to end users as well as designers that design for the project that is led by such Digital Account Manager. Additionally, the Digital Account Manager supervises the work of the Digital Planner whose responsibility is the investment plan into the online advertising type and channel. Digital Planner develops the plan, invests money into different forms of online ads and analyzes costs and results.

IT or programming department is the department in which sites are programmed, SEO is performed, SEM also, which programs and develops software that is part of a digital campaign. Employed programmers and developers are overseen and managed by Digital Account Managers headed by the Account Director. These three basic departments of each digital agency have teams that are managed under one client. Their interaction is frequent and daily. Accounting (Finance) Department is in charge of all financial transactions within a company, accounting, procuring purchase invoices, residence certificates as well as preparing sales invoices. It is in constant communication with the Account Department including payment and collection plans.

## 5. CONCLUSION

After the analysis, we will elaborate specific configuration traits to conclude configuration hypothesis. Digital marketing agencies are young organizations by definition of the industry which had emerged less than two decades ago. Thus, formalization of behavior is at the minimum, which is in line with the matrix organizational structure. Elaboration of structure is also minimal – just the basic division of work on account, creative, IT and auxiliary jobs defines the organization. Next, average unit size is small, fitting agile teams

demanding by the organization's mission. According to the recent data in the USA (Ibisworld, 2018), 19 406 digital marketing agencies employ 68 059 workers, giving mean value of 3.51 employees per agency. We can find parallel with the multi-sided platform, which is in general network broker organization aimed at investigator or analyst strategies (Miles, Snow, Meyer and Coleman 1978; Snow, Miles and Coleman 1992), acting as a center which outsources most activities. Due to large number of one-employee digital marketing agencies. Technical system is not too regulated, which is aligned with more organic and less mechanic organizational forms and business model described above, however it is sophisticated, which explains large influence of IT staff. Also, operating core is not automated as in Mintzberg's internal assumptions, but crowdsource, leaving organization able to work in flexible organic, forms. Based on analysis of eight assumptions of internal fit given above, we can assume that H1 is correct, based on the Mintzberg's framework. After the analysis of the organization we can conclude that multisided platform and the matrix structure satisfy the Mintzberg's hypothesis of configuration for effective organizational design, because of the internal consistency of the parameters.

External factors are also fit with eight Mintzberg's assumptions on external alignment. Dynamic environment fits organic form of matrix structure and dynamics of the multi-sided platform. Environment is complex, so the decentralization immanent to the matrix teams is more than desirable. Diversified environment asks for dedicated departments, but here we have collision with the internal factor, because digital marketing agencies are small organizations, with average mean of 3.51 employees and slightly higher modulus. This is solved dually – matrix organization facilitates dynamic teams with multiple assignments, and multi-sided platform places digital marketing agency in the role of the broker in the continuum of stable to dynamic network, which promotes decentralization of network members and keeps the small size of the organization. There are no significant hostile impulses, but more elaborate analysis on that, using the Michael Porter (1998) structural analysis framework is a guideline for the future research. Selective decentralization is present as a solution of non-homogeneous task, resulting in general division on creative, account management, IT and auxiliary tasks. There are no significant external entities which control the organization, as can be illustrated by the liberal legal framework, and environment does not imply need for additional power, thus the forms presented in this paper are not centralized, confirming sixth assumption of external fit. We can conclude that this general solution satisfies congruence hypothesis, and that it can become starting point for organizational design as a in-vogue structure in the field. Since the congruence hypothesis is satisfied, we can confirm our hypothesis 1.2, and bearing in mind that there are no collisions between external and internal factors, we can conclude that Mintzberg's extended configuration exists, because both configuration and congruence fit at the same time, confirming our hypothesis 1.3, and finally general hypothesis that matrix organizational structure and multi-sided platform are appropriate solutions for the digital marketing agency business.

**Abstract:** *This paper analyses network models, as a form of network organisation in recent times in the efficiency function of the company's organisational restructuring. It considers their behaviour to changes in business environments that are becoming faster, more turbulent and more unpredictable. The aim is to provide a concise way to explain the possible advantages and disadvantages of network organisation model, which can be used in the process of restructuring the companies, as a priority step towards a more efficient recovery of the companies in the Republic of Srpska and B&H as a whole. Empirical theoretical research and case studies analysis indicate that strategic changes have gone in the direction of network organizations and thus have become a significant source of competitive advantage for companies. Companies in Republic of Srpska most often have a massive and irrational organization, so it is necessary to redesign their organizational structures.*

**Keywords:** *internal, stable, dynamic networks, company, risk*

### 1. INTRODUCTION

The survival and success in the environment characterised by risk, sudden and radical changes are accomplished only by those organisations who adapt to new conditions successfully and on time. In such uncertain and high-risk environment, models of organisation that were effective in relatively stable conditions have now become inadequate (Nelson, 2011).

Managers in modern organisations realise that traditional hierarchical designs are often inadequate for dynamic and complex environment they are facing. Responding to market demands in terms of flexibility and innovation managers find creative ways of structuring and organising work and creating organisations that respond better to, employees and other organisational factors. In the mid 80's years of the last century, organisations around the world, responding to stronger influences of global competitive environment, left the central coordinated approach accepting the structure with different hierarchical levels as more flexible, and who are more similar to the networks than to the traditional pyramids (Achrol, 1997; Powell, 1990; Snow, Miles & Coleman, 1992; Rice & Gattiker, 2000).

One of the important characteristics of modern business is related to the efficient process of business restructuring. The main objective of restructuring is to better market positioning in the context of constant changes in the business environment. With the increasing and unpredictable changes in market environment, the company management is expected to adjust fast and on time, and to realise the possibility of these changes beforehand and to react properly. Although today a network organisation, as a form of the network connected companies, is quite successful, especially as it stimulates development of new products by engaging suppliers whose talents and skills are often better than those of the employees in the company and with relatively little capital and small management team can achieve high business performance, managers have to consider the possible losses of key skills and control over suppliers as one of the potential business risks.

Flexibility, innovation and continuous improvement of business are the elements that are becoming the part of a strategic approach in building the competitive advantage. Great scientific and technological achievements in recent decades have turned the world into a global village in which the production methods and techniques are becoming more uniform. Companies are facing an increasingly common problem of finding a way to adapt to the new, altered business conditions. Due to these characteristics the process of transformation of companies is inevitable and unstoppable. Despite the fact that the network organisation in various forms exists in practice for a number of years, the concept of network business is still very important.

The previous period in the Republic of Srpska, as well as in B&H showed that privatisation was not enough for successful transformation of public companies into joint stock companies, without changing their organisational structure. That is confirmed by the bad business results and company's productivity indicators measured by total income per employee. In the process of revitalising large companies it is essential that managers create models of organisational structure that will be adequate with the environment and compatible with organisational design of company's market economy. Accumulated activities in the value chain in large companies, especially in public companies are giving the importance to the study of network forms, which are created using the concept of the value chain.

## **2. INTER-ORGANISATIONAL DESIGN AND EFFECTIVE ORGANISATIONAL STRUCTURE**

The organisational design should be viewed as an element of strategic capability of the company. It is an essential element of strategic competence or the potential of the company that chooses its strategic position. During the last two decades the highest level managers in many companies have been working on the development of the new structural opportunities to help their companies be more competitive (Robbins & Judge, 2017). When an organisation is developing or changing the structure it makes an organisational design, with decisions about six key elements: specialisation, departmentalisation, commands, the control, centralisation, decentralisation and formalisation (Daft, 2015). The Network organisation is a form of inter-organisational design with a specific purpose. In this sense, the organisational design must be aligned with the strategies as a possibility of achieving the objectives of company's business (Oliveira & Takahashi, 2012; Lunenburg, 2012).

In order to realise the contribution of the organisational structure to successful adaptation and impact on the environment, it is necessary to define the key dimensions of the company's reactions to changes in the business environment. Decisions on the organisational structure must be made in the light of the company's strategic position, as the application of the strategy will be unsuccessful if the organisational structure is not designed to fit the strategic needs and constraints. Managers in modern organisations realise that traditional hierarchical designs are often inadequate for the dynamic and complex environment they are facing (Lin, Tsai & Wu, 2013). Reacting to the market demands in terms of flexibility and innovation managers find creative ways of structuring and organising work and creating organisations that will be able to respond better to the needs of customers, employees and other organisational factors (Twomey, 2002).

New forms of organisational structures are different network approaches of organisational structure. The network structure implies that the company divides its activities into separate entities that are associated with organisational core of the parent organisation. The network structure as a new structuring approach indicates greater competitive advantage, greater flexibility, faster response to changes and the use of information technology as an effective form of organisational structure.

The company managements in the Republic of Srpska, in both private and public sectors, should initiate a reorganisation to reduce the size and "thinning" of the organisation in order to increase the efficiency and market competitiveness. Resistance to the reorganisation exists on many levels because it has resulted in layoffs of employees. However, the transformation is a radical change that entails sacrifices and managements of large and public companies are left with no choice. Managers of large companies in the Republic of Srpska of whom a number are in public companies: Railways RS Stock Company Doboje, Mixed Holding "Electric" Republic of Srpska, Stock company Trebinje and Public Enterprise "The forests of the Republic of Srpska" Sokolac need reject a strategy known in literature as "all under own it's own roof" and a hierarchical organisation. Following the example of companies in other transition economies, it is necessary to adopt an organisation based on the principles of competency-based firms and inter-organisational design which hold the interdependent companies together. Network models can serve businesses to be revitalised and to introduce the principles of market business within larger systems, rather than introducing administrative relations. The network is a group of independent companies that specialise in particular stages in the business chain. The network consists of the central company (core) and peripheral companies where the central company coordinates their activities and takes the role of a broker by connecting the other participants in the network.

Professional and academic communities have a strong and consistent view of how new organisation logic should be predicted according to the capabilities offered by current and upcoming trends in information technology and information systems. In the Republic of Srpska, as well as in B&H, most companies do not keep up with the development trend of information technology as a possibility to influence the economic and organisational performance. That presents a limiting factor for the new approach of introducing technical and technological base for the implementation of organisational change.

### 3. NETWORK ORGANISATION AS A FORM OF NETWORK FORMS

Classical forms of organisations are becoming increasingly dysfunctional influenced by environmental factors that management should effectively respond to. The search of managers for high flexibility resulted in the creation of new forms of organisational design which is called the network structure (Donaldson, 2001; Markides, 2013; Snow, Miles & Coleman, 1992). The basis of the network structure means that the organisation divides the most important functions into separate companies that are connected with organisational core of the parent organisation. The presence of a strong organisational core is significant for this structure, which is surrounded by other organisations, vendors, suppliers, traders, brokers and financial institutions (Snow & Fjeldstad, 2015).

Network organisation as a network form is a flexible structure, which should answer demands with speedy response, high competitiveness and high risk (Hall & Tolbert, 2009). Today, the companies in a restructuring process, as a form of business-technical cooperation often use the network concept developed by Miles and Snow. According to the degree of dislocation, they sorted all the network forms into: internal, stable and dynamic types of networks (Miles & Snow, 1992).

The specific purpose for which the organisations are connecting into the network is the access to the efficient production, distribution, marketing and any other essential business function under the contract. The network structure is inconsistent with parts of the structure that have accentuated vertical level of management and with organisations that seek to control their own development through ownership. In such organisations, research and development are carried out at headquarters, production takes place in the manufacturing facilities owned by the company and sales and marketing are performed by its employees. It is a set of organizations with multilateral relationships that work with one another to achieve common goals (Ahuja, Soda & Zaher, 2012). In the network structure most of these functions are performed outside the organisation and coordination are connected by the computer. That provides managers with a high level of flexibility and allows the organisation to focus on what it does best.

Modern companies are responding to the new dynamic of market conditions and increased uncertainty with insurance risk strategies, entering into cooperative relations with other companies or restructuring the existing organisational structures by creating strategic networks of more tightly or loosely related companies. Such a potential structural possibility for managers who want to reduce or eliminate organisational restrictions is the network organisation. This is a small organisation that performs key business functions with the external supply. (Vega-Redondo, 2013). Quinn (1992) notices that more and more managers are trying out seemingly radical organisation structures in order to implement their strategy of providing "knowledge and services" (p.172). Services and technology of providing services have created a variety of opportunities for new organisational forms driven by knowledge based on fragmentation concept. An example of fragmentation is the relocation practice of production into other organisations. In past times, relocation was considered a sign of weakness, with the organisation admitting it was not able to do a specific task. Quinn (1992) is emphasizing that now the relocation may be a key element of managing an "intelligent company" (p.173). This approach enables organisations to concentrate on what they do best and to bring other activities to companies that are best able to perform such activities. Many large organisations apply the network structure in their production. The form of network structure also suits the production companies whose productive activities require cheap labour, and which can be best used under a contract with foreign suppliers (Robbins, 1992).

Companies like Nike, Reebok and Cisco System realised that they can engage in a big business, without being the owners of production facilities. Ericsson gave its production and even some research and development capacities to the more productive contractors in New Delhi, Singapore, California and in other locations around the world (Reed, Reinhardt & Sains, 2002). The essence of the network organisation is to distinguish the old forms of creating the organisational structures that carry a certain degree of bureaucracy. Organisations are required to be both flexible and stable at the same time with the extreme efficiency. The need for adaptation and concept innovation of business, initiated by a wave of global economic crises is inevitable for most companies. In such circumstances, managers are forced to re-examine the existing and seek new forms of organisational structures to resist the complex and continuous changes in the environment. The idea that comes from this environment is to keep the basic strategic functions as its own, while the rest of the business is given to the most competent suppliers (Carpenter, Banner & Erdogan, 2009).

Moving towards the network form becomes visible in the 80's, last century. With a new model of organisation companies are reducing their competition and managerial hierarchy in the company's core creating a wide range of external activities. New companies have abandoned the growth model through vertical integration and instead tried to make alliances with independent suppliers and / or distributors.

In a search for more efficient organisational structure the managers experimented with different organisational arrangements. As illustrated by figures 1, 2 and 3 some networks have linked suppliers, manufacturers and distributors into long term and stable business relations. Other networks were much more dynamic; with components along the value chain connected under a contract for possible individual or separate projects. Later, managers within firms have created internal network architecture for business units to gradually become competitive in the market and outside the company (Snow, Miles&Coleman, 1992).

In the past, companies used the old structure trying to keep all the components on the organisation level that were necessary for production of a given product or a service. Opposite to that the network organisations are using the components from several companies in the value chain (Quinn &Paquette, 1990).

Although the network organisations show characteristics that are different from the old forms, stable, dynamic and internal network (Figure 1.2 and 3) in addition it still includes elements of earlier organisational forms as their basic elements. Stable network organisation of these changes has: core of the company is associated with numerous limited and carefully selected partners. On the other hand, large multinational matrix organisation with different production units, design and distribution, could replace centrally determined price transfers with originally sales ratio among these units, resulting in creation of an internal network (Kirkpatrick, 1992).

#### **4. FORMS OF NETWORK ORGANISATION: THE ASSUMPTIONS AND LIMITATIONS**

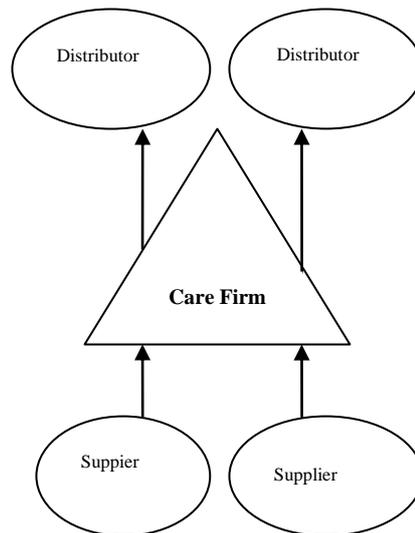

In some economic sectors a significant number of companies are accepting the network model of organisational structure. These activities originate from both; small companies that are trying to connect in order to create favourable market conditions, and from large companies that want to achieve greater flexibility through disintegration, with often used concept of three basic network forms, such as: stable, internal and dynamic network types (Miles & Snow, 2001).

Stable network consists of central (core) organisations whose great number of activities is performed by other companies. It changes the components of firm that is linked with the firm's core by contractual package, trying to increase its flexibility and the competitive ability through the network. The company Nike has become the highly efficient stable network. That way, Nike is specialised in research and development, while the rest of the organisation is in the manufacturing, distribution and sales (Miles & Snow, 2001). Partners who produce exclusively for Nike have a program under the strict tutorship of Nike, which plans to turn them into top-level suppliers.

A stable network comes as the result of a strategic management decision to dislocate the activities to the more competent ones, who can more quickly and at lower costs do the job, while keeping the activities for which is more competent. Instead of producing on its own, company establishes cooperative relations and business and technical cooperation with other organisations. Its stability is based on trust, firm and stable business cooperation between the headquarters of the company and its branches. The company that runs a network form of organisational structure seeks to recruit a certain number of mostly small businesses that perform delegated activities with its support (Fig. 1). However, if there is a radical departure from established standards and if the core of the company can not change their behaviour, there is a reorientation to new subcontractors, which changes the layout of the network. By networking, companies are trying to reduce their centralised functions by dislocating them to the other organisations. Stable type of network allows the company to achieve seemingly unreachable strategic goals with little capital, mobilising small managerial teams (Gottfredson, Puryear & Phillips, 2005).

The parent companies are interested in network members to market-operate outside of existing businesses, considering that in this way it will strengthen those components that support innovation with flexibility. Suppliers are in relation with innovations and services related to design and they develop their adaptive skills through a variety of clients.

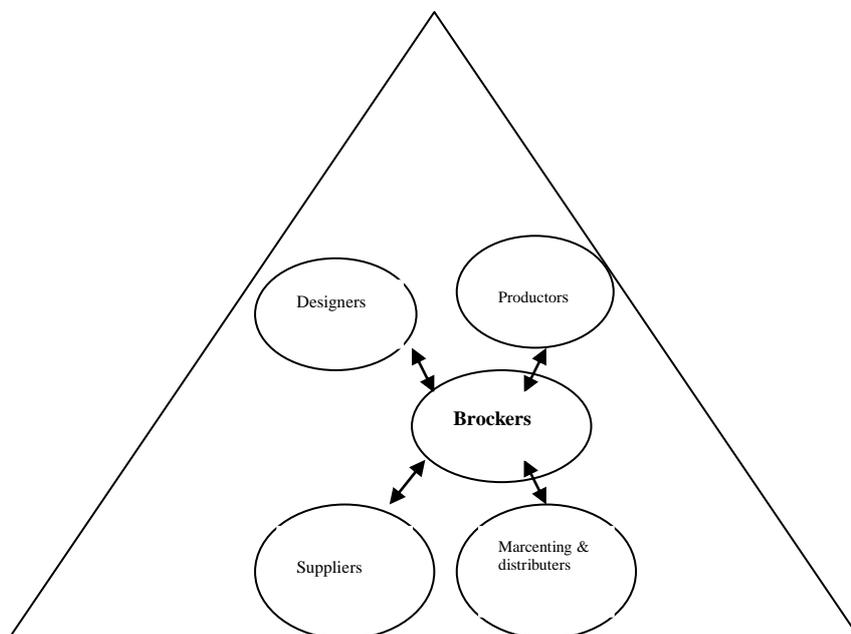

Additionally, stable network can be damaged by reckless and careless modifications. Seeking to ensure that suppliers, some leading companies are trying to determine processes that network partner should use. Within limits, it is useful to have close cooperation to ensure effective connections. However, the leading firm may ultimately be found to manage the property of its partners and to accept the responsibility for their products. In addition, when a independence of a member in network is restricted, creativity come from their managers and staff can bee reduced, Really in its zeal to ensure compliance with its requirements, leading company again transforms the network into a vertically organisation, with all its associated rigidities (Miles&Snow, 1992).

**Figure 1:** Stable network (according to Miles & Snow, 1992).

Internal network is a model of organisational network form where new organisational units are created within the existing model, as separate profit centres. It is often the result of the management's strategic orientation in answering this question: whether to produce or to purchase? It seeks to make a decision to retain the existing and to introduce new activities necessary for completing the product or services forming the network within the organisation by creating more stable and more secure way of supplying the spare parts of semi-finished products, raw materials etc.

These organisational entities are trying with their competitiveness to also produce services that work for both, the company and the market, creating the possibility to improve existing performance. The company management often goes for this model of organisational network because of more efficient quality control of components that are incorporated into the final product. The company management assumes the role of a broker and specialised organisational units become members of the network (Figure 2). Organisational subjects interact with each other as well as with the parent company with established contractual relations based on market principles. The point of an internal network is for company to gain competitive advantage through stable and more secure way of supplying the key components of the parent company and continuous know-how. Internal network can be a bad approach of forming the structure by excessive engagement or by lack of efficiency of internal organisational units (Taylor, 1991).

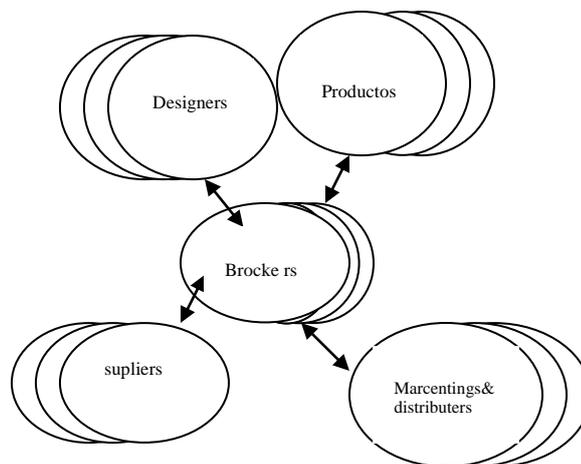

**Figure 2:** Internal network (according to Miles & Snow, 1992).

In such way the internal networks can experience failure due to excessive expansion and badly managed modifications. A rather frequent managerial error in internal networks is in determining the price level and in the supply of resources. Such prices can be accepted because of the greater benefit for the company by creating the stability and more secure way of supplying with more efficient results.

Despite the possible problems, the switch from centrally hierarchy to the internal structure of the market is a new trend of most companies in an effort to change their major units in self-organised businesses, who have a freedom in business (Magidson&Polcha, 1992). Often cited potential risks of internal network model of organisation are: a) that they lead to a potential loss of operational control among partners; b) they are a common cause of losing the strategic control over new technologies; c) that it is hard to acquire new managerial skills that company needs with such organisational form (Miles & Snow, 1999).

Dynamic network is the most flexible form of organisation networking. In competitive environments characterised by rapid and unpredictable changes, companies form networks that are very dynamic. In order for dynamic network to achieve its full potential, it is necessary to have a sufficient number of companies which operate at each point along the value chain and who are willing to work together for a certain job or project. After the job is finished, this network form of organisation is dismissed, so it can later become a part of another strategic alliance. By finding a contractor and by engaging the experts, leading company as network initiator takes the role of a broker (Figure 3).

Dynamic network is created when leading companies, based on a business idea in a specific activity, hire the most competent firms under the best conditions to implement that idea as a project task. It is a temporary form of organisational connectivity suitable for business collaboration based on the contractual relations with a purpose of realising an innovation and making a quick profit. This network form allows organisations to achieve significant results by investing a small capital and by having a small number of permanent staff, with basic competence, knowledge and management abilities. In such circumstances, the main company sees the chance and collects funds that are for the most part or wholly owned by other companies. Company management typically relies on a limited set of basic skills such as: manufacturing, design and marketing services (Sollosy & Parboteeah, 2015).

**Figure 3:** Dynamic network (according to Miles & Snow, 1992).

A dynamic network organisation is focused on efficiency. The efficiency of the network organisation can bring the structuring companies into operating units with a small number of employees or work teams who manage themselves. It is a convenient form for those companies with innovative and entrepreneurial behaviour.

Besides tangible assets being a limiting factor for the development of network organisation for many companies, today more and more pronounced limiting factor in developed economies are the human resources. Companies are basing their business success in a modern business on the know-how rather than on the technical and technological superiority. Thus the economies of developed countries do not have the problem of technology as a limiting factor of business compared to the organisational culture which represents one of the major barriers for development of network structures.

Despite numerous advantages of network form it is important that managers recognise the possible risks of this type of organisational structure. Important strategic issues could be loss of key skills and loss of control of the supplier. Lack of network organisation occurs when products produced by external associates give

suppliers too much power over producers. This situation is possible when a certain manufacturer of key components depends on only one supplier, or a few of them (Quinn & Hilmer, 1994; Cesarani, 2014).

## 5. CONCLUSION

Previous observations show that the network organisational models are generated by strategy changes in companies and large enterprises, which have been faced in recent years with the appearance of rapid, often unpredictable changes in the global environment. A powerful wave of changes caused by the development of sophisticated technology, and new categories of customers with high demands, marked the modern business. In such circumstances, company management chooses new strategies that enable companies to compete in a rapidly changing and unpredictable environment. Theoretical studies and practical examples show that strategic changes went in direction of network organisations and thus became a significant source of company's competitive benefits.

All assumptions regarding the new model of network organisation as a network form of organisational structure suggest that the choice of organisational structure model must meet several criteria and conditions. Network organisation has significant advantages and disadvantages for the successful implementation of this structure. Despite the benefits, company management must reckon with the risk that accompanies the online organisation. The presented examples of companies known in the theory and practice to have successfully applied a form of network organisational structure can not be understood as regularity, but rather as a system of consideration in the selection of appropriate solutions.

It could be argued that the theoretical assumptions presented in this paper should be guidelines for decision making about problems of structure for analysis and adequate access for validation. In this regard, any particular organisation should review its structure, it should study the theoretical models and to eventually find a solution that is appropriate for particular case. Selecting a specific model should be based on the situational approach. This means that when designing the organisation a whole set of heterogeneous variables of organisational design that characterise the global business environment should be on mind. The best organisational structure is the one that allows the company to successfully achieve goals and that is at the same time favourable to its size, technology and competitive environment.

Companies and large corporations in the Republic of Srpska, as well as in B&H have massive, inefficient and costly organisation because the conditions that they are in are favourable for it, and changing the conditions must inevitably lead to changes in their organisational structure. As a possible solution for redesign of the organisation model of the network form, despite the hazards and risks, is one of the acceptable solutions. Proximity to the developed European markets is a priority for faster delivery of goods, and also allows the transfer of knowledge, technology and production. It is also convenient to connect the companies from the Republic of Srpska with foreign partners and spread the inter-organisational learning through modular form of networking. In addition, companies can use the convenience of an internal network to attract investments, and this is an opportunity for investors to invest in a distinct and attractive technologies and productions. Stable network is changing the organisational design and allows more efficient decentralised decision making, while implementation of a dynamic network as a temporary form of connectivity allows convenient way of cooperation in the realisation of business ideas between companies and entrepreneurs.

**Abstract:** *Organizations are forced to adapt to impulses from the environment in order to develop their business performances. The aggravating circumstance is that they often lack the knowledge to determine the direction of these changes, so sometimes they seek help from consultants who can create a framework for successful organizational adaptation or even restructuring, thanks to their expertise and experience. However, it is never an easy task, since consultants have to take into account all the specificities of their clients and create solutions that are suitable for them. Also, these experts must be prepared to cope with all kinds of the resistance that they will face during these projects. This paper presents approaches that they use to identify appropriate suggestions, as well as to help top management in overcoming the barriers that could jeopardize the successful implementation of these projects.*

**Keywords:** *consulting, organizational change, organizational restructuring, resistance*

### 1. INTRODUCTION

The consulting industry in the 21st century is experiencing great expansion (Orr & Orr, 2013), and its current value at the global level is over 250 billion US dollars (Consultancy.uk, 2018). As such, it has managed to find its place in a large number of different business areas (Krivokapić, Savić, & Čudanov, 2016). The consultants' assistance is of particular importance in designing and implementing organizational changes (Kubr, 2002). Organizational restructuring is based on organizational changes, and can be projected in many ways, which depends on the specificities of the client's problems. Regardless of the modality of organizational restructuring, the role of consultants is to provide guidance through the successful implementation of this project, and to help with the easiest possible implementation of the proposed changes. They analyze the problems through the prism of their previous experiences (Perchthold & Sutton, 2010) and then try to determine how these problems can be solved in the most effective manner.

Despite the unquestionable awareness that the help of experts is needed to get out of the crisis, managers are reluctant to opt for their engagement because they do not want to jeopardize their own expertise, integrity or authority, and sometimes they want to protect some of their interests, so they can be afraid of the arrival of external and objective participants who could threaten them. Also, recommendations from the consultants can be considered as a critique of their work, so it is not uncommon situation where the proposed solutions are bit adjusted in order to be in line with the views of top management. On the other hand, consultants' skills will reduce the effort the organization has to invest in order to reach the desired effects of this transformation (Sperry, 2013). They are expected to propose a restructuring direction, taking into account the specificities of a particular organization and considering its real possibilities.

The consultants often try to re-sell the solutions they have used on previous similar jobs, in order to make as little effort as possible, although there is the fact that each organization is different and that something that has brought success in one does not guarantee the same result in another organization. The client, on the other hand, may have different opinions on such solutions. Sometimes he opposes them because he thinks that the consultant will not give proper attention to his problem, but there are also situations in which he insists on these tried and tested solutions that have previously yielded results because new alternatives carry some sort of uncertainty (Baaij, 2013). Earlier solutions can be a good starting point that needs to be further developed into a model that will be suitable and compatible with the key characteristics of a client's organization, so it is necessary for consultants to become familiar with its problems, experiences and knowledge (Lilja & Poulfelt, 2001), which will be the basis for successful cooperation and generation of enhanced solutions that will help in solving identified problems.

### 2. FOCUS OF CONSULTING EFFORTS

If the proposed changes are more radical, it should be expected that the client organization does not have enough resources, knowledge, or ability for their adequate implementation. In such situations, it is suggested

that the problem is not accessed at once, but through a series of smaller improvement projects that can be achieved in iterations. That way client gradually adjusts to the necessary modifications, with less clutter in its structure (Scott & Barnes, 2011). On the other hand, this approach requires more time for final implementation, given the fact that restructuring takes place in several phases and that each of these partial solutions needs to be brought to life in order to move to the next step. Special attention should be paid to the relationship between these smaller projects and their coordination, in order to achieve full restructuring effects.

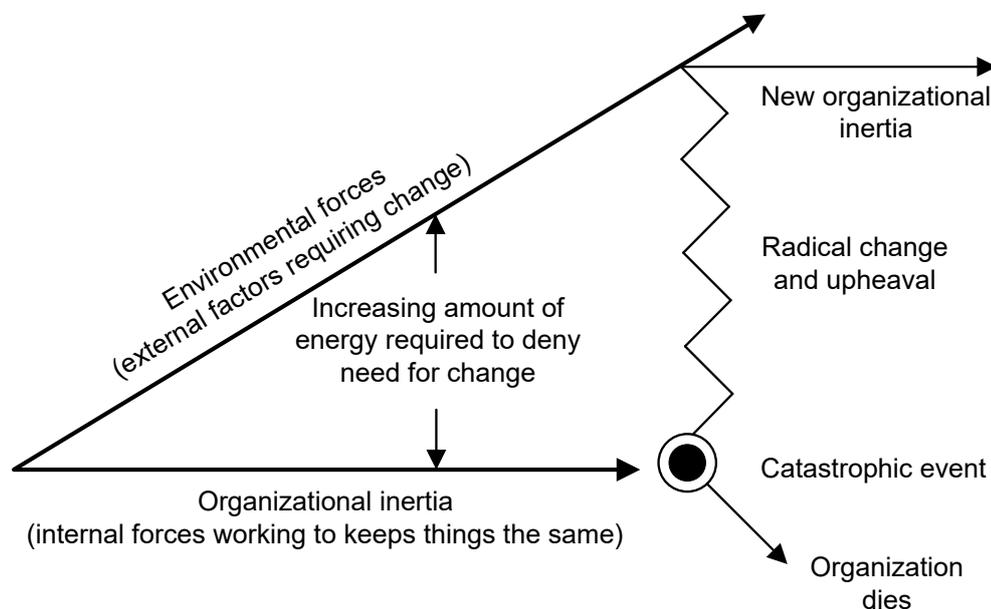

Generally, at the beginning consultants first suggest some simplification in the structure and create preconditions in the form of (Kubr, 2002):

- Removing organizational units that do not have good results or simply are no longer necessary;
- Experimenting with the structure, in order to find the right - the one that best fits into the situation and has the proper interaction with the environment;
- Choosing a new perspective to influence employees' attitudes and thinking about the situation that should be achieved;
- Aligning the efforts of employees and creating a friendly atmosphere that will produce mutual trust between the employees who need to deliver the transformation.

When determining the direction of organizational restructuring, consultants use a range of different methods and models in order to identify main causes for weaker results (Phillips, Trotter, & Phillips, 2015), if they have already appeared in the organization, or potential factors that could endanger those results in the future, if the company still has outputs that are on a satisfactory level. Special attention is paid to key activities, in an attempt to rationalize them in order to achieve maximum efficiency, while the auxiliary activities are reduced to a minimum, which is also rational if one takes into account that their function is to provide support to those that directly affect creation of product or services, and which actually generate revenues for the organization.

In general, organizational transformation is always a delicate and complex process. When companies consider option of hiring experts who can help in planning and implementing organizational changes, many factors should be taken into account. Consultants must assist the client organization by simultaneously taking care of (Kubr, 2002):

- Preparation for organizational transformation, and
- Identification and overcoming resistance to change.

**Figure 1:** The change-resistant organization (Kubr, 2002)

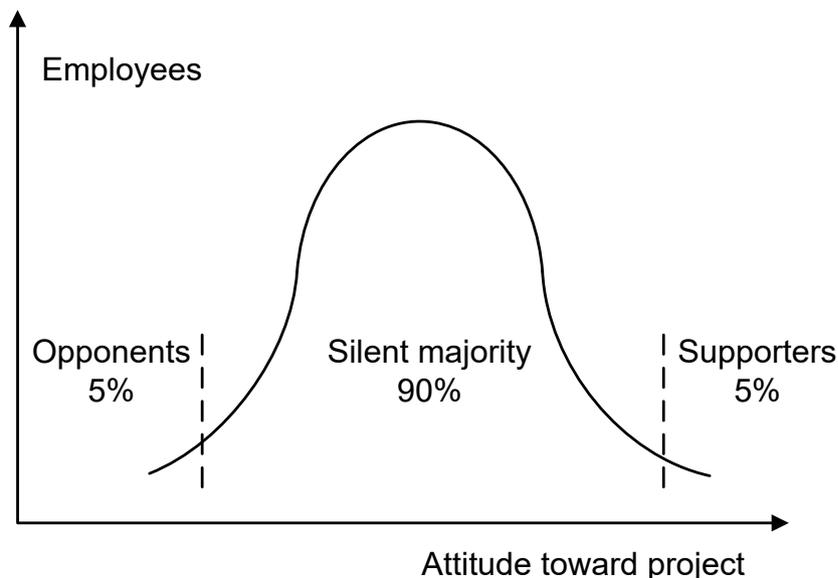

When it comes to preparing an organization for this kind of project, then it is important to analyze its attitude toward change. There are organizations that are highly adaptable, where it is relatively easy to carry transformation processes, but practice shows that there are a far greater number of those who, for some reason, oppose these processes, so they significantly impede the implementation of organizational changes.

These inert organizations do not respond quickly enough to the external influences that endanger their results, and even when they decide to do something, it usually means that they will take some actions that helped and solved problems in the past. However, given the change of the context and environment in which the organization operates, it is very certain that this kind of reaction will not be of great help and will not allow the organization to adapt to the new situation. If management accepts this fact too late, the recovery of the organization and the return to the right path will become even more difficult because the difference between the required and the actual behaviour continues to increase, which means that more effort will be needed to reduce that gap. Consequently, at some point, catastrophic results will be achieved, and then it becomes clear that major changes are necessary in order to avoid the disaster for the organization.

Organizations that are sensitive to organizational change, on the other hand, are better in finding out when such encounters come from the environment. They constantly monitor the situation and continually make some incremental organizational changes in order to adapt to it (Cawsey, Deszca, & Ingols, 2012). This approach requires much greater attention and focus from top management, but at the same time provides better opportunities, given that these organizations have the chance to have a greater influence on changing the environment than the organizations that are inert or just reactive. However, the willingness of the organization to cope with these changes will depend on a number of factors, such as type of management, organizational culture, organizational flexibility, type of change to be implemented, stakeholder requirements, and so on. If management decides that it is better to opt for constant adaptation, it will also affect other elements of the organization.

### 3. OVERCOMING RESISTANCE OF EMPLOYEES

Resistance to organizational change manifests through the resistance of employees in the organization (Cummings & Worley, 2015). Research shows that people generally oppose changes because of uncertainty, since they are afraid for their future. Same situation is with organizational changes - employees fear that they will be left out of work, that their positions will be compromised, their wages will be reduced, they will lose their benefits, and so on (Harris & Gresch, 2010). This fact greatly hampers organizational transformation and puts management and consultants into a situation where it is necessary to create the conditions for a successful implementation of organizational changes. This is primarily related to the change of the awareness and attitudes so that employees realize that such changes will bring progress and that otherwise the existence will be questioned, and everyone will feel the negative consequences. There is also a paradox that lies in the fact that employees are more aware of the need for change when the situation becomes very critical, so that greater problems actually facilitate psychological preparation for the transformation itself.

**Figure 2:** Employees' attitudes toward change (Dulanović & Jaško, 2005)

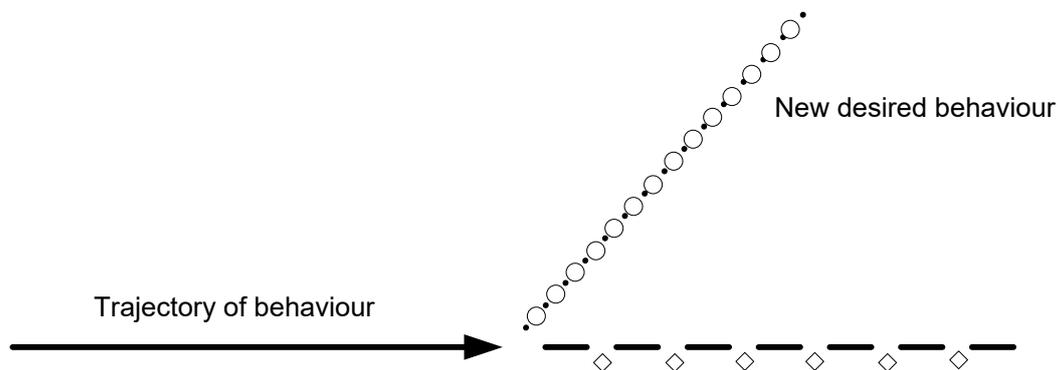

Employees are not easily convinced of why they should work differently, even if they really start doing it. It is crucial that they understand the need for it, not only to mechanically adopt new principles because of fear of punishment. Research shows that their willingness to change depends on the frequency of change, their involvement in planning these actions, as well as on the impacts and effects that these changes carry (Rafferty & Griffin, 2006).

In general, there are three factors that are considered to affect the behaviour change of employees, but only one of them essentially leads to the desired results. These factors are (Weiss, 2002):

- Power,
- Normative pressures, and
- Awareness of the satisfaction of one's own interests.

Management through the power of its authority can require certain behaviour in the workplace. If employees really act the way they are expected, then they can be rewarded, otherwise they may face a certain kind of punishment. Accordingly, they are trying to comply with the requirements, which can lead to the desired changes, but these are often short-term and do not encourage essential motivation. It should also be remembered that the punishment and elimination of those who oppose change can cause opposite effects and even greater problems in the organization (Lines, 2004).

- Constant reward must be provided
- ◇ Constant punishment must be provided

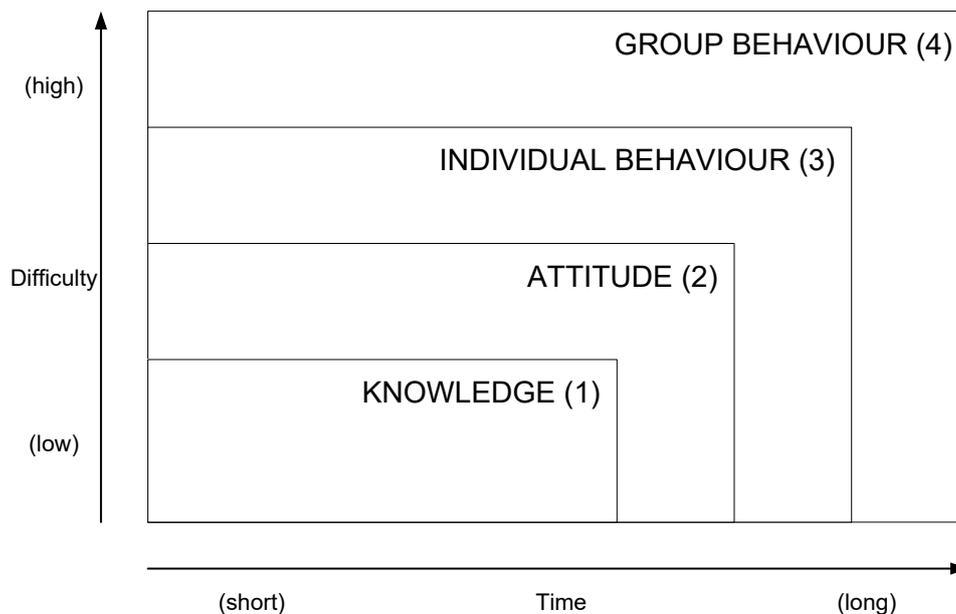

**Figure 3:** Impact of reward and punishment on behaviour (Weiss, 2002)

Similar, mainly short-term results are obtained by normative pressures. These pressures influence the psychology of employees, in an attempt to convince them that the targeted behaviour is actually accepted as the best approach for solving the problem, although in practice this does not have to be the case (Jaško, Čudanov, Jevtić, & Krivokapić, 2013). Employees comply with these pressures and act in accordance with them, but they are still not motivated to find something that will benefit them in this new behaviour. The awareness of satisfying one's own interests is in fact the only real trigger for change. Employees need to be familiar with the essence of these changes, and find something that will have a positive impact on them, so they will accept them and sometimes even affect other employees in order to make these changes easier to live.

Sometimes it happens that some key persons from the client organization disagree with the proposed solutions, which reduces the possibility that the other employees will behave in accordance with them. In these situations it is necessary for consultants to pay attention to the conditions that need to be met in order to implement those changes. First of all it involves (Weiss, 2002):

- *Identifying key people who can support the requirements* - they are mostly those who have a strong impact in an organization, respected by other employees, significant for the implementation itself or who have already had experience in similar situations in the past;
- *Prioritization* - with the help of management, it is necessary to recognize who are the most opposed to change, what are the reasons for such behaviour and how to act on them in order to accept changes, especially if these people have a strong influence on other employees;
- *Planning a specific approach that is tailored to each key person* - people will accept changes if they expect them to improve their situation, so presenting a change plan to each of key people who do not support them can be good solution, because it will be the way to explain the benefits that will be reflected in tackling specific problems they are facing;
- *Client involvement in decision making* - representatives of the client organization should certainly be involved in the work of the consultants in finding an adequate solution, and for later implementation it is especially good to provide them with open criticism and suggestions, as this creates confidence and conditions for the ultimate solution of a higher quality;
- *Setting and monitoring accountability* - defining specific responsibilities in both planning and implementing stages creates conditions for each involved party to focus better on its part of the work, thus making cooperation more successful.

However, changing behaviour and thinking is a very complex and difficult process. Research shows that the change in human thinking occurs through different phases (Chitale, Mohanty, & Dubey, 2012). In the first step, the key is the acceptance that in the organization things should be done differently than before, and this is the moment where it should be clear why management is insisting on it. In the next step this will affect the change of employee's attitudes on specific issues, because he will accept the change as something that is necessary for the survival and further development of the organization. (Un)Consciously, his behaviour becomes different; he begins to work in a new manner, as requested from him. Finally, when more employees reach this stage, then there will be changes in behaviour at organizational or group level, which increases the chances of successful organizational restructuring. Each of these phases requires a certain time investment, but is necessary in order to meet the goals that are set.

**Figure 4:** A model for creating planned change (Chitale, Mohanty, & Dubey, 2012)

In general, key barriers to organizational change are (Dulanović & Jaško, 2005):

- *Retirement schemes that support the old way of work* - employees are afraid to change their behaviour and ways of doing work if the salary systems are not designed so that they follow and reward those efforts appropriately;
- *Threats to the established balance of power* - in the organization at any moment there is an established hierarchy of authority and power, and organizational changes can impair this existing system, thereby exacerbating individuals or groups from the influence they had before, so they are firmly opposed to any kind of change;
- *Intra-bulk conflicts that hinder cooperation between employees* - given the degree of competition that exists between employees or between organizational units, which arises from personal goals or resource constraints that are necessary for carrying out activities, it is not uncommon for organizations to encounter conflicts that can significantly impede the implementation of organizational changes, especially if one takes into account that the successful implementation of such ventures requires the cooperation of all employees at all levels;
- *Incompatibility of changes with the existing organizational culture* - employees in the organization have a common, generally accepted set of values and beliefs that are difficult to change, and problems can arise when organizational changes bring something that is not in line with the existing organizational culture, and requires from them to behave according to other norms that differ considerably from those they are used to;
- *A large amount of financial resources needed for the implementation of changes* – it happens that none of the above-mentioned obstacles occurs - the need for change is obvious and the employees are aware and willing to carry the burden of organizational transformation, but that the organization does not have enough financial or other resources which are necessary for the implementation of these kind of ventures, so in such situations restructuring practically becomes impossible.

Employees often do not accept the inevitability of changes as long as the organization achieves results that are on a satisfactory level. Even when the results start to get worse, many of employees do not want to accept changes, especially if the measures that are taken at the very beginning affect them in some way.

There is also a group of people that is not affected with the decline of the results, because it does not concern their part of the job or they already have an alternative plan in the form of moving to another organization or starting their own business. However, if transformation is the only solution, employees must accept the necessity of organizational changes (Mitchell, 2015). In the long run, it can be the only real way out of the problems which the organization has. Experts believe that managers and consultants must work on it together with the employees, and it is recommended that they introduce the experiences of other organizations that have found themselves in similar situations.

#### 4. CONCLUSION

Consulting has a very important role in designing and creating a new look for the organization. The impact of consulting is multiple and can be reflected in changing the organization's strategy, its structure, culture, relationships among employees, reward systems, processes and activities being implemented, personnel development, and so on. Depending on the specific focus of the consulting activity, it is possible to consider consulting at the level of the whole organization and consulting specialized in its particular field. Sometimes the needed focus is very obvious - if problems arise in a large number of processes and activities, then it is quite clear that it is necessary to make changes throughout the organization. However, the more common situation is that the symptoms are not so visible, so the diagnosis cannot be precise without looking at the wider picture, in order to determine what is bothering the organization in its attempts to achieve better business results.

Considering the character of the organization on the one hand, and the complexity of the environment and the interaction with it on the other, these rounds cannot be made without major organizational changes. In practice, such transformation is generally very difficult to implement (Ahlstrom & Bruton, 2010). The reasons are different, but are mostly related to the fear of what the future brings (Cummings & Worley, 2015), because it is not certain how the organization will perform in these new circumstances, with the aggravating fact that the employees usually resist change. If there are a number of factors that hinder business and generally have a negative impact on the business performance of the organization, then top management is in a very unfavourable situation because it is unable to determine where the organization actually is going and what the goals it aims for are. Strategic goals are brought into question, and then through the hierarchy they drop to the operational level, so the problems and uncertainties appear throughout the whole organization. Then it becomes clear that the help of the experts is necessary, because further development is threatened, and over time existence can be endangered.

In general, it is considered that organizational restructuring actually creates a framework for effectively running the process within the organization, as well as for the functioning of the entire organizational systems, but there are also rapid and major changes in this field that transform previously established structures into rigid entities that do not match new demands in the right way (Kubr, 2002). What makes this type of restructuring very delicate is the fact that it is impossible to find a model that will fit into any situation without any minor or greater adaptation, and it is imperative to set every new consultant task in the appropriate context and to perceive its specificities and key elements. The consultant's experience, however, is of great help, and serves to set the starting assumptions, and the recognition of symptoms and potential directions of action (Baaij, 2013), but it should in no way ignore the specificities of the organization itself and its environment, so even solutions that were once applied with successful results no longer guarantee a positive outcome, nor can be a pattern for success. For this reason, in the process of organizational restructuring consultants pay special attention to the situation analysis and try to identify the critical points so they can generate a model that will, as an output, have a solution that corresponds to the specific situation and lead to an improvement of the client organization's performance.

# AUTHENTIC LEADERSHIP: CONCEPTUALIZING AND DEVELOPMENT

Vuk Mirčetić  
Institute for Law and Finance  
e-mail: vuk.mircetic@ipf.rs

**Abstract:** *This article addresses authentic leadership and examines its conceptualizing and development. Numerous data regarding leadership effectiveness can be found in literature and some of it single out authentic leadership as the most effective leadership approach of contemporary time. In modern time, changes occur due to digitalization and uprising of techniques, technologies and globalization. Effectiveness of a modern leader is reflected not only through developing and reaching goals, but also in having motivated followers. Individual must have knowledge regarding activities that he should undertake in order to become effective leader. This paper examines and sublimates rich theoretical approaches on authentic leadership into simple steps and proposes guide on becoming authentic leader, which can be used as a tool by a reader who wants to become effective authentic leaders. Reading this article will give individual an opportunity to nurture his authenticity and become an authentic leader by using tool and following simple steps.*

**Keywords:** *Leadership, Authenticity, Modern Leaders, Authentic Leadership Development, Leadership Effectiveness*

## 1. INTRODUCTION

The corporate world is changing more rapidly. Digitalization and uprising of techniques, technologies and globalization are calls for a renewed focus on what constitutes genuine leadership. The world economic crisis began in 2007 and it is still one of the current issues facing public, private, governmental and other organizations. Business environment has witnessed numerous cases of fraud and governance failures, especially over last few decades (Detert, Trevino, & Sweitzer, 2008; Sumanth & Hannah, 2014). In addition to that, constant changes of contextual factors are making negative influence to the business environment.

Numerous authors struggled to single out the most effective type of a leader of contemporary time and for some of them. This paper analyzes George's (2003, 2007) authentic leadership theory, expands on similar approaches and sublimates them contributing to leadership literature by offering readers guide on becoming authentic leader. As George (2003) stated, there is a need for leaders who lead with purpose, values, and integrity; leaders who build enduring organizations, motivate their employees to provide superior customer service, and create long-term value for shareholders. Leader should have established values, nurture and share them with subordinates. Some pools suggest that twenty percent of workers in United States of America share feeling that their senior managers do not live the values they espouse (Bates, 2002) and authors (Simons, 2002; Simons, Friedman, Liu, & McLean Parks, 2007) share opinion that inconsistency between espoused and enacted values has serious implications for organizations' viability and employees' health and well-being.

Avolio and Gardner (2005) suggested that such challenges have precipitated a renewed focus on restoring confidence, hope, and optimism; being able to rapidly bounce back from catastrophic events and display resiliency; helping people in their search for meaning and connection by fostering a new self-awareness; and genuinely relating to all stakeholders (associates, customers, suppliers, owners, and communities). Leader is observed as an individual who brings people together to pursue a shared purpose. In order to learn about effective authentic leadership, first we have to define leadership itself.

## 2. DEFINING LEADERSHIP

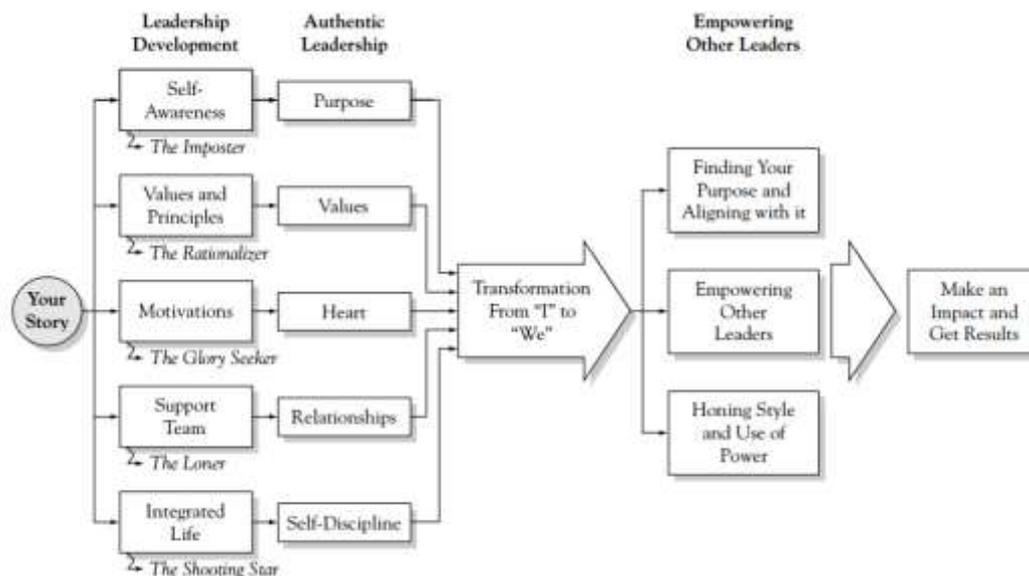

Leadership is a complex process that is difficult to characterize. In the years of studying leadership so far, numerous theoretical approaches to the complexity of the leadership process have arisen. Stogdill (1974) points out that there are as much leadership definitions as authors that tried to define those. Rost (1991) analyzed more than two hundred leadership definitions conducted in period 1900 to 1990. His work gave us insights of leadership approaches in that period and its development. A significant number of authors, such as Burns (1978), Jago (1982), Heller & Van Til (1983) and Hollander (1992) share opinion that leaders need followers and that followers need leaders. Analogously to that, leadership does not exist without leaders or followers. One of the first leadership scholars More (1927) considered leadership as ability of a leader to transfer his will to followers and encourage obedience, respect, loyalty and cooperation. Other authors in that time also define leadership as making followers act as leader wants. Follet (1924) determined leadership as a possibility to increase feeling of power existence rather than demonstrating power to followers.

Nowadays, leadership is observed through mutual relations of leader and followers. New concept is called group dynamics and it puts group members in focus. Tannenbaum & Schmidt (1973) in their research regarding directive leadership came to the evidence that there is a need for acknowledging motivation and interpersonal relationships. In years to come, Burns (1978) defined leadership as a process of mobilizing followers by an individual with certain motives and values, in context of competing and conflict and in order to achieve common or individual goals. One of the modern approaches to leadership that puts group and group members in focus is authentic leadership.

### 3. CONCEPTUALIZING OF AUTHENTIC LEADERSHIP

Until present days, there is no consensus reached regarding unique authentic leadership style. If there is only one approach to authentic leadership, that would not be authentic leadership because leadership would be all the same everywhere. Having different approaches to authentic leadership and being different as a leader makes authentic leadership truly authentic.

There is no unique definition of authentic leadership and Chan (2005) points out that there are several different approaches to this leadership style and its' models of development. According to different leadership scholars such as Bass (1990), Bass & Steidlmeier (1999), Burns (1978), Howell & Avolio (1993) authentic leadership was identified in transformational leadership research but never fully articulated and exploring of it continues today. Branson (2007) proposed authentic leadership development is more than just having explicit knowledge of values and acting of individual. Berkovich (2014) finds that authentic leadership development theory can be explained by functionalist discourse paradigm. Mabey (2013) introduces this paradigm and defined it through improving organizational performance through developing leadership capabilities. Some authors analyzed life story approach to authentic leadership. Accordingly, in work of Shamir and Eilam (2005) life stories have great role in development of authentic leaders as they reflect upon and attach meanings to their life events. Sparrowe (2005) found that process of life story telling is very convenient to authentic leadership development. Authentic leaders are unique, honest to themselves and their close friends and they do what they believe in. They have positive and negative characteristics. Although they make mistakes, by accepting their imperfections and admitting their mistakes, leaders connect to followers and empower them. There is no unique way of becoming authentic leader, but there are several segments of authentic leadership development: becoming self-aware, creating values and principles, finding motivation, building support team, making and having integrated life, as illustrated in Figure 1.

**Figure 1:** Getting to Results and Making an Impact  
Source: George & Sims, 2007.

Additionally, Northouse (2016) outlines three perspectives of authentic leadership: intrapersonal, interpersonal and developmental. Intrapersonal perspective incorporates the leader's self-knowledge, self-regulation, and self-concept. Shamir and Eilam (2005) elucidate that leader is an original not copy. Eagly (2005) described interpersonal perspective as relational, created by leaders and followers together. Avolio analyzed authentic leadership through developmental perspective with several associates (Avolio & Gardner, 2005; Gardner, Avolio, & Walumbwa, 2005; Walumbwa, Avolio, Gardner, Wernsing, & Peterson, 2008). They conceptualized authentic leadership as a pattern of leader behavior that develops in people in time and can be triggered by major life events.

Authentic leaders inspire and empower followers to lead. George and Sims (2007) analyzed this approach to authentic leadership and proposed new definition of leadership: *The authentic leader brings people together around a shared purpose and empowers them to step up and lead authentically in order to create value for all stakeholders.* Having authentic leadership development segments in mind George (2007) stated there are five dimensions of authentic leadership: *pursuing purpose with passion, practicing solid values, leading with heart, establishing connected relationships and demonstrating self-discipline.*

### 3.1. Becoming self-aware

Self-awareness is defined as conscious knowledge of individual's own character, feelings, motives, and desires.

As individuals, we are complex human beings, constantly evolving and adapting to environment changes that makes knowing ourselves very difficult. George (2007) stated that it is very important for a leader to be self-aware because that would make him feel comfortable. There is possibility to get caught up in chasing external symbols of success if leader is not self-aware.

It is easier for individual to lead effectively when he develops consciousness about his needs, desires, values, strengths and weaknesses, vulnerabilities, motivation and other segments that makes him who he really is. If leader is being mindful about himself, he can develop a pattern of behavior. If behavior template exists, it is easier for a leader to lead because he knows how to act in a certain situation before it happened.

Being self-aware enables authentic leaders to analyze their life stories, passions, values and principles and to use that knowledge to make an impact or effect change. Acknowledging vulnerabilities and accepting weaknesses allows leaders to work and build on their strengths. Once leader has consciousness about himself, it enables him to correct his course direction when he finds that he is not on the right path.

### 3.2. Creating Values and Principles

Values present person's principles or standards of behavior; individual's judgment of what is important in life.

Maio, Olson, Bernard & Luke (2003) define values as *abstract ideals that function as important guiding principles.* For the purpose of this paper, values and principles are observed as guides for leadership. Although in different part of the world values are ordered and prioritized differently, there are researches on managerial behavior which strongly suggest that value categories for managers remain the same (Hofstede, 1991; Schwartz, 1992).

Getting to know what is important in a life for a leader, he can use that knowledge to guide his acts. George (2007) discussed that values are derived from individual's beliefs and convictions. There are different sets of values such as making an impact or a change, devoting life to family or helping someone. There is not one right set of values, because it is individual's judgment of what is important.

Leadership principles are values translated into action. Having mindful about values and what is important in his life allows leader to establish principles by which he intends to lead and share it with subordinates. Established principles should include role ethicality and role morality. Role morality is a term that has been discussed mostly in philosophy (Andre, 1991; Gibson, 2003), and it was defined by Applbaum (1999) as *claim[ing] a moral permission to harm others in ways that, if not for the role, would be wrong.* Radtke (2008) stated that this term has principally referred to entire professions and different to that term, role ethicality is organization specific. It is important do have in mind difference between role-based determination of ethicality and personal ethics that are based on individual's personal ethics. Gibson (2003) defined this difference as *genuine and useful moral distinction.*

Having clear understanding of ethical boundaries is very important for an authentic leader. These are limits of leader's actions that are based on his values. Ethical boundaries restricts leader of taking actions that are not based on his standards and values. Set of these boundaries help leader decide what actions to undertake in times of uncertainty or when he is under pressure.

Unethical behavior is frequently present in contemporary time and it is considered as violating norms of society for moral behavior (Appelbaum, Iaconi & Matousek, 2007). George (2007) argues that having ethical boundaries coordinated with moral compass, allows leader to let his leadership autopilot to take charge in less important activities. When leader is self-aware and have developed values and principles, he knows how he would react in certain situation before it happened and stakeholders do not see hesitance. This also allows him to be himself no matter if people he deals with at the moment are unethical. Current business environment could be corrupted but that will not make leader adapt to negative system. He will maintain to be true to himself and his values.

### 3.3. Finding Motivations

Motivation is defined as a general desire, need or want that generates the energy required for someone to behave in a particular way. Authentic leaders need to sustain motivated, it is very important to understand what motivates them. There are two types of motivations, extrinsic and intrinsic, as presented in Table 1.

**Table 1.** Extrinsic and Intrinsic Motivations (George, 2007)

Extrinsic Motivations	Intrinsic Motivations
• Monetary compensation	• Personal growth
• Having power	• Satisfaction of doing a good job
• Having a title	• Helping others develop
• Public recognition	• Finding meaning from efforts
• Social status	• Being true to one's beliefs
• Winning over others	• Making a difference in the world

Extrinsic motivations are measured by other people. This type of motivation takes the form of power, title, earnings, social status, fame and prestige. Intrinsic motivation represents own internal satisfaction or fulfillment and it refers to behavior that is driven by internal rewards. The key to developing as an authentic leader is balancing extrinsic with intrinsic motivations.

### 3.4. Building Support Team

Support team is defined as a solid network of trusted people who are available to counsel and care for an individual. This trusted network may include individual's spouse or partner, family members, best or close friends, mentors, or even a small personal group.

George (2007) highlights that having a close network of friends on whom they can call when in doubt or in need of help has proven to be extremely important for many authentic leaders. Life is full of unexpected turns and opportunities that can put leader in an unenviable situation. Having built support system that cares for leader and can hold him accountable to his values is important in order to leader stay on the right path. Christansen (2010) struggled to answer his own question - *How can I ensure that my relationship with my family proves to be an enduring source of happiness?* Answering this question is important because family members sometimes are not supporting leader enough or at all. Support team should provide leader with honest feedback, so in times of doubt and uncertainty, leader can rely on his trusted network, but also celebrate with them in times of success. George (2007) share opinion that strong support teams provide affirmation, advice, perspective, calls for course corrections when needed, and, above all, love. Without trustworthy relationships to provide perspective and call for course corrections, leader can be pressured by external forces to respond to their needs and seduced by rewards for fulfilling them and it is easy to go the astray. When leader has developed self-awareness and knows what his values are, role of support team is also to keep him grounded in reality and in course. It is very easy to lose right way without trusted network that provides perspective and guidance and the support leader needs as you venture on your leadership journey.

### 3.5. Making and Having Integrated Life

Having an integrated life means bringing together major elements of individual's personal life and professional life, including work, family, community and friends. Integrated life allows individual to be the same person in each environment.

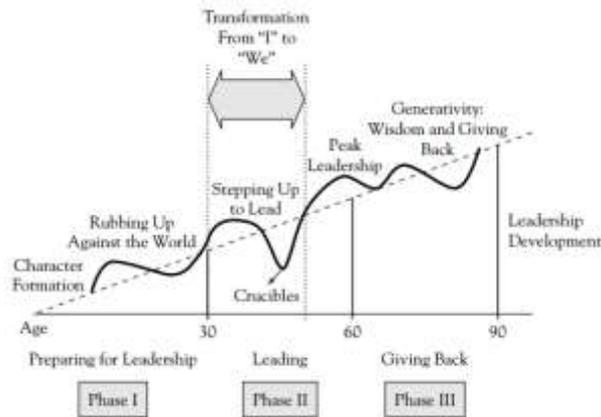

Authentic leaders are their true selves at all time and in every environment. Making integrated life means bringing together all major events in leader's life, both personal and professional life. No matter if leader is surrounded by family, friends work colleagues or strangers, he is at all time the same person. Leader should first identify and prioritize personal goals including spending time with family or friends. It is equally important for a leader to find time for realization of scheduled tasks as well as prioritizing them. Harvard Business School literature (2006) provided a practical time-management methodology which consists of several steps:

1. Articulation of critical and enabling goals;
2. Prioritizing goals and breaking them into tasks;
3. Using daily log to understand how individual currently spends time and what are unimportant activities that crowd out the things that really matter to individual;
4. Scheduling priority tasks, leaving enough time open for unanticipated situations and opportunities.

George (2007) stated that authentic leaders are constantly aware of the importance of staying grounded. They need to stay grounded during the high points and not forgetting who they are during the low points.

#### 4. EFFECTIVE AUTHENTIC LEADERSHIP

It is very important for authentic leader to find his locus of action because that gives him opportunity to perform effectively and enjoy doing that. As illustrated in Figure 2, there are three phases in developing authentic leadership effectiveness: preparing for leadership, leading and giving back.

**Figure 2.** The Transformation from “I” to “We”  
Source: George & Sims, 2007

Being self-aware, knowing what motivates him, understanding his strengths and weaknesses allows leader to discover his sweet spot. George (2007) first introduces sweet spot as a term and it represented the intersection of leader's motivations and his capabilities. Authentic leaders lead effectively if he achieves good results and have a great feeling doing that. The transformation from “I” to “We” is made and his subordinates are mentored, motivated and empowered to lead. Followers can be empowered by many different actions, from listening to them, helping and guiding them to engaging them, but also by simply showing up and supporting. At different times, different forms of empowerments should be used. It is important for a leader to use appropriate action depending on situation but also follower's characteristics. For authentic leaders is crucially important to hone his leadership style and make it as unique as possible.

#### 5. CONCLUSION

Differences are what make authentic leadership truly unique and authentic. Developing leadership style by learning from own and someone's experiences and not copying is what makes an authentic leader. Therefore, the purpose of this study was to analyze George's authentic leadership approach, expand on research of other authors and to offer reader guide on becoming authentic leader with simple steps. In order to develop authentic leadership style, individual needs to go through all principal areas that were analyzed in this paper: gaining self-awareness; knowing and practicing your values and principles; knowing what drives him and balancing extrinsic and intrinsic motivations; building and maintaining support team; staying grounded by having integrated life; and understanding passions and purpose of his leadership.

Self-aware leader has developed consciousness about segments that makes him who he really is. Having developed values ensure guiding principles for leadership of an individual, that is important also for staying grounded. Another important segment of authentic leadership is having knowledge regarding what drives leader as a person, what are his intrinsic and extrinsic motivations. Because life is full of challenging situations that can be misleading, it is important for authentic leaders to have strong support system, network consisted of trustworthy and important persons in their life, such as family and close friends. Accordingly, leaders should integrate all stated segments into his life and lead authentically, because he is the same in every situation. Followers trust authentic leaders and that motivate them to achieve superior results. Having relation like this with subordinates empowers them to take control and lead.

All leaders work on optimizing their effectiveness in order to achieve superior results. Authentic leader are more effective because they achieve desired results, enjoy while leading and motivate and empower followers. Development of authentic leadership results in getting the best from leaders, their subordinates and organization. Success of authentic leaders is to be lead by their passion and to lead effectively doing what they enjoy doing. Achieving high levels of performance permanently, maintaining motivation of followers and empower them are the ultimate mark of authentic leaders.

## ACQUIRING THE KNOWLEDGE ABOUT STANDARDS IN THE DIGITAL ERA – CASE OF SMES OPERATING IN SERBIA

Ivana Mijatović<sup>1</sup>, Biljana Tošić<sup>1</sup>, Milan Jovanović<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, e-mail: ivanamt@fon.bg.ac.rs

**Abstract:** *In European Union only 0.2% and in Serbia only 0.6% of all enterprises are not Small and Medium Enterprises (SMEs). Improving capabilities of SMEs to be competitive in the global market in a knowledge economy is an important, specific and complex task. How can SMEs be helped to acquire needed information and knowledge? What sources of knowledge in the digital era are most suitable to SMEs? The aim of this paper is to explore main factors which affect SMEs' choice of a dominant source for acquiring information and the knowledge about standards. The questionnaire survey research method was used to seek the response from representatives of 130 SMEs operating in Serbia. Our findings indicate four sources – relevant Web sites, service of consultants, customers and business and other partners. The larger SMEs with the long tradition in business will have more chances to use Websites as the primary source for gaining knowledge about standards. Domestic SMEs shape their decisions to hire consultants services predominantly because of the negative perception of standards. The usage of customer inputs as the dominant source for gaining information and transfer of knowledge about standards are influenced by SMEs' experience in business (years) and negative perception of benefits of standards. In the digital era, SMEs still suffer from lack of resources or capabilities to use the WEB and the Internet for acquiring information and knowledge about standards.*

**Keywords:** Standards, SMEs, Certification, Knowledge, Digital Era

### 1. INTRODUCTION

In the European Union, 99.8% of all enterprises are SMEs and about 23 million SMEs provide around 75 million jobs accounting for 67% of total employment in a non-financial business sector (European Commission, 2018). According to the Annual Report on European SMEs (2017), SMEs are a major source of entrepreneurial skills, innovation, and employment. In Serbia, 99.4% of all enterprises are SMEs. SMEs in Serbia contribute a share of roughly 60% of employment and less than 50% of value added, compared with the respective EU averages of 67% and 57%. Micro-firms make a particularly small contribution, providing only 10% of value added, 11 percentage points lower than in the EU (SBA, 2016).

Capabilities of SMEs to be competitive on the global market in a knowledge economy are high in agendas of many actors – governments, international organizations, chambers of commerce, professional and industry associations. In emerging economies, the contribution of SMEs is to drive the development of a knowledge-based economy and on the other side, in developed countries, SMEs support is seen as crucial for the recovery after the global financial crisis (Massaro et al., 2016). However, SMEs are most vulnerable to – lack of information, knowledge, and incentive; skill shortages; limited market power; high dependence on partners; market behavior of competitors and information asymmetry affect them in many ways (La Rocca et al., 2011; Chong et al., 2016). Study of Chong et al. (2016), based on data collected from owners and managers of SMEs, showed that "external knowledge is believed to be an important need by the enterprises". In many cases, the ability of SMEs to acquire new knowledge is dominant prerequisite to develop and sustain competitive advantage.

The aim of this paper is to explore main factors which affect SMEs' choice of a dominant source for acquiring information and the knowledge about standards. In the digital era, it would be logical that the answer can be found on the Web and the Internet. However, information and knowledge about standards, standardization, and related activities might be quite specific. In the next part of this paper, the literature review is given in order to explain needs of SMEs for knowledge about standards, standardization, and certification. Part 3 is dedicated to research methodology (study design, data analysis, and study participants). At the part 4, results of research are given with the summary statistics for discriminant function analysis (DFA). In the part 5, and are given discussion and conclusion remarks.

## 2. LITERATURE REVIEW

According to the European Committee for Electrotechnical Standardization (CENELEC) (2018), a standard is “a document that sets out requirements for a specific item, material, component, system or service or describes, in detail, a particular method or procedure”. A standard can be defined as “an agreed way of doing something” (BSI, 2018). Essentially, standards are base for the functioning of industries on global levels. Not only that standards facilitate the global economy, they are base for the global trade. Standards can help or hinder entrance on specific markets. One of the roles of standards on the global market is to lower an informational asymmetry – fact that producers have much more information than B2B customers and end-users. Standards are commonly accepted benchmarks that transmit information to customers and about a product’s quality and safety characteristics (Nadvi, 2008).

Do you know what is common for DVD, Bluetooth and Wi-Fi? Generally nothing, except that the DVD Forum, the Bluetooth Special Interest Group and the Wi-Fi Alliance are standards development organizations (SDOs). The global economy is shaped, not only by power and competitiveness related to prices, “but increasingly by technological and organizational innovations that are codified in a series of global standards” (Coe and Hess, 2007). Standardization is booming discipline; many organizations develop standards – special agencies of the United Nations, formal standardization development organizations (e.g. ISO, IEC or ITU-T), professional associations (e.g. IEEE), industry associations (e.g. API) and companies. Standards can be very different in their nature. Some of them are generic and applicable to many organizations, no matter their size, area of business or other features. “Product standards include specific designs, technical characteristics, and attributes of a given product, as well as sector-specific technical standards and product safety standards. Such standards are of critical importance, especially to well functioning global production networks without which globally dispersed supply chains could not function” (Nadvi, 2008). Many standards for systems, processes or products define requirements that can be used as a base for certifications.

According to the International Organization for Standardization (ISO), certification is “the provision by an independent body of written assurance (a certificate) that the product, service or system in question meets specific requirements” (ISO, 2018). There are many specific types of certifications, some of them are provided by first parties (e.g. organizations provide objective evidence that can be used in quality assurance), others by second parties (e.g. B2B consumers), or by third parties (by neutral organizations) (Loconto and Busch, 2010). Nowadays, companies perceive certification as a mechanism to signal credibility, build a reputation and provide objective evidence to their B2B customers, partners or actors in the processes of public procurements. Study of Rillo & Mijatovic, (2016), based on data from 5632 small and large manufacturing and service firms of 26 Eastern European countries, showed positive influence of quality certifications of quality management systems as well as that larger, more experienced companies and companies with good ICT capabilities are more likely to be certified. International certification is more important to the companies from developing countries and it is connected with “building of reputation” (Rillo & Mijatovic, 2016).

Li at al. (2018) argue about signaling effect of certification in innovative SMEs in China, finding many issues related to the strength of SMEs to provide certificates to signal to outside potential capital providers, reducing information asymmetry without increase of cost. In the specific economy of China, same authors underline the role of government as a provider of certification which can send a signal to outside capital providers, reduce information asymmetry and cut cost. Study of Heinz and Guldenberg (2010) concludes that modern technologies and management practices such as quality management and flexible production technologies allow SMEs to simultaneously reduce costs and differentiate products. In that way, SMEs can improve their competitiveness on the global market. Same study findings indicated that SMEs with an ambition to grow have higher growth and profitability which support claims that the attitudes and values of SMEs owners and managers impact development and performance.

One of the myths in standardization is that standards are applicable only to large companies, that implementation of standards can cause high expenses and that SMEs cannot benefit from standards (BSI, 2018). While SMEs may be underrepresented in standard writing groups and their interests may thus not be sufficiently taken into account (CEN/CENELEC, 2018), SMEs can definitely benefit from standardization itself. Standards can help them reduce costs, improve their innovative capacity and enhance their competitiveness (European Commission, 2018). That is why it is important to explore the interests of SMEs as potential users of standards. “Through addressing their needs, the use of standards may be significantly increased. Furthermore, if standards take more account of the SMEs perspective, considerable benefits would accrue to all stakeholders in standardization” (European Commission, 2018).

European non-profit association Small Business Standards (SBS) was established to – represent and defend SMEs interests in standardization at the EU and international level; raise SMEs awareness of the benefits of

standards and get more SMEs involved in the standardization process (European Commission, 2018). The SBS is collaborating with all the European organizations for standardization, such as CEN, CENELEC, and ETSI, national standardization bodies as well as the ISO. Amongst one of its main activities, SBS is committed to “raise the awareness of SMEs interests within the European Standardization System through its cooperation with standardization stakeholders and its representation in committees, working groups and task forces related to standardization” (SBS, 2018). This way, SMEs are “given a voice in the standardization process and are given the opportunity to actively shape the outcome of standards” (SBS, 2018).

Based on experience of South Korea, study of Choung et al. (2011) revealed that transition to the technological frontier is increasingly related to standardization; latecomer countries improve their technological capabilities from mature towards new technologies; and successful technological catch-up is related to abilities of companies to take part in global (ICT) standardization – “... slow progress can be expected, but once a minimum level of capabilities is achieved, a nation pro-active in standards from the beginning may attain higher rates of catch-up near the technology frontier.” Knowledge about standardization is important because of the role of standards and standardization in global and knowledge economy –, especially for less developed countries.

The ability of SMEs to acquire new knowledge is dominant prerequisite to develop and sustain competitive advantage. Based on our literature review we found that an information and a knowledge about standards as a base for certification is an important asset of the SMEs, especially in developing countries. In this study, we would like to explore dominant sources for acquiring knowledge about standards. Our research questions are:

RQ 1: What are the main predictors of the usage of the relevant Web sites as a dominant source for information and knowledge about standards in the case of SMEs operating in Serbia?

RQ 2: What are the main predictors of the usage of the services of consultants as a dominant source for information and knowledge about standards in the case of SMEs operating in Serbia?

RQ 3: What are the main predictors of the consumers as a dominant source for information and knowledge about standards in the case of SMEs operating in Serbia?

RQ 4: What are the main predictors of partners and others as a dominant source for information and knowledge about standards in the case of SMEs operating in Serbia?

### **3. RESEARCH METHODOLOGY**

#### **3.1. Study Design**

In order to find answers for our research questions, a questionnaire survey research method was used to seek a response from representatives from SMEs which operate in Serbia. We used several sources for reaching representatives of SMEs – database of companies of the Chamber of Commerce of Republic of Serbia (publicly available contact and basic information on the website of Chamber of Commerce), LinkedIn profiles of companies and direct e-mail contacts. In order to receive as many as possible responds, we created relatively short and compact questionnaire, taking into account recommendation for defining a questionnaire and a survey design of Czaja and Blair (2005). In order to find out what influence choice of SMEs operating in Serbia, to use predominantly one source for seeking the information and the knowledge about standards, examinees are asked to choose only one dominant source for gaining knowledge. We observed four sources – relevant Web sites, service of consultants, customers and business and other partners (dependent variables, coded as dummy use=1 and no use=0).

#### **3.2. Data Analysis**

For the data analysis and answering our RQs we used descriptive statistics and we conducted a two-group Discriminant Function Analysis (DFA) based on the Wilks' lambda. Interpretation of the DFA is based on discriminant loading because it is less affected by multi co-linearity and more suitable for interpretation in explorative research (Hair et al., 2009). According to the same author, discriminate loadings above  $\pm 0.40$  should be used to identify substantive discriminant (independent) variables even when they are not included in DFA analysis. The Canonical Correlation (CC) coefficient is used to define the percentage of variance in the dependent variable explained by the mutual influence of independent variables. Based on the study of Harlow (2005), the substantial value of canonical correlation is 0.30 or higher, for example, the value of 0.30 corresponding to about 10% of the variance explained.

### 3.3. Study Participants

Questionnaires were sent via LinkedIn and E-mail to 540 companies and we received 143 responds (26.5%), 13 questionnaires being invalid for the reason of not being SMEs or incomplete data and a total of 130 or 24 % questionnaires have been taken into account. Characteristics of the responding companies are presented in Table 1.

**Table 1.** Characteristics of Responding SMEs

	Total		Ownership				Ownership2			
	Number	%	Public		Private		Foreign		Domestic	
			Number	%	Number	%	Number	%	Number	%
	130	100	10	7.7	120	92.3	30	23.1	100	76.9
	<b>Industry</b>									
<b>Manufacturing</b>	31	23.8	2	6.5	29	93.5	10	32.3	21	67.7
<b>Service</b>	72	55.4	8	11.1	64	88.9	18	25	54	75
<b>Trade</b>	22	16.9	0	0	22	100	1	4.5	21	95.5
<b>Other</b>	5	3.8	0	0	5	100	1	20	4	80
	<b>Number of employees</b>									
<b>0-10</b>	49	37.7	1	2	48	90	1	2	48	98
<b>11-50</b>	41	31.5	1	2.4	40	97.6	9	22	32	78
<b>50-250</b>	40	30.8	8	20	32	80	20	50	20	50
	<b>Experience in certification of processes or products</b>									
<b>Experience in certification with process and products</b>	42	32.3	6	14.3	36	85.7	14	33.3	28	66.7
<b>Experience in certification with process or products</b>	27	20.8	1	3.7	26	96.3	6	22.2	21	77.8
<b>No experience</b>	61	46.9	3	4.9	58	95.1	10	16.4	51	51

## 4. RESULTS

### 4.1. Reliability Analysis

In order to analyze the reliability of the used items, we used reliability coefficient of Cronbach's alpha. According to Hair et al. (2009), the lower limit for Cronbach's alpha is 0.70, although it may also be decreased to 0.60 in exploratory research. The reliability analysis showed an adequate consistency of the entire scale, wherein it is possible to form a summated scale for: 1) perceived benefits from certification ( $\alpha = 0.807$ ) and 2) perceived reputation benefits of application of standards ( $\alpha = 0.738$ ).

### 4.2. RQ 1: WHAT ARE THE MAIN PREDICTORS OF THE USAGE RELEVANT WEBSITES AS A DOMINANT SOURCE FOR INFORMATION AND KNOWLEDGE ABOUT STANDARDS IN THE CASE OF SMES OPERATING IN SERBIA?

The dominant variable that influences usage of Web sites at observed SMEs, as the dominant source for gaining information and transfer of knowledge about standards, is the number of employees (Table 2). Only variable x2: Experience in business (years) have discriminant loadings higher than 0.4 (0.43) and can be discussed in this results. The larger SMEs with the long tradition in business will have more chances to use Websites as the primary source for gaining knowledge about standards. Values of squared canonical correlations suggested that influence of the number of employees is positive and significant, but it corresponded only about 4% to variation between SMEs that use Web sites and SMEs that do not use Web Sites as the dominant source of knowledge about standards.

**Table 2.** Summary Statistics for Discriminant Function Analysis

Dependent variable	Wilks' Lambda	p	Discriminant loadings (structure correlations)									Canonical correlation
			X1	X2	X3	X4	X5	X6	X7	X8	X9	
Websites	0.967	0.04	<b>1.00</b>	<b>0.43</b>	0.28	0.11	0.12	-0.38	-0.27	0.23	0.09	0.18
Consultants	0.909	0.02	-0.34	-0.06	-0.195	<b>-0.516</b>	<b>-0.70</b>	<b>0.71</b>	-0.07	-0.21	0.19	0.34
Customers	0.924	0.01	0.19	<b>0.70</b>	0.101	<b>-0.440</b>	<b>-0.623</b>	0.04	-0.30	-0.11	-0.02	0.28

Legend: x1 – Number of employees; x2 – Experience in business (years); x3 – Experience with certification of processes or products; x4 – Perceived benefits from certifications; x5 – Perceived benefits from standards;

x6 – Domestic or foreign ownership; x7 – Public or private ownership; x8 – Industry (manufacturing or service and others) and x9 – Connections with other smes in same industry.

#### **4.3. RQ 2: What are the main predictors of the usage of services of consultants as a dominant source for information and knowledge about standards in the case of SMEs operating in Serbia?**

Variables that have a statistically significant influence on the usage of consultants' services as a dominant source for gaining information and transfer of knowledge about standards are the negative perception of standard and domestic ownership (Table 2). The variables that have discriminant loadings higher than 0.4, but are not included in function, are the negative perception of benefits of certifications perceived benefits from certification. Those results suggest that domestic SMEs shape their decisions on hire consultants services predominantly because of the negative perception of standards and standardization. Values of squared canonical correlations suggested that influence of the negative perception of benefits from standards and domestic ownership is significant, but it corresponded only about 12 % to variation between SMEs that hire consultants and SMEs that do not use services of consultants for the purpose of gaining knowledge about standards.

#### **4.4. RQ 3: What are the main predictors of the consumers as a dominant source for information and knowledge about standards in the case of SMEs operating in Serbia?**

Variables that have a statistically significant influence on the usage of customer inputs as the dominant source for gaining information and transfer of knowledge about standards are: experience in business (years) and negative perception of benefits of standards (Table 2). The negative perception of certifications has discriminant loadings higher than 0.4 (-0.44). Those results suggest that domestic SMEs are pressured by their B2B customers, trough requirements for standards adoption and second part certifications but SMEs have the negative perception of standards and certification. Values of squared canonical correlations suggested that influence of experience in business, negative perception of benefits from standards and domestic ownership are significant, but it corresponded only about 9 % to variation between SMEs that see customers and SMEs that do not see customers as the dominant source for gaining information and knowledge about standards.

#### **4.5. RQ 4: What are the main predictors of partners and others as a dominant source for information and knowledge about standards in the case of SMEs operating in Serbia?**

Our data analysis failed to find any statistically significant influence of observed dependent variables on the choice of observed SMEs to have business partners and other partners as the dominant source for information and gaining knowledge about standards.

### **5. DISCUSSION AND CONCLUSION**

More than ever before, global and regional initiatives for education about standardization are intensive and actual. The Joint Initiative on Standardization under the Single Market Strategy of European Commission, which started at June 13th, 2016, gives high priority on education about standardization (Action 3) and position of SMEs in standardization in supporting European competitiveness in the global market. The International Cooperation on Education about Standardization (ICES) together with ISO, IEC and ITU organize back to back events for exchanging experience related to education about standardization. University Jiliang from China initiated the establishment of The Universities and Academics Alliance for Standardization Education and membership were accepted globally.

The main intention of this article was to explore key factors which affect SMEs' choice of a dominant source for acquiring the information and the knowledge about standards. In the digital era, SMEs still suffer from lack of resources or capabilities to use the WEB and the Internet for acquiring information and knowledge about standards. Our results showed that observed SMEs operating in Serbia use Websites as the main source for acquiring information and knowledge only if they are larger (medium) and more experienced. In the broader sense, our results agree with findings of the study of Neirotti et al. (2018) that adoption of Information and Communication Technology (ICT) in SMEs "has some peculiarities that may depend on the combined effect of size and competitive environment" and that ICT-based capabilities are more diffused among larger SMEs.

Our results showed that domestic SMEs, due negative perception about standards, use services of consultants for the purpose of gaining knowledge about standards. Two problems that have roots in the

negative perception of standards are already visible in practice – the inability of domestic SMEs for successful technological catch-up and lowering quality and effects of consultants' work. The best consultants cannot help SMEs with negative quality culture and cannot do anything if owners and/or managers have negative perceptions towards standards. Consumers, predominantly B2B consumers, are: choice of a dominant source for acquiring information and the knowledge about standards of experienced SMEs' and negative perception of benefits of standards. Those results might be influenced by requirements of B2B buyers or consumers, who require from their suppliers to fulfill requirements of specific company standards.

Richard Stallman's, scientist and one of the pioneers of free software movement said: "Sharing is good, and with digital technology, sharing is easy" (note 1). However, our research results suggest that more attention should be paid to improve capabilities of SMEs for more active use of digital technologies in order to acquire the knowledge about standards, standardization, and related activities. On the other side, the task of many actors: governments, universities, organizations for standardization, consultants and others is to explore why domestic SMEs are missing a chance to benefit from the implementation of standards due to their lack of abilities to use technology-enhanced learning in the digital era.

## SMART STANDARDIZATION

Milan Dronjak<sup>1\*</sup>

<sup>1</sup>Aeronautical Plant "MomaStanojlovic"

\*Corresponding author, e-mail: dronjakm@ptt.rs

**Abstract:** *The third industrial revolution is behind us. We are on the doorstep of a new technological revolution whose key elements are Cyber-Physical Systems and the Internet of Things, and this revolution is known as the Fourth Industrial Revolution. This study was conducted using the methods of analysis and synthesis, in order to explore the meaning of smart standardization and to review its place and role related to the Industrie 4.0. The research was done using relevant academic and scientific books and papers during a four-month period of time. The results of this paper suggest that the smart standardization, at this moment, poses the highest level of social awareness related to the importance of technical integration. The role of standardization supporting the emergence of Industrie 4.0 is discussed. It was concluded that the standardization is ubiquitous and has very important place in the development of Industrie 4.0 model and associated technologies.*

**Keywords:** *Smart standardization, Fourth Industrial Revolution, Smart Factory, CPS, IoT*

### 1. INTRODUCTION

We are living in a very dynamic environment. The world around us is evolving very fast, the production of data and information is so high so we are not aware of changes in many cases. One of things that are happening right now is something that many people call the fourth industrial revolution (Industrie 4.0). Steam power was the main characteristics of The First industrial revolution. The Second was related to electric power. The Third was digital revolution and this Fourth is continuation of previous revolution and comprises of many advanced technologies, mainly focused on the Internet (Hatzakis, 2016, p.1). Now, we have Cyber-Physical Systems (CPS) that represent some kind of smart systems. In the world of CPS, standardization is a must and it should be smart.

The objective of the current study was to explore the meaning of the term "smart standardization" and to see its impact in the modern world that is distinguished by the Fourth industrial revolution. This paper is divided into 5 logical blocks. The first part is the Introduction which announces the topic. The second part introduces terms "smart" and "smart standardization" and it also presents related standardization efforts. Nowadays, term "smart" is used for many things from our daily life. Probably, the first association is smartphones but there are also Smart Cities, Smart Farming, Smart Grids or Smart Factories. In this paper focus is on Smart Factory concept which is described with emphasize on the Internet of Things (IoT), as a base, and this is presented in the third part of the paper. The importance of integration of CPS and IoT in Smart Factory concept as well as the ways for achieving high flexibility and efficiency are very important. The main sections of smart factory are listed, while self-awareness and self-comparison of machines are underlined. IoT technology is explained and the growth of connected things is noticed. Additionally, current reality with dominant concept of digital factory is presented. The importance of standardization is accentuated. Architecture Model for Industry 4.0 (named: RAMI 4.0) is shown as the most important reference standard for Industrie 4.0. Finally, there are discussion and conclusion sections, respectively.

### 2. SMART STANDARDIZATION

The term "smart" has a very broad use, and if we look at dictionary, there can be found about its formal and informal meaning. In formal way, it is some fashionable and upmarket place or some clean, tidy, and well-dressed person or rather bright object and fresh in appearance. In informal meaning, we are speaking about something that has or shows a quick-witted intelligence. If we have a device in our mind, it must be programmed so as to be capable of some independent action (Smart, 2018).

If we look at standardization, NATO defines "smart standardization" as a voluntarily creation of standards, their institutionalization in a Standardization Agreement (STANAG) and making them a habit (Cihangir, 2014, p.1). And, if we try to google the Internet for any formal definition, it will not be found.

Bearing this in mind, we can look at the world of standards. Very often, we can find something „smart“. A good example is ISO 37100 series of standards, which helps communities, including cities to define their sustainability objectives and put strategies in place to achieve them. Behind this series of standards, we can recognize Smart city concept. There are also other standards related to this Smart city concept, as ISO

17742:2015 (Energy efficiency and savings calculation for countries, regions and cities), ISO 39001:2012 (Road traffic safety management systems - Requirements with guidance for use), ISO 24510:2007 (Activities relating to drinking water and wastewater services, Guidelines), ISO/IEC 30182:2017 (Smart city concept model - Guidance for establishing a model for data interoperability) etc. In the last-mentioned standard, it can be found the definition of a smart city as „ an effective integration of physical, digital and human systems in the built environment to deliver a sustainable, prosperous and inclusive future for its citizens”. This ISO/IEC standard referenced a term from the BSI PAS 180 which provides common language about Smart cities in the United Kingdom (BSI, 2014).

Not only cities can be smart, but also farming can be smart. Recently renewed standard for serial data control and communications networks in forestry or agriculture, ISO 11783-1:2017, provides open system interconnect (OSI) for electronic systems in this industry (ISO, 2017). In ISO Focus, it can be found that the AGCO Corporation, American agricultural equipment manufacturer, participates in the development of ISO standards because of their importance to overall company strategy (ISO Focus, 2017, p.9). More specifically, AGCO uses ISO 11783 to connect devices and to exchange data between tractors. As we can suppose, Smart farming concept is behind.

In the energy domain, one of the most often used words is the term Smart Grid. In this case, we have international standard ISO/IEC 30101:2014 which characterizes the requirements for sensor networks to support “smart grid technologies for power generation, distribution, networks, energy storage, load efficiency, control and communications, and associated environmental challenges” (ISO, 2014). As we can see, smart concept is behind, again. Smart Grid can be interpreted as a complex system that is capable to operate at different operation modes, ranging from sensing and actuation to command and control (ISO, 2014).

Nowadays, much more attention is paid to the Smart manufacturing, which is process that is capable to use advanced information and manufacturing technologies in order to improve manufacturing efficiency, enabling at the same time flexibility of physical processes. Smart manufacturing is seen as the next Industrial Revolution or Industry 4.0 (Trade Magazine, 2018). Behind this we can also see the Smart Factory concept. For those who work in this area, it is well known ISO 10303 standard for the computer-interpretable representation and exchange of product manufacturing information or IEC TS 62832 for Digital Factories. We can go even further, and find Smart infrastructure concept, Smart energy concept, Smart transportation concept etc.

### **3. SMART FACTORY CONCEPT**

Presently, one of the most demanding projects is the Factory of the future (known as Smart Factory concept), which is also described in IEC White Paper. There are many local initiatives directed towards creating Smart Factory: Advanced manufacturing (in USA), e-Factory (in Japan), Industrie 4.0 (in Germany) and Intelligent manufacturing (in China). Behind those concepts there is the Smart Manufacturing Leadership Coalition (SMLC) or the Industrial Internet Consortium (IIC) in USA, and industrial associations including VDMA, Bitkom and Zvei in Germany, for example (IEC, 2015, p.25).

It is important to emphasize that there is no unique definition of the term named Smart Factory. This term is used both by specialists from the industry and academic writers (Radziwon&Bilberg, 2014, p.1185). Probably, the optimal definition of Smart Factory for the purpose of this study is that it is as a Factory that “context-aware assists people and machines in execution of their tasks”. In the backward definition, “context-aware” means that the systems running in background (so-called “Calm-systems” and “context-aware applications”) can access to context information (position or status, for example) during processing of tasks (Lucke et al., 2008, p.116). Calm systems, previously mentioned, are the hardware of a Smart Factory with ability to communicate and interact with its environment.

In Smart Factory concept, it is possible to collect, distribute and access to manufacturing relevant information anytime and anywhere. Horizontal and vertical integration of information systems, the assignment of material and flow of information within an enterprise is *condicio sine qua non* for this concept. If we take Industrie 4.0 as example, it includes horizontal integration, through value networks, of data flow among partners, suppliers and customers, and also vertical integration within organization (from development to final product) (Hozdic, 2015, p.29). The vertical integration is referring to Cyber-Physical Systems (CPS) or Internet of Things (IoT). By this type of integration of hierarchical subsystems, it is possible to form flexible and reconfigurable manufacturing system inside a factory. There is an another integration. It is engineering integration from one end to another, which extends through the entire value chain in order to support product customization (Wang et al., 2016).

On the other hand, in the process the Smart Factory concept implementation, smart objects should be combined with big data analytics. Those objects can be reconfigured dynamically in order to achieve high flexibility. Achieving high efficiency via global feedback and coordination can be provided by big data analytics (Wang et al., 2016, p.159). This leads to the profitable and efficient production of products that are tailored to the user needs and in small lots.

There is only one responsibility of the Smart Factory during production of finished products, and that is to process raw materials and semi-finished products. The Smart Factory, as well as any other real today's factory, consists of many subsystems which can be either physical or informational. In today's factories, disruption of the information flow can occur for a variety of reasons. Therefore, it is very difficult to provide the continuity and consistency in those factories. At the same time, there is a flexibility problem of material flow because of reasons related to the fixed production lines (Wang et al., 2016).

Overall framework of smart factories can be divided into three major sections: components, machines and production systems. Smart machines use real-time data from their own components and other machines which brings self-awareness and self-comparison. This enables machines to assess their own performance in order to prevent potential failure and to adjust their settings and performance properly through the knowledge they gained from their working history (Lee, 2015, p.231).

### **3.1. Internet of Things (IoT)**

Some individual authors believe the Internet of Things, wireless sensor networks (WSN), big data, cloud computing, embedded systems, and mobile Internet will be emerging technologies (Wang et al., 2016, p.159) that will make the backbone of the Smart Factory. Currently, IoT turned out to be more powerful.

The Internet of Things can be interpreted as the interconnection of things in real time in purpose of sense and report. According to definition of International Telecommunications Union (ITU), IoT is a "global infrastructure for the information society, enabling advanced services by interconnecting (physical and virtual) things based on existing and evolving interoperable information and communication technologies" (ITU-T, 2012, p.1). IoT is also one of the core technologies for the 5G network 5G communications.

Every sensor in a factory and also every actuator is a participant in the IoT. All of them have IP address and are networked. In order to achieve Smart Factory concept, it is needed to develop and make available standardized connectors and connection protocols and allow exchange of information between device and connector without loss (IEC, 2015, p.48).

In ISO FOCUS (2016), it can be found estimation (p.8) from Technology consulting firm Gartner, Inc. that 6.4 billion connected things will be in use worldwide by end of 2016, which is 30% growth in one year. And they expect nearly 21 billion things by the year 2020, which is growth by more than three times. This consulting firm announced a prediction that, by the end of 2020, some elements of IoT will be applied in more than 50% of major new business processes and systems.

### **3.2. Integrate digital factory and Smart Factory**

In order to make shorter and to improve planning (both product and production), the idea of the Digital Factory came up. When someone mention the Digital Factory term, it means that he implies general digital support of planning following the process chain from product development over process and product planning to production by using virtual working techniques. Based on this definition, it can be made a conclusion that the whole process of developing a product that is new has to be completely simulated prior to realization (this includes also a production equipment that is associated with that product). To sum up, term digital factory encompasses simulation of all activities (research, development and also production) which are conducting physically in the factory (Arndt, 2004, p.27).

The Digital factory is more than pure usage of simulation tools. It has impact on the organization of the factory and all activities in the factory have to be standardized (i.e. impact is on the whole workflow). At every step, data outcome of the workflow should be specified and then saved in a central database (of the whole factory). If it is determined by the process of simulation that the production will meet a given requirements (quality and time schedule), then it can be started with development and production (Arndt, 2006, p.28).

The Digital factory is the model of a real factory, and in the smart factory, this digital factory developed during engineering should be integrated with the real time data and inferred statistics and information of the smart factory. So, an important issue here is integration. Data should be received to the IoT platform of smart factory from IT applications of digital factory, with providing feedback.

### 3.3. Standardization activities in area of Smart Factory

Many standards development organizations (SDOs) such as the Institute of Electrical and Electronics Engineers (IEEE), the International Electrotechnical Commission (IEC), the International organization for Standardization (ISO), and the International Telecommunication Union (ITU) are working towards developing the Smart Factory standards. Also, some consortiums are working together with SDOs to promote standard technologies for the Smart factories. This standardization process will achieve interoperability, enabling information exchanged and understanding between different components of the Smart Factory.

If we want success of any industrial solution, we must keep cost and deployment effort low and guarantee high availability and durability during their lifetime. All of that is successfully possible only when those solutions are based on vendor independent open standards (Zuehlke, 2010, pp. 130-131).

It can be found in a significant number of sources that some authors suggest that IoT (Muhonen et al., 2015) is the most important technology concerning Smart factories, and it can be said that standards play important role in developing IoT. They allow all players to access IoT equivalently and to use it. The IoT standardization can include plenty of different standards, such as architecture standards, application requirements standards, communication protocol standards, information processing standards, data standards, identifications standards, security standards and public safety standards, and it is the reason of standardization's complexity. It is very important to have common standards in building a successful IoT system. Diverse standards and technical solutions will significantly slow down the development of IoT. The most relevant organizations related to IoT and industrial Internet are: ETSI, ISO, IEC and ITU. Also, there are some number of unofficial alliances and forums that play very important role (GS1/EPC Global, AllSeen Alliance, HART Communication Foundation etc) (Muhonen et al., 2015).

However, reliability and safety of these technologies under industrial environment should be certified in order to persuade users to forget existing control cables by future wireless connections (Zuehlke, 2010, p. 131).

In addition to devices' hardware, software and communication standards, design standards are also needed (Zuehlke, 2010, pp. 130-131). They enable achieving a seamless planning, design and operation environment.

There is no general, worldwide standardized model of the Smart Factory, but it exists for example a reference model that was developed by German Association of Electrical and Electronic Manufacturers. It is named the "Reference Architecture Model for Industry 4.0" (RAMI 4.0), and is considered as a key standard for Industrie 4.0.

RAMI 4.0 is a three-dimensional layer model that contains the most important aspects of Industrie 4.0, and its axis are: Hierarchy levels, Process (value stream process) and Architecture (FMEAE, 2016). The "Hierarchy Levels" axis are hierarchy levels from IEC 62264 series of standards (this series of standards describes enterprise IT and control systems) and IEC 61512 standard (which address batch process control). The "Life Cycle & Value Stream" axis represent the life cycle of facilities and products, based on IEC 62890 for life-cycle management for systems and product used in industrial-process measurement, control and automation. Architecture Axis consists of 6 layers. Those layers are: Asset, Integration, Communication, Information, Functional and Business (Amman Zaheer, 2017).

## 4. DISCUSSION

Today, the world is changing so fast. The appearance of IoT and many other new technologies has influenced not only the development of mobile communications, but also the industry. And, standards are the fundamental component of the evolution to smart systems. Term "smart", here, have informal meaning, i.e. it is something that has or shows a quick-witted intelligence. There are many examples of smart systems where standards play key role. We can talk about Smart cities, Smart farming, Smart Grids or Smart factories. Regardless of which smart system is considered, the influence of many international and national standardization organizations can be seen, as well as of the number of unofficial alliances and forums. Determining the real impact and the scope of standardization in those smart systems it can raise the awareness about the role of standardization.

The International Electrotechnical Commission pay particular attention to the Factory of the future, and worldwide many local initiatives support that idea. One of them, Industrie 4.0, which is in the focus of this study, is launched by German industrial associations encompassing VDMA, Bitkom and Zvei. As the key elements of these factory are identified (Monostori et al., 2016, pp. 621-641) cyber-physical systems (they are considering to be one of the largest advances in technology) and IoT, which is in accordance with literature. In order to ensure communication and control of cyber-physical systems it is needed to make a

standards based on an international consensus taking into consideration existing standards (national and regional) for industrial automation.

Furthermore, Gartner, Inc. is assured that, by the end of 2020, some elements of IoT will be applied in more than 50% of significant new business processes and systems. If it is achieved even only part of this prediction, it can be understood that without integration standards, as soon as possible, there will be a big variety of different protocols and impossible mission to integrate those systems.

However, the reality has to be considered as well. In this case of the Smart factory concept, that is the digital factory as a model of the real factory. Existing machines and equipment cannot be simply thrown away, forgotten, or a new factory cannot easily be built. That would be a very expensive investment that would not pay off at all. Therefore, the digital factory should be integrated with the real time data and inferred statistics and information of the smart factory. Again, the role of integration standards can be spotted.

At this moment, many formal and informal standardization bodies are working toward developing standards related to smart systems, and more specifically Smart Factories. Their efforts are directed toward information exchange between different components of that factory. Standards play important role also for the development of components for a smart factory. Good example is IoT, where standardization efforts are also present.

Due to the emergence of a large number of different technologies, it was needed somehow to find a way towards their integration. For this purpose, reference architecture models and integration standards are developed. The three-dimensional layer model RAMI 4.0, developed by German Association of Electrical and Electronic Manufacturers, was introduced. Research showed that, in this model, the standards are a key integrative element.

As we can see from smart factory example, there is no necessity to use certain standards. Everything is voluntary. Behind this volunteerism are hidden different motives. Therefore, some need to use those standards exists. By accepting those standards, their users are creating some habits.

All standards are accepted on a voluntary basis, regardless of motivation behind it. After a certain period of time, these standards simply become a habit. In many cases, their acceptance by the authorities also helps in that direction. This study was conducted using methods of analysis and synthesis, in order to review the key aspects of smart standardization and its contribution to the industry. It was concluded that the smart standardization is ubiquitous and it can be seen from the way the Fourth Industrial Revolution pays special attention to it. We should be aware of that there is so much to do in the area of standardization.

## **5. CONCLUSION**

In this study it was shown that standardization is very important element of new technological revolution. During time, conscience about standards has evolved to the level of smart standardization. All standards are accepted on a voluntary basis, regardless of motivation behind it. After a certain period of time, these standards simply become a habit, and that is the state we have today. In many cases they are promoted from the authorities which helps in direction of making them a habit.

Term “smart” is very often in the world of standards. There are many of them related to Smart city, Smart farming, Smart grid or Smart factory. But, the Smart factory is one of the most demanding projects today, because it is capable to collect, distribute and access to manufacturing relevant information anytime and anywhere. It includes horizontal, vertical and engineering integration. Many standards development organizations and some consortiums are promoting standard technologies for Smart factory, but there is no worldwide standardized model of it. Effort were made regarding the IoT standardization, which is the most important technology concerning Smart factories so it is expected that they will allow all players to access IoT equivalently and to use it. This will probably result in making IoT the backbone of the Smart factory.

The results of this study underscored the importance of standardization which is a key component in evolution towards Industrie 4.0. Common standards enable participation of a wide range of stakeholders (for example, companies), regardless of size or location. They help development of systematic, repeatable and efficient systems.

The topic is relevant and this paper can be used by students of the Faculty of organizational sciences as well as by those to whom standardization belongs to the domain of job description. The area of this topic can also be extended in some further papers to other areas of social activity, not only in industry, which would give a real picture of the impact of standardization in the present.

**Abstract:** *Using of exploratory and descriptive research in work points to the importance and the need of managing the continuity of business in higher education institutions. The aim of the paper is to propose a model of the management system to the continuity of business. Usage of this model will ensure to higher education institutions continuity of provision of education services to all stakeholders. The model is of a general character and can be applied in any higher education institution. Especially, the model is convenient for implementation in the Western Balkan countries in the context of reforms and development of higher education.*

**Keywords:** *business continuity management system, business continuity plan, ISO 22301, higher education institution, model*

### 1. INTRODUCTION

In recent years, a significant challenge for higher education institutions (HEI) is providing continuity in the process of using education services to its users, especially for those in transition countries.

The Business Continuity Management System (BCMS) offers a good response, because it represents the management system. The usage of such system would facilitate identifying potential threats and hazards, recognizing external and internal factors which influence risk increasing, defining measures that would reduce the probability of their occurrence, responding in case of their occurrence and continuing with providing services besides preserving the image and reputation of the institution (according to SRPS ISO 22301: 2014; 14).

By analyzing the relevant and accessible literature, the paper highlights the importance and advantages of business continuity management in the HEI. The main aim of the paper is to propose a model for the implementation of the business continuity management system in the HEI that would be enable continuity in the provision of education services by the HEI. The development of the model is based on the PDCA (Plan-Do-Check-Act) cycle, the life cycle of business continuity management and good practice examples of the HEI which were to a certain extent engaged in the continuity of business. The proposed model would create an environment for raising awareness of the importance of continuity in providing education services, as well as for improving the quality of education services.

### 2. METHODOLOGY

The principal method of research is based on existing theoretical results and examples of good practice in the specified field. The methodology of the research is based on the collection and examination of available literature, its analysis and systematization, with the aim of demonstrating the importance of business continuity management in the higher education institution, as well as the justification and utility of developing new model for applying the management system to the continuity of the provision of education services.

With regard to the type of research, exploratory and descriptive research was used in this paper. During exploratory research, international standards, reference documents and guidelines governing this field have been used in order to perceive BCMS in higher education institutions. Also, the exploratory research includes experiences of universities in the world that approached the implementation of the BCMS to certain extent, as well as publications available through the search of scientific and professional journals and index databases. The following key words were used for searching publications in electronic journals: Business Continuity Management System (BCMS), Business Continuity Plan (BCP), model, higher education institutions and risk. The search included published works in the last 12 years. In the use of the relevant literature, BCMS and BCP publications in higher education institutions have been prioritized, as well as more recent publications describing the risks to the higher education institution.

Currently, a relatively small number of scientific and professional papers on the subject of using the management system in higher education institutions and in general the implementation of the business continuity management system in higher education in the country and the region are available in the literature. One of the additional motives for this research is a particularly small number of researches on the BCMS, the methodological approach and the results of its implementation. The main purpose of this research is an attempt to point to the possibilities and benefits of the using of BCMS in higher education institutions and to propose a general BCMS model applicable to all higher education institutions, especially for those countries that are still implementing reforms in the higher education system..

### **3. BUSINESS CONTINUITY MANAGEMENT SYSTEM IN HIGHER EDUCATION INSTITUTIONS**

#### **3.1. General**

The continuity of business represents the ability of HEI to continue providing education services at an acceptable, pre-defined level after the incidence which causes a disorder (adjusted according to SRPS ISO 22301: 2014; 14).

In accordance with the previous said, Business Continuity Management (BCM) in a higher education institution is a holistic management process that identifies potential threats and risks to the institution, as well as their impact on the implementation of the process of providing education services (teaching process), if they are achieved. This way of management provides the basis for reducing the possibility of occurrence of unwanted events, increasing the ability to effective respond to unwanted events, protecting the interests of its key stakeholders and allowing the recurrence of activities to pre-disorder conditions as soon as possible. This is the way of protecting the reputation of the institution and enabling the fulfillment of the activities that create values (according to SRPS ISO 22301: 2014, 14).

Academic continuity points to the commitment of the institution in providing opportunities for the students and teachers to remain in the process of providing education services despite external influences and disorders (SchWeber, 2011, 68).

An early approach to business continuity management was focused on interruptions in information systems of organizations (Elliott, Swartz, & Herbane, 2007, 3), and it can be said that BCM literally derived from the world of information technology (Guide, 2009, 6). However, in recent years, the approach to business continuity management has become much wider. The broader consideration of capabilities of business continuity management is mostly influenced by the adoption of the ISO 22301 standard which defines the requirements for this type of management.

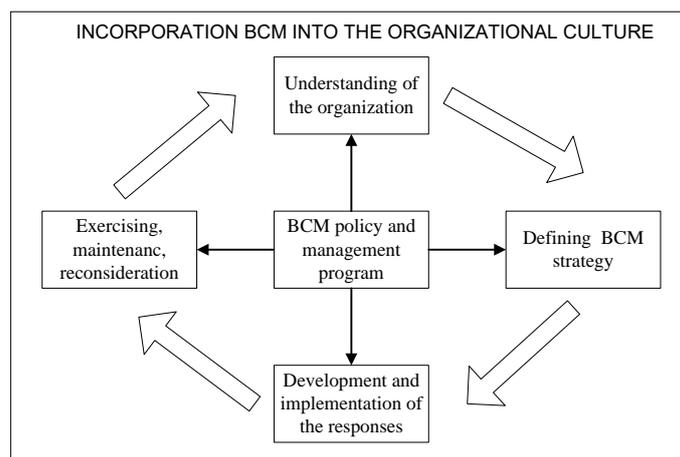

Herbane (2010, 978) BCM links to crisis situations and points to the fact that since 1970 BCM has been evaluated from form of management in crisis situations, as response to technical and operational risks that jeopardize the recovery of organization from the dangers and termination of business. Crisis situations can be defined as organizational functions or processes whose weak implementation can cause damage to stakeholders and further destabilize the reputation of institution (Coombs, 2014, 3).

The general requirements, which refer to the business continuity management of an organization from the point of view of standards SRPS ISO 22301: 2014, include the following areas:

- understanding and determining external and internal factors that affect the ability of organization to achieve the desired results,
- understanding the needs and demands of stakeholders,
- leadership commitment to the BCMS in terms of defining the business continuity policy, defining roles, responsibilities and powers,
- the BCMS planning, in terms of considering risks and opportunities, as well as the measures applied to them,
- providing support, in terms of the necessary resources and their competence, accessibility, as well as the necessary and up-to-date information,
- planning and managing the processes that are necessary to meet the requirements and apply measures related to risks and opportunities,
- establishment, implementation and maintenance of process for analyzing business impact and risk assessment,
- defining a business continuity strategy, from which procedures and business continuity plans are obtained,
- evaluation of performance and improvements (SRPS ISO 22301: 2014, 26-54).

When it comes to terminology, methodology and requirements regarding this system, the authors Lindström, Samuelsson, Hägerfors (2010, 243-255) indicate that private sector employees are basically more aware of BCM concept and its importance than their colleagues in public sector. Anyway, whether it is a private or public sector, understanding of the business continuity management philosophy should be a strategic concern at the highest level within the organization.

For a higher education institution, it is important to promote business continuity management as one of the key values of the organizational culture, as shown in Figure 1 through the life cycle of business continuity management. This requires the commitment of the leader in the institution and communication with employees about this issue. Beside the leaders, employees need to understand how business continuity is linked to the purpose of the existence of the institution and how they can and should contribute to it in accordance with their roles, responsibilities and authorizations (according to with SRPS ISO 22301: 2014, 30).

**Figure 1:**The life cycle of business continuity management (in line with: GPG, 2010, 20; Cornish, 2007, 107)

Business continuity management and recovery after the incident aim to give confidence that the quality of the service will be at the maximum level even during the crisis period and that the departments and institutions will be recovered as soon as possible (Guide, 2009, 2).

When it comes to higher education institutions in our area, the impression is that the theme of risk management in higher education is recently open issue, which is emphasized by the authors Ružić-Dimitrijević and Dakić (2014, 137-152).

Several authors points to the possibilities of applying this system in education but in the educational systems in the world (Asgary, 2016, 49-72; Durmo, 2016,57-74; McGuinness and Marchand, 2014, 291-310). Durmo (2016, 57-74) points to the importance and advantages of the business continuity plan and describes the BCM methodology. In his work Durmo points out that we should not proceed from the fact that the danger cannot happen to us and that the BCM should be seen as a huge competitive advantage. Asgary (2016, 49-72) emphasizes the importance of risk management and business continuity today, to the extent that York University has developed programs and courses in this field. McGuinness and Marchand (2014, 291-310) point to the practice of BCM in institutions in the United Kingdom. They also emphasize the importance of communication in case of incidents.

An analysis of the available university data in the world indicates that universities, although they do not have a certified system of business continuity management, to a certain extent, and in accordance with their needs and possibilities, deal with the business continuity, and most of all, by continuously planning their business. The key components of BCMS's for the higher education institution are the business continuity policy, personnel with defined responsibility, process management related to planning, testing and improvement of business continuity management, as well as internal documents which is a subject of audit and updating and which relate to the assessment risk and impact analysis on business.

### **3.2. Development of the model of business continuity management system in high education institutions in Serbia**

Bearing in mind that the universities in the world have realized the importance of maintaining their business (maintaining the continuity of providing education services) at any time and have worked on a well-defined framework of business continuity management, it is necessary that the higher education institutions accept

this concept and improve their business in this context, especially in the countries of the Western Balkans in the context of development and reform of higher education system.

If we take into consideration higher education institutions in Serbia, the greatest risk for the continuity of providing service by a higher education institution is the process of accreditation, namely re-accreditation. In the process of re-accreditation of higher education institutions, they have to fulfill the standards defined by the Rules on Standards and Process for Accreditation of Higher Education Institutions and Study Programs. Usually, in fulfillment of these requirements, the highest risk of the standard refers to teaching staff and space. First of all, it refers to teaching staff and their competence, in the sense of formal education, and in terms of representative references (published works), teachers' consent, i.e. the willingness of the parent institutions to give or even fulfill the conditions for retirement. Changes in the management structure of the institution also carry the risk if the leaders in the institution do not provide competent successors who are ready to continue with development of the culture of the previous management structure business. The challenge may also be space, in the sense that the institution does not have its own space, than renting it, where there is a change of purpose of space.

A significant threat that could jeopardize the continuity of a higher education institution is reduction of the number of students. This phenomenon can be the result of economic changes on the micro and macro plan (education financing, purchasing power of the population, price growth, state of the economy branches of interest, etc.). However, this phenomenon is not only a problem at the level of one higher education institution, it is a demographic problem at the state level.

An important step in the construction of such a system, especially for developing countries, is the raising of awareness among employees and its incorporation into the organizational culture and the value of the institution.

Building such a system in a higher education institution is a long-term process, which must be well-designed, with well-formulated strategy, designed business continuity plan and with respect to available resources.

In the development of a general model for the application of BCMS in higher education institutions (Figure 2), the basis was the PDCA cycle (Plan-Do-Check-Act) given in SRPS ISO 22301: 2014 standard.

The central place in the model is occupied by the basic processes of PDCA cycles which take place in a higher education institution in order to ensure the business continuity. Each of the elements of this cycle is further expanded by elements related to ensuring the continuity of the provision of education services.

In order for the institution to provide and respond to possible incidents, it is necessary to have a business continuity plan and a clear recovery strategy, which is ensured by business continuity planning. In the planning process, a higher education institution must take into account external and internal issues which are of importance for its ability to provide education services. It must also take into account the needs and expectations of stakeholders. The model also highlights the importance of the relationship between business continuity planning and stakeholders which realize an environment for continuous work in an institution, as well as support for students and other stakeholders in the learning process. It is very important that the top management demonstrates commitment in relation to the BCMS. When determining the BCMS, a higher education institution must necessarily examine the risks and define measures in order to reduce the adverse effects. The higher education institution should have competent human resources to carry out business in the context of ensuring business continuity with developed awareness of the importance of the BCMS (adjusted according to SRPS ISO 22301: 2014, 26-38).

According to Schweber (2011, 71), the key outcome of business continuity management is the plan of resistance, namely elasticity. Plans are not made for any possible situation that can cause interruption of work, already the effects of these interruptions are anticipated. For example. if there is a flood, a fire, a renovation, an expired lease of space, or a danger to chemicals in the laboratory, regardless of which of these events occurred in that institution, a certain period of time it can not continue to provide education services (Guide, 2009, 2). A business continuity plan must at least contain critical services and key activities and in which order they will be realized (i.e. defined priorities) if an emergency situation occurs (Resilience, 2014, 60). Every business continuity plan should be unique to the institution.

In accordance with the Best Practices in Business Continuity Planning in Higher Education (2010, 4-5) and SRPS ISO 22301 (2014, 40-48), the model also shows the BCMS implementation activities in a higher education institution, which refer to an element "Do":

1. *Business Impact Analysis* - This analysis identifies the critical processes of the institution, provides the maximum limits of estimation for delays and defines priorities among business processes for renewal.
2. *Risk assessment* – This assessment identifies specific threats for the institution, assesses the vulnerability of the institution for each threat and assigns a degree of risk to each potential threat.
3. *Risk management* - Analyzes the results of the risk assessment and defines the risks that require specific management, and the result of this phase is the documented widespread plan which defines the procedures necessary for restoring business processes to the original state in the event of an interruption.
4. *Testing, training and updating* - Determining the methodology which the institution uses in order to consistently train employees, test and update the plan and to communicate the plan between employees due to changes.

The plans need to be practiced and tested through an appropriate well-planned scenario in order to ensure that they are consistent with its goals. The reports on acquired experience arise as a result of exercises and testing, which are significant for recommendations and measures for implementation the improvement (SRPS ISO 22301: 2014, 46-48).

In the BCMS implementation process, it is important to determine a team that will be responsible for developing a plan and for managing the continuity of the provision of education services. The emphasis is on analyzing the impact on critical processes and activities, as well as on well-defined communication channels.

In the higher education institutions, critical business processes can be classified into one of three categories:

- Security and safety - all activities that are necessary to maintain a safe and a secure environment,
- Support processes - include activities which enable the financial sustainability of the institution and
- Learning, education and research - include activities and programs which support and realize an academic mission of the institution (Best Practices, 2010, 5).

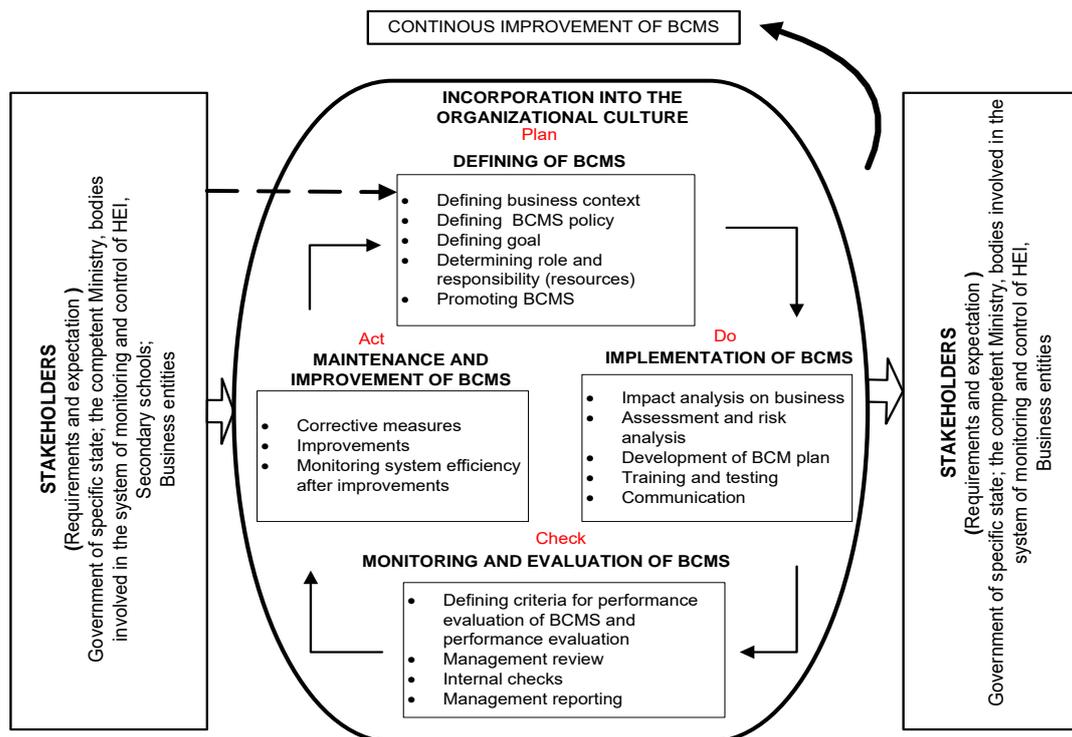

Identification and protection of critical business processes and resources are needed for maintaining an acceptable level of business, protecting those resources and preparing procedures in order to ensure the survival of the institution at the time of interruption.

The elements related to checking "Check" and which are presented in the model, are: defining the criteria for performance evaluation of BCMS, internal checks, management review and management reporting. The higher education institution must know what monitoring and measurements implements and when implements them. As a result of training and testing of plans, monitoring and measurement and internal verification, changes in business continuity plans are being made, i.e. plans are adapted to new situations. Elements of the "Act" include: corrective measures, improvement and monitoring of system efficiency after improvement. After a certain period of BCMS application, some results of its application and outcomes can be seen, on the basis of which it is necessary to perform BCMS improvements. (according to PDCA and SRPS ISO 22301, 2014, 48-54)

In the development of the model, through the PDCA cycle, the basic activities are considered important for ensuring the continuity of the provision of education services by the higher education institution, as well as their interconnectedness. Evaluation processes can be recognized at the institution level (internal audits and performance appraisal of the BCMS) and at the national level (connection with bodies included in the monitoring and control system of the HEI).

Other significant components of the model are the requirements and expectations of stakeholders and their fulfillment that indicate the relation between the higher education institution and the environment. The environment, in which the higher education institution operates, includes direct beneficiaries (students) and stakeholders, as well as the relationships that the institution achieves with them. The stakeholders are the Government of a specific state, the competent Ministry, bodies involved in the system of monitoring and control of HEI, secondary schools and business entities. The relation that it realizes with stakeholders on the one hand can symbolize social responsibility in terms of ensuring the continuity provision of services of education, which defines the relationship of the institution according to the set requirements of the environment and the level of their fulfillment, but on the other hand, the autonomy of the institution that is reflected in defining of their own goals, policies, strategies and plans, and continuous monitoring of their own results in order to be achieved and constantly improved. The relations with interested parties show that in higher education there is general dependence on the economic, political and social structure. Although the higher education institution has its own autonomy, it is integrated with multiple connections into social and economic affairs with increasing influence that individual stakeholders realize at the institution (the

Government, the competent Ministry, business entities, students, etc.). It is emphasized that the model is dependent from the organizational culture.

**Figure 2:** Proposal of BCMS model for higher education institutions in Serbia (harmonized with PDCA cycle and ISO 22301)

Based on the set model, it is possible to obtain a valid picture of the processes which take place in a higher education institution in terms of ensuring the continuity of the provision of education services. In this respect, the proposed model justifies its application by providing a good basis for ensuring the continuity of the education process. The model can be applied in order to:

- facilitating higher education institutions to improve the quality of education services,
- increasing the ability of the institution to absorb, react and recover from disorders,
- ensuring the continuity of the provision of education services,
- encouraging the implementation of BCMS in higher education institutions,
- facilitating the management of the institution by giving recommendations in the planning process, but also by other processes,
- creating an institution's resistance to disorders from the internal and external environment, and inter alia for achieving a competitive advantage over other higher education institutions.

The significance of this model is reflected in its ability to serve as the basis for the development and application of the business continuity management system.

Considering above, it can be seen that the business continuity management is not a set of some specific processes that need to be kept in reserve for some extraordinary circumstances, which can certainly occur at some point. The elasticity of operations at the operational and cultural level may be the best solution in the preparation of the institution for extraordinary activities, with providing additional resources and flexibility that permeates all academic and business activities of the higher education institution (Yanosky, 2007, 157).

BCM presents one type of investment whose benefit and return can hardly be determined as in other strategic investment decisions (Kato and Charoenrat, 2018, 578). The ultimate goal of the BCM is to build the resistance of the institution and ensure the provision of services, despite damage to property and the lack of necessary resources caused by an unwanted event (Guide for SMEs, 2011).

#### 4. CONCLUSION

Research and analysis of relevant literature, which refer to ensuring continuity of business in higher education institutions, have resulted in the development of a model for the implementation of the business continuity management system in conditions of interaction with stakeholders in the environment. The model

has been developed on the basis of the PDCA cycle and systematically provides the basis for understanding the basic activities in terms of ensuring the continuity of the provision of education services.

The PDCA cycle, extended by elements related to ensuring continuity in the process of providing the same service, is a good basis for ensuring the quality of education services and the right solution in the context of reforms and development of higher education system, especially for Serbia and other countries of the Western Balkans.

The proposed model is of a general nature and should help higher education institutions in undertaking a comprehensive approach to ensuring business continuity, enabling them to connect with already established processes, which was the goal in developing the model.

The development of the model has arisen from the need to systematize in a comprehensive manner and show the activities of planning, providing, managing and improving the continuity of the provision of education services. The model defines the business continuity management system in conditions of external relations with stakeholders, from the perspective of a higher education institution. The proposed model gives freedom to higher education institutions in defining their own activities in terms of ensuring continuity of provision of education services, but basically keeps the PDCA cycle as the core of the management of the institution. In realistic implementation of this model, leaders in the institution play an important role in the context of their commitment and the development of awareness among other employees of the significance of such a system.

In theory, this work has resulted in a deeper consideration of the meaning and importance of planning business continuity in higher education institutions and, in general, the importance of application of BCMS in higher education. Considering the insufficient research of this phenomenon, the basic contribution is also reflected in the definition of the general model proposal for the implementation of BCMS in a higher education institution. The developed model can be applied to all types of higher education institutions. Considering the insufficient research of the BCMS problem in higher education institutions, this model can serve as a basis for further research in this field, as well as for reviewing the introduction of certain changes in higher education institutions in our area. In this respect, a new challenge has been posed to the higher education system in Serbia and in other countries undergoing reforms of the higher education system.

## INFLUENCE OF SOME ASPECTS OF DISTANCE LEARNING ON QUALITY OF STUDYING

Đorđe Lazić<sup>\*1</sup>, Tamara Mitrović<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, e-mail: djordjelazic96@gmail.com

**Abstract:** *The great influence that online learning has on the quality of studying is the importance of observing and analyzing the correlation between the acceptance of online learning among students and their success at college. From the student's point of view, the success of the faculty is considered to be the result of their learning, and in this paper it is expressed through an average grade. The aim of the research is to determine the influence of online learning on the quality of studying. For comparison of these two factors, the questionnaire and the ANOVA test were used, as well as the selection, analysis and synthesis of the collected information in order to obtain the most relevant data. That's exactly the main contribution of this research. Given that there is a small number of papers that explore this issue, this research has a vital importance for the area to which it relates. The analysis carried out concluded that there is an influence of online learning on the quality of studying, but that a large number of students are not yet ready to replace traditional learning with distance learning.*

**Keywords:** *distance learning, online learning, quality of studying, e-learning, e-learning tools*

### 1. INTRODUCTION

The traditional context of learning is experiencing a radical change. Teaching and learning are no longer restricted to traditional classrooms. Electronic learning referring to the use of electronic devices for learning, including the delivery of content via electronic media such as Internet, audio or video, satellite broadcast, interactive TV, CD-ROM, and so on has become one of the most significant developments in the information systems industry. With the evolution of wireless networks, it is easy to understand how the mobile devices have gained importance in day-to-day life and in education, too. Today many students want to learn online and in turn get degrees from worldwide colleges and universities, but still cannot go anywhere as they live in isolated areas without proper communication systems. Consequently, many researches encourage learning courses under the e learning system as it saves time and energy of those students staying at any far off distant regions from the universities or colleges they have enrolled. There is also a financial impact. Networks and access to online materials offer an alternative to place-based education which reduces the requirement for expensive buildings, and the costs of delivery of distance learning materials. Although studies and statistics show that between 20 and 30% of those students who begin a distance-learning course do not finish it in the last few years there has been sharp growth in the size of the distance learning market. One of the most important factors relating to e-learning is the element of interaction. Distance students, due to their backgrounds, may also feel more pressure to collaborate and be part of the team (Valentine, 2002).

The need for education has changed because of an increased demand for a highly educated workforce who will be expected to learn continuously. E-learning has become an increasingly important part of higher education. However, the employment of distance education by universities and colleges highlighted issues relevant to the quality and effectiveness of online distance higher education compared to conventional educational patterns. Faculty positive attitude to ICT also does affect the students' perceptions of their distance learning experiences (Valentine, 2002). A lot of evidence has been also provided that the quality and quantity of communication give a raise to the overall student learning perception and satisfaction (Sloan, 2002).

### 2. LITERATURE REVIEW

The rising use of internet and supporting systems constructed the innovative and easy learning environment for students to acquire more skills and knowledge. ICT has transformed the conventional based education system into technology based education system. The classroom environment is moved from teacher centered to student centered form. The radical changes in educational technologies prepared the students to be more responsible in their learning. Viciano et al. describe a computerized system that allows researchers creating, applying and tabulating surveys and paper instruments in an automatized way and consider them

as a useful tool since it permits to input data with higher precision and no need for previous codifications. According to Granados (2015), the use of ICT means breaking with traditional media, boards, pens, etc., and it has given way to a teaching role based on the need for training in and updating one's knowledge of teaching methods based on current requirements.

Recent studies have shown that e-learning implementation is not simply a technological solution, but also a process of many different factors such as social factors (Schepers and Wetzels, 2007; Tarhini et al., 2014b; 2015), and individual factors (Liaw and Huang, 2011), organizational such as facilitating conditions (Sun and Zhang, 2006) in addition to behavioural and cultural factors (Masoumi, 2010). Such major factors play an important role in how an information technology is developed and used (Kim and Moore, 2005). Recent studies have shown that a basic element in traditional classroom learning is communication among the students: the ability to ask questions, to share ideas with others, or to disagree with others is a basic need in the learning process (Picciano, 2002).

Martino (Martino, J., (2007) & Van den Brekel (Van den Brekel, A.J.P., (2007)) found that Virtual environments are best substitutes for those students unable to attend traditional face to face teaching systems. According to A., Jamaluddin, Virtual experiments give great environment for Teaching & Learning (A., Jamaludin et al., (2009)). Fatih Baris and Tosun described the influence of using e-tools in the education process at the high school and concluded the positive influence of this tool on students. More than anything else (34.8% in our research), flexibility is what makes e-learning programs attractive to the learners (Schoech, 2000). In distance-learning courses students can take courses from preferred locations that are convenient for their schedules. This advantage is appealing to most adult learners because it accommodates their work schedules and permits flexibility to manage their family life (Kember, Lai, & Murphy, 1994). Distance students, due to their backgrounds, may also feel more pressure to collaborate and be part of the team (Valentine, 2002).

For beginners, it has been reported that confronting computer technology was more stressful and consumed more time than the actual learning activities at the beginning of a course (Atack, 2003; Atack and Rankin, 2002; Billings et al., 2001; Scollin, 2001). In addition, feeling isolated and missing social contact have been reported in studies of computer-assisted learning. Particularly, the absence of non-verbal cues in solely Web-based learning left students feeling they have been communicating largely with a machine rather than other human beings (Atack and Rankin, 2002; Billings et al., 2001; Andrusyszyn et al., 1999; Bullen, 1998).

The fact that gaps in one's knowledge may be compensated for, and are complemented by virtue of, the knowledge of such person's classmates, constitutes an important advantage of learning in a group (Picciano, 2002). Moreover, people who work together provide social and emotional support to each other (Haythornthwaite, 2001). Different research studies (Lai, 1997; Klemm & Snell, 1996; Jonassen & Kwon, 2001) assert also that subjects that involve discussion, brainstorming, and reflection are best suited to the online format despite the fact that online discussions are significantly different from face-to-face discussions. Courses must be designed so that students could benefit from the interactive potential of online learning (Thorpe, 2002), so instructors require extensive training on how to utilize new technologies and adapt teaching methods to distance learning environment (Valentine, 2002).

Faculty positive attitude to ICT also does affect the students' perceptions of their distance learning experiences (Valentine, 2002). A lot of evidence has been also provided that the quality and quantity of communication give a raise to the overall student learning perception and satisfaction (Sloan, 2002). Gibbs and Simpson (2004) advocate for regular, comprehensive, and detailed feedback as the main interactive component of teaching. They conclude that only immediate and specific feedback provided by instructors enables students to gain control over their learning and monitor their own performance.

Individual background variables found to have an impact on students' acceptance of e-learning are: gender, learning styles, age and organizational factors (i.e. school). Gender seems to be the most influential background factor as it affects the level of computer anxiety (Shuell & Farber 2001), perceived usefulness and ease of use (Shuell & Farber 2001, Ong & Lai 2006). A direct relationship between gender and acceptance is also proposed by Mitra et al. (2000), who concluded that men were more positively predisposed toward computers and tended to use computers more than women. Age influenced students' levels of computer confidence, as younger students were not so anxious in using computers (Jennings & Onwuegbuzie 2001).

The quality of higher education is affected by many requirements and some of them are requirements by (Lazic, 2007):

- Beneficiaries of higher education - stakeholders
- Bologna process, international standards and international organizations (international requirements)

- Requirements of national standards for accreditation,
- Quality management system requirements,
- Requirements of the standard of work and higher education institutions and
- Requirements of technological standards of work or pedagogical subsystem.

### 3. RESEARCH METHODOLOGY

#### 3.1. Aim of this research

The aim of this research is to see what way of studying is the best for Serbian's students, what students prefer in their learning and what are the biggest problem in distance learning. As well the aim of this study is to examine are the students ready to replace traditional way of learning by distance learning and to see what aspects of quality studying have influence on distance learning.

#### 3.2. Research questions and hypothesis

The first distance learning system was developed in America in the 1960s and has a huge impact on learning in developed countries today. On the other hand, the fact that Serbia is still a developing country, this system began to develop several years earlier. In the beginning, he encountered the great resistance of the supporters of the traditional way of learning, while today, every year, the number of students who are interested in this form of learning grows. Two research questions and three hypotheses can be defined about influence of quality of studying on distance learning in Serbia in this paper:

- **Research Question 1** - Most students in Serbia considered that online learning make studying easier.
- **Research Question 2** - The largest number of students is not yet ready to replace traditional learning with online learning.
- **Hypothesis 1** - The basic criteria of the student's success (average grade) have no impact on using online learning among students.
- **Hypothesis 2** - Availability of materials has the greatest influence on the quality of studying.
- **Hypothesis 3** - The biggest obstacle (barrier) to online learning is the lack of social interaction.

#### 3.3. Population and sample characteristics

The population of this research are students from Serbian universities. In this paper were used online questionnaire as method for collecting data that will be used in this research. The questionnaire was sent to 150 random Serbian students and only a few of them were not usable. The respondents were male and female students from first year to graduate year of study. Most of them (42%) were 2<sup>nd</sup> year of study. They cover almost every field of study. Majority of respondents are from technical and engineering fields of study. Priorities was faculties that have developed system of online learning. As well the most respondents were students who spend more than 6 hours on the Internet (58%).

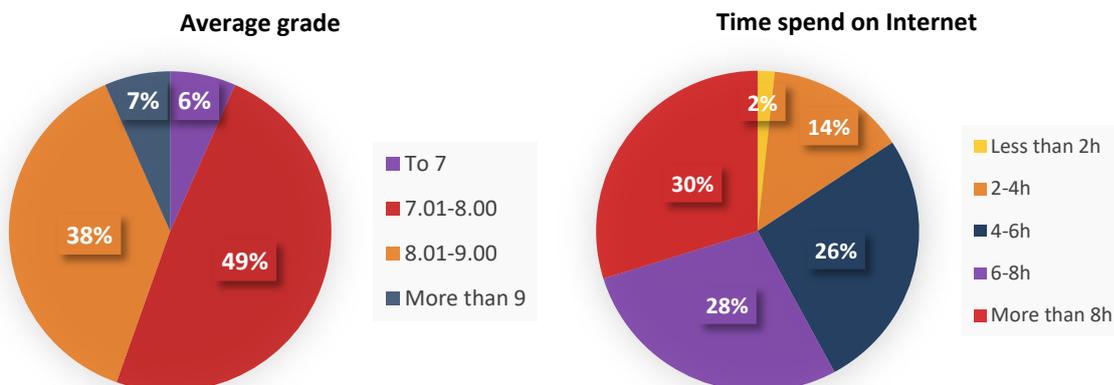

Figure 1: Basic information about average grade and time spend on Internet

#### 3.4. Research instrument

Questionnaire was created and distributed online. It was consisted of three parts. First one was related to basic criteria of the students success about respondents. Those included: time spend on Internet, year of

study and average grade. Second part included questions about students way of learning and different e-tools like are online courses, online tests, online dictionaries and searching literature. Questions in third part were about influence of different aspects of quality on distance learning. This include influence of appearance of the interface, availability of materials, interaction with the professor and flexibility in learning on online learning. They consisted from Likert scale, where one is extremely small influence and five is extremely big influence.

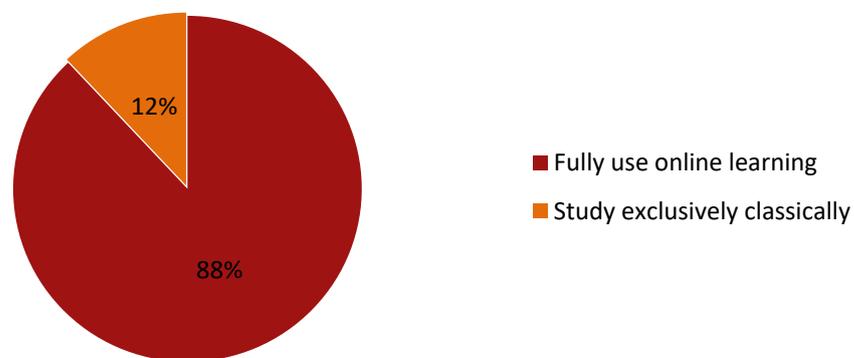

#### Data Analysis Methods

To examine above mentioned hypothesis, after conducted questionnaire, statistical analysis was performed using SPSS 22. Various tests were used in order to get most precise data.

### 4. RESULTS

To support the following results, sample characteristics were collected and analyzed. Some of them are more particularly described by giving the answers to some basic questions related to distance learning. One of them is “Do you use any types of electronically supported learning (online learning) during your studies?” The results are represents on picture 2.

**Do you use any types of electronically supported learning (online learning) during your studies?**

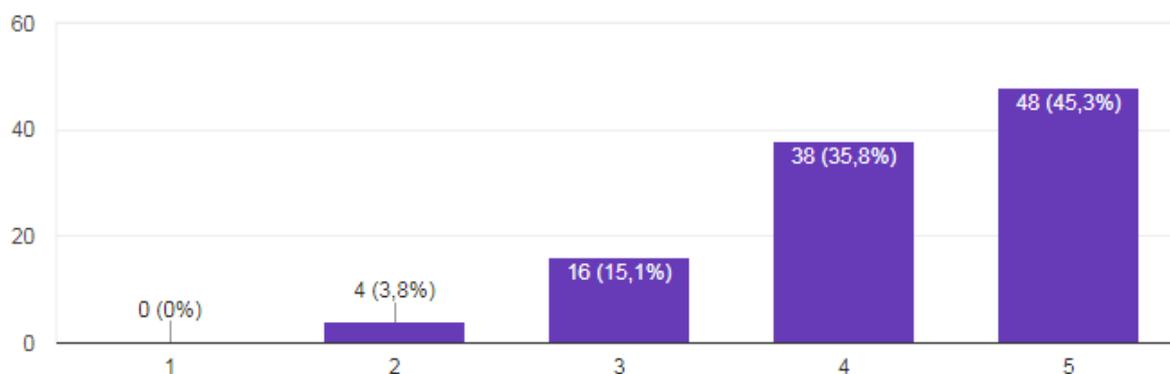

**Figure 2:** Uses of online learning among students

Now, will be represented the results of two research questions and three hypotheses.

#### **Research question1 - Most students in Serbia considered that online learning make studying easier.**

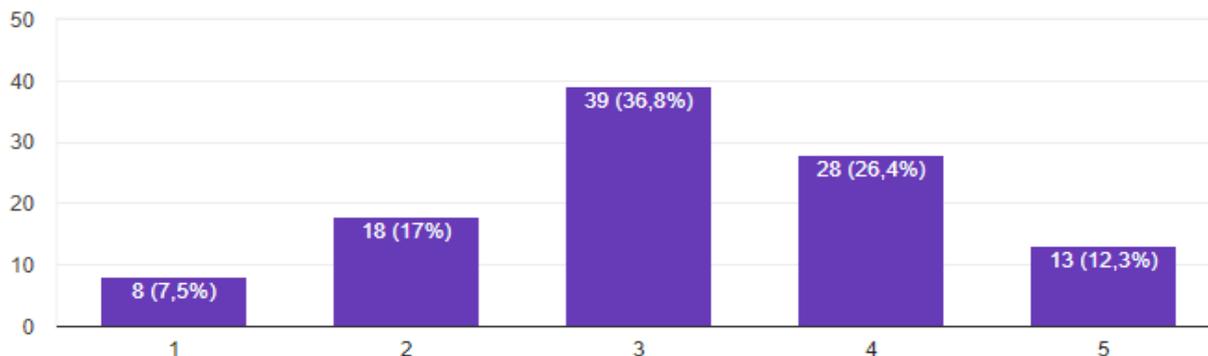

Turned out that thatwas right. Using questionnaire it can be proved that most students in Serbia considered that online learning make studying easier. Question consisted from Likert scale, where one is extremely small influence and five is extremely big influence. The results of this research are given on the figure 3.

**Figure 3:** Positive impact of online learning on studying

**Research question2 - The largest number of students is not yet ready to replace traditional learning with online learning.**

Using questionnaire, results show that students are not yet fully prepared to switch from traditional way of learning to online learning. Question consisted from Likert scale, where one is extremely small influence and five is extremely big influence. The results of this research are given on the figure 4.

**Figure 4:** Student willingness to replace the traditional way of learning

**Hypothesis 1 -The basic criteria of the student's success (average grade) have impact on using online learning among students.**

Using ANOVA test it can be concluded that this hypothesis turned out to be right. Significant influence does exist and it is less than 0.05. Average grade truly have impact on using online learning among students. The results of this research are given in the table 1.

**Table 1:** Average grade and online learning

Influence of average grade on using online learning	Descriptives		
	N	Mean	Std. Deviation
To 7.00	9	2,44	,726
7.00-8.00	59	1,66	,685
8.00-9.00	45	1,69	,596
More than 9	8	1,50	,535
Total	121	1,72	,674

### **Hypothesis 2 - Availability of materials has the greatest influence on the quality of studying.**

Using ANOVA test, significant difference was not recognized, considering availability of materials as an aspect of online learning and quality of studying. P value was greater than 0.05. The results of this research are given in the table 2.

**Table 2:** Literature and quality of studying

Influence of literature on the quality of studying	Descriptives		
	N	Mean	Std. Deviation
Mostly does not influence	7	4,71	1,604
Partly influence	17	4,76	1,786
Mostly influence	8	4,12	2,100
Completely influence	25	4,96	1,620
Total	57	4,75	1,714

### **Hypothesis 3 - The biggest obstacle (barrier) to online learning is the lack of social interaction.**

Using ANOVA test it can be concluded that hypothesis was right. Significant influence does exist and it is less than 0.05. The results of this research are given in the table 3.

**Table 3:** Social interaction and online learning

Influence of social interaction on online learning	Descriptives		
	N	Mean	Std. Deviation
Mostly does not influence	10	1,40	,516
Partly influence	32	1,38	,492
Mostly influence	35	1,57	,502
Completely influence	29	1,72	,455
Total	106	1,54	,501

## **5. DISCUSSION AND CONCLUSION**

Information systems are something that is constantly evolving. With the development of information systems, learning methods are being developed. Thus, it is possible to hear terms such as distance learning, online learning, and so on. Due to the enormous importance of the influence of online learning on the quality of studying, we decided to look more closely at this topic. The aim of this research is to examine whether students are ready to replace traditional way of learning by distance learning and to see which aspects of quality study have a bearing on learning distance. Also the aim of this study is to see which way of studying is best for Serbian students, what students prefer in their learning and what is the biggest problem in distance learning. Based on the research, we found that most students in Serbia considered that online learning makes learning easier and most students use some aspect of online learning, but the largest number of students is still not ready to replace traditional learning with online learning and the reasons for this are mainly lack of social interaction, lack of interaction with professors, etc. It can be concluded that online learning in Serbia is still in the development phase and it is necessary for students to learn more about the benefits of online learning.

Results from first research question proved that most of Serbian students considered that online learning make studying easier. This refers to thought on some e-tools like online courses, online dictionaries,

searching literature and online tests. Fatih Baris and Tosun described the influence of using e-tools in the education process at the high school and concluded the positive influence of this tool on students.

In second research question, it can be concluded that the largest number of students is not yet ready to replace traditional learning with online learning. Only one third of students who participate in survey said that are ready to replace traditional learning with distance learning. This show that student must be more informed about advantages of distance learning.

In first hypothesis, it can be concluded that there is significant difference between average grade that student have and using online learning. That means that students who have higher grades, using online learning more than students who have lower grades. That shows that student who have higher grades are more opened to try something new in learning. This is telling that students with lower grades accept things that are easy to use and that require minimum effort and they have no interesting in trying some new ways of learning, like online learning. But some students aren't conscious that online learning can make study a lot of easier.

Results from the second hypothesis were interesting. Some thoughts are that availability of materials has the greatest influence on the quality of studying. But this is not right. It seems that there is no significant difference between availability of materials and quality of studying. That means that availability of materials have the similar influence on quality of studying like others aspect of online learning.

By the third hypothesis is proved that the biggest obstacle to online learning is the lack of social interaction. Picciano (2012) concluded that a basic element in traditional classroom learning is communication among the students: the ability to ask questions, to share ideas with others, or to disagree with others is a basic need in the learning process. Also, Atack and Rankin, Billings, Andrusyszyn and Buleen says that feeling isolated and missing social contact have been reported in studies of computer-assisted learning. Particularly, the absence of non-verbal cues in solely Web-based learning left students feeling they have been communicating largely with a machine rather than other human beings. Research has proven that, indeed, social interaction is something that students most miss in online learning.

**Abstract:** *In this paper, we discussed the importance of additional services in airlines, their quality and related quality management approaches. Different concepts of providing additional services for both organizations that offer full service and low-cost organizations are presented. We overviewed wide range of services in airline industry, and dedicated special attention to the additional services. The paper also deals with problems related to the definition of quality and quality assessments of these services, followed by the example of RATER model and its use. Key elements of the Gap model are analyzed in order to provide understanding of customers' expectations and perceptions, along with business performances in context of basic quality planning, control, improvement and assurance activities. At the end, new challenges for improvements of additional services in airlines, as well as potential overall advancement of the system perspectives are presented. We concluded that additional airline services will continue to grow along with the trend of adjustment to different groups of customers, thus creating even wider possibilities for the customers. As the new technologies will enable growing information, one of the best mechanisms for achieving greater customer satisfaction and successful business is the use of quality management concepts in this field.*

**Keywords:** *quality management, airlines, additional services, chargeable services, non-chargeable services, improvement*

### 1. INTRODUCTION

Although we are learning from ancient myths about the attempts of flying from men Dedail and Icarus and the traces of ancient Chinese civilization, the history of aviation can be accommodated in the last 100 years. From the time when the Wright brothers in December 1903 performed the first flight with a heavily air-borne, managable drive, the aviation's rapid development began. The first regular airline company was DELAG (Deutsche Luftschiffahrts-Aktiengesellschaft) and it was founded in 1909 with the help of the German government and Cepelin Corporation (Schmitt and Gollnick, 2016). During the First World War, bomber planes were used, and the largest could carry a load of up to 5 tons. In 1919, the first flight was made across the Atlantic, and between 1920 and 1930 there was also progress in the field of civil aviation. The first commercial passenger plane was Douglas DC-3. From this period there are companies that exist today - RDA (Royal Dutch Airlines) founded in 1919 and Qantas (Queensland and Northern Territory Aerial Services) from 1920.

After the Second World War there was a further development of civil aviation thanks to the overflow of resources from the military sector. In 1956, American Airlines transported more passengers than US railways, and in 1957 more passengers crossed the North Atlantic by plane than by boat. Significant events in the development of aviation took place in 1958, by introducing Boeing 707 as the most economical, then Airbus in 1970, and the first plane on solar and electric power in 2010. The largest and most comfortable airplane today is the Airbus 380 with a capacity of 850 up to 1000 passengers.

Over the years, most airline companies were established at the national level and operated in accordance with state interests. However, globalization and new ownership relations and the strengthening of competition lead to permanent changes in the market. The airline's independent operations are more difficult now, so that they associate themselves in partner groups to unite their strengths and resources. Consequently, competitors become strategic business partners, and their cooperation takes place in commercial and operational businesses such as: flight scheduling, marketing, frequent flyer program, and codeshare (bound flights).

Examples in this paper are inspired by the practices of some of the most famous alliances:

- Star Alliance – Lufthansa, SAS, Thai International, United Airlines;
- Oneworld - British Airways, American Airlines and Cathay Pacific;
- Skyteam – Air France, Delta Airlines, KLM, Aeromexico, Aeroflot and Korean Air (Szakal, 2017);

## 2. AIRLINES AND THEIR SERVICES

Airlines are inherently unique and operate in a unique and different way in comparison with other companies. The basic function and purpose of the existence of airlines is to provide the service of safe and efficient passenger transport from point A to point B. Regarding the basic service, different airlines may include a variety of accompanying and additional services. Additional services complement the quality of the basic service and increase its value. In low cost companies (LCC), the price of the ticket includes only basic passenger transport services, while all other services are considered as additional and charge separately. Full service companies (FSC), in addition to the basic transportation services, include tickets, luggage transportation to a certain weight, flight overnight and other services depending on the selected class. Most of them offer two basic categories - service classes: economic and business.

The economic class includes seats in the central part of the aircraft, luggage within the permitted dimensions, meals and entertainment depending on the length of the flight. Business class passengers can use Premium lounge services, and within the airplane they are sitting in comfortable seats that can stretch and order meal and drinks as desired at any time, and have more options for fun.

On the other hand, many companies offer services to their customers grouped into packages with a distinctive tariff name. For example, the company British Midland International (BMI) classifies several types of packages (economy saver, economy, economy flexible and business) and depending on what service they choose (checking and scheduling, acquiring rights for loyal passengers or some additional benefits) customers gain the right of advantage in checking, collecting and doubling miles or the ability to read newspapers or the use of hot and cold meals and alcoholic drinks (Vinod and Moore, 2008). All other services outside the basic package are considered as additional, so they can be chargeable and non-chargeable, and it is needed to make a special requirement when booking a ticket.

### 2.1. Chargeable services

Additional services (ancillaries) that are charged separately are optional services that a customer can buy along with the ticket. The airline decides which service will be chargeable and under what conditions. For example, a particular service may be chargeable for one destination, and for the other not, the service may be chargeable to an economy class, and free for business, while frequent flyers may be exempted from paying additional services. Some additional services can be purchased exclusively with the airline tickets, while other services can be purchased as a separate service, with or without booking a flight. The spectrum of chargeable services can be very wide and varies from LCC to FSC. The payment services can be classified into three groups (Marcenko, 2015):

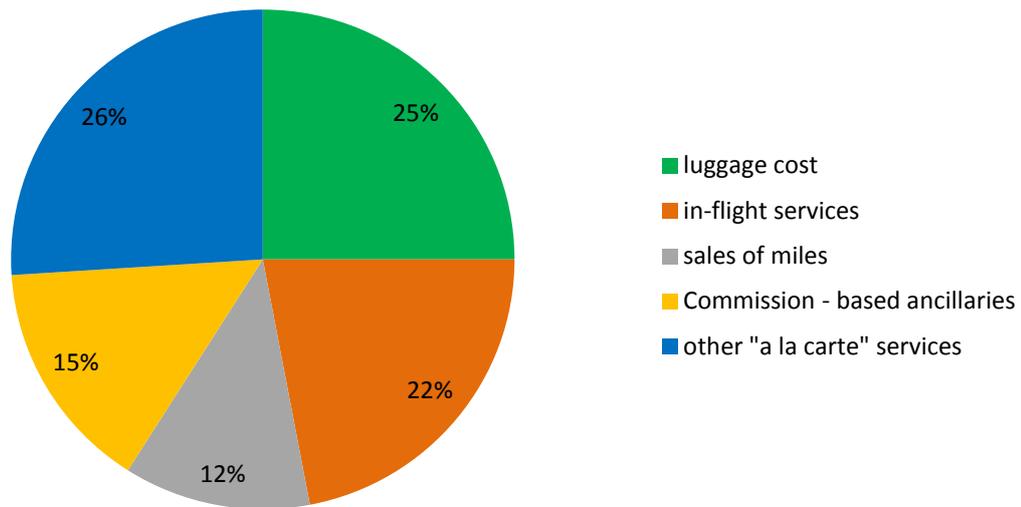

- 'A la carte';
- Commission – based ancillaries (third party services);
- Frequent flyer programme – (services intended for frequent flyers).

The passengers have the opportunity to use such a varieties: food and beverages during the flight, an advantage in "check-in" and boarding, luggage, seats with extra legroom, fun during the flight, wi – fi, etc. are included in 'a la carte' services. Provision-based services relate to hotel accommodation, car rental and travel insurance, while services intended for frequent flyers allow discounts on airline or other product prices (wrist watches and hotels). Together with basic (transport), additional services round up the entire package offered by one company to the passenger (O'Connell and Warnock, 2013).

#### 2.1.1. The economic significance of chargeable services

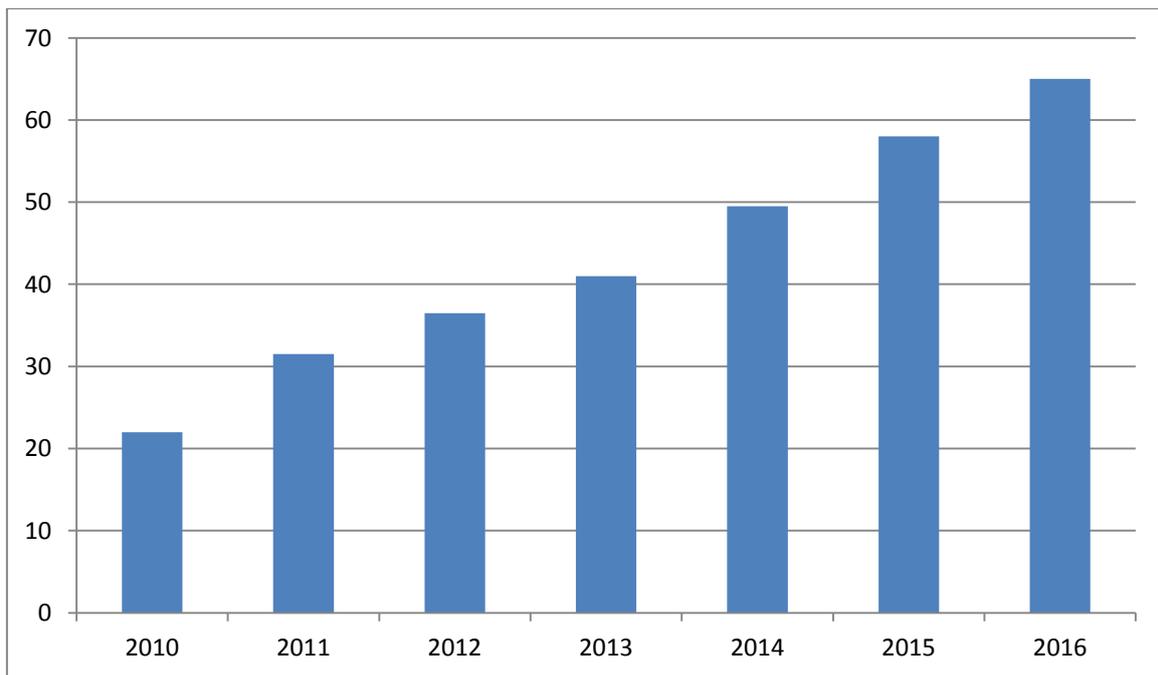

Airlines make significant revenues from additional services (Figure 1). Key services with the largest share in the revenue from chargeable services are luggage transportation (25%), a la carte services during the flight

(26%), commission based services (15%) and sales of miles for frequent flyers (12%) .

**Figure 1:** Key components of the revenue from additional services (Idea Works Company, 2016)

Revenue from additional services as well as its share in the overall revenue of airlines, grows year after year. Figure 2 shows an increase in the revenue from additional services ranges from \$22 billion in 2010 to \$65 billion in 2016. At the same time, the increase in revenue is recorded from additional services against the total revenue of 9.2% in relation to 4.6% in 2010 (Amadeus IT group, 2017).

**Figure 2:** Total revenue from additional services (\$ billion)

## 2.2. Non-chargable services

Companies that provide a complete service, within the price of the ticket, allow passengers and a range of other services that make travel easier, and to get those services, they need to submit a special request. Some of them are: the use of a baby basket, a meal for children or special meals, the use of wheelchairs, transport of bicycles, musical instruments, sports equipment, passengers with reduced mobility, persons with special needs, those who require special medical care, medical carriers, dogs to help blind, deaf and psychiatric patients, the transport of fragile luggage and weapons, etc. Each passenger has the right to use

these services, but it is necessary to make a special request when booking a ticket. The company is obliged, in accordance with its procedures, to consider and assure the execution of the request.

### 3. QUALITY MANAGEMENT OF ADDITIONAL SERVICES

Quality management is a set of coordinated activities to direct and control an organization in terms of quality (ISO, 2015). All quality management activities are grouped into four processes: planning, control, improvement and quality assurance.

Quality planning is determining the quality objectives by examining the needs and requirements of the customers, translating them into the service specification and planning the necessary resources for the service realization. This phase of quality management includes the design of all processes by providing answers to the questions: who are customers; what are their expectations; how to meet expectations; what resources are needed?

Quality control focuses on meeting the quality requirements and includes the activities of monitoring, controlling and reviewing all activities involved in the service delivery process. It aims to realize planned, i.e., projected quality, permanently, with as few variations as possible. It answers the following questions: whether we are able to fulfill the expectations of the customer; to what extent we fulfill the expectations of the customers; whether we constantly meet the expectations of the customers; whether we are implementing preventive and corrective measures. Quality improvement should enable increased ability to meet quality requirements and involves the implementation of preventive measures for setting up and implementing a new higher quality. Answers to questions: how to improve the quality of service; how to overcome customers' expectations.

Finally, quality assurance aims at assuring that the quality requirements are met. It represents a system of policies, procedures and practices that result in a consistent service in accordance with predefined quality requirements. It is necessary to answer the question: Do we apply policies, practices and procedures?

One of the ways to assure quality is the implementation of international standards. The specific standards, guidances and guidelines developed by the IATA - International Air Transport Association apply to the airline industry. This international airline association was founded more than 70 years ago in order to help companies to cope with their processes and increase customer satisfaction with cost savings and efficiency gains (IATA, 2017). IATA develops standards, instructions and guidelines that enable airlines to safely, efficiently and economically operate according to strictly defined rules. At present, 275 airlines have IATA accreditation. With integrated quality management system and security management system, IATA provides evidence of efficient and effective business in the field of quality and safety for all interested parties.

#### 3.1. Defining the quality of additional services

Quality is the degree to which a set of inherent characteristics of an object fulfils requirement (ISO, 2015). Based on the stated definition of quality, it is clear that the basis for defining the quality of service is to determine the characteristics of the service and the needs of the customers. Most often, this process is not easy due to the specificity of the services in terms of tangibility, durable results, quality consistency and customers' needs. Incomplete service makes it difficult to define service quality characteristics as well as to identify customer needs. The durability of the results is based on the memory and the subjective experience of the received service and can be difficult to measure. The stability of the quality of the service depends to a great extent on the competence, kindness, physical and psychological state and other characteristics of the service provider (Filipović and Đurić, 2009). To evaluate the quality of the service, the most commonly used RATER model is defined by Parasuraman, et. al. and represents an acronym of English words Reliability, Assurance, Tangibles, Empathy, and Responsiveness (Parasuraman, Zeithamel and Berry, 1988). The essence of this model is a questionnaire for the customer regarding his expectations and experience of service in relation to 5 quality dimensions (Electronic commerce group, 2017):

- Reliability - the ability to deliver the promised service in accordance with the specifications specified at a specified time;
- Assurance - having the necessary knowledge and skills to perform the service, the confidentiality and honesty of the service provider, safety (no danger, risk and doubt);
- Tangibles - the existence of physical objects, equipment, printed and video materials;
- Empathy - the effort to get to know the customers and recognize their needs;
- Responsiveness - Readiness to help customers get the service at a given moment, availability.

Below, in Table 1, we present an example of a charge service will be shown – the use of Premium lounge.

**Table 1:** RATER model for the use of Premium lounge

Quality dimension	Characteristic of the service
Reliability	Consistency and availability of offered content
Assurance	Ability to meet customers requirements
Tangibles	Interior design, modern technology and accessories
Empathy	Understanding customers needs
Responsiveness	Availability of staff for the sale of passes and service personnel

This example shows that the use of Premium lounge, for the quality dimension of the participation of tangible products, the characteristics of quality - the appearance of the interior, modern technology and additional equipment - derived from the question: Are the equipment and technology modern?

Through its quality research, previously, Parasuraman has developed a GAP model (Parasuraman, Zeithaml, Berry, 1985), according to which the quality of the service directly depends on the differences between the customer expectations and the achieved performances. It can be said that the quality of the service can be measured by the size of the gap between the expectations of the customer and his experience of the delivered service, that is, the quality of the service is higher if this difference is lower. The starting point for defining the quality of a service is the customer, his needs and expectations. The task of the marketing function is to research, recognize and understand these expectations, and based on that, specifies the quality of the service. The delivered service must correspond to the specified and promised service. The circle is closed by the customer and his perception of services received in the sense of meeting his expectations.

### 3.1.1. Understanding expectations and perceptions of the customers

Customers' expectations are not uniform, and often can not be clearly defined. It depends on the demographic, cultural, social and individual characteristics of the customers, so companies constantly make efforts to better understand and assess the needs and expectations of their customers.

Numerous studies analyze the importance of individual services for customers in the field of air transport. One of them is Hong Kong, where 26 airline services are considered (Gilbert and Wong, 2003). Customers evaluated the importance of services with ratings from 1-8, and the results showed that with the highest rating - of the highest importance for the customer - basic services: safety and accuracy in the order of flight. Additional services such as: the ability to use the Internet and mobile phones, car rentals, hotel accommodation and travel insurance are of the least importance for the customer with ratings below 5. The impact of individual services on the loyalty of the customers was also examined and presented with appropriate weighting using AHP method (0.085), leisure time (0.045), and extended service (0.044) (Tsauro, 2002). It is clear that priority customers provide basic airline services, as well as hospitality and cleanliness, while additional services are of minor importance. Nevertheless, the data on the growth of revenues from additional services and their share in total revenue shows that interest in using these services is rising, and that additional services should always be taken in account.

It is known that the price of a service affects the customer's perception of quality, and therefore his expectations. Therefore, the customer's payment ability also affects the expectations and understanding of the quality of customers. If the customer choose a lower ticket price, he decrease his expectations and accepts less benefits and lower quality. On the other hand, customers who are willing to pay extra service expect all service quality dimensions at a high level.

After receiving the service, the customer summarizes the impressions and forms a subjective attitude about the quality of the service. This attitude also depends largely on the accompanying services whose evaluation makes a difference in the perception of the quality and determines the behavior of the customers in the future in relation to the service and the supplier. The positive perception of the service has a positive impact on the evaluation of the service, customer satisfaction and the image of the airline. If the customers' perception of received service is higher than expected, customer satisfaction will be higher, as well as positive image of the airline, customers will remain loyal to the same company and recommend it to others (Park, Robertson and Wu, 2004).

It can be concluded that, in order to achieve customer satisfaction and loyalty, airlines must completely fulfill and even exceed the expectations of the customers.

### **3.1.2. Business system performance and service quality**

One of the definitions of quality was given by Stout, which showed quality as a relationship between performance and expectations. This means that higher performance results in higher quality (Stout, 1985). The performance of the whole system depends on the performance of all of its parts. The gap model indicates the importance of all the organization's functions in the processes of defining, developing, delivering and monitoring of services, from marketing, research and development, through acquisition and quality, to service delivery. In order to minimize the gap, the system performance has to be raised to the highest level. The process of providing the service of the airline is made up of a chain of processes that relate to one another, and the successful realization of each of them depends on the realization of all others. The process success criteria are effectiveness and efficiency, and they depend on the effectiveness and efficiency of the entire business system. Process management involves clear defining of the activities, resources, and the roles and responsibilities of all employees.

The performance of service based business systems is based primarily on employees' work and their direct or indirect contact with the customer, and the competence, motivation and awareness of each individual is crucial for achieving positive business results.

In order to achieve the consistency of the service - that is, the right of every customer to receive a particular service in the same way at any time, from each employee, safely and efficiently, it is necessary to specify the service as accurately as possible and to respect all the rules and procedures for its delivery. In order to avoid improvisation each airline company develops procedures. One of the techniques for graphic overview of processes and relationships between key factors is process mapping (Mijatović, 2015) which is demonstrated through the process of receiving the request for the transport of a bicycle.

The process of receiving a request for the bicycle transport begins with customer request for transporting the bicycle to the booking service. The service receives a request and imports it in the system that checks the inventory for the received request. If it is available on inventory, the specialist confirms the request; however, if it is not available, the booking service receives information and informs the customer about it. Upon receiving the notification, the customer requests for a second flight. If there is an alternative, it resends the bicycle request and repeats the same procedure, and if there is no other flight, the process ends. Upon confirmation of the request, the specialist for this function checks the compatibility of the requirements with respect to the type of aircraft. If the dimensions of the bicycle correspond to the aircraft type specifications, the specialist confirms the request and informs the passenger about it, and if not, rejects the request and transmits the negative message. Thereby, the process of receiving the request for the bicycle transport ends.

## **4. THE CHALLENGES AND FUTURE OF THE SERVICE QUALITY IMPROVEMENT**

The specificity of the airline's basic service related to flight safety is that it must not vary depending on the carrier. However, the economic crisis, fuel price variations, and many market participants have led to increased differences in supply and prices of additional services. The expansion of the LCC for the past 20 years has increased the competition for airlines that provide a complete service, so they often reduce the number and quality of services included in the ticket price, which leads to additional pricing of additional services. With this in mind, the size of the seat gradually decreases, so today the most extensive economy class seats in the four largest airlines are narrower than the smallest seats offered in the nineties of the last century (Wu, 2014).

On the other hand, companies that are monopolists on certain lines reduce the quality of their services (take off in time), while at the same time raising prices and lowering the quality of additional services because they do not have competition (Mazzeo, 2003). In this way, they provide themselves with great revenue because passengers do not have many options to choose air carriers.

One of the problems with additional services is the insufficient information about the possibilities and the right to use the special services of the airline.

It is estimated that the number of passengers on the global level in air transport is growing by 5% annually, and that in 2020 it will reach a figure of 3.8 billion passengers. It is therefore expected that the sale of additional services will grow. In order to meet the customer needs as fully as possible, in the race with the competition, continuous improvement and improvement of the assortment and quality of services is necessary.

Modern trends in improving the quality of additional services of airline companies are moving in two directions. Companies that base their business strategy on a low-cost model are decreasing their services

by offering passengers a minimum of service and expecting that each individual can subsequently purchase a service of his choice. On the contrary, other companies are specifically focused on adaptability to certain categories of customers. In this regard, they develop special programs in which they combine more services into special packages at lower prices (branded tariffs). Connection of optional services that airlines have previously charged separately as a la carte services with common basic services are defined as branded tariffs. The airline benefit is to increase the sales of additional services, but also to target service packages according to customer requirements. Beside the opportunity to fully satisfy customer needs, the customer benefit is ability to get discount of 10% to 12% on the individual additional. Branded tariffs enable the company's brand recognition and customer loyalty (Macnair travel management, 2017).

An example of a successful company is the Emirates Airlines whose motto is "Flexibility" and which has established high standards for all of its services, is the leader in technological innovations, and provides value-added services that are tailor-made and customer-oriented. Customers of the services of this carrier can do the check-in at the airport - at the counter, in the lounge and on the self-checking machine (Dubai airport) or via Internet and SMS. This company is a pioneer in services - fun and communication during the flight (IFEC - In flight entertainment and communication) (Anwar, Hussein, Moosa and Faris, 2012). The first class offers personal rooms with special benefits, which are considered as luxury and significantly increase the price of the tickets, and will only be chosen by more prosperous passengers. Therefore, most airlines will not include them on their regular flights. However, in order to satisfy the needs of majority, it is advisable to expand the range of services so that each passenger can choose between several options. This does not necessarily have to increase the cost of airlines.

Better customer informing includes: arranged and updated websites, transparent chargeable and unchargeable services, available call centers and provision of complete information by agents. Besides good promotion, it is also necessary to provide feedback from the customers. An unsatisfied passenger will almost certainly appeal to the responsible airline service, while the perception of most passengers will remain unknown to the company. In order to keep track of customer satisfaction, the passengers could fill in a questionnaire during the flight, to show their satisfaction with services. In order to improve and enhance the level of service quality, continuous monitoring and analysis of the results, is needed.

## **5. CONCLUSIONS**

Research incorporates authors' knowledge of quality management and work experience with subject literature. This paper presents additional airlines services (both chargeable and non-chargeable), methods for monitoring their quality and quality management functions of these services. The significance of chargeable services for airline companies is expressed by the economic indicators of the growth of revenues coming from additional services and their share in total revenue. Considering that there is a steady increase in the number of passengers in the air transport, an increase in the sales of additional services can also be expected. Stronger competition, desire for profit and new markets are encouraging airline companies to be creative and introduce new content at affordable prices. At the same time, the development of information and communication technologies is changing the needs, expectations and demands of the customers, and airlines have to adapt and respond to these challenges.

Bearing in mind that the general trend in service activities is customization, airlines will increasingly abandon the concept of universal service and switch to service-oriented models for different target groups. Expectations and customer satisfaction must be constantly monitored and reviewed, and based on those expectations and reviews, airline companies should define and specify the quality of services. All the functions of the organization and all employees must work effectively and efficiently to meet all the goals of the organization and the quality objectives. In regard to this, continuous review and improvement of system performance is also necessary.

The aim of this paper is to point out the importance of quality management of additional services to increase customer satisfaction, resulting in a better image of the airline, retaining existing ones and acquiring new passengers. The focus of the work was on the theoretical considerations of the function and importance of quality management of additional airline services, especially for the purpose of improving quality, and the ultimate effect of this is the creation of benefits for all stakeholders of the process.

# RISK MANAGEMENT INTEGRATION THROUGH ISO 9001:2015, ISO/IEC 27001:2013 AND ISO 22301:2012 STANDARD REQUIREMENTS

Ana Cobrenovic<sup>1</sup>, Milica Rajkovic\*<sup>1</sup>, Mladen Djuric<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences

\*Corresponding author, e-mail: rajkovicmilica@outlook.com

**Abstract:** *The main purpose of this paper is to indicate how the organization can deal with risks related to quality, information security and business continuity through the coordination of different risk management methods, and to present the importance of risk management for organizations nowadays. We analyzed the requirements of ISO 9001:2015, ISO/IEC 27001:2013 and ISO 22301:2014 related to risk management. This served to create a base for integrating the requirements of the above-mentioned standards into a simple system that helps organizations to examine and continually treat risks is shown through this paper.*

**Keywords:** *risk management, quality, information security, standards, integrated management system*

## 1. INTRODUCTION

The notion of risk, as a situation where the undesired variation from the intended outcome is possible, always exists in our environment, and for the business of today, this situation is inevitable. Risk management is reflected in the systematic prevention of occurrence of harmful events and by undertaking well-directed actions in connection with any business activity, whether financial or non-financial (ISO, 2015 a).

Risk management is an important business activity for companies of all sizes. Implementation of risk control that complies with the requirements of management systems standards is a much easier approach for the organizations. The companies that efficiently manage their risks will much more probably succeed and produce high quality products and services, aligned with its business goals.

Current trends in the field of security and quality management systems are focused on finding solutions that act preventively to losses through efficient and effective tools. Economic crises, migration and globalization have caused constant changes regarding all business dimensions and in that way force management to analyze and manage the risks it recognizes. A risk analysis based on a scientific approach, can be defined as a systematic process with iterations, that implies the assessment and interpretation of accurate information about system analysis and following identified hazards. Implicit results of the analysis, qualitative or quantitative, express the level of risk. The results help us make a decision whether the risk is acceptable or not (Pačaiova, Sinay, Nagyova, 2016).

The fact is that risk management as well as quality management is a 'journey, not a destination', and this road leads to the continual improvement of the business processes, since the creation of the term quality, to the present and in the future (Loosemore, Raftery, 2006). The management system nature is based on Deming's PDCA (Plan-Do-Check-Act) cycle which drives continual development, reviews and improvements of the system. Each review may result in corrective and preventive actions or identification of positions for risk management improvement.

The steps that risk management involves are different authors define through different approaches. For example: setting and defining objectives, forecasting, planning with decision making, obtaining resources, organization, motivation and instruction, realization, coordination, adaptation and learning (Vujošević, 2008); or for example: identification, analysis and risk control (Đapić, Lukić, Kilibarda, 2012).

For the purposes of this paper, the following processes can be singled out for each approach:

- Risk identification,
- Risk analysis and ranking,
- Risk control and
- Risk inspection and monitoring.

## **2. THE RISK CONCEPT IN STANDARDS FOR QUALITY, INFORMATION SECURITY AND BUSINESS CONTINUITY MANAGEMENT SYSTEMS**

### **2.1. The Risk Concept in the Quality Management Systems**

In terms of the ever growing competition on the global market, customer satisfaction is among the critical success factors for the processes related with products and services. The ISO 9000 Standard Series since the first version in 1987 have so far been developed. By collecting numerous examples from business practices, standards are expanded, revised and kept up-to-date. The famous, wise Aristotle's quote: "For the things we have to learn before we can do, we learn by doing", completely describes the development of standards (Soyle, 1994).

In order for the user to always feel that in "safe hands" while using a particular product or service, it is necessary, in addition to the quality of the output product or service itself, to provide continuous stability and inspection of the company's internal organization. One of the cornerstones of safe and continuously business is an effective risk management that makes the quality constantly ensured.

A new version of the International Standard specifies requirements for an organization to understand its own context and to identify risks as a basis for planning. It represents the use of the new concept of 'risk-based thinking' in the planning and implementation of quality management system processes and helps in determining the scope of documented information. One of the key role of the quality management system is to act as a preventive tool (ISO, 2015 b).

### **2.2. The Risk Concept in the Information Security Management Systems**

The fact is that in this so-called. cyberspace happens a lot of undesired events. The important goal of each organization is business safety, which largely depends on the protection of information property, other property and resources. Therefore, the introduction of the information security management system represents the implementation of the necessary actions to achieve a satisfactory level of information security within the organization. The emphasis is on the risk management process that accelerates the selection of preventive and corrective actions and inspections that, if properly implemented, ensure that the system evolves towards a change management system in a safe environment (Kokic, 2016).

The risk in ISO/IEC 27000 is defined as the effect of deviation from the expected and it is indicated by the level of risk that is defined as the relationship between the consequences of the risk and the probability of their occurrence (ISO, 2016). When we talk about the security risks of information, we can notice the three spheres influenced by this management system. These are: information security, information technology security, and corporate (physical) security and protection. The information security refers to all forms of data that an organization has at its disposal. It relies on the classic Confidentiality-Availability-Integrity (CIA) triad for expressing security objectives. The CIA triad was introduced in the Nineties as a multipurpose, standard way to express security requirements regarding information assets (Abdulhadi, Damiani, 2017).

The risk management is according to ISO/IEC 27001:2013 standard presented through clear requirements for risk management and different rules of conduct designed in the form of inspections presented in Annex A of this standard. The inspections in Annex A provide the correct protection and classification of information. This is also achieved through the security of information technologies that includes vulnerability management, incidents, configurations, networks, availability, back-up activities, changes, and everything related to the functional safety of computers and portable devices (ISO, 2013). Corporate (physical) security and protection is a segment that deals with the physical aspects of protection, employee checks, protection against theft, violence, sabotage and any other harmful behavior or situation.

### **2.3. The Risk Concept in the Business Continuity Management Systems**

Business continuity according to ISO 22301:2012 represents the capability of the organization to continue delivery of products or services at acceptable predefined levels following disruptive incident. Business continuity management is defined as holistic management process that identifies potential threats to an organization and the impacts to business operations those threats, if realized, might cause, and which provides a framework for building organizational resilience with the capability of an effective response that safeguards the interests of its key stakeholders, reputation, brand and value-creating activities (ISO, 2012).

Despite the big caution imposed by quality and information security management systems, the hazards still remain present in the organizations. As much as organizations are trying to reduce the risk probability or effects to the acceptable level, those risks continue to exist. If some risk has been identified and especially if

the risk has not been brought to an acceptable level, the probability of occurrence, i.e. the realization of possible undesired outcome, still exists. When a business breaks, organizations are facing with huge financial and reputational losses.

If the interruption of the business is longer, the damage is bigger and more serious. Business continuity management systems emphasizes the need for a well-defined structure of response to incidents. This assures that when incidents occur, there are prepared plans that define the responsibilities and concrete actions that the responsible persons must undertake in order, to return the system to the normal state of functioning. Depending on which interested parties, incidents have an impact, appropriate communication schemes are also defined in times of crisis, for example with the public or state authorities (Tangen, 2012).

### 3. MANAGEMENT SYSTEMS STANDARDS' REQUIREMENTS RELATED TO RISK MANAGEMENT

Standards can generally be viewed as the 'best practices' of management in some business areas, resulting from the experience of dissimilar companies with different environments and conditions, as well as detailed analyzes and requirements imposed on the market. Standards are designed to represent a set of requirements or guidance that organizations need to conform to or follow, in order to achieve the appropriate level of regulation of their business functions, such as quality management, information security, environmental protection, compliance, anti-bribery etc.

The latest versions of the management systems standards are accordance with the Annex SL High Level Structure and recommendations. According to this document, the standards must contain the scope, normative references, terms and definitions, and requirements relating to:

- Context of the organization,
- Leadership,
- Planning,
- Support,
- Operation,
- Performance evaluation and
- Improvement.

Through most of these groups it requires standards, which is especially noticeable in ISO 9001:2015, those who are related to risks are intertwined, which will be presented in this chapter of work.

#### 3.1. Requirements Related to Risk in the Quality Management Systems Standard

In the ISO 9001:2015 standard, requirements related to risks and opportunities are intertwined across all clauses of the standard to a greater or lesser extent. Below are the locations in the standard that mention the risks:

**Table 1:** Requirements related to risk in the ISO 9001:2015

Clause	Title	Description
0.3.3	Introduction	▪ Describes the concept of risk-based thinking.
4	Context of the organization	▪ The official request for actions concerning risks and opportunities is directly addressed to this point.
5	Leadership	<ul style="list-style-type: none"> <li>▪ It is required to promote the concept of risk-based thinking throughout the organization by the top management.</li> <li>▪ It is required to determine the risks that affect the conformity of the product/service by the top management</li> </ul>
6	Planning	▪ The organization is required to consider issues relating to the context and interested parties, and in accordance with that, determine the risks and opportunities to deal with, as well as to apply and evaluate the effectiveness of risk-related actions.
7	Support	▪ The organization is required to identify and provide the necessary resources, taking into account the inherent risks and limitations.
8	Operation	▪ It is required to apply actions to prevent human fault.
9	Performance evaluation	▪ It explicitly requires the establishment of actions relating to risks and opportunities.
10	Improvement	▪ It is required that the organization, if necessary, again review and update the risks and opportunities it identifies.

Requirements 4 and 6 represent the most important risk-related requirements. In Clause 6 – *Planning* specify that the organization must plan risk-related actions, however, there are no requirements relating to formal risk management methods or a documented risk management process. The organization is responsible for the implementation of its *risk-based thinking* and for the actions that it undertakes to deal with risk, including whether it keeps or does not keep documented information as evidence of its risk assessment.

The Clause 4 entitled ‘*Context of the organization*’ is another novel concept in the new version of the standard for quality management systems. We note that before the requirements are complied with, at the very beginning of the reading of the requirements of the standard, there is a need to identify the organizational environment, but also all internal issues. Also, at the outset, it is necessary to identify all the interested parties that have an impact on the organization, in order to meet their requirements faster and faster. To apply this requirement, there are multiple methods, the choice of which, depends on the type and size of the organization.

In the light of fulfilling requirements about Context of the organization must identify internal and external issues that may affect the effectiveness of the quality management system. This means that these issues are subsequently used for the purposes of defining actions that address risks and opportunities.

### 3.2. Requirements Related to Risk in the Information Security Management Systems Standard

Standard ISO/IEC 27001:2013 is developed as a set of requirements, which are very similar to those for quality management systems due to the compliance of the Annex SL. Many clauses have the same title as the ISO 9001:2015 standards’ clauses, but they refer to the consideration of these topics in terms of information security. Also, besides the requirements (clause and subclauses), there is a Annex A with a large number of inspections related to information security. Below is a summary of the ISO/IEC 27001:2013 related risks (ISO, 2013):

**Table 2:** Requirements related to risk in the ISO/IEC 27001:2013

Clause	Title	Description
4	Context of the organization	<ul style="list-style-type: none"> <li>▪ Determining internal and external issues relevant to the information security management system refer to ISO 31000:2009 for risk management systems;</li> <li>▪ The organization is required to identify interested parties relevant to the information security management system.</li> </ul>
6	Planning	<ul style="list-style-type: none"> <li>▪ It is required that the organization defines and applies the risk assessment process for information security;</li> <li>▪ It is required that the organization defines and applies the risk-based process for information security based on the results of risk assessment.</li> </ul>
8	Operation	<ul style="list-style-type: none"> <li>▪ It is required that the organization defines and applies the risk-based process for information security based on the results of risk assessment.</li> </ul>
	Annex A	<ul style="list-style-type: none"> <li>▪ Inspections and goals related to documented information, information technology and physical security.</li> </ul>

Clause 4 - *Context of the organization* is very similar to that of ISO 9001:2015, while clauses 6 - *Planning* and 8 - *Operation* are the remaining clauses that mention risks, by requiring a clear process of assessing and handling risks that are not explicitly exist in ISO 9001:2015.

Assessed and analyzed risks should be compared with those inspections and their objectives from Annex A and link them with the impact on the relevant information property that the organization owns. If the identified risk coincides with one of the inspections or can jeopardize the realization of any of the stated objectives, the actions to mitigate this risk must include all those standards specified in this inspection. In other words, the action will include at least the one that requires the appropriate inspection in Annex A.

### 3.3. Requirements Related to Risk in the Business Continuity Management Systems Standard

Although ISO 22301 also has the structure prescribed by the Annex SL and a large number of the same requirements as the previous two analyzed standards, it is important to note the requirements related to risks that this system will emphasize in an integrated management system. The most specific requirements that complement the risk management projection in relation to ISO 9001 and ISO/IEC 27001 are contained in the

Clause 8 - *Operation*. These requirements, as well as other generic requirements in which the aspects of business continuity are stated, are explained in the following table (ISO, 2012):

**Table 3:** Requirements related to risk in the ISO 22301:2014

Clause	Title	Description
4	Context of the organization	The organization is required to identify interested parties relevant to the business continuity management system.
5	Leadership	Management must demonstrate its commitment by participating in: <ul style="list-style-type: none"> <li>– defining the criteria for accepting risks;</li> <li>– testing of Business Continuity Plans;</li> </ul>
8	Operation	This clause of the standard explains in detail that it is necessary: <ul style="list-style-type: none"> <li>– implement an impact analysis on business;</li> <li>– implement risk assessment and ranking;</li> <li>– define a business continuity strategy based on the results of the impact analysis of threats to business, as well as to provide all necessary resources for the implementation of this strategy, and then implement actions that reduce the probability of termination of business, shorten the interruption period or limit the termination of business;</li> <li>– establish procedures and Business Continuity Plans that respond to potential incidents and business disruptions;</li> <li>– implement regular testing of Business Continuity Plans.</li> </ul>

It is particularly interesting to point out that the inspection A.17 *The aspects of information security* in business continuity management in Annex A of ISO/IEC 27001:2013 is very familiar with this standard because it requires information security continuity to be embedded in the organization's business continuity management systems. This inspection further requires: planning the continuity of information security, implementing the continuity of information security through appropriate processes and documented information, and conducting verifications, reviewing and assessment the continuity of information security (ISO, 2013).

#### 4. RISK MANAGEMENT INTEGRATION

How to start the implementation of the management systems and how to integrate multiple management systems at once? The answer to the question is an *integrated management system*. The preceding chapters of this paper have analyzed the requirements of the standards for quality management systems, information security and business continuity. Although all these standards are the same in structure, we paid attention to the places with emphasis on risk management i.e. which requirements related to risks are specific to ISO 9001, ISO/IEC 27001 and ISO 22301.

Integration of the management systems implies the upgrade of one management system with another, precisely those aspects that are unique to that management system. The essence of this paper is the integration of risk management in standardized management systems, and in this chapter, based on the analyzed requirements of three standards for management systems, will be presented the way in which risk management can be applied in the organization of any type, so that it meets the requirements of the three International standards.

The following are the aspects that need to be addressed in the implementation of risk management, in accordance with the requirements of ISO 9001:2015 for quality management systems, ISO/IEC 27001:2013 for information security management systems and ISO 22301:2012 for business continuity management systems:

**Table 4:** The main aspects of risk management for integration of standardized managements systems

ISO 9001:2015	ISO/IEC 27001:2015	ISO 22301:2012
Context of the organization	Context of the organization	Context of the organization
Risk-based thinking	CIA triad	Implementation of Business Impact Analysis
Risk consideration related to interested parties and stakeholders	Evaluation of probability and consequences of risks	Implementation of business continuity strategy
Risk consideration related to processes	Application of risk treatment plans and inspections from Annex A	Implementation of Business Continuity Plans

We can see that the basis for integration is to determine the context of the organization, in particular, its internal and external environment and interested parties in relation to quality, information security and business continuity. If we look at risk management separately from the implementation of the overall management system, it can be said that establishing the context of an organization is the starting point of the risk identification step.

It can be noted that when the requirements of the ISO 9001:2015 standard are fulfilled, the risks remain only upgraded by looking through information security and business continuity, by evaluating their likelihood of occurrence, consequences and impact on business, defining the way of risk treatment, and determining special treatment of risks that jeopardize the continuity of business and determine the manner in which it is handled if the risks are realized. In the continuation of this chapter, analyzes are proposed that can support this way of integrating risk management.

#### 4.1. Implementation of Integrated Risk Management

**Risk identification** is the initial and at the same time the most difficult phase of risk management. As an initial method of identification, a *brainstorming* method can be used to identify the risks, associated with the quality, effectiveness, and efficiency of the implementation of the process, together with the owners and executors of the process. In the identification step, it is important to generate as many ideas as possible regarding potential unforeseen situations, whether they have already occurred or are likely to occur, by looking at the results of the SWOT and PEST analysis, but also by using benchmarking. Sometimes it is difficult to identify risks related to information security and business continuity without a person who has expertise in those fields, and in that situation as a help we can use, a risk assessment matrix created and filled out by an expert for information security. For identifying risks related to business continuity, consultations with the physical-technical protection manager, corporate security specialists or employees in charge of evacuation and fire protection are needed in order to define general business continuity risks.

**The step of risk analysis and ranking** usually consists of assigning a qualitative description or quantified value to the identified risks. The risk analysis is the fundamental of the FMEA method. This method represents structured approach to risks and thus helps system designers understand the outcomes and priorities even before the formal completion of an analysis risk (Jenab, 2015). FMEA analysis is often used to detect possible causes of a technical and technological nature, but has recently been recognized as suitable for the analysis of the cancellation of various types of systems related to the providing of services. If there is any system like the quality management system, FMEA analysis can be applied. In the risk analysis step, it is most important to clearly identify the scope and significance of risk assessments in order to obtain as precise results as possible. In this step, it is also possible to join the Business Impact Analysis by looking at its results and deciding what needs to be done as an activity to combat these risks.

**Risk control** should answer the following questions: How can positive effects be strengthened? How to reduce or prevent unwanted effects on the desired result? The management of the organization should determine how to deal with the analyzed risk, i.e. which risks will be accepted and for which they will define and implement certain actions for their suppression. For risks related to the security of information, according to the requirements of the standards, it is necessary to develop Risk Treatment Plans, and for the risks that cause a business stoppage, it is necessary to develop and regularly test the Business Continuity Plans.

**Risk inspection and monitoring** should respond to the question of how the organization evaluates the effectiveness of the actions undertaken in the risk control phase and how the organization can achieve continuous improvement in risk treatment. It is precisely this step that relates to the identification of new and reevaluation old risks in order to assess the effect of the conducted action and, if necessary, define additional or correct the already established actions. The following is an overview of a possible combination of tools and methods by which integrated risk management can be applied:

**Table 5:** Useful tools and methods for the implementation of integrated risk management

	<b>Quality management system</b>	<b>Information security management system</b>	<b>Business continuity management system</b>
<b>Risk identification</b>	SWOT, PEST(EL), Brainstorming, Benchmark	SWOT, PEST(EL), Brainstorming, Benchmark,	SWOT, PEST(EL), Brainstorming, Benchmark,
<b>Risk analysis and ranking</b>	FMEA worksheet (analysis)	FMEA worksheet (analysis)	FMEA worksheet (analysis) Business impact analysis
<b>Risk control</b>	FMEA worksheet (actions)	FMEA worksheet (actions) Risk Treatment Plans	Business Continuity Plans

<b>Risk inspection and monitoring</b>	Monitoring the implementation of the actions from the FMEA worksheet (actions); restarting the risk identification process	Monitoring the implementation of the actions from the FMEA worksheet (actions) and implementation of the Risk Treatment Plans and their correction; restarting the risk identification process	Monitoring the implementation of Business Continuity Plans; restarting the risk identification process
---------------------------------------	--	--	--

## 4.2. Obstacles for Implementation of Risk Management

Until we achieve the benefits of risk management integration, many problems can arise during its implementation. When we talk about the information security management system, there are many aggravating occasions for its effective implementation. It often happens that there is a lack of expertise and competencies, necessary to deal with information security at all hierarchical levels of the organization, while imposing constant changes in the form of restructuring, merging organizations, various acquisitions and alliances. Each of these changes has a major impact on the security of information (Asheden, 2008).

In order for organizations to understand the importance of dealing with risks at all, it is necessary to create an appropriate internal culture, that is often very difficult to achieve. It develops in line with the behavior of employees and their awareness of risks, in the same way that organizational culture develops in accordance with the behavior of employees in the organization. It is based on the interaction of employees with information property and the safe behavior they implement in the context of organizational culture. For the purposes of this paper, a culture of risk is defined as habits, assumptions, principles, values and knowledge that employees and stakeholders have in interaction with the organizational system and procedures at any time. From interaction arise acceptable or unacceptable behavior (e.g. incidents). The culture of risk and information security comes in time (Da Veiga, Eloff, 2009).

Of course, for many organizations there is a problem of lack of time for systematic risk management, resulting in misinterpretation of risk management at different hierarchical and organizational levels.

## 4.3. Benefits of the Implementation of Risk Management Integration

Implementation of a quality management system requires the organizations to plan their steps carefully with consideration of all factors that can disturb efficient business processes and thus reduce the quality of final products and services. Implementation of the information security management system improves the quality of the information system and information security in general, and raises awareness of safety among employees, customers, suppliers, etc. It also contributes to a better integration of information technology with business (Pelnekar, 2011).

The business continuity management system assures that organizations are always ready for a quick response and return to operational conditions if incidents that have interrupted business happen. Planning and testing of Business Continuity Plans are the activities that employees learn to react in emergencies, and therefore, they more easily handle crisis situations.

If an organization wants to benefit more from the management system, it should understand that their implementation is influenced by the business strategy, the size and structure of the organization, the environment and changes in the environment as well as the risks that arise from the organization's internal and external environment (Kaziliunas, 2012). Thus, the risk management integration related to quality, information security and business continuity gradually becomes part of every business segment.

The principle of risk-based thinking becomes part of everyday activities, different projects, organizational changes and control over any type of resource. This means that employees become aware of the risk of the listed business segments in relation to quality, information security and business continuity. In this way, activities and resources are protected, while barriers that can deter organization from reaching set goals are considered.

## 5. CONCLUSION

We can conclude that risks have become one of the key roles of business quality. After considering the notion of risk management from different sides, risk management steps are presented, which are very close to the fundamental management steps and the famous Deming PDCA cycle.

Meeting the requirements for quality management systems standards creates the fundamental for upgrading the system to the aspects of information security management. By analyzing the requirements of the

standards for Information security management systems it can be concluded that they can easily be complemented by requirements for Business continuity management systems. This provides an indication of how the risk management required by these three standards can be integrated into an effective and efficient system by selecting appropriate tools and methods for its implementation. The FMEA method is proving to be very efficient and effective when used with other tools such as SWOT, PEST, brainstorming, benchmarking, Risk Treatment Plans for Information security and Business Continuity Plans.

The initial point of the quality management system, information security and business continuity (as well as other management systems) is *the context of the organization*, which examines everything on which the business of an organization is based and what it surrounds. With a higher level of integration of the quality management system, information security and business continuity, a modern framework for safe and secure business is being created.

Organizational culture based on awareness of the importance of security and safety, will reduce the risks to quality, information, bad behavior and harmful interaction with information property and inadequate handling in emergencies. It is necessary to present the first effects of such a system in the right way to the employees. Once employees understand that risk management is not a burden, but simply helping to raise their daily work to a higher level, then it is possible to talk about the effective implementation of risk management.

By cyclical repetition and continuous improvement of actions and methods, we have proved that risk management is a 'journey, not a destination'. Risk management is to be 'built-in' in every business process, and it teaches employees to think ahead, which speaks of its necessity for business. By integrating the requirements of standards for quality management systems, information security and business continuity, a holistic system is provided that is capable of predicting and responding to an organization of any kind on the risks that can occur inside or in its surroundings.

# THE SOFTWARE IMPLEMENTATION OF THE PROTECTION MEASURES OF INFORMATION IN THE BANKING INFORMATION SYSTEM

Dejan Hadži-Milosavljević<sup>\*1</sup>, Jovan Filipovic<sup>2</sup>

<sup>1</sup>Raiffeisen Bank Serbia, Belgrade, Serbia

<sup>2</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, e-mail: dejan.hadzi-milosavljevic@raiffeisenbank.rs

**Abstract:** *The ISO 27001 standard is a significant standard for organizations dealing with services in areas that are related to Information Technology and the need to preserve confidentiality of information. Implementation of the system of protection and security of information provides conviction to the clients and business partners of the organization to be accountable according to the information. Examples of organizations that pay tremendous attention to data security, and in which the ISO 27001 standard is applied, are banks and other financial organizations. This paper deals with the software implemented measures for ensuring data security and the original privacy protection measures for users of the bank's information system.*

**Key words:** *ISO Standard 27001, Information security management system (ISMS), Security Information, User privacy protection, The Banking Information System*

## 1. INTRODUCTION

Information security is becoming increasingly important in modern society. Modern state and business entities are increasingly dependent on information and communication infrastructure that allows the flow of large amounts of information between entities, thus providing information and information systems to numerous attacks and abuses. The concept of security of information includes the following types of protection measures:

- Technical protection measures - use passwords, encryption, access rights, network security, and more;
- Administrative protection measures - include security policies, bylaws, procedures harmonized with laws;
- Physical protection measures - include video surveillance, room protection, physical access control;
- Organizational measures - include the division of duties and responsibilities for security, and for human resource management, and others.

All these protection measures include the ISO 27001 standard. When talking about this standard, information is primarily meant as they represent the core business of the largest number of companies in the present day. Information can be created and used in various forms: written on paper, in electronic form, sent by class mail or by electronic means, mentioned in the conversation, and the like. Information protection is necessary because there are threats to information assets from various sources. These sources of threat may be internal, external or incidental, and increasingly threats arise from the abuse of new powerful technologies. Exactly the ISO 27001 standard offers the ability of the organization to effectively and efficiently manage risks due to the likelihood that a threat will exploit existing information system problems and do damage.

Organizations that provide their services using information technology are undoubtedly interested in the ISO 27001 standard. Banks, insurance companies and other financial institutions are the real example of organizations whose business activities have IT support. In addition to physical, organizational and administrative measures that imply the ISO 27001 standard, it is obvious that, due to financial information in the banking information system, banks will be most interested in the application of measures to protect this information that the software should provide.

In this paper, attention will be given to software implemented measures to achieve the security of financial information, as well as to protect the privacy of the users of the information system of the bank.

## 2. ISO STANDARD 27001 AND SECURITY INFORMATION

In the era of current information technologies, information is not only easily accessible but also very "vulnerable". This particularly applies to information of a confidential nature. Today, when almost complete business, from production organizations to banks, is done through specialized information systems, information security becomes very important. In accordance with the security of information, a whole series of ISO 27000 standards are developed that closely define requirements, methods, controls and processes

processes and activities related to the security of information within the organization. In addition, ISO 27001 is one of the most important standards in this series because it defines the requirements for the Information Security Management System. As such, it is applied in all organizations that want to provide their information systems and information for which their security is guaranteed.

Benefits and advantages that the organization can achieve by implementing the ISO 27001 Information Security Management System are:

- evidence of compliance with the requirements of ISO 27001;
- compliance with the best practice of risk management, in accordance with ISO 31000 and ISO 27005;
- Compliance with laws;
- establishing a framework for systemic protection of information resources from malware software, computer abuse, cybercrime and other negative impacts;
- improving credibility among staff, clients and partner organizations;
- the financial benefit of returns through investment in information security;
- Improving the sales of services by raising the level of customer confidence;
- practical decisions relating to security techniques and development solutions;
- the existence of responsibility for the security of information in the organization by all and at all levels;
- better market opportunities by introducing a safer environment for customer data and the knowledge that the organization is exposed to competent assessment.

The official name of the ISO 27001 standard is ISO / IEC 27001: 2013, and in Serbia the official name is SRPS ISO / IEC 27001: 2014. The standard is part of the 27000 series. ISO 27001 is an international standard that relates to the protection and security of information. The Standard provides a comprehensive framework through which an organization identifies, analyzes and addresses security risks of information and ensures compliance with security arrangements in order to keep pace with changes in security threats, vulnerabilities and business impacts. ISO 27001 provides the framework that is necessary to create a secure system. The ISO 27001 compliant system will provide a systematic approach to identify and combat the full range of potential risks to which the organization's information is exposed. It defines four main areas of the information protection system with its requirements:

- Information Security Management System (ISMS)
- Responsibility of the management
- Rating of the management
- Improving the ISMS.

ISO 27001 is a specification of the information management system (ISMS). ISMS is a framework of policies and procedures that includes all legal, physical and technical controls involved in the organization's risk management processes. According to his documentation, ISO 27001 was developed to "provide a model for the establishment, implementation, operation, monitoring, review, maintenance and improvement of information security management systems". ISO 27001 uses a top-down, risk-based approach and is neutral in technology. The specification defines a six-part planning process:

1. Defining a security policy
2. Defining the ISMS scope
3. Conducting a risk assessment
4. Management of identified risks
5. Selecting the control objectives to be implemented
6. Preparing a statement of applicability.

The specification includes: documentation details, management responsibility, internal audit, continuous improvement, and corrective and preventive action. Standard requires co-operation between all parts of the organization. The ISO 27001 standard is comprehensive because it treats information security from three aspects:

- informatics - analyzing and defining the performance of IT equipment, access rights, encryption, passwords, protocols, policies from the point of view of risks to data and information security;
- administrative - defining clear instructions, policies and procedures for generating information, their distribution, storage (storage);
- physical - physical access control, employee records, video surveillance, workstation protection.

The Standard treats information as asset and provides basic guidelines for its preservation, safe management and use. Like most other standards, it is compatible with ISO 9001 but specifies additional requirements for identifying information security risks and establishing mechanisms to eliminate or reduce them to an acceptable level. Implementation of the system of protection and security of information provides conviction to clients and business partners to act responsibly according to information and to use them and distribute them professionally and safely.

ISO 27001 is also compatible with ISO 22301: 2012, in Serbia officially SRPS ISO 22301: 2014 - Social Security - Business Continuity Management Systems - Requirements, which refers to the identification of potential threats per system and which through the established business continuity management system aims to protect the company from potential threats, reduce the likelihood of termination of business, prepare for adequate response if it comes and provide appropriate recovery plans. The incidents covered may range from the sudden break of the IT system to natural disasters and terrorist attacks.

### **3. UTILIZATION OF STANDARD ISO 27001 IN THE BANKING INFORMATION SYSTEM**

The ISO 27001 standard applies in various areas where there are different processes in the organization that are related to security management control such as: security policy, security of organization, control and classification of resources, staff security, security of material goods and the environment, operational management and communication, access control, development and maintenance of various systems and business continuity management. ISO 27001 can be implemented in any organization, profit or non-profit, private or state, small or large. It was written by the world's best experts in the area of information security and prescribes a methodology for the application of information security management in an organization. The organization receives a certificate or certificate that the organization has implemented information security in accordance with ISO 27001.

The ISO 27001 standard is important for organizations that rely on information technology in their business. In these organizations, the basic goals of introducing standards are:

- continuous availability of IT equipment and communications
- protection of information from unauthorized access
- protection of data from loss
- protection against leakage of information
- to ensure business continuity and provision of services in the event of an unforeseen event.

Information protection through the ISO 27001 standard will enable organizations: establishing correct account settings, controlling access to information, controlling network services, securing personal data protection, and securing media protection with transit data.

Implementation and application of ISO 27001 standards allow for better cooperation with similar organizations around the world operating under this model. This standard of organization demonstrates to its users and other stakeholders that they work with business processes based on the principle of security and that business policy is focused on continuous improvement in the information management system and the services related to its services. The benefits of the organization are reflected in the following:

- competition advantage
- reducing the risk of damage and loss of information, and therefore costs
- compliance with applicable legal regulations
- greater confidence of clients, employees, associates, institutions and all stakeholders due to the knowledge that their data is safe
- the existence of responsibility for the security of information by all and at all levels of the organization.

Implementation of the system of protection and security of information provides conviction to clients and business partners to act responsibly according to information and to use them and distribute them professionally and safely. For all these reasons, the ISO 27001 standard is applicable in banks and other financial institutions.

Due to the specific financial nature of the majority of the data in the information system, huge attention is paid to the security of data in both data transmission and access to data and their modification. Priority information security measures in the bank relate to security measures such as encryption of information, regulation of data access rights, network security and others, but at the same time implies the implementation of administrative, physical and organizational measures. The Assembly of the Republic of Serbia, by harmonizing Serbia's legislation with the legislation of the European Union, adopted a set of laws related to information security:

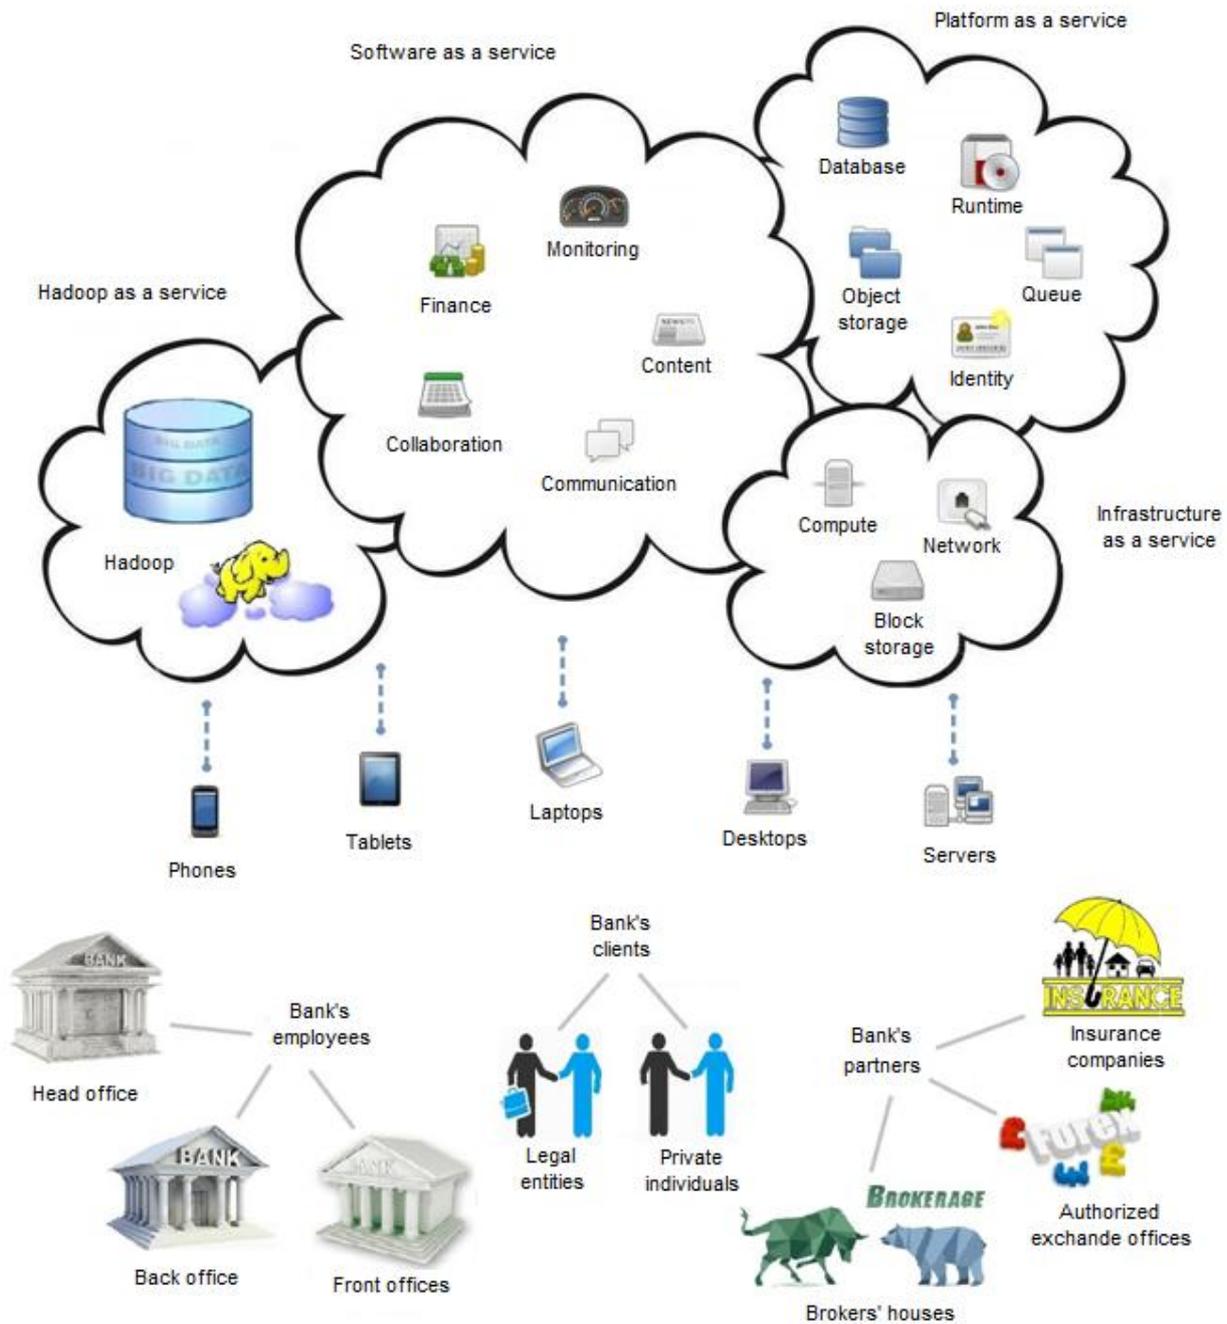

1. The Law on Personal Data Protection
2. The Law on Secrecy of Data
3. The Law on the Keeping of Business Secrets.

In accordance with the Law on Secrecy of Data, the Government of the Republic of Serbia adopted a Decree on special measures for the protection of classified information in information and telecommunications systems. Article 10 of this Regulation explicitly states that in order to maintain the security of the system during its use, the public authority or legal entity shall implement the implementation of new technical and

program resources in the system in accordance with the relevant technical standards SRPS ISO / IEC 27001. Therefore, information protection is in accordance with the ISO 27001 standard, and the basic and most reliable way of implementing information security measures in the bank is just programmatic.

#### 4. THE SOFTWARE MEASURES TO PROTECT INFORMATION IN THE BANK INFORMATION SYSTEM

Software solutions for data protection measures follow the modern accelerated development of information technology. The most up-to-date solution for the platform model of the Bank's information system is Hadoop in Cloud, Hadoop as a cloud service.

**Figure 1:** Hadoop in cloud as a solution for an IT banking platform

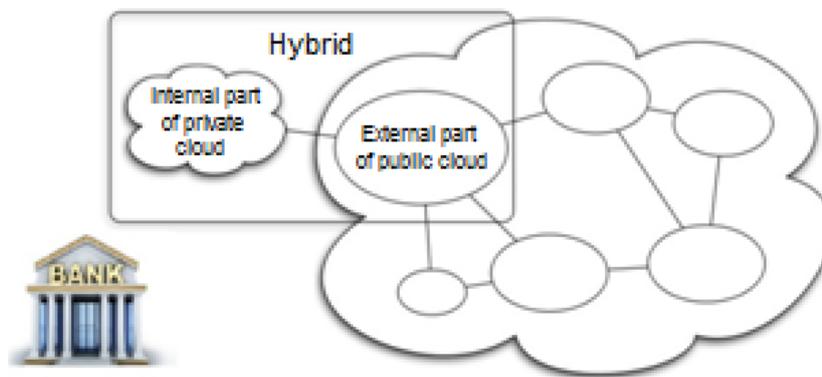

Hadoop Cloud technology ensures the placement of large amounts of data in cloud computing clusters as well as rapidly distributed processing of these data, with software and infrastructure and platforms in the remote cloud of the provider, i.e. vendor. With the appropriate infrastructure in the cloud, users come to

access the information system in a modern way using smartphones, tablets, laptops and other modern devices. The customers in the bank are: bank clients (legal entities and private individuals), bank partners (insurance companies, brokers, authorized exchangers and others) and bank employees - at front offices, back office and bank management (head office) A cloud cloud with services as an IT platform for the bank's information system is given in Figure 1.

If the Hadoop in the cloud is selected as the IT platform solution in the bank, it is necessary to consider also which cloud model to decide - for a public, private or hybrid model. Choosing a cloud model also means ensuring data security and user privacy. The decision on the choice of cloud models is made by a commission comprised of representatives of the following organizational parts of the bank:

- Executive Board
- Information Systems Division
- Department of Security
- Department of Legal Affairs
- Financial Division.

Bearing in mind the financial nature of data in the banking information system and even that most important data should be stored privately in the bank, and also having in mind that due to the need of users of some application can be publicly available to the clients of the bank, it is undoubtedly that the hybrid model cloud a solution for choosing a cloud model. The hybrid model will integrate the internal part of the private cloud of the bank in which the important bank data is located, and the external part of the public cloud in which certain client applications will be specified. The merging of these two parts is shown in Figure 2.

**Figure 2:** Hybrid cloud as a choice of cloud models for the banking information system

The business data model in the bank implies the following data groups:

1. Clients
2. Organizational structure and employees
3. Market data
4. Segmentation and rating of clients
5. Loans
6. Accounts
7. Collaterals
8. Derivatives and Repo
9. Limits
10. General Accounting and Profits & Losses
11. Cash flow
12. National and international payments
13. Security
14. Financial information
15. Regulatory reports.

These data are allocated to the internal part of the private cloud and to the external part of the public cloud, and the allocation is under the responsibility of the Finance Department. Obviously, for example, data from all bank strategies will be secure in private cloud, for example. data on the bank's product sales campaigns for customers will be secure in the public cloud. Data groups are deployed in the confidentiality classes defined by the Department of Security. Based on the confidentiality class, it is known which data is stored in a public cloud, and which is in a private cloud. The confidentiality classes are: (1) Public data, (2) Internal data, (3) Confidential data and (4) Strictly confidential information. Preservation of data security and user

privacy is regulated by program implementation of measures for achieving data security and privacy protection of users.

#### **4.1. Data security**

Data security is achieved by program implementation of data encryption when data is transmitted, when the data is made by the data transmitted from the bank to the cloud and from the cloud to the user, both in reverse and in data restraint, at the following levels: the application level, the level of the Hadoop Cluster, and the file level, i.e. level Hadoop Distributed File System (HDFS).

Data encryption uses different algorithms from simple to cryptographic algorithms such as:

- Symmetric algorithms
- Asymmetric algorithms
- Cryptographic functions for compression - hash functions
- Digital envelope, digital signature, digital stamp and digital certificate.

#### **4.2. User privacy protection**

Users' privacy to access cloud applications would be provided by introducing programmatic measures such as, for example:

- authentication of bank clients when using applications via the Internet;
- assigning passcode to the bank partners (brokers, authorized exchangers, authorized appraisers from insurance companies and others) for authentication during Internet access to the information system;
- Authentication of employees both at the level of the operating system and at the level of each application from the information system.

### **5. THE INFORMATION SECURITY IN THE BANKING INFORMATION SYSTEM**

Information security should also be provided when storing data while transferring a transfer between the bank and the cloud, and vice versa. Significance depends on the following information properties that are also requests for information:

1. confidentiality
2. integrity
3. availability
4. authenticity
5. intolerance
6. authorization.

There are three general categories of cryptographic algorithms that are used today in database systems - symmetric algorithms, asymmetric algorithms, and hashing algorithms, and a more specific category of hybrid algorithms: Digital envelope, digital signature, digital stamp and digital certificate. Symmetric algorithms use the same key both for encryption and decryption of data. Equivalent names for symmetric algorithms are: conventional, secret key, classical, and private key algorithms. The most well-known symmetric cryptographic algorithms are Data Encryption Standard (DES) and Advanced Encryption Standard (AES). Unlike secret keys with one shared key, asymmetric algorithms use two keys. One of the keys is public and other secrets. These algorithms are also called public key algorithms, and their operating principle is as follows: based on the secret key assigned by the recipient, a public key is generated. Known as cryptographic asymmetric algorithms are: RSA, ElGamal, i Diffie-Hellmann.

Cryptographic functions for compression - hash functions are categorized into cryptographic algorithms without a key. Hash function denotes a function that compresses an array of data of arbitrary length into a fixed-length data set. Hash functions are used to protect the integrity of the data and work on the following principle - when the new data is received, it is hashed and then compared to the original hash value. The hash function is used as an accessory, for example, when saving passwords in the database. The famous hash algorithms are, from the older ones - SHA-1 and MD5 algorithms, and the newer ones - SHA-224, SHA-256, SHA-384, and SHA-512. Given which data is encrypted and at what level encryption is performed, there are different types of encryption that are applicable in the protection of the database system, and accordingly the following division:

- encryption for data protection during transmission
- encryption for data protection during hibernation:
- encryption at application level
- encryption at the database level
- encrypting the file.

Data encryption during transmission protects data on the way from bank to cloud and from cloud to user, and vice versa. Data transfer is done via the Internet or via wireless networks. Encrypting data during transmission is necessary to prevent the content of the message after the interception of traffic is detected. This encryption type is most used in data protection since it does not bind to applications and requires minimal development efforts. There are different security protocols for this type of encryption, such as: SSL (eng. Secure Sockets Layer), TLS (eng. Transport Layer Security) and IPSEC (eng. Secure Internet Protocol).

Encrypting data that is idle is the encryption of information in warehouses, i.e. clusters of computers. In this case, there are three most commonly accepted encryption methods: at the application level, at the database level, and at the file level. An example of the most basic protection of information by software at the application level is data masking. Banking ISs usually mask the amounts, bank identification numbers of the bank's clients, their card numbers and others. In Figure 3, a screen display is displayed on which the client card numbers are masked. The procedure for masking the card numbers is software solved by placing six '\*' characters from the seventh position in card number data. In Figure 4, there is a screen display of the application where the amount for the premium client is masked. The masking of the amount is software implemented by setting the black color for the color field property for the amount.

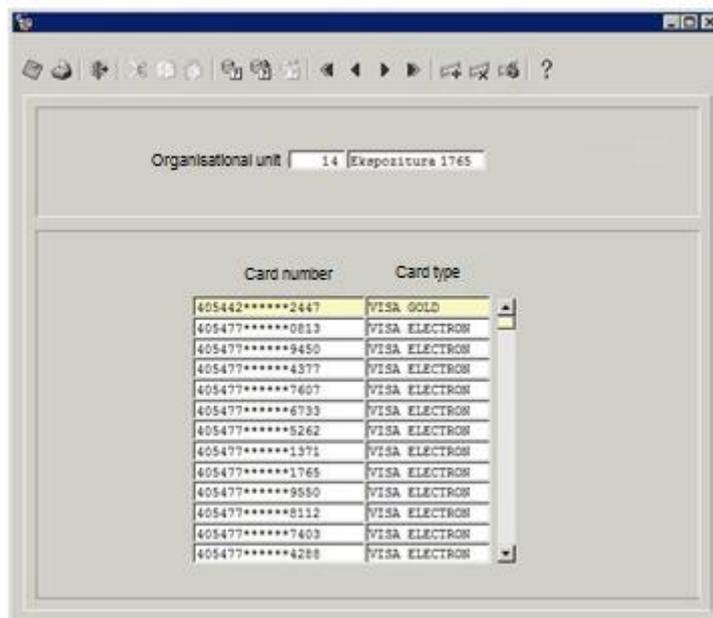

Figure 3: Standard masking the data Card number in banking information system

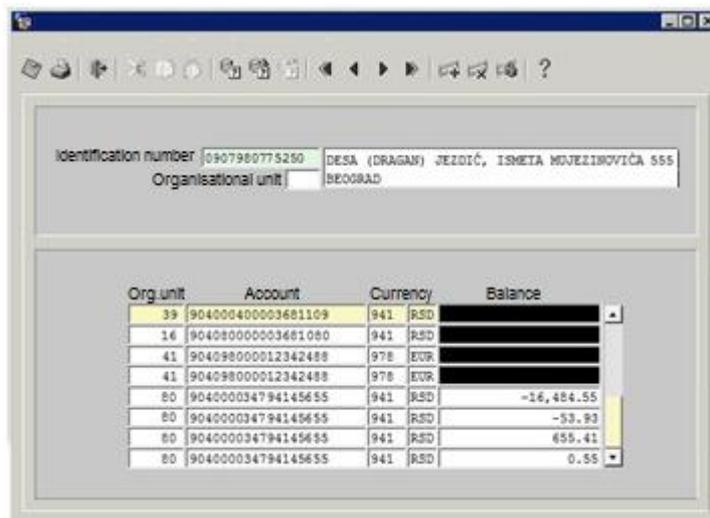

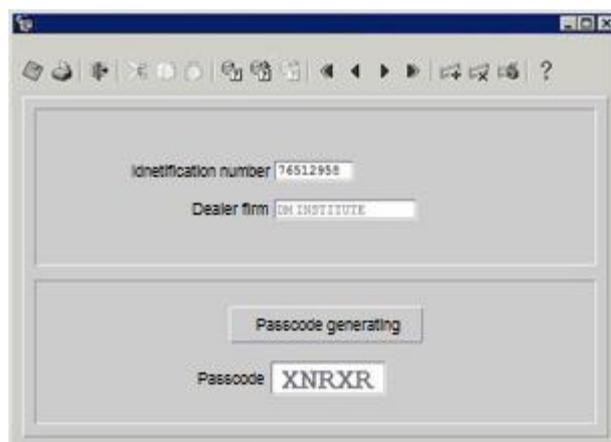

Figure 4: Standard masking the data Balance in banking information system

## 6. PROTECTION OF USERS' PRIVACY IN THE BANKING INFORMATION SYSTEM

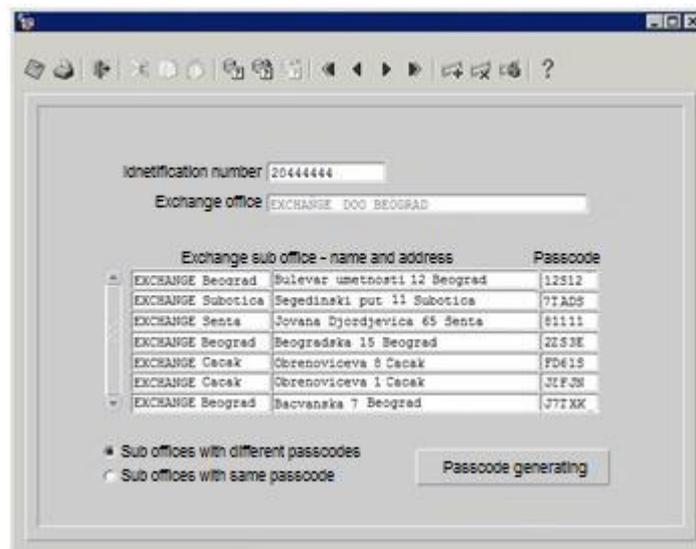

The users of the bank's information system are bank clients, bank partners and employees of the bank. The policy of access control to the system over the Internet, in terms of user recognition, is realized through software implemented user authentication. Each user is embedded in a unique client record. When tricked, the user gets a unique combination of two data code and password, which he can later change in the system. User authentication is accomplished by a program test whether the combination of these two data, which the user has entered, is the same as an existing combination in the system. If it is, it is considered that the authentication is successful and the user is identified by withdrawing his name from the client's records, otherwise authentication is considered unsuccessful. Further work of users in the information system is done in accordance with the set of privileges it has to perform banking activities.

Interesting is the additional authentication of the bank's partner when they access information in the bank by telephone by interviewing a bank employee. In this case, for reasons of safety, measures are taken to record a telephone conversation and program the user's recognition by the employee. This situation occurs in the bank every morning on a business day, when authorized exchangers and partner companies who perform dealer business and who use the money from the bank's vault for these jobs, contact the employees in the bank, ie the dealers in the bank, and ask for a sales course and a purchase the rate that the bank has internally adopted for the current day.

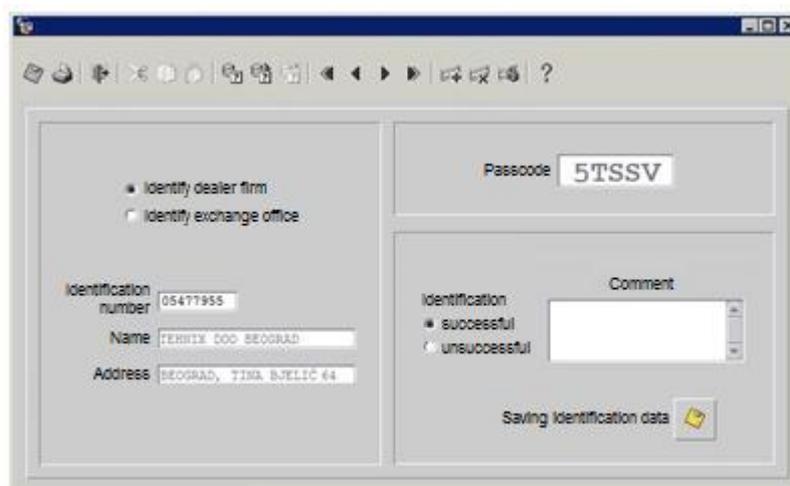

The original software-implemented authentication of authorized external dealers consists of generating a password, i.e. passcode for each external dealer and checking the pascode at the beginning of a telephone conversation between an external dealer and a bank dealer. Passcode is a unique alphanumeric data of a certain length and consists of large letters of the alphabet and digits, excluding the letter 'O' and the digit '0' in order to avoid possible confusion when writing these two signs. The bank automatically generates a bank account for each external dealer and sends it to him at the address he applied to the bank. An external dealer can be a partner company or a currency exchange office. Each company gets its own unique passcode. The exchange office has one or more exchange offices located at different addresses. In agreement with the exchange, it is decided whether the same exchange rate will be assigned to all exchange offices of that exchange office, or a different board will be generated for each exchange point. In a telephone conversation initiated by an external dealer, the bank dealer pays an ex-dealer for his passcode. When an external dealer announces a passcode, a bank dealer in the system on the basis of that passcode recognizes which external dealer is working and tells him the information stored for him. In Figure 5, a screen display for generating a passcode for an external dealer firm is given. In Figure 6, a screen display for generating a passcode for an authorized exchange office is given, in the case where different passcodes are generated for all of its exchange sub offices. On the screen display there is a radio group that defines whether the exchange sub offices will have the same passcode or different passcodes. In Figure 7, a screen display is used to identify an external dealer, whether it is a dealer firm or an authorized exchange.

**Figure 5:** The passcode generating for external dealer firm

**Figure 6:** The passcode generating for exchange sub offices of exchange office

**Figure 7:** Identification a dealer firm or an external authorized exchange office

## 7. CONCLUSION

Efficient data protection is required both for storage on computer systems, as well as for transmission by communication paths. The problem that has arisen either by disrupting information security by unauthorized access to information can cause catastrophic consequences in organizational systems such as, for example, banking, judiciary, military, medical and other systems.

The ISO 27001 standard provides organizations with a framework for securing information security. All types of measures that comply with the ISO 27001 standard, and in particular program measures, can be applied in banks. By selecting the appropriate encryption method and program implementation of the encryption algorithm, the basic measure of protecting "sleeping" data and data transmitted by communication channels is realized. Each cryptographic algorithm has its own advantages and disadvantages. Symmetric algorithms are best suited to solve the required confidentiality because they are faster and look for smaller keys. Symmetric algorithms solve all requirements except intangibility.

Asymmetric algorithms are best suited for solving integrity and authenticity requirements, and they also solve non-compliance requirements. When it comes to confidentiality requirements, asymmetric algorithms are only used to exchange a symmetric key that encrypts the message and ensures its confidentiality. Hashing algorithms are used in integrity protection, and the best way to solve is authorization requests. Some

systems use a combination of these algorithms and thus exploit their stronger sides. Such cryptographic systems are called hybrid systems. Examples of algorithms of these systems are: digital envelope, digital signature, digital stamp and digital certificate.

## BENCHMARKING AS THE QUALITY MANAGEMENT TOOL FOR THE EXCELLENCE ASSESSMENT OF MEDICINES REGULATORY AUTHORITIES IN EUROPE

Gordana Pejović<sup>\*1,2</sup>, Biljana Tošić<sup>1</sup>, Jelena Ruso<sup>1</sup>

<sup>1</sup> Faculty of Organizational Sciences, University of Belgrade

<sup>2</sup> Medicines and Medical Devices Agency of Serbia, Belgrade, Serbia

\*Corresponding author, e-mail: jelena.ruso@fon.bg.ac.rs

**Abstract:** Nowadays, majority of European Union (EU) member states use international benchmarking as a quality management tool for guiding medicines regulatory policy priorities. Unfortunately, there is limited research on how medicines regulatory authorities use this tool for continual improvement. The concept of Benchmarking of the European Medicines Agencies (BEMA) aims at harmonizing regulatory performance and procedures in each Member State's medicines regulatory authority. Therefore, the paper strives to explore how medicines regulatory authorities in EU perceive the significance of the BEMA methodology itself, thus highlighting its positive and negative aspects. Although some limitations of the BEMA have been identified, the key findings indicate that all the medicines regulatory authorities involved in the BEMA process are confident that the BEMA methodology can be a useful tool for continuous improvement. It should be noted that only the authorities within the EU member states could be the part of BEMA exercise, although it could be potentially used in candidate countries in preparing for the EU membership.

**Keywords:** quality management, quality assessment, benchmarking, medicines regulatory authorities, EU

### 1. INTRODUCTION

Quality improvement in medicines regulatory authorities has required a series of changes that have had a significant impact on medical practice. These changes have led to the creation of such an organizational culture, based on appropriate social and moral principles, in which the medical world, supported by many other disciplines, is trying to find the optimal way to take care of each individual patient (Tosic et al. 2017). In the European Union, a well-established regulatory system ensures that the human and veterinary medicinal products available for patient use are acceptable in every way and this means encompassing various activities that aim to ensure the safety, efficacy and quality of medicines as well as the appropriateness and accuracy of product information (Pejovic et al., 2014). The majority of researchers agree, on a wider scale, that regulatory work in medicines regulatory authorities should be performed with accountability and transparency (Ibid.). The regulatory performance of the medicines regulatory authorities should be regularly and systematically monitored in order to identify problems in the process and to determine if all the implemented activities are in line with the strategic goals of these authorities. Various methodologies can be used to assess the performance of medicines regulatory authorities, such as self-assessment, supervisory authority assessment as well as a review by another medicines regulatory authority dealing with the same activities – peer review. These approaches can all complement each other in assessing the performance of medicines regulatory authorities, but can also help them identify number of areas for continual improvement.

Various tools and/or models like Total Quality Management (TQM), European Foundation for Quality Management, Balanced Score Cards (BSC) and terms like “Best Practices” and “World Class Manufacturing” have prevailed in discussions about quality management in different years. In order to improve operations they first had to be measured and a new target had to be set. For this, a tool called benchmarking was created (Putkiranta, 2012). The benchmarking, defined as the comparison using a set of specific indicators, was, until recently, the domain of market specialists. This changed, however, with the publication by the World Health Organisation (WHO) of its report *Health Systems: Improving Performance* (2000) which thrust international health system comparisons to the forefront of high-level political discussions, highlighting the potential role and pitfalls of such comparisons (Wait and Nolte, 2005). Since then, many countries have used international benchmarking as a basis for guiding medicines regulatory policy priorities.

The concept of Benchmarking of the European Medicines Agencies (BEMA) was first discussed at the Heads of Medicines Agencies (HMA) meeting in Rome in November 2003. It builds on an earlier initiative (such as the Pan European Regulatory Forum (PERF)) whose main role was to help candidate countries for EU membership to fully prepare and adjust their regulatory systems to EU requirements (Pejovic, 2012). The initiative for this methodology was given by the HMA which established a steering group that had exclusive jurisdiction to coordinate the implementation of the BEMA methodology and analyze the results (HMA, 2006). A steering group was established in January 2004 to develop proposals for the exercise, including a series of

key performance indicators as well as methodology of how to identify and share the best practices (HMA, 2012). To the best of the authors' knowledge, there is no paper that deals with such subjects generally. According to the Heads of Medicines Agencies (2018), the aim of the BEMA methodology is "to contribute to the development of a world-class regulatory system for medicinal products based on a network of authorities operating to best practice standards". The main purpose of BEMA is to gather the information on best regulatory practice thus enabling identification of areas for continual improvement within authorities. It is also significant to point out that BEMA is not designed for direct comparison of, or ranking of, medicines authorities. Medicines authorities are encouraged to develop suitable best practices in order to enable an improved operation of the network of medicines authorities. The entire process of anonymization has been agreed so that none of the information held in the centralized database is attributable to any authority. Therefore, HMA (2016) claims that the most valuable part of the BEMA is that it is a form of self-assessment enhanced by consultancy carried out by authorities that are also fulfilling national responsibilities under EU legislation.

In this paper, after the introduction, the review begins with the brief description of the BEMA methodology and the BEMA questionnaire. The next section of the review is dedicated to the research methodology. The results follow. Additionally, the paper presents key findings thus presenting all areas of strengths and weaknesses, as well as all the positive and negative aspects of the BEMA. These findings provide an indication of the status of the medicines regulatory authorities with respect to their willingness for continuous improvement within BEMA in any area where improvement might be made. Finally, the review offers some conclusion remarks.

## **2. BENCHMARKING OF THE EUROPEAN MEDICINES AGENCIES (BEMA)**

During time, the benchmarking has evolved into a well-established methodology for comparing individual management systems and it is not just an inspection or an audit designed to identify non-compliance. It is a business practice which stimulates process improvement by determining best practices across organizations through performance measurement and understanding those factors which enabled the higher performance of the organizations (Watson, 1994). Actually, the essence of benchmarking lies in the fact that it is "the process of identifying the highest standards of excellence" (Milosevic et al., 2013). In the following chapter, we will discuss the implementation of this popular methodology within medicines regulatory authorities in EU.

### **2.1 BEMA Methodology**

In order to identify the best practice and improve their system, medicines regulatory authorities apply BEMA methodology. The BEMA is a quality management tool for continuous regulatory and public service performance improvement. It is based on comparing and finding best practices, sharing positive experiences, ad hoc consultations from colleagues coming from a similar work environment and/or working on similar jobs (Pejovic et al. 2014). Therefore, the BEMA methodology does not serve for the competition or self-promotion of medicines authorities but solely for the purpose of assisting the internal improvement of the whole process. This is the basic concept of the BEMA methodology, but in its background is the tendency of the HMA to monitor the work of all the medicines regulatory authorities in the EU by standardizing their work and raising their performance to the highest possible level (Ibid.). The BEMA methodology includes both self-assessment and peer-review assessment and is broadly based on ISO 9004 guidelines. "Self-assessment against a performance excellence model by organizations within a multi-organizational network can provide an effective basis for cooperative learning and benchmarking" (Saunders and Mann, 2005). On the other hand, according to ISO 17000:2004, peer-assessment is "assessment of a body against specified requirements by representatives of other bodies in, or candidates for, an agreement group". The peer review assessment is important as it allows each medicines regulatory authority to be visited by teams of specially trained assessors for an independent assessment against the performance indicators. The usage of ISO standards in the BEMA methodology ensures mutual understanding between different parties in the process in order to develop a world-class pharmaceutical regulatory system based on the mutual cooperation of best practice standards. Using the ISO 9004, a reference questionnaire was defined, which initially included only the areas of pharmacovigilance and documentation assessment activities which were later added to parts related to the general organization and the connection with the inspection bodies. From September 2012 to October 2014, the total of 47 benchmarking visits to medicines regulatory authorities or ministries responsible for the field of medicines were made, of which 17 agencies regulate both human and veterinary medicines, 14 regulate human medicines only and 14 regulate veterinary medicines only (HMA, 2016). Forty two assessors from 18 countries and 24 authorities participated in these visits, with three assessors from different authorities in each team (Ibid.). First three BEMA cycles showed some weaknesses, which were reflected in the inadequate training of BEMA assessors, unequal evaluation criteria etc. Therefore, the steering group within the European Medicines Agency (EMA), "the key central body for European regulatory decision-making activities" (Pejovic et al. 2011). has launched an action to define a new version of this questionnaire, which has been significantly improved as well as a series of very serious BEMA assessors

trainings (twice a year), removing deficiencies observed in previous visits. Therefore, this enhanced version is often referred to as the BEMA IV methodology and, according to this version, medicines regulatory authorities are currently being evaluated. The key findings of these visits were entered into an anonymized database which is not designed for direct comparison of, or ranking of, medical regulatory authorities, but will be used for analysis and as a useful source of good practices for the benefit of the network of authorities, continuous improvement within the BEMA methodology or at any stage when the network of authorities is considering improvements. The description of each BEMA cycle from January 2004 to September 2018 is presented in the Table 1.

**Table 1: BEMA Assessments (Heads of Medicines Agencies, 2018)**

<b>BEMA I</b>	<b>BEMA II</b>
Began in January 2004 with the establishment of the steering group and the development of the KPIs, questionnaire and methodology. Visits to agencies took place between June 2005 and May 2006 and successfully established the methodology as a tool for benchmarking of the network of agencies in the EU/EEA.	Development of the second cycle was based on formal feedback gathered from agencies and assessors at the end of the first cycle and the experiences of the steering group and logistics team, in order to make amendments, including the KPIs for the revised questionnaire. Visits took place between June 2008 and July 2011.
<b>BEMA III</b>	<b>BEMA IV</b>
The HMA Strategy 2011-2015 was used to direct an extensive review of the KPIs resulting in a more streamlined and focused questionnaire. Formal feedback gathered from agencies and assessors at the end of the second cycle, and the experiences of the steering group and logistics team, were used to make amendments to programme. The BEMA III began in September 2012 with 47 agencies to be visited by October 2014.	It was established following a positive outcome of the previous BEMA cycles, allowing its development into a tool for the improvement of quality management system and consistency of best practices across the EU network of medicines agencies. Revision of the KPIs and updates in line with the EU Medicines Agencies Network Strategy to 2020 resulted in development of comprehensive, yet focused questionnaire. BEMA IV began in June 2016 with 47 agencies to be visited by October 2018.

## 2.2. BEMA Questionnaire

In order to achieve quality and excellence, every organization should review its performance in relation to the specified criteria, determine the current levels of maturity and determine its strengths and weaknesses (Horvat, 2018). Criteria given for a higher level of maturity can help the organization understand the issues to consider and help it determine the necessary improvements to achieve a higher level of maturity (ISO 9004:2009). Hence, the new rating system was introduced based on the concept of Capability Maturity Model (Table 2) in which a rating scale (5 levels) is complemented by a statement of maturity for each rating level, specific for each indicator (HMA, 2016). According to the rating system presented below, each question from the questionnaire is evaluated and the final assessment for the given question is obtained by the consensus of all team members. If the team decides so, it is possible to make estimates that correspond to the half of one score (0.5). Based on the experience, it has been decided not to give a final rating to an authority, but to evaluate each individual segment defined by the questionnaire. The BEMA evaluation ends with an exchange of experiences between the two sides and with the comparison of the obtained grades during BEMA visit with the grades achieved after the self-assessment phase. If there is a significant deviation in the rating, this is an exceptional opportunity to discuss it with team members. Also, "the best in class" grade is never given, because it would mean that further improvement of the process is not necessary, which in practice is never the case. Contrary to the implementation of the BEMA I, the tendency of the evaluators, during the visits to the authorities is often focused on interviews and on concrete evidence, rather than on the presentation of the results contained in the self-assessment questionnaire itself (Ibid.).

**Table 2: Capability Maturity Model: The Rating System Applied in the BEMA Procedure**

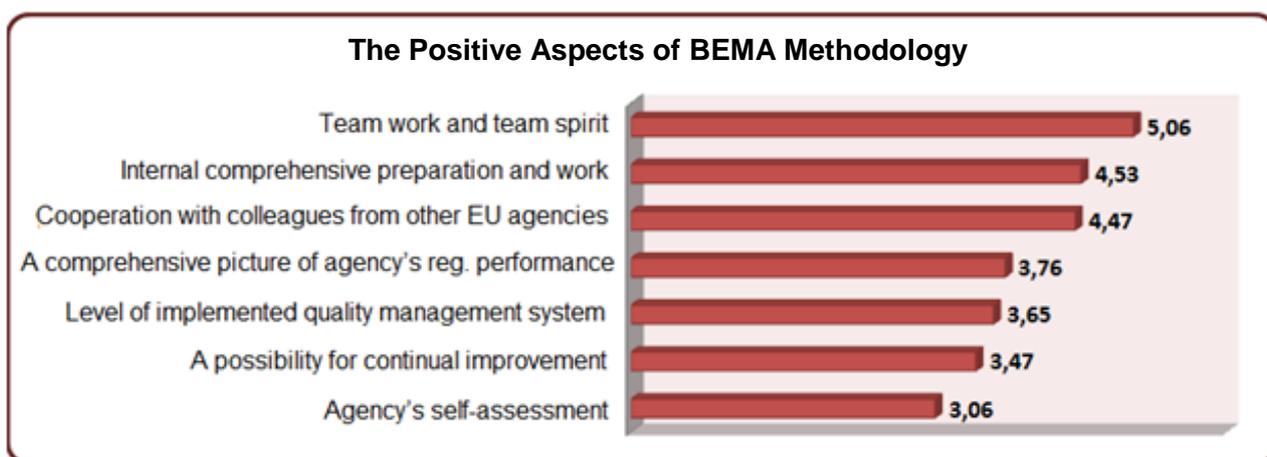

<b>Maturity</b>	<b>Performance Level</b>	<b>Note</b>
1	There is no formal approach	No systematic approach, no matching results, poor or unpredictable results
2	Reactive approach	Approach based on problem solving or the implementation of certain corrections, a minimum number of data is available
3	A stable, formal system approach	Systematic approach based on processes, the initial phase in stematic improvement; there are data on compliance with set goals and the existence of an improvement trend
4	Continuous improvement is emphasized	The improvement process, good results and a constant improvement trend are used
5	Performance "best-in-class"	The improvement process is fully integrated; benchmarking results matching "best-in-class" performance are displayed

#### 4. RESULTS

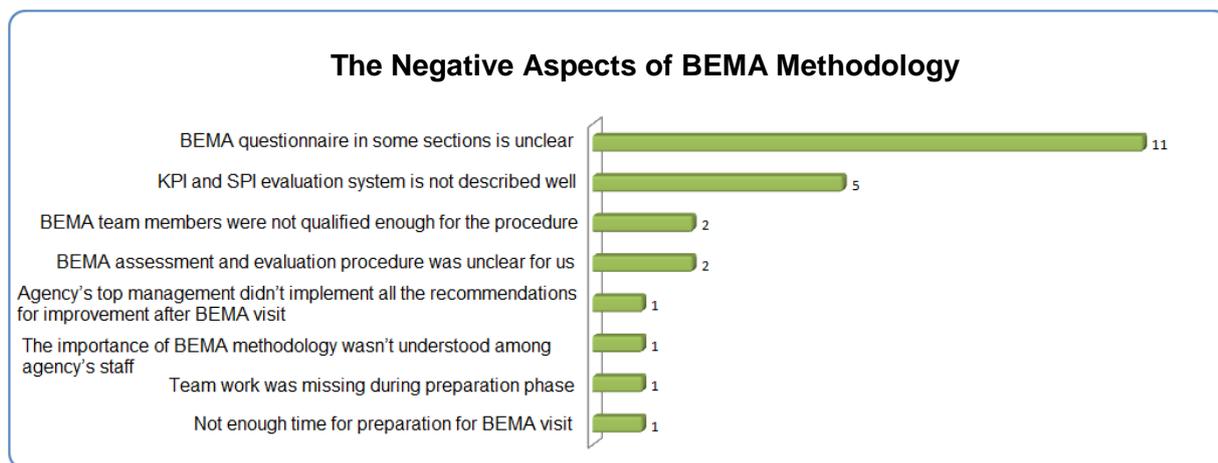

Finally, a total of 17 replies were received, which makes 43.59% of the total number of questionnaires sent. Respondent regulatory authorities have within their jurisdiction human, veterinary medicines, medical devices, but also a number of specific areas, such as cosmetics, tattoo products, precursors, price fixing and medication consumption monitoring, etc. Regarding the size of the authorities that responded to the questionnaire, the highest number is those with more than 200 employees, which indicates good potential for adequate performance of all regulatory functions when human resources are in question. The majority of medicines regulatory authorities have a well-established and certified quality management system, while in a few authorities the quality management system is not formalized, or is being implemented.

By analyzing the responses, all medicines regulatory authorities involved in the BEMA process believe that the BEMA methodology is a useful tool for continuous improvement of performance and they support its further organization by the HMA. Furthermore, it was possible for respondents to evaluate certain positive aspects of the BEMA methodology, as well as to indicate those negative. Seven positive aspects of the mentioned methodology were evaluated, where it was necessary to rank on the scale of 1 (the most useful aspect) to 7 (least useful aspect). Figure 1 shows a summary of this assessment, i.e. the mean value of the assessments given by the respondents for each aspect of the BEMA.

**Figure 1:** Mean Values of the Assessments of the Positive Aspects of the BEMA

The results have shown that the respondents, as the most important and beneficial aspects of the BEMA methodology, highlighted the need to carry out self-assessment in the preparatory phase (grade 3.06), giving it the possibility for continual improvement (grade 3.47), as well as the ability to assess level of the implemented quality management system (grade 3.65). Relatively high rating (3.76) respondents gave an aspect "it is an opportunity to get a comprehensive picture of agency's regulatory performance, as whole". On the other hand, low ratings indicate the aspect of cooperation with colleagues from other European agencies (grade 4.47), who are actually members of the BEMA assessment team, which is also indicated by the individual comments of the respondents that there is not enough education for the members of the BEMA team, or that their criteria for assessing the regulatory functions of the medicines regulatory authorities are uneven. However, the results in this part of the questionnaire also point to the fact that there are obvious problems with the internal organization and preparation for the BEMA methodology (grade 4.53), which must be comprehensive, long-lasting and involve multidisciplinary teams, because the aspect of teamwork is marked the lowest ratings (5.06). It can be concluded that, with the development of the regulatory performance level, the importance and role of the BEMA methodology are changed, so that it is not viewed only as an additional obligation, but also as a possibility for continuous improvement of performance as well as a quality management tool that medicines regulatory authorities should introduce into their everyday work.

**Figure 2:** Mean Values of the Assessments of the Negative Aspects of the BEMA

Regarding the negative aspects of the BEMA methodology (Figure 2), the dominant number of responses concerned the fact that the BEMA questionnaire, which is the basis for the implementation of the BEMA methodology, is, in some areas, unclear. This is actually an essential problem for the implementation of the entire procedure, because, according to the questionnaire, self-evaluation of the medicines regulatory authorities is carried out at the preparatory stage followed by the actual assessment by the BEMA team. If there is a fundamental lack of understanding of the questionnaire, this can lead to poor results of assessing and representing the regulatory performance of a given authority worse than it actually is. The second prominent problem, which is directly related to the questionnaire, is the system of evaluating key and specific performance indicators, which causes a suspicion in the investigated medicines regulatory authority, and a doubt about the correctness of the assessment.

## 5. CONCLUSION

The BEMA methodology is an excellent way of sharing best practices in the work of regulatory authorities across Europe, helping the medicines regulatory authorities with less developed capabilities to find the most appropriate way to organize their regulatory functions. The primary goal of organizing and implementing this methodology within EU is to create such a quality regulatory environment in which any regulatory body will be able to accept and recognize the work of other authorities. This will significantly save resources and ultimately create preconditions for creating a single market for medicines in Europe, thus creating the unique capacity of all medicines authorities to implement adequate health protection. All surveyed medicines regulatory authorities support the further organization of the BEMA because they consider it to be a unique opportunity to compare regulatory functions between them. General conclusion indicates that medicines regulatory authorities in Europe accept BEMA methodology as a quality management tool for improving regulatory functions, but do not perceive its' all aspects. Some limitations of the BEMA have been identified, which directly influence the acceptance of the BEMA questionnaire in the regular processes of measuring and improving the performance, which is its main goal. As it is already emphasized, there are no similar data available in the scientific literature on examining the role of the medicines regulatory authorities in quality infrastructure, their consideration of the significance of the quality management system, as well as data on the possible application of the benchmarking methodology for the continual improvement of regulatory functions. The role of medicines regulatory authorities in public health system in every country is undeniable, as they are responsible for assuring quality, safe and efficacious medicines and medical devices. Therefore, the measure of their quality performance impacts the general population, in terms of medicines access and availability. The significance of the conducted survey is that it provides the basis for further research of the new ways for the quality management system improvement within the medicines regulatory authorities in Europe. Such research would be unique, having in mind the fact that there are no similar published results.

## QUALITY OF LIFE AND DIGITAL TRANSFORMATION IN HEALTHCARE

Tamara Jakovljević  
International postgraduate school Jozef Stefan  
e-mail: tamara.jakovljevic@hotmail.com

**Abstract:** *Paper explores the perception of the quality of life and its relations with the overall health of the population and the healthcare system. New technological improvements have led to a transformation in business, hence the healthcare system as well. Paper presents the main trends in the field of healthcare digitalization process and illuminates the problems which can occur, such as safety of privileged patient information, use of different applications, managing and storage of patient data etc. As well as selecting benefits of digitalization process and its impacts on quality of life.*

**Keywords:** *quality of life, quality in healthcare, digital transformation, healthcare industry*

### 1. INTRODUCTION

The quality of life is not simple to define, for it involves several aspects of individual satisfaction in different spheres of life, as well as the psycho-physical condition of a person. However, this term is used more and more today and it is considered that the way citizens grade the quality of life will replace the accepted GDP analytics. It should also be noted that the well-being of citizens is most commonly related to the term of quality of life. And so, to begin, we will consider the definitions of the quality of life, health status, as well as health-related quality of life.

The quality of life can be also defined as an overall well-being comprising objective descriptors and subjective evaluations of physical, social, material and emotional well-being along with the level of personal development and purposeful activity weighted by a personal set of values (Felce and Perry, 1993). It can also be formulated in terms of one's context (standard of living), absence of well-being (depression), or in a collective manner (Pollard and Lee, 2003). As written in the report "Wellbeing and policy", countries worldwide are becoming attracted to these appealing ideas but are worried about how they can be implemented in real life. The authors of the report are of the opinion that such ideas could encourage the governments and individuals to make 'better' decisions that would contribute to enhancing the overall wellbeing.

Chancellor Merkel pointed to the relevance of the notion of wellbeing by stressing the following: Industrialized countries do not only have the GDP and growth issues. Even hard-nosed central bankers, like Ben Bernanke, have argued: "The ultimate purpose of economics, of course, is to understand and promote the enhancement of well-being." Very few academics would argue that a country should invest efforts into maximizing the GDP (O'Donnell et al., 2014).

Besides that, the digitalization of the process leads to completely new relations in doing business. And when we discuss the healthcare system, the data relating to the well-being of citizens has become more valuable on the grey market than credit card information. This paper deals with the perception of the quality of life and its relationship with the health status of the individual, as well as the way in which the digitalization of the healthcare industry affects the quality of life; but also, how one measures quality within the healthcare system.

### 2. QUALITY OF LIFE, HEALTH-RELATED QUALITY OF LIFE AND HEALTH STATUS-WHAT IS THE DIFFERENCE?

World Health Organization (WHO) provide a highly influential definition of health, they defines health as "a state of complete physical, mental and social well-being, and not merely the absence of disease and infirmity" (WHO, 2014). WHO definition include some key aspects like social well-being and the emphasis on more than the absence of disease. That is important because not everyone agrees on the inclusion of social well-being in the definition of health (Torrance,1987). For example, some authors define health as "an individual's level of function" (Patrick et al.,1982), where "optimum function" is judged in comparison to "society's standards of physical and mental well-being".

Defining QoL, Quality of life has proven challenging (Brazier et al., 2014), (Moons, 2006) and many approaches to defining quality of life exist (Ferrans, 1990). There are approaches based on subjective well-being, expectations and human needs (Bowling, 2005).

A related literature on well-being distinguishes between approaches based on objective lists, preference satisfaction, hedonism, flourishing, and life satisfaction (Peasgood et al, 2014). Other examples of definitions of Quality of life are: "an individual's" perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns" (Kuyken and Group, 1995) , "a conscious cognitive judgment of satisfaction with one's life" (Rejeski and Mihalko, 2001).

Defining HRQoL, Health-related quality of life has also been problematic (Bowling et al.,1995) and in the literature we can identified a few definitions of HRQoL. For example, HRQoL can be defined as "how well a person functions in their life and his or her perceived wellbeing in physical, mental, and social domains of health" (Hays, 2008), other definition relates HRQoL directly to QoL: "quality of life is an all inclusive concept incorporating all factors that impact upon an individual's life. Health-related quality of life includes only those factors that are part of an individual's health" (Torrance, 1987). According to Torrance non-health aspects of QoL, like economic and political circumstances, are not included in HRQoL.

### **3. QUALITY IN HEALTHCARE**

Numerous reasons testify why it is important to improve quality of healthcare, including enhancing the accountability of health practitioners and managers, resource efficiency, minimizing and identifying medical errors while maximizing the use of effective care and improving outcomes, and aligning care to what patients want in addition to what they need (Subhash, 2003).

When it comes to quality assessment, there is only but a handful of frameworks used for analytic purposes. These frameworks have guided the measure development initiatives in both the private and public sectors, and the most influential among them was implemented by the Institute of Medicine (IOM). The framework itself examines six criteria throughout the healthcare system (Institute of Medicine, 2001): Safety; Effectiveness; Patient-centeredness; Timeliness; Efficiency; Equitability.

The measures used currently give priority to some of these criteria more than to others. For example, the present majority of measures is focused on safety and effectiveness, whereas only a small portion gives importance to timeliness and patient-centeredness. And even fewer measures assess the importance of efficiency and equitability (Institute of Medicine, 2005).

Frameworks like the ones implemented by IOM domains also prove to be a good learning curve for helping others understand the true meaning and importance of quality measures. And research has proven that by having a framework with which you can grasp the relevance of quality measures, you in fact are capable of valuing a wider range of quality indicators. So, if you were to offer a detailed explanation about the importance of safety, efficiency and patient-centeredness, consumers would have no trouble grasping the relevance of all three criteria. Better yet, when you take those three IOM domains and present them in user-friendly versions of the measures they represent, consumer are able to comprehend the importance of those measures more clearly and from a personal healthcare perspective (Hibbard and Pawlson 2004).

It is important to mention that the rising cost of health care have led to situation that healthcare industry has become especially oriented on improving outcomes and patient satisfaction (Sarkissian, 2017). We can compare it with definition of quality system "a set of interrelated or interacting elements which is using a variety of resources to achieve objectives related to quality" which are focused on fulfilling and overcoming user's requirements (Filipović and Đurić, 2010). According to the National Association for Healthcare Quality (NAHQ) we can found a set of main functions which are recognized to advance the profession and ensure that health care quality leaders are sufficiently prepared: Patient Safety; Regulatory and Accreditation; Quality Review and Accountability; Performance and Process Improvement; Health Data Analytics; Population Health and Care Transitions (Curdy et al., 2017).

Setting quality as top priority of organization it can result in achievement changes in goals, guidelines, attitudes, and activities.

### **4. DIGITALIZATION AND DIGITAL TRANSFORMATION IH HEALTHCARE**

When it comes to the comprehension of the influences and alterations on the business side of things, as it is written in I-scoop text, it's important that we research digitization, digitalization and digital transformation right form the beginning.

When it comes to aspect of digitization, there are two closely-related meanings that we can consider crucial:

Digitization presents the transformation of analog/physical things (paperwork, photographs, sounds etc.) and creation of their digital counterparts (bits and bytes). Digitized information is not limited to a specific set of materials, in the final instance, it is grounded in the configurations of materials. Relying on that fact we can see how digitization mediates between the material and the immaterial (Manoff, 2006) which makes digitization a united process (Hayles, 2003).

Digitized information is the only one that can be represented on any set of transistors, “all forms of data such as alphanumeric text, graphics, still and moving pictures, and sounds” can be digitized (Verhulst, 2002). “All signals are chopped into little pieces” (Van Dijk, 2005) and encoded as strings of 1s and 0s, and that is the fundamental process. It is also important that this process can be applied to almost every information, occurs through specific technical mechanisms and requires specific technical infrastructures that modify the original signal itself.

On the other hand, digitalization serves to: Create revenue; Improve business; Replace/transform business processes (instead of digitizing them); Create the foundation for digital business processes; The structure of this endeavor uses digital information as the core, whereas digital technologies and data (digitized and natively digital) are used as the building material.

If digitalization is also about changing business operations, business models and even revenue streams and new business opportunities, then what is the difference between digital transformation and digitalization?

It all comes down to the range and scope of it all. In comparison to digitalization, digital transformation is a much broader concept of upgrading to digital business. The foundation you build with a digital transformation strategy is much bigger because it requires more elements to help it function. Digital transformation originally served a very simplistic purpose of converting paper into digital information – since that time, it has significantly evolved.

Nextgov reports that: “Around three-quarters of the \$80 billion the federal government spends on information technology each year is used just to keep legacy systems running.” Even though technology is considered a crucial element in terms of digital transformation, this goes to demonstrate that rather than invest into new tech, it is often more about ridding ourselves of outdated process and legacy technology (Moore, 2015). According to a study done by Triger Text (and using research conducted by HIMSS Analytics): “Despite widespread use of smartphones and other mobile devices among healthcare providers, 90% of hospitals still use pagers and overpay by 45% to maintain legacy paging services.” (Landi, 2016).

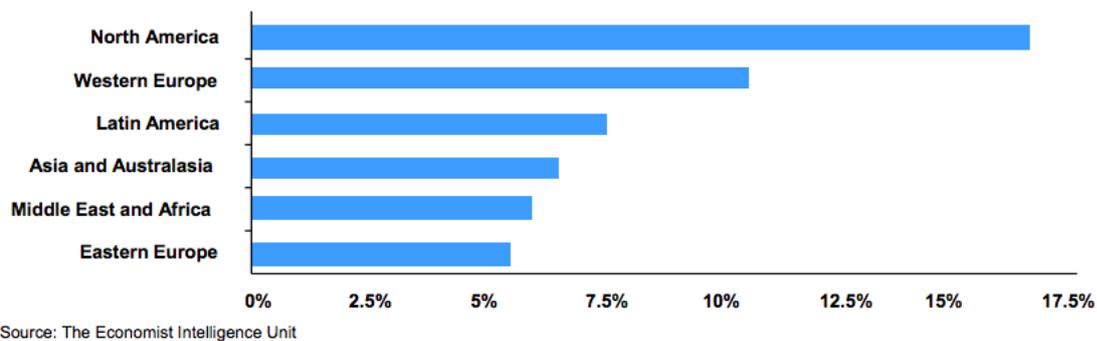

And these types of examples are present in all industries, where the prevalence of legacy technology stand in the way of a revolutionary digital transformation strategy that can only contribute to a business (Mark Samuels, 2015).

#### **4.1. Digital Transformation In Healthcare Industry**

Smart care, care anywhere, empowered care and intelligent healthcare enterprise – these are the four digital themes that will prove to be essential to the digital transformation of healthcare in the future.

- 1) Smart Care will use precision medicine, robotics and medical printing to improve patient outcomes and lower healthcare costs.
- 2) Care Anywhere will make household healthcare a reality, with the help of advances in connected homes and virtual care.
- 3) Empowered Care will give citizens more control in managing their well-being and healthcare through the development of “living services”.
- 4) Intelligent Health Enterprises makes possible for healthcare workers and their enterprises the option of monitoring patient health more effectively in real time, with the help of data-driven solutions.

Value-based healthcare is quickly becoming reality with the advancement of the digital aspect. With new technological advancements, the gap between the physical and digital world is becoming much smaller. As a result, hospitals and other healthcare facilities are now available to consumers with a simple click, scroll or tap. You now have combined smart sensors, devices and highly connected software that can lead patients to exactly what they need – low-cost healthcare outcomes with top-quality experience and convenience (World Economic Forum, 2016).

**Figure1.** Digital Transformation of Industries Healthcare Industry, (World Economic Forum, 2016)

Nearly 18% (\$3.2 trillion) of the total GDP of the United States was accounted to national health expenditures in 2015. Additional research found that as much as \$300 billion can be saved in the healthcare sector with the help of the digital revolution. This alone should paint a picture of how influential the introduction of new technologies could be when it comes to the healthcare market. In fact, CISCO research goes to define several more influential ways this can happen:

#### Telemedicine

Back in 2015, a majority of doctors and physicians were surveyed to answer whether telemedicine is a better way of managing chronic diseases or not. More than 80% of those surveyed answered that it was a more efficient method than a traditional visit to the office (AHA, 2015). The fact is that with telemedicine, both doctors and patients gain more freedom and accessibility. For one, patients would no longer be limited in terms of geographical location and distance from their physicians. This means that even patients in the most remote of areas would be eligible to receive the highest level of care afforded to those living downtown. And all it would take is a good Internet connection and a smartphone. This in itself ends up saving patients both time and money. Instead of wasting hours waiting and travelling for a simple check-up or prescriptions, they could receive it within minutes on a conference call.

#### Mobility and Cloud Access

It's estimated that over 65% of interactions with healthcare facilities will occur via mobile devices by the end of this year. In fact, the number of physicians using smartphones and medical apps already exceeds 80%, most of which access drug information on the mobile devices daily. You can wave farewell to the days of extensive paperwork and file rooms, given that all medical facilities and insurance companies are now storing patient records on the cloud, giving you 24/7 access to your test results, bloodwork etc.

#### Wearables and IoT

With the constant progress of technology come many perks, even in medicinal terms. ECGs, DIY blood screening, thermometers and other types of tests can now be conducted in the comfort of your home with mobile devices the size of car keys. With the introduction of automation, patients are even able to keep track of their weight, pulse, oxygen levels etc. all of which they can then post online for their physician to inspect. And as a result, people are able to prevent and avoid risks of heart disease and other chronic illnesses, which can ultimately save their lives (PWC, 2018).

#### Artificial Intelligence and Big Data

Big data holds the true power of the digital world, and the same goes for healthcare. Most people consider big data as a great feedback and review tool. However, it holds a much greater potential for identifying health-related risk factors and preventing them with pre-emptive treatment. Even more exciting: with the rise of the Internet of (Medical) Things (IoMT), mobile and wearable devices are increasingly connected, working together to create a cohesive medical report accessible anywhere by your healthcare provider. And this type of data goes beyond the individual patient – it holds the key of studying entire cultures and countries to help predict mass healthcare trends (Newman, 2017).

#### Empowered Consumers

Everything we mentioned up until now has led to the creation of a completely new and game-changing trend in the world of healthcare – empowered patients. We as patients are finally in a position where we get to dictate it all. No more long waits and unplanned overcharges associated with healthcare – we now have equal access to all forms of healthcare, which leads to higher overall satisfaction rates (Sherman, 2015).

## 4.2. Quality in e-Health

It looks really clear that e-health includes more than just technological development. The Internet created new opportunities and challenges to the traditional health care information technology industry, the use of a new term to address these issues seemed appropriate. According to Eysenbach, e-health can be defined as an emerging field in the intersection of medical informatics, public health and business, referring to health services and information delivered or enhanced through the Internet and related technologies. In a broader sense, the term characterizes not only a technical development, but also a state-of-mind, a way of thinking, an attitude, and a commitment for networked, global thinking, to improve health care locally, regionally, and worldwide by using information and communication technology (Eysenbach, 2001).

In terms of medicine, ICT (Information and Communication Technologies) development can lead to better quality of healthcare. A typical example here would be the application of high-tech sensors (i.e. pulse, body temperature, ECG, etc.), able to provide real-time data via wired or wireless communications technologies, interactive interface etc. This improvement actually presents “e-Health” – which is the primary engine for assisting patients. It does this by combining the use of electronic communication and information technology with the use of digital data transmitted, stored and retrieved electronically, both locally and at distance.

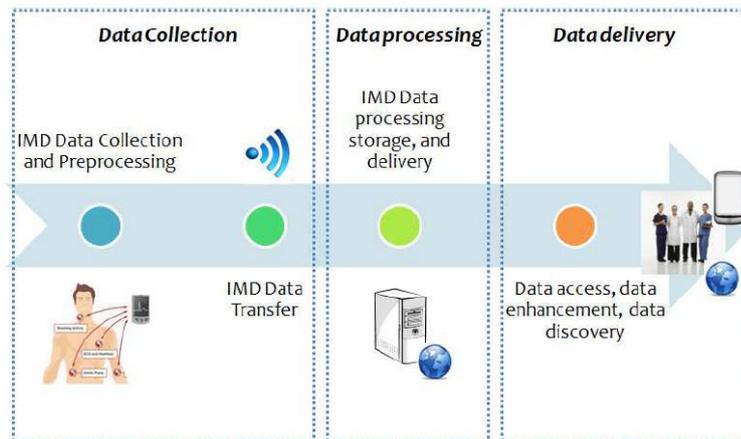

You are now capable to constantly monitor and record the condition of patients with chronic diseases, which you can then log within a larger database. The data that is gathered from these sensory devices is usually analyzed, monitored and managed by medical professionals. And the main advantage of such applications is that they trump time and space. They can capture any atypical symptoms or bodily activity at any time and in any place, so you are no longer limited geographically. Which means that patients can be monitored at their natural environment (Varshney, 2007).

The only re-occurring issue here is the complexity when it comes to managing this type of data. There are times when medical specialists are confronted with inaccurate, incomplete or overwhelming amounts of input. This, in term, leads to questions concerning the quality, security and privacy of the data in this domain. The fact remains that the quality of the data gathered in the healthcare domain always was and should be the priority. Otherwise, we risk achieving a negative effect of the applications used to collect all the information necessary. And if we choose to ignore the data collected, it also impacts the decision-making process.

In the last couple of years, technological improvements have been opening new possibilities in healthcare and the practice of medicine. But those possibilities also carry inherit risks and leave decision-makers with numerous unanswered questions regarding: quality, security, privacy, ethics and risk management and other important matters. Some surveys and approaches have showed the importance of data quality for end-users, in particular, in healthcare domain (Shaw et al. 2009). Many quality criteria have been proposed without a general consensus; in fact, each domain has its specific vision of data quality as well as the solutions to solve the quality problems (Wang and Strong, 1996). Data quality is often considered as “fitness-for-use”. It is based on the specific use of data and the requirements to be satisfied. To tackle this issue, based on existing quality modeling approaches (Wang and Strong, 1996), (Naumann and Rolker 2000), (AHIMA, 1998), we can analyze the e-health monitoring systems according to appropriate quality criteria. Such strategy aims to manage data quality at every point, which should lead to the minimization of potentially poor data quality from spreading.

### 4.2.1 Impacting data quality

To correctly identify data quality issues, we have firstly to identify the source of the quality problems, analyze its impact and, where possible, propose a solution. Some difficulties are related to technology (i.e. equipment, QoS (Quality of Service), to human intervention (input errors, misunderstanding...), or to process of data transformation (i.e. optimal analysis and processing). According to Gutiérrez and Riveill (2011) there are three main levels of data management and processing over the system defined as: Data collection (sensor data collection, pre-processing and transfer), Data processing (data processing, storage and delivery) and Data discovery (data access, enhancement and discovery).

**Figure2.** Data quality analysis for e-health monitoring applications, (2010).

## 5. INFORMATION SECURITY MANAGEMENT (ISM)

Just like any other knowledge intensive and information-based enterprise, the healthcare industry depends on the IT sector to analyze, acquire, manage and disseminate all information and expertise related to healthcare (William and Herbert, 2009). IT solutions are used to: Develop the decision-making process; Promote information exchange; Aid in self-care and professional support; Improve the effectiveness of healthcare facilities; Make electronic records of patient information (Economic Commission for Africa, 1999).

Information that relates directly to the health of a patients in defined as personal health information. This type of information includes everything – from a person’s health condition and use of health services to any potential disability or other relevant information (Office of the privacy commissioner, 2001). The way to gain access to such information is through health information systems (HIS). As an integral part of any healthcare system, HIS lays the foundation for processing, analysis and reporting of healthcare information. In additions to this, it also supports the development of the top healthcare indicators needed to monitor and evaluate the overall performance of a particular healthcare system (Matshidze and Hanmer, 2007). In comparison with paper-based data collection, and on the negative side of things, HIS-based collection and data storage can cause certain complications in terms of information protection measures and security (Quynh, 2005).

Information security management (ISM) has a primary goal to ensure business continuity while it reduces the business damage. It can do so with prevention and/or minimization of any security incident impact (Krause and Tipton, 2003). The goal of ISM is to establish, implement, operate, monitor, analyze, revise, maintain and boost information security.

The ISO/IEC 27001 (ISO 27001, 2005) is an internationally recognized standard that provides a specification for ISM systems. One of the standards that supports the implementation of ISO/IEC 27001 is the ISO/IEC 27002 - Code of practice for ISM (ISO 27002, 2005). This standard provides implementation guidance in support of the security controls specified in its clauses and is cross-referenced for this purpose in the ISO/IEC 27001 (ISO 27001, 2005). In 2008, a new standard was published for ISM in healthcare. The ISO/IEC 27799 international standard provides guidance on how best to protect the confidentiality, integrity and availability of their information with the implementation of ISO/IEC 27002 standard (ISO 27799, 2008).

## 6. CONCLUSION

Since the introduction of electronic medical devices (EMRs) back in 2009, the healthcare industry has undergone a major transformation. Providers, payers, and other medical organizations have undertaken the long-term project of securing every patient medical record electronically in order to comply with government regulations. The rewards for current players and new entrants are likely to be quite substantial for creating transformational digital services as scale, considering that the overall amount of finances spent on healthcare annually amounts to \$7.5 trillion. Digitization is still defined as complex and challenging, mostly due to the effect it has on every piece of data, relationship and business interaction. Just consider this – healthcare providers are now able to use apps to track patients and assets, and thus support the experience of the consumer with wayfinding, mapping and scheduling. The potential that such a system carries is endless in terms of: Handling big data; Mass records analysis and comprehension; Creating a top-quality

healthcare system. With all this in play, the old data gathered from centers and CRM systems can now be combined with the data collected from digital sources (mobile networks, social media, medical apps, equipment sensors etc.).

As it mentioned, HRQoL means “how well a person functions in their life and his or her perceived wellbeing in physical, mental, and social domains of health”, not surprising the fact that governments invest such a big money in improvement of healthcare system in order to achieve better conditions for their citizens aligned with new technologies. As is told at the beginning of the paper, new measure for GDP will be a QoL score, which is directly connected to healthcare system.

Regarding to that fact healthcare records are among the most hacked data in the world. It is estimated that medical information is worth 10 to 20 times more on the black market than credit card data because of its potential for fraud, identity theft, and abuse (Humer and Finkle, 2014). With the development of technology comes the growth of potential threats and risks as well. So, as the Internet of Things grows, the security of medical devices is beginning to be questioned more and more.

In Nederland’s National Institute for Public Health and the Environment report it is also mentioned that nowadays digitalization in health care is equal to common good. Health data are measured, stored and exchanged in bits and bytes. Digitalizing health data can bring benefits as well as challenges for patient safety. Accordingly it is important that health care providers are aware of the risks related to hackers, viruses, and the safe transfer of data.

A set of different benefits might be achieved by digitalizing health data, and some of the are dedicated to next goals: Improving public health by electronic health data which can be used by health care professionals. This can be done by combining databases with medical information or using electronic medical data to identify intervention or surveillance strategies. (Lin and Schneeweiss 2016). Securing the privacy of the individual patient is the main challenge in using electronic health care data to improve public health. Empowering the patients in direct online insight and use of digitalized health data. Direct access of health care services improves patient self-management and safety, but will also affect the workload of health care professionals. In these way communication technologies change the interaction between patient and health care professional (Mold and Lusignan 2015); Cost reduction can be achieved through implementation of the medical data in electronic health records. (Shen et al. 2015).

As mentioned above, when we discussed the healthcare system, all the digital transformations that are occurring today have a goal to satisfy the demands of the users. By meeting those demands, the level of the quality of life also grows. However, this also brings new issues related to the quality of services, security measures etc. Digital transformations definitely introduce a new era to our way of life and conducting business, and this is what we set out to demonstrate with this paper, as well as to predict new movements and trends. Those who manage to get behind these trends first and meet user demands the most will also gain the largest advantage. The next step in the continuation of this research can be the analysis of the healthcare system in the Republic of Serbia, as well as grading the quality of life of its citizens.

## PUBLIC ADMINISTRATION QUALITY DETERMINED BY CUSTOMER-RELATED CAF MODEL

Nedeljko Zivkovic<sup>1</sup>, Maja Glogovac\*<sup>1</sup>, Ana Horvat<sup>1</sup>

<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia

\*Corresponding author, e-mail:maja.glogovac@fon.bg.ac.rs

**Abstract:** CAF model, developed to support the introduction of the idea and the principles of total quality management (TQM) in the public sector, has today become an important tool for measuring quality improvement in public administration. On the other hand, any quality improvement should be directed according to customer satisfaction. Thus, the CAF model is used in this study to evaluate and compare public administration quality including customer-related results, as part of the CAF model. Furthermore, CAF results are compared with the municipalities' quality system maturity level assured by ISO 9001 certificate. The results show significant correlation between CAF scores and maturity level as well as between citizens/customers results and overall CAF scores.

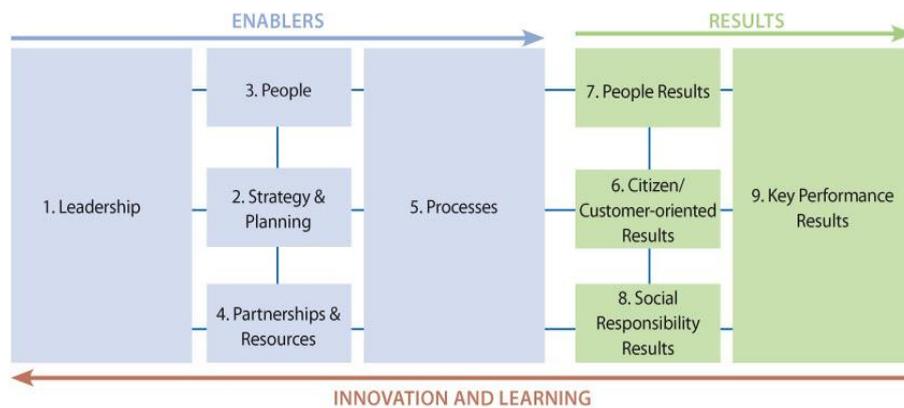

**Keywords:** service quality, public administration, customer satisfaction, municipality, CAF model

### 1. INTRODUCTION

The public administration function is a crucial element of any country, and has many times been a starting point for economic growth and social justice. The need for improvement of performance and results in the area of public services has never been more important (Vakalopoulou et al., 2012). In accordance with the quality management movement, customer focus has become a key issue, with the satisfaction of customer needs and expectations being a major concern (Flynn, 1997; Nwankwo, 1995). According to Schainker (2013), to achieve exceptional service, an organisation must first listen to its customers. In line with this, Hill (et al., 1999) recommend that in order to identify things that are important to customers and to measure the degree by which they are satisfied, it is useful to make an internal assessment.

The Common Assessment Framework (CAF) method is used for public administration in order to define the level of fulfilment of criteria which have an influence on quality, so the CAF has become an important tool regarding quality improvement in public administration (Luczak & Wolniak, 2013). It was developed in 2000, under the authority of the Directors General of Public Administration of the EU member states in order to support the introduction of the idea and the principles of total quality management (TQM) in the public sector across the EU and beyond. The model was revised in 2006 and after that in 2013. It already has more than 2010 registered users (organisations that have implemented the CAF) spread in 38 countries, while it has been translated into 20 languages (Staes et al., 2010). Among the non-EU states working with the CAF are candidate members and neighbouring countries like Bosnia-Herzegovina, Croatia, Macedonia, Russia, Serbia, and many others (Patrick & Nick, 2010). The CAF may be applied in all types of public organisations regardless of the number of employees (Staes & Thijs, 2005). It has been designed for use in all parts of the public sector, and is applicable to public organisations at a national/federal, regional and local level (Thijs & Staes, 2006). Rickards (2013) showed the distribution of CAF users by sector in 2010, highlighting that local governments were the most represented.

The basic structure of the Common Assessment Framework has been derived from the European Excellence Model, although in a slightly modified way. The CAF thus handles a set of 9 evaluation criteria (figure 1): five criteria are used to assess the performance of the enablers, meaning what the organisation does in order to achieve excellent results, and then four criteria are directly used to assess the results that an organisation achieves.

**Figure 1:** CAF model structure (Vakalopoulou, 2012)

The CAF has been developed by making use of the "European Excellence Model" promoted by the European Foundation of Quality Management (EFQM), various national quality management tools derived from the Excellence Model and the Speyer Quality Award Scheme widely used in German-speaking European countries. One of the aims of the CAF is therefore to serve as a bridge between different quality management instruments and quality management cultures in Europe. It is not in competition with these instruments, but tries to complement them and to bring together their most important elements. The CAF is designed to be an easy-to-use tool for quality management in the public sector. It aspires to bridge the different quality models and to serve as a useful 'starter model' before moving on to more sophisticated quality management models (Van Dooren & Van de Walle, 2004). It is a simple, cost free and easy to use self-assessment tool (Vakalopoulou et al., 2012).

The most important reason to use the CAF is to identify a number of strong and weak points, which will then serve as a basis to set up targeted improvement actions (Dearing et al., 2006). On the other hand, many authors (Kelly & Swindell, 2002; Higgins, 2005; Wood et al., 2007; ) use the CAF performance for comparing with the customers' satisfaction. Taking this into account, as well as that any quality improvement should be directed according to customer satisfaction, the CAF model for three municipalities is examined in this paper, aiming at analysing the quality of three observed municipalities.

## 2. THE FRAMEWORK OF THE RESEARCH

For the requirements of the research, the CAF Scoring and assessment panels (2006) were used. An instrument for data collection was prepared for the purpose of scoring according to the CAF model.

### 2.1. Objective of the research

The basic objective of the research in this study is to determine and compare the results obtained using the CAF model related to citizens/customers in three municipalities. This would be a way to gain additional trust in the results obtained using the CAF model which refer to users of local self-governments. Moreover, the results obtained using the CAF model in this research can be compared with similar research for additional confirmation of their results.

### 2.2. Research questions

Based on the literature review, the following research questions are set out:

- A higher average score for each of the citizens/customers results for the local government obtained using the CAF model corresponds with a higher average overall CAF score;
- Municipalities with ISO 9001 certificate and higher maturity level gain higher CAF score comparing to the municipality without the certificate and low maturity level.

### 2.3. Research instruments

The first instrument was prepared according to the CAF fine-tuned scoring (2006 version) which served for data collection in order to determine individual scores for each component of the model relating to the work of local governments. The model was used according to the proposed structure of the criteria (Figure 1). The sixth criteria, "Customer results", was considered in detail in order to be able to compare the results with overall CAF scores. The following items were considered:

1. Results of citizen/customer satisfaction measurements (item 6.1 from the CAF model) – examples:

- Results regarding the overall image of the organisation (e.g. friendliness and fairness of treatment; flexibility and ability to address individual solutions);
  - Results regarding involvement and participation;
  - Results regarding accessibility (e.g. opening and waiting times, one-stop-shops);
  - Results relating to products and services (e.g. quality, reliability, compliance with quality standards, processing time, quality of advice given to the customers/citizens).
2. Indicators of citizen/customer-oriented measurements (item 6.2 from the CAF model) – examples:
- Indicators regarding the overall image of the organisation:
    - Number and processing time of complaints (e.g. resolution of conflict in cases of interest);
    - Extent of public trust towards the organisation and its services or products;
    - Waiting time;
    - Handling/processing time of services delivery;
    - Extent of employee training in relation to the effective handling of citizen/customer relationships (e.g. professionalism and friendly communication with, and treatment of, citizens/customers);
    - Indicators of complying with diversity and gender aspects;
  - Indicators regarding involvement:
    - Extent of involvement of stakeholders in the design and the delivery of services and products and/or the design of decision-making processes;
    - Suggestions received and recorded;
    - Implementation and extent of use of new and innovative ways of dealing with citizens/customers;
  - Indicators regarding accessibility;
  - Indicators regarding products and services:
    - Adherence to published service standards (e.g. citizens' charters);
    - Number of files returned with errors and/or cases requiring repeated processing/compensation;
    - Extent of efforts to improve availability, accuracy and transparency of information.

From the previous division it is noticeable that, in general, both items of this criterion (6.1 and 6.2) may be observed using the same 4 elements:

- Overall image of the organisation;
- Involvement and participation;
- Accessibility;
- Products and services.

During the scoring of the three municipalities according to the CAF model, the same team of appraisers used the following scale of scores:

- 0-10 points: No results are measured and / or no information is available.
- 11-30 points: Results are measured and show negative trends and / or results do not meet relevant targets.
- 31-50 points: Results show flat trends and / or some relevant targets are met.
- 51-70 points: Results show improving trends and / or most of the relevant targets are met.
- 71-90 points: Results show substantial progress and / or all the relevant targets are met.
- 91-100 points: Excellent and sustained results are achieved. All the relevant targets are met. Positive comparisons with the relevant organisations for all the key results are made.

## 2.4. Population and sample characteristics

Since this research is related to the views of citizens regarding the quality of the municipality services, it was necessary to place it in an appropriate situation in the municipality. This situation had to satisfy certain conditions, such as: a) offering a whole range of municipality services, so that all citizens were exposed to at least one of the services, b) being a unique institution for offering the services available to all citizens, in order to avoid confusion between different authorities, c) homogeneous delivery of the services in order to have similar levels of service available to all respondents, d) being a somewhat dense, urban type of population, in order to exclude distance from being an obstacle to the service experience, and e) interest of the municipality authorities. All the above stated conditions were met by three municipalities in Northeastern Bosnia and Herzegovina, with an estimated total population of 47,000 inhabitants.

For the purpose of researching the scores acquired using the instrument according to the CAF model, visits by the appraisal team were organized to each of the local areas during 2011 according to the given plan of assessment. The data were collected working with a selected team which included managers from particular

organisational units of the local governments. The work was organised through workshops and focus groups several times during the course of the project.

### 3. RESULTS

In order to facilitate the display of the data, abbreviated marks were assigned to the municipalities:

- A – for the municipality A (Municipality with no ISO 9001 certificate and low maturity level);
- B – for the municipality B (Municipality with ISO 9001 certificate and medium maturity level);
- C – for the municipality C (Municipality with ISO 9001 certificate and high maturity level).

Table 1 shows the results of scoring for the three municipalities according to the CAF model, where the average values of the scores are shown according to each criterion related to this model. The scores show the rank of the municipalities A-B-C, where the municipality A has the highest total score, as well as the highest scores for each individual criterion.

**Table 1:** Scores for the three municipalities according to all the items of the CAF model

	max	A	B	C	Relative	A	B	C
1. Leadership	400	45	66.25	147.5	100	11.25	16.56	36.87
2. Strategy	400	33.75	47.5	85	100	8.43	11.87	21.25
3. People	300	37.5	38.75	55	100	9.37	9.68	13.75
4. Partnership	600	135	138.75	151.25	100	33.75	34.68	37.81
5. Processes	300	43.75	53.75	123.75	100	10.93	13.43	30.93
6. Citizen results	200	20.75	28.75	34.375	100	5.18	7.18	8.593
7. People results	200	20	20	32.5	100	5	5	8.12
8. Society results	200	45	47.5	47.5	100	11.25	11.87	11.87
9. Key performance	200	70	72.5	77.5	100	17.5	18.12	19.37
<b>TOTAL</b>	<b>2800</b>				<b>900</b>	<b>112.68</b>	<b>128.43</b>	<b>188.59</b>

From the results shown, the same rank of the municipalities is observed for each of the items, and in total:

- Municipality A is the municipality with the lowest score (total of 112.68) and is therefore categorized as the worst municipality compared with the other two municipalities observed;
- Municipality B is the municipality with the middle score (total of 128.43) and is therefore categorized as the middle compared with the other two municipalities observed;
- Municipality C is the municipality with the highest score (total of 188.59) and is therefore categorized as the best municipality compared with the other two municipalities observed.

Table 2 has separate scores for the “Customer-related” item, which consists of two parts:

- Results of citizen/customer satisfaction measurements (item 6.1 from the CAF model);
- Indicators of citizen/customer-oriented measurements (item 6.2 from the CAF model).

**Table 2:** Scores for the three municipalities according to the items 6.1 and 6.2. of the CAF model

		A	B	C			A	B	C	
Citizen R	6.1.	<b>Trends</b>	26.75	26.75	27.75	6.2.	<b>Trends</b>	3	4	5.75
		<b>Targets</b>	6.5	19	27.5		<b>Targets</b>	5.25	7.75	7.75
			33.25	45.75	55.25			8.25	11.75	13.5
		<b>TOTAL</b>	16.63	22.88	27.63			4.125	5.875	6.75
Max 200	A	20.75								
	B	28.75								
	C	34.375								

Scores for the above mentioned 4 elements (Overall image of the organisation; Involvement and participation; Accessibility; Products and services) as the common elements of the two items (6.1 and 6.2) of “Customer-related” criteria can be found in Table 3.

**Table 3.** Scores for the three municipalities according to the common elements of the items 6.1. and 6.2. of the CAF model

## 4. CONCLUSION

The CAF model is increasingly being used in different ways, one of which is to identify space for improvement, particularly in the public sector. However, this is an easier method in relation to other self-assessment management tools (such as EFQM Business Excellence Model, the ISO 9000 or 14000 series, Balanced Scorecard approaches, Six Sigma, etc.), which enables all organisations, regardless of their size, to perform self-evaluation. Therefore, the goal of this study was to evaluate and compare public administration quality including customer-related results.

Comparing the results obtained by the analyses in this study performed on both the total average values and individual elements of the noted models, it may be concluded that the ranking of municipalities regarding Citizens/Customers results is proportional to the overall CAF scores. Such results confirms the first research question set in this study. Therefore, the CAF model may be considered a sufficiently reliable method for obtaining data on real user satisfaction. In other words, based on this conclusion it is expected that as the customer-related CAF scores increase/decrease for a municipality it may be expected for the real degree of its user satisfaction to be higher/lower. This conclusion may be significant for the municipalities which have conducted or which regularly conduct self-assessment, but which are not able to examine their user satisfaction in a certain period in a direct way.

The analysis also showed that the CAF scores of three observed municipalities differ according to the maturity level. Results also confirms that the municipality with the high maturity level gains the best CAF score, while the municipality with no ISO 9001 certificate and the low maturity level gains least CAF score.

**Abstract:** *Blockchain is the main driver of the world's decentralization and initial coin offerings is the main driver of the investment decentralization. Initial coin offering represents a new model of financing start-up projects. Investors invest in projects and receive digital coins/tokens for their investments. After the initial coin offering investors can trade those coins/tokens on the cryptoexchanges. Therefore, technology development is creating a new class of securities through the initial coin offering. However, legislation connected to the initial coin offering is still loose and no real uniform framework exists, which enables that some offerings can be of very poor quality. Crowdfunding reward-based platform introduced its first initial coin offering, and we investigate whether critical success factors are the same for the real and blockchain project. We find that there are similarities.*

**Keywords:** *Initial coin offering, crowdfunding, blockchain, token, case study*

### 1. INTRODUCTION

Fourth industrial revolution brought many changes into the world we know. Technology and Internet became the essential in conducting almost any type of business. Financial service industry is undergoing profound changes as well. Currency is not just a currency, Internet and technology introduced cryptocurrencies. ValueWeb affects banking: retail, commercial, transaction, and private. Also, technology affects investment banking, asset and wealth management. Stock exchanges move to block exchanges (Tapscot & Tapscot, 2016). Initial public offering of stocks are getting competition of initial coin offerings, which are starting to be much discussed topic in the cryptocurrency community. Trading strategies, trading analytics and alternative finance are the main FinTech categories in the investment and capital markets settings (Skinner, 2016).

Crowdfunding is an alternative financing source of new ventures and an informational mechanism. Investors' allocations can provide information regarding how they value the project, and entrepreneurs use this information to decide on product release. In this way, they test and validate their innovative ideas on the Internet. Music is one of the main categories in the terms of the number of crowdfunded projects (da Cruz, IN PRESS). Platforms are used to finance cleantech or alternative energy projects (Cumming et al., 2017). Crowdfunding could even help raise funds for the Academic libraries (Bushong et al. 2018). This type of an alternative financing also has its place in the global healthcare. Different types of health projects can use crowdfunding platforms to raise capital, and they introduce certain economic benefits and risks (Renwick and Mossialos, 2017).

Now, established crowdfunding platforms are incorporating new kind of ventures, they are moving to the territory of coins offering. Coins represent the first generation of cryptocurrency assets. Tokens are the second generation of digital assets, which cover broader purpose of use than coins (Hale, 2018). Through the sale of the tokens entrepreneurs can obtain financing for the initial development of the digital platform (Catalini & Guns, 2018).

The rest of the paper is structured as follows, in the section 2 phenomenon of crowdfunding is defined and different models are presented. In the section 3, blockchain technology and initial coin offering (ICO) were introduced along with a case study of a first ICO on one of the reward-based platforms. Section 4 gives concluding remarks and directions for further research.

### 2. CROWDFUNDING

Crowdfunding is a process of funding a project or a business by a large group of people, or a crowd, where open call is performed essentially through web-based intermediary platform. Crowdfunding is a generic term which combines crowdinvesting and a crowdfinancing. Fundraisers, entrepreneurs and others seek funds through certain platform, and investors invest in these projects assuming risk and expecting payoff. Value of the platform stems from the number of existing and potential users, essentially from the ability to attract new users which represents network effect (Forbes & Schaefer, 2017; Tomczak & Brem, 2013). Therefore,

crowdfunding represents online alternative finance practice of financing an innovation idea, through electronic platform which involves a large number of people (Davies & Giovannetti, IN PRESS).

There are four models of crowdfunding: reward-based, equity-based, lending-based, and donation based. Reward-based crowdfunding model assumes that backers or funders provide finance to individuals, projects or companies in exchange for non-monetary products or rewards (Zhang et al., 2016). This type of crowdfunding is supported by platforms like Kickstarter and Indiegogo (Forbes and Schaefer, 2017). A backer or investor receives an award based on the size of the donation, and reward can take the form that entrepreneur chooses, like a product itself or some type of an artwork. Furthermore, platform itself can be of a different format. "All or nothing" is a platform that requires that a funding goal must be reached, in order for entrepreneur to obtain funds. "Keep it all" is a type of a platform that allows entrepreneurs to keep all the funds raised, irrespective of whether goal is reached or not (Davies & Giovannetti, IN PRESS).

Equity-based crowdfunding assumes that individuals or institutional funders purchase equity issued by a company (Zhang et al., 2016). Platforms that back equity-based crowdfunding are for example, Seedrs and Crowdcube (Forbes & Schaefer, 2017). Lending-based crowdfunding can take a form of peer-to-peer consumer lending and peer-to-peer business lending, where individual or institutional funders provide a loan to a consumer or a business borrower. The Funding Circle represent an example of a lending-based platform (Forbes and Schaefer, 2017; Zhang et al., 2016). Donation-based crowdfunding is a model of crowdfunding where donors provide funding to individuals, projects, or companies based on philanthropic motivations with no expectations of monetary or material return; where donations could be placed through Just Giving, for example (Forbes & Schaefer, 2017; Zhang et al., 2016).

When engaging into crowdfunding, the key is to know which crowdfunding practices can lead to a successful fundraising. Therefore, it is essential to determine characteristics of the crowdfunding practices and to exploit them. We can distinguish between individual crowdfunding practices and practices on standardized platforms. In the case of individual crowdfunding, it is found that crowdfunding helps entrepreneurs to attract attention of the crowd or potential customers on their venture. Such practices are proven to be especially important for artists. Furthermore, non-profit entrepreneurs proved to be more successful in the crowdfunding and reached their capital targets. If entrepreneurs are less focused on profits, investors believe they are more committed to deliver greater benefits to the community (Belleflamme et al, 2013). Significant motivation for investors' participation in the crowdfunding platform campaign and their willingness to pay are product oriented, which stem from the investors' desire to make-the-product-happen (Zvilichovsky et al., 2018). In order for crowdfunding to be successful, Forbes and Schaefer (2017) propose several guidelines in the domain of product development. Platforms are very different, not just according to the alternative finance model they implement, but some of them favour smaller projects and other support a big scale projects. Moreover, platforms could be oriented to the certain industry. Critical for success is to adequately determine funding goal and to compile the list of rewards, although backers are usually motivated to buy a product as a reward. Also, campaign should have a video, which should give all the relevant information in the first 30 seconds, since it is found that investors lose interest for the video afterwards. Petitjean (2017) find that backers react positively when reward-based campaign is connected to a video. The first week of a campaign is critical for the success of the project, as well as, the past success rate of the projects category. Crowd values comments and reviews regarding the project, since anticipation of the participation is important for project success (Petitjean, 2017). Success of an equity crowdfunding is dependent on the stage of the production process, where developed products are more likely to get financed than ideas. Also, ventures with large corporate clients have more chance to succeed in equity crowdfunding campaigns. Furthermore, entrepreneurial teams that consist of more members are more prone to success, and returning entrepreneurs' that previously were funded by angel investors have greater success rate (Mamonov & Malaga, 2018).

### **3. INITIAL COIN OFFERING**

#### **3.1. Cryptocurrencies and blockchain technology**

Cryptocurrencies represent a mixture of a computer science, cryptography and economics. Therefore, they are digital tokens that consist of peer-to-peer network, consensus mechanism and a public key infrastructure (Hileman & Rauchs, 2017). Cryptocurrency is a digital/virtual currency (Hale, 2018). Specific to cryptocurrencies is that, that there is a diversified infrastructure which supports them and no central authority oversees this network. Rules governing this type of the cryptocurrencies system are enforced with all nodes or network participants. Transactions are written in a shared ledger called blockchain. Transactions can be verified by each node since everyone has a copy of shared ledger. Cryptocurrencies use cryptography and blockchain for security (Hileman & Rauchs, 2017; Hale, 2018). Blockchain technologies enable digital assets

to be moved, and they have capability to prove that sender of an asset does no longer possess it. Blockchain technology is connected to the cryptography, where the owner of the private key can dispose of an asset by moving it, where movement is performed by changing the key pair (CMS, 2018). Therefore, it can be said that cryptocurrencies are primitive tokens. They represent an atomic element from which open public blockchain network is created. In contrast to primitive tokens, secondary tokens are created on top of a blockchain network and are representation of some property rights (real world asset or a blockchain product/service) (Sehra et al., 2017).

New tokens can be created through deployment and scaling of a new blockchain network or through issuance of tokens on the top of the existing blockchain network, which is not an easy process. Introduction of Ethereum opened the way for creation of smart contracts. Smart contracts represent applications that run atop of the decentralized network. In this way tokens can be created and distributed to users, and made tradable afterwards. Process of creating tokens and distributing to the users in return for cryptocurrency is an ICO process. ICO can be seen as a new distribution channel for assets. One should separate the primitive tokens which are cryptocurrencies like Bitcoin and Ethar, and secondary tokens (Sehra et al., 2017).

### **3.2. Properties of the Initial coin offerings**

Initial coin offering represents a mechanism for financing a project by the means of selling future cryptocurrency or tokens for current and liquid cryptocurrencies, such as Bitcoin (Hale, 2018). Therefore, with ICO, companies are trying to attract investors to finance the implementation of their projects and in exchange investors receive cryptocurrencies or tokens, depending on a project. Coins or tokens can be traded on exchanges after the ICO, for the price that is higher than in the process of initial coin offering.

We can compare real and digital world in the sense of the issuance process, and differentiate between initial public and initial coin offering. Initial public offering (IPO) is a way that an existing, established, successful and large-scale company can raise capital by selling shares to the public (Hale, 2018; Norman, 2017). IPO represent a very long and an expensive process, where company needs to satisfy number of the requirements of the exchange. Only limited number of shares enter the market. Initial coin offering is similar in this respect to an IPO, since only limited number of coins/tokens enter the market (Norman, 2017). Companies that launch ICOs are start-ups', they only have an idea and they do not have minimum viable product (MVP). ICO can go through several phases: pre-sale or pre-ICO, crowd sale, and post-ICO (Hale, 2018; Norman, 2017). Pre-sale can be private and public, and one ICO can have both phases of pre-sale. Pre-sale is a token sale event that goes before ICO campaign or crowdsale, and it is run by blockchain enterprises. Both, fundraising target and price in pre-ICO are lower than in ICO, where tokens could be sold for a 10-50% discount in this phase. Speculators usually buy tokens in pre-sale phase and resell it on the exchange afterwards. Crowdsale assume mass sale of tokens. After ICO, some post-ICO activities can be organized such as fulfilment of commitments or even additional token sale (Hale, 2018). Main challenge with an ICO and issued tokens is that there is substantial difference between the qualities of individual offerings. It is still not defined what the boundaries for tokens issuance are and how regulators around the world see the issuance process (Sehra et al., 2017).

During the launch of the ICO, tokens are issued by adding transactions to the blockchain with description, number and unique ID. After the ICO, tokens are placed and can be traded on the crypto exchanges. Price of the token is formed according to the laws of supply and demand, and in many cases it follows a certain trend (Hale, 2018). Tokens market price rise up sharply after they are placed on the exchange and that is usually followed with a large drop in price. Such price movement is connected to the characteristics of investors that participate in digital market. Investors in ICO are usually small and non-professional, and they could be motivated by ideology. Moreover, other group of investors in the ICO are motivated to pursue speculation. Investors that participate in ICO's could be risk takers, and they can speculate that they will earn high returns in a short period of time. As soon as they make a return, they withdraw from the market, which is a viable strategy connected to the ICO since there is no lock-up period (Norman, 2017). Speculators sell their tokens when they are placed at the exchange, which introduces sharp drop in price and capitalization, and could stimulate the remaining token owners to sell them. Therefore, investors with ideological or intangible motivation are crucial for the ICO (Hale, 2018).

There are different types of the initial coin offerings. ICO could be in a form of payment tokens (currency tokens), utility tokens, and asset tokens. Payment or currency tokens are used as a means of payment for acquiring goods or services. Utility tokens provide access to an application or service. Asset tokens represent an assets in the economic sense much like equities, debt, and derivatives are different asset classes. Also, tokens which enable physical asset to be traded on the Blockchain are considered asset tokens (CMS, 2018). Investors in tokens can earn dividends or capital gain. Dividends in a digital world are based on smart contracts (Hale, 2018).

### 3.3. Case of the reward-based crowdfunding platform ICO

ICO's are loosely regulated worldwide and the quality of offerings can vary significantly. Even Security and Exchange Commission (SEC) see this area as the wild west of financial services. Value is created in a regulatory arbitrage (Sehra et al., 2017). That is why we turn our focus to the well-established crowdfunding reward-based platform, Indiegogo since they are making an effort due to their experience to select quality cryptocurrency investments. We are going to investigate whether successful crowdfunding practices related to funding a project are implemented when initial coin offering is launched. This is going to be tested on the first such an offering on Indiegogo.

We have collected information regarding the Fan-controlled Football League ICO from the Indiegogo website and relevant legal documents. The Fan-controlled Football League (FCFL) represents a professional football league that let fans control the course of a match, who trains a team and who will play the game. Fans can engage into the league by using Fan Access Network (FAN) tokens, which are smart tokens based on the Ethereum blockchain. This initial coin offering is over, and the project is funded.

Previous research find evidence that non-profit entrepreneurs are more successful and that investors are product oriented (Belleflamme et al, 2013; Zvilichovsky et al., 2018). Since this reward-based ICO provided fans with access to decisions making in professional sports, we can see that investors were very product oriented and supported this campaign since it is funded. This product makes fans more in control of football. Funding goal is reached, which means that it was adequately defined which is in accordance with finding of Forbes and Schaefer (2017). Existence of an informational video is seen as critical success factor, and especially in a reward-based crowdfunding platform. Backers lose interest in watching a video after 30 seconds, and that is why it is important that all vital information are disclosed in that time span (Forbes and Schaefer, 2017; Petitjean, 2017). FCFL creators did not put all relevant information in the 30 seconds of their video. In that time period accent was more on a video then on the information. Perhaps, sport itself is motivation enough for the backers to buy tokens. Petitjean (2017) find that crowd values reviews, but no comments were provided on a website, and social networks were not part of this analysis. Total number of team members that created FCFL is 15, which is a large team and this project wasn't completed by an individual and was successful in fundraising. Therefore, we can say that this finding is in accordance with Mamonov & Malaga (2018).

## 4. CONCLUSION

ICO's are much discussed topic recently and many market participants are against them, since there is no firm regulatory framework and the quality of many offerings are of very poor quality. However, blockchain start-ups have raised more than \$7B since 2017 (Catalini & Guns, 2018). Many of them oppose to the ICO but many investors are keen to invest, which is evident from the amounts raised in just one year. Maybe with such results we could expect that blockchain crowdfunding would have an impact on the stock markets. Although, backers in a crowdfunding are small investors and stock markets attract investors of various sizes and sophistication, we could assume that number of small investors could decrease connected to the stock exchanges.

ICO's influence traditional, product/service crowdfunding industry in a way that we can see introduction of blockchain projects and their corresponding initial coin offerings on one reward-based platform. Practices that proved to be successful in product crowdfunding industry are mostly implemented in the case of the blockchain project. Those practices proved to be fruitful and in the case of the blockchain project.

Limitation of this study is that it looks only at one ICO on a reward-based platform. However, this ICO is a first of its kind on this platform and no comparison to other projects was possible. Further research should follow future ICO's and check for the consistency of the results and to test whether there are peculiarities connected to the ICO on a reward-based platform.

# HE WHO DARES WINS: NEUROFINANCE APPROACH TO FINANCIAL DECISION-MAKING

Tijana Obradović\*<sup>1</sup>, Milica Latinović<sup>1</sup>, Veljko Dmitrović<sup>1</sup>  
<sup>1</sup>University of Belgrade, Faculty of Organizational Sciences, Serbia  
\*Corresponding author, e-mail: tijana@fon.bg.ac.rs

**Abstract:** *It is not a secret that some underlying assumptions of traditional financial theories appear to be wrong. One of the most obvious is that investors are rational and that they make sound investment decisions. Emotions seem to be the missing part, and the impact of affect behavior on decision-making process should not be neglected. The question is what is happening in investor's brain and how do they really make their decisions. Neuroscience can give the answers, by studying the human mind, and explaining how and why a particular behavior occurs.*

**Keywords:** *neurofinance, the human brain, investment decision, risk, emotions*

## 1. INTRODUCTION

The traditional model of decision-making process assumes that humans are rational. Therefore, it provides with the set of explicit assumptions and axioms that would ensure rational decision. However, traditional finance theories fail to answer the questions like why do investors trade, how successful they are, how do they make decisions, why are they not behaving rationally, and why they do not play according to utility theory? The rational aspect of decision making is evident and understood, but the emotional element was neglected.

A few decades ago, scientists were intrigued with what is happening in the humans' brain shortly before, while and after making a financial decision. Why do some investors become reach, while others fail? There must be something more than just following financial theories and making the calculation. However, it is also more than just bravery, self-confidence, or understanding of risk and returns. What makes successful trader, why is he so special? There are countless examples of financially very educated people, even Nobel prize winner, people who are deeply familiar with every financial theory, who still failed on the reality of financial markets. Why? Neurofinance can give the answers. The problem was obviously inside them, not outside on the market. It was all in their brain. The answer lies in about 60.000 miles of brain's neural wires (Turcan & Dedu, 2010). Humans are irrational.

## 2. TRADITIONAL VIEW OF INVESTMENT DECISIONS

The standard economic theory claims that humans behave rationally, and therefore, they will make decisions in alignment to maximize their utility. Rational behavior means that people choose the best solutions based on logic and currently available options (Sadeghnia, Hooshmand, & Habib, 2013). Markowitz's portfolio theory states that rational investors choose their portfolio based on expected reward and variance, optimizing it through diversification. Portfolios that lie on efficient frontier are rational, and individual risk aversion would determine individual portfolio. One of the basic assumptions he made in his mean-variance theory was that people are risk averse, and that decision they make would be rational as a result of the overall cognitive assessment of different investment options (Markowitz, 1952).

Risk and return certainly play a central role. However, do investors use risk and return on the investment decision? The answer is no (Sadeghnia, Hooshmand, & Habib, 2013). Much of unexplained is classified under "market anomalies," but these anomalies force researchers to see what will happen to their theories if we clear it from its assumptions (Shariff, Al-Khasawne, & ElSharif, 2012). For example, Fama (1993) introduces three-factor asset pricing model, and much empirical research was conducted over it. Whenever researchers have shown that the model did not work, it was classified as market anomaly: when small companies made higher returns due to higher risk adaptability, this was named "small firms effect" (Banz, 1981); abnormal return in January was called January effect (Thaler, 1987); and abnormal return in December were explained with Christmas decoration and named December effect (Rozeff, 1985). The existence of these anomalies shows the necessity for the further development of these theories.

### 3. THE ROLE OF EMOTIONS

Early researchers of decisions in uncertainty conditions considered investors to be rational and did not consider their emotions. Financial theories did not include the role of emotions in the financial decision-making process. Still, the practice has shown that it is not enough just to be smart nor highly educated. There are too many extraordinary scientists, genius minds of economics and finance who did not make a fortune on their theories put into practice, and oppositely, there are people who did not go to college, but no meter made billions on financial markets (Turcan & Dedu, 2010). Many organizations do not achieve the set goals in the execution of their projects and many of them seem to fail to achieve business goals, even though they were managed in accordance with the most contemporary project management systems and tools (Petrović, Mihić, & Obradović, 2014).

Decision-making process involves emotional assessment along with cognitive one, in fact, emotions color cognitive assessments, and cognitive risk assessment is often different than their emotional reaction to the same risk (Tseng, 2006). This can be easily observed from research that has shown that people in the negative shape of mind make a more pessimistic judgment, they overanalyze and overjudge, and vice versa, people in the positive mood, express enthusiasm and self-confidence tend to make more optimistic decisions and take a risk (Lucey & Dowling, 2005). Zajonc assumed in early 1980. The year that in financial decisions emotion play the much more important role than people were ready to acknowledge (Zajonc, 1980). When making a decision, investors encounter set of emotions, like fear, concern, satisfaction or pleasure regarding their return on investment (Jinda & Bahl, 2016). Emotions influent cognition, so decisions are not rational, in traditional financial theory way. It becomes clear that emotions must be understood to appreciate their obvious and deep influence on the decision-making process.

Despite the knowledge about standard financial theories and principles, people want to avoid possible future regret, which is powerful cognitively developed emotion, and end up with decision different from rational ones (Coricelli, Dolan, & Sirigu, 2007).

Emotions are specially awakened in the risk circumstances, more precisely, emotions influent decisions depending on how the risky, uncertain and intangible decision is. The more complex decision is, the more emotions influent it (Lucey & Dowling, 2005). Emotions play an important role in taking or avoiding risk; people love to believe that they use common logic when choosing an investment. The truth is that emotional decision making is a default option for our brain (Montier, 2007), and most of the business cycle is determined by the volatility of satisfaction in people's brains, as Keynes concluded (Kolev, Njegovanović, & Čosić, 2015).

Comprehending the emotions and their influence on decision process in finance requires researchers to go into the human brain and observe its functioning with a goal to understand how investor's brain works.

### 4. AWAKENING OF NEUROFINANCE

Decisioning in a real world worked in an opposite way than traditional financial theory suggested, real people, do not behave rationally and do not make rational decisions. The practice confuted theory since investors do not choose their portfolio solely on risk and return basis, and their decisions do not always maximize their utility. (Simon, 1957) (Kahneman & Tversky, Judgment under uncertainty: heuristics and biases, 1974) (1979) So, why real investor's behavior differs from rational one?

Questioning existing theories about financial decision-making made quite a confusion among researchers, and standard, widely accepted theories started to lose over the new theories that were dealing with behavior in finance. The new field, called behavioral finance, examines finance from a broader perspective. It combines finance with sociology and psychology and tries to explain how emotions influence financial decisions. (Turcan & Dedu, 2010) Behavioral finance has its roots in cognitive psychology, and according to it, emotion represents the result of the cognitive assessment of stimulus or event (Merkle, 2008). The issue is that people have cognitive limitations which lead to cognitive disorders and cause biases in behavior (Pompian, 2006). Behavioral finance tries to explain causes for exceptions in financial literature and investigates how investors make organized and mental errors in their judgments (Sadeghnia, Hooshmand, & Habib, 2013).

Even though theories in behavioral finance were beneficial for decision science, with enormous impact on the illuminating decision-making process, their research scale was limited since they explain the behavior of investors that can be seen on the outside. They could not explain how and why this behavior occurs. Furthermore, behavioral finance could not quantify emotions or look inside the source of these emotions and resulting behavior. (Shalini, 2012)

The next step in understanding the financial decision was to examine the human brain, to comprehend how and why it affects investor's irrationality. This led to a new field called neuroeconomics, and its subfield neurofinance. Standard financial theories explain and deal with the investors should behave, behavioral finance study how real investors truly behave, and neurofinance investigates how and why this investors' behavior occurs (Jinda & Bahl, 2016) (Edwards, 2004) (Zaleskiewicz, 2006). The closer difference between behavioral finance and neurofinance is in that behavioral finance explores how people react and interact in financial decision making, while neurofinance explores how and why these reactions and interactions occur based on human brain and hormonal activity (Tseng, 2006). The human brain becomes central intention of recent research of financial decisions. Neurofinance is a science that combines psychology, finance, and neuroscience to analyses the role of the human brain in investment choice (Peter & Hilke, 2005).

Neurofinance explains why human behavior differs from the principles of traditional finance; it explores human behavior, affective states, and psychological biases by keeping track of brain activity right before, during and right after making a decision. It deals with neural basis of emotions and how these neurons influence financial decision-making (Jinda & Bahl, 2016). In that way, it can be determined which mental factors influence financial choice (Greenfinch, 2008). A neuroscientist is mapping human brain to find out how fear and greed color financial markets (Turcan & Dedu, 2010).

It is important to note that neurofinance is not contradictory to theories of rational choice, it widens the horizon by observing variables that were not considered in traditional theories. (Camerer, 2008) Neurofinance should be seen as a bridge between brain and financial decisions which enables a better understanding of financial decisions made by humans (Sadeghnia, Hooshmand, & Habib, 2013).

Development of modern technologies for brain scanning recently made a path for a deeper understanding of brain physiology, enabled simultaneous stimulation of a different part of the brain and made a foundation for experimental research in this hypersensitive area (Kolev, Njegovanović, & Ćosić, 2015). Kuhnen and Knutson (2005) performed the very first study on neurofinance by using human brain, using event-related fMRI. Their study has shown that emotions had an important role in the decision-making process and gained a set of brain images proved that emotions caused by anticipating gain or loss could have different neural signatures.

## **5. CONTRIBUTION AND SIGNIFICANCE OF NEUROFINANCE**

Neurofinance, as a young science, tries to understand internal processes in investor's brain that lead to thinking which manifest in external (re)action, since behavior arises from thoughts laying behind them (Shalini, 2012).

The basic premise of neurofinance is the existence of differentiated brain regions that independently or in interaction with each other involved in making financial decisions (Kolev, Njegovanović, & Ćosić, 2015). The question is whether activation of certain part of the brain can predict subsequent behavior (Knutson & Bossaerts, Neural antecedents of financial decisions, 2007). Recognition of brain regions involved in making investment choice proved that emotive aspect interacts with rational ones since human decisions are the product of two decision systems (Shalini, 2012). First one is emotional, more primitive, effective, intuitive and quick. It resolves that more complex decisions are providing approximate solutions and helps in narrowing set of possible choices. The other one is rational, more calculative, biological and slower. It can solve only well-defined problems, makes well-thought decisions, but function in a much slower way. (Olsen, 2007)

In order to detect activation of certain brain regions, and track brain function during decision making process, neurofinance use the latest technology such as functional Magnetic Resonance Imaging (fMRI), Magnetic Resonance Imaging (MRI), Electroencephalography (EEG), Positron Emission Tomography (PET), Computed Tomography (CT), Steady State Topography (SST), Magnetoencephalography (MEG), Transcranial Magnetic Stimulation (TMS), eye tracking or blood pressure (Jinda & Bahl, 2016) (Turcan & Dedu, 2010).

The capability of investors to perform the optimal behavior in decision making probably depends on the functions of a set of brain structures, including the prefrontal cortex, which is responsible for complex cognitive decisioning, memory, analysis and making conclusions. Neurofinance researches shown that whenever investors make a cognitive mistake, it is due to insufficient and incomplete information gathered in the prefrontal cortex (Jinda & Bahl, 2016). Neuroscience found that these two systems constantly interact, even fight each other, and influence decisioning. It is shown that emotional part often wins in this interaction, stressing out how strong our subconscious instincts are (Morse, 2006).

The brain reacts to the aspiration for gaining reward and avoiding loss, and both behaviors can be activated or deactivated autonomously (Peterson, Neuroeconomics and neurofinance, 2010).

Risk seeking and risk aversive choices can be activated from two different neural circuits, including nucleus accumbens (NAcc) and the anterior insula. Activation in Nacc and insula respectively can lead to a change in investor's risk preferences. Risk assessment means that person choose between potential gains and losses. When people expect to gain money, the Nacc ventral stratum is activated, and when someone expects a feeling of pain, anger, disgust or fear, anterior insula is activated. The research has shown that risky choices and mistakes because of risk-seeking were succeeding activation of Nacc, and less risky decisions and mistakes because of risk-averse behavior was due to activation of anterior insula. (Kuhnen & Knutson, 2005) Another research in neurofinance found that Nacc activation spontaneously increases just before taking financial risk (Knutson, Wimmer, Kuhnen, & Winkielman, 2008) (Turcan & Dedu, 2010).

Nacc releases two neurotransmitters (Peterson, 2007) (2007). The first one is dopamine or pleasure chemical. Brain reward system, activated by profit expectations, communicate through dopamine neurotransmitter and gen that regulates them influent investor's judgment about gaining reward and avoiding risk (Kuhnen & Chiao, 2009). Dopamine has a great impact on reward expectations and increases risk-taking behavior (Sadeghnia, Hooshmand, & Habib, 2013). The other one is serotonin, responsible for the feeling of anxiety and depression. When unfulfilled expectations like investment lose occurs, the level of serotonin lowers, and it leads to investor's loss of enthusiasm. To avoid further losses because of risk-aversion, investors with a low level of serotonin make bad investment choices, sell investment too early and increase their loses (Jinda & Bahl, 2016). In decision process, one more brain activation is happening, in the amygdala, brain's center of fear. Fear can be an emotional expression of uncertainty in financial assessment (Hsu, Bhatt, Adolphs, Tranel D, & Camerer, 2005). This is a system for loss avoidance. Both gaining reward and avoiding loss systems lay in a limbic system, an emotional region of forebrain and they guide investors behavior through subtle emotional influence on judgment, thinking and acting (Peterson, 2007).

Neurofinance attempted to understand increased deeply and decreased activation of these brain systems, to change biases in behavior that led to huge money losses (Sadeghnia, Hooshmand, & Habib, 2013). Next step might be to explore modifications of different generations thinking process, since their business behavior significantly changed, especially obvious in Millennials comparing to generation of Baby Boomers (Obradović, Mitrović, & Pavićević, 2017).

## 6. CONCLUSION

Financial researchers recently realized the necessity to understand better how emotions influent decision-making process and what can be done about it. In an attempt to deal with investor's choice under risk and uncertainty, a new scientific field arises. Neurofinance, as a completely new business concept, became top topic around the world, the new trend in economic thinking (Kolev, Njegovanović, & Čosić, 2015). Neurofinance provides the possibility for a deeper understanding of emotions and their influence on decision making; it explains how and why investor's specific behavior occurs (Cohen, 2005). Furthermore, neurofinance can tell us how to drive investor's behavior closer to optimal, by learning how to overcome subconscious emotional reactions.

Neurofinance, with its diagnostic tools, enables much profound analysis of human brain in the light of financial decisions, enables further explanation of investor's behavior and their emotional biases. It is a very young scientific field. The future will show its limits, and how far they reach. The unthinkable of impact on all areas of business is to be expected yet.

**Abstract:** *The platform business model operates as a many-to-many business model with the infrastructure controlled by a particular entity. Various industries have so far seen the radical changes due to the emergence of this phenomenon. However, the full platform strategies have not been actualized in banking by now. The infantile platform concept, such as branchless banking are the outmost reaches of banking platforms. Our aim is to explore the costumers' expectations regarding the platform and branchless banking. For this purpose, we collected primary data using the questionnaire as a research tool. The results indicate that costumers find platform businesses to have the first mover advantage. Also, the study finds that perceived risks and attributes of banking-as-a-platform are strong predictors of the future use.*

**Keywords:** *platform banking, fintech, customer expectations, retail banking*

### 1. INTRODUCTION

Developments in technology have changed the way in customers and suppliers interact (Teece, 2010). In a traditional or linear model, companies create values such as products or services and then sell them to customers downstream the supply chain. The platform business model operates as a many-to-many business model with the infrastructure controlled by a particular entity. This concept attracts more and more scholarly attention (Kornberger, Pflueger & Mouritsen, 2017).

As such, it is a potential panacea for the improvements in the efficiency and decrease in costs. Accordingly, the popularity of platforms has grown exponentially in last decade. Some platforms even dominate the industries in which they operate. As seen by Manville (2016) 'The networks and markets forming around—and orchestrated by-- Google, Airbnb, Uber, and other virtual exchange enterprises are the maws into which traditional companies are now disappearing.'

The banking sector has already been challenged with disruptions in service providing. For instance, the emergence of payment card transactions created a two-sided network with strong network externalities (Rochet & Tirole, 2002). This disruption was only incremental by nature, because the consumer's bank – the issuer – and the merchant's bank – the acquirer – only have to obey simple rules such as 'honor-of-all-card' or 'no-surcharge' rule. The essence of banking remains untouched. Nonetheless, platform banking may completely change the role of the bank in the supply chain. Instead of actively controlling depositing and crediting activities, the bank (if even a bank) only maintains the platform, and the service is provided by many to many. This might seem as a clairvoyant-type of prediction, but it is even became a cliché at fintech conferences to see at least one success story in what is now known as Banking-as-a-Platform (BaaP) model (Brear & Bouvier, 2015)

Even though the platform models could potentially change the landscape of banking, only a paucity of research has tackled consumers beliefs, expectations and acceptance toward this phenomenon (Karjaluoto, Mattila & Pento, 2002). To the best of our knowledge, this is the first study examining consumer's perspectives related to the emergence of platform banking.

Our aim is to explore the consumer's attitudes and expectations regarding the platform banking. Particular aim is to determine which companies have the "first mover" advantage. An additional aim of the study is to explore the main risks and drivers of the future platform banking use as seen by customers.

We proceed as follows. To start off, we review the literature related to economy of sharing, platform banking as a business model and the main risks associated with the consumers' use of platforms. Second, we elaborate on the methodology used in the study – the questionnaire as a research tool, sampling procedure, data collection and processing. Third, we explain the results of the study. Finally, we place our findings in the context with previous work in this area, leaving the space for concluding remarks.

## 2. RELATED WORKS

In this section, we depict the platform as a business model. Afterward, we delineate the use of platform business models in the banking industry with a particular emphasis on disruptive competitors in the banking sector and the main risks associated to the implementation of this model in the banking.

### 2.1. Sharing economy and platforms as business models

In popular and academic literature there is no unanimous consent on the concept and term of sharing economy. However, a common element in various definitions is sharing of underutilized assets in ways that improve efficiency, sustainability and community. Sharing economy became an umbrella term for spectrum of non-ownership forms of consumption activities (Habibi, et al., 2017). Hawlitschek, et al. (2018) proposed seven criteria to distinguish sharing economy among the ocean of related terms, such as collaborative economy, on-demand economy, peer economy or gig economy: (1) increasing utilization rates, (2) peer-to-peer principle, (3) existence of reimbursement, (4) no transfer of ownership, (5) resource tangibility, (6) leveraging of information systems, and (7) temporariness.

Bucher et al. (2016) describe this new culture of making people's belongings accessible through online networks with one simple sentence: "What's mine is yours, for a nominal fee". Depending on who owns the asset and who sets the conditions of sharing, there are three distinct models that prevails in sharing economy: decentralized platforms (i.e. Airbnb), centralized platforms (i.e. Zipcar), and hybrid platforms (i.e. Uber). According to Vaughan and Daverio (2016), these platforms generated revenues of nearly E4bn in Europe in 2015. This research also predicts that global revenues of sharing economy could hit the value of \$335bn by 2025.

Due to complex nature of sharing economy, some authors even suggest avoiding academic debates about finding common single definition. Acquier, et al. (2017) state that instead of narrow definition, the efforts should be made to find organizational framework for mapping its perspectives. Their research proposes three foundation pillars of sharing economy:

1. "Access economy – sharing underutilized assets (material resources or skills) to optimize their use"
2. "Platform economy – intermediation of decentralized exchanges among peers through digital platforms"
3. "Community-based economy – coordinating through non-contractual, non-hierarchical or non-monetized forms of interactions".

Fintech has fully enabled the implementation of sharing economy. In general, Vives (2017) states that 'new digital technologies automate a wide range of financial activities and may provide new and more cost-effective products in parts of the financial sector, ranging from lending to asset management, and from portfolio advice to the payment system.' An important game-changer in the banking industry are technologies that enable Banking-as-a-Platform models.

A platform can be described as a business that facilitates direct interaction between two or more distinct types of customers. Platform business models generate value by connecting and organizing transactions and create strong network effects (Acquier, et al., 2017). These effects help in structuring the innovation process and accelerate the adoption and use of platforms (Gawer & Cusumano, 2015). Within the sharing economy, it is possible to distinguish four types of platforms: (1) accommodation sharing platforms; (2) car and ride sharing platforms; (3) peer-to-peer employment markets; and (4) peer-to-peer platforms for sharing and circulating resources (Martin, 2017).

### 2.2. Business case for platform banking

Banking-as-a-Platform model is still a working concept without solid definition in theory. Other than tech-based studies, most of the scholarly effort has so far been put to, the use for unbanked population (Dermish et al., 2011) or the general social impact (Fernandez, et al., 2017).

Mas (2009) states that 'a branchless banking platform is made up of three key elements: (1) The retail network, composed of the collection of retail outlets where transactions are originated (2) The payment network, which aggregates the transactions from the collection of retail outlets and routes them to the appropriate issuer (3) The account platform, which manages the service logic by authorizing individual transactions and maintaining the value of accounts.' Further on, Porteous (2006) illustrates the difference between bank-based and non-bank-based models. These categories depend on the nature of the scheme provider. On one side, bank-based models are push strategies provided by the existing banks. On the other

side, non-bank-based models are pull banking schemes of telecommunication or other companies with the expertise in technology.

Following the all aforementioned, we set one research question and two hypotheses:

RQ1. Whom do customers trust more in setting the banking platform – banks or platform businesses?

H1. Perceived risks negatively affect the adoption of platform banking

H2. Perceived benefits positively affect the adoption of platform banking

### 3. METHODOLOGY

#### 3.1. Research instrument, measures and variables

We used questionnaire as a research instrument to collect the primary data. It was distributed in a paper-and-pencil form. This technique was used in order to assure that sophisticated examinees are the only sampled ones. Prior to providing a questionnaire to them, they were pre-tested for the awareness of the Banking-as-a-Platform model.

The questionnaire had five sections. After the demographic section, we asked the examinees if they would prefer platform to be operated by banks or platform business, such as Google, Airbnb, Uber etc. The third section examined a perception of the main risks associated to the use of platform banking. This section was developed following Yousafzai, Pallister, & Foxall (2003) and Mha (2015). We developed the fourth section on the main drivers for the use of platform banking inspired by Martins, Oliveira & Popovic (2014) and Vankatesh et al. (2003). Finally, the last section examined the overall readiness of the examinees to use platform banking services in the future.

#### 3.2. Sampling procedure and data collection

The sample used in the study was random. The examinees were interviewed by trained assistants (four year students from the Faculty of Organizational Sciences mentored by the authors). The examinees were asked first about their knowledge of banking services and the concept of Banking-as-a-Platform model. Out of the population of 423 examinees, 146 (slightly more than a third) of them fulfilled the criteria on the awareness of the concept. The gender was slightly misbalanced in terms of gender structure as 56.8% of examinees were male.

#### 3.3. Data processing

The data was entered in the Statistical Package for Social Sciences (SPSS). Quantitative data was analyzed with descriptive statistics: percentages, means and standard deviations. Interdependence of determinants (independent variables) and contract management efficiency (dependent variable) was determined by correlation (Pearson moments two tailed correlation coefficient analysis) and multiple regression.

## 4. RESULTS

### 4.1. RQ1 – Who has the advantage in creating banking platforms?

The results for RQ are displayed in Table 1. Interestingly, less than one fifth of examinees would join platform banking if it would have been developed by a bank. Contrary to that, nearly 90% of examinees would use the services if they were provided by platforms such as Airbnb, Amazon or Google.

**Table 1: Costumers' opinion**

	If banks would create banking platforms, would you use the services		If platform businesses would create banking platforms, would you use the services	
Valid	3	2.1	0	0
Yes	26	17.8	131	89.7
No	117	80.1	15	10.3
Total	146	100	146	100

## 4.2 Hypotheses H1-H2

Before testing the hypotheses, we conducted pre-analysis including descriptive statistics (mean, standard deviations, and internal reliability tests) and correlation analysis.

**Table 2: Descriptive statistics and correlation matrix**

	Mean	StD	CA	1	2
Risks	2,44	,83	.89		
Drivers	3,49	,99	.90	-,01	
Overall use	3,55	,95		<b>-,29</b>	<b>,55</b>

bold – significant at .01

Since we found both correlations to be significant, the next step was to examine the influence and intensity of variables seen as independent to the overall use of platform banking (dependent variable) in the model. The results of the regression analysis indicated that the research model predicted 63% ( $R^2=.63$ ) of the variance which is displayed in Table 3.

**Table 3: Regression analysis for the potential use of platform banking**

Variable	Coefficient	SE	t-statistic	Prob
Constant	2.49	.29	8.53	.00
Risks	.33	.07	-4.41	.00
Drivers	.53	.06	8.48	.00
R square	.63	F		46.05
Adj R square	.39	Sig		.00
SE of regression	.75	Dependent variable: Potential use of PB		

## 5. DISCUSSION AND CONCLUSION

### 5.1. Key findings, implications and contributions

Our study had two basic aims. The first one was to explore a perceived 'strategic' advantage in platform banking. As seen by costumers, platform businesses have far better position in establishing the full scale capacity for platform banking. Banks are, obviously, not perceived by customers as key innovators in the future and they will need to proactively manage the disruptive forces of the emerging financial technologies (Reddi, 2016; Kumar, 2017). This seems to be in line with the studies focused on the inability of incumbent firms to identify new markets in the face of disruptive technologies (Vecchiato, 2017).

The second aim was to explore the effects of perceived risks and main motivators on the future use of platform banking services. The results of our study provided support for the research model and hypotheses tested. Examinees were aware of the potential risks. The most important risks was related to the cybercrime and potential loss of private data (see Appendix 1). Additional aim was to examine the driving forces for the use of platform banking. The most important force is the facilitating conditions and the availability of resources for platform banking (see Appendix 2).

Our study has twofold implications. As for the implications for researchers, this study is the first to examine the potentials of platform banking. Future studies should concentrate on the development of this business model in banking and capture on evolutionary characteristics of this phenomenon. From the practical point of view, this study is particularly interesting for platform businesses and banks. The first ones could harvest the perception of the 'first movers'. It could, however, be speculated that they could experience barriers related to regulatory environment (e.g. Makaya & Nhundu, 2016). The second ones should develop key competencies related to fintech development and position themselves as the 'domain' leaders.

### 5.2. Conclusions

Platform businesses are gaining importance nowadays. The wealthiest incumbent firms are platform businesses. Still, banks are still out the platform ecosystem. Nonetheless, not only digital, but traditional banks consider modular banking (in Banking-as-a-Platform or Banking-as-a-Service model) will be the future of banking. This study puts an additional light to this forecast. We demonstrate that customers envisage platform banking to be an important and widely used concept. Moreover, they see current platform businesses to be possible leaders in the field of offering banking services through their or new platforms.

The most important pillars of future platform banking are risk mitigation related (especially to the security of data) and driving forces – particularly the ones related to the sufficient resources of banking service users.

# PAYMENT PROCESSING IN WEB BASED ENVIRONMENTS: THE BENCHMARK OF THE WORLD'S LEADING PAYMENT PROCESSORS

Milenko Radonić<sup>1</sup>

<sup>1</sup>Faculty of Organizational Sciences

\*Corresponding author, e-mail: radonic.milenko@gmail.com

**Abstract:** *With the development of ecommerce industry and payment processors such as PayPal, the concept of electronic payment models and payment processing has become crucial for the success of web-based businesses. There are several ways to collect the funds, from using e-cash to using e-wallets. E-wallets have the huge potential, while credit cards as payment alternative are still one of the mostly used payment methods during electronic purchases and payments. What are the trends of using e-payment methods, what should the businesses pay attention to when choosing a payment processor and what are the top payment processors worldwide are the questions that are answered in this paper. By reviewing the offer of payment processors, the author has analyzed the key factors which could affect the costs, efficiency, conversion rate and the profitability of any web business which uses e-payments as a way of collecting funds. By reviewing the current literature and based on the empirical experience, the author has chosen the top 8 payment processors and gave their opinion – which of the payment processors could have the biggest impact on the web businesses.*

**Key words:** *payment processing, benchmark of payment processors, payment methods, web companies, credit cards*

## 1. INTRODUCTION TO ONLINE PAYMENT PROCESSING AND PAYMENT METHODS

E-commerce and internet have brought the third industrial revolution and all of its benefits. The internet traffic has increased at a significant rate from the beginning of third industrial revolution until now. Conventional payment methods rates are reducing in favor of e-payment methods. With the e-payment trends, overall spending for the goods and services bought via Internet have been increasing constantly over the years (Lowry, Wells, Moody & Humphreys, 2006). United States as the most developed e-payments market have reported 1.18 trillion US dollars in online spending in 2016. In Europe, this number has reached 281.5\$ billion. With more than 311 million consumers who are actively paying through e-payment channels, this number will keep growing (Statista, January 2018). With the market globalization and stronger e-commerce industry, companies operate in a tough economic environment which require a strong focus on cost optimization, timescales and resources optimization in order to boost efficiency. Also, in order to increase competitiveness, companies tend to adapt to new business models, to react quickly and to raise efficiency (Scheer & Brab, 2010).

Nowadays, the vast majority of businesses use e-banking systems for payments. That trend continues for B2B <sup>1</sup>segment. However, during the 90's, e-commerce industry has created a need for the fast and efficient payments in B2C <sup>2</sup> segment, as well as in PtP (peer-to-peer) segment (Jeffrey, 2002). Peer-to-peer payments enable one side (not registered as a business) to transfer the money easily to the other side. But, before that, wire transfers and cash as the traditional payment methods have been replaced with credit card payments, which became a dominant payment method. On the other hand, new payment methods became available due a significant growth of e-payments. Although internet banking has reached its peak, considering the security and the quality of the service, money transmitting systems search for a full replacement of money orders through wire transactions and paper checks (Joseph, 2002).

The concept of online payment processing is defined as the process of connecting the buyer and the seller through an online platform by exchanging the data (Lowry et al, 2006). On the other hand, online payment systems are defined as an online monetary system which connect all stakeholders in the process of online payment such as sellers, buyers, banks and other financial institutions.

The first online PtP payments worked as an online auction e-Bay and Amazon. Zhang and Haizheng have shown that there are several factors which could affect the choice of a payment method in an online auction. The payment method customer will choose, depends on product attributes and seller's characteristics as

<sup>1</sup> B2B – Business-to-Business segment

<sup>2</sup> B2C – Business-to-Consumer segment

well. If the surrounding is more secured, the use of credit cards will increase, otherwise cash-equivalents will dominate as a payment method (Zhang & Haizheng, 2006).

One of the main reasons for introducing this paper is to show the benchmark of types of online payments and types of payment processors which could help the tech companies to increase the overall business performance, especially those in the early development stage– startup companies. In order to understand the importance and purpose of online payment processors, it is crucial to have an overview of the e-payment industry and companies which operate within this industry.

Based on a sample of more than a million websites (n=1.066.419), PayPal is the global leader in an online payment industry with more than 72% of market share. The top 10 payment processors based on the market share according to the **Datanyze**<sup>3</sup> are the following:

**Table 1:** Top 10 Payment Processors by market share (n=1.066.419 domains)

Source: Datanyze, 2018

No.	Payment Processors	Domains	Market Share
1	PayPal	778,385	72.99%
2	Stripe	113,132	10.61%
3	Square	20,644	1.94%
4	Authorize.net	18,811	1.76%
5	Amazon Pay	17,716	1.66%
6	Klarna	16,623	1.56%
7	CCBill	11,923	1.12%
8	Braintree	11,735	1.10%
9	Google Checkout	10,654	1%
10	WorldPay	5,125	0.48%

There are several payment methods which are crucial to mention as e-payments methods. According to Hsieh (2001), payment methods could be divided into:

- Electronic credit card payments - e-credit,
- Electronic cash payments - e-cash and
- Electronic check payments – e-check (Hsieh, 2001).

In Table 2, there is an explanation to the difference between these three types of payment methods, considering the advantages and disadvantages of each of them (Peffers & Ma, 2003).

**Table 2:** Overview of e-payment methods and their characteristics

Source: Peffers, K. and Ma, W. (2003), An Agenda for Research About the Value of Payment Systems for Transactions in Electronic Commerce

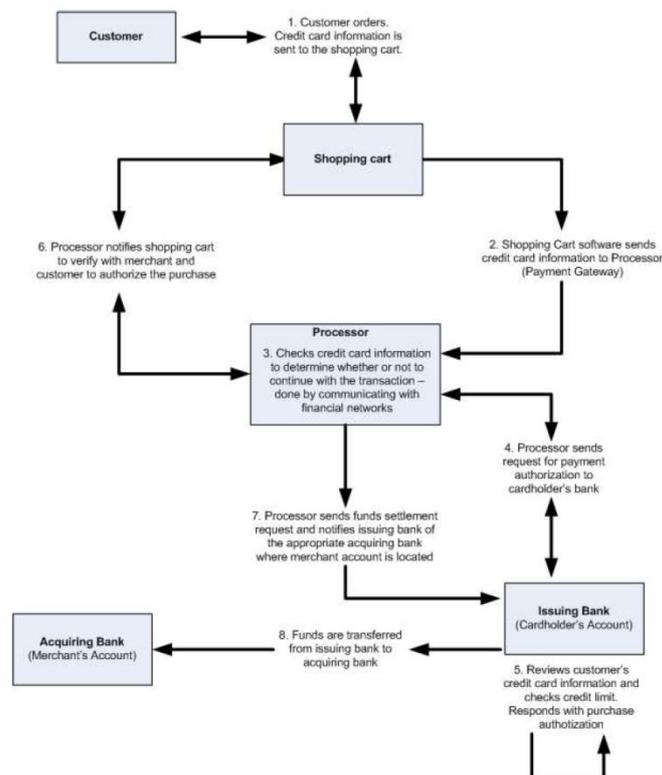

Payment method	Advantages	Weaknesses
e-credit card payments	This payment method solves the anonymity issues by supporting users in processing the transactions without showing their personal information. It can also be used in an offline mode.	It is hard to implement a sustainable system of anonymity with data that are hard to trace. That data security is necessary in order to prevent the fraud and allow disputes of the transaction (Hou X.& Tan C., 2005)
e-cash payments	E-cash payments are based on cryptography in order to provide and sustain the security of transactions.	Overlooked due to the popularity of e-credit. It can take longer for transactions to settle. The speed of settlement and disbursement also depends on the processor.
e-check payments	This method is widely used and trusted and could be used both, online and offline. It leverages the existing credit accounts.	These transactions can't provide anonymity and have security issues due to fraudulent activities.

<sup>4</sup>Datanyze is a platform for collecting information on the usage of payment processors.

Many companies search for the increase of purchases by accepting additional forms of payments and by increasing the number of credit cards by which a customer can pay. However, there are certain risks businesses have to face. Some of those risks could be reduced by using e-payments. During the period from 1994 to 2001, the usage of the traditional payment methods, such as cash and checks have reduced by 10% and 3% retrospectively. The usage of credit/debit cards have been increased over the years. As well as the total amount of spending (Rysman, 2007)<sup>4</sup>. The alternative payment methods such as e-cash and usage of e-wallets will also face a growth in the upcoming years. Therefore, the risk of not being able to collect the funds is one of the biggest issues web companies could have. The benefits of using e-payments could be related to decreased costs, improved cash flow efficiency, increased protection of information and protection of payment provider.

## 2. PAYMENT GATEWAYS AS PROCESSORS AND PAYMENT PROCESSING TYPES

Payment gateways or online payments processors are defined as the companies which are authorized to process credit card transactions between buyers and sellers. In order to buy or sell via online channels, the customer needs to submit the information on his/hers credit card to an online business (2Checkout, 2014). Payment gateway is also defined as the processor for collecting the funds through credit card or e-cash payments. There are several types of processors based on payment methods mentioned in Table 2. The first one is a conventional credit card payment processor. It is connected to several objects such as the merchant's website and shopping cart, merchant's bank and cardholder's bank. The overall concept of this type of processing could be seen in the Figure 1.

**Figure 1:** Credit Card (E-credit) Payment – Concept

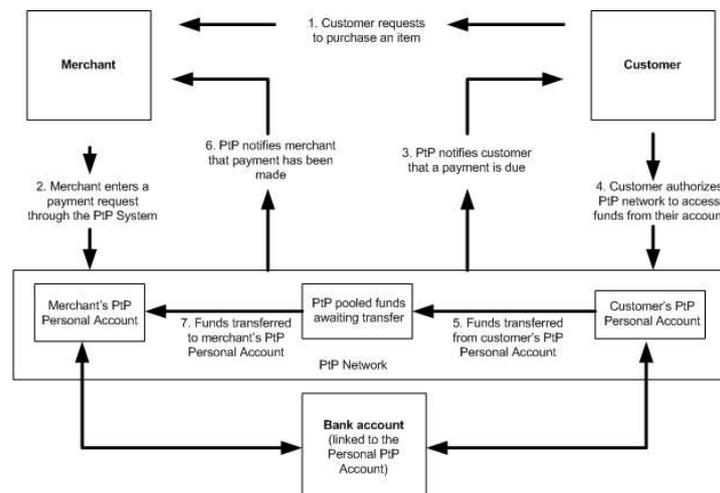

Source: Lowry, P. B., Wells, T., Moody, G., & Humphreys, S. (2006). Online Payment Gateways Used To Facilitate E-Commerce Transactions and Improve Risk Management

Merchant's bank accounts established at bank in order to collect the funds from credit card holder. Internet merchants, such as web companies, usually do not keep the funds as a business checking or business savings but use them as daily or weekly transfers to another bank account. The whole process starts with the customer orders a certain good or service through the shopping cart. The payment gateway coordinates the communication between entities by handling the information collected from them through several phases from authorization and submitted for settlement phase to the final settlement and disbursement of the funds to the merchant's bank account. In the first phase – authorization phase, the credit card information of the client/customer is being sent from the merchant's website to the payment gateway (processor) by the shopping cart with verification of the credit card information. As soon as the information gets verified, the

<sup>4</sup>The study done by Mark Rysman (2007) has taken in consideration the usage of payment methods in non-online environment.

request is being sent to the cardholder's bank for the card to be charged (Lowry et al., 2006). When the information from the credit card is being processed and validated, if it's valid and there are enough funds on the customer's bank account, the credit card company sends an approval to the payment processor. Later on, the payment processor communicates with the merchant's website and shopping cart and confirms the authorization of the purchase/reservation. After the authorization is done, the payment processor initiates a funds transfer. This phase is known as the "submitted for settlement" phase in which the processor allows the transfer of the funds from the customer's bank (credit card) to the merchant's bank account.

With the PtP, it is necessary for both, customer and merchant to have an opened account with the PtP provider. All the payments are processed and handled through PtP provider. There is no need for other financial institutions to be an intermediate between two parties. However, in comparison to the credit card payments, the use of PtP services is limited, so not everyone could subscribe. The main condition to process the transactions using PtP is that both sides have the accounts opened at the same PtP provider. Figure 2 is illustrating the flow of the system. The communication (both-sides) goes through a PtP platform, first by initiating a purchase, through creating invoices and money requests to the final stage - the transfer of the funds.

**Figure 2:** PtP Payment – Concept

Source: Lowry, P. B., Wells, T., Moody, G., & Humphreys, S. (2006). Online Payment Gateways Used To Facilitate E-Commerce Transactions and Improve Risk Management

The PtP system's simplicity makes it suitable for low-volume sellers or for sell through auctions. There are no monthly fees for maintaining the account, although there are fees paid on each transaction which (in the case of PayPal - 2.9% of the transaction value + 0.3\$ per transaction). Considering all the facts, PtP accounts have several benefits:

- Automatically invoicing;
- Accepting payments directly from the website through API;
- Both ways transactions (selling and buying) with the members of the same PtP network;
- Payment without credit cards, using e-cash.

The comparison between these two types of processing could be seen in the Table 3. The main difference between concepts shows both – benefits and disadvantages of each type of processing.

**Table 3:** The comparison between e-credit and PtP concepts of processing

	<b>E-credit processing</b>	<b>PtP processing</b>
Duration of the payment settlement	0-5 days	instantly
Duration of the payment disbursement	2-6 working days	0-1 working days <sup>5</sup>
Type of disbursement	Automatic	Manual (on demand)
Communication	Communication with the third-party intermediaries (banks and credit card companies); Only one side is required to have the merchant account opened in order to process payments	The direct communication between two sides without intermediaries; Both sides need to have an opened PtP account
Verification	Multi step verification	One step verification after the account is being made

<sup>5</sup>The data are based on a empirical research;

It would be devastating for any business and its growth, if the credit/debit cards are excluded as a payment method, since they are still the mostly used method of payment. Without processing credit cards, the potential growth that a business may expect from this type of plan is limited to the number of similar users that would be potential customers. Many PtP providers offer an upgrade, called a premium, or business account. Both PtP and Credit Card payment processors operate using a similar fee model. They collect the fees as a percentage of the value of processed transactions and add a fixed fee price per transaction. The model of paying cost per transaction could be seen in the Equation below.

$$FC = \sum_{i=1}^n (TV_i \times \beta + \theta_i) \tag{1}$$

$$TTV = TV \times n + FC \tag{2}$$

FC – Total costs of the transaction fees

TV – Transaction value

TTV – Total value of the transaction

i – number of transactions

i = 1, ..., n

TV – the value of transaction

$\beta$  – relative fee per transaction [%]

$\theta$  – fixed fee per transaction

In the case of the refund, the payment processor returns the amount with the relative fee, but keeps the fixed fee amount.

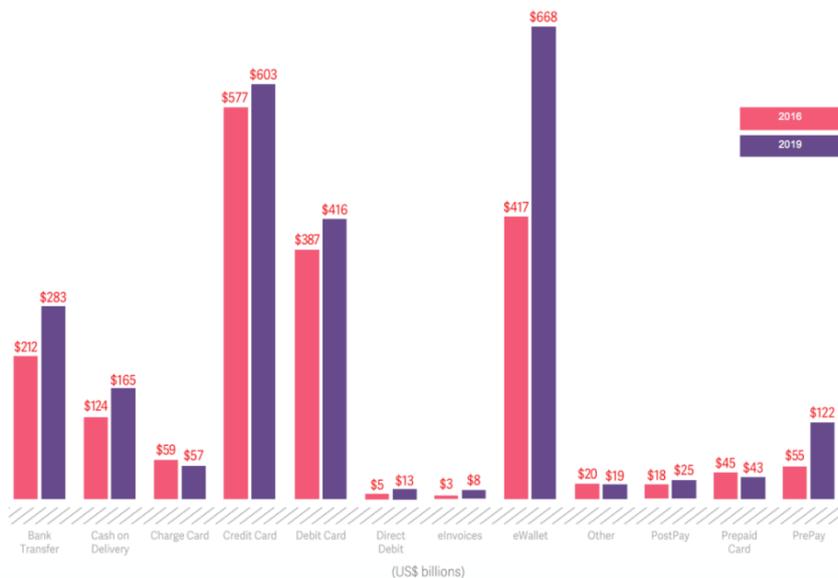

$$TRV = TTV + (FC - \theta) \tag{3}$$

TRV – Total refund value

Most of the payment processors offer  $\beta$  as 2.9% and  $\theta$  as 0.3\$. The more transactions the company has, the bigger chances are that the company could negotiate lower fees. Some of the processors have highlighted this option on their websites. For example, the payment processor - 2Checkout has put a target of 50.000\$ in monthly transactions in order to lower the fees for the merchant.

### 3. THE TRENDS OF E-PAYMENTS

In order to make a benchmark of payment processors, the author has focused on the e-payment trends. For making a decision which processor or portfolio of processors to use, it is important to understand the consumer market and the trends of processing. Based on various researches and analyses, debit and credit cards are still dominant as a payment method. According to the research of the Total System Services Inc (2016), people still tend to trust more on paying through credit cards (42%), than on PayPal (26%) and Debit Cards (12%)(Total System Services Inc., 2016).

**Figure 2: Payment Method Forecast for 2019<sup>th</sup>**  
Source (WorldPay, Global Report, 2015)

The trend of online payment through payment processors is increasing. With 577\$ billion, credit cards are on the first place based on the volume of processed transactions and total processed amount. It is expected to have a growth of 4.5% until 2019<sup>th</sup> and to participate with 24.4% of all payment methods and by 2020<sup>th</sup> to reach 711\$ billion in processed transactions with 20.2% participation in payment methods. In the Figure 3, there are the data which represent the structure of payment methods used in 2015 and the predictions for 2019. It is expected that credit and debit card payments will decrease in the upcoming years in the favor of alternative ways of payment which are recording a growing trend of usage. Considering the credit cards, Visa is the most dominant credit card with more than 50% of participations, with the following MasterCard, Amex and Discovery retrospectively.

Based on the forecasts, the credit card usage will drop to the second position from 2019, due to strong expectations of e-wallet growth. The digital wallet or e-wallet is a form of online payment platform based on using virtual money. With the development of trade market for cryptocurrencies and blockchain technology it became one of the most important payment methods. Digital wallets could be defined as a software application which enable the secure transfer of money without the need to enter all the credentials (Gulati, Nadeau, & Rajgopal, 2015). Credit Card with the biggest participation in total credit card transactions is Visa, which goes from 14% in China to 64% in Netherlands and India, 65% in Poland and 61% in Russia. MasterCard is the second biggest credit card provider. Third and fourth are American Express and Discovery. United States as the most developed market has recorded 53% of Visa transactions, 24% of MasterCard and 15% of American Express transactions, considering the total volume of processed transactions by using different credit card types.

The biggest growth of alternative payment methods is expected in the North America, Asia Pacific countries, while in Europe this trend will have a negligible growth in comparison to North America and Asia Pacific. Considering the Global Market, it is expected that the credit cards participation in e-payments will drop from 29.9% in 2014, to 24.9% in 2019. The similar estimation goes for debit cards – from 20.1% in 2014 to 17.2% in 2019. On the other hand, e-wallets should record a growth – from 21.7% in 2014 to 27.6% in 2019. In North America, the credit cards usage will drop, but it will remain the number one payment method, while in Europe and Asia, e-wallets will be the primary payment method (WorldPay, Global Report, 2015). However, it was shown that people tend to trust more to credit card payments while purchasing online - 42% in comparison to PayPal payments - 26% (Total System Services Inc., 2016). There is no doubt that the credit card usage will keep having a strong impact on e-payments. Therefore, it is important to analyse both payment methods – the ones that support e-cash and e-credit payments.

#### **4. THE BENCHMARK OF PAYMENT PROCESSORS**

Not all payment processors have the ability to process the transactions in each country or to connect to the merchant's website. Therefore, the author took into consideration several factors as a key determinant for choosing the payment processors. The first one is the availability on the market where the website is being established. Since most of the web businesses offer their products or services to at least several markets, it is crucial to have the exchange office implemented by the processor which allows to process the transfer in currencies different than the domestic currency. All types of costs are important for the company, so are the processing and maintenance costs and chargeback fees. People tend to trust more if the purchase is done directly through the website and if it has an additional security certificates shown on the check-out page (Schlosser, White, & Lloyd, 2006). By having an option to pay directly from the merchant's website, the company could turn more visitors into buyers. This is also one of the factors which was analyzed. Every modern web business tends to increase its conversion rate. Conversion rates could be increased by applying the payments directly from the website where the merchant offers its product or services. By using the API payment, processors offer as an extension for developers. Based on the analysis of several payment processors (PayPal, Authorize.Net, 2Checkout, Stripe, Braintree, WePay, Dwolla, Paymill, Square), the author has made an overview of their offer in the Table 4. The selection of the processors was made based on the number of countries the service is available on the first place. The market share was not crucial when making a selection.

The collected data is related to location where payment processors are providing their service, use of the exchange office for payments in the foreign currencies, monthly maintenance costs, transaction fees, chargeback fees and the information could it be implemented on the merchant site through the API or is it *off site* oriented. PayPal has recently adopted the use of credit cards for payments as well, which made it a hybrid version of payments – PtP and E-credit. However, it doesn't offer the possibility of *on-site* payments. Therefore, many businesses consider using multiple processors as a best practice. Considering the trend of payment methods, the author has selected only the processors which operate through the PtP and e-credit methods, since they are the most dominant ones.

**Table 4:** Payment processors benchmark

Payment processor (Market Share)	Location availability and support	Use of the exchange office	Monthly maintenance costs	Transaction fees ( $\beta + \theta^6$ )	Chargeback fees	Onsite/Offsite payment (PtP/E-credit)
PayPal (73%)	193 countries	Yes	0\$	2.9% + 0.3\$ per transaction	/	Offsite (PtP)
Authorize.Net (1.76%)	US, Canada, UK and some European countries	In process	45\$ setup + 25\$ a month	2.9% + 0.3\$ per transaction	/	Onsite & Offsite (E-credit)
2CheckOut (0.16%)	Over 200 countries	In process	0\$	Varies according to the location: 2.4% (EU)/ 2.9%(US)/3.9% (non-EU) + 0.3\$ per transaction (Volume discount for processing more than 50.000\$ a month)	25\$	Onsite & Offsite (E-credit)
Stripe (10.61%)	US, Canada, UK, Belgium, France, Ireland, Netherlands	Yes (1% conv.fee)	0\$	2.9% + 0.3\$ per transaction	15\$	Onsite (E-credit)
Braintree (1.10%)	US, Canada, Australia, Hong Kong and part of Asia, Europe	Yes	0\$	2.9% + 0.3\$ per transaction (Amex 3.2\$ + 0.3\$ per transaction)	15\$	Onsite (E-credit)
Wepay (0.04%)	US	No	0\$	2.9% + 0.3\$ per transaction	/	Onsite (E-credit)
Dwolla (0.02%)	US	No	25\$ (basic)/250\$ (premium)/1500\$ (custom) per month	0.25\$ per transactions (for transactions less than 10\$ - free)	/	Offsite (E-credit)
Paymill (0.06%)	39 countries (mostly in Europe)	No	0\$	2.95% + 0.28 eur per transaction	/	Onsite
Square (1.94%)	US, Canada, Australia, Japan, UK	Yes	0\$	2.9% + 0.3\$ per transaction	/	On site + Application (E-credit)

<sup>6</sup> Cost per transaction/merchant account fees

PayPal as the world's leading payment platform has over 137 million active accounts which makes it an absolute leader. With presence in 193 markets, it is possible to use it for payment in more than 26 currencies. It is easy to transfer the funds and easy to request payments. PayPal has many advantages, such as its recognition as a payment processor, pricing policy, enormous customer base, multiple account option, ability to accept and send international payments as well as no monthly maintenance cost. Many authors see PayPal as the best alternative for processing e-payments (Niranjanamurthy M, 2014). However, not all countries have fully adopted PayPal in their economies. In the Republic of Serbia, online payment processors such as PayPal and others were being banned and restricted for opening as an option until the late 2016. One of the reasons is that PayPal and other well-known payment processors didn't have the license for processing payments in some countries and were not interested in smaller markets (Narodna banka Srbije, 2016). However, there were other possible payment processors beside PayPal.

Web companies which offer the services worldwide should have an option for collecting the funds in as much countries as possible. Therefore, processors such as PayPal, 2Checkout, Authorize. Net, Braintree and Stripe are the most important. If the company considers that as a priority, then Paymill, Dwolla and We pay would be excluded from further analysis.

Authorize.Net is one of the most popular processors. On the other hand, the exchange office is something which is necessary to have in order to transfer different currencies. It also has a monthly maintenance fees as well as the setup fees. It doesn't have any special benefit in comparison to the other processors. If the company seeks only for the lowest costs, Dwolla could be the best payment alternative, but only on the US market. Square has a unique benefit through a hardware extension and an application for e-payments which could process the payment online and on the spot of sale. However, it excludes Europe and most of the Asian countries. Stripe is a huge payment processor, which takes 1% of each payment paid in a different currency, besides the transaction fees. Therefore, PayPal, 2CheckOut and Braintree are recommendations by the author.

Based on the empirical experience from the processing of one online reservations company, the best way to be able to collect the funds is to have a portfolio of both PtP and E-credit processor. There is one leading PtP processor - PayPal, which is highly recommended to be implemented. The fact that PayPal has acquired Braintree, could help choose between 2CheckOut and Braintree. Since it's easier to open the merchant account on Braintree if the PayPal account is previously opened, the combination of PayPal and Braintree could make a good payment infrastructure for each web business. If a company combines both types of processing, the disadvantages of each type mentioned in Table 3 could be reduced. By having a PtP processor, the overall liquidity of a company could get improved, and with E-credit processor the possibility of global mass payments through using credit cards would be available. In Serbia, there are several startup companies which operate like this, such as FishingBooker, CarGo, ActiveCollab and others.

#### **4. CONCLUSION**

By further growing ecommerce industry, the electronic payments and payments processors will grow as well. By 2020, it is expected that ecommerce will reach the value of more than 2.4\$ trillion. As a support for this kind of trade, payment processors will need to follow the trends in e-payments.

Even though e-wallets represent a huge potential and the future of e-payments, e-credit as a payment method is currently the mostly used method of payment. People still tend to use credit cards for their online purchases. Visa is the most used type of credit card with the following MasterCard, Amex and Discovery at the last place. The fundamental problem of this paper is how to choose the best payment alternative for web business which collect the funds by using a certain platform (payment processor). Through the analysis of concept of payment processing, payment methods and e-payment trends, the author highlighted the important features of processing which could be a guideline for choosing the proper processor for business. By benchmarking the top payment processors and advising on which to use, the author tends to help businesses through stimulating key results, such as payment efficiency, cost reduction, conversion rate and overall profitability.

As today's businesses need to adopt online payment systems and technologies, they need to understand the benefits of e-payments methods, type of payment processors and potential problems for not implementing the proper payment processor. Besides having an opportunity to lower the transaction costs, companies could use existing payment processors systems to manage the cash flow.

It is the opinion of the author that it's valuable for businesses to have a diversified portfolio of implemented payment processors on their websites. PayPal is one of the most important processors for PtP processing. By comparing the available locations for providing services and support, transaction and maintenance costs,

the specifics of the processors and benefits and disadvantages of each type of e-payment and payment processor, the author suggests using a combination of PayPal and Braintree as a best combination and a great payment infrastructure.

All in all, the author calls out for a research of the current use of e-wallets and its benefits, since it starts showing a huge potential for global e-payments, with cryptocurrencies as their type of payment. By combining credit card and e-wallets, companies could get a wider perspective of a potential for their businesses.

## ACCOUNTING FOR EXPECTED CREDIT LOSSES – CROATIAN CASE

Davor Vašiček<sup>1</sup>, Josip Čičak<sup>1\*</sup>, Ana Marija Sikirić<sup>1</sup>

<sup>1</sup>University of Rijeka, Faculty of Economics and Business, Croatia

\*Corresponding author, e-mail: josip.cicak@efri.hr

**Abstract:** *This paper discusses the results of application accounting for expected credit losses IFRS<sup>1</sup> 9 model. Accounting for expected credit losses (AECL) should provide to users of financial statements useful information about an entity's expected credit losses on its financial assets and commitments to extend credit. This field of accounting is substantial in banking business and it is inevitable to research AECL through its effect on banking business regulation. Although AECL was covered by accounting standards, last financial crisis has shown weak spots of the regulation. Delayed recognition of credit losses on loans (and other financial instruments) was identified as a main weakness in existing accounting for expected credit losses model. This is why accounting in this area has changed. Due to recognition of credit losses would decrease financial result and value of assets, banks have found solution through claims management companies so there is visible correlation of claims management business results growth and IFRS 9 introduction in Croatia.*

**Keywords:** Accounting, IFRS 9, expected credit losses, banking business

### 1. INTRODUCTION

Issue of accounting for expected credit losses was subject of huge debate among accounting standard setters. Also researchers have made great efforts to create a model which will improve the quality of accounting standards and the quality of accounts produced in accordance with these standards. Last financial crisis has shown weak spots of the accounting standards for expected credit losses. Delayed recognition of credit losses on loans (and other financial instruments) was identified as a main weakness in existing accounting for expected credit losses model.

As demonstrated during the financial crisis, the financial condition of a bank is highly sensitive to rapid increases in credit risk. Therefore, appropriately determining how, when and in what amount to recognize the effects of increases in credit risk should be a priority for all stakeholders in the banking industry, including bank directors and management, supervisors, investors and other users of bank's financial statements (Basel Committee on Banking Supervision, 2015).

The significant role of accounting in this financial crisis is to minimize the pro-cyclical impact of accounting on bank capital regulation in order to achieve financial stability (Song, 2012). Marton and Runesson (2016) pointed out three main reasons why accounting for credit losses must be studied in context of IFRS and the incurred loss model and its effect on banking business. First, accounting for credit losses in banks is characterized by high measurement uncertainty of loan loss provisions, which reflects the estimation of credit losses and constitute an innately high-judgment item. Thus, it is possible to write accounting standards that allow high judgment in this area. Second, loan losses play a central role when evaluating risks and stability of banks; as such, credit losses have substantial economic significance. Third, there exists a favorable research setting in that the change from local GAAP<sup>2</sup> to IFRS happens at different points in time in the EU, enabling a difference-in-differences (DID) test.

The incurred loss model in IAS<sup>3</sup> 39 resulted in credit losses being recognized only when a credit loss event occurs, which is corrected with IFRS 9.

In July 2014 the IASB added to IFRS 9 the impairment requirements related to the accounting for expected credit losses on an entity's financial assets and commitments to extend credit (IFRS 9, 2014). Previously in March 2013, IASB published Snapshot: Financial Instruments-Expected Credit Losses where they described a three-stage approach model for expected credit losses accounting. That model is the current model required by IFRS 9 for expected credit losses accounting.

<sup>1</sup> International Financial Reporting Standard

<sup>2</sup> Generally Accepted Accounting Principles

<sup>3</sup> International Accounting Standard

US GAAP and IFRS do not have a converged standard for credit losses accounting. At the beginning of the project for credit losses accounting, the FASB and IASB worked jointly. Due to the lack of support for a three-stage approach in the US, the FASB developed a single measurement model, while the IASB decided to continue with the three-stage model. FASB also decided it would not continue to pursue a classification and measurement model similar to the IASB. As a consequence, IFRS 9 is not a converged standard.

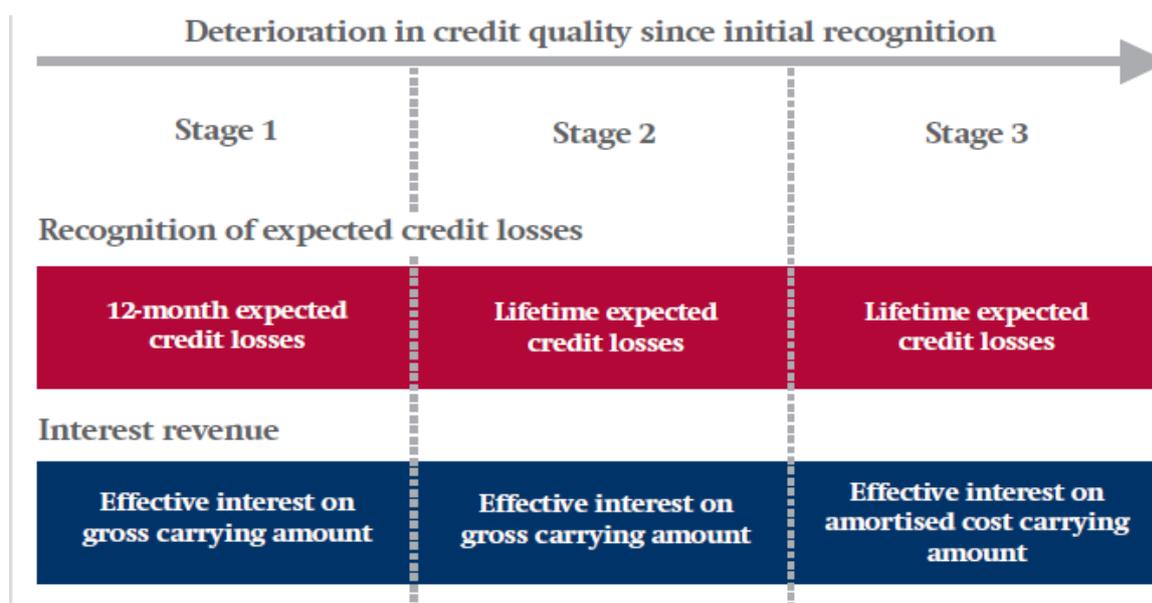

## 2. EXPECTED CREDIT LOSSES MODEL – IFRS 9

Expected credit losses model should be applied to:

- investments in debt instruments measured at amortized cost,
- investments in debt instrument measured at fair value through other comprehensive income,
- all loan commitments not measured at fair value through profit and loss,
- financial guarantee contracts to which IFRS 9 is applied and that are not accounted for at fair value through profit or loss, and
- lease receivables that are within the scope of IAS 17; leases, and trade receivables or contract assets within the scope of IFRS 15; revenue with contracts with customers.

Expected credit losses are expected to be recognized before financial assets become delinquent, as a forward-looking information, and when credit risk has increased since initial recognition, and when contractual payment is more than 30 days past due.

Expected credit losses model required by IFRS 9 is defined with a three-stage model for impairment based on changes in credit quality since initial recognition. The model is shown in Picture 1 below:

**Figure 1:** Expected credit losses model – IFRS 9; Source: IASB, 2013, Snapshot: Financial Instruments: Expected Credit Losses

The model is based on expected credit losses in the period of twelve months, in which recognition of expected credit losses through IFRS 9 is divided into three stages. Stage 1 recognizes expected credit losses when a financial instrument is originated or purchased. Immediately, twelve month expected credit losses are recognized in profit and loss and an allowance for expected credit losses (loss allowance) or provision is established. Stage 2 considers instruments with increased credit risk from initial recognition. At stage 2, full lifetime expected credit losses are recognized. Stage 3 is a situation when credit losses are incurred or the asset is credit-impaired. Interest revenue is then calculated based on the net amortized cost carrying amount.

At initial recognition, a financial debt instrument is supposed to be in stage 1 (except for purchased or originated credit-impaired financial assets). At each reporting date, the entity holding such an instrument will

have to assess whether credit risk has increased significantly since initial recognition and if there is any objective evidence of impairment in order to maintain it at stage 1 or downgrade it at stage 2 or 3 (Salhi and Théron, 2014).

IFRS 9 ECL model requires that more than 90 days past due must be shown as loss in profit or loss account, which is why it was big issue for entities who had bad receivables in their balance sheets.

### 3. PRESENTATION OF IMPAIRMENT EXPENSE

According to IFRS 9 (2014) impairment expense can be presented in statement of profit or loss, or in other comprehensive income. If the impairment is the result of changes in market interest rates, reducing the market value of financial instruments, the effect of value loss should be presented through other comprehensive income. However, if increased credit risk is caused by subjective risk, the risk of bad assessment, the effect of expected credit losses is to be presented through profit or loss. The following example shows the investment in a financial instrument, where expected credit losses are caused by the change in fair value of financial instruments as well as by subjective risk. In that case, the total expected credit losses are allocated in the statement of profit or loss and fair value of other comprehensive income (FVOCI).

#### Example 1 – Presentation of impairment expense

An entity purchases a debt instrument with a fair value of CU 40,000 and measures the debt instrument at fair value through other comprehensive income. The instrument has an interest rate of 3% over the contractual term of 5 years, and has a 5% effective interest rate. At initial recognition, the entity determines that the asset is not a purchased or originated credit-impaired asset.

**Table 1:** Recording

		Debit	Credit
<i>Purchase of a financial instrument</i>	Financial asset - FVOCI	40,000	
	Cash		40,000

On the reporting date, the fair value of the debt instrument has decreased to CU 38,000 as a result of changes in market interest rates. The entity determines that there has not been a significant increase in credit risk since initial recognition and that expected credit losses should be measured at an amount equal to 12-month expected credit losses, which amounts to CU 600.

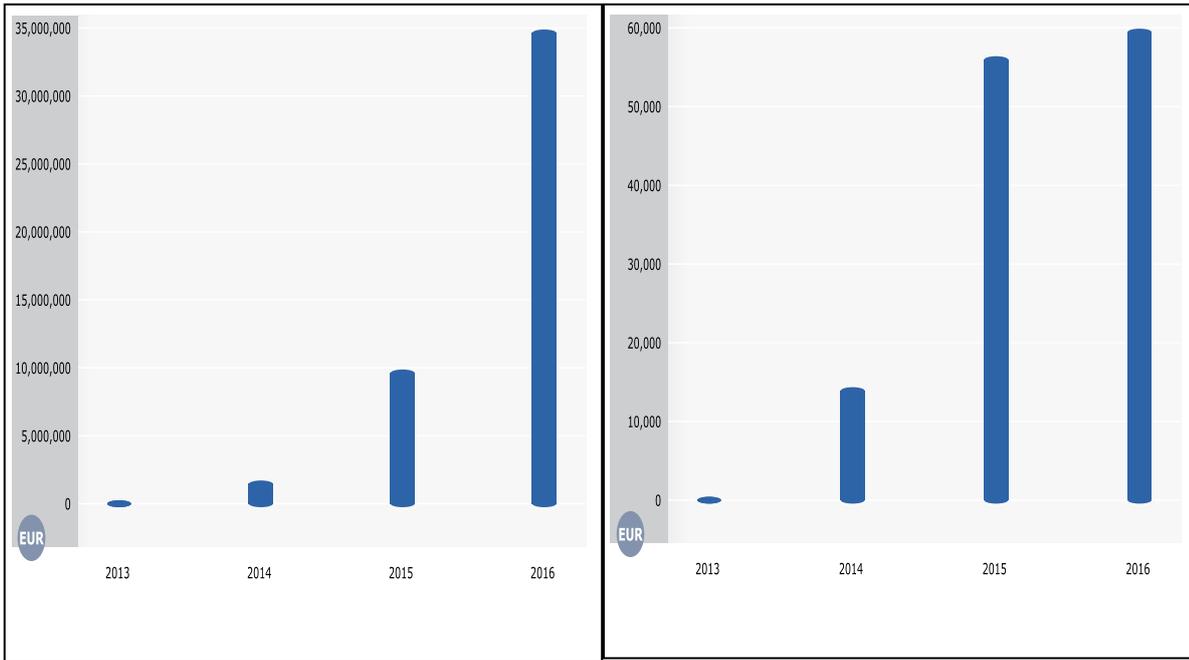

**Table 2:** Recording

	Expected credit losses	Debit	Credit
<i>Increase in credit loss during the period</i>	Impairment expense (P&L)	600	
	Other comprehensive income	1,400	
	Financial asset - FVOCI		2,000

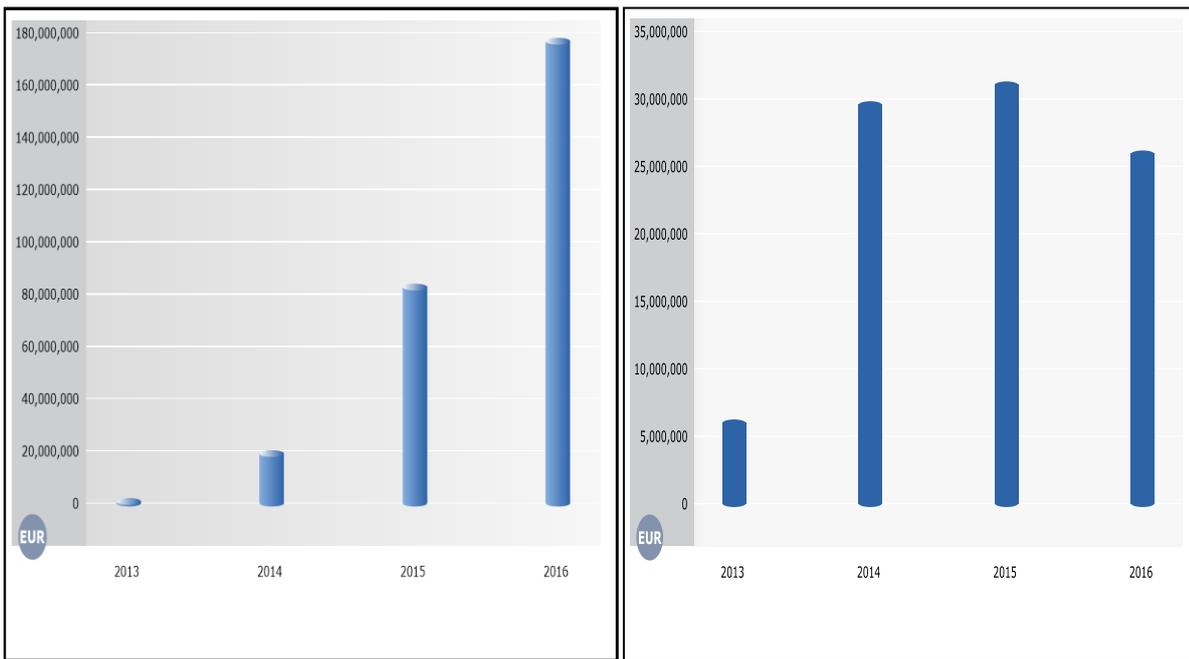

The cumulative loss in other comprehensive income at the reporting date was CU 1,400. That amount consists of the total fair value change of CU 2,000 (that is, CU 40,000 – CU 38,000) offset by the change in the accumulated impairment amount representing 12-month expected credit losses that was recognized (CU 600).

### 4. CLAIMS MANAGEMENT GROWTH IN CROATIA

Although, for example in UK under Ministry of Justice exists claims management regulation office and publishes annual report on data about industry, in Croatia does not exist data about industry at one place. Hypothesis is that new AECL model has led to growth of companies in claims industry. Data on financial performance of companies in the industry of claims management indicate correlation of claims management companies' performance and IFRS 9 introduction. Recognition of credit losses would decrease financial result and value of assets, so for that reason banks have found solution through claims management companies. Biggest claims management companies, which are operating on Croatian market are funded by banks and owned by banks. From case of chosen companies, it is clear that after publication of IFRS 9 AECL banks have start solving problem of credit losses through claims management companies. On January 1 2018 when started application of IFRS 9 recognition of credit losses would lead to decrease of financial result so banks have solved that problem by transferring ECL to, sometimes their subsidiaries, and rearranging contract details about payment date.

**Figure 2 and 3:** Turnover of two chosen Croatian claims management companies after IFRS 9 introduction; Source <https://amadeus.bvdinfo.com>

**Figure 4 and 5:** Total assets of two chosen Croatian claims management companies after IFRS 9 introduction; Source <https://amadeus.bvdinfo.com>

Shown data about total turnover and total assets are data from two Croatian claims management companies related to banks. One of the companies is owned by bank and the other one is related to bank and solves financial claims, in most cases related with real estate business. From shown figures it is clear that in those two cases exponential growth started in 2014. The implementation of the standard model of AECL was a burning issue in the concrete terms in Croatia. In Croatia, late payments of credit receivables are very frequent due to general insolvency of business entities, although generally speaking, most of the claims are still paid within the limits that do not deviate significantly from the environment. The literal application of the IFRS 9 and Basel Guidelines in described conditions on January 1 2018 would lead to serious problems presented result. That is why banks in Croatia have transferred their ECL to the claims management companies. Hypothesis of this paper was that there is correlation between IFRS 9 introduction and claims

management companies' growth. Although Croatia is small market with less than thirty banks operating, information about their real ECL is hard to get. At the same time in Croatia there is no claims management regulation office which usually publishes annual report about the industry. Also claims management companies are not under the same NACE classification number so researcher must take case study to confirm the hypothesis. Case study of two banks related claims management companies confirmed that there is correlation between IFRS 9 introduction and increase of claims management sector in Croatia. From turnover and total assets data it is clear that growth of those two financial statement elements was significant, especially in 2014 and 2015, first two years of IFRS 9.

## 5. CONCLUSION

This paper analyzed and presented the accounting treatment of expected credit losses. Credit losses have become issue since the start of the financial crisis in 2008, leading many financial institutions and companies with a significant share in financial investments to the edge of existence. In such situations, timely prediction and accounting for expected credit losses are crucial. IASB and Basel Committee on Banking Supervision identified it as a priority problem to be solved through accounting procedures, although belatedly.

Standard accounting model for predictions of credit losses during the period records, along with anticipated credit losses recorded at the beginning of the period, additional credit losses estimated on a basis of the dynamics of collection of financial assets receivable. Every delay in collection of receivables is recognized in accounting as an increase in ECL. In this way, a portion of realized profit is reserved for possible expected losses, which, if not effectuated, return to profit.

The implementation of the standard model of accounting for expected credit losses was a burning issue in the concrete terms in Croatia. The model is based on deterioration in credit quality due to the time lag from the due date, which in given conditions calls for recording of credit losses. However, in Croatia, late payments of credit receivables are very frequent due to general insolvency of business entities, although generally speaking, most of the claims are still paid within the limits that do not deviate significantly from the environment. Thus, the literal application of the provisions of IFRS 9 and Basel Guidelines in described conditions on January 1 2018 would lead to serious problems presented result. That is why banks in Croatia have transferred their ECL to claims management companies. Hypothesis of this paper was that there is correlation between IFRS 9 introduction and claims management companies' growth. Although Croatia is small market with less than thirty banks operating, information about their real ECL is hard to find. At the same time in Croatia there is no claims management regulation office which publishes annual report about industry, and claims management companies sometimes have different classification in NACE, so researcher must take case study to confirm the hypothesis. Case study of two bank related claims management companies confirmed that there is correlation between IFRS 9 introduction and increase of claims management sector in Croatia. From turnover and total assets data it is of clear that growth of those two financial statement elements in two Croatian claims management companies has been significant.

Without predictions and recording of credit losses, the presented financial result, being the subject of allocation, can be seriously overestimated and sometimes a condition for an organization's survival, even though it can generate excessive reserves of financial results. But regulation in one field of business must be covered with regulation in related field. Otherwise, there is possibility to delay problems, which sometimes can result with serious issues.

**Abstract:** *SME sector and its financing mechanisms have received significant attention in the last several decades. In today's business environment which is characterized by tremendous competitiveness and globalization of business, the discrepancy between the development of SMEs and availability and affordability of financial resources becomes a critical success factor. Despite comprehensive literature reviews on similar topics, studies focused on SMEs financing opportunities in Serbia are still at the initial phase. This paper aims to provide an overview of upsides and downsides of currently used SMEs' financing methods, to illustrate alternative financial sources such as venture capital, private equity and crowdfunding and to make recommendations in order to improve SME financing practices in Serbia.*

**Keywords:** *SMEs financing, access to finance, alternative financing sources, venture capital, crowdfunding*

### 1. INTRODUCTION

Over the last decade, Serbian government has made a significant progress in promoting the importance of small businesses and even announced 2016 as the year of entrepreneurship in Serbia (CCIS, 2016). Nevertheless, poor access to finance remains one of the biggest problems that affect the majority of SMEs in Serbia, especially in the sense of country's economic recovery and development. Compared to the regional EU counterparts, Serbia is ranked below them, and has to deal with some of the highest costs of finance (Schwab, 2016). The discrepancy between the development of SMEs and availability and affordability of financial resources for them is a very attractive topic.

SMEs have a vital role for economic and social development in Serbia. Their flexibility and responsiveness to changes give added value in the process of economic transformation. What is more, SMEs give support to the development of society by not only employing people, but also, concentrating on improvement of their abilities and skills. SMEs should be considered as an unavoidable part for creating a sustainable, competitive and well-developed economy.

Many bank business models are oriented to traditional corporate lending and are unadjusted to the special needs, risks, and profitability requirements of SMEs. Their funding structure, lack of risk management tools, and legal requirements force banks to redirect market and credit risks to enterprises through toughening their lending terms. The general lack of market knowledge about the SME sector and financial illiteracy makes it difficult for lenders to identify good financing opportunities. Traditional financing resources such as small business loans, overdrafts and personal credit cards represented a commonly used way of financing SME sector in Serbia (Rupeika-Apoga, 2014). Banks have been more averse to provide loans even for companies that they already have had experience with. But also, new SMEs face numerous difficulties accessing alternative funding. Having in mind higher interest rates, shortened maturities and increased request for collateral, it seems logical that harmful situation in banking sector has affected real economy in Serbia. Therefore, we need to rethink traditional ways of financing SME sector. The rapid growth of alternative ways of financing opens a new door for significant amount of capital. Alternative finance is very broad term which covers several financial models, but in this paper we will be focused on venture capital, private equity funds and crowdfunding.

The small and medium-sized enterprises' operating environment is facing tremendous changes, especially considering globalization and economic integration. More serious competition has affected SMEs by new financing challenges and strong expectations from regulatory environment that will support development and improvement of SME sector. This paper aims to illustrate different financial sources for SMEs and make recommendations in order to improve SME financing practices around the country. Despite comprehensive literature reviews on similar topics, this kind of research is very rare in Serbia and has a potential to be very useful for different types of stakeholders, such as SMEs, banks, regulatory and financial institutions, international financial institutions, as well as companies which provide alternative ways of financing.

The first part of this paper relates to the definition of key features of SME segment, and the literature review. The financial challenges which SMEs face are described further on, as well as the need of traditional and alternative financing mechanisms. A special emphasis is placed on financial constraints in emerging economies such as Serbian economy and findings of research are presented in this part. Moreover, conclusions from a public discussion which was organized within USAID Business Enabling Project are presented as well. Finally, the paper provides a brief description of the economic importance of small and medium-sized enterprises and recommendations for practitioners and academics.

## 2. LITERATURE REVIEW

Angilella and Mazzù (2015) point out that innovative SMEs face more obstacles regarding financing, because of insufficient and unreliable financial data. Ryan et al. (2014) examine bank market power and SME credit constraints in an international, highly developed economy setting. They find that the effect of bank market power on financing constraints increases in financial systems that are more banks dependent. Keasey et al. (2015) examine the relationship between leverage and the willingness of listed family firms to share control. The results show that owners with a greater equity capital prefer to raise finance via debt rather than dilute their position via equity, and that young family firm's face a trade-off between their control risk aversion and the need for external financing.

After the 2008 financial crisis there has been an increasing focus on access to financing SMEs especially for small innovative firms. Credit conditions have been rationalized and analyses have shown that commercial banking financing is one of the most expensive ways of gathering financial assets. Lee et al. (2015) find that innovative firms are more likely to be turned down for finance than other firms, as well as that this situation worsened significantly during the crisis. They emphasize two issues in the financial system caused by the financial crisis. The first is a structural problem which restricts access to finance for innovative firms, and the second is a cyclical problem which has had a relatively more significant impact on non-innovative firms. Eniola et al. (2015) offer methods that could help entrepreneurs on alternative financing and discuss its positive impact on small and medium enterprises performance. Moving away from traditional ways of financing and pointing out the high information asymmetry and uncertainty, Davila et al. (2003) argue that venture capital has an important role in the first phase of a start-up. Moreover, in favour of the alternative ways of financing, Blow et al. (2015) find out that private equity owned firms are much better organized and therefore more successful relative to those that use traditional financial resources. Mollick (2014) points out that success of the project depends on its quality and suggests that practitioners and researchers should invest more effort towards an analytical understanding of crowdfunding.

Simmons-Süer (2016) raises very interesting question: Does financing matter after all? The author focuses on the role of the cost of capital and the importance of the type of financing. His findings challenge the concept that the type of financing is irrelevant to the investment process. Additionally, El Kalak et al. (2015) developed models for SMEs in order to forecast the bankruptcy probabilities and point out that there are differences between micro, small, and medium enterprises considering financial constraints. Moreover, the authors suggest that these categories need to be considered separately when modelling their credit risk and therefore financing opportunities. Boscoianu et al. (2015) propose new tools based on innovative mix of private management and governmental support on a new type of financial public-private partnership. Moreover, Rupeika-Apoga (2014) discusses the fact that it is vitally important to understand the financing needs of SMEs and entrepreneurs in order to overcome the main obstacles to finance availability and accessibility. Mason et al. (2015) focus on the constructs of entrepreneurial orientation and their ability to improve performance through innovative attitude, risk taking behaviour, aggressiveness, autonomy and competitive energy. Moreover, Prohorovsa and Beizitereb (2015) analyse the amounts and the structure of micro-enterprises financing with regards to the three main sources – bank loans, leasing and factoring.

The lack of non-bank financial institutions, capital markets and inter-firm financing mechanism is a crucial reason for the current situation in Serbian SME sector. Banks are not able to overcome all important financial gaps and are very limited in providing different financing options as business of their SME clients is growing. Some of the limitations affecting access to alternative ways of financing in Serbia are (USAID, 2012): no regulatory framework for non-bank lenders; under-developed leasing; under-developed debt capital markets; under-developed markets for inter-firm financing; underdeveloped Asset Appraisal Services. Having all previously said in mind, there is a need for alternative ways of financing in Serbia. According to the discussion presented, the study sets out following research questions:

RQ1. Access to finance is one of the main challenges for SMEs in Serbia.

RQ2. Alternative financing sources are becoming more important for SMEs in Serbia.

## 2.1. Key features of SME's

Small and medium-sized enterprises and entrepreneurs are the most efficient segment of the economy in almost all countries of the world. Individually, these enterprises make the largest contribution to the increase in employment, gross added value and turnover, and are, therefore, considered to be the backbone of growth and development of a national economy.

SMEs sector comprises over 99% of business entities in EU. For the EU economy growth, SMEs have produced 85% of new jobs in the last five years. Totally, SMEs in EU generate two-third of entire private sector employment in the EU economy (<http://ec.europa.eu/growth/smes/>). Similar is for the US economy since SMEs in this country also representing 99% of all businesses. This sector provides work for over 50% of employment in US private sector and creates two-thirds of net new private sector jobs in recent decades (<https://ustr.gov/issue-areas/small-business>). SMEs in US generate more than 50% US non-farm GDP, represent 98% of all U.S. exporters and 34% of US export revenue. From the data for 2013 (last known official data) SMEs in Serbia represent 99,8% of total business entities in Serbia. It also generates jobs for two-third of employment in Serbia and generates around 50% of GDP and 43% of non-financial export (Ministry of Economy, National Agency for Regional Development, 2014).

The role of SMEs is particularly important in emerging countries which are faced with problems of high unemployment, low level of economic activity, insufficient competition and lack of investment, and where large inefficient state-owned enterprises are still present. As a reliable source of employment, small and medium-sized enterprises have an important social role in absorbing surplus labour generated in the processes of transition and ownership transformation of state-owned and socially-owned enterprises.

Basic characteristics of small and medium-sized enterprises and entrepreneurs, primarily referring to their size, flexibility, propensity for innovative and risky ventures, and greater opportunity for specialization, enable them to adapt much easier to continuous changes in consumer demand and business conditions in the global market. In this way relative to large business systems, SMEs encourage the strengthening of competition, which results in the improvement of the quality of products and services and lower prices, innovations and development of new technologies, and the growth of the national economy in general. Additionally, successful SME management can be defined as flexible and well prepared to analyse the environment and to evaluate important information in order to create a successful strategy for the enterprise (Vrchota & Rehor, 2016).

Survival, growth and development of small and medium-sized enterprises are primarily determined by funding opportunities from favorable sources. Limited access to the sources of finance, both on the money market and the capital market, especially in terms of prices and conditions of use, is perhaps the most important feature and the biggest problem of these companies. In an effort to provide the necessary funding from the most favorable sources, companies face, throughout their existence, the following dilemmas: should the investments and business development be financed from own resources or borrowed; how much capital should be obtained from loans; should the capital be provided by banks and other financial institutions, on the securities market, or by attracting formal or informal investors; and what is the desired capital structure. Depending on the objectives of growth and development, stage in the life cycle, financial status, nature of business activity and investment structure, the stability of cash flows, the relationship to risk management and the availability of certain resources, companies decide to obtain capital from one or a combination of funding sources, while aiming for the optimal capital structure. The number of available sources of financing SMEs is small and they meet their needs for capital much harder than large business systems (Milosevic et al, 2014).

## 4. RESEARCH METHOD

The study employed a mixed-method approach, having in mind that it incorporates both quantitative and qualitative data on financing SMEs (Lor, 2012). This method uses advantages of both qualitative and quantitative analysis, and creates a synergy (Lieberman, 2005). The study explored the contextual background of the SME financing and the role of banks and other financing sources available to SMEs in Serbia.

Accurate secondary data were used for addressing the research questions proposed above. The sources of data were carefully chosen using only high quality datasets, such as the OECD Scoreboard: Financing SMEs and Entrepreneurs 2015. Also, in this paper authors have used Survey on the access to finance of small and medium-sized enterprises in the euro area, conducted by European Central Bank in 2014 and European investment fund working paper - European Small Business Finance Outlook for December 2015. Additionally, results of the public dialogue performed by the WM Equity Partners with the support of USAID

Business Enabling Project in 2017 is used too. Moreover, we provide the explanation for any potential weakness of the data used in the study.

## 5. RESULTS

As indicated in RQ1 and issues of access to finance of Serbian SMEs, the study is focused on three broad issues. Firstly, the study analyses the readiness of banks to provide loans to SMEs. Secondly, the focal point is on the share of short-term SME loans as a proportion of total loans. Finally, the study sets up a scene for trends in SME loan rejection rates.

In 2013 some countries showed a reversal of the growth of SME loans. In particular, Columbia, Hungary, Ireland, New Zealand and Serbia all experienced negative loan growth in 2013, in contrast with 2011 (in the case of Serbia and Ireland) and 2012 (in the case of Columbia, New Zealand and Hungary). On the other hand, Estonia, Japan and United States experienced an increase in outstanding SME loans after years of decline (OECD, 2015b). Table 1 examines the consistency of growth patterns over time, by comparing the growth of outstanding SME loans between 2012 and 2013 with the growth trend recorded over the 2007-2012. It illustrates that in Serbia, the SME loan market in 2013 had not yet recovered from the financial crisis. SME loan growth turned negative in 2009, 2012 and 2013.

**Table 1:** Growth of SME business loans, 2007-2013

Country	2008	2009	2010	2011	2012	2013
Serbia	39.7	-0.7	5.9	2.8	-10	-8.1

Source: OECD, 2015b

One would expect from banks to restrict long-term lending more than short-term lending under severe economic situations, but SMEs rely more on long-term lending in Serbia (see Table 2) which can be an interesting topic for further research.

**Table 2:** The share of short-term SME loans as a proportion of all SME loans

Country	2007	2008	2009	2010	2011	2012	2013
Serbia	34.9	31.6	34.	34.1	30.2	27.2	29.7

Source: OECD, 2015b

It is important to keep in mind that large firms are generally less dependent on bank finance than SMEs. This fact leads to the conclusion that SMEs usually have limited financing sources available which makes them dependant on the changing conditions in credit market. The perception of the riskiness of SME lending has changed over time, resulting in relatively higher average interest rates charged to SMEs. Between 2007 and 2013 the interest rate spread between large firms and SMEs widened significantly in most countries, with Serbia being one of the countries that is exception (OECD, 2015b). For the year 2013, for most of the countries from OECD research average interest rate declined for the SME sector. Other fees associated with SME lending and commissions, are usually not available and privately held by the banking sector. In the United Kingdom only 30% of all loans were collateralized in 2013, while in Serbia data suggest that collateral requirements were higher than 30% (USAID, 2012). This means that a higher percentage of SMEs had to provide collateral in order to access bank finance in previous years which is relative to negative economic changes. Data on collateral and rejection rates are usually unavailable for most countries, but the OECD (2015b) research has shown that loan applications illustrates that the most reasons for rejection are: 1) the terms and conditions of the loans on offer are seen as unacceptable 2) the average creditworthiness of loan applications have deteriorated or 3) banks are rationing credit. Next table represents trends in SME loan rejection rates from 2007 to 2013 in Serbia.

**Table 3:** Trends in SME loan rejection rates: 2007-13

Country	2007	2008	2009	2010	2011	2012	2013
Serbia	18.7	17.2	28.4	27.1	15.8	31.5	31.8

Source: OECD, 2015b

Lee et al. (2015) show that innovative firms find it harder to access finance especially after financial crisis. Moreover, Zeneli and Zaho (2014) suggest that information asymmetry between banks and enterprises are the main reason for the SMEs' gaining funds so hard. Moreover, they pointed out that the banks do not know the operating conditions and credit situation of SMEs. Onyiriuba (2015) educates bankers on how to identify, exploit, and optimize lending prospects and possibilities in the SME sector. It is very important to do good quality credit analysis having in mind SME business goals and banking liquidity issues. Within emerging countries such as Serbia, which, generally speaking, do not have an opportunity to raise money from

alternative sources or do not have access to equity financing markets, banking industry is the only way of financing. On the high side, 42% of SMEs in Greece, 23% in Ireland, 19% in Italy and 18% in Spain and Portugal mentioned access to finance as the most pressing problem, compared with around 6% of SMEs in Germany and 9% in Austria and Finland on the low side (ECB, 2014). At the euro area level, on balance, 4% of SMEs reported an increase in their demand for bank loans and 7% reported an increased need for bank overdrafts. The situation was similar for trade credit. Fixed investment and inventory and working capital remained the two most important factors affecting SMEs' need for external financing (ECB, 2014).

In order to analyse SME financing, ECB have done the research on the access to finance of enterprises. The results have shown the most important problems faced by SMEs over the first half of 2015, were for the Euro Area and the four largest economies. For the Eurozone, 10.8 percent of SMEs reported access to finance as their most important problem. Moreover, ECB have illustrated the relative importance of different funding sources used by Euro Area SMEs. On the other hand, bank products (loans and overdraft) remained the most popular financing products for SMEs (ECB, 2014).

In a EIF Working Paper, Moritz et al. (2015) have done an analysis of the use of various financing instruments by SMEs. The authors have done cluster analysis including 12,726 SMEs in 28 European countries and come to the conclusion that there are six distinct SME financing types: mixed-financed SMEs, state-subsidised SMEs, debt-financed SMEs, flexible-debt-financed SMEs, trade-financed SMEs and internally-financed SMEs. A holistic perspective taking into account the interrelationships between different financing instruments and their determinants can be a very interesting topic, especially because there is a lack of studies that have discussed and investigated this problem. Although the general economic outlook might have improved after the 2008 financial crisis, market situation in Europe is still fragile and unstable. Looking forward, Serbian SME sector will be faced with numerous problems especially with those linked to access to finance, but if this becomes one of the priorities, future investment climate will improve. As for the RQ2, and a potential increase of the importance of alternative financing sources in Serbia, it should be noted that the access to financing for SME sector should be improved and supported by financial reforms and development of alternative financing resources. When a company thinks about gathering money through external resources, one of the first decisions is to take bank loans. Financing by issuing bonds and shares is characteristic for developed countries more than for those struggling with unsecured market conditions. The tendency for companies to borrow from capital markets instead of banks is a common situation in the US although in Europe the most important external resources are bank loans and other banking products and services. From the supply side, SMEs in euro zone indicated a further improvement in banks' willingness to provide a loan in the period from October 2013 to March 2014 (-11% compared with -17% in the previous survey period). Broadly unchanged from the previous survey period, 25% of euro area SMEs applied for a bank loan, while 47% did not apply because of sufficient internal funds (ECB, 2014). As for the Serbia, main financing sources are business earnings and personal savings, mostly used for working capital financing (81%). According to the research, the most common source of external funding are bank loans (35%), overdrafts (8%) and finds and family borrowings (7%) (Ministry of Economy, National Agency for Regional Development, 2014).

Survey on the access to finance of small and medium-sized enterprises in the euro area which has been conducted by European Central Bank in April 2014, has shown that the financial situation for large euro area firms remains more favorable than for SMEs. Availability of financial funds depends on the company's development level. That is the most important reason for SMEs to focus attention to alternative resources such as venture capital funds and business angels. SMEs should try to find more competitive funding sources than bank loans. Looking ahead this is rather new, but necessary direction for Serbia in order to become innovative driven economy one day.

## **5.1. Alternative financial opportunities**

Turning to the factors affecting the availability of external financing, in ECB survey (2014) respondents indicated that the general economic outlook continues to have a negative effect, but less so than previously (-12% compared with -24% in the previous survey round). Although access to finance is one of the most urgent problems in SMEs in most European countries, the situation significantly differs based on a country's development level and overall business environment. SMEs in Serbia are mostly using bank loans and overdrafts according to very risky and volatile market conditions, but the importance of alternative financing sources are growing, especially for innovative SMEs with very high growth potential. Although official data (Ministry of Economy, National Agency for Regional Development, 2014) imply that the Serbian economy is composed of over 97,000 small and medium-sized companies, these companies still have a significant need of external financing sources. For start up companies financing sources from the banking sector are particularly unapproachable.

In order to encourage public attention to diversified financing opportunities, adapted to each business stage development of domestic companies, WM Equity Partners, on the 14th September 2017, with the support of USAID Business Enabling Project, organized a public discussion related to that issue with the title "Public-private dialogue on equity-based financing for SME's in Serbia". Public discussion was very successful and brought together over 96 participants, of which 31% were representatives of small and medium-sized companies in Serbia, concerned in collecting new information and knowledge on this subject. Other participants included state institution representatives, regional equity funds managers, domestic and foreign financial institutions representatives. Participants were asked to evaluate current availability of alternative funding sources for SMEs in Serbia. The average score was 2.76 for being 1 – low and 5 – high. Second interesting question regards their opinion if SMEs in Serbia are sufficiently familiar with alternative sources of funding. The answers show that professionals in SME industry in Serbia with the vast majority of 92% think that SMEs are not familiar with the alternative source of finance.

Along with the previous question stands the fact that just 30% of participants had experience with Venture Capital and Private Equity funds so far in Serbia. Still, conclusions for the future of alternative source of funding in Serbia state increasing engagement of professional equity investors, with the clear current focus on IT industry and usage of IT solutions in other industries, is evident in the Serbian market.

The dialogue clearly indicated that professional equity investors bring much more than financial support to company, professionalization of management, improvement of organizational structure, improvement of financial management system, support to development of existing and new markets are just some of the added values of professional equity investors that go beyond pure financial support. This conclusion clearly indicate that it is newer about competitiveness between different financing sources (loan vs equity), but the right mix of financing sources available. At the beginning of cooperation with a professional equity investor, it is crucial to clearly define all responsibilities and activities, as well as a planned Exit strategy indicating that transparency and good corporate governance represent the basis of successful cooperation. Cooperation between management and owners, clearly defined product or service, stable cash flow in the later stages of development are the key requirements for professional equity investors. Acknowledged challenges in cooperation with professional equity investors are primarily related to more formal way of doing business. Management control can bring growth of certain costs and decline of profitability in the short-term, but in medium-term it contributes to growth and stability of business operations. Growth of venture capital industry in the region has been recognized through the cooperation between regional countries governments and international financial institutions.

Furthermore, Serbian Government recognizes the importance of innovation and entrepreneurship for the growth of domestic economy. The Government is actively working on establishing a more favorable climate for development of the local SME sector, with particular emphasis on improving the education process and the creation of favorable environment with less administrative burdens for companies. It could be concluded that there is always space for progress on the state level, but required improvements are also needed at the business level. Companies should invest in the process of innovation, promote professionalism in their operations, which will consequently create basis for a new generation of entrepreneurs.

Venture capital is financial capital provided to early-stage, high potential and high risk companies and it is usually focused on innovative fields of business (Rupeika-Apoga, 2014). Venture capital is a subset of private equity and can be provided by a group of venture capitalists or by an individual business angel. Private equity is a relatively new industry in much of the world but it will play an important part in the future. IT is the most relevant industry for venture capital, although European market shows a significantly higher preference for biotech. According to OECD research (2015a), venture capital represents a very small percentage of GDP, (less than 0.05%) for most of the countries, except for Israel and the US where the venture capital industry is more mature and represented respectively 0.38% and 0.28% of GDP in 2014. Venture capital investments in the United States represents more than 80% of the OECD total in 2014. The crisis rigorously distressed the venture capital industry, more later-stage financing than seed and start-up stage financing. Venture capital investments were higher in 2014 than in 2007 in just a few countries: Hungary, Korea, US, Russia and South Africa (OECD, 2015a).

Most European countries faced a sharp decline in venture capital after the financial crisis. This decline was uniform over venture capital for seed and early growth investments, later stage capital investments and growth capital investments (OECD, 2015b). Serbian equity market has started to develop before the financial crisis and it seems very encouraging. However, measures intended to support alternative ways of financing were not successful because of the unstimulating regulatory changes. Although there were chances for public and private co-investment in venture capital programmes it is not enough in comparison to other sources such as bank lending. Also, it should be kept in mind that venture capital is limited to mature markets and according to general opinion euro zone is one of them. Trends in venture capital are hard to analyse and interpret especially for SMEs and start-ups.

Referring to corporate venture capital (CVC), in Europe, Germany was the most active market in 2014 with investments of around EUR 2 billion (OECD, 2015a). Second most active market was the UK with corporate investments of around EUR 847 million. The activity in the European markets is significantly lower than in markets like the US (around EUR 23.4 billion) – driven in particular by Google and Intel – or China (around EUR 8.9 billion – driven by China based internet companies like Alibaba, Tencent or Baidu (who are also active beyond their home country and in particular in the US).

According to Serbian Government Strategy for SME one of the pillars of the Strategy is enhancement of access to financing sources. Within this pillar important dimensions are: development of new models for SME financing and improving capabilities of SME and entrepreneurs for different funding sources. When analysing new models of financing, strategy focuses on venture capital, private equity and business angels are seen as important sources for future SME funding in Serbia (Government of Serbia, 2015).

Up to now, there are just a few private equity funds that are active in Serbia. Also, in Serbia exists business angel's network that promotes entrepreneurship and investing culture. Nevertheless, this market is still on its early stage considering the growth potential for start-ups and entrepreneurship in Serbia. Having in mind that 2016 was promoted as the year of entrepreneurship, one could expect better support and potential for this industry in Serbia. On the other hand, bank-oriented economy is still limited factor for any other source of financing, since around 92% (National banks of Serbia, 2015; SEC, 2015) of all financial assets in Serbia hold banks.

Finally, for Serbia, interesting source of finance could be crowdfunding. Crowdfunding is a relatively new finance technique that uses the internet to match investors and borrowers for projects of common interest (OECD, 2015b). It could be a way to bypass the venture capital and business angels. Although it may impact future development of SME market, it needs good infrastructure in order to use all the benefits of crowdfunding. To be exact, crowdfunding depends on well-functioning bank instruments such as bank accounts, credit cards, online payment system, tax issues etc. The main advantage of using this type of financing is that it covers the finance gap that SMEs face. Consequently, crowdfunding presents some risk, but generally its market is in an upward phase and expects to rise in terms of finance potential. Non-financial benefits should be analyzed as well as financial, especially having in mind that idea owners are able to control business, validate R&D outputs, estimate the potential product demand and share knowledge, expertise and experience through founders' network. So far, there are just a couple of examples of using this technique for start-up financing in Serbia. But, for sure, the use of alternative ways of financing, such as crowdfunding, will be discovered and promoted in the future.

#### **4. CONCLUSION**

Survival, growth and development of small and medium-sized enterprises are primarily determined by funding opportunities from favourable sources. This study discusses the importance of different financing opportunities of SMEs. Moreover, it focuses on SMEs' access to finance and availability of alternative financing, as one of the major obstacles to doing business in Serbia. Results show that RQ1 (Access to finance is one of the main challenges for SMEs in Serbia) and RQ2 (Alternative financing sources are becoming more important for SMEs in Serbia) are fully supported. Many bank business models are oriented to traditional corporate lending and are unadjusted to the special needs, risks, and profitability requirements of SMEs. On the other hand, access to alternative financing is one of the main challenges for SME sector, both in Serbia and in well developed countries. Alternative financing for SME is a relatively new field of research, but it is, undoubtedly, very important for competitive and innovative economies.

Despite comprehensive literature reviews on similar topics, studies focused on limited financing options are still at the infantile phase. The study offers quality basis of information for different types of stakeholders, such as SMEs, banks, regulatory and financial institutions, academics, as well as companies which provide alternative ways of financing. The study incorporates both quantitative and qualitative data on financing SMEs. The analysis in this study has some limitations due to the fact that results are limited by the secondary data and the method, used in OECD Scoreboard and European investment fund working paper. However, the limitation of the analysis provides interesting research directions to further investigate alternative ways of financing in the context of improving overall performances of SME sector. Finally, the results can support policy makers in adapting access to finance options to the specific characteristics and needs of SMEs.

**Abstract:** *The expansion of the use of social networks has led to changes in the communication of brands and companies with consumers. Currently, the leading trend in marketing, according to the magazine Forbes, is influencer marketing. The paper examines this new trend in a social media context. The purpose of the paper is to explain the concept of influencer marketing in a social media context by finding its "roots" in a marketing concept known as word of mouth and by setting the same concept in the digital era and in a world connected by social media. Lastly, the paper presents the classification of influencers into different types to help campaign creators in monitoring, analyzing, and choosing the most appropriate influencers for a specific campaign and brand.*

**Keywords:** *influencer marketing, word of mouth, social media, eWOM*

## 1. INTRODUCTION

The expansion of social media has reached an even higher level according to the latest results in the Global Digital Report 2018 made by "We are social", a global marketing agency, and "Hootsuite", a well-known social media management platform. Data from this research show that the number of social media users worldwide has passed 3.1 billion. Social media has changed the way companies and consumers communicate. Companies began addressing consumers' issues with social media by hitting clicks, sending links and being responsive and interactive. This especially refers to Generations Y and Z (Obradovic et al., 2017), as 85% of them learn about new products on social media and 59% of them are more likely than older generations to connect with brands on social media (researched by Hootsuite and Pew Research Center).

Motivated by the rise of innovative approaches and strategies in marketing on social media and by statistics from different surveys, this paper examines the new trend of influencer marketing in a social media context. Data from an influencer marketing survey conducted by Collective Bias, an influencer marketing company, which included 14,000 respondents in the United States, reveal that 70% of millennial consumers are influenced by the recommendations of their peers in buying decisions. In the next few years, influencers will become a vital staple in marketing in a social media context and in the service of businesses around the world. Some of the most popular and successful companies, such as Microsoft, Starbucks, Rolex, Virgin America, etc., have started implementing influencer marketing in social media campaigns (Solis&Webber, 2012).

The rise of using influencers in marketing campaigns on social media motivated us to examine this trend by explaining the relationships between some well-known marketing concepts and relatively new but increasingly important phenomena, such as influencer marketing. As the paper deals with a subject that is not yet sufficiently represented in academic work, the authors seek to explain the roots and basic elements of this concept, especially in the context of social media.

The purpose of this paper is to explain the concept of influencer marketing in a social media context by finding its "roots" in a marketing concept known as word of mouth (WOM) and by setting the same concept in today's world and digital era where everything is connected by social media.

## 2. WORD OF MOUTH AS A PRIMORDIAL CONCEPT

### 2.1. Word of mouth

Word of mouth marketing is mostly defined as the process of sharing information from one person to another through face to face contact, telephone, social media, etc. The term "word of mouth" was coined by Whyte (1954) and on the basis of observations he claimed "People who talk about products and services together

---

\* This paper has been financially supported by the University of Rijeka for project ZP UNIRI 9/17

also show alike purchase behavior and have similar product preferences". Arndt (1967) was one of the earliest researchers of the influence of WOM on consumer behavior. He characterized WOM as oral, person-to-person communication between a receiver and a communicator whom the receiver perceives as non-commercial, regarding a brand, product or service. He also concluded that senders of WOM messages may be motivated by "the desire for enhanced status, ego-defense, or dissonance reduction" and that messages flow through shared-interest groups, friendships, or family members in a multistage interpretation process.

Brown and Reingen (1987) claim that word of mouth plays one of the most important roles in consumer behavior by shaping consumers' values, attitudes, preferences and behaviors. Nowadays, this notion is widely accepted. Additionally, consumers are more likely to trust in informal communication when they make a purchase decision than in advertising campaigns (Bansal and Voyer, 2000). A similar conclusion was reached by Silverman (1997), who argued that word of mouth has been proven to be an effective method of obtaining useful information for purchase decisions.

Word of mouth has been acknowledged as an enormous influence on people's knowledge, feelings and actions (Hennig-Thurau et al., 2004). The main cause for presenting this concept as very important in communication with potential consumers is the rising occurrence of lack of trust in advertising. For this reason, customers prefer to find out information from other sources. The findings of the research by Buttle and Francis (1998) support the previous claim that consumer behavior is more submissive to and influenced by word of mouth than by other marketer-controlled sources.

As markets change, marketing theories, concepts and strategies must also change to accommodate them. So, WOM theory and practice has developed in parallel with the development of technology and the emergence of new approaches in marketing (Kozinets et al., 2010). With the expansion of the Internet and the advent of the digital and social media era (the emergence of posted-views, discussion forums, personal mails, chatrooms, instant messaging, blogging, use of social media, etc.), the WOM concept has evolved into eWOM, which is more pervasive and more important in purchase decision-making (Chang et al., 2010).

## **2.2. Social media and eWOM**

The phenomenon and growth of the Internet gave consumers a new empire in which they could communicate and thus influence each other (Negroponte and Maes, 1996). The Internet has become an important source of information for consumers. We can find a great deal of content on the Internet for "entertainment and providing reviews on products and services" (Minazzi, 2015). As a sustainable marketing channel, the Internet has allowed "the democratization of knowledge giving companies, public or private; brands, small or big; and people local or celebrity, an equal footing to share information" (Booth and Matic, 2011). This led to the conceptualization of electronic word of mouth (eWOM).

Hennig-Thurau et al. (2004) define electronic word of mouth as a communication process where one individual may influence others on the Internet. Furthermore, the authors explain that eWOM refers to a "positive or negative statement made by potential, actual, or former consumers about a product or company, which is made available to others via the Internet" (Hennig-Thurau et al., 2004). eWOM is a particular form of communication that has emerged especially with the advent and great evolution of social media. "Thanks to the shifting landscape of information and communication technologies, users have begun to electronically exchange opinions and information about products and services" (Tabbane and Debabi, 2015).

Social media and eWOM have radically changed the relationship between consumers and companies. Also, social media platforms allow eWOM to be seen by consumers around the world (Hennig-Thurau et al., 2004). These platforms give the chance to their users to collaborate and share opinions and experiences as well as sharing different perspectives. Social media provides a sharing platform with its tools, such as social networks, forums, e-mails, and blogs. The shared views, experiences and opinions of online users are actually an electronic type of word of mouth (Cheung&Thadani, 2012).

eWOM information shared in social media can be presented in several different ways. Users can intentionally post information about products and services made by some brand. Furthermore, users can show and display their preferences to their network, such as becoming fans of brands, they can be interactive with brand posts through engagement they provide by liking, commenting and sharing. Also, users can post a brand content without any advertising purpose (Erkan and Evans, 2016).

### 3. SOCIAL MEDIA INFLUENCERS

Katz and Lazarsfeld (1955) refer to “influentials” as “consumers who influence the purchase decision of other consumers”, and Watts and Dodds (2007) use this term for “highly-connected people”. Goldenberg et al. (2009) claim that influential people are believed to have three important traits: (1) they are convincing (may even be charismatic), (2) they know a lot (i.e. are experts), and (3) they have a large number of social ties (i.e. they know many people).

Nowadays, digital influence is becoming one of the hottest trends in social media. With an effective digital influence strategy, “businesses will spark beneficial word of mouth, create brand lift, and ultimately influence the actions of other consumers much more authentically than does traditional marketing” (Solis&Webber, 2012). These authors define digital influence as the ability to cause effect, change behavior, and drive measurable outcomes online.

Influencers, as they are often labeled, form strong unions with like-minded individuals within social networks and fortify those connections with value and meaningful interaction. These influencers are individuals who may possess the capacity to influence based on a variety of factors, such as a substantial or concentrated following in social networks, notable stature, or authority within a community, and the size or loyalty of an audience. Because competition in eWOM marketing has become fierce and social networks are now the most important marketing channel for communication with consumers, identifying influencers is vital to increasing the efficiency of social network-based marketing (Liu et al., 2015).

Social media influencers represent a new type of independent third party endorsers who shape audience attitudes through blogs, tweets, and the use of other social media (Gorry and Westbrook, 2009). They can be also defined as a new type of “independent actors who are able to shape audience attitudes through the use of social media channels in competition and coexistence with professional media” (del Fresno García, Dely and Segado Sánchez-Cabezudo, 2016).

Influencers are usually novel information contributors who have the ability to affect the behavior and attitudes of others (Liu et al., 2015). Due to the persuasive power of social media influencers, technologies have been developed to identify and track the influencers relevant to a brand or organization. Most of these efforts rely on factors such as the number of daily hits on a blog, number of times a post is shared, or number of followers (Freberg et al., 2011).

Uzunoğlu and Kip (2014) explain that when companies and brands started considering the Internet as a strategic communication tool and channel, they also recognized the power of influential users of this platform. The authors conclude that digital influencers have an impact on the members of particular groups, all gathered around similar values and interests.

Kempe, Kleinbert and Tardos (2003) suggest that the main question should be how to select initial influencers who will take part in a social media campaign. To do that, managers need to have “an intelligent system that supports them in finding the optimal group of influential customers”. The selection of a group of individuals who are most likely to generate the largest cascade of influence through eWOM is also known as the influence maximization problem. Roelens, Baecke and Benoit (2016) add that there are several developed approaches to resolving the influence maximization problem. They also warn that these algorithms typically are “not based on data that represent influence flow as it is not straightforward to gather such data set”.

A framework for influence is built upon three pillars to clarify the role they play in assessing the capacity to cause change or effect. These pillars are reach, resonance and relevance (Solis&Webber, 2012):

- **Reach** is “a measure of popularity, affinity, and potential impact”.
- **Relevance** is “the glue of the interest graph and the communities of focus. Individuals aligned through subject matter create a series of linked relationships that send information along communities of focus”.
- **Resonance** is “the measurement of the duration, rate, and level of interactivity around content, a topic, or conversations. High resonance ensures that more people will see each post or update”.

According to the same authors, in the world of social media, practitioners are transforming the way to communicate with their target audiences. With the immense growth of bloggers and their increasing power as influencers for media and consumers alike, analyzing and evaluating the most influential will be a vital part of any social media campaign.

Through social networks, blogs and videos, consumers are entrenched in the dissemination of information.

Long gone are the days when the media would communicate a brand's message to consumers. Consumers are now the individuals broadcasting personal or second-hand stories to their social networks and the world – they are a brand's storytellers – the new brand ambassadors (Booth and Matic, 2011).

### 3.1. Typology of social media influencers

The classification of influencers into different types can help campaign creators in monitoring, analyzing, and choosing influencers most appropriate to a specific campaign and brand. There are different ways to make a typology of influencers. In his article in *CRM* magazine, Sam Del Rowe (2018) suggests that influencers can be categorized by the number of followers in their networks. Accordingly, there are two main types of influencers: mega-influencers and micro-influencers. Mega-influencers have a big community and a huge number of followers, numbered in hundreds of millions, while micro-influencers are “everyday people” who promote a specific brand on social media. Also, influencers may be segmented by the industry in which they are promoting products and services (fashion, beauty & cosmetics, gaming, food, electronics, etc.).

In most cases, influencers are segmented by two types of classification: the 4Cs or the 3Rs. According to the online marketing company SEO.com, the 4Cs represent a combination of context, consistency, connection and content that should relate to the selection criteria for influencers. The second classification, the 3Rs, is based on reach, relevance and resonance, which are explained above (Solaris and Webber, 2012).

On the other hand, Traackr, a leading influencer management platform, suggests ten types of influencers. Their typology is based on three pillars that clarify the influencer role: reach, resonance and relevance. Table 1 shows the characteristics of all types of influencers based on the 3Rs typology.

**Table 1:** Types of online influencers by Traackr

Type of influencer	Reach	Resonance	Relevance
The celebrity	High	Medium	Low
The authority	Medium to High	Medium to High	Medium to High
The connector	Medium to High	High	Low
The personal brand	Medium to High	Medium	Medium
The analyst	Medium to Low	Medium to Low	Medium to High
The activist	Medium to Low	Medium to High	High
The expert	Low	Medium to Low	High
The insider	Medium to Low	Low	High
The agitator	Medium to High	High	Medium to Low
The journalist	High	Medium to Low	Medium to Low

Solis and Webber (2012) emphasize that the choice of influencers in a campaign needs to be aligned with campaign objectives. For example, if raising brand awareness is the desired outcome, then the campaign should engage individuals who are popular or have earned image and reputation, while if the desired result is to establish thought leadership, the campaign should engage individuals who possess authority or trustworthiness.

## 4. CONCLUSION
