However, convergence is not so easily achievable, if there are no open economies and macroeconomic government policies meant to stabilize excessive fluctuations. In the context of free competition, of real economic freedom and liberalized markets, all of the above can achieve the desideratum of convergence together. The problem of *sustainable convergence* cannot be solved in the short term because it depends on what was actually achieved in the past, and criteria have their essential role not to hinder this difficult process of convergence as a whole, by their level or timeliness, especially when, placing themselves above allowable thresholds, they may lead to an actual increase in disparities, virtually resulting in *economic divergence*.

THE IMPORTANCE OF LEGAL AND FINANCIAL SYSTEMS FOR DOING BUSINESS IN INDIA

Anna Jaškova[1]
[1]Faculty of Economics, University of Belgrade, anna.jaskova.92@gmail.com

Abstract: *This paper researches the importance of legal and financial systems for the functioning and development of an economy. In addition to the theoretical discussion on this issue, the paper draws on empirical research of legal and financial systems of India as one of the representatives of the emerging economies. The research has shown that the rapid and steady growth of the India's economy is largely owed to the development of informal institutions and their impact on the regulation of business operations in India.*

Keywords: *financial system, legal system, business, company, India*

1. INTRODUCTION

Analysis of legal and financial systems occupies an important place in the theory of economic growth and development of countries. In the scientific literature one can find numerous papers in which the high growth rates of developing countries are explained by the effective functioning of the legal and financial systems. The most important early works that deal with this issue come from a group of prominent scientists such as La Porta, Lopez - de - Silanes, Shleifer, and Vishny. In their papers in the field of law and finance they point out that the English common law countries provide stronger legal protection of shareholders , creditors and investors , which is achieved through the efficient functioning of the institutions, resulting in better financial and economic outcomes (Allen etal.,2007). The above views on the importance of legal and financial systems for the development of countries as well as the superiority of English common law were used to explain the high growth ratesof the India's economy since its liberalization in 1992. Later papers to have explored the causes of the high rates of Indian GDP growth highlighted the methodological shortcomings of previous studies and pointed at the possibility that the above conclusions on the high importance of English common law for the growth of India's economy might be incorrect.

For an objective and thorough understanding of any economic phenomenon, and therefore the growth of the India's economy and English common law as its factor, it is necessary to take into account a number of different approaches. For this reason the paper will present a theoretical discussion on English common law, India's financial system, and their importance for doing business, as well as the research into this topic based on empirical findings related to India.

2. THEORETICAL CONSIDERSTIONS OF ENGLISH COMMON LAW

The basic principle of common law is the principle of judicial precedent. Strict adherence to this principle ensures consistency of judicial decisions, which means that all decisions must be in accordance with the judges' decisions brought in the past. This creates a legal system with predictable results of litigation. In addition, many law schools have emphasized the superiority of common law compared to civil law when it comes to the regulation of business practice. In legal and economic literature this assumption is formalized through a *hypothesis on the effectiveness of common law*, which was first set up by Coase (1960) and later systematized and expanded by Posner. (e.g., Ehrlich and Posner 1974, Landes and Posner, 1994). According to this hypothesis, the rules of common law provide effective allocation of resources, where the efficiency implies Pareto's or Kaldor - Hicks 's effectiveness (Parisi , 2004) . This is explained by the fact that common law is based on the regulations and laws that are formulated by judges, based on the rules that have been already applied in practice. On the other hand, in the countries in which civil law is applied the laws and rules are passed by parliaments and they are not necessarily based on existing methods of dispute resolutions in real life. Hence it follows that English common law is easier to apply in practice. Besides, the application of this legal system provides greater certainty, as a parliament may decide to change the law at any time, while the rules of common law do not change.

The importance of a legal system as a factor of companies' business environment is reflected in the fact that numerous prominent theorists in the field of economy and law have been engaged in the analysis of efficiency in the regulation of business practices. This includes Nobel Prize winners F. Hayek and R. Posner

who came to the same conclusion: English common law manifests superiority when it comes to the regulation of the economic sphere. It is interesting that they both came to the same conclusion, even though their analyses were significantly different. Posner explained the conclusion of his research in two ways. His initial reasoning was based on the assumption that judges, who determine the law at common law, prefer effective to ineffective rules. These preferences are derived from judges' decisions to affirmatively choose to prefer efficiency as a normative value against other values (such as the redistribution of wealth or any measure of social egalitarianism), or because even though in theory judges may incline to other values, in practice they still tend to maximization of wealth, i.e. efficiency, as to a goal that can be achieved most easily, in contrast to other goals, which, due to the limitations of judicial processes , cannot be achieved (Zywicky and Stringham , 2010) . Posner gives an alternative explanation of a *hypothesis on the effectiveness of common law* which is based on the philosophy of utilitarianism. He believes that judges are guided by the utilitarian philosophy according to which the social welfare is getting maximized by attaining the highest possible utility of each individual. Since the utility is not directly measurable, judges try to maximize the usefulness of economic efficiency or wealth instead. In the analysis of English common law Hayek (1974) raises an interesting analogy of the functioning of common law and the market. In fact, in the same way on which market prices are formed as a result of millions of individual decisions, common law has been developed on the basis of numerous independently made judicial decisions. By analogy to the market prices that cannot be affected by any individual, no judge or lawyer can specify the basis of common law, but it is rather created by all citizens. Finally, in the same way that the free market operation leads to the achievement of Pareto - efficiency, the common law results in effective outcomes.

The general conclusion of a brief overview of theoretical views of English common law is clear: English common law leads to effective judicial outcomes and exhibits superiority to civil law when it comes to the regulation of business practices. Consequently, the countries in which the legal system is based on English common law, which includes India, should have an effective legal system, which involves a high protection of creditors, debtors, minority shareholders, legislative, and transparency in operations when it comes to business. However, theoretical considerations are often not fully in accordance with the actual state of affairs, and the legal system in India is just one example that proves the possibility of discrepancy between reality and theory.

3. APPLICATION AND IMPORTANCE OF FORMAL LEGAL AND FINANCIAL INSTITUTIONS IN INDIA

The India's economy has experienced high growth rates after gaining the independence in 1951. While the average growth rates from 1951 to 1979 were lower than 4 %, during the 80s they experienced accelerated growth. On the basis of annual data on the Indian GDP it has been calculated that from 1980 to 2004 the average growth rates for a five- year period were higher than 5 % (Kotwal et al ., 2010) . Based on this we can estimate that in the period after liberalization, despite the difficulties that India faced in the 90s, the Indian economy has had a steady growth. After 2004 a further acceleration of growth occurs with the economy achieving average annual growth rates of up to 11% (2010) and the average annual growth rate for the period 2004-2012 amounts to 7.64 % (World Bank data) .
Fast-growing economies are in the focus of a large number of scientists. Economists are especially interested in the cause of high growth, i.e. what initial assumptions must be met in order to gain the opportunity for a rapid economic growth. In literature a frequently cited precondition for economic take-off points out at the existence of an effective legal system. As the basis of the legal system in India is English common law, so the rapid growth of the India's economy is interpreted as the result of a well-established legal system and efficient functioning of financial institutions.

When it comes to research into the economic growth of India, great importance is attached to the India's legal system. One of the causes of high rates of economic growth is the fact that India is among the countries with the strongest legal protection of investors and creditors (Allen et al., 2007), according to official indicators. This conclusion follows from the comparison of the index values indicating the degree of legal protection of investors and creditors (Creditor Right Index, Anti -Director Index, etc.) in different countries. The values of these indices for different countries are presented in Table 1.

Table 1: Calculated values of the indices indicating the degree of legal protection of investors and creditors by countries

	Creditor rights	Anti-director rights	Corruption perception index	Legal formalism index	Legality index	Disclosure requirement	Earnings management score

Source: Allen F, Chakrabarti, R.,De, S, Qian, J., Qian & M. (2012), Financing firms in India, Journal of Financial Intermediation, 21.409-415.

Based on the data presented in Table 1 it can be concluded that countries that during the colonial period were under the governance of England, i.e. English -origin countries, have on average higher values of all the calculated indices compared to the average of the total number of analyzed countries, i.e. former colonies of France, Germany, England and the Nordic-origin countries. As an individual country, India is also characterized by a high index value of protecting the rights of investors and creditors. It is particularly interesting to note that the calculated index value of protecting rights of creditors - Creditor Right Index for India is maximal, i.e. calculated index value is 4, which is the maximum value of the index). In terms of *Anti - Director Right index* whose maximum value is 6, the value of this index calculated for India is 5, which is the highest value of the index of an individual country amongst 100 analyzed countries. The survey was conducted in2007 by the already - mentioned authors Djankov, La Porta, Lopez-de-Silanes, and Shleifer, and it was the basis for the conclusion that India had a well-established legal system that undoubtedly contributed to the growth and development of its economy.

However, in the literature that examines the causes of rapid growth of the India's economy, there are also some alternative explanations. We can say that these viewpoints are somewhat controversial because they assess previously conducted research as methodologically incorrect, which implies that the conclusions obtained from them are wrong. Allen et al. (2012) advocate an alternative explanation for the growth claiming the following methodological shortcomings of previous studies:

- Most of the existing studies were carried out on the basis of data obtained by comparing different countries without taking into account essential differences between them, including differences in geographical size, population, level of GDP and so on. The differences between countries in research and interpretation of results should not be left neglected, because they determine the differences in the initial conditions of countries and have a great impact on the further growth of economy. On the other hand, in the existing research, countries such as

Singapore and India were treated as equal, which clearly indicates methodological flaws in research. To highlight why it is important to take into account the differences between countries, the authors give an example related to the implementation and effectiveness of legal and financial systems : taking into consideration the essential difference between India and Singapore, we can expect Singapore to have a more efficient legal and financial system, because it can be adapted to the conditions of economy at a relatively low cost, while any change in the legal or financial system of a large and diversified country entails high costs.

- Research based on a data comparison of more countries treats each country as a homogenous unit, omitting potentially significant variations in the efficiency of financial and legal institutions typical of different sectors, such as differences in the importance of financial institutions e.g. stock exchange for the operation of small and large companies and/or regions, which is particularly important when the research includes large countries i.e. India.
- In previous research, the focus of analysis refers only to formal legal mechanisms (courts) and formal financial channels (stock exchanges and banks), while it excludes other (informal) ways of financing enterprises and resolving business conflicts.

To overcome these shortcomings of previous research, the authors Allen et al. (2007) have used a different methodology. They focused on a study of legal and financial environment in which companies do business in India. The results have not been compared with those of other countries, but they only compared the differences in the results by different regions of India. What makes this study particularly interesting and important is the fact that the research subjects were not only formal institutions (courts, stock exchanges, banks, etc...), but also informal business relationships, rules, conventions, funding channels, etc. By analyzing the economy of India in this way the authors came to a surprising conclusion:

1. Formal legal system is little applied

Based on a number of theoretical findings, lawyers and economists consistently emphasize the importance and strength of the legal system in India, yet the country's citizens attach little importance to these theoretical findings. In fact, India shows great distrust of the legal system and the effectiveness and fairness of the judiciary. Numerous empirical studies have shown that people rarely turn to the judicial authorities when they encounter irregularities in business practice, because they do not believe that such a step would contribute to solving the problem. If the research is correct and the legal system does not work as efficiently as the previous scientific considerations claim, undoubtfully the following question arises: How is it possible for a large economy like India's to have achieved relatively stable and rapid growth for more than two decades without meeting basic preconditions for economic take-off such as the protection of property rights and contracts and the corresponding financial system. The group of authors has given the answer to this seemingly contradictory question based on the research into the business environment and business practices in India.

The authors have come to the conclusion that strong legal protection is not a necessary condition for a successful operation of an enterprise, and consequently the growth of the whole economy , as long as there are strong ' institutional ' substitutes for formal legal system such as fear of loss of reputation, partners, future business opportunities and alike. Social connections and informal institutions attached to them are of major importance for doing business in India. A famous economist P. Adler wrote and spoke about the importance of trust between market actors for the functioning of economy. He believes that trust is the key coordinating mechanism of a society (Adler , 2001) and that it can be seen as the third component of a cooperation mechanism of the capitalist economy as a whole, in addition to government and markets. In India, this type of coordination has a special place, as amid the lack of implementation of legal measures to ensure the execution of contracted obligations, the Indians rely heavily on mutual trust and established social norms.

2. Formal financial channels (banks and stock exchanges) are a key source of corporate financing

Companies in India obtain only 26 % of capital through formal financial channels (Allen et al., 2007).This includes large corporations, which means that small and medium-sized businesses are almost entirely financed from informal sources i.e. from their own savings, borrowing from friends, relatives, and alike. The main reason for the use of informal sources of finance lies in that bank lending is expensive and the terms of loans are too harsh. We might conclude that companies in India are in an extremely unfavorable financial position due to high funding costs, causing problems to the very production activity of companies. Specifically, companies which are facing difficulties in obtaining funds have little or no opportunity for growth. In western countries such companies are often forced to decrease production, employment, and sometimes to exit the market.

However, there are important differences between the companies operating in western countries and those in India. In Europe, banks finance about 2/3 of the total financial needs of companies (Chaldwell , 2001),

while in the United States about 60 % of the invested capital is acquired through issuance of shares or bonds,26 % of net investment comes from retained earnings, and only 17 % from other sources, including banks' financing(Gregory and Stuart , 2014). Thus, if banks tightened financing conditions in Europe, or if there was a deterioration of the situation on the stock exchanges in the U.S., the companies would be faced with a big problem because they finance business from formal sources, and finding new ways of financing requires time and additional costs. On the other hand, companies in India rely on bank financing to a much lesser extent, or financing by issuing shares, which makes their performances much less dependent on credit terms or conditions on stock markets. This can also explain why India was able to achieve relatively high rates of output growth although companies have had limited funding opportunities from formal sources.

3. Although a large number of companies operate outside the formal legal system and institutions, India has achieved high economic growth

Despite the poor investors' protection in practice, India's economy was growing faster than most other emerging economies of the 90s, which contradicts the belief that the key and unavoidable assumption of rapid progress lies in the stable financial system and the application of strong legal regulations in business. Proponents of the institutional theories of the development of capital markets consider the development of capital market and its successful functioning as a necessary condition for growth. If it is not developed, development costs can be high, which can lead to slower growth, or even to a change of this trend. High growth rates in India considerably weaken their conclusions. Other authors who hold the position that the developed and efficient legal system is primary conditions of growth, have very little opportunity to justify their claims on the example of India.

It should be noted that the assessment of the legal and financial system of India as "underdeveloped" does not imply a lack of legal and financial institutions, but is rather related to their poor implementation and therefore little significance for the development of economy. In fact, as it is said in the previous section of this paper, the legal system in India has its roots in English common law which is seen as superior. But citizens have little confidence in legal institutions, so that business irregularities are usually solved outside of judicial processes. When it comes to the financial system, the two major stock exchanges in India, according to the value of the market capitalization, the *Bombay Stock Exchange* and *National Stock Exchange* are of the world level significance. The total value of the market capitalization of the stock exchange in Mumbai is 67 443 983.8 INR, and the National Stock Exchange 65 907 848.1 INR (World Federation of Exchanges), which places these stock exchanges among the top twenty in the world. When it comes to the banking system, there is still a distinct dominance of state banks (state banks make up about 80 % of the total bank deposits). After the liberalization, several private banks have emerged, and several foreign banks entered the market. Private bank ICICI Bank is currently ranked the second by the size, while the state bank is ranked first. What is also important to note is that the banking system in India is characterized by much fewer non -performing loans thus making it more profitable and more stable compared to the banking systems of other countries in the region. However, the status of a "healthy" banking system is owed primarily to strict requirements set by the banks when issuing commercial loans; therefore, borrowing from banks is considered expensive and inappropriate to real possibilities of enterprises that need funding.

Despite the fact that India has two stock exchanges of the world significance, and the "healthy" banking system, the authors who deal with the entire financial system of India make the following conclusion (Allen et al . , 2007) : 1) stock exchanges , as well as the banking sector , are relatively small compared to the size and the needs of the economy , 2) the financial system is dominated by efficient (low overhead), but largely untapped (when it comes to providing loans) banking sector .

The results of the research conducted by Allen et al. (2007, 2012) may be summarized as follows: It is strong informal institutions that maintain India's economy steady; despite the results of previous research, formal institutions are under-utilized and have relatively little importance to the economy.

The support to the fact that the functioning of institutions in India is far from ideal is illustrated by the information on the rank of India by the Global Competitiveness Index and Index of Economic Freedom.

4. GLOBAL COMPETITIVENESS INDEX AND INDEX OF ECONOMIC FREEDOM

By the value of the Global Competitiveness Index (Global Competitiveness Index GCI) India ranks at 60th amongst 148 economies. Other BRIC countries (except Russia) have higher values of GCI, indicating the higher competitiveness of these economies compared to India's (World Economic Forum). We can conclude that India is ranked relatively low in terms of the total number, as well as in relation to the BRIC countries. According to the Global Competitiveness Report 2013-2014, a high level of innovation in an economy and a strong institutional environment have an increasing impact on the competitiveness of countries (PHD

Chamber), which is an alarming fact for India given its current performance in terms of the functioning of institutions . As India ranks at 72nd position by the efficiency of institutions, and at 110th by the benefits of the macroeconomic environment, it is not surprising that its competitive edge is relatively low. In addition, the three most significant problems companies face doing business in India are: 1. corruption; 2. inefficiency of state administration, and 3.In adequate infrastructure. From this follows that, according to the World Economic Forum, India is characterized by low efficiency of institutions and extremely unfavorable macroeconomic environment, which contradicts the results obtained by Allen et al. (2007,2012).
A similar conclusion can be reached on the basis of information that India is ranked 120 according to the Index of Economic Freedom (Index of Economic Freedom) constructed by the *Heritage Foundation* (2014). The report states that institutional shortcomings have largely a negative impact on long-term growth of the economy. The report also points out that India is characterized by a relatively stable democratic system, but that the size of the country and diversification of population are major challenges to effective and efficient governance/ management, or to achieve, what is known in economic literature as good governance. Excessive state intervention in the economy, and a relatively high level of state ownership, which has increased over the last years, contribute to the inefficiency of institutions and poor functioning of the whole economy. Companies are faced with a number of administrative barriers to business, while the private sector growth is largely prevented by a lot of non-tariff barriers and a high level of administrative regulations that burden the private investments (The Heritage Foundation, 2014).

When it comes to the rule of law, India has better protection of property rights than the average of the analyzed countries (53rd place), but, by the fight against corruption, it is well below the average and ranks at 97th place. Although the corruption is still one of the biggest obstacles to the development of India, there has been an increasingly strong pressure to reduce it in recent years. The executive branch of the judiciary system is considered to be independent, but trials are subject to political pressures, they are characterized by high costs, and individuals belonging primarily to political "elite" are protected from court charges. In order to facilitate a long-term growth and development of the India's economy, the primary task of the government must be committed to a resolute fight against corruption, given that the high level of corruption is said to be a major source of inefficiency of formal legal and financial institutions. Establishment of an effective judiciary and reducing bureaucratic barriers would provide significant opportunities for the development of India. Although the Indian government has strict measures in order to reduce corruption, the effectiveness of these measures are brought into the question due to the fact that little effort is made to reduce a large number of administrative and regulatory measures, as well as the state ownership of economy, and it is exactly the excessive administrative regulations and state owner ship that is recognized as the major sources of growth in corruption.

5. CONCLUSION

The development and effectiveness of the legal and financial systems of countries are key components of their macroeconomic environment. The way companies do business; their profitability and the possibility of further development are largely dependent on the general business climate in the country, which is defined above all, by the protection of property rights and contracts, bureaucratic restrictions on operations, the level of corruption in state institutions, access to finance, etc. The professional literature demonstrates the consent at countries with a legal system based on English common law have better regulations of business and more efficient functioning of legal institutions (e.g. Hayek 1974 Zywicky and Stringham, 2010). India, as one of the representatives of the BRIC countries, is characterized by a legal system based on common law and developed financial system, which involves primarily a sound banking system and developed stock market. According to official indicators (Creditor Right Index, Anti -Director Right Index) India has a particularly strong protection of investors and creditors (Allen et al., 2007). In the economic analysis of the Indian economy, a favorable macroeconomic environment, and a strong legal framework of business and a sound financial system in particular, are recognized as key factors of its high growth rates after the liberalization. However, later studies have pointed to the methodological shortcomings of previous studies, for which the conclusions drawn on the basis of them do not correspond to the actual state of the economy of India. According to the research conducted by Allen et al. (2007) companies in India are heavily reliant on informal institutions in their operations, such as trust, responsibility towards families and authorities, informal agreements, etc. The importance of informal institutions stems from the lack of confidence in the country's legal system, and a limited use of formal financial channels to raise the necessary funds. Although informal institutions are extremely important for the coordination of the market economy, they are still insufficient to establish a stable macroeconomic environment conducive to growth of competitiveness of the economy and its rapid progress. For these reasons, India is by the Global Competitiveness Index (60th place) and the Index of Economic Freedom (120th place) ranked relatively low as compared to the other BRIC countries, as well as in relation to the total number of analyzed countries . Excessive bureaucracy, high levels of corruption and the legal institutions subject to political pressures are the primary problems whose reduction is necessary in order to enable further growth and development of India's economy.

KNOWLEDGE MANAGEMENT

KNOWLEDGE MANAGEMENT SOFTWARE APPLICATION IN ICE-CREAM COMPANIES

Ana Ristevska
Faculty of economics – Prilep, email: ana.ristevska12@gmail.com

Abstract : *In this paper will be explained the meaning of knowledge management software application and the importance of using this kind of software applications in companies. Also in this paper will be listed types of knowledge management software applications that can be used in the companies. In this part will be given some facts from the ice-cream industry and will be mentioned possibilities for using knowledge management software in this industry. After the theoretical explanation of knowledge management software applications, the practical research in this paper will be done in the biggest ice-cream company in the Republic of Macedonia. In this part will be explained why ice-cream companies should use knowledge management software application and what kind of benefits the companies can get by using this application. The aim of this paper is to contribute for raising the awareness of ice-cream companies to use this kind of software application through the example of the biggest and the most successful ice-cream company in the Republic of Macedonia.*

Key words: knowledge management software application, ice-cream company

1. KNOWLEDGE MANAGEMENT SOFTWARE APPLICATIONS

1.1. Definition and meaning of knowledge management software applications

Nowadays more and more companies are turning to modern and advanced operations. All working processes in companies are increasingly computerized in order to obtain faster, simpler and accurate execution of all work activities. In addition to work activities, companies start to computerize also the knowledge that they possess. This can be done by using the appropriate software that helps companies to use effectively their intellectual capital. The knowledge management software applications need to distribute and maintain knowledge of the company. The basic principle of knowledge management software applications is to disseminate knowledge in appropriate and easy to use format to the appropriate person and appropriate place in order companies to be competitive on the market and to have effective execution of all tasks.

The knowledge management software application is not a software application with standard size, shape and look. In fact, knowledge management software applications can be very different from one company to another. This is because of the different activities of the companies and different intellectual capital owned by each company. But whatever the differentiations between the companies, we can say that knowledge management software application in the companies can support generation, storage, update and distribution of knowledge.

The company's ability to learn and change, and more importantly to learn faster than other companies and to turn learned things into action, is the greatest power of a company. (Mašić and Đorđević, 2008). With the help of software knowledge management, company will be able to make changes in order to transfer knowledge and to improve processes, develop new products or services in order to meet the needs of customers, attract new customers and achieve all the company's goals.

Companies that want to use the knowledge management software need to know what goals want to achieve by using this kind of software. If companies start to use the knowledge management software that means these companies realized how precious are intellectual capital and knowledge which they possess.

The future of knowledge management software applications can be clearly predicted. As companies move into the age of knowledge, the need for proper software tools is increasingly growing because those tools will help companies to sort big quantities of data and information. Companies are inundated with e- mails, electronic newsletters, articles, graphs, customers' requests, prices etc. Regarding this issues companies spend a lot of time in sorting, filtering, answering and managing of all the things listed. (Kurucz, 2003). To avoid all this, companies should have a software solution that can properly handle with all electronic and written data, information, documents and knowledge and thus contribute companies to have constant progress and achieve their goals.

1.2. Types of the knowledge management software applications

Each company, depending on its business activity, can use different type of knowledge management software application. Knowledge management software application should fit and conform with the company's activities and tasks.
Companies can buy knowledge management software solution from software companies and also can order from them to create special software regarding their needs.
The most important goal of knowledge management software application is ensuring that data and information are collected and stored in proper way in order to be effective and efficient for use for the members of the company.
There are a variety of companies prepared to provide knowledge management solutions. Some of the leading providers are: Cobble Soft International Ltd, ePath Learning, Knowledge Powered Solutions, KANA Software, Inc., Overtone Software, Inmagic, Inc., LegalEdge Software, AHG, ICCM Solutions, Kanda Software, AccessData, Accusoft, Apple, ASG Software Solutions, Attensity, Brainware,Connotate, eTouch FTI Technology, Google, IBM, Oracle, Kana, Microsoft, K2, Kofax and many other software companies. Knowledge management has become increasingly important in a data-centric and service-focused economy. Regarding this the knowledge management software is also essential for company producers and service companies.

Knowledge management software can exist in many forms, including:

- Process-driven applications
- Automated data integration
- Data capture and workflow solutions
- Purpose-built databases
- Content life cycle management systems
- Automated document and classification solutions
- Document, content and imagine solutions
- Secure file sharing
- Optical character recognition
- Social analytics and engagement solutions
- Integration of enterprise search
- Business intelligence

Some of the already developed knowledge management software solutions are:[1]

- PHPKB (PHP Knowledge Base Software) is produced by PHP's leading knowledge management software bases, and offers assistance to companies through the support and management of their knowledge bases. PHPKB knowledge management software database provides statistical knowledge that is crucial for decision making in relation of existing and potential customers, and offers professional view using charts and diagrams that review all the information. The features of this software are especially suitable for companies that have a lot of information. With this software companies are able to process the information for potential customers and adjust their activities based on the processed information.

- SEM Knowledge Management software is produced by software company Kana and it is knowledge management software that allows access to all databases of the customers, as well as certain external databases of consumers made by another company or institution. This software can answer on demand estimated by the set of pre- entered contextual specifications. These specifications can be: setting value of the consumer, type of application, previous experience, number and type of the order etc.

- Safeharbor KMS is software developed by Safeharbor Knowledge Solutions. In the last decade, this software was used by more than 500 companies. It maximizes the management of knowledge in the company. Apart from storing data about potential customers, markets, prices, suppliers etc. this software offers several solutions, including: making assessments of the work, creating a strategy for attracting new customers, perform testing, analysis and compliance of information and creation of the best practices in the company in order for the company to meet the demands of the new customers and market.

- KBPublisher made by the same name manufacturer is a web-based software for managing knowledge. With this software companies can share the knowledge with other members and also they can publish and manage with articles, guidelines, processes, frequently asked questions and other information and items

[1] http://www.capterra.com/knowledge-management-software/

from the company. In order to use this knowledge based software, companies should have internet connection and web browser.

- Novo Knowledge Base Software is produced by software company Novo Solutions and this software allows quick and safe access to the entire knowledge of the company. This software is designed for companies that want to have a central repository of knowledge and all employees to have access on it. In this software has been implemented and training for employees.

- Archivd Research management knowledge software is produced by Archivd. Using this software, a company can collect and present all inquiries from potential customers that are made online. Furthermore they can easily be shared among the employees. This software is commonly used by production managers, sales managers and advertising agencies in order to process all the information obtained from the Internet for the new customers and to take actions that will contribute to satisfy their needs.

- Smart Support is produced by Safeharbor and it is software for knowledge management with main purpose to connect people with the proper answers. The software is intuitive, easy to integrate into web-based environment and offers advanced tools that can easily be managed and edited in knowledge base of the company. It should also be noted that this software offers templates for workflows, writing comments, documents etc. It is assumed that the return on investment of this software is in a period of six months or less.

- Akiva WebBoard Knowledge Base is produced by Aktiva and it is a software that collect and organize group information and content in the company. It has ability to collect, manage and query very large amounts of data, information, documents, photos and other contents. It performs fast and safe sharing of documents and verification of all data and information. Users can perform self-evaluation and management of content which are part of the company.

- Dezide Advisor is produces by Dezide and it is web based software that serves the employees and their existing and potential customers. If consumers have any questions or specific requirements, this software provides multiple solutions and answers of the questions. On this way customers get the most optimal answers in the shortest time.

- Traction Teampage is produced by Traction Software and it is software for knowledge management enabling seamless communication, collaborative work, quickly finding the data etc. This software allows monitoring of activities, discussions, collaboration between different sectors in the companies and control the execution of the employees' tasks.

- Column Case Management produced by Column Case Investigative is software that eliminates natural processes, increases efficiency, reduces errors, and thus the companies will be able to reduce costs and obtain better solutions. Through this software can be provided safe and secure management and sharing of information and processes, as well as cooperation between various sectors in the companies.

These and many other software solutions are developed and used by different kind of companies. Knowledge management software solutions are upgrading all the time in order to satisfy the needs and requests of the companies.

2. ICE-CREAM INDUSTRY AND USING OF KNOWLEDGE MANAGEMENT SOFTWARE APPLICATIONS

Ice-cream industry round the world takes great participation in global economy. The global retail ice cream industry revenue is estimated to reach $74 billion by 2018. Favorable demographic factors, rising consumer disposable income, and consumer's awareness toward frozen dessert mainly drive the demand. The retail ice cream industry includes retail sales of classic ice creams and frozen novelties. Classic ice cream includes special ice cream such as low-fat and non-fat, take home, and bulk ice creams. Frozen novelties include flavored ice, sorbet, and frozen yogurt.[2]

The industry is moderately capital-intensive as large numbers of players are competing with each other to maintain their place in the market. The classic ice cream segment contributed approximately 80% in global retail ice cream industry in 2012, whereas Nestle and Unilever, the two largest players captured one-third of the total market. New product development and innovation plays an important role as a growth driver for industry. Maintaining price and quality, brand loyalty, and consumer group retention are the biggest challenges for industry due to the large number of competitors in the market. (Euromonitor International, 2013). Also in Republic of Macedonia ice-cream industry has a big part of all the economy incomes. In

[2] http://www.idfa.org/resource-center/industry-facts/ice-cream/

Republic of Macedonia there are two big companies that produces ice-cream (classic and novelties of ice-cream), but also there are a lot of retails that sell ice-cream in the territory of Republic of Macedonia. That means that competition is on very high level. In order to be competitive on the market, to get bigger number of customers and to archive bigger profit, ice-cream companies should work regarding proper strategies in order to archive their own goals.

The proper work strategy can be done and helped by knowledge management software application.

With the help of knowledge management software application ice-cream companies can have proper execution of their tasks and can have effective usage of the knowledge they possess.

Knowledge management software application can help ice-cream companies to collect knowledge that they possess, to collect new knowledge, store all the knowledge, then process it, transfer it between all the employees and do update on the knowledge all the time.

On this way ice-cream companies will have proper view of all of their activities, their data, documents, employees' knowledge and they can manage with all of them much easier and faster. Also they can collect and proceed knowledge about their customers, their needs and wishes regarding different types of ice-creams, then knowledge about the market, competition, prices, new technologies for producing ice-cream, new ways of sales etc.

3. PRACTICAL RESEARCH - Cermat Doo – biggest ice-cream company in Republic of Macedonia

The research in this paper is descriptive and it is made by interview with the general manager and owner of the biggest ice-cream company in Macedonia and owner of the other ice-cream distribution companies in Serbia, Montenegro and Croatia.

Cermat Doo is an ice-cream producer company that have the biggest part of Macedonian ice-cream market. Cermat produces different kinds of ice-cream: impulse ice-cream (ice-cream on stick, cornets and ice-cream in cup), family ice-cream and horeka ice-cream (ice-cream for catering).

With all this assortment of ice-cream Cermat satisfy wishes and needs of a lot of customers from Macedonia and other European countries where this company sells: Germany, Austria, Slovenia, Croatia, Serbia, Montenegro, Albania etc.

Not only the rich assortment of ice-cream gives this company competiveness and biggest market share, but also its proper work strategy and its proper use of all the knowledge they possess through knowledge management software application helped this company to be biggest, innovative and advanced ice-cream company in Republic of Macedonia.

Cermat uses knowledge management software application which is created regarding the needs of the company, sectors in the company and needs of the employees.

The name of the knowledge management software application that Cermat use is "CFMA".

This software works with the large databases where are stored all the information and knowledge from the past years and from daily operations. All the stored knowledge go into the company server where they are stored one more time in order to have proper security of all of their knowledge and information.

With the help of this software Cermat has the information of each customer regardless if the customer is small shop, market, supermarket, restaurant, coffee bar etc. Also there are written all the purchases that each customers have done with the exactly articles and time of purchase.

Cermat gives refrigerators with codes to each customer and these codes entered into the database that is connected with the knowledge management software. With the help of this software, Cermat knows where is located each refrigerator that it possess.

Every customer has a different need, wish and opinion regarding the ice-cream quality, ice-cream price, ice-cream size, ice-cream package etc. Cermat on certain time period makes market research in order to collect information of customers on different market regions where it sells in order to discover what customers want and to adjust work strategies and production regarding their needs and wishes. All of this information are stored into the knowledge management software and there are possibilities to be done different analysis and reports. All of these reports and analysis allow Cermat to has a clear view of what kind of ice-cream should produce and sale on different market regions.

Also this software gives Cermat possibilities to make analysis regarding realized sales through the years and to make comparisons regarding the sales year by year.

In the database of this software are also stored information for all suppliers of the company and all the purchases that Cermat have done to them. The software gives opportunity for analysis of prices comparisons of the prices from the suppliers in certain time period.

With this software employees can write and print documents with standard size, look and characteristic which are suitable for the needs of the company.

In CFMA software are stored also all the information of each employee regarding the their education, skills, performance, experience etc. All this information allow managers to know how to allocate human resources to different work positions.

With this software are covered all the aspects of working of this company: sales, financials, human resources, production, customers etc.

4. CONCLUSION

From the theoretical part of this paper can be concluded that knowledge management software applications can help different kind of companies to have view of the knowledge, to work efficient and to reach their goals through proper using of the knowledge that they possess.

Also companies can use all the listed software applications if they are suitable for their needs. If they want, they can order from the software companies software applications that will fit with their needs.

Ice-cream companies also need to use knowledge management software application in order to produce ice-creams regarding the needs and wishes of the customers, to reach bigger market share, to have bigger profit and to adjust all the work process regarding the needs of the company and employees.

With the example of the biggest ice-cream company in Republic of Macedonia it can be seen that all the work process and activities are completely covered by knowledge management software application. All work tasks are very good organized which allows this company to have overview of all the situation on the market, on wishes of the customers, orders, documents, information, tasks, employees etc.

Cermat company should be sample for successful ice-cream producer company that use knowledge management software for all its work activities and tasks. All ice-cream companies should use this kind of software application if they want to be advanced, innovative and successful.

MEASURING IMPLICIT AND EXPLICIT KNOWLEDGE IN ORGANISATIONS

Ivan Vukić,[1] Mladen Čudanov,[2] Gheorghe Săvoiu[3]
[1]University Pierre et Marie Curie, vukicivan@yahoo.com
[2]University of Belgrade, Faculty of Organizational Sciences, mladenc@fon.bg.ac.rs
[3]University of Pitesti, gsavoiu@yahoo.com

Abstract: *This paper provides review of different approaches to measuring implicit and explicit knowledge in organizations. Based on review of existing literature, we combine theoretic view on measuring and variation with practical measurements suggested by other authors. We analyze the possibility of measuring such implicit and sometimes elusive organizational phenomenon as knowledge. Further we synthesize knowledge measuring methods and measurement units. Next, a set of knowledge indicators used in literature and practice for measuring organizational knowledge is presented.*

Keywords*: Knowledge, Measuring, Knowledge management, Learning organization.*

1. INTRODUCTION

Despite the attempts, there is still no consensus within the academics about definition of knowledge. Western epistemologists often start with Theaetetus, where Plato (2013) discusses "true belief with an account" as the closest acceptable definition of knowledge. Johannessen, Olaisen and Olsen (2001) define knowledge as "systematized and structured information of specific purpose". Dixon (2000) says that "Knowledge stands for important links between the information, that people make in their minds, and application of those links as actions in specific contexts". Suknović and Delibašić (2010) define knowledge as concept which "represents triplet of problem, context and solution". Authors offer the following definition of knowledge: "Knowledge is the system of patterns for information processing, which suggest a solution of a problem in particular context." Therefore, knowledge is defined by three components (Suknović (2010) p. 192, modified): ***context*** (current and desired state), ***problem*** (gap between current and desired state) and ***solution*** (selection of one of the possible ways of achieving the desired state from the current state).

The existence of the system of knowledge is based on several basic assumptions: 1) ***Absolute truth.*** There exists objective truth, which is the convergence of subjective perceptions of reality. (Borgatti and Carboni, 2007), 2) ***Encoded***. People represent the information and knowledge through various processes of encoding, therefore these structures are represented by the system of symbols enforced with particular meaning (Kanwar, Olson and Sims (1981) p. 122-127, modified), 3) ***Understanding***. People can understand the encoded knowledge and information (Reich, 1994), 4) ***Stored***. Knowledge is stored in the memory of the individual in more or less organized (structured) way and makes the network of more or less related concepts (Kanwar, Olson and Sims (1981) p. 122-127, modified), 5) ***Accessible*** (concept or set of concepts may be retreived from the memory as a result of attention focused on the external or internal impulses) (Kanwar, Olson and Sims (1981) p. 122-127, modified).

2. FEATURES OF THE SYSTEM OF KNOWLEDGE

By the term "desirable characteristics" this paper will involve features that it is good that a system has. Well structured knowledge is characterized by the following features: (features 1, 2 and 3: Rief (1984); Elio&Schaf (1990); De Jong and Ferguson-Hesstler (1995) p. 105-113), (features 4, 5 i 6: (Reich, 1994)): 1) ***Durability***. (continuance of acquired knowledge through time), 2) ***Accessibility***. (quick and efficient searching and knowledge finding process), 3) ***Modularity*** (easily adding new elements of knowledge without having to change the existing knowledge structure), 4) ***Transferability***. (knowledge can be shared between systems or reasoning mechanisms), 5) ***Cumulativity*** (knowledge of two quantities can be added to make the third greater), 6) ***Measurabilty*** (that is, it can be measured directly, by direct counting of the elements of structure).

Poorly structured knowledge can be characterized by the following features (according to: Possible anomalies of model and according to: Structural faults of system of knowledge (Ramaswamy, Sarkar and Chen (1997), Yang, Tsai and Chen (2003)): 1) ***Incompleteness***. Knowledge system does not contain all the

parameters (situations) that may occur or do not cover the whole set of possible solutions (Cheng and Huang, 2009). 2) ***Inconsistency***. Knowledge system contains a number of rules, which when applied lead to mutually contradictory consequences. These errors are difficult to identify in large knowledge bases. For details of the measurement and treatment of conflict if-then rules, see: (Cheng and Huang, 2009). 3) ***Ambiguity***. Within the knowledge system two or more actions should be applied, while their order is not defined. 4) ***Inaccuracy***. Model in the knowledge system does not match the real system, therfore the rules applied do not lead to correct conclusions. 5) ***Circularity***. Applied set of rules leads to the reuse of one of the rules in the sequence and creates a circle that has no beginning and no end, and from which it is not possible to get out using the rules in the knowledge base. 6) ***Redundancy***. The case when two or more rules lead to the same conclusion. By eliminating one of these redundant rules knowledge system would still be able to solve the problems. Redundancy usually occurs when different rules lead to a conclusion through a different number of intermediate results.

4. SPECIFICITY OF APPROACH TO MEASURING KNOWLEDGE AND ITS VARIATION

Measure is the homomorphic model (Reich, 1994), which in a formal manner expresses specified property of the real system. It carries information of a specific feature of the system, i.e. information about the quantity of the particular quality, while neglecting all other qualities. Measures have three important roles: 1) ***Informing***. Measures are the carriers of information, which are thus more accurate and complete. 2) ***Comparability***. Measures allow comparison of different systems on the observed features. They are a standard of comparison - etalon. 3) ***Integration***. As a medium of communication between people, the measure has a large effect on strengthening the integration between them, because, lowering transaction costs, facilitates communication and cooperation. Indead, the development of civilizations followed the development of the measurement system.

As the measure is a model of the real system, its quality is basically expressed as the quality of any other model. The following are the basic features that determine the quality of the model. (Radenković, Stanojevic, Markovic (2004), Culligan (2004), Kerzner (2009)): 1) ***Relevancy***. Contextual compatibility of measure, that is: relevance of the information carried by the measured values. We need to make sure that the measurement instrument actually measures what we want to measure. 2) ***Accuracy***. The degree of vicinity of the measured value to the actual value. How the measured value is close to the actual value after measuring. 3) ***Precision***. The consistency of the results over time, in the situations with the same circumstances; That is: the degree to which repeated measurings under the same conditions, give the same result. 4) ***Sensitivity***. If specific feature is measured, what is the probability that the system actually has this feature. 5) ***Specificity***. If the absence of some feature is measured, what is the probability that the system really does not have that feature. 6) ***Cost of measurements***. The total cost of the measurement process (in cash). 7) ***Measuring speed***. The time during which measuring can be performed. 8) The measure is ***valid*** if it is *accurate* and *precise* (Culligan, 2004). It follows that the test cannot be more than what is valid reliable, ie. reliability is the upper limit of validity .

First of all, anyone must measure in a scientific way, to find the variation limits, in any type of scientific knowledge and knowledge management. Appearing in philosophy as an antithesis to Socratic identity, *variation* is the natural consequence of the impossibility of there being several identical things: “How can several objects be identical if there are more of them?” An answer formulated in a purely philosophical spirit becomes the most pragmatic vision of variation: “They are not identical. I need to distinguish them by something. If they did not differ, we would not be able to perceive them as such” (Ionescu, 1993). Such multidimensional and implicit phenomenon as knowledge is very hard to be abstracted toward comparison among different instances. Identity, formulated by Socrates “ab initio” as an intrinsic quality of the object, evolves towards defining through comparing and relating, and generates the *stationary* or the “premise of variation”. Plato placed variation within two of the five universal concepts applicable to all things, viz. *difference* and *change*, which followed *existence* and *identity*, yet before *resistance*. The paradoxes of ancient Greece, generated by the absolutely special depth of ancient Greek thought, provided the essential delimitations between variable and constant, dynamic and stationary. Zeno’s arrow paradox can be answered, after nearly two and a half millennia, by modern statistical physics, through describing the opposition between wave and particle, since *what is in a point cannot be moving or evolving, and what is moving and evolving can be found at no point*, as the memorable formulation of Louis de Broglie runs (1966). The development of logic, along with the use of mathematical induction, had the final premise of *apparently limiting independent variation*. The very “aletheia”, or the visible truth of classical Hellenic logic, has the two faces of Janus and expresses *spatial and temporal variability*.

Identity in itself contains its opposite, in the concept of difference (variation)*, in the inimitable Hegelian spirit*. The logic of falseness and truth is transformed, by the paradigm of variation, into a simple *alternative type variable* (F/T). In Stefan Odobleja's philosophical thought (1938), against the backdrop of the logic of the apparent or related variables, as well as that of real or free variables, the "variability of species and natural selection" develops resonantly. Even Darwinism finds that variations occur without apparent cause, spontaneously, and distinguish three major types: a) defined variations, which occur when all or nearly all the offspring of individuals, subject to the influence of certain conditions for several generations, change in the same manner; b) undefined variations or changes, which occur in some individuals of a population and "can be regarded as indefinite effects of the conditions of life" (while effects appear as random in relation to the conditions, undefined variations are either useful, or indifferent, or even harmful); c) correlative variations, which are the result of the logic of the correlation between organs (causing virtually the modification of an organ in a certain way, and entail the modification of the organ it is correlated with).
Phenotypic variation, seen as the totality of all biological variations (Vp), is the sum of two components of the aggregate type, namely the variation caused by the influence of environmental factors (Ve, or the "environmental variation" component), and the variation caused by the contribution of segregating genes (Vg, or the "genetic variation" component):

Vp = Ve + Vg < – resonant or interfered – > $(\sigma_g^2)=(\sigma^2)+(\sigma^2)$ (1)

Similarity with the statistical rule of adding explained variance (the mean value of group dispersions) to residual dispersion (the average of group dispersions), the resulting amount being nothing else than the dispersion of the population or general community, confirms the existence of the *paradigm of variation* as *isomorphism*, the computing relations being resonant with the rule of adding dispersions, they finally indicate the calculation formula for the coefficient of determination (Săvoiu, 2009).
Heritability or the proportion of the total variation that is controlled by heredity ($H = h^2$) is a relation between the variation determined by multiple genes with additive effects (V_a) and phenotypic variation (V_p):

$$H = h^2 = \frac{V_a}{V_p} \text{ or } H = h^2 = \frac{V_a}{V_e + V_g} \quad (2)$$

hence:

$$h = \sqrt{\frac{V_a}{V_p}} = \sqrt{\frac{V_a}{V_e+V_g}} \text{ <- resonant or interfered – > } R = \sqrt{\frac{(\delta^2)}{(\sigma_0^2)}} = \sqrt{\frac{(\delta^2)}{(\delta^2)+(\sigma^2)}} \quad (3)$$

The two essential Darwinian categories, heredity, as a property of living beings to develop *the same* characters, and variability, i.e. the permanent emergence of *differences* between the individuals of the same species, are the support of evolution by selection (in the sense of transformation of species), and, englobed in a much more general biological notion, they represent the support of speciation (the emergence of new species from old ones, or the evolutionary development of a biological species, as by geographical isolation of a group of individuals from the main stock). Teleonomy has currently become the science of researching living organisms, due to their specific features, which include causality, finality, and especially due to their development towards higher *differentiated, functionally superior structures* (teleonomic capacity). The temptation of *lex*ification of biology, in the scientific manner of thinking (Săvoiu and Iorga Simăn, 2012), focused on the *paradigm of variation* in biology, is resonant with the scientific fields of logic and mathematics (as vague final influences of thermodynamics):
Prima regula: Variation (variability) does not exist alone, but it co-exists in a balanced manner along with stability (heredity).
Secunda regula: The total variation is the sum of two components, bringing together key / essential factors, which are explanatory and nonessential or residual.
Tertia regula: The proportion of the total variation, which is *controlled* by a key factor, is a determinable ratio.
Quarta regula: The various partial variations are correlative, and one can determine the existence, the direction and the intensity of the relationship between the partial variations in the total variation.
Quinta regula: Evolutionary processes contain both correlative and non-correlative variations, and, in so far as the system in which they occur is temporarily closed or static and there is a universal unit of measurement, the total sum of the variations becomes relatively constant, and the regressive evolution is irreversible (entropic). A final remark to the variation paradigm, as applied to social and natural sciences and scientific knowledge, is that biological variation can be considered the fundamental factor in the process of evolution, including knowledge and knowledge management evolution.

One of the main characteristics of knowledge that causes a specific approach to its measurement is the inability of measuring knowledge directly. In contrast to physical measurements, where certain features of the object can be measured directly (for example, length), knowledge measurement in most cases can not be performed directly (Kyburg, 1984). Therefore specific approaches need to be developed. In the first

category of approaches, knowledge is viewed in a static way, while in the second in a dynamic way. In the static perspective structural measures of knowledge are used, and in the dynamic perspective functional measures of knowledge are used. ***Structural measures*** include, for example, the number of models either in textbooks, computer programs, the college courses etc. Disadvantages of static perspective are as follows (Vukić, 2012): 1) The uncertainty in the prediction , 2) Separation from the experience, 3) Externalisation. On the other hand, the ***Functional measures*** include the Performance Measurement. The basic idea of performance measurment system has been expressed by modified composite score model, consisting of the following elements: time, resources, information, quality, quantity, performance and knowledge. Fixing of the five elements and measuring sixth, the seventh element (which in this case is knowledge) can be indirectly measured. For example, fixing the information, resources, time, effects and quality, reached quantity points to level of knowledge. In second case: fixing the quantity, quality, effects, time and resources, the amount of required information needed indicates the level of knowledge. By performing the analysis of the current practices in knowledge measuring methods, classification given in the following table can be made (Vukić, 2012):

Table 1: Knowledge measuring methods and measurement units

	Category	Subcategories	Examples	Possible unit
A	**SIMULATION**	***Readings***. ***Listening***. ***Training***.	*-Read literature-* -Lectures/Talks attended- -Computer simulation*, Real simulation-*	*-Number of characters-* -Number of hours- -Number of hours-
B	**EXPERIENCE** Implicit knowledge	***Cycluses***. ***Events***. ***Outputs***.	*-Project realized, Repeated activities-* *-Events/Situations carried out-* *-Generated outputs-*	*-Number of repeated cycluses, of standardized size/complexity-* *-Number of elementary events-* *-Number of generated outputs, of standardized complexity-*
C	**AKADEMISM** Explicit knowledge	***Patents***. ***Publications***. ***Speeches***.	-Papers*, Models, Tables, Formulas, Code, Patents-* *-Articles, Books-* *-Presentations, Talks-*	-Number of standardized papers, models etc- *-Number of characters-* *-Number of hours -*
D	**RECOGNITION** & RANKING	***Test***. ***Tournament***. ***Assessment***.	*-Questions, Assignments-* *-Competitions-* *-Performances, Interview-*	*-Number of standardized score points-* *-Number of standardized score points-* *- Number of standardized score points -*

Current challenges in measuring knowledge are numerous. Literature and research in this area is so fragmented that there is no widely accepted model or theory. (Fisher and White, 2000) . Therefore, humanity is limited to the lack of an integrated approach to the knowledge measuring (Boudreau, 2002). The following challenges in measuring knowledge had been identified (Reich, 1994) 1) ***Confusion***. Dispersion in understanding the concept and defining the term “knowledge”. 2) ***Chaotic state of measures***. Chaotic state of dimensions and indexes of knowledge, with the complete absence of system of them. 3) ***Nonmodularity of knowledge***. Inability to observe large blocks of knowledge as the sum of fundamental (unit) elements without significant loss of information. This is particularly true for the knowledge measuring, because the important feature of knowledge is a huge number of potential connections between those elements. Therefore, the binary operations are here critical and must be taken into consideration when establishing measures, and their preservation is essential to the validity of the measure. Therefore, a valid measure must guarantee preservation of binary operations (that is connections) of the real system. 4) ***Operationalization***. It is interesting to notice that there is a lot of attempts for conceptualization of cognitive structures, but very few attempts for their operationalization, that is practical application. Hardly anyone has attempted to directly measure those cognitive structures. (Kanwar, Sims and Olson (1981), and Borgatta Carboni (2007)).

5. KNOWLEDGE INDICATORS

Knowledge indicators (indexes) are measures that indirectly point certain *dimensions of knowledge* (Vukić, 2012). According to the authors, it is important to distinguish between the two. While on the one hand, the dimensions are describing certain features of the knowledge system (and they are permanent), on the other

hand indicators point to one or more of these dimensions (moreover indicators may change as better are adopted). The following are indicators proposed by different authors:

Bodreau (2002) had classified indicators of knowledge into three categories: indicators that indicate the knowledge stocks, indicators that indicate the knowledge flow and indications of knowledge enablers.

A) ***Knowledge stock*** refers to the current level of knowledge in the observed time. Next set of index should indicate the level of knowledge in the system at a given time: 1) *Accounting for Intangibles* (Nick Bontis, 2001). Knowledge assets are blocks of knowledge that are expected to generate added value for the company in a period of time that is difficult to predict (Boisot 1998). 2) *Financial Statement Augmentation* (Intellectual capital report). This report is neither standardized nor obligatory and what it will include varies from organization to organization. 3) *Patents, Publications, Citations*. Patents and publications are the product of knowledge while number of citations indicates the quality of knowledge. Spencer (2000) examined archival data on issued articles within the Japanese and U.S. companies. He was measuring the volume (number of articles), quality (number of citations from outside the organization) and breadth (number of different organizations whose scientists have cited the work). 4) *Education and Training*. Number of hours dedicated to education and training and assessment scores. 5) *Organizational Experience and Rivalry Patterns*. Experience includes the amount of output the system produced or time spent in producing particular type of product. According to this idea, the more time the system spends generating output, the more knowledge about it system has, as a consequence of selicting those decisions over time that give better effects. Experience is also measured according to the degree of exposure to competition and the degree of rivalry - competitive experience (Ingram and Braum, 1997). 6) L*earning curve* indicates the experience and thus the knowledge, by showing the dynamics of declining of product unit cost. Decline in unit cost comes with experience in the respective manufacturing process. 7) *Team performance* indicator is used to measure the knowledge of a team. Team performance is measured as a percentage of accomplishment of the mission, that is the proportion of tasks completed successfully and the total number of tasks. Another way to measure performance is to measure the time it takes to perform the mission and to devide that number with planned time. The third way is to calculate the number of tasks that are executed per minute. (Cooke, Preston, Kiekel, Salas and Stout, 2003).

B) ***Knowledge flow*** can be measured as the difference between two consecutive levels of knowledge (that are measured by previously defined indexes). 1) *The knowledge flow between individuals*: a) The degree to which individuals share information with each other - Does the staff provide information to their colleagues? b) The convergence of attitudes and perceptions (beliefs and mental models) is also one of the indicators of knowledge transfer among individuals. c) Degree of standardization - Consistency of terminology and formal models indicates transfer of knowledge. 2) The knowledge flow among teams: a) Change the observed performance of the team. b) Formal transfer of technology: procedures, techniques, tools, patents. 3) *Knowledge spillovers and the loss of knowledge in the system*: a) Number of patents and citations that took the competition. (Jaffe, Trajtenberg and Fogarty, 2001). b) Staff turnover ratio - In particular, key managers and professionals. (Deeds, 2003).

C) ***Enablers*** are the structures and processes established by the organization, which aim to change or maintain knowledge stocks or knowledge flows. Enablers facilitate changes in the knowledge levels. These include social networking, organizational structure, transactional memory, procedures, etc. However the very fact that they are present does not mean that their features are used and that the knowledge has been generated or modified. Therefore, this group of indexes only carries additional information about the potential and not the actual events in the system of knowledge. 1) *Geographical, Character, Political vicinity*. Several authors have studied the physical, character and political (attitudes, beliefs) vicinity (Maskell&Malmberg, Torstensson, Capello, Zahra) and concluded that those parameters have a positive impact on knowledge transfer. (Bordeau 2002). 2) *Organizational structure*. The organizational factors that can encourage or discourage the acquisition and use of knowledge are formalization, centralization, specialization, incentives, emphasis on scientific research and publications in the company etc. For example, high interdependence (specialization) requires a lot of contacts, which allows preconditions for an exchange of diverse knowledge. 3) *The number of joint ventures with other systems*. This indicator follows the next idea: The greater the number of joint ventures, the greater the chances of raising the level of knowledge. These include: alliance, joint ventures, franchises and the like. 4) *The costs of R&D* indicate how the organization deals with the generation of new knowledge that is innovation in a systematic way. (For more details see: Bitzer, 2005) 5) *Aquisition Capacity* stands for the capacity of a system to adopt new knowledge. 6) *Network*. The characteristics of the network within the system (individual or organizational network) are to be observed - The following network characteristics are important: Size, Scope (the contacts in different categories), Strength, Intensity (frequency, duration and intensity of interactions), Structure, Communication, Individual movement. 7) The degree of trust. The greater degree of trust between people is, the more open for learning system will be (Fiol, 1985). 8) *Tacitness*. (1/ knowledge formalisation that is 1/degree of knowledge formalisation). Tacitness indicates

the ease of knowledge transfer. The greater the degree of formalisation is, the transfer of knowledge is done with fewer losses and thus the potential spread of knowledge is greater. This is neither good nor bad by itself (tacitness is harmful in the context of cooperation, but it is useful in rivalry and competition context since it makes the knowledge copying process more difficult.

ICM group had classified the knowledge indicators in 5 categories: Customer capital, Structural capital, Human capital, Value creation and Value extraction. (Liebowitz and Suen, 2000)

Customer capital : 1) Market share, 2) Customer rating, 3) Satisfied customer index, 4) Number of new customers, 3) Annual sales/Customer, 4) Average customer size, 5) Average time from customer contact to sales response, 6) Ratio of sales contact to sales closed.

Structural capital. 1) Administrative expence/Total revenues, 2) Processing time, outpayments, 3) Computers/Employee, 4) Corporate quality performance, 5) Investments in IT, 6) Contracts filed without error.

Human capital. 1) Number of employees, 2) Number of managers, 3) Average years of service with the company, 4) Revenues/Employee, 5) Profits/Employee, 6) Employee turnover, 7) Average age of employees, 8) Percentage of company managers with advanced degrees

Value creation. 1) Training expence/Employee, 2) Average customer duration with the company, 3) R&D invested in the basic research, 4) R&D invested in product design, 5) R&D invested in applications, 6) Investment in new product support and training, 7) Satisfied employee index, 8) Relationship investment/Customer, 9) Training expence/Administrative expence.

Value extraction. 1) Profits resulting from new business operations, 2) Revenues resulting from new business operations, 3) RONA resulting from new business operations, 4) Total assets, 5) Return on net assets, RONA, 6) Market value, 7) Patents pending

Roos, Roos, Dragonetti, Edvinsson (1998) classify knowledge indicators into two categories: Human capital and Structural capital, which is also described by Liebowitz and Suen (2000):

Human capital. 1) Percentage of employees with advanced degrees, 2) IT literacy, 3) Hours of training/Employee, 4) Average duration of employment, 5) Hours spent in debriefing, 6) Hours spent by senior staff explaining strategy and actions – overlap expertise, 7) Leadership index, 8) Motivation index, 9) Savings from implemented employee suggestions, 10) New solutions or products or processes suggested, 11) Background variability index (both on individual and group level), 12) Company diversification index.

Structural capital. 1) Percentage of supplier/customer business accounted for, 2) Length of relationship, 3) Partner satisfaction index, 4) Customer retention, 5) Administrative expences/Total revenues, 6) Revenues from patents, software, data, databases, 7) Processes completed without error, 8) Cycle/process times, 9) Training Expenses/Employee, 10) Training Hours/Employee, 11) New patents, software etc, 12) Renewal expenses/Operating expenses.

Canadian Management Accountants (CMA) stated the following list of knowledge indicators in the organisations: 1) Number of new products, 2) Number of new customers, 3) Success ratio, 4) Percentage of customer business, 5) Productivity index, 6) Number of processes reviewed, 7) Number of processes changed, 8) Percentage rated acceptable at first review, 9) Numbers of patent filed, 10) Number of ideas implemented from the suggestion box, 11) Ratio of temporary/total employment, 12) Traditional quality indicators, 13) ISO and customer satisfaction. (Liebowitz and Suen, 2000). **Leif Edvinsson i Michael Malone** The two authors offered a set of indicators in a report on intellectual capital (Universal Intellectual Capital Report). Indicators are classified in five categories: Financial focus, Customer focus, Process focus, Renewal and development focus, Human focus. (Liebowitz and Suen, 2000)

Jay Liebowitz i Ching Suen (2000) sugested several new indicators as as a complement to the ones previously mentioned: 1) Number of new collegue to collegue relationships spawned, 2) Reuse rate of freequently accessed-reused knowledge, 3) Dissemination of knowledge sharing (distribution of knowledge to apropriate individuals), 4) Level of knowledge sharing profficiency, 5) Interactions with academicans, consultants and advisors, 6) Number of apprentances that one mentors in the company, and the sucsess of the apprentances, 7) Number of patents/trademarks produced, Number of articles/books written, Number of talks/workshops given, 8) Number of lessions learned and best practices applied, 9) The number of new ideas gennerating new products or services.

6. CONCLUSION

The main advantage of the indicators is that they can be easily obtained. Most of them are already available because of their wide use for other purposes. The main limitation of these indicators is their stochastic nature. They do not measure the dimensions of the knowledge directly, instead they only can (but need not)

to point some of them (Liebowitz and Suen, 2000). This brings a significant amount of uncertainty in decision making based on knowledge indicators. Moreover, some indicators have narrow scope of application, that is, they are constrained to certain industries. Examples which may be mentioned are numerous, and the following is to name a few: 1) Patents and citations are not applicable in most industries . Their absence does not mean lack of knowledge. 2) R&D investments are reflecting the invesments into knowledge but not the knowledge itself. As the generation and accumulation of knowledge depends on the process of acquisition (it is highly “path – dependent”) this characteristic makes it almost impossible for precise approximation with this indicator (Bettis and Hitt, 1995). 3) Intellectual capital, which is calculated as the difference between market value and book value (Edvinsson , Malone, Sveiby) cannot be a valid indicator of knowledge. Otherwise, the intellectual capital could be expressed as a mathematical function of accounting methods. Detailed review is presented in the Larsen, Bukh and Mouritsen, 1999). Therefore, humanity is in the initial stages of establishing a system that will successfully measure their knowledge . This "young" system of measures, naturally, is not sufficiently integrated nor consistent. However, current measures, although insufficiently integrated and therefore suboptimal, are a good starting point for both operational measurement of knowledge, and for the further development of measures.

Further work of standardizing units of measure for different listed indicators, as well as integrating indicators and model them as regressional models (or other statistical models), proposing their contribution to the features of knowledge is to be taken.

MARKETING MANAGEMENT

CONSUMERS´ ATTITUDES TOWARDS PURCHASING FASHION COUNTERFEITS

Milica Kostić - Stanković[1], Jelena Cvijović[2]
[1] University of Belgrade, Faculty of Organizational Sciences, milicak@fon.rs
[2] University of Belgrade,Faculty of Organizational Sciences, jelenacvijovic85@gmail.com

Abstract:*The rapid growth of counterfeiting can be attributed to the increase in world trade, emerging of new markets, technology advancements and the increasing number of product categories that can be counterfeited. Copies of luxury fashion brands represent themost common category, as they incur low manufacturing costs and are easy to be solddue to growing consumer demand.Reason for the expansion of counterfeiting around the worldis based on consumers' attitude that there is nothing unethical about buying or acquiring fakes. In order to supress this activity, greater efforts should be put on creating consumers' awareness about multiple negative social and economic effects that counterfeiting actually have.*

Keywords*:fashion counterfeits, consumers, attitudes, motives, demand, negative effects*

1. INTRODUCTION

The phenomenon of counterfeiting,which is the general name for production, distribution and consumption of counterfeit goods,has significantly arisen during last two decades, expanding globally and affecting both developed and developing countries and, therefore has become a serious social and economic problem. Today, counterfeiting trade accounts more than 7% of the global trade and grows at the rate of 15% per annum (Ergn, 2010). Republic of Serbia, as developing country, represents one of the markets suitable for selling and buying such products, due to poor state of the economy and low purchasing power. China is the main producer of the counterfeit products in the world (Hung, 2003). Other sources of counterfeits are Russia, Argentina, Chile, Egypt, India, Israel, Lebanon, Thailand, Turkey, Ukraine, Venezuela, Brazil, Paraguay and Mexico (Chaudhry and Zimmerman, 2009).

Counterfeiting has been expanding due to strong worldwide and national demand (Amendolara, 2005). Therefore, greater interest has to be put on understanding consumer behaviour with regard to motivation for purchasing counterfeit goods. Legal consequences and consumer education are most effective options for addressing the demand side of the counterfeit issue (Norum and Cuno, 2011). Berman (2008) stated that companies that produce genuine brands should contribute to the reduction of the counterfeiting problem through the development of consumer education programs that emphasize the personal, social and economic dangers it causes.

Chaudry and Zimmerman (2009) noticed that the types of products being counterfeited are broadening (Figure 1). Although there is a huge number of product groups that can be copied, products with a high brand image and low production technology are the preferred targets of counterfeiters (Penz and Stöttinger, 2005). That´s why branded or luxury fashion counterfeits represent the most common group of counterfeits (Pollinger, 2008). The OECD (2008) reported that fashion items (clothing, jewellery, accessories and footwear) represent the largest part of counterfeit trade, taking into account that textile sector and jewellery together make up 66,2% of all interventions by European Customs.

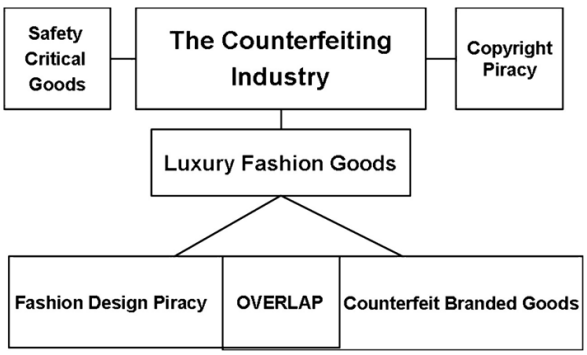

Figure 1. Mapping out counterfeiting (Wall and Large, 2010)

2. TYPES OF COUNTERFEITS

Generally, counterfeits are defined as reproduced copies that are identical or substantially indistinguishableto the legitimate articles, including packaging, trademarks and labelling(McCarthy, 2004). Theyattract consumers as they clearly look like the genuine brand, yet ”cost only a fraction of the price of the original” (Rathet al., 2008). According to Yang and Fryxell (2009), counterfeiting represents the unlawful imitative manufacturing of products and services that are protected by owners' intellectual property rights with the goal to earn profit. The definition proposed by Staake et al. (2009) is following: “Counterfeit trade is the trade in goods that, be it due to their design, trademark, logo, or company name, bear without authorization a reference to a brand, a manufacturer, or any organization that warrants for the quality or standard conformity of the goods in such a way that the counterfeit merchandise could, potentially, be confused with goods that rightfully use this reference”.

As suggested by Yang and Fryxell (2009), generally, there are two main kinds of counterfeits - the counterfeiting of commodities and the counterfeiting of symbols attached to products. One of earlier studies, made by Phau and Prendergast(1998), divided counterfeits into six categories. In case of first category,high-quality fakes, both stores and consumers can be misled, by confusing them with originals. Second category, called “piracy”, considersthat the customer is aware of the faked object which is usually sold at a significantly lower price. Third, imitations or ”knock-offs” are not identical to the original, but they are similar in substance, name or form with a widely known product (Berman, 2008). Fourth category represent so called”grey products” that factories, contracted by the genuine brand manufacturers, produce in greater quantities than required and then sell as overruns illegally (Vida, 2007). Fifth category, custom-made copies or ”super fake” products are replicas of trademark designs of branded products made by legitimate craftsmen and the only item missing from the original is the logo or brand name(Hilton et al., 2004). Goods that are similarly packaged or with similar trademarks and labellingare also considered counterfeits and represent the sixth group (Phau and Teah 2009).

Regarding the consumer’s perspective, counterfeits can be either deceptive or non-deceptive. Deceptive counterfeiting involves purchases where consumers believe they have bought a genuine article when in fact it is a counterfeit (Staake et al., 2009), as is often the case in categories such as automotive parts, consumer electronics and pharmaceuticals (Vida, 2007). In other cases, however, consumers are typically aware that they are purchasing counterfeits, which is non-deceptive form of counterfeiting. It is particularly prevalent in fashion brands (Nia andZaichkowsky, 2000) where consumers are ”often able to distinguish counterfeits from genuine brands based on differences in price, the distribution channels, and the inferior quality of the product itself”. Nevertheless, the quality of fashion copies has improved dramatically during recent years, even resulting in the existence of ”super copies” (Wilcox et al., 2009). Gentry et al. (2006) also supported that the quality of counterfeit luxury products has improved over the years thus it is harder and harder to differentiate the counterfeitsfrom the genuine luxury brands.

3. NEGATIVE EFFECTS OF COUNTERFEITING

Empirical and academic evidence show that counterfeiting is a harming and risky business (Lewis, 2009). It is more than evident that counterfeiting causes general negative influences on government tax revenues, market order and fair competition, as well as on overall economic development. Counterfeiters participate in the economic black market, because they pay no taxes, causing states to lose legitimate revenue (Ha and Lennon, 2006), so their damaging effect on businesses, national economies, consumers and on society as a whole is more than obvious. Consumers who purchase counterfeited articles risk funding nefarious activities, contributing to unemployment, creating budget deficits and compromising the future of their country in the global economy(UNICRI, 2009; Santos and Ribiero, 2006). The negative effects include loss of goodwill of brand names,lowering consumers’ confidence in legitimate brands and company reputations which further lead to loss in sales or elimination from the market (Monirul and Han, 2012).Furthermore, there are increasing cases of health hazardsand threats to consumer health and safety and severe economic anxiety for some developing countries that can be linked to counterfeiting (Gessler, 2009).

Gessler (2009) divides ”the true costs of counterfeiting” - the consequences of the phenomenon, in six categories: the cost to brand owners, government burdens, the effects counterfeiting has on consumers, child and forced labour issues in the production of these counterfeits, organised crime and terrorist funding activities and the moral cost of counterfeiting. Some authors differentiate between two types of harm caused by the purchase of counterfeit goods: personal and societal harm. Personal harm means that the individual itself is affected by purchasing counterfeit products, whilesocietal harm implicates that counterfeit trade affects the society as a whole. Thompson (2004) posit that ”the average consumer does not consider overall societal issues when faced with the option of purchasing an original or a counterfeit product”, which is the main reason for expansion of counterfeiting.

4. ATTITUDES TOWARD COUNTERFEIT FASHION PRODUCTS

In the case of explaining counterfeit purchase behaviour, Veloutsou and Bian (2008) and De Matos et al. (2007) suggest that the attitude towards buying fake products depends on the overall perceived risk, which is the most important variable to predict consumer attitude toward counterfeits. If it is moderate, it is highly likely that consumer will do the purchase. Bian and Moutinho (2009) found evidence that perceived risk is a factor that negatively influences the purchase intention of counterfeits. A person's overall perceived risk consists out of six different risk dimensions: financial, performance, psychological, physical, social and time risk (Veloutsou and Bian, 2008). Social risk can be defined as the negative outcome one attaches to "being caught by significant others" when possessing or purchasing a counterfeit. Time risk is seen as the time one might lose searching for a counterfeit article. Financial risk involves the potential loss of money when buying a counterfeit. Physical risk is the possibility of bodily harm or health hazard. Performance risk refers to the chance of malfunctioning of the fake product that is bought. In explaining psychological risk, the most appropriate definition is given by Penz et al. (2009): "psychological risk refers to the experience of anxiety or psychological discomfort arising from anticipated postbehavioral affective reactions such as worry and regret from purchasing and using the product".

As consumers obviously play a leading role in the maintaining of counterfeit trade (Yoo and Lee, 2009; Bian and Moutinho, 2008), it is important to gain a deeper insight in potential motives of consumer's willingness to purchase non-deceptive counterfeit products. Vida (2007) concluded that a consumers' attitude toward counterfeit luxury products refers to the degree people are able to rationalize counterfeiting practice with respect to the costs, pricing and quality of genuine with counterfeit products. The attitudes could be divided into two specific issues: attitudes towards counterfeiting and attitudes towards market practices. If a person's attitude towards counterfeiting is favourable, it is likely that he or she would consider the purchase of counterfeit products. The attitude towards market practices actually represents person's beliefs and feelings towards the operations of some organization. If a person holds an unfavourable attitude towards the high-profile operations of branded goods manufacturers and the snob appeal of their products, it is less likely that person would purchase the branded originals. Rather, these people are more likely to purchase the counterfeit version of branded goods(Wee et al., 1995).

The two major reasons why consumers develop positive attitudes toward buying counterfeits are economic benefits and hedonic benefits. The most obvious factor that motivates purchases of counterfeit brands is their relatively low price. In cases when consumers cannot afford to buy original fashion designer products because they are too expensive,but want to possess something that look alike, they are likely to decide on buying counterfeits. Consumers are not affected by low quality and poor materials because they do not see counterfeits as inferior choices when they experience such budget constraints. On the contrary, most of these consumers appreciate the economic benefits counterfeits provide them (Penz et al. 2009; Ang et al.,2001). Consumers believe they will have the identical appearance whether they wear or carry a counterfeit or an original brand, so they will get the prestige/status of the original brand without paying for it (Penz and Stottinger 2005). The hedonic benefits of counterfeit purchases impose that consumers buy counterfeit brands because they want to demonstrate that they can afford branded goods, to show that they belong to a particular social group, or to use the product for symbolic self-extension. They view that the brand names, labels, various design characteristics such as logo, colour etc. are valuableby themselves and they satisfy a desire for symbolic meanings such as social and financial status, recognition and superiority (Wee et al., 1995).

When it comes to the selection of fashion-related goods, some very specific factors determine buying behaviour. Determinants on intention to purchase counterfeit goods have been classified as psychographic (attitude toward counterfeiting, brand status and novelty seeking), demographic (age, educational attainment and income) and product-attribute (appearance, image, perceived fashion content, purpose and perceived quality) variables(Rath et al., 2008).Smith et al. (2008) found self-reported past buying behaviour as a strong predictor of future purchase intentions. Also Ouelette and Wood (1998) suggest that the frequency of performing certain behaviour in the past has a direct impact on future behaviour.

In literature, following factors are mentioned as major determinants of person's attitude towards counterfeiting and purchase intentions: fashion consciousness, public self-consciousness, ethical judgment and ethical obligation.

Fashion consciousness refers to a person's degree of involvement with the styles or fashion. An individual does not have to be either a fashion opinion leader or a fashion innovator to be considered fashion conscious. Fashion involvement represents a consumer's perceived importance of fashion clothing (O'Cass,

2001). Previous researches had demonstrated that fashion involvement influences consumer behaviortowards purchasing fashion products (Penz and Stottinger, 2005; Bertrandias and Goldsmith, 2006). Penz and Stottinger (2005) found that fashion involvement had a strong influence on an embarrassment potential and weakens the attitude that purchasing counterfeit products is a desirable behaviour. On the other hand, Wee et al. (1995) revealed that ”for fashion related counterfeit products, purchase intention is determined by the similarities in appearance, quality and image projected by the counterfeit version compared to the originals”, which means that those who are more fashion consciousare more likely to seek for ”perfect counterfeits”. Gentry et al. (2006) also found that consumers consider counterfeits as a relatively cheap way to keep up with the latest fashion trends.

It has been shown that consumers form positive attitudes toward things that help them define their social and personal identities, express who they are, who they want to be and how they want others to see them. Fashion-related goods may be seen as an especially effective product category in this regard (Dodd et al., 2000). Individuals who have a rather vague and uncertainself-concept tend to possess low self-esteem, which renders them less certain that they will be able to meet what they believe are others' standards for worthiness and make them more exposed to the outside influences on their self-concept. When people move on social scale, they may adopt new patterns of consumption to symbolize their new social position. Consumers who are buying branded products may be described as self-conscious and especially concerned about the impressions that they make (Penz and Stottinger, 2005). According to Roux and Korchia (2006), consumers who choose buying counterfeitsover a genuine product are similarly concerned about impressions they leave on other people, although those projected images sometimes seem to create a tension or conflict between an original identity and a borrowed appearance.

The desire to possess various things can lead to a consumer acting unethically. ”Consumer ethics can be defined as the moral rules, principles and standards guiding the behaviour of an individual (or group) in the selection, purchase, use or selling of a good or service”(Penz and Stottinger, 2005). The perception of an ethical issue is an important basis of the ethical decision-making process. A person who perceives an ethical problem tends to behave more ethically than an individual who does not. Ethical obligation represents an individual’s internalized ethical rules, which reflect personal beliefs about appropriate behaviour (Shaw et al., 2000). According to Trevino (1992) ethical judgment is a cognitive process in which an individual judge which course of action is moral and form behavioural intentions based on that. In other words, if an action is judged as ethical, one is more likely to form an intention to perform it. Oppositely, if an action is judged as unethical, one is less likely to form an intention to engage in the action (Nguyen and Biderman, 2008).According to Penz and Stottinger (2005) the ethical perception plays an important role in the consumption behaviours, as it may have a self-binding effect on the individual. Consumers who have a higher ethical disposition would be more embarrassed if they were discovered wearing counterfeits and, therefore, most often choose not to buy such products.

5. STRATEGIES TO FIGHT COUNTERFEITING ACTIVITIES

Although governments and manufacturers of genuine brands, who experience both economic and noneconomic losses, take some action to protect their products from being copied, it is difficult to protect intellectual property rights in many countries, especially in less developed countries like Serbia, due to weak legal structure, their implementation and corruption. Law enforcement strategies, based on legal issues and concerns, in the form of more stringent penalties for convicted counterfeiters should been implemented by states authorities. Some manufacturers introduce product and packaging changes in the form of magnetic codes and special inks, holograms and implanting high technology “fingerprints” on parts of the articles as a symbol for authenticity (Figure 2). Retailers are most commonly blamed for the proliferation of counterfeits (Prendergast et al.2002), as they perceive the selling of counterfeits as risk and cost free and those counterfeiters rarely go out of business (Green and Smith, 2002). Olsen and Granzin (1992) stated that retailers would accept the responsibility in fighting counterfeits only if the government and manufacturers share the obligation. If they feel that it is a trivial problem, they will neither share the responsibilities nor support the manufacturers and the governmental authorities.

But, law enforcement targeted at counterfeit manufacturers and retailers may not solve the entire problem, as its root derives from the consumers’ willingness to purchase copied products. Manufacturers of original brands, together with the countries’ policy makers,should more intensively expand public awareness of the harm of counterfeiting through advertising, public forums etc. Marketing campaigns designed to evoke public awareness of counterfeiting may have a positive echo and change the attitude towards buying such products. Especially successful can be integrated marketing communications campaign that has a goal to directly influence the behaviour of a heterogeneous target public (Kostic – Stankovic, 2011). Synergy of various communication channels should be used for informing the consumers about the societal

consequences of counterfeiting, in order to lower purchase intentionsof counterfeit products. Penz et al. (2009) found that ”informing consumersabout the business practices of counterfeiters may change their attitudes toward thephenomenon”. Thus, it is needed to change consumers’ attitude in order to reduce demand for such counterfeit luxury products and reverse this growing trend.

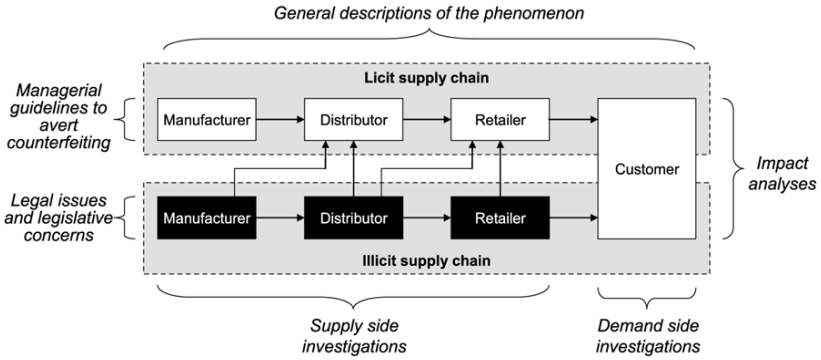

Figure 2. Strategies to suppress counterfeiting (Staake et al., 2009)

6. CONCLUSION

Despite the general favourable attitude of those consumers who believe that fashion counterfeits bring benefits such as cheaper price and luxurious image, negative effects of purchasing copied products are nowadays more than obvious and serious.Therefore, it is necessary to change consumers’ attitude in order to reduce demand for counterfeit fashion products and. Besides imposture of legal restrictions, it is important to create public awareness that purchasing fashion counterfeits is unethical activity that holds certain risks, such as poor quality, loss of time and money, potential social embarrassment, as well as participation in the economic black market.

Abstract: *Nowadays, a growing number of companies is focusing on cost optimisation and lowering labour expenses. In this climate, companies are turning to talented and educated individuals who are ready to participate in their projects. Whether it is for profit or non-profit purposes, or it is done by using online technologies or without them, this new business model is called crowdsourcing. This term is used for describing outsourcing process that focuses on the power of people for solving different types of tasks. The aim of this paper is to define crowdsourcing and its difference from similar models such as open innovation, user innovation, open source and outsourcing. The authors put focus on the application of crowdsourcing in marketing, particularly in market research, product development and promotion, as well as on examples of successful practice in these areas. Finally, the conclusions regarding further use of this model will be presented by taking a closer look at its advantages and limitations.*

Keywords*: crowdsourcing, business model, marketing, market research, product development, promotion*

1. INTRODUCTION

The introduction of Web 2.0. opposite to the traditional Internet has marked the beginning of new business era that companies are currently adapting to. Le Deuff (2007) and O'Reilly (2005) describe Web 2.0 as "the utilisation dimension and not to the physical network that supports it", which tends to encourage sharing between users and collaboration that opens many new options for everyday business. By using Web 2.0, a company can switch from outsourcing activities to other countries or firms specialised in certain field to engaging individuals in its everyday activities (Nešković et. al., 2012). This model enables companies to gather ideas and suggestions regardless of the person's location. Crowdsourcing is one model of using people's ideas for improving everyday business, as well as gathering ideas for future projects of the company.

The concept of crowdsourcing has been present for a while, but the first use of the term was in an article published in Wired magazine in 2006 and written by Jeff Howe and Marc Robinson. Since 2006 the word "crowdsourcing" has been mentioned many times in the growing Internet community, in magazines and books. The term "crowdsourcing" has been discussed by Dahlander and Magnusson, (2008), and Agerfalk and Fitzgerald, (2008) and it has only been mentioned as an example of Web 2.0 by Tapscott and William (2007) and Albors et al. (2008). "The power of the crowd" (Howe, 2006) is related to many different versions of the contribution that a crowd makes, as well as different areas of use. Therefore, it is very important to distinguish crowdsourcing from similar models of using the contribution of a crowd. Most commonly, the terms mistaken for crowdsourcing are open innovation, user innovation, open source and outsourcing.

Open innovation and user innovation start from the same point as crowdsourcing – in the world of distributed knowledge, companies should not rely on their own research and development, but they should decide to gather some of their ideas and R&D functions from other companies and individuals. Open innovation is related to cooperation between firms, and user innovation is focusing on cooperation between product users who are solving issues with final products. Both open and user innovation are focusing on innovations and originality, while crowdsourcing is not restricted to innovations and often provides solutions that are not innovative at all. Open source can be explained as the application of crowdsourcing in IT industry. Howe (2008) describes crowdsourcing source as "an application of the open source principles to other industries". Brabham (2008) adds to that by saying that "it is obvious that crowdsourcing is not restricted to software development". While it is obvious that there are undisputable similarities in the business model of open source and crowdsourcing, crowdsourcing is a wider area and has a wider application than solely IT industry. The basic process of crowdsourcing and outsourcing is the same, with a client company that is seeking help from another subject. The basic difference between these two is that outsourcing is mainly focused on getting support and help from institutions, while crowdsourcing focuses on getting ideas from individuals.

2. DEFINITION OF CROWDSOURCING

Crowdsourcing is composed of two words: crowd and outsourcing and basically it means outsourcing to the crowd. It was first used on an Internet forum, but it was widely popularised by Howe and Robinson after they published an article in Wired magazine. Howe (2008) gives definition of crowdsourcing: "Simply defined, crowdsourcing represents the act of a company or institution taking a function once performed by employees and outsourcing it to an undefined (and generally large) network of people in the form of an open call." He adds that "the crucial prerequisite is the use of the open call format and the wide network of potential labourers". In a book he recently published and in posts on his blog (2008 and 2009), Howe gives two more precise definitions of crowdsourcing – *The White Paper Version*, and *The Soundbyte Version*. In *The White Paper Version* he describes crowdsourcing as "the act of taking a job traditionally performed by a designated agent (usually an employee) and outsourcing it to an undefined, generally large group of people in the form of an open call", while *The Soundbyte Version* describes crowdsourcing as "the application of Open Source principles to fields outside of software".

This is the basic process of crowdsourcing: First of all, a company identifies processes and activities that need to be improved by outsourcing them. Instead of turning to another company for help, or trying to complete these actions within a company, they are "released to a crowd of outsiders who are invited to perform the task on the firm's behalf for a stipulated fee" (Whitla, 2009). It can be done in two ways: by limiting the crowd to a group of people with qualifications of previous experience in the area, or by issuing an open call to all interested parties. These two options can be combined by limiting the call to the people from the area of expertise or to people who are most likely to have skills for successfully completing the task. Whitla (2009) notices that "sometimes a single task can be completed by many different users and each can be paid if they successfully complete the task". This sentence sums up the idea of crowdsourcing – enabling talented individuals to get paid for the jobs they do in their own dynamic and by using available resources. It also explains why crowdsourcing is becoming widely used: companies are able to get the solutions they need by paying less and being able to choose who they are hiring for the job.

Whitla (2009) describes the crowdsourcing process by using an example of Amazon's Mechanical Turk. Amazon's Turk was named after Hungarian nobleman Wolfgang von Kemplen who invented "the Turk" - the first machine capable of beating human at a chess game. Mechanical Turk is a platform that provides simple tasks - HIT's (human intelligence tasks) to individuals. These tasks require very little time and effort to complete, but they cannot be done by computers. Therefore, individuals are solving them and getting paid from couple of cents up to a US dollar, depending on their effort. Whitla (2009) uses HIT's to describe the process of crowdsourcing.

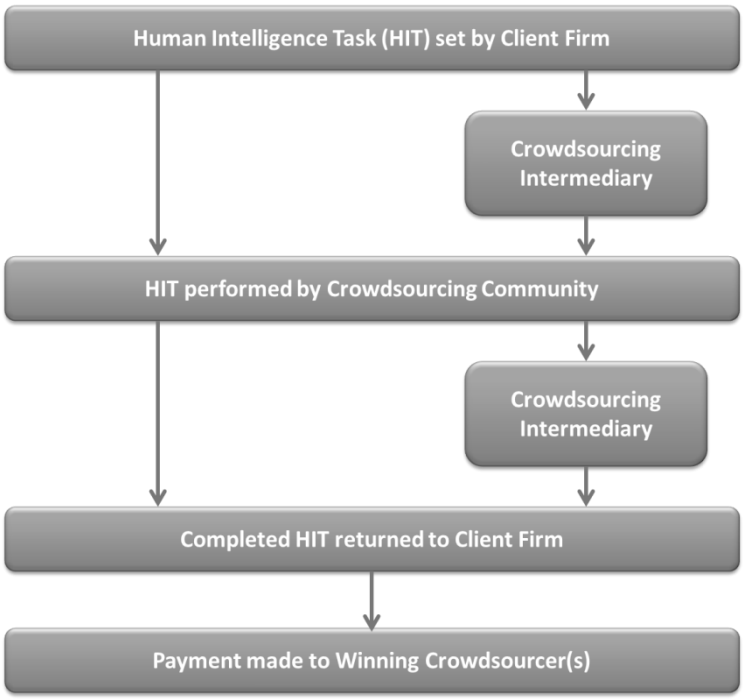

Figure 1: Crowdsourcing process

The basic model of crowdsourcing is the same and it is shown in Figure 1. There are alterations to this model depending on the industry and the type of tasks, but the idea of paying the crowd to complete certain processes remains as previously explained.

3. APPLICATION OF CROWDSOURCING

A call for crowdsourcing can be published in form of an open call or it can be limited to a certain number of people, as was previously mentioned. The question that arises is: What types of tasks can be crowdsourced? There are three types of tasks that can be outsourced to a crowd: routine tasks, complex tasks and creative tasks (Schenk and Guittard (2009)).

Routine tasks are a type of tasks that can be done very quickly and easily while requiring minimum time, such as data collection or marking text and images. This type of effort is usually awarded by micropayments. A perfect example of this routine are ReCaptcha, Open Street Map (OSM) and TxtEagle. ReCaptcha is widely used by websites for text recognition, when it is necessary to distinguish virtual robots from humans. OSM is used for collecting geographical data for creating a world map. Finally, TxtEagle helps mobile phone users to complete tasks by sending a text message. Routine tasks are, in most cases, published as an open call, given that almost anyone can participate in solving them.

Complex tasks that require more skills and knowledge are often limited to a closed group of people. This type of tasks can be solved in both profit and non-profit sector, and the companies pay more due to the effort required to complete the task successfully.

Finally, the third group of tasks are creative tasks. This is the earliest type of crowdsourcing which started long before the Internet, in the form of designer contests and competitions.

Companies usually crowdsource creative tasks with limitations only in the form of the solution that is required. This way the original and creative solutions are provided to the company. Monetary compensation for these tasks depends on the type of task, but usually these tasks are paid the most, varying from couple of hundred to couple of thousand US dollars.

4. APPLICATION OF CROWDSOURCING IN MARKETING ACTIVITIES

Even though there are many areas where crowdsourcing can be used, this paper will focus on the application of crowdsourcing in marketing. The main reason to do so is due to the fact that a growing number of firms is turning to customers and focusing on their requirements and preferences. The best way to do it is by turning to crowds for inspiration and ideas by using crowdsourcing.

According to Dawson (2011), there are several ways of applying crowdsourcing in marketing. These are shown in Table 1.

Table 1. Marketing application of crowdsourcing

Application	Description
Content creation	Generating marketing content such as videos, images or copy.
Idea generation	Creating ideas to identify or develop marketing initiatives.
Product development	Identifying insights to enhance existing products or develop new ones.
Customer insights	Gathering customer perspectives on current or potential products or marketing initiatives.
Customer engagement	Building greater participation and affiliation with the brand and company.
Customer advocacy	Tapping customers to spread word to their personal networks about products or services.
Pricing	Gaining insights on attitudes to possible pricing strategies.

Content creation is widely crowdsourced by giving customers a chance to provide content in different forms. Idea generation has been one of the most useful applications of crowdsourcing, given that there is a number of companies that benefited from having creative ideas coming from the crowd. One of the best examples is Starbucks's portal My Starbucks Idea, which has generated over 100.000 ideas for different aspects of business. Some of these ideas are related to the third area of application – product development. Dell's IdeaStorm portal is another great example of company benefiting from its loyal and creative customers, as

well as people with good ideas for new products. Customer insight, engagement and advocacy are a type of crowdsourcing primarily focusing on a narrow crowd – the customers, given that it is required to be a user of a product/service to be able to contribute in these areas. Finally, the question of pricing is often resolved by asking the people how much are they willing to pay for a certain product or a service.

Whitla (2009) was researching Human Intelligence Tasks (HIT's) and he identified the fields of marketing that are most suitable for their use, taking into consideration the nature of the tasks. By reviewing literature and already published HIT's, he singles out marketing research, product development and advertising and promotion as areas of marketing where crowdsourcing is most successfully used.

4.1. Use of crowdsourcing in market research

The most common form of applying crowdsourcing in market research is collecting data through surveys and questionnaires. Respondents are given a number of simple questions and the results are later used for creating product strategy. Given that these surveys provide monetary compensation to respondents, there is one big problem when using crowdsourcing for research: providing false data. Whitla (2009) notices that firms may restrict online surveys to a targeted population and that there is no way to prevent someone from imitating demographic to earn extra money. The payment may affect responses in another way – by keeping in mind that the company is paying them, many respondents may provide responses that represent an unrealistic image of a company or so called "desired responses". The best way to prevent this from happening is by using complex questionnaires that require some fields to be filled in own words, as well as requiring a minimum number of words. Poynter (2013) argues that, in recent years, many companies are researching the market by placing projects on crowdfunding sites to see if people are willing to back it with their money. The clear distinction between people's opinions and their will to pay for something can be noticed, which is a very useful pointer for future success of the project. A popular example of using crowdsourcing in market research is Springwise, a company that keeps a network of over 8.000 professionals who contact the firm when they discover an interesting product, service or a business model. The company later sells the trend predictions to interested parties. Kaggle.com is another popular example, as the website gathers information from the crowds and does predictive analysis based on it.

4.2. Use of crowdsourcing in product development

Product development based on crowdsourced ideas is a constantly growing branch. Even though open innovation is most commonly used in product development, as companies are looking for innovative solutions to their issues, crowdsourcing is widely used as well. Von Hippel (1998, 2006) states that firms have been using consumer inputs for a long time and that manufacturers have been collecting inputs for developing new products for years. In crowdsourcing for product development there are three key differences to open innovation. Firstly, it is not limited only to customers, but includes potential customers or anyone willing to assist and provide their ideas. Secondly, in enables companies to get direct feedback, without the third party (such as distributors) involved in the process. Finally, companies can select specific areas where the improvements should be made and limit enquires to these areas. There are numerous examples of applying crowdsourcing in product development, including a crowdsourcing company InnoCentive, specialised in offering solutions to R&D problems to companies. Their clients include Proctor and Gamble, Boeing, DuPont, and they offer up to 100.000 US dollars as a winning prize for best solutions.

4.3. Use of crowdsourcing in advertising and promotion

Third most common use of crowdsourcing is in advertising and promotional activities. This model of crowdsourcing has become very popular in the past couple of years, given that its main advantage is enabling companies to save a lot of money and use the crowd to spread their message. The companies with bigger advertising budgets have been collaborating with the crowds for a while by including them in projects in the form of an open call, or even by paying them to post positive comments on blogs and websites. In a recent article, Kirby (2013) mentions six new modes of advertising for the future, and crowdsourcing is one of them. Her article focuses on a successful example of Oreo's campaign "Daily Twist". The campaign was based on launching a 100-day series of cookies inspired by the news nominated by the crowd. The campaign resulted in 4.400% rise in sharing Oreo's Facebook page in just three months, with a significant rise in sales.

Crowdsourcing can be used in promoting or re-building brand identity of an institution, or even a location, as was the case with Connecticut (Birkner, 2013). With limited marketing budget and expensive media markets in targeted areas (especially Boston and New York City), the Office of Tourism switched to a creative approach by inviting locals to take part in a campaign "What's Your Connecticut Story?" in February 2012. The campaign focused on getting personal experiences from Connecticut and promoting them on a website

and a Facebook page. Following a success of this campaign, a new campaign “Still Revolutionary” was launched in May 2012. These two campaigns generated a total of 1.1 billion media impressions, 140.000 Facebook fans and 18% increase in awareness of Connecticut as a place to visit among neighbouring states. The successful campaign tends to become a tradition, given that another Fan Favourite campaign was launched in April 2013.

5. CONCLUSION

This paper presented many areas where crowdsourcing can be applied, even though it is a business model that is still in its developing stages. The increase of competition and limited budgets are some of the drivers that will help crowdsourcing become widely applied and popular model in the future. The authors presented successful examples of application of crowdsourcing in marketing; however, there are downsides to this model as well, and in the future the improvements must be taken into consideration.

First and the biggest problem arises from the sample – even though it is common to believe that more people guarantee better results, it may not be the case, especially when applying crowdsourcing in market research. This can prevent relevant information from getting to the companies. That is why it is important to work on improving mechanisms for filtering information and choosing participants. There are issues and limitations regarding the areas of expertise and qualifications required to successfully participate in crowdsourcing. Further research should focus on participants and better segmentation and profiling, so that results they provide can be improved.

Further use of crowdsourcing in marketing is heading towards social media and the use of social networks, as the source of the crowd, as well as the channel for placing a message and implementing marketing activities.

METHODOLOGY FOR EXPLORING FACTORS THAT AFFECT PEOPLES INTENTION TOWARDS COSMETIC SURGERY

Marija Jovic[1], Vinka Filipovic,[3,] Marko Jovic[2]
[1,2] University of Belgrade, Faculty of Organizational Sciences, marijaj@fon.rs
[3]Clinic for Burns, Plastic and Reconstructive Surgery, Clinical Center of Serbia, markojovic01@yahoo.com

Abstract: *In this work authors developed methodology for exploring factors that contributes to peoples intention towards cosmetic surgery. From the available literature, one could not find the method to follow throughout process of analysing different factors that could contribute to formation of intention to undergo cosmetic intervention. Authors have proposed that methodology presented in this work could significantly contribute to revealing and understanding these factors. Methodology was developed applying the Theory of Planned Behaviour which provides good basis for empirical research on attitudes, subjective norms, and perceived behavioural control that together influence peoples' intention. Proposed methodology is applied on domestic – Serbian market, and the results are shown in further text. According to the results of conducted statistical analyses, authors created three scales for measuring intention of patients to undergo cosmetic surgery, namely attitudes toward cosmetic surgery, subjective norms, and perceived behavioural control, as main constructs of intention towards undergoing cosmetic surgery. Methodology presented in this work provides an excellent guide throughout the process of revealing and understanding factors that affects intention towards cosmetic surgery. At the same time, this methodology can be applied in different fields of contemporary business issues in the process of understanding behaviour of a modern customer.*

Keywords*: Methodology, Theory of Planed Behaviour, intention towards cosmetic surgery, attitude towards cosmetic surgery, subjective norms, perceived behavioral control.*

1. INTRODUCTION

In society, where celebrities are presented as extremely good looking, where information technologies and new ways of doing business are dominating, peoples look at each other more critically, and aesthetic improvements of the body are more and more fashionable. In such a society, cosmetic surgery is another one of alternatives in choices during life, besides fashion, recreation, and different kinds of therapy (Elliott, 2008).

There are opinions that the increase in cosmetic surgical procedures leading to a dangerous direction and fulfilment of themselves should be closely linked with a perfect physical appearance, but it can be acquired through spirituality, art, nature, love, learning and other activities (Lusted, 2010). On the opposite side are opinions that the existence of cosmetic surgery has many positive aspects. Correcting birth defects, burns, wounds, physical characteristics help the man to restore confidence and the ability to patients to feel more attractive and confident (Lusted, 2010).

In the past, people who were born with defects such as cleft lip, cleft palate and other deformities, were forced to live with it. These people were sentenced to others lifelong staring at them, to hide them or, in some cases, to be held in the circus. Cosmetic and reconstructive surgery can improve many of these birth defects, thus the children spared from teasing, and then have more confidence. The benefits of cosmetic surgery also have people with minor deformities, such as droopy ears, which can be corrected, or large and ugly marks, that may be utilized.

Aesthetic procedures depend on the age, gender and ethnicity of the patient. Women usually opt for interventions that will rejuvenate them and made them more attractive. Among women, the most common cosmetic procedures are breast enlargement, liposuction, eyelid surgery, abdominoplasty (removal of excess skin from the abdomen), and breast reduction. Men undergoing procedures that will make them younger and more handsome with them is the most common hair transplantation, liposuction, eyelid surgery, nose surgery and breast reduction. Among teenagers, the most common operations are corrections of the deficiencies, which others laugh at, and the most common operation is nose reshaping (Lusted, 2010). Belonging to a certain ethnic and cultural environments can also have an impact on whether someone will have cosmetic surgery. Some people will undergo surgery to make them look less ethnic, for example. Asian women are

doing the surgery of the eyelids to make their eyes were round and large, some American Jews and African-Americans are changing shape of the nose to make it smaller and more rounded and more like the nose of the Western nations.

Many of researches shows that, in temporary culture and society, people that looks younger and more pleasant, progress faster at work and earn more money than their colleagues who are less attractive and look older (Rinzler, 2009). Beautiful people are seen more positively than others (Lorenzo et al. 2010). Cosmetic surgery produces psychological effects that could be quantified by quality of life, self-confidence, satisfaction with personal appearance, less weight dissatisfaction, and increased psychological well-being (Rankin et al. 1998). To the extent that people are exposed to messages about the importance of attractiveness, they should be more concerned with their own appearance and, perhaps, more open to using the various means through which cultural standards can be achieved.

Despite the expectations of some authors that cosmetic intervention are becoming a common practice in achieving the cultural norms of appearance and the way to restore or gain beauty, youth, sex-appeal, reputation and happiness, (Lusted, 2010), a large part of the population has not yet accepted this type of intervention and does not intend to undergo cosmetic surgery.

From the available literature, one could not conclude what factors affect patients during the formation of one's intention to undergo cosmetic surgery. Some authors have attempted to identify factors that influence the decision of the patient to undergo cosmetic intervention. Among these factors stand out dissatisfaction with some parts of the body, feeling unattractive, lower self rating, gender, education and culture, aging anxiety, and previous experiences among friends (Brown et al. 2007; Davis, 2013; Von Soest et al. 2006, Haas, 2008; Slevec and Tiggemann, 2010; Delinsky, 2005).

In addition to undeniably important role played by these factors in the determination of the subjection of aesthetic interventions are omitted some important factors relating to subjective norms and perceived behavioural control, as important factors preceding behaviour.

As noted by Sarwer et al. (2004), numerous factors may be contributing to this increase in popularity, including advances in surgical procedures, lower costs and higher disposable income of patients, and increased emphasis on physical appearance. Moreover, individuals are increasingly exposed to the possibility of cosmetic surgery through their social networks. Media coverage of cosmetic surgery is now commonplace, as advertisements promise enhanced attractiveness, magazines tout the latest developments in surgical procedures, and television reality shows celebrate physical makeovers. Psychological research on cosmetic surgery has focused on patients' expectations and satisfaction regarding surgical outcomes. However little is known about attitudes regarding cosmetic surgery more generally. Questions about cosmetic surgery attitudes among the general population, the degree to which they are changing over time, and the factors related to such attitudes, remain largely unexplored. In this paper, we present the development of the methodology for exploring factors that affect people's intention towards cosmetic surgery that will allow researchers to more readily pursue this issue.

2. METHODOLOGY

The Theory of Planed Behavior, proposed by Ajzen (2006) was applied. The Theory of Planned Behavior – TPB, (Fig. 1) offers a framework for understanding and predicting behavior based on three constructs that influence behavior (Ajzen 1991; Ajzen and Fishbein, 1980). The TPB has been used extensively to predict various kinds of behaviors, including health behaviors. Godin and Kok (1996) made a review application in explaining the different behaviors in the medical field including screening, eating, exercising, addictive behavior, use of condoms, HIV/ AIDS, and oral hygiene.

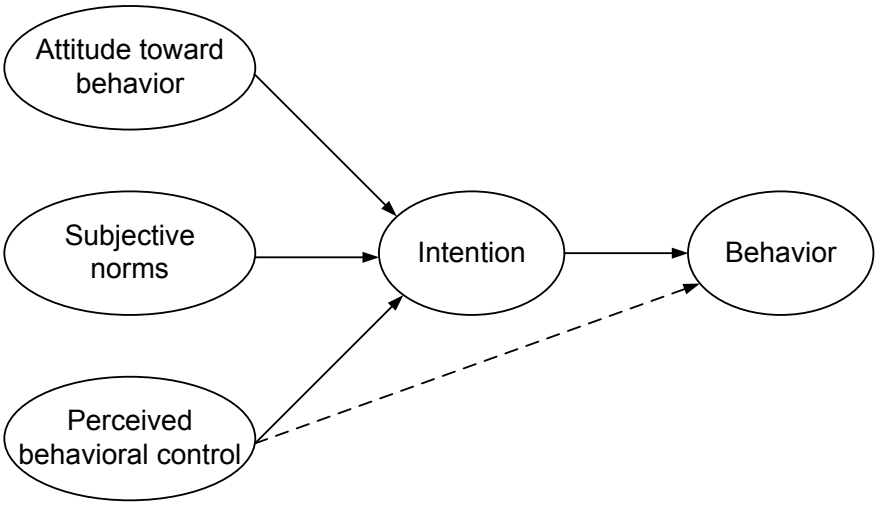

Figure 1: Theory of planned behavior (Ajzen 1991; Ajzen and Fishbein, 1980)

The theory of planned behavior postulates three conceptually independent determinants of intention: (1) attitude toward the behavior - refers to the degree to which a person has a favorable or unfavorable evaluation or appraisal of the behavior, (2) subjective norm - refers to the perceived social pressure to perform or not to perform the behavior, and (3) behavioral control - refers to the perceived ease or difficulty of performing the behavior and it is assumed to reflect past experience as well as anticipated impediments and obstacles (Ajzen 1991; Ajzen and Fishbein, 1980).

Authors developed questionnaire in order to measure direct constructs of TPB related to the intention to use cosmetic surgery services. Questionnaire was distributed to 631 people in period from February to March of 2014th. Of all respondents, 53.7 percent were woman and 46.3 percent were man (M = 1.46, SD = .499), years between 20 and 63 (M = 31.61, SD = 10.139). Most of them (93.2%) never had cosmetic surgery before (M = 1.93, SD = .252), but 81.2 percent, knew someone who had (M = 1.19, SD = .394). For the analysis of data obtained from the questionnaire was used SPSS software.

Respondents attitude toward cosmetic surgery services was measured using nine semantic differential scales (Undergoing cosmetic surgery would be healthy; Undergoing cosmetic surgery would be useful; Undergoing cosmetic surgery would be profitable; Cosmetic surgery would help me feel more satisfied; Cosmetic surgery would help me feel more confident) scored from -3 to +3 (α = .913).

Subjective norms was measured using four items (Opinion of people close to me is important when deciding on cosmetic surgery; I think that my family and close friends would support me to undergo cosmetic surgery; I think that my partner would support me to undergo cosmetic surgery) scored from -3 to +3 (α = .775).

Perceived behavioral control was measured using two items (If I had the money, I would undergo a cosmetic surgery; I expect to be able undergo some cosmetic surgery in the future) scored from -3 to +3 (α = .909).

Intention to undergo cosmetic surgery was measured using twelve items (i.e. I would like to undergo cosmetic surgery; I intend to undergo cosmetic surgery; I would like to undergo cosmetic surgery soon; I intent to undergo cosmetic surgery soon; I would undergo cosmetic surgery in order to remove some congenital defect) scored from -3 to +3 (α = .904). The variable score was calculated for each construct by obtaining the mean score for all questionnaire items included under that construct. On fig. 2 is represented by the structural model intentions to undergo cosmetic intervention.

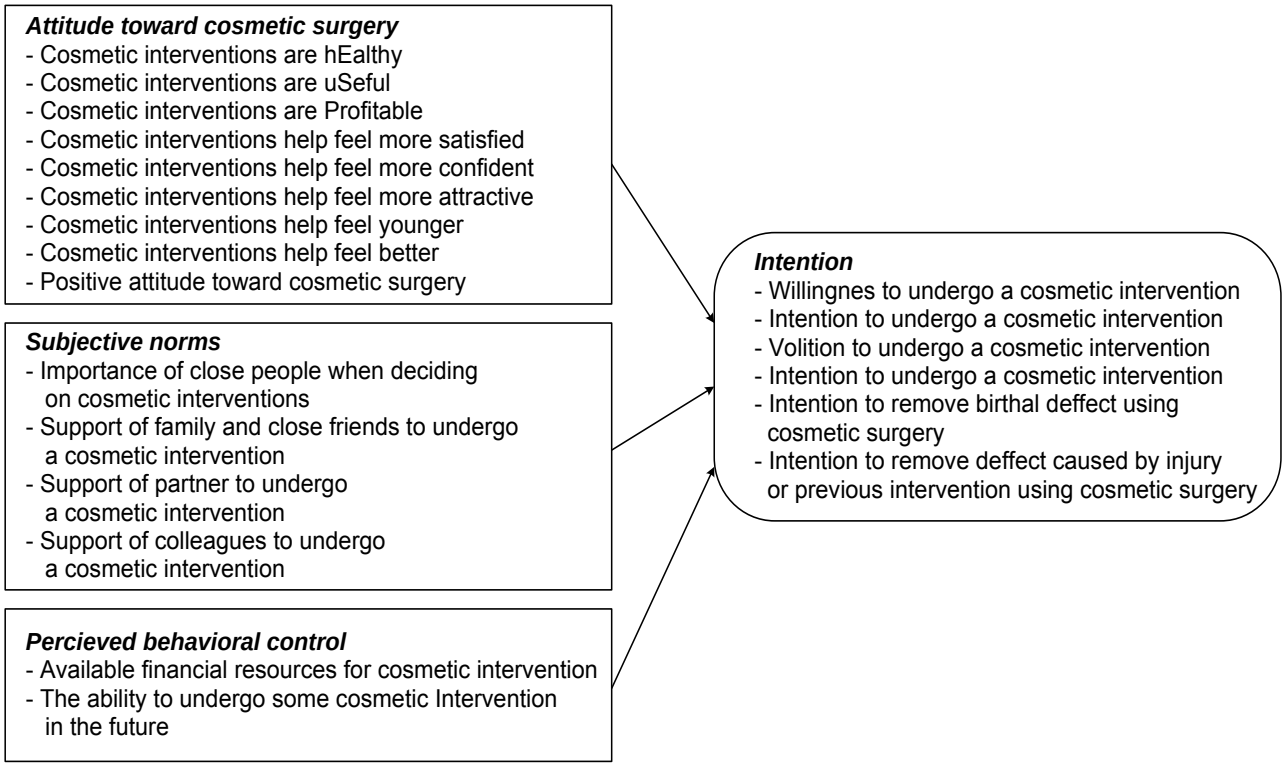

Figure 2: Structural model of intention to undergo a cosmetic intervention

3. RESULTS

To the test the model, and examining how the combination created scale that can predict (attitudes toward cosmetic surgery, subjective norms, and perceived behavioral control) intention to undergo cosmetic surgery, was used linear multiple regression (Fig. 3). Preliminary analyses were conducted to ensure no violation of the assumptions of normality linearity, multicollinearity, and homoscedasticity.

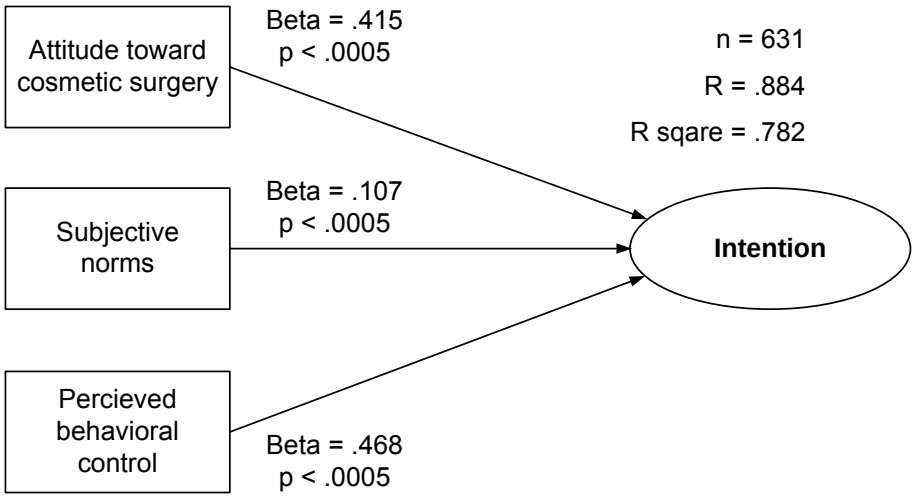

Figure 3: Results of multiple linear regression

The model reached statistical significance (F [3, 627] = 748.658, p < .0005), and explains 78.1% variance of the intention toward cosmetic surgery (R square = .782). Perceived behavioral control had the greatest influence (Beta = .468, p < .0005), followed by attitude toward cosmetic surgery (Beta = .415, p < .0005), and subjective norms (Beta = .107, p < .0005).

4. CONCLUSION

Analysing the previous works dealing with the factors that influence undergoing cosmetic interventions, it can be concluded that the majority focused on motivational factors that drive people to think and want this type of intervention. Von Soest et al (2006) think that body image, teasing history, acceptance of cosmetic surgery in the individual's environment, and self-monitoring are in relation to motivation for undergoing cosmetic surgery. Brown et al. (2007) emphasize that factors that affect the likelihood of undergoing cosmetic surgery lower self-ratings of physical attractiveness and the vicarious experience of cosmetic surgery. Haas (2008) stands the importance of education and culture, as predicting factors in the decision to undergo cosmetic surgery. Slevec and Tiggemann as the main factors that influence the position of the plastic surgery point body dissatisfaction, appearance investment, aging anxiety, and media variables.

All these factors are primarily involved in the formation of attitudes towards cosmetic surgery as an option that gives them the opportunity to rectify their shortcomings, and to restore youthful appearance and beauty. These authors are the factors looked at in isolation and analyse their individual impact on the acceptance of cosmetic surgery, with the lack of a comprehensive approach to the analysis of behaviour in deciding subjecting aesthetic interventions.

It can be concluded that they were not analysed some of the most important factors that influence the intention to undergo cosmetic surgery such as subjective norms, which constitute an important dimension in the psychological process that precedes behaviour, as well as a perceived behavioural control, or the availability of these services to potential patients.

In this work, the authors present an analysis of previous reference works, dealing with the factors that influence the acceptance of cosmetic surgery and, following the example of Theory of Planned Behavior, developed a model for exploring factors that affect peoples' intention towards cosmetic surgery. According to the authors' knowledge, this is the first application of Theory of Planned Behaviour in the field of cosmetic surgery, and the results contribute to the understanding of the intentions of people to undergo cosmetic interventions.

The present study contributes to identifying and understanding numerous factors that together influence one’s intention to undergo a cosmetic surgery. That way the results provide the valuable basis for creating strategies and tactics to increase the intention of people to undergo cosmetic surgery.

Abstract: *Many modern companies around the world are trying to maintain competitive advantage through development of modern Relationship marketing (RM) program and other programs which provide customer loyalty. Because of the specific characteristics of postal traffic and postal services, one of the recommended programs and strategies for maintaining and nurturing long-term profitable relationships with selected group of strategic customers/users of postal services is a modern marketing management strategy of Key Account Management (KAM). It is a strategic decision and the imperative to improve competitiveness and business performance success of contemporary participants, both at the global postal market and the postal market in Serbia. In this paper we present the framework of the modified KAM model in postal traffic, which has not yet been exploited. Marketing management research, testing the possibilities its application were performed in the selected company, PE Post of Serbia, the undisputed leader in the postal market in Serbia. Developed and presented KAM methodology for the postal service can be one of the best solutions that contribute to the successful future development and transformation of the postal sector.*

Keywords*: strategic model, key account, postal services, marketing management*

1. INTRODUCTION

The process of KAM, combined with a comprehensive Customer Relationship Management (CRM), will provide increased sales from 20 percent of customers who represent 80 percent of revenues to organisation, and more importantly, will ensure a key basis for the successful development Key Account Management (KAM). KAM is not a matter of choice of management company already strategic imperative of modern business. However, many companies still do not understand how to develop a strategy for working with key customers, as well as which tools to use in order to ensure the delivery of complex solutions to key customers and develop and improve long-term profitable partnerships (Filipović and Kostić, 2003).

The main point of view of science and practice today, represent the activities directed towards the establishing, developing and in maintaining successful business relationships with customers. In the early 1980s, parallel to the development of new marketing paradigm – the relationship marketing, the concept of KAM was also developed as a specific relationship marketing program that is focused on selected group of strategically significant customers, key account. In the context of development and advancement of the concept of KAM in the postal services in the Republic of Serbia, the application of modern and modified strategic management scenarios, models, techniques and tools is proposed (Ožegović et al. 2013).

In this paper, KAM was viewed as a multi-phase strategic management process, while its application is based on the postulates of *Project Management*. The primary objective of this study is to develop a modified multi-phase strategic model Key Account Management in the postal services. The model presented in this paper is called “***PostAIM”*** *(Ožegović, 2010).* This multiphase and multidisciplinary model approaches the problem from analytical, organizational and technological aspects. The model implies that the focusing of strategy and activities is performed before, during and after the process of sale. This approach has not been used yet and, with it, “***PostAIM”*** can be considered as the original model for key account management. The applicability of this model in the postal services has been confirmed during the research in the Republic of Serbia. This paper presents the results of the application of “***PostAIM”*** model as well as the model of “customer value" to the postal services, dubbed “***PostPPA”.*** Model “***PostPPA”*** (Ožegović, 2010) was used during the realization of selection process and categorization of customers in postal services. Testing the proposed modified model for key account management was performed in selected postal services company, PE Post of Serbia, using data from four main sources: data from the company's business reports, managers and sales teams, data obtained on the basis of the survey and interviews with managers at all levels and the data collected based on interviews with managers responsible for customer care and sales teams, goals and views of strategically important customers involved in the research which was conducted in the period from 2010 to 2012 in order to create a solid basis for building the proposed model for key account management in

postal services. During the research to identify critical success factors of KAM, the study identified the special importance of the quality of services, personnel responsible for care of customer, support of top management, while in contrast to studies done in Taiwan (Chun et al., 2009) a very small influence of geographic factors was observed (p.803).

2. RESEARCH METHODOLOGY

The primary objective of this research is to improve current models for managing key account in postal services. KAM methodology, with whose research dealt McDonald M, Rogers B, Woodburn D, Capon N, Pardo C, Cheverton P, Kotler Ph, Millman T, Wilson K, so far did not have an important application in the postal services. Based on the research, analysis and comparison of the results obtained and presented in the works of these authors, a modified model for key account management in terms of management process was proposed. Such modified model can be applied to the postal services. The outline of proposed Ožegović and Šarac (2012) point out that modified KAM model is based on the methodology of project management. In order to verify the implementation of the new model, a case study method was used. We came to most findings in the research using the test methods, conducted through structured interviews and surveys, which are often used in research on the behavior and attitudes of customers, markets, customer and seller relationship, as well as all relevant information to cause or result from these relationships.

The purpose of the research in the selected company postal services was to make a ranking of key customers at market elements and the level of profitability that is achieved, as well as investment in building long-term relationships with key customers of postal services. Based on the results of research and comparative analysis of existing models of management to key customers was developed a model of key account for postal services.

For the purpose of research conducted in the period 2010-2012 was established three representative samples: The first established the pattern (systematic, stratified) included 106 managers at all levels of management in the selected company postal services. This pattern is formed so that it has the basic set (all managers) previously divided the membership manager management level (top, middle, operational) to be followed by each of the three strata (randomly) selected by 50% of the total manager of that level in the sample for the management level. The second sample (systematic, deliberate, quota-sample) participated in 53 companies (customers) based on the percentage of participation in the annual income of sales. In this study used a semi-standardized interview *face to face* as a method tests. The aim of this study was to determine the attitudes of selected customers group to the importance of certain factors of success offered by KAM for the purpose of their comparison and cross tabulation of the results that were obtained, the same issues in the company's vehicles postal services. Conclusions which have been adopted are (the resulting conclusions are presented) a significant starting point for the formulation of methodologies and models for managing key accounts in the postal traffic. The third sample (systematic) included 56 companies of customers of postal services, with areas of southern Banat. In this study, we used a modified questionnaire UPU, and data collection was done by mail (Self-completion Questionnaires and Mail). The aim of this study was to determine the level of satisfaction of the user groups, as well as their views on the quality and competitiveness of the postal service used. The results of this research support the claim stated confirming the hypotheses, the formulation and development of management strategies to key customers based on customer satisfaction and profitability. All questionnaires were processed using specially developed software solutions in line with the objectives of these studies, on the basis of terms of reference drafted by the author of this paper.

3. THE NEED TO MANAGE KEY ACCOUNT IN POSTAL SERVICES IN THE REPUBLIC OF SERBIA

Majority of large postal service organizations are mainly divided into business units established on the basis of their subject criteria or territorial criteria. Managers of modern organizations are challenged to successfully coordinate the activities of these units and use their knowledge and business skills for the benefit of the organization as a whole. Very often the work of these business units is not in sync and in line with the mission and purpose of the organization. Key account management is one of the most important changes in selling that has emerged during the past two decades. KAM is a radically different organizational process used by business-to-business suppliers to manage their relationships with strategically-important customers, and it produces measurable business benefits" (Lynett, 2012).

KAM in postal services represents a modern strategy and marketing management approach that is based on building and nurturing long-term profitable relationships with strategically important customers in order to achieve mutual benefit for companies involved in this business relationship.

Due to the prevailing competition in the market of communication and distribution of goods, many companies build stronger and closer relationships with key customers. However, many companies still do not sufficiently understand how to develop strategies for working with key customers and which tools have to be used in order to achieve and improve their competitiveness. Key account management assumes consideration of mutual interest of both customer company, and on the part company of the seller as well as inter-organizational coordination at all levels, Table1.

Table1: Mutual key benefits of key account management in postal services

Key benefits for the vendor company in postal services	***Key benefits for key customers***
Long-term increase in profits and competitiveness	Better information on postal services
Joint appearance – joint bid with customers	Increase of delivered value
Improving knowledge about customers	Better understanding of the level of charges for postal services
Close business relationships	The reduction in input costs
Better information about the competition	Better knowledge about the benefits of service for the customer
Measurable levels of objectives achievement	Capacity to build individual customer profiles
Association of business plan and strategies	Guaranteed execution of services in cases of limited resources of the seller company
Creating complex business solution s to identified problems of key customer	

Ožegović (2010) emphasize the importance creating the mutual long-term benefits for related companies (p.85). According to the results of conducted research during the development of the model in the selected company of postal services, Post of Serbia, the public postal operator and leader in the postal services in the market of the Republic of Serbia, it is concluded that there is a need for key account management in the postal services because:

- Less than 5% of customers generate about 79% of revenue;
- Competition develops modern strategy for key account management;
- About 70% of total customer servicing cost generate customers who earn less than 20% of revenue;
- There is a need for allocation of company's available resources;
- Strategically important customers of postal services belive that single postal and other services intended for mass customers do not constitute an adequate response to their needs, etc.

The power of the small number of major market participants is notably increasing. Well known Pareto principle, 80/20, can be applied in postal traffic. Namely, approximately 20% of participants achieve about 80% of total turnover in one branch, that is, the postal sector. They require special treatment.
In this balanced inter-organizational relationship value, **key customers should not be identified with "big buyers"** who, with planned management activities, can over time be converted into a group of potential key customers. Key customers are strategic partners with whom the success is achieved and shared. There cannot be many, neither that type of relationship can be determined in advance.

Key account management in the postal service using the above definitions, is a modern business concept based on building and nurturing long-term profitable relationships with strategically important customers, in order to improve the competitive power and increase profitability, both on the side company of postal services and on the side of company's key customer.

4. METODOLOGY OF KEY ACCOUNT MANAGEMENT IN POSTAL TRAFFIC

In accordance with the primary objective of this study and presented key research results, the proposed methodology for KAM in the postal services, whose function is to formulate the framework of the strategic model for key account management.***„PostAIM"*** developed by Ožegović (2010) is the result of modeling and essentially defines key account management as a single whole. It is designed on the basis of scientific knowledge on the management of key customers and "good practice" to be enforced widely, primarily with

the postal service, as well as in other activities of service sector. This model is based on the fact that key account management is a multi-stage strategic management process.

In accordance with this methodology and based on we present only the framework of developed model for KAM in postal services, named **„PostAIM“** which is based on the application of the same. Framework of this model is presented through 3 key management processes: Analysis and planning, **I**mplementation and monitoring, Figure 1.

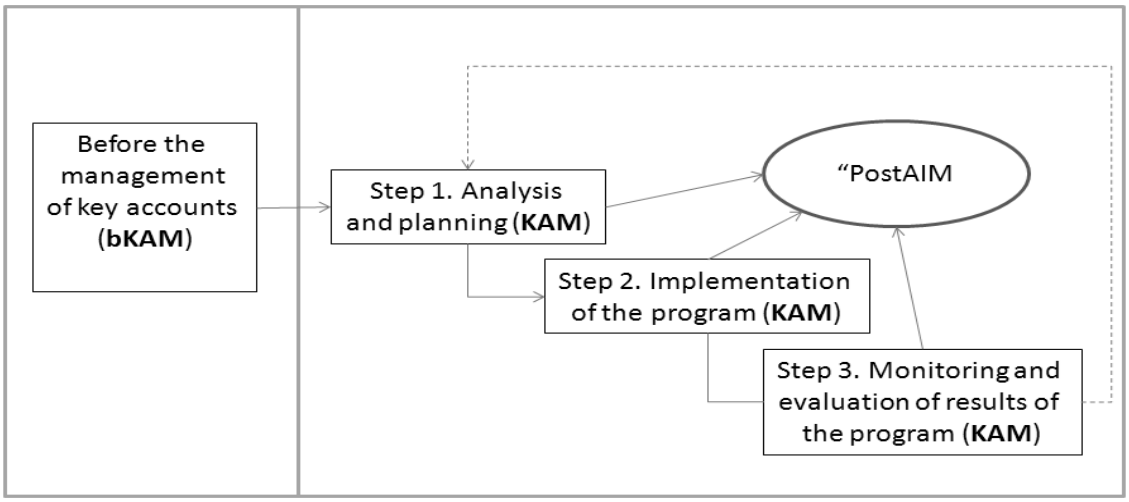

Figure 1: Suggested framework of modified strategic multiphase management model of KAM in postal traffic “PostAIM” (Ožegović, 2010)

In addition to these three key management processes (**A**nalysis and planning, **I**mplementation and **M**onitoring) that occur by the **“**step by step” system, the proposed methodology for key account management, based on a multiphase model of key account management, defines and conditions the progress of the following processes:

- adoption and management of ethical issues and norms of relations and possible conflicts,
- establishment and analysis of management accountability in the process of key account management, primarily based on developing and maintaining successful, profitable and lasting relationships with key customers, and
- establishment of accountability and the creation of management models for managing the cost and benefits in order to ensure achievement of optimum effects in the of key account management.

During the process of modeling „PostAIM“, another model of “***customer valu***e" has been developed, called “**PostPPA*”*** (Ožegović, 2010) which was used as a new approach for the realization of the process of identification, selection and categorization of key customers in the postal service, as one of the key processes of KAM, because its application is to determine which potential customers will obtain the status of key account, as well as the strategies that will be applied based on the portfolio of key customers towards a certain categorie of customers (Ožegović and Šarac, 2012).

A preliminary categorization of customers in the selected area could be carried out by customer classification into A, B and C category by using the known Pareto 80/20 rule. In determination of criteria of identification, selection and categorization of strategically important customers, key customers, that is customer value for the selected company we have used the following criteria: profitability of key customer, share in revenue from sales, attractiveness. Identification of key customers as customers with the highest value level, that is, the highest impact on performance indicators and competitiveness. In formulating the model for segmentation of customers, we started from the fact that the value delivered to key customer is critical for KAM (Pardo et al, 2005). The proposed model **“PostPPA”** a general **model for calculating the total value of the customer (Vk**) as the basis for segmentation of customers in the postal services companies, can be represented by the following expression:

$$Vk = \sum_{i=1}^{n} ti \cdot pi \qquad (1)$$

ti- weight of i-th element

pi- coefficient (calculated or estimated value)

$$Vk = tup \cdot pup + tpfk \cdot ppfk + tpak \cdot ppak \qquad (2)$$

Where are:

Vk – coefficient of customer value

pup- % share in total income

ppfk-% of customer profitability

ppak- % of assessed customer attractiveness

tup- weight factors of customer participation in the total income

tpfk- weight coefficient of customer profitability

tpak- weight coefficient of the estimated customer attractiveness

$$t = 0{,}3;0{,}5;0{,}2 \qquad (3)$$

$$Vk = 0{,}3 \cdot pup + 0{,}5 \cdot ppfk + 0{,}2 \cdot ppak \qquad (4)$$

During the implementation of complete process of identifying key customers, as well as on the basis of obtained results, it can be concluded that the biggest customers are often not the most profitable customers, because the distribution of customers in the ranking, following the procedure of their selection using the proposed model **"PostPPA**" has considerably changed. Most profitable customers are usually a little behind the biggest customers because they cause lower costs. Based on received indicators, ranking of preliminary categorized customers has finally been made and identifies 25 potential key customers in selected postal services company, Figure 2. The results of numerous studies suggest the conclusion that the optimal number of key customers is between 20 and 30 (Ryals and Rogers, 2007; McDonald and Woodburn, 2007; McDonald et al, 2000; Pardo and Ivens, 2008).

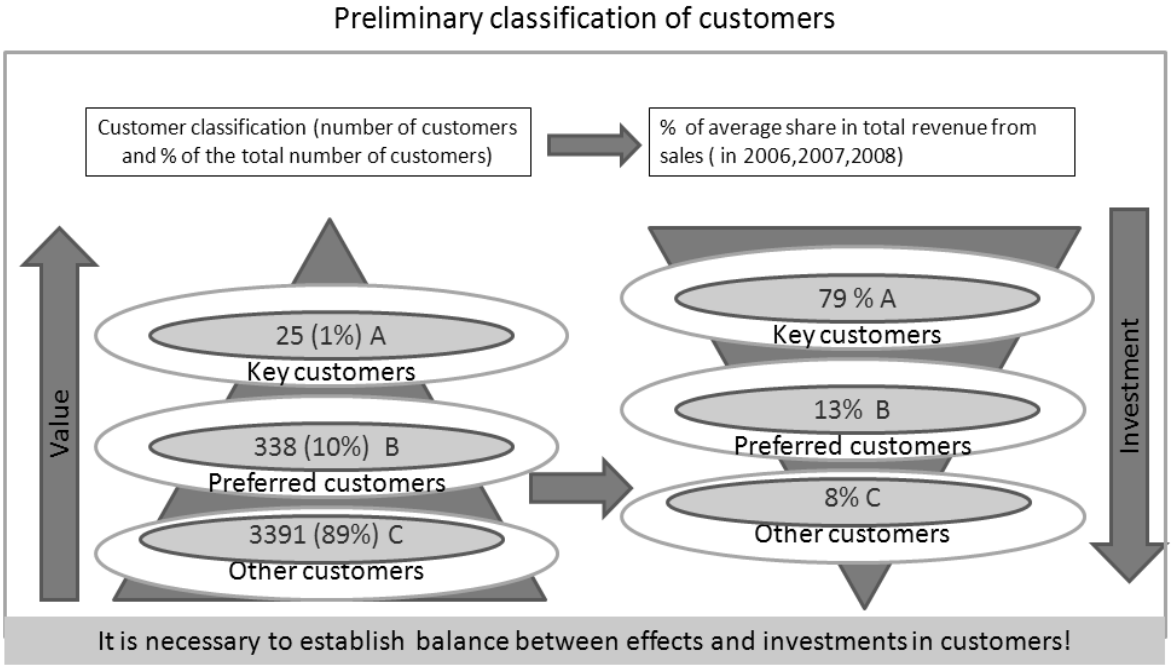

Figure 2: Pyramid of customers in the selected postal services company in B2B market and the Pareto principle 80:20

Identified a number of potential key customers during the research complies with best practices and research results published in the world for the number of key customers. The reason for this situation is contained in the fact that KAM is much more than a dedicated business relationship. In order to meet key buyers, it usually means supply them with highly customized business solutions, rather than existing products and services, which require significant investments throughout the organization. In addition to the proposed method for determining the cost of customers, same can also be determined by cost per process/activity

specific to customers with an essential condition, namely the existence of systems for accounting costs based on activities (*Activity Based Costing – ABC System*).

In accordance with the adopted methodology, testing the application possibility of the proposed modified model of the author,"PostPPA" was conducted in the Post of Serbia on identified potential key customers. After application of the model "PostPPA" positions of key customers in the ranking have changed significantly compared to the previous one, which was the aim and purpose of the same.

KAM as a strategy represents an integral part of RM concept. This is also strategic approach used by companies to implement the principles of RM into their policy and strategy towards customers**.**

5. CONCLUSION

"The Post is starting rank awareness and knowledge of the human mind, a means for the exchange of material and cultural goods, a supporter of of peace and goodwill among people and nations, the messenger of sympathy and love, a mediator between separated friends, the Comforter the bereaved and the lonely soul, the connection between separated family members, a reflection of the joy of of society in which we live." (Jullus Juhlin, president of the VIII Congress of the UPU (Universal Postal Union - UPU), Stockholm, in 1924).

Postal service companies should establish management activities for key customers through the process of planning strategic business relationships that will provide insight into the status of a key customer, collecting and analyzing data, setting measurable goals and accountability. After developing criteria for identifying key customers, we decided to adopt and develop the concept of key account management, based on the proposed model, to ensure that other key elements of the strategy (systems, processes, organization) are aligned. The organizational structure should allow flexibility and creativity of professional managers for key customers in the application of modern business concepts. The role of top management should be directed at understanding the benefits that can provide the application of key account management concept, while at the same time understanding their own opportunities and risks. The implementation of continuous training and training of personnel while implementing the system of incentives would create the essential preconditions for supporting and improving the key account management. Managers of key customers are expected to be flexible, intelligent, stable, open to customers, skilled in communication and able to avoid conflicts. Strategy for key account management in postal services may be effective only in situations where there has been inter-organizational alignment of requirements and expectations of key customers and the organization of postal services. We have come to the conclusion that the proposed KAM model is applicable in the postal service and that it provides the following key results:

- Provides efficiency and effectiveness in the process of segmentation and categorization of customers;
- Provides identification of key customers based on marketing criteria and profitability;
- Contributes to lowering of risks as a result of wrong choice of customers in which should be invested;
- Allows definition of objectives and choice of optimal strategies for each key customer, as well as their alignment with corporate strategic objectives and capabilities of the company;

Results of the research possibilities of the proposed modified model of managing key accounts in the postal service, confirmed the hypothesis that effective governance model key customers based on the performed segmentation and categorization of customers based on pre-established criteria and the level of marketing profitability.

The growing importance of key accounts, and the question of how to realize mutual benefits of partnership relations, suggests that the management of relationships with key client area of vital importance for further marketing research management.

Abstract: *Considering the current statistics, it can be concluded that Serbia is one of the countries with a high rate of incidence of different cancer types, which represents the alarming problem nowadays. Innovative marketing campaigns and promotional activities can successfully contribute the improvement of public health by raising level of general knowledge about health issues and benefits that change of habits, eradication of undesirable behaviour and regular checks and controls have. The focus should be on continuous marketing campaigns that include mass communication through various media - television, radio, print, internet or direct communication between medical staff and patients.*
Keywords*: promotion, marketing communications, health care, cancer prevention, information, education, media*

1. INTRODUCTION

Current statistics indicate that, worldwide, every two minutes one woman dies of cervical cancer. Globally, cervical cancer is the third most common cancer type in women - every year approximately 500 000 women are being diagnosed with it, and more than half of that number die from that disease (Ferlay et al., 2010). The disease is especially common (80% of the overall number of diagnoses) in less developed regions where there is no organized prevention programs. According to the data pertaining to Serbia, cervical cancer represents the cause of 6% of all deaths in women in Serbia. Serbia has the highest incidence of cervical cancer (24.3 to 100 000) in relation to all the other republics of the former Yugoslavia and one of the highest prevalence among the countries of South Eastern Europe. The incidence of cervical cancer in Serbia is two times higher than the incidence in Western Europe (10.43 per 100,000 women) and about three times higher than in the EU countries (where the figure is 8.1 per 100,000 women). Age representation of cervical cancer shows a typical increase after the age of 30, with the most common detection in the age groups from 45 to 49 and from 70 do74 years. When it comes to breast cancer in the world, each year about 400,000 women are being diagnosed with it and about a million of them die from it. In Europe, about 129,000 die each year, and about 370,000 women are diagnosed. Breast cancer is the most common malignant tumour in women in Serbia. There are about 4,000 new cases every year and about 1,600 of them die, which makes 18% of overall number of deaths from all cancers types. Statistics indicate that one in eight women either already has breast cancer or will become ill during lifetime (Jankovic et al., 2004).

Such prognoses indicate the necessity of introducing marketing communication into the area of public health in order to inform and educate public about methods of prevention and early detection of cancer (Plsek and Wilson, 2010). Although developed countries place greater attention to intensive and continual media campaigns dedicated to health promotion, in Serbia still dominate conventional approaches, which are related to the rehabilitation and cancer treatment rather than to disease prevention. By creating awareness about the possibilities and ways of application of certain preventive measures, the mortality rate of certain types of malignancies, including breast and cervical cancer, would be significantly reduced. The focus of activities in health care should switch from reactive to proactive activities - health promotion and prevention activities in which marketing communication can have significant role.

2. PREVENTION AS A BASIS FOR IMPROVING PUBLIC HEALTH

Significant political, economic and social transformation at the global level that have taken place in recent decades, have caused major changes in the conception and organization of health care. One consequence of the above mentioned transformation is making increasing efforts to improve and enhance public health. There are three main aspects of prevention activities. The first aspect focuses on preventing or reducing the incidence of risky behaviour (such as poor eating habits, smoking, heavy using of alcohol and the like) and requires education of the public about the possible consequences. The second aspect relates to the promotion of health-protective behaviours, such as screening, immunization and regular check-ups or acquiring certain skills, for example, ways how to perform breast self-examination. The third approach involves the impact on legal authorities, in order to ban some dangerous issues (smoking in public places to

protect non-smokers from the effects of passive smoke inhalation, banning of GMO food, ecologically unfriendly products etc.) (Killoran and Kelly, 2004; Kelly et al., 2004).
The goal of improving public health is enabling individuals to gain greater control over their health and its determinants. For example, many activities in the area of health improvement are directly related to (Watson and Platt, 2002):

- Communication and health education - strategies that are used to increase knowledge and awareness of the public so that individuals can make rational decisions regarding their own lives and health. Evles and Simnett (2003, p.27) emphasize the necessity of using mass media to inform the general public about health practices; distribution of flyers and leaflets on health care, conducting of special programs for vulnerable social groups, etc.
- Training and consulting – ways of how medical practitioners can enable patients to develop the necessary skills for early detection of some diseases.
- The development and involvement of the wider community and capacity building - the fundamental forms of social organization and collective action aimed at improving public health.

Rifkin (2003), one of the well-known theorists of improving of public health, identified the five most important aspects in this process:

- The development of personal communication skills of medical staff (for successful education of patients or working with marginalized groups);
- Creating a supportive environment (which provides confidence and respect, especially in schools and workplaces);
- Strengthening actions within the community;
- Construction of adequate public policy that supports initiatives to improve public health;
- Transformation of health services from a reactive to a proactive sphere of action (better balance of resources in order to promote preventive action).

Practice has shown that the problem of improving public health is closely linked to the informing and education and of the population (Labonté and Schrecker, 2007). At the international level, it has been shown that investments in marketing communication about prevention are more significantly associated with improved general health of whole population than economic growth and investment in other social spheres (Labonté and Laverack, 2008). The results suggest that higher awareness level about prevention can lead to improved health outcomes in developing countries (Bratt et al., 2002), such as Serbia.

3. MARKETING COMMUNICATION ON HEALTH PREVENTION

Marketing communication on health prevention includes providing health information with the aim of influencing the behaviour and attitudes of the public and raising awareness about ways to prevent various diseases and potential hazards of unhealthy behaviour (NCHEC, 2007). Roman et al. (2003) indicated that effective communication is the key to prevent disease and reduce health care costs on national and global levels. Marketing communication on prevention involves conveying messages to target groups about the potential risks and nature of diseases, whereby the target group should receive and correctly interpret the message and use information in decision making on individual health care. Messages can be transmitted through direct communication of medical staff with patients or through the mass media if communication demands wider audience (Pérez and Raffy, 2008). If properly planned and implemented, marketing communication in the field of prevention can be very effective, with a tendency to influence the general public and policy-makers and to promote positive change in the community, ways to improve the quality of health services and to attract sponsors and donors from the private sector and create the stimulating partnerships. As the public becomes more informed, changing the social consciousness and recognition of the health problems would arise in the community. In addition to initiating behaviour change or the introduction of new legislation on health care, marketing communication can help other positive changes in the community, such as changes in the physical environment. Such examples include the provision of public space for physical activity and recreation, building bike paths or sidewalks that will allow people to walk more and use transportation means that does not pollute the environment and so on (Pokhrel and Sauerborn, 2004).

There are four factors to be considered when planning and implementing marketing communication campaign about health issues (Nicholson, 2001): the level of health literacy of the target group (ability to receive and understand health information), the level of knowledge and awareness of health and disease, the current attitudes of the target group towards health, disease and prevention and structural barriers (limited access to health care, lack of funding, lack of health insurance, insufficient number of health workers and the like). Cheng, Kotler and Lee (2009) defined following phases through which a promotional campaign aimed at creating awareness about prevention must pass:

- Defining of health problem(s) and the ways of its suppression:

When defining prevention campaigns, it is essential to identify public health problems and summarize the factors that led to the decision on creating that type of campaign. Reasons for the decision may be based on the various research results, epidemiological or scientific data that can quantify defined problem and explain prevention possibilities.

- Analysis of the situation:

By conducting SWOT analyses, some conclusions based on internal factors such as the level of funding support from government and relevant institutions, current partners and sponsors of the campaign, can be drawn. Also, it is necessary to define how to take advantage of opportunities and to eliminate or avoid threats to the implementation of the campaign. In this phase, situational analysis of environmental factors - demographic, psychographic, geographic, economic, cultural, political, legal and technological, is also of essential importance. At this stage it is also necessary to analyse the results of current and previous campaigns, particularly those with similar goals and summarize the main activities that have been conducted, achieved results, positive or negative experiences etc.

- Identification of target group(s):

The selection of target group(s) is done by the segmentation of the public based on certain common demographic, psychographic, geographic and/or behavioural characteristics. After selection of the target group, the current level of knowledge and awareness of its members about specific health problems and prevention possibilities should be estimated by using the knowledge scale, which has following levels: absolute unfamiliarity with the problem, recognition of the problem, basic knowledge, significant knowledge about the problem and absolute familiarity with the problem (Siegel and Lotenberg, 2007).

- Determination of communication objectives:

The objectives are usually applied as: change in behaviour, attitudes and/or beliefs, higher knowledge and information level about health problems etc. Objectives of these type of campaigns are sometimes difficult to quantify, but, for example, can be presented as a greater number of people doing preventive screening, greater number of cancer detections in the early stage etc.

- Creation of a message and determination of appropriate source:

This phase consists of following decisions: what to say (message content), how to say (creative strategy) and who should say it (message source). Generally, messages of this type can be classified into two broad categories - those that include informational or transformational appeal. Informational appeals assume that members of the target group rationally process communication messages and that their behaviour is based on logical reasoning. This type of message is used when the target group has a highly developed awareness of the disease and prevention and is prone to self-initiated behavioural change when there is a real need for that. Transformational appeal is used when attempting to provoke negative or positive emotions of the target group. Many health promoters use negative emotions such as fear, guilt and shame to motivate people to change their behaviour (for example**,** to take care of the teeth hygiene and go for regular check-ups per year), or to stop doing certain things (for example, to reject smoking or uncontrolled overeating) (Kotler et al., 2008). Selection of proper message source is significant when it comes to health prevention. Three main factors that give more significance to sources are: expertise, credibility and likeability.

- The choice of marketing communications mix:

The choice of an adequate communication instruments ensures that the message reaches the target group. Marketing communications mix is a combination of these instruments, with optimal participation of each of them, which will ensure the achievement of marketing communication objectives (Kostic – Stankovic, 2013). Campaign dedicated to health prevention requires a synergy of the instruments in a way that enables a fully successful communication process.

- Establishing a budget for communication:

The budget for the marketing campaign reflects the cost of development and its implementation, which include those associated with the promotional mix and additional costs anticipated for monitoring and evaluation. Additional funding sources may include a variety of companies, institutions, foundations, media partnerships, donations and sponsorships. Budget must be sufficient to ensure continuity of the campaign and policy of its adoption must be flexible in order to enable adaption to the current changes and situations (Kostic – Stankovic, 2011).

- Measurement and evaluation of the results

Results should be aligned with the objectives set for the campaign. Monitoring is conducted after the beginning of the campaign, but before its completion in order to determine whether adjustments are necessary to ensure that program objectives would be achieved. Evaluation refers to the final report on what was actually achieved through the campaign.

4. EMPIRICAL RESEARCH

The survey based on polling a sample of female patients of the Serbian Railways Medical Centre was conducted in October, 2013. The main purpose of the research was to examine the level of awareness of the respondents about ways to prevent breast and cervical cancer and major channels of communication that are used for informing about those topics.

The sample was structured by age into four groups: from 20 to 29 years (31% of respondents), from 30 to 39 years (21%), from 40 to 49% years (16%) and 50 years or more years (32%). Greater percentage of the respondents (69%) comes from urban areas, while the rest (31%) live in rural areas in Serbia. In terms of education, the approximate percentages of the sample have completed their secondary school education (44%) and higher education (43%), while the remaining 14% have only primary school.

4.1. Results and analysis

The research results indicate that women who belong to the age group of 20 to 29 years, in most cases (51.6 %), gynaecological examination perform annually, while 16.1% do not do such examination at all. More than half of those who regularly go for check-ups always done Papanicolau test (in further text abbreviated as Pap test), approximately 42% sometimes and 6.5% never. When it comes to the age group of 30 to 39, 47.6% of women go to gynaecological examination once a year. About 52% of them regularly do Pap test, 38.1% sometimes and 9.5% never. Approximately 19% of the members of this age group do not go to a gynaecologist´ at all. Among women aged 40 to 49, the highest percentage (56.2%) goes to annual examinations, the quarter twice a year and 12.5 % never. Pap test regularly does half of them, 37.5% sometimes and 12.5% never. A significant percentage of women who have 50 or more years (71.9%) goes to gynaecological examination once a year, 9.4% twice, and 15.6% never. Pap test always does 59.4%, while 28.1% does that test irregularly and 12.5 % never.

From the perspective of areas that respondents come from, it can be concluded that there are variations in responses. About 56% of women who live in urban areas do gynaecological examination ones a year, 18.8 % twice a year and 14.5 % do not go to such medical examinations at all. Among those who visit a gynaecologist at least once a year, 62.3 % always demand Pap test, 30.4% irregularly and 7.2% never. When it comes to respondents who come from rural areas, 61.3 % go to such examinations once a year, 9.7% twice and 19.4% never. Pap testing regularly does 35.5%, 48.4 % sometimes and 16.1% never. It can be seen that women in rural areas have less developed awareness of performing Pap test on regular basis, which is the main indicator of early cancer stages.

The results indicate the existence of some differences in frequency of performing gynaecological examinations and Pap tests observed by education level. More than half (53.5%) of higher educated women do annual gynaecological examination, 18.6% do such examination twice or more and 9.3% never. A significant percentage (67.4%) regularly does Pap test, 27.9% sometimes and 4.7% never. When it comes to women with secondary education, the survey results indicate that the greatest percentage (65.9%) does annual gynaecological examination, while 13.6% does not. Pap test is a regular item for 54.5% of them, for 34.1% occasional, while 11.4 % do not consider that it should be done. Equal percentages of women who have completed primary school do gynaecological examination ones a year and never (46.2%). Slightly more than 69% of women of this age group are not doing Pap test regularly, while only 7.7% of them do it every year and 23% never.

The results indicate that the largest percentage of respondents from all age categories are familiar with the way of performing breast self-examination: 77.4% of women aged 20 to 29, 71.4% of women aged 30 to 39, 68.8% women aged 40 to 49 and even 96.9% of women who have 50 or more years. The percentage of women who perform self-examination is slightly higher in urban (84.1%) than in rural (74.2%) areas. The awareness of the necessity of performing self-examination increases with level of education. In the group of women with only primary education, the percentage of those who are not familiar with this type of examination is higher - 61,5%. Approximately 80% of women with secondary education are familiar with the way of carrying out this examination, as well as 95.3% of those with higher education. A high percentage of women of all age groups has never performed mammography or ultrasonography: 84% of women aged 20 to

29, 76% of women aged 30 to 39, 63% of women aged 40 to 49 and 43.8% of women that have 50 or more years. The percentage of women who have done mammogram screening is higher in urban areas (37.7%) than in rural (25.8%), but it remains evident that the overwhelming percentage of the women had never performed this type of examination. In the group of women with only primary education, this type of examination has already done 23%, as well as 40% of women with secondary and 30% with higher education.

The largest number of women of all ages has been informed about the possibility of preventing breast and cervical cancer by the media - more than 60% of those who belong to the first three age groups and 43.8% of women older than 50. Such information have been received from the medical staff when it comes to 22% of women aged 20 to 29, 24% of women aged 30 to 39, a quarter of women aged 40 to 49 and 43.8% of women aged 50 years and more. Among women aged 20 to 39, there is no uninformed about these issues. Within the age group of 40 to 49, 6.2% identified themselves as uninformed, as well as 3.1% of women aged 50 years and more. For women who come from urban areas, the main source of information is medical staff (53.6%), media (34.8%) and none of them are uninformed. In rural areas, 64.5% of respondents have received the information by the media, significantly less (19.4 %) by medical staff, while 6.5 % are not informed about this topic at all.

From the perspective of the educational structure of the sample, women with primary education are mostly informed by the media (46.2%), slightly fewer (38.5%) by the staff in medical institutions and 7.7% are not informed about prevention possibilities. Women with secondary education are also generally informed about prevention by the media (56.8 %) or in health care institutions (34.1%). A small percentage (4.5%) have had an opportunity to hear lectures about prevention at work or at school, while 2% are not informed at all. Women with higher education prefer to get information by the media (60.5 %), but consider medical staff being also a significant source of information (23.3%). Approximately 14% have heard lectures on this topic at work /university. There are not uninformed within this educational category.

When it comes to information by television, 74% of respondents had the opportunity to watch TV programs dedicated to the prevention of cervical and breast cancer, while 17% only during special media campaigns dedicated to these topics. A small number of respondents (7%) are not interested in watching this type of content on television, while 2% believe that national television stations lack this type of content (Figure 1).

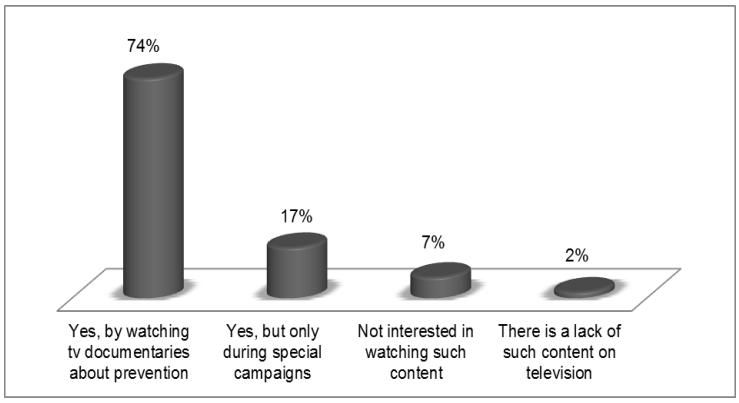

Figure 1. Informing about cancer prevention through television

Radio shows dedicated to the prevention of cervical and breast cancer has so far listened 48% of women and 20% of them only during specific campaigns. A small percentage (6%) is not interested in listening to the radio content of this type, even though they have had a chance to do it, while 26% of women believe that radio stations lack information of this type (Figure 2).

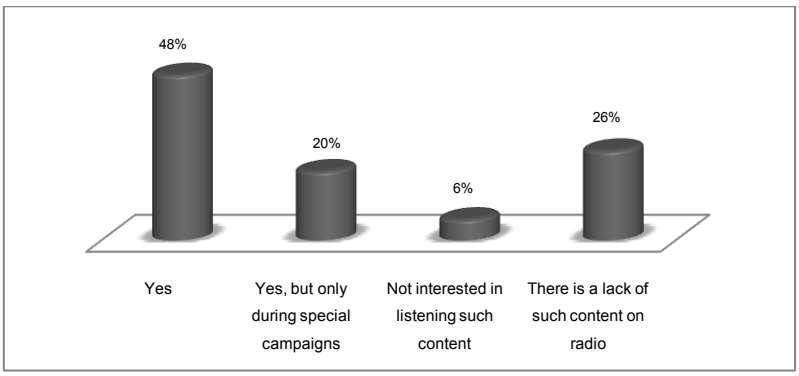

Figure 2. Informing about cancer prevention through radio

When it comes to information by printed media, 34% of respondents have had the opportunity to read the articles dedicated to prevention of breast and cervical cancer in daily newspapers and 54% in specialized magazines about health. A small number of women (8%) are not interested to read this type of articles in the press, while the lowest percentage, 4%, considers that these issues are not provided enough attention to in national newspapers and magazines (Figure 3).

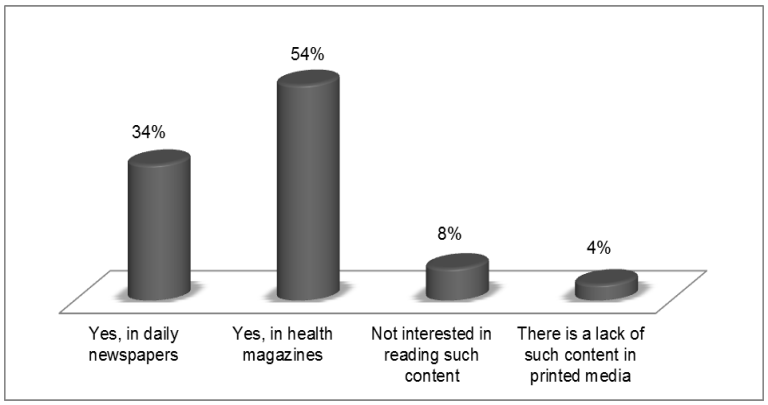

Figure 3. Informing about cancer prevention through printed media

As shown in Figure 4, 42% of women have informed themselves about preventive measures on sites dedicated to health and one fifth of them on the sites of medical institutions. Blogs or forums on health, follows 13%, mostly younger, women, while a quarter of respondents have not read about these topics on the Internet.

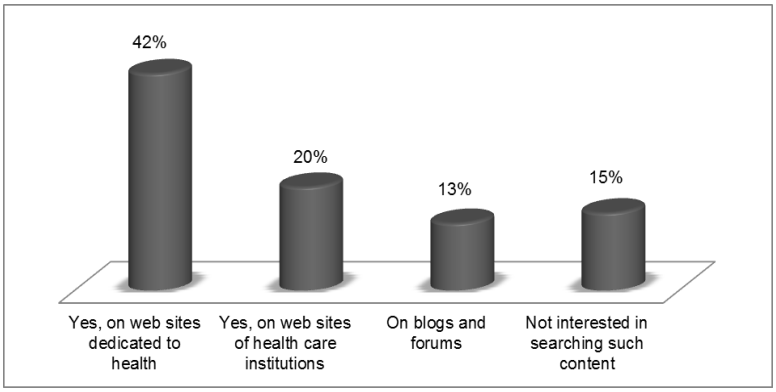

Figure 4. Informing about cancer prevention on Internet

The highest percentage of women (84%) have informed about methods of prevention through posters in health facilities or brochures that have been given to them in these institutions. Among them, 71% have read the promotional material in detail, while 13% have not been interested in reading it. Sixteen percentages of respondents had never seen or received promotional material of this type in medical institutions (Fig. 31).

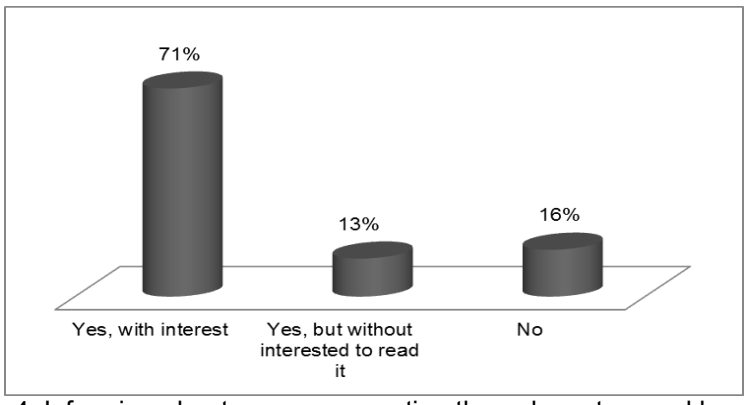

Figure 4. Informing about cancer prevention through posters and brochures

In relation to the attitude of respondents regarding the most responsible subjects for the education of women about cancer prevention, in most cases these were health institutions and the Ministry of Health. Most women who belong to the age group of 20 to 29 (38.7%) believed that the Ministry of Health played a major role, followed by the media (29.8%) and healthcare institutions (29%). Only 6.5% of younger respondents stated that every woman should educate herself on her own initiative. Women aged 30 to 39 thought that the main role belonged to health care institutions (52.4%), media (28.6%) and the Ministry of Health (19%), while the initiative is not on women themselves. Women aged 40 to 49 also stated that health care institutions played the main role in education (56.2%), then the Ministry of Health (31.2%), media and women by themselves (6.2% each). Women, who are 50 or older, as the most important, considered the role of health care institutions (43.8%), but a significant number (31.2%) highlights the importance of taking self-initiative. A quarter of women within this age category considered that the Ministry of Health had a fundamental role in encouraging the education of women in the area of cancer prevention (Figure 5).

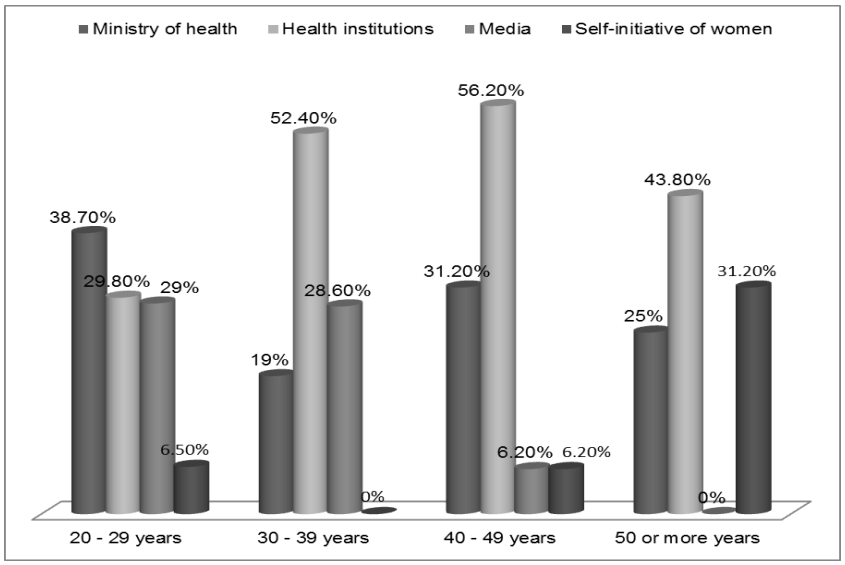

Figure 5. Role of different subjects in informing and education about cancer prevention

The largest percentage of respondents from both, urban areas (39.1%) and rural areas (51.6%) believed that health care institutions were the most responsible, followed by the Ministry of Health (30.4% in urban and 25.8% in rural areas). Respondents from urban areas also emphasized the role of the media (18.8%) and, at least, self-initiated education of women (11.6%). Women in rural areas valued more the role of women self-initiative (16.1%) than the role of the media (6.5%). From the perspective of the level of education results are as follows: women with primary education equally valued the role of the Ministry of Health and health services (38.5% each), followed by the role of the media (15.4 %) and self-initiative of women (7.7%). Women with secondary education considered that institutions played the main role (59.1%), followed by self-education of women (20.5 %). Around eleven percentages thought that the media played a major role, while 9.1% thought that the Ministry is more responsible. Higher educated women, at most, emphasized the responsibility of the Ministry of Health (46.5%), then health care institutions (27.9 %), media (18.6%), while the lowest percentage (7%) emphasized the role of self-initiative of women.

5. CONCLUSION

Changes in medical practice in recent decades have caused the introduction of marketing communication in this sector. Social and economic trends that affect the health care sector show imply an increased need to inform and create awareness of target public in order to motivate behaviour change in the way of adoption of preventive measures. Such measures could contribute the reduction of the mortality rate of certain types of cancer, including breast and cervical cancer. Results of the research indicate that television is the leading media when it comes to information on these topics. Posters in health facilities or brochures given to women in these institutions are also considered significant. When it comes to the attitude of respondents regarding the subjects that are most responsible for the education of women, health institutions and the Serbian Ministry of Health are considered as the most important.

Abstract: *Creating a tourism destination brand is a demanding and time-consuming process. It necessarily involves local population as it plays an active role in the creation of the brand and image of the destination. This study includes an empirical research which examined the views and opinions of the citizens of Vojvodina regarding Vojvodina as a tourism destination. We have identified the main characteristics and values of the destination, which can be the basis of a successful brand positioning. Research has highlighted the main advantages that should be used to attract tourists, as well as main features that can be used for positioning this region in the minds of tourists from the perspective of local population.*

Keywords*: destination brand, brand identity, brand image, positioning, Vojvodina*

1. INTRODUCTION

The development of tourism, business and a growing number of people that allocate a part of their earnings for visiting places around the world contributed to the development of geographical locations branding. Cities, states, regions and continents are active in branding and promotional campaigns with the goal of positioning and developing desired association for the location and arousing interest to visit it. Tourism is one of the most developed service branches in almost all developed countries, as well as the industry that achieves the biggest progress in developing countries (Gabor et al., 2012). States, regions, cities, tourist organizations and agencies, affected by economic and cultural globalization, have to fight for its place in the tourist industry. One of the ways to do so is differentiation, or the creation and development of the destination brand. The importance of the state, city, or a particular region brand is not only to attract tourists, but also in creating the image and the reputation of the state (Morgan et al., 2011).

Tourists face a lot of information on various tourist destinations. In order for those destinations to become recognizable in the market and to become famous and attract tourists, one of the starting points is to build an identity, differentiate from other destinations and to build and successfully maintain their positive image. The paper by Pike (2009) presents scholars researches that emphasize the importance of the development of destination brand identities and monitoring destination brand position in time.

In Serbia, there are significant, yet still unused opportunities in tourism, which require a serious approach, knowledge, creativity and commitment to the process of building identity and image of tourism destinations. One of these options is autonomous province Vojvodina, a region of Serbia, and it is necessary to systematize the rich and diverse offer of Vojvodina and position it as a destination brand.

This paper describes the basic concepts of tourism destination brand. As literature review points out, the basis of creating and positioning a destination brand are the brand values. Therefore, the research that is presented is aimed at identifying the values and characteristics of the destination. The survey was conducted in Vojvodina, and based on the opinions and attitudes of citizens the basic features and brand values of Vojvodina as a destination have been defined, and they can be used as one of the basis for creating a branding strategy for this destination.

2. BASIS OF A TOURISM DESTINATION BRAND

In today's market environment, one of the basic conditions for successful business is building positive relationships with stakeholders. Brand creation is one of the ways to establish and maintain positive relations, because the brand is not only the name of the company/product, but the brand is a functional and emotional well-rounded story about it (Cicvarić, 2006, p. 9).

The concept of the brand was created with the idea to differentiate one manufacturer's products from the products of other manufacturers (Kotler & Keller, 2006, p. 274). Brand represents a distinctive set of elements (name, logo, symbol, design and message) that identify and differentiate: organizations, products, services, as well as people, places, and ideas, and create unique rational and emotional associations, beliefs and expectations of customers/consumers/users (Cicvarić, 2006, p. 29). The essence of the brand is to create relationships between brand and stakeholders, and it was analyzed by Chevalier and Mazzalovo (2004). Through this relationship they define the brand as a kind of contract, which is basically the relationship of trust that includes expectations of stakeholders on one hand, and promised features of the brand on the other side. Relationship and the benefits are mutual and not purely rational, but they also involve an emotional connection.

According to Kotler (1997, p. 430) product is everything that can be offered in the market to meet a certain desire or necessity, so these products can be: physical goods, services, retail stores, a person, organization, a place or an idea. In accordance with Kotler's product concept, brand concept can be linked to all categories previously mentioned.

In this context, the concept of the brand can also be applied to places or geographical locations and destinations, so the destination brand involves a name, symbol, logo, word and/or other elements that serve to identify and distinguish one destination from competing destinations. In this case, brands provide a promise of a positive traveling experience to a specific destination to potential visitors, and they are used to reinforce and strengthen the memory of a beautiful experience for those who have already been there (Kerr, 2006, p. 277).

According to Anholt (2007) branding is the process of creating, planning and communicating an identity in order to build and manage image and reputation (p. 4). Identity is the way in which the brand should be seen and understood. The basis is a visual identity, but in addition to visual representation, identity should include core values, history, culture and other specific features (Balmer, 2001). The image is public opinion about a particular brand and it is based on many factors and influences from the environment (Kapferer, 1997, p. 32). Given that image and reputation are comprised of a range of experiences, memories, expectations and other emotions that are associated with the brand, these feelings are important drivers of human behavior, so Anholt (2007) concludes that brand image is one of the key concepts relevant to the development of nations, cities and regions (p. 5).

In the process of strategic destination branding the starting point is defining the vision and mission of the destination brand. According to Chernatony (2010), the vision of a strong brand is composed of three components that are interconnected, and they are: 1. Projection of the future environment that will be realized if the brand achieves its goals; 2. The purpose of the brand, which is the reason for its existence, 3. Values that will represent the characteristics of the brand, respectively the values that will enable the brand to achieve the purpose for which it exists. The mission of the destination brand should present the reasons for starting the destination branding process, as well as the expected benefits the brand will bring to a geographical location in the future.

Park & Petrick (2006, p. 263) cited following as main reasons for destination branding: building identity and image that can attract tourists, differentiation of destination from others and positioning in order to stimulate the consumption of tourists, image management, as well as the increase of economical contribution of tourism to the destination development. Therefore, destination branding is focused on differentiating destination from the competition, especially by developing awareness and recognition among potential customers, as well as creating a positive image of the destination. By achieving this goal, it is possible to affect the attraction of tourists, attracting investors to invest in a destination, creating trade and political engagements and agreements with other destinations/countries, the organization of events on an international level and the number of other benefits that positively contribute to the development of a destination (Anholt, 2003).

The process of branding a tourist destination is quite complex and time consuming, because it is conditioned by the nature of a tourist destination, respectively its characteristics, cultural and historical heritage and natural features, a set of activities, attractions, tourist facilities and services that a destination offers. Many of these characteristics, such as the names of destinations, geographical location and natural characteristics are already defined and can not be changed in the process of branding. Therefore, the creation of a brand identity is based on them as starting elements and further includes defining other elements of identity and a campaign that will present the destination in a best possible way, bringing it closer to potential tourists and making it desirable and attractive.

Echtner and Ritchie (2003) believe that the destination image includes the perception of its characteristics (such as, for example, location, climate, accommodation facilities, hospitality of the population), as well as some of the holistic impressions (mental images or imagination) on the spot (p. 42). Therefore, it is necessary that the image is created so that it takes into account the existing resources of destinations that are specific to a given destination, while the other side must also contain personal impressions and perceptions of visitors that are a result of creating and delivering the promised brand value.

One of important conditions for success of the process of branding a tourism destination is the involvement of all relevant stakeholders in the process, in fact that all those who have an interest in the way the destination will be presented (Garcia et al., 2012). The identity of the local population should be the starting point for creating a destination brand identity. In addition to population of the location, the following groups can be identified as the stakeholders in destination branding: the representatives of local, regional and national tourism organizations, government, businesses, the arts, culture and education organizations, media and the general public.

The study of destination image is a relatively new field in the problem of positioning tourism products. So far, several studies have been made and they clearly demonstrate that destination image has an impact on consumer behavior, and in the case of a destination with a very positive and powerful appeal there is always a great chance that in the process of decision making the customer/tourist will opt for it, in comparison to competing destinations (Gallarza et al., 2002, p. 56).

3. POSITIONING A TOURISM DESTINATION

Position of the product (brand) is a complex set of perceptions, impressions and feelings that consumers have regarding a particular brand in comparison to its competitors. It includes a ratio of own brand's image to competing brands (Veljković, 2010, p. 108). Each brand is perceived differently by an individual consumer in relation to the competitor and on the basis of attributes which are important to consumers.The position of the destination on the market is the way in which the destination is seen by the potential and current visitors in terms of experience and the potential benefits it offers in comparison to competitive destinations (Reich, 1999, p. 1-2).

According to the same author, elements that assist in positioning a destination are the name, symbol and message of the tourist destination. The destinations have their own names that it is impossible or very difficult to change. It is a constant on which tourists have already developed associations. Symbol and/or logo of the tourist destination can help identify the destination and reflect its personality. Visual or graphical display which will be linked to the destination brand are considered by the author as the mandatory element of the brand. The importance and impact that a symbol/logo can have derives from the constancy of its use and recognition over time. The message of a tourist destination is an element that is often used to describe the essence of the destination brand, but is not a mandatory element for positioning.

Genov (2013) defines four principles of successful positioning of tourism destination: clarity, consistency, visibility and competitiveness (p. 165). Clarity refers to the communication with the market and emphasizing competitive advantage, where it is important to have clear and accurate communication, as well as specific, clear and precise message. Consistency as a positioning element refers to the persistence and insistence in communicating basic ideas into messages that are broadcast to consumers. Visibility is an important element of positioning because in that way the competitive advantage finds its place in the minds of consumers in the target market. Competitiveness of tourist destinations in the process of positioning must have a good and relevant basis so its competitors could not compete with it or copy it. The destination brand values that are the basic component of the brand vision represent previously mentioned basics.

The research that is presented aims at identifying the values and characteristics that the destination has which actually should be the starting point of creation and brand positioning of a destination.

4. THE CHARACTERISTICS OF VOJVODINA AS A TOURISM DESTINATION: CITIZEN PERCEPTION

In order to identify the values and characteristics of Vojvodina as a tourist destination, the authors conducted an empirical study among inhabitants of Vojvodina, on the basis of which further steps in destination branding can be determined. As it was previously identified that residents play an active role in the creation of the brand and image of the destination (Gallarza et al., 2002, p. 61), for the purposes of this study authors

examined the attitudes of people living in Vojvodina. The study was conducted in 2013, and it was based on primary data collection and employed questionnaire as a research method. On a random sample, 128 valid responses were collected, where the share of women with 75.8% was three times higher compared to the share of men at 24.2%. The age structure of the sample included respondents aged 18 to 58, where 66% of all respondents belong to the group of 21-30 years of age.

Respondents were offered responses of values and characteristics, among which it was necessary to opt for the one with the open possibility to write additional charachteristics on their own if they believe that the stated values and characteristics do not reflect their views. The answers were offered on the basis of short interviews with 32 residents of Vojvodina, made prior to the making of a questionnaire, as well as on data from a research and development project "Marketing strategy of tourism in Vojvodina", which was the basis for the design of the questionnaire.

In the opinion of interviewed citizens of Vojvodina, homesteads (typical Vojvodina farms) (32%) and the natural beauty of the Pannonian lain (27%) are the responses that have been recognized by largest number of examinees as most expressed features of Vojvodina (Figure 1). The other three answers offered are approximately equally represented: rich in tradition and culture (16%), tasty, traditional food and wine (13%) and authentic towns of Vojvodina (10%).

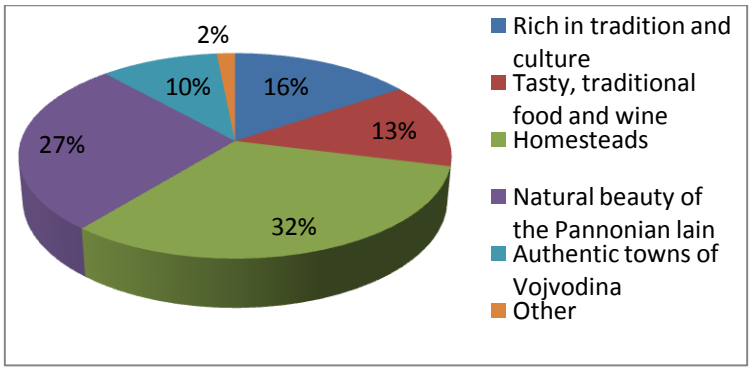

Figure 1. Most expressed features of Vojvodina

The local population was assessed by 2/3 of respondents as friendly and hospitable (Figure 2). This information is extremely important when we consider the importance that local people have in the creation of a positive brand image of the destination. When a bohemian life (13%) and preserving tradition (18%) are added to the cordiality and hospitality, it could be said that the citizens of Vojvodina are seen as a repository of friendly people.

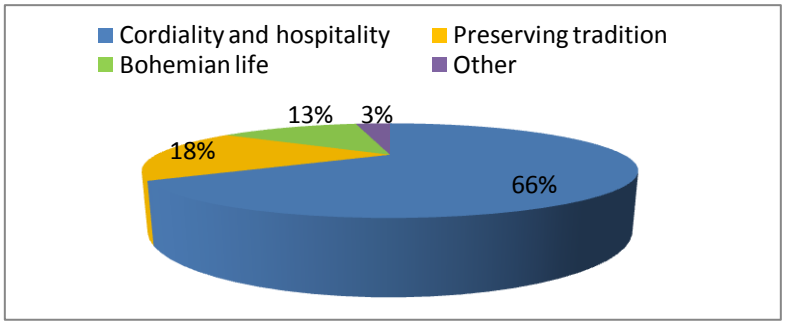

Figure 2. Features of Vojvodina inhabitants

When asked what is the main advantage of Vojvodina as a tourist area, the responses were equally represented (Figure 3). The rich cultural and historical heritage (22%), the Pannonian plain (18%), multiculturalism (19%), romantic and dreamy destinations (16%), wine and delicious traditional food (17%), and unspoiled nature with somewhat lower percentage of responses (7 %) are significant advantages in the region, while also representing a part of their resources as usable for further development, as well as to creating a destination brand.

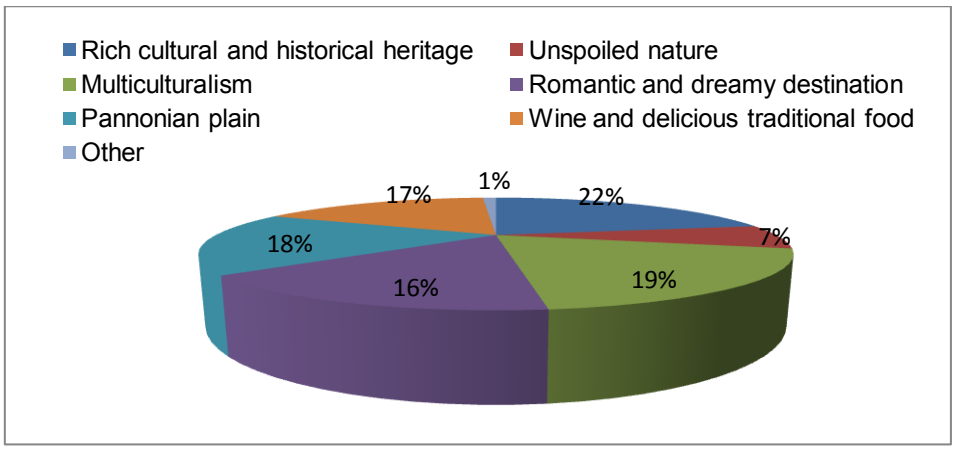

Figure 3. Main advantages of Vojvodina as a tourist region

As the result of pre-investigation, Vojvodina was described as quiet and peaceful oasis for relaxation, in the survey 88% of respondents agreed with the insignia of the region (the degree of agreement examined on a Likert five-point scale), which can be a basis for attracting tourists and creating a specific brand.

Based on the questions and answers above, the main features of Vojvodina are summarized, and they can be a starting point for building a destination brand: quiet and peaceful oasis for relaxation of mind, natural beauty of the Pannonian plain colored with fertile fields, rich culture and tradition, hospitality and kindness of Vojvodina, exceptionally delicious food and wine, homesteads and tamburitza players, as well as romantic and dreamy destinations.

Based on the survey results, by identifying core values and characteristics of the destination according to the public, Vojvodina can be positioned as a destination rich in natural beauty, as calm and quiet oasis for relaxation, with delicious food, wine and the sounds of tambourine, where with every aspect of offering there is a feeling of warmth and comfort, where the beauty and grandeur are inexhaustible.

Such positioning can include rational and emotional values, which are more expressed in this case, and it can be argued that they should lead in creating the tourism product of Vojvodina. Based on the above, Vojvodina occupies the position of a destination that promises all the benefits of rest, where every tourist can find a way and a place for enjoyment and fulfillment of expectations. In creating a destination brand strategy, it would still be necessary to explore the views and opinions of other stakeholders, and define common values on which a brand identity and further image of Vojvodina as a destination can be built.

Destination brand is a promise of an experience that potential tourists can expect from the destination. Brand positioning of Vojvodina should attract the interest and attention of potential tourists to come and visit it, stay in it and come back again.

5. CONCLUSION

Creating a successful destination brand is a complex process. Nowdays, it is no longer enough to offer basic features and attributes of a particular destination, such as geographical features, services, climate; it is necessary to create a unique and attractive offer, based on the unique characteristics and values that will attract tourists. The battle for tourists at a very competitive marketplace has become an emotional process, so the goal is to create a brand that will also affect the senses and emotions.

Destination branding is a major challenge and it requires a strategic approach in creating, positioning and maintaining brand. As one of the regions of Serbia that is rich in natural resources, culture and tradition, which respects traditional values that make its inhabitants so warm, hospitable and friendly, Vojvodina has the potential to become a preferred tourist destination. In this regard, it is necessary to precisely determine its characteristics and position it on realistic and impressive grounds, with a package of services that fully express the essence and brand promise. This paper identified the values and characteristics of Vojvodina as a tourism destination from the perspective of local population, and they can be used as one of the basis for creating a branding strategy for this destination.

Abstract: *The main subject of this research were particularities of media campaigns that are designed to draw attention of children, as targeted audience, to services and products. The analysis refers to TV advertisements and examples of product ads in magazines on territory of the Republic of Serbia, which point out the main characteristics, types of message placement, and media vehicles and communication tools used in media campaign. In the research results discussion, the authors explain the managerial implications based on the research, and give directions enhancing the quality of planning and realization of media campaigns directed to children, having their better efficiency and effectiveness as a goal.*

Keywords*: marketing, media campaign, media, children, advertising*

1. INTRODUCTION

Nowadays, when the combination of modern ideas with creativity and consistency represent a prerequisite, a great deal of effort is necessary for companies and advertisers in general, to betake the market. According to Perić (2010, p. 8) the goals of media campaigns have to be conceived in accordance with the goals of customers, taking into consideration all relevant market opportunities, consumers' characteristics, their habits, as well as the primary media they are using.

Market opportunities are constantly changing, therefore, it is not sufficient anymore for a product to be in the center of attention, to be made out of the best ingredients, to be placed originally; making the field of the research itself, in the concept of modern marketing, shift towards building-up a relationship with targeted groups, indicated Filipović and Kostić-Stanković (2011, p. 94). Consequently, during a media campaign analysis targeted for children in this research, it has been noted that they are the result of combining, applying and placing special emotional aspects. The proposals, according to this study, have been organized in a way to present a planned combination in choice of media, key messages, design and presentation of ads and advertising spots.

From the communicational perspective, the goal of promotion is stimulating sales and growth of profit. Moreover, it could be redirected to creation of consciousness about the brand, encouragement of product testing, as well as placement of a product in consumers' consciousness. It can also be used for correcting wrong pictures about a product or service, as well as for reminding the consumer about the product or a special offer (Jobber and Fahy, 2006, p.237). Considering the importance and impact that media campaigns potentially have, it is important to choose adequate tactics and instruments for addressing children as targeted audience. It has been concluded in this research that it is necessary to adjust techniques and the language that is used, so that the message is clear and unambiguous, being in accordance with ethical and legal standards.

Two basic aspects of media communication are advertising and publicity. That implies the knowledge of media editing policy, the method of content production, as well as all relevant quantitative data on viewership, listenership, and readership. In order to organize a good and successful media campaign, it is also essential to understand the current media scene, its atmosphere, and the position of the primary targeted audience, and their affinities. Mainly, the goal of a media campaign is the creation of desirable media identity and organizational image, that becomes an integral part of corporate identity, and image; on long-term basis, it can be of major importance in creation and maintenance of a company's reputation (Vlastelica, 2007, p.9).

Due to a limited research and information in regards to specifications, manner of planning, and placement of media campaigns targeted to children, the authors have decided to investigate this topic and define managerial implications for improving the quality of planning of media campaigns directed to children, having their better efficiency as a goal.

2. CHILDREN AS CUSTOMERS

To understand better the behavior of children, and their contribution on the process of purchase, it is necessary to examine the determiners of their environment that influence them at a great extent. The family is the primary, relevant, and referential group that has the highest influence on an individual in consumption. The reason for that lies in the fact that the relationship between family members is much closer than in any other social group. It is only the household that is based on a set of people that form a life unit, and have socio-economic group features (Maričić, 2010, p. 219).

According to Filipović (2011) "Children are not the miniature versions of grownup people, as many companies would think when approaching them, they actually represent a very specific segment of customers. Nowadays, it has been established that children are different from grownups in the psychological profile, the manner of creating social ties, and overall perspective of the surroundings in which they are growing up. Most importantly, they possess significantly bigger amounts, and they are free to use that money independently".

One of the most common ways of defining a child is the United Nations definition, and it is read: "Thanks to the Convention, it became very simple to define a child, which is a human being under 18 years of age, unless the law of his or her country deems him or her to be an adult at an earlier age, which is rare" (Zakon o ratifikaciji konvencije Ujedinjenih Nacija o pravima deteta).

Research has shown that children, younger than 8 years of age, according to their cognitive and psychological characteristics are incapable of defending themselves from advertisers' influence. Thereby, that implies that they are not able to recognize that the goal of somebody's addressing is sales, and they accept the information that is placed through advertising to be accurate without any further pragmatic analysis. Western European countries such as Sweden and Norway forbid all advertising directed to children younger than 12 years, Greece has forbid toy advertising after 10.00 p.m., and Denmark and Belgium have made some general restrictions and bans in advertising for children (American Academy of Pediatrics, 2006).

Parents and extended family members are training children to become consumers, communicating their own experience and knowledge on products, services, shopping facilities, concept and importance of company or brand image, pointing out the price- quality relation. Social interaction in which children are familiarized with the information about a product is done through the Internet, as well as at public places (Maričič, 2010, p. 308).

Children learn how to become consumers throughout the next five following phases (Maričić, 2010, p. 309):

- observing
- demand placing
- choosing
- doing smaller (ancillary) shopping
- and independent shopping.

Beside the consumer characteristics, in this research, it has also been taken into consideration how much time children spend in consumption of media, including all ethical and legal standards that need to be consulted and respected during a production of a media campaign for children.

Act on advertising contains a range of regulations that are protecting the rights of minors during advertising (Unicef, 2011). The Act provides certain norms that do not directly apply to children, but contain norms that are of great importance in protecting minors, such as: norms on freedom of advertising, norms on verity, completeness, and singularity of a message, norms on advertising messages, norms against discrimination, and hurting moral values etc. The message must not contain elements that openly support violence or unjustified fear or addressing minors, economically and

generally dependent persons, in a dominant way. When talking about bans on influencing minor persons, according to Article 48, Act on Advertising, the use of personal property of public persons, musicians, actors, TV speakers, and others) must not be exploited in product advertising for minors. (Unicef, 2011).

Along these Acts, the following Acts are also represented that contain regulations that contribute children, as targeted group, and they are listed as Act on radio and television broadcasting, Electronic Communications Privacy Act, The Public Information Act, Law on Free Access to Information of Public Importance, Data Secrecy Law, and Personal Data Protection Act.

3. RESEARCH METHODOLOGY

The methodology that was used to identify and analyze the particularities in certain advertising campaigns was the cross case study analysis. It represents an analysis and presentation of relative cause, which is based on deduction and combination of sets of data in order to get the same conclusions (Eisenhardt, 1989). For the purpose of this research, seven TV commercial were reviewed. All spots are taken from the video-sharing website YouTube. Advertising spots are from the food product domain, and are related to products that are aimed to children in shape and manner of promotion. The products are the following: "Juhu" chocolate bars, "Barni" biscuit, Grated Plazma biscuit, "Cipiripi" cream, "Smoki smokić" flips snack , "Cokić na eksić" beverage. The October editions from 2013 of "Bravo", "Hey", and "Mali zabavnik" were the subject of analysis. The analysis covered 20 newspaper-advertising pages and 8 advertorials. According to Vlastelica (Vlastelica, 2007, p. 89), advertorial is a paid text in a magazine or daily paper in a form of a newspaper article or some other editorial.

During the analysis of TV advertisements, four criteria were taken into consideration and based on them their behavior and use of certain instrument in a product presentation was monitored. Those are the following criteria: The usage of animated characters, the usage of music, the usage of family patterns, and the usage as part of social environment. Every abovementioned criteria can be seen in the Table 1, including their presence in TV advertisements.

Table 1: The criteria for analyzing television ads

	"Chipita Fineti"-sticks and dips	"Cokić na eksić"-beverage	"Mlevena Plazma"-ground biscuit	"Barni"-biscuit	"Cipiripi"-cream	"Juhu"-chocolate bar	"Smoki smokić"-flips snack
Usage of animated characters	No	Yes	No	Yes	Yes	Yes	Yes
Usage of music	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Usage of family patterns	Yes	No	Yes	yes	Yes	Yes	No
Usage of children as part of social environment	Yes	No	No	Yes	No	No	Yes

In the following graph, we can see the relation between advertorials and magazine advertising pages. Apart from that, it was also observed if the magazine contained a certain extra supplement, what is the size of the advertisement, as well as what were the advertised products and brands.

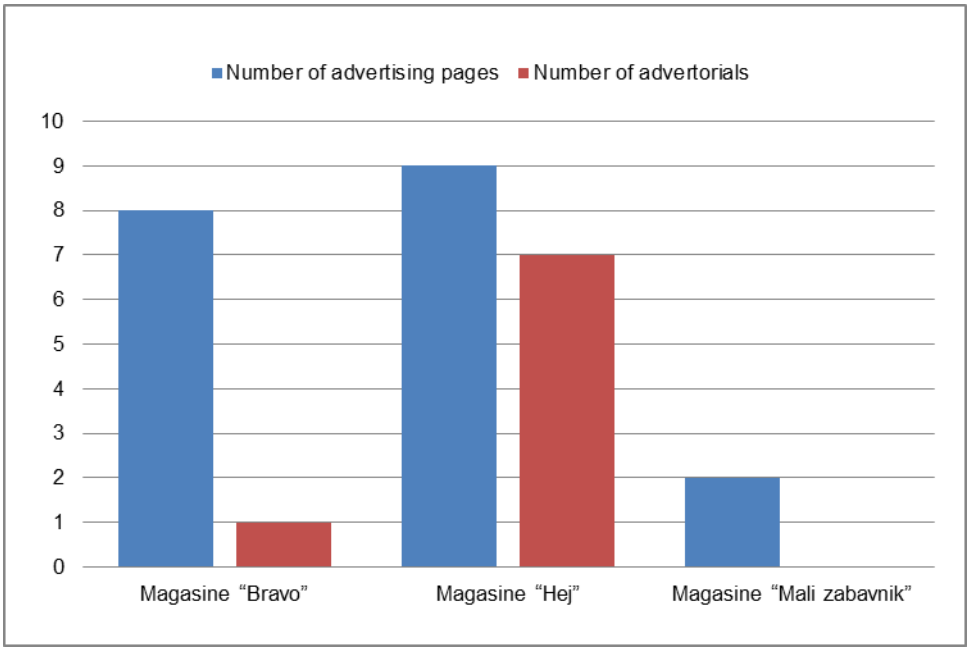

Figure 1: Relationship between number of advertising pages and advertorials

4. RESEARCH RESULTS

Using analysis and research, we can conclude that all advertisement spots last for 30 seconds in average. Looking the manner and details in choice of presentation and formulation of TV ads, and ads in children's magazines, it could be noted that the preparation was detailed and in accordance with targeted audience addressed by the advertiser or company. The ad space in the magazines was designed to make the ads notable, with adequate choice of design. The ads were usually printed on an A4 advertising space in order to present the information clearly. The ads printed on one-half of the pages were mostly brief, with too much text presenting the wrong picture of a product or service that was advertised. Every media campaign in Serbian language that went under this research had a good musical background, tune, and an adequate choice of words addressing the audience. It has been noted that if the TV advertisement is in a foreign language, the words are not pronounced properly, and the text itself is difficult to be understood

Animated characters are used in almost every TV advertisement covered in this research. If the companies decided to implement this way of advertising, they usually used an animated animal character that had some good characteristics that are related to the product that was advertised. It has also been concluded in this research that a great deal of visualized effects were used describing the ingredients of the advertised products. In addition to that, the printed editions contained photographs of a mascot in its promotional surroundings that overlaps with the promotional message that needs to be presented to targeted audience. Within the ad space in printed media, photographs of mascots and celebrity endorsers were used. These photographs remind the audience of colors of the brand, animated character, the distinctive appearance of the product. Using analysis, it has been concluded that the children are told which product they should use during their everyday activities, and if the product is to be their choice, unreal benefits of the product are represented. In advertising spots, the process of fantasizing about some certain abilities and physical manifestations after the use of a product or service is not separated clearly from the part where the product is being presented. It can also be seen that in printed media the ad spaces advertise certain services that suggest an unreal image after their use.

The use of advertorials is present in large amount in researched magazines and ads. Advertorials, in certain editions, became a basic component of magazines, such as redacted columns. Products in form of Gifts are popular, and they are pointed out in advertisements.

It has been concluded in the research that the advertisers usually use the traditional forms of the Internet activity and social media. It is shown in the next Table which of the advertisers has a

corporate website, product website, Facebook page for their product, and Twitter or Instagram account.

Table 2: Online activities of advertisers

	"Chipita Fineti"- sticks and dips	"Cokić na eksić"- beverage	"Mleveni plazma"- ground biscuit	"Barni"- biscuit	"Cipiripi"- cream	"Juhu"- chocolate bar	"Smoki smokić"- flips snack
Corporate web site	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Product web page	No	No	Yes	No	No	No	Yes
Facebook page	No	No	Yes	Yes	Yes	Yes	No
Twitter	No	No	No	No	No	No	No
Instagram	No	No	No	No	No	No	No

5. DISCUSSION

Considering the fact that the advertiser and the company address a specific targeted audience, an adequate approach has to be made. In that way, all advertising spots last in average up to 30 seconds, which is short enough to keep the viewers focused, and to be efficient since it is enriched with varied contents. On the other hand, it is long enough to present the necessary segments and advantages of a product.

Certainly, an adequate research of media characteristics has to be made in order to have the realization of a campaign within the right media that will have an adequate influence on the targeted audience. Therefore, the planned budget and costs for a certain media campaign will be covered having realistic results. The size of an advertisement in printed media is also one of the factors that need to be taken into consideration. Big, simple ads, with clear photographs are clearly transmitting the advertiser's intended message.

TV advertisement that had a good musical background, tune, and an adequate choice of words, represented the product in a more explicit and proper way. Though some information indicated that, some tunes where described as irritating among the consumers, at the same time they were the trademark of a certain product. The amount of presented characteristics of a product is less notable if presenting a simple dialogue between the actors within TV advertisements, including simple music in the background. When the children are suggested a product within a tune, that has some stylistic components such as rhymes and jokes, they will acquire the message more easily, and be informed in a way that is familiar to them. In the process of placement and organization of an advertising spot, it is recommended that the music follow the characteristics of the product and its purpose. By using a control test group, it could be determined if the tune is catchy, pleasant, and if the text is notable. The tune is of essential importance, but the text has to be adjusted. Since the children at that age are still not completely familiar with other languages, a Serbian language form of a text is suggested. Apart from that, the voice in the advertisement should be adjusted with the character pronouncing it; the language should be simple and clear.

All the media campaigns that fell under the research had a celebrity endorser or a mascot for every product. The latest products, or products that are to be placed on the market, should connect main attributes and key messages to a certain designed mascot or character if there is not an animated character or a real presentation of a mascot, the visualization of the product character is harder, including its association with a certain company. Product branding and its placement on the market are certainly eased if there is an adequate character designed for the product. The option of combining photographs, sound, and movements on the TV gives the anticipated results with an occasional appearance of the product character. It has been noted that he photograph of a mascot within printed media, evokes same associations with the same product as in TV commercials. Hence, a photograph of a character is suggested, which would enable its connection to the product, as well as to the advertiser.

Visualization and conjuring the taste throughout real pictures of ingredients are a better choice than animation of main ingredients. The analysis of spots advertising sweets, which are pointing out the appearance of ingredients of products to targeted audience, gives a better insight of a product itself. Based on the research results, a presence of a photograph within a TV advertisement is suggested along with the ad space in printed media. The analyzed media campaigns for children have not shown a notable list of ingredients, or certain components, which raise questions on everyday basis (i.e. suggested daily sugar intake). Children as targeted audience will not understand the importance of the abovementioned characteristics, but the financially solvent family members will, even within a smallest research or having the smallest interest in the product, more easily decided to buy that product.

Apart from previously provided parts of the research of advertisement campaigns, it has also been noted that special attention was paid to some special gifts that are granted with the original product. It has been noted that the ad campaign for chocolate bar "Juhu" designed a package that has free scrapbook pictures. The child sees it as a way of amusement and granting beside the basic product, enabling an extra activity for him or her. Emphasizing the importance of the present within a product in media campaign, a positive reaction is evoked. That data can be clearly presented in all types of media advertisements, and upon presenting the extras and presents, it is necessary to introduce their diversity and ways of getting a hold of them. It is also important to put the appearance and the purpose of presents into a media campaign, making the targeted audience better understand why the product is targeted to them. Innovations that could be presented at the market are the new kind of products that is offered within the packing Therefore, apart from the usual scrapbook pictures and rubbers, those products could also be designed for males or females, in forms of hair bands, simple makeup, or key ring flashlights. In addition to that, a groundbreaking move would be making of an exclusive partnership with some of the grand chains of toy stores, or with popular heroes from certain companies where small figurines are distributed with the product. That would enable a possibility to make a new TV advertisement which could be posted as an advertisement in the newspapers, representing a new partnership.

While doing the analysis, it was noted that apart from the animated characters, the context of the ad is very often put in a realistic time, situations and children's activities. That is why the children become far more happy and capable after the use of the product. The use of certain products and services that contribute physical and psychological advance is often suggested in TV and newspaper ads. This trend of showing realistic situations should be continued in future media campaigns, but overemphasizing and delusion making in what are the effects after using a product should be avoided.

In the retrospect of the use of advertorials in printed media, that were the subject of this analysis, it can be noted that the texts are related to the use of some cosmetic products and consumption of food products. This mode of disguised advertising, that suggest the use of products, is not in accordance with ethical standards, and could jeopardize the company image, once recognized by the consumer.

In addition, an essential part of good media campaign is an active and adequate communication with the targeted audience on social media and on the Internet in general. The shortage of an official web page, as well as a well-organized corporate review of information regarding the product, creates the impression of inadequate care of the company for consumers, and a bad image that is being built. In addition, use of new social media is necessary to keep communication with target groups in pace with modern times. Certain products, that were a subject of this research, were largely criticized on blogs and forums. Given the fact that the Company feedback was missed out, the criticism continued spreading towards social networks. By following announcements and being present in online community, the Producer gained bad publicity. The advantage in following some relevant blogs is multiple, since we can get information on companies, services and products, and in that way, we can be prepared on time for potential crisis. It has also been determined that if a product possesses its own website, its information is more complete, the product seems to be more serious, and it is more accentuated on the market. Interactive websites and Facebook pages where the children are offered special activities, such as games and different creative contests are proven to be very dominant. Based on the research, if the information on a product is strictly within a domain of the corporate website, it is desirable to have a specially determined and technically presented part within the website, so that the user does not spend too much time on finding the right information.

6. CONCLUSION

Children as consumers are being noticed at a greater extent by marketing experts and media planers. Nowadays, it is not questioned if children have influence on the process of buying, but how big that influence is, and how it changes during the time. Along with the process of socialization, they also notice a great amount of products, which have been surrounding them in the everyday communication. Family, as a primary social group, builds certain consumer habits toward the youngest family members. Children under the age of eight are not aware of the nature of certain advertising messages, and are not able to protect themselves from their influence. They notice that there are products, which are placed through various media, on every-day basis.

The aim of this paper was to give an insight into media advertising towards children in Serbia, which covered a certain number of television spots and advertisements, by researching specific media campaigns for children in general. Research was done using seven television spots, and three editions of children's' magazines where 20 pages of advertisement and 8 advertorials were observed and processed. Research included activities on social media, on the Internet in general. Television spots were observed using four types of criteria and those were Usage of animated characters, usage of family motives, usage of motives of children in social environment and usage of music as a factor.

The study concluded that media campaigns aimed at children generally use certain mascot or trademark personality of the product. In addition, music and tone of voice are important factors that affect the level of understanding and interest in the promotional message. TV spots last for thirty seconds, and the most common format of advertising in printed media is one full page. It was concluded that spots mainly present ingredients that are consisted in the advertised product. The analysis shows that the use of the product is associated with real situation and activities of the children, and it often suggests unrealistic benefits of consuming the product. The use of advertorials is very pronounced in certain editions of the magazine. The study also concluded that advertisers generally use traditional forms of the Internet activities and social media. In order to increase efficiency and effectiveness, in the implementation of activities targeted at the youngest audience, it is necessary to further research the topic and area of advertising and specificity of media campaigns for children.

Abstract: *Contemporary information and communication technologies and the Internet have, to a great extent, altered the conventional manners of business and market appearance. A prerequisite for a successful business in a situation characterized by extremely strong competition and the need to, along with existing and potential consumers, build long term partnerships, implies finding new manners of appearance and communication with the consumers. Combining marketing knowledge and contemporary technologies is a recipe for achieving competitive advantages, creating an image and conquering consumers. Therefore, companies pay more and more attention to the introduction of internet marketing strategy that enables interactive communication with their consumers, 24 hours a day, 7 days a week. This paper shall attempt to highlight the significance of internet marketing to the companies that want to outperform their competition, expand their business beyond national borders and to establish continuous and interactive contact with the consumers. The aim of this paper is to point out the most important factors that contribute to the increasing use of internet marketing, challenges it still faces, as well as the situation in Serbia and the world when speaking of the use of this type of marketing.*

Keywords: *internet marketing, challenges, opportunities, Serbia*

1. INTRODUCTION

"If your business is not on the internet, then your business will be out of business." Bill Gates

Modern trends in almost all business segments, extremely rapid changes in the market and consumer preferences are getting more and more difficult to track. The development of technology and increasing use of the Internet have led to the need for quicker and more flexible appearance in the market, continuous monitoring of business and effects achieved, as well as fast response to potential problems. For this reason, marketing appearance in the Internet field has taken a special place in the business of a vast number of companies, as an effective means of achieving competitive advantage, interaction with consumers and building long term relationships with them.

An increasing number of individuals and households have access to the Internet, and the number of those who get informed about products and services via this medium or exchange opinions with other consumers via social networks, forums etc. grows daily. Today, companies have two choices, not to be present in the global network and be unaware of what consumers think of them and their products, or to take advantage of all the benefits offered by the Internet as a medium, and to always be informed regarding the attitudes and opinions of consumers, changes in their preferences, activities undertaken by competition etc.

Therefore, the majority of marketing communication in contemporary business environment consists of a bidirectional communication between the company and consumers. That said, internet marketing has opened up space for practical interactive marketing action, aimed at consumers not as a group of similar individuals, but a consumer as an individual. In addition, the intrinsic characteristics of marketing concept or key principles of marketing remain the same in this case: to create value for consumers, achieve competitive or special advantage and direct and focus aims, resources and efforts of the company to achieve the highest possible degree of customer satisfaction and their loyalty. Specificity or a new qualitative factor that has primarily been introduced to the marketing context by internet marketing is interactivity – direct or immediate with consumers and potential consumers.

Modern trends point out a remarkable growth and expansion of activities based on the use of possibilities and potentials of Internet marketing throughout the world. Today, this type of marketing is highly ranked as means of communication of companies with various profiles that have on that basis already built or wish to set up their future business orientation.

2. INTERNET MARKETING – CHALLENGES AND OPPORTUNITIES

In the last 15 years, Internet has become one of the most significant media of communication of companies with consumers. Moreover, the Internet has become a business tool, instrument of socialization, excellent place for entertainment, limitless encyclopedia and database… At the same time, Internet marketing is one of the most important phenomena in marketing theory and practice, thanks to which companies have access to consumers throughout the world and appear in the global market. David Siegel says: Internet marketing is not about building a web site, but building a web business... harmonising the power of customers (Chaffey and Smith, 2013).

Within its actions, Internet marketing uses Internet space to expand traditional marketing. That said, Internet marketing has many similarities with classic (traditional) marketing. Its aims, as well as aims of traditional marketing are to build relationships with consumers, so that the companies, through offering superior products and services, as well as through continuous communication with consumers, could gain maximum yield. In accordance to the said, it must be creative, interesting and constantly subject to change. What guarantees the success of Internet marketing is, on the one hand, a good product and attractive website, and on the other hand the attention of selected target consumers. The following four pillars of Internet marketing provide the aforementioned to the companies (McAllister, 2013):

- ***Relationships*** - Companies want their customers to buy from you, but customers want to know that they are buying the right thing from the right companie and that after they've bought it they'll continue receiving the right support. Companies can not simply tell them that they're doing the right thing (although this actual statement does help). Companies have to convince them that they interested in THEM, not just their money, and that they interested for the LONG term. The fact is, it is easier to get a group of customers with whom they developed relationships with to purchase from companie again than it is to find and develop new customers. So companies must treat their customers right, as a friends, and help them to find the real answers to the problems they bring the companie, and it will help their business soar.
- ***Tips of the Trade*** – Companies must develop their skills at advertising and internet marketing. They need to invest in a high-quality program that is developed by the true gurus - the people who: 1) know how to succeed in the internet marketing business, 2) know how to teach others how to succeed in the internet marketing business, and 3) are going to be there supporting you as you take the steps necessary succeed in internet marketing.
- ***Value Marketing*** - Many internet marketers make the mistake of pushing their products to the point of forgetting Pillar 1 of Internet Marketing. People want to have a relationship with companies. They want to purchase their product, but they want to know that company have their best interests at heart. And they dont want to be sold to. So, instead of pushing something at them, even if it is the best product ever created, create an attraction for them by building company's credibility. The company must show them that she is a leader in the industry by providing them with value.
- ***Have a HIGH Quality Product*** - In this technological day, customers are being bombarded with sales offers, and it is often difficult to decide which item is the best one. People are willing to spend money, and they are willing to pay the price for something they find valuable, but it is got to be worth the price (even if the price is giving their attention). And since the companies are attempting to develop relationships with customers, and experiences with these customers that will cause them to provide company with good word of mouth, they should make sure that their product's quality towers above its cost.

The implementation of Internet marketing campaigns increases the efficiency of the entire marketing communication, which is achieved by creating a communication strategy aimed at creating relationships and mutual values among the company and its consumers. Internet marketing can help create a business where the customer participates – through a constant dialogue, expressing interests, requesting products and services, suggesting improvements, giving feedback and where ultimately, the customers drives the business.

2.1 Opportunities and incentives of internet marketing

Growth and development of global economy, i.e. the elimination of importance of geographical borders thanks to the development of information technology, including electronic commerce, have provided incentives for the increasing use of Internet marketing by companies around the world. New information technology that involves the use of Internet as a medium has an extremely strong impact on the development of this type of marketing. First, the Internet as a communication medium contributes to the expansion of the marketing communication field, in terms of the number of people involved. Second, the Internet allows the increase of diversity of marketing communication by combining text, video and audio components. Also, the availability of a large number of contents, outreach to a wide range of consumers and the ability of interactive control of experience make the Web one of the richest media today. Third, the

Internet has significantly expanded the intensity of information regarding the market by supplying the marketers (and consumers) with detailed, real-time information about consumers and their transactions in the market (Laudon and Traver, 2009).

The Internet and Web have revolutionized the conventional business models and greatly contributed to the appearance of new ones. The use of Internet is expanding in all sectors of the economy, which allows companies to provide a personalized experience to the consumers through adapting websites to individual preferences and allowing bypassing those contents that are irrelevant to them. This is achieved by monitoring consumer movement on the Internet and combining such information with those obtained from the consumers themselves, including, among other things, payment information, interests, hobbies and the like. Personalization greatly simplifies and makes Internet surfing and finding desired contents more comfortable.

Although today a large portion of promotional campaigns still takes place through traditional marketing media such as television, newspapers, magazines etc., the Internet is playing an increasingly important role in the positioning and continuous strengthening of brands. Personalization technology may help companies to understand the needs of their consumers and direct their marketing campaigns towards precisely defined market segments, thus achieving high response rates. The Internet, as a new medium, enables the broadcasting and publishing messages in the form of bidirectional communication, where direct communication between individuals and organizations occurs thanks to interactivity, independently of space and time. Thanks to the Web, the network is practically unlimited, so there is a possibility of constant presence and establishing contacts with potential customers throughout the world. Thus, the World Wide Web has provided marketing with new tools and benefits that may increase the success of marketing efforts, so it is rightfully considered one of the most important stimulating factors of Internet marketing.

In the mid nineties of the twentieth century, in developed countries, the concept of electronic commerce based on EDI technology started its establishment. Large and costly experiments lead to a combination of electronics and communication with traditional commercial activity. E-business greatly improves Internet marketing and represents an important factor of strengthening companies' competitiveness. Thanks to e-business, the performance of business operations through electronic technology based on interactivity has been enabled. Through horizontal and vertical integration, Web sellers will develop direct e-mail marketing while ensuring consumer protection in the processes of sending and receiving e-mail.The following table shows the impact of e-business technology on internet marketing.

Table 1: Influence of e-business technology on Internet marketing (Laudon & Traver, 2009)

E – COMMERCE TEHNOLOGY DIMENSION	SIGNIFICANCE FOR INTERNET MARKETING
UBIQUITY	Expanding the impact of marketing communications at home, work, etc.; losing significance of geographical boundaries for marketing. Classic market is replaced by virtual, and temporal and geographic boundaries are removed. Consumer benefits are improved and purchase costs are reduced.
GLOBAL REACH	Providing services and marketing communications with consumers around the world. Promotional messages can reach out to a vast number of consumers, regardless of geographical location.
UNIVERSAL STANDARDS	Costs of sending messages through internet marketing, as well as receiving feedback from consumers are greatly reduced due to common, global standards on the Internet.
INTERACTIVITY	Consumers may be involved in dialogue, establishment of communication contents and structure of information, as well as customizing products and services to their own needs and requirements. In this way the provision of individual offers for each consumer is made possible.
INFORMATION DENSITY	Possibility to collect and analyze individual, very detailed information about individual customers. Data mining Internet technology allows everyday analysis of large amounts of data about consumers in order to design adequate marketing campaigns.
PERSONALIZATION/ CUSTOMIZATION	Ability to adapt products, services, and promotional and other messages to individual consumers. In this way long-term relationships with customers are established, as well as ensuring their loyalty and strengthening the ability of marketers to create a brand.

Pursuant to the data from the table, it can be concluded that intensive and continuous changes in information technology open the door to internet marketing and represent an opportunity for its affirmation and increasing use by companies. At the same time, they lead to improvement and increase in the efficiency of internet marketing, as well as to certain alterations and transformations within organizations. This primarily refers to acceptance of new technologies with new products, services and processes by the organizations, or the formation of a virtual organization that in the future shall be one of the most significant organizational forms of business.

In addition to the Web and e-commerce as new technologies, one of the important opportunities for the increase in share of internet marketing are the changes taking place among consumers. Namely, the specificity of contemporary consumers is sophistication that is manifested in the possession of more initiative in making a choice what and how to buy. Prior to the decision on purchase, consumers seek for a large number of information provided by the Internet, i.e. the World Wide Web. Consumers search through offers and information that are available to them, evaluate the offers, consult and exchange experiences with other consumers and users, and make their decision in such a way that they themselves design (create) "their own" product. In such way, companies are trying to adapt to individual customers by providing them with personalized content. Personalization and mass customization can be used in order to deliver individualized content to individuals or groups through websites or e-mails, and to remind the consumers of a product or service offered by the companies.

Personalization can be used in order to offer innovative services to the customers. Online bookseller BOL (www.bol.com) allows consumers to choose their favorite parts from different types of tourist guides, for example, historical facts from one (Rough Guides), maps from another (Lonely Planet), but also include information about nightclubs and restaurants. Such personalized book can be printed at consumer request. Also, personalized services are provided by portals such as iGoogle, Yahoo and Excite (Chaffey, 2011). They provide an opportunity to the consumers to create their own home pages in order to deliver information they are interested in, such as weather data, interesting facts in fashion, film, technology areas etc.

Thus, under the influence of new technology there is a change in relations with customers that operates on an interactive basis, in order to create a more flexible, responsive and long term relationship with target market segments. Personalization and mass customization allow manufacturers to, taking into account every customer, create products in accordance with their needs. In order for the companies to carry out mass customization in the best way possible, today they use integrated Internet, internet and extranet in order to implement various marketing activities.

2.2 Challenges and limitations of internet marketing

Although the development of new technologies, manners of communication and changes in the needs and desires of consumers opens up numerous opportunities for advancement and growing presence of internet marketing in the strategy of company market appearance, there are also many difficulties and challenges that lead to limitations in its wider use.

The most significant of these challenges is related to the use of Internet as a medium in establishing contact with consumers. Internet access is one of the limiting factors, but there are also certain consumption related barriers that may occur with consumers that have access. In fact, a large percentage of current non-users of the Internet (51%) said that they will never connect to this network (Chaffey, 2011). Most people accept innovations with a certain amount of distrust and disinterest. Identical situation is with contemporary information technology and use of the Internet as a medium in marketing communication. Internet as a brand new form of communication was initially accepted by only a narrow circle of people – innovators, primarily scientists, military personnel and university professors. Over time, more and more people started using the Internet and the benefits it provides (Stankić & Krsmanović, 2007). However, it will take many years for the Internet and Internet business to be accepted and implemented in all parts of the world.

Technical challenges of Internet marketing encompass a large number of factors, whose influence shall, due to the continuous development of new technology and finding solutions to current problems, be largely reduced and the impact of some shall be eliminated completely. This type of limitation includes the following categories (Turban, King, Lee, Liang & Turban, 2010):

- lack of security, reliability, standards and some communication protocols;
- narrowness of the field of communication;
- software development tools are still evolving and changing radically;
- it is difficult to integrate the Internet and e-commerce software with certain existing applications and databases;

- customers have a need for special Web servers, network servers and other infrastructure;
- some e-commerce software does not necessarily have to be in accordance with some hardware or may be incompatible with some operating systems and other components.

As for non-technical challenges that Internet marketing has been facing, they cover a range of factors, from legal and ethical issues related to internet marketing, through high costs and other limiting factors. The most significant non-technical challenges are:[1]

- **Effects and impacts of Internet marketing are not yet fully studied and documented.**
  The Internet marketing environment is a rapidly changing field and up to now only speculations concerning its success have been made. There have been successful examples but it is only now that we are entering the maturity stage and realizing its implications. A lot of organisations are waiting for the situation to stabilize before engaging in Internet matketing activities.
- **Several unresolved legal and regulatory issues exist.**
  International and national laws are slowly adjusting to the changes caused by the appearance of this new kind of online activities. Issues like taxation, ownership and ethics on the net need to be addressed.
- **Privacy issues have arisen.**
  Many people are willing to offer some of their personal data in order to have more personalized services. Still, with all the modern technologies and software applications on the one side, and the lack of technical expertise and awareness on the other side, the thin line of privacy may be crossed.
- **People resist to change and are not used to faceless / paperless / non-physical transactions.**
  Most consumers are used to conducting "look and feel" transactions. They are used to touching and examining the product they want to buy. Also the face-to-face contact is very important in business deals and transactions since it is related to trust. But in the new environment of faceless transactions, the concept of trust has to be reconsidered.
- **People feel that there is a lot of exaggeration and are cautious.**
  People feel that there is a lot of enthusiasm but there is undocumented evidence and lack of real and concrete results.
- **People are concerned about possible breakdown in human relationships.**
  People feel that transactions are de-humanized and that personal, social contacts will be reduced.
- **Many business face cultural obstacles and linguistic challenges**
- **Limitatons of support services**
  This limitation implies financial costs and sourcing tech support in foreign languages.
- **Costs and justification**
  Development costs can be extremely high, and errors due to inexperience can result in delays. In addition, it is important that system confirmation is performed with some intangible benefits that are difficult to quantify.
- **Lack of online touch and feeling**
  Potential customers are unable to see and feel the product before the purchasing act, and many of them want to know exactly what they are buying.

An important limiting factor of internet marketing is the possibility of causing negative impact on the company image, especially at a time when consumers are exposed to its impact on a daily basis. Many internet marketing activities are considered intrusive and irritating and consumers perceive them as an invasion of privacy. Unwanted electronic mail (junk mail), a growing number of promotional messages, poor targeting and the like lead to negative consumer reactions and represent a limiting factor in the success of internet marketing. On the other hand, internet marketing can be quite expensive for communicators, since the costs of acquiring consumers are high.

Certainly, plenty of time shall pass until the solutions to the challenges faced by internet marketing are found, but as the understanding of new technology and experience in its use improve, there shall be an increase in the number of internet marketing users and a higher degree of its acceptance in communication with consumers. Until then, numerous legal and ethical issues, such as the issues of privacy, intellectual property protection, freedom of speech on the Internet, as well as protection of customers and sellers from fraud and deception, shall be relevant and encourage finding modern solutions.

(2012)., Electronic Commerce, Turban E., King D., Lee J., Liang T.P., Turban D.C. (2010). Electronic Commerce 2010, A Managerial Perspective and http://saravanesh.files.wordpress.com/2009/06/lecture-02.pdf (May 2014)

3. INTERNET MARKETING IN SERBIA AND THE WORLD

In order to show how rapid is the growth of Internet economy, Boston Consulting Group (BCG) published in 2012 the results of a research according to which Internet business is playing an increasingly significant role in economic growth and that it shall in 2016, as anticipated, participate with 4,2 billion dollars in the gross domestic product (GDP) of the members of the Group of 20 most developed countries of the world (G-20) (http://wd.rs/novosti/internet-zarada-jaca-od-nemacke-ekonomije.html). It also showed that the Internet economy shall grow at a rate of eight percent per year in developed countries, and twice as more in the developing markets. The fastest growing sector is e-commerce, and it is estimated that online market shall double its value by 2018, given that consumers are increasingly demanding access to products and services 24 hours a day, 7 days a week, and the easiest way to do so is to perform operations online.

BCG researches state that the total Internet economy in the UK shall continue to increase over the next four years at a rate of 11 percent per year, reaching a total value of 221 billion pounds by 2016. This is compared to the expected growth rate of 5,4 percent in the USA and 6,9 percent in China. Such trend forecasts are particularly good news for small and medium companies, since the research has shown that in many countries, including France, Germany and China, small and medium companies that actively operate their business in the Internet, have obtained significantly higher sales growth, in comparison to companies that are not present enough on the Internet, and that in the past three years, their revenues increased by 12,5 percent each year. All of the above indicates that Internet marketing plays a very important role in achieving success in the contemporary, highly competitive market.

This is corroborated by the fact that the global network has become the second most important medium for advertisers for the first time, and digital promotion today covers 25,6% of the advertising market in Europe. Advertising on the internet rose last year by 11,5% in Europe and 17,29% in Serbia, as stated in the results of recently published research of the Interactive Advertising Bureau (IAB). Internet advertising revenues in the United States totaled $42.8 billion for the full year of 2013, with Q4 2013 accounting for approximately $12.1 billion and Q3 2013 accounting for approximately $10.6 billion. Revenues for the full year of 2013 increased 17% over 2012 (www.iab.net). The following figure shows the trend of growth in revenues from Internet advertising in the period between 1996 and 2013.

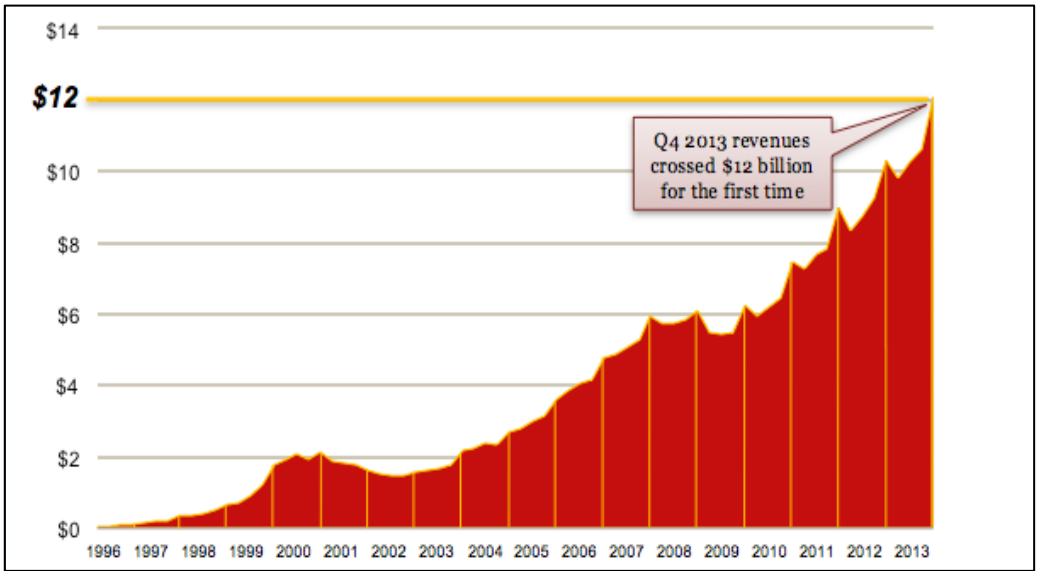

Figure 1: Revenue growth trends 1996 – 2013 ($ billions) (www.iab.net)

This growth is attributed to the increasing number of Internet users who order products and find information on various brands in the global network. This refers to advertising on websites, social networks (Facebook etc.), and search engines (Google, Yahoo) and include promotional messages on computers and mobile phones. Only in Europe there are 426,9 million users of the global network. In America, another enormous digital market, there are more and more members of the auditorium who watch films, series and TV shows on websites. Apart from the above, advertisers have noticed that an increasing number of readers read their papers in electronic format. Analysts have estimated that Internet marketing shall, from its current share of 18 percent in marketing industry, reach a share of 23,4 percent in 2015. According to recent estimates of the European Commission, this year's rise in revenues from advertisements in online and mobile sector shall be 1,9 percent in the UK and 1,2 percent in Germany. Eastern European countries have recorded even larger growth since this market has started to develop later in these countries.

What indicates the growing importance of Internet marketing is the research how the world's top 100 companies use the Internet for marketing purposes, and the results show the following (Miljković, Alčaković & Alčaković, 2011):

- 100% of companies has a website,
- 33% have a corporate blog,
- 54% have Facebook fan pages,
- 65% have Twitter accounts.

Companies that operate in Serbia also increasingly recognize the importance of Internet marketing and the advantages it brings in reaching out to existing and potential consumers. Online advertising market is increasing along with growing habits of domestic customers to order goods and pay bills on the global network, but also to "consult" websites and forums prior to purchasing. The value of the digital advertising market in Serbia last year amounted to 14,32 million Euros, with most advertisements relating to consumer goods (18%), mobile phones (16%) and IT industry (11%) (rs.ejo-online.eu). The following table shows what techniques of appearance on the Internet and Internet marketing tools are used by companies operating in the domestic market.

Table 3: Internet marketing of top 10 companies in Serbia in 2012

Rang	Kompanije	Web site	Blog	Facebook	Twitter
1.	NIS	√	x	√	√
2.	EPS	√	x	√	x
3.	Telekom Srbija	√	x	√	√
4.	Delhaize Srbija	√	x	√	√
5.	Srbijagas	√	x	x	x
6.	Tarkett	√	x	√	√
7.	Merkator - S	√	x	√	x
8.	Delta Holding	√	x	√	√
9.	Victoria Group	√	x	√	x
10.	Koncern Farmakom M.B.	√	x	x	x

√ - exists; x – does not exist

Regardless of the presence of the majority of domestic companies in the market, their management still does not observe seriously enough their appearance on the Internet. Although 95% of the companies have their own website, they sometimes are not updated and improved for a longer period of time, or they do not follow current trends. Also, in case of holding companies, a very common situation is that every subcompany does not have its own individual website, but that the main information of all subcompanies is on the main website of the holding company. On the other hand, none of the companies have a corporate blog. Some companies have a news category where they post information which fall into the category of PR announcements rather than a blog. Given the importance of blogs in the world of Internet, it is essential for companies to change this attitude (Miljković, Alčaković & Alčaković, 2011).

The fact is that Internet marketing in our country is becoming increasingly popular, whereas budgets dedicated for online promotion from one year to another have been growing, so that in the future we may expect a large number of creative solutions in this type of marketing. Also, most analysts predict further growth of online marketing industry, since millions of people around the globe conduct business via the Internet or spend their free time on it. Therefore, the use of Internet marketing is something that companies of all sizes need to recognize as an opportunity to conquer and to better understand their consumers, as well as to construct a distinctive competitive position in the market.

4. CONCLUSION

Internet marketing is an activity that is in growth phase and gains significance daily, especially due to its great impact on the creation and maintenance of partnerships between companies and consumers. Every company that wants to be successful and recognized in the market must have a high quality Internet presentation and well-designed Internet marketing campaign. Internet marketing brings benefits to both

consumers and companies. On the one hand, consumers benefit from the availability of a large number of data and information, interactivity and immediate, continuous communication with companies 24 hours a day. On the other hand, companies have gained a powerful tool that enables flexibility in appearance in the global market, as well as the development of long term relationships with customers. Therefore, it is still unacceptable that a successful company does not have its own website, as it borders with the fact that it is almost non-existent.

Due to the growing number of Internet users in the world, online marketing is experiencing long term growth trend. Millions of people have access to the Internet from personal computers, laptops or mobile phones, which provides access to various consumers and gives a strong boost to the internet marketing industry. For those wondering what the future of internet marketing will be, it is very important to point out that the answers are diverse and numerous. Some experts say that web design will greatly affect future online success of the companies because it is a great way to attract attention and interest of the consumers. Great design is also a great way to build trust with target audience. Besides that, content marketing will be bigger than ever, considering the fact that the sole purpose of this type of marketing is presenting clear and valuable content to the consumers through variety of channels. Judging by the latest trends, the next step in advertising will be directing resources towards mobile devices which are the future. In fact, predictions say that the 87% of connected devices sales by 2017 will be tablets and smartphones. Therefore the companies must provide positive experience for the consumers that are browsing via a mobile phone through creating the alternative mobile versions of the website or by using the appropriate web design. Otherwise, it's easy to lose customers to competitors who have adapted to this trend. So called "Native Advertising", which is mentioned more and more often should provide greater efficiency of net advertising regardless of the type of format. This way of advertising implies thematic sync of the advertisement with the content consumed by the customer, i.e. even more precise targeting of the target group as well as more efficient placement of the ads. Social network advertising is becoming more and more popular due to the fact that these types of websites are appearing on a daily basis. In addition, the advertising on those types of websites is much cheaper than, e.g. banners on the most visited native websites, and at the same enables various payment models as well as much more precise selection of the target audience.

Internet marketing in our country is experiencing increasing popularity, and budgets allocated to this form of promotion grow yearly. However, despite the trend of growth of digital advertising, many domestic companies still do not realize that Internet appearance requires constant innovation and improvement, since otherwise they shall not be competitive in the future. What businesses need to take into account is to adhere to a code of conduct on the Internet, follow the examples of successful global companies and create a distinctive strategy for Internet marketing.

Abstract: *The aim of this paper is to compare ATL and BTL advertising tools and to examine consumers attitudes towards these channels of communication. By analyzing several examples of global companies, we came to the conclusion that companies are increasingly turning to BTL activities and reducing their ATL budgets, allocating it for BTL campaigns. The survey we conducted showed that consumers themselves consider that BTL techniques are more efficient and effective than traditional forms of ATL communications. However, companies should not disregard the ATL activities, but they need to be creative and innovative when making campaigns.*

Keywords*: Above the line, Below the line, Through the line, Advertising, Marketing*

1. INTRODUCTION

Considering the changing requirements of today's business, many companies wonder how to best represent their products or services to customers, and therefore to encourage sales. The solution is certainly in the quality of communication with end consumers. Defining the advertising as a creative communication process, we distinguish ATL, BTL and TTL advertising techniques. Lots of companies spend large ammounts of money on marketing campaigns, combining these three techniques of advertising. The aim of this paper is to examine consumer attitudes on effectiveness of these types of advertising, as well as to indicate on what kind of communication should companies be oriented.

"Marketing is the science and art of exploring, creating, and delivering value to satisfy the needs of a target market at a profit. Marketing identifies unfulfilled needs and desires" (Kotler, 2012). Marketing points out to the process of preparing the product for the marketplace. "Advertising is any paid form of non-personal presentation and promotion of ideas, goods and services through mass media such as newspapers, magazines, television or radio by an identified sponsor" (Kotler & Armstrong, 2001). Advertising is just part of the whole marketing process and it refers to making your product and service known to the marketplace. Advertising is a way of communication with customers in order to familiarize them with the product or service and therefore encourage sales.

In the context of advertising, more and more often we hear the terms "Above the line" (ATL), "Below the line" (BTL) and "Through the line" (TTL). ATL, BTL and TTL are advertising techniques. ATL is a term that indicates the promotional activities of the companies done through the mass media channels of communication. BTL is a type of advertising that encourages immediate or delayed purchase, and TTL points out to the activities that try to integrate both ATL and BTL.

2. ATL, BTL AND TTL

These terms were first used in 1954 when Procter & Gamble began paying advertising firms separately from other suppliers who dealt with more direct promotional efforts (Manral, August 22, 2011). The term originated spontaneously while composing a budget of Procter & Gamble. Only traditional advertisement costs were listed in the draft budget (television, radio, printed media, outdoor and movie theatre ads). Employees in company then considered free sampling, discount programs, sweepstakes, sponsorships, etc. which made them draw a line below initial costs, in order to include these previously uncharted costs of promotion (In the Beginning, There Was ATL, n.d.). Advertising agencies made commission from booking different types of media – TV, cinema, radio, press, magazines and out-of-home. Since BTL activities had no involvement of media, no commission was made for these agencies. The accountants marked different types of media as ATL an BTL depending on where it would sit in the balance sheet and profit and loss accounts (ATL stands for profit oriented activities, and BTL stands for non profit activities). During the time, this advertising budget structure became popular and became practiced around the world. Now, "above the line" stands for capital expenditures and "below the line" for current expenditures (Advertising, n.d.).

“Above the line” is an advertising strategy based on all types of communication, which involves the use of mass media channels such as television, cinema, radio, print, and out-of home, in order to promote brands or present special offer (Pritchard, 2011). The objectives of ATL activities are to strengthen brand awareness, to build a brand identity and to improve the brand image about company’s product or service. This type of communication is conventional and impersonal to customers, and much more effective when the target group is very large and difficult to define. One of the major drawbacks in the ATL campaigns is the inability to evaluate the commission based on the campaign. It is impossible to calculate how much the sale increased due to campaign. For this reason, companies spend large ammounts of money on ATL campaignes, without being able to measure their effectiveness. It happens that these campaigns do not give results, and companies do not have a way to deal with it. Looking at a longer time period, it is certainly necessary to communicate with consumers using ATL tools, in order to acquire the habit of consumption of the specific product. However, ATL is necessary, but uncertain.

“Below the line” uses less conventional methods than ATL, focusing on direct communication, like promotions, sampling (tastings), sweepstakes and contests, loyalty programs, “guerilla marketing”, direct mail and event marketing. BTL refers to non-media communication which is short-term incentive and mainly oriented at consumers (Pritchard, 2011). Main advantages of BTL are better targeting, direct and often personalized communication, with measurable performance (ROI can be calculated) and more tightly attached to sale than ATL. Advantage of BTL is also in communication flexibility. BTL campaigns take place at the point of sale, where consumers can make the final decision on the purchase. There is a direct interaction with customers or potential customers, indicating the opportunity for personalization of communication. Once you achieve effective personal approach, sales should increase. BTL is a common technique used for “touch and feel” products, where the customer will rather rely on immediate information about product, than previously researched items. This technique ensures recall of the brand while at the same time highlights the characteristics of the product.

ATL is facing creation awareness of the product while BTL is facing creation of a desire for purchasing the product. Above the line is much more effective tool of advertising when the target group is very large and difficult to define, while below the line is more advisable when the target group is limited and specific.

“Through the line” is related to an advertising strategy which involves both above and below the line forms, where one form of advertising indicates the target market to another form of advertising, thereby crossing the “line.” In recent years, agencies and clients have switched to integrated communication (Pritchard, 2011). Mix of ATL and BTL is used to optimize returns from these separate investments and to integrate marketer’s efforts. The main idea is to optimize the return on marketing budget spent on BTL battles than on ATL wars with well-funded competition. (PR Newswire, January 23, 2006).

3. ATL VS. BTL TRENDS AND EXPENDITURES

In the case of Canon India, this company has taken various activities (photography workshops, activities in retail touch points, consumer engagement activation, exclusive lounges, experience corners in retail shops) to engage more consumers with its products. This company’s annual marketing budget was 9,592,000.00 EUR in 2008. In 2008, the company’s marketing spend came down by 2,398,000.00 EUR, leaving it with 7,194,000.00 EUR to spend in the economic downturn, with consumers increasingly deffering their buying decisions. Technology is such a category of products where the obsolescence rate is high, so as the level of brand loyalty. Consumers decisions depend mainly on practical experience and experience of others. Company management decided to increase the BTL spend by 20 per cent, in order to provide consumers with more than “hands on product“ experience. Canon India's BTL share now stands at 70 per cent. Canon India has decided to create a better relationship with customers by sharing with them the technical knowledge on how to use the product better. The company has developed BTL strategy which included all parts of its marketing chain: consumers, traders and promoters (Tyagi, January 30, 2009).

Large corporations and well-known brands know that experience and engagement of consumers can be achieved only through BTL, so more and more marketing money is spent to connect with consumers (Balasubramanian, August 01, 2013). Estimation is that the BTL industry is growing at 25-30 per cent and will continue to grow exponentially over the next few years (Ernst & Young Report, 2012). Goal of the BTL activations is that the consumers elicit an emotional response so that they remain inspired and touched. In this way, consumers are not only introduced with the core benefits of a product, but they are honored to try or test the product, give their contribution in the form of feedback, and participate actively in the process of brand building. Thus, consumers feel special and treated with care, and the information you get in return are very valuable. Brands can’t just talk down to customers, they need to be part of a two-way communication.

Companies like Voltas, LG and Whirlpool indicate that their in-store activation budgets have been upped by as much as 20 per cent compared to last year. In many cases, BTL spendings give better return on investment than ATL. LG's inclination towards BTL has come at a rise of 15 per cent as compared to last year. Despite the high brand recall, LG feels that the process cannot be completed unless there is direct customer engagement, in-shop demonstration. Whirlpool is expecting its BTL spends to go up by 15-20 per cent than the previous year, which includes adding more hands-on in stores (Pal, May 28, 2013).

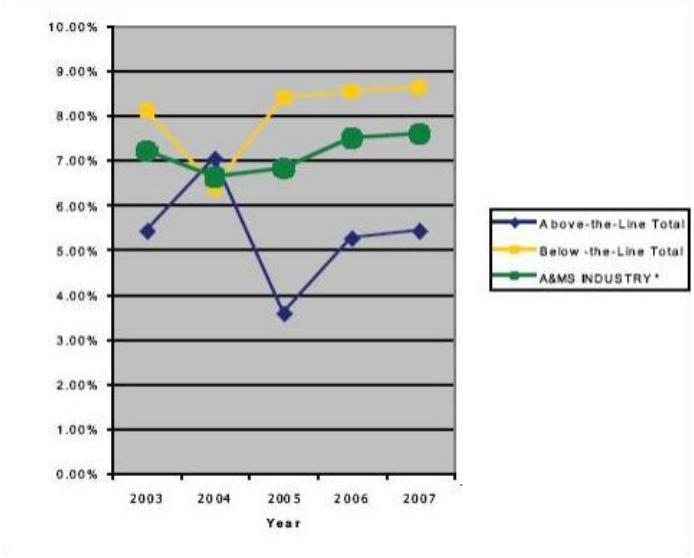

Figure 1: Growth in expenditure of BTL and ATL activities
(V12 Group & Winterberry Group LLC Report, 2006)

As we can see on the Figure 1, ATL expenditures compared to BTL expenditures have decreasing trend over the years. On this figure, we can see where the efforts are, but we can not see why. It is interesting that after so many successful years with ATL methods, companies are increasingly turning to BTL approach. Also, consumers are more willing and open to BTL communication rather than ATL. There are seven trends exploring the internal and external factors that are contributing to this emerging marketing emphasis. These trends are directly impacting the allocation of marketing budgets for both ATL and BTL campaigns. Trends are given in the table below.

Table 1: Seven trends impacting the allocation of marketing budgetes for ATL and BTL campaigns
(Atl and Btl Activities Research Paper, 2008).

1. Changing consumer demographics decrease the influence of traditional mass media marketing messages.
2. Growing consumer sophistication heightens the demand for channel-agnostic communications.
3. Widespread marketing "clutter" diminishes the impact of commercial messages that don't address specific and individually relevant consumer needs.
4. Enhanced information availability empowers both marketers and consumers with insight that allows for precise customer targeting and intelligent purchase decisions.
5. Heightened client pressure to deliver quantifiable value by evaluation of ROI of the marketing initiatives , forces marketing service providers – especially agencies – to re-evaluate services platforms.
6. Growing effectiveness of "multichannel" campaigns (those that cross multiple media) reinforces demand for tactics that establish one-to-one relationships between marketers and consumers.
7. Rapid technological advances allow for consumer/marketer interactions that are more frequent, easier and more relevant than previously possible.

4. SURVEY: CONSUMER'S POINT OF VIEW

In order to examine the consumer's point of view regarding the efficiency of ATL and BTL campaigns in Serbia, we conducted an online survey, with 200 participants, where 45 % respondents are male and 55 % are female. Survey participants are Serbia citizens, where 67 % of them are currently students, 20 % are

employed and 11 % are unemployed. 26 % of respondents make buying decisions on their own, while in 61 % of respondents households, that decision is made together with other family members. In Table 2, you can see an overview of the respondents age.

Table 2: Respondents age overview

Age	Response	%
Less than 20	4	2 %
20 – 25	176	88 %
26 – 30	16	8 %
31 – 35	0	0 %
36 – 40	2	1 %
41 – 45	0	0 %
46 – 50	0	0 %
More than 50	2	1 %

Our aim was to examine the attitudes of consumers and their reactions to various types of ATL and BTL advertising techniques. The survey is designed to first examine the attitudes related to ATL, then BTL, and then to compare these techniques.

As a response to question how do the respondents react when they see a commercial break while watching televison programs, 45 % said they immediately change the channel, 6 % watch commercials, while the rest devote to other activities. Many respondents do not have clear attitude about what does the TV commercials try to say and more than 50 % of them think that those commercials do not affect their opinion on products/services. Also, most of them are sure that TV ads do not encourage the purchase of goods. High percentage of the respondents consider that quality TV commercial must be short, funny, true and of course, original. Commercial that will evoke emotions, connect us with a brand and thus encourage the purchase.

Taking into consideration other ATL channels of communication, the results are given in the table below.

Table 3: Attitudes towards ATL channels of communication

	Question	Disagree	Mostly disagree	Neither agree nor disagree	Mostly agree	Agree
1	Radio commercials attract attention.	36,45 %	18,69 %	20,56 %	21,50 %	2,80 %
2	Billboard advertisements affect my opinion about product/service.	17,76 %	31,78 %	35,51 %	14,95 %	0
3	Advertising in print media inform me about product/service.	19,63 %	22,43 %	38,32 %	16,82 %	2,80 %
4	I always read the leaflet I get.	23,36 %	24,30 %	18,69 %	24,30 %	9,35 %

When ranking the advertising type that most influences consumers opinion on product/service of all ATL communication channels, first of all are TV commercials. Billboard advertisements take second place, while radio and print media took an equal number of votes for third place.

When we look at the consumer's point of view of ATL campaigns, generally it seems that they are not too enthusiastic and thrilled, on contrary, they are tired and they feel this kind of marketing does not affect their awareness about product or service. Therefore, companies need to be more innovative and creative in their ATL campaigns, which is very difficult to do in a saturated market.

Talking about BTL campaigns, 42 % survey participants like to be informed about promotions in sales objects where they usually do shopping, but more than 50 % participants are not willing to inquire about the promotion by themselves. They are not ready to make first step and approach to the promo stand. Companies therefore have promo teams who have to be very communicative and pleasant, but not intrusive, who will provide necessary information at the right place, at the right time. Around 68 % of participants like to get free samples of some products at the point of sale. It is important for consumers to be able to feel, touch and taste a product which is being offered. On the other hand, less than 50 % of respondents do not like to

taste free food at the point of sale. Depending on the purpose of a product, companies need to consider whether to do free sampling or to allow testing the product at the scene.

Beside the promotion, some other BTL activities like sweepstakes and direct mails are interesting for consideration. The same percentage of respondents is interested, disinterested and neutral towards taking part in the sweepstakes at the point of sale. One of the consumers favourite BTL activation is receiving gifts when buying a certain product. Most of them declared that branded shelves in sales objects attract their attention, but great majority of them ignore informational e-mail about new products or services.

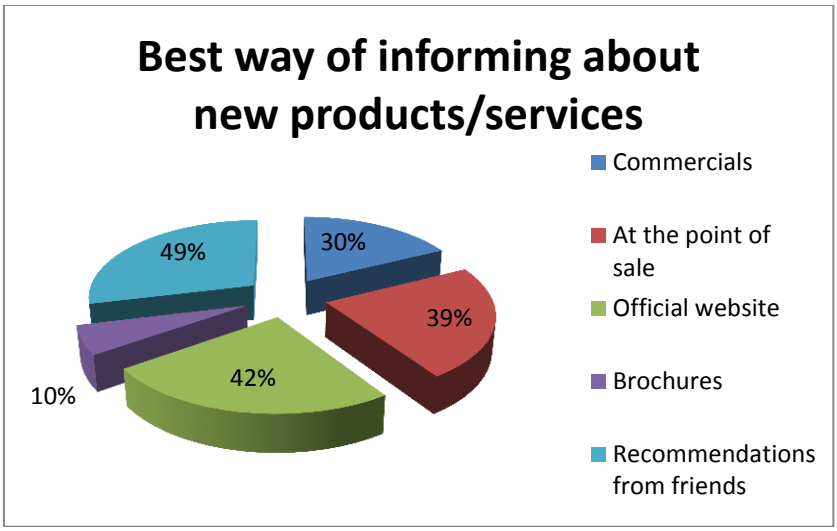

Figure 2: Best way of informing about new products/services

As we can see in the Figure 2, most of the survey participants trust a friend's reccomendation when informing about new products or services. Brochures and commercials are becoming more and more the past, while websites and points of sale are becoming the future. Companies need to spend less on print materials, and to invest more in quality staff who will be qualified and capable of explaining to potential buyer everything he wants to know about certain product/service.

As a result of the survey, we found that consumers in Serbia prefer BTL communication. They are much more ready and willing to engage in BTL mechanisms than to be left to television and other ATL media. Personal, 1-1 communication makes them feel special, which contributes to the effectiveness of BTL campaigns. In this way, consumers feel like someone cares about their needs and they are creating desire for buying that product they will be thrilled about.

5. CONCLUSION

Analysing the practice of few global companies, so as results of conducted survey, we have concluded that BTL campaigns are gaining more and more importance. Marketing activities which are left to the consumer's free will, meaning that he has a choice to see them or not, are doomed to failure. Customers have less time for shopping, their taste is more refined, their money is requiring maximum quality and their wishes are more and more specific. Because of that, companies need to maximize efficiency of communicating with target customers. The effectiveness of BTL activities is rising, that is why companies are ready to invest more in BTL than ATL mechanisms. They should invest more in BTL activations and on 1-1 communication. ATL should not be disregarded, but people are getting bored with classical way of advertising. Less budget should be spent on ATL, but ATL sector must increase innovation and creativity when inventing a campaign.

OPERATIONAL RESEARCH AND QUANTITATIVE METHODS IN MANAGEMENT

APPLICATION OF SOME LOCATIONAL MODELS IN NATURAL RESOURCES INDUSTRY - AGRICULTURE CASE

Bisera Andrić Gušavac[1], Dragana Stojanović[1], Željko Sokolović[2]
[1]University of Belgrade, Faculty of Organizational Sciences, {bisera; stojanovicd}@fon.bg.ac.rs
[2]Railroad Technician School, zex.sokolovic@gmail.com

Abstract: *Nowadays large scale, uncertainty and multiple objectives appear increasingly in decision processes. One of the very important strategic decision for starting a business is where to locate facility. Application of operations research methods and models has had a great success throughout the years, including modeling and solving various location problems. Natural resources industry, especially agriculture sector, is a significant factor of growth and prosperity most commonly for developing countries. Operations research/management science (OR/MS) contributions in each one of applied areas of natural resource industry – agriculture, fisheries, forestry and mining are very significant. In this paper we present application of Capacitated Facility Location Problem (CFLP) in agriculture sector and we are encouraging researchers to use quantitative techniques in order to manage the use of different natural resources.*

Keywords*: Natural resources industry, Agriculture sector, Location analysis, Capacitated FLP*

1. INTRODUCTION

By using natural resources according to their needs, a man survived and evolved as a cultural, social and spiritual being. The development of various technologies shaped the life of modern man, but led to the rapid exploitation of its environment, and the rapid depletion of resources. People have changed the face of the earth more than any other species in the history of the planet - and the speed of these changes is increasing. People today spend between one-third and one-half of what the global ecosystem created.

The natural resources of a country determine its wealth and status in the world economic system, its power and political influence. According to this, it is obvious that operations research, as a discipline that deals with the application of advanced analytical methods to help make better decisions has a significant impact on decisions in this area. Application of operational research methods and models to modelling of complex realities and development of algorithms for problems increasingly difficult to solve has had a great success throughout the years (Weintraub, 2007).

Operations research has played an important role in the analysis and decision making of natural resources, specifically, in agriculture, fisheries, forestry and mining, in the last 40 years (Weintraub, 2007). There are natural differences related to the form of managing the production in each application. For example, the time horizons of growth and extraction vary from months to a year for fisheries and agriculture, to almost a century for some tree species. Mining is non-renewable, and, as such, is associated with a different type of natural resource (Bjørndal et al., 2012). Mine lives can run for a few years to centuries. In agriculture, farmers are primarily concerned with how to plant crops and raise animals more efficiently.

Decisions in forestry are centered around the strategic, tactical and operational levels of managing plantations and public lands to meet demands while adhering to supply restrictions, which are coupled with events such as forest fires and policies, e.g., environmental regulations and concerns (Bjørndal, 2012).

Operations research, e.g. location analysis has been applied to handle various problems in agriculture and forestry area, elaborating on mathematical techniques and successful applications. In this paper we present one more application of OR/MS in agriculture sector and we are encouraging researchers to use quantitative techniques in order to manage the use of different natural resources efficiently from an economic as well as an environmental point of view.

2. NATURAL RESOURCES INDUSTRY AND OR/MS

According to the significance of natural resources especially today, it would be expected that operations research (OR) could have made a significant contribution to decision making in this area. But achievements in practice have been disappointingly small. The industry comprises of a large number of small individual businesses which do not permit specialisation in management functions. Consequently, technical advice and

much R and D is provided from public funds. OR applications for agriculture have mainly been developed by Universities, Colleges, State Advisory Services and Quangos. Quango is a quasi-autonomous non-governmental organisation is an organisation to which a government has devolved power. In the United Kingdom this term covers different "arm's-length" government bodies, including "non-departmental public bodies", non-ministerial departments, and executive agencies. The Forestry Commission, which is a non-ministerial government department responsible for forestry in England and Scotland, is an example of a quango (Wikipedia, http://en.wikipedia.org/wiki/Quango).

Some techniques are frequently used in agriculture like linear programming, dynamic programming and simulation. Other techniques have had limited uptake and application. Reasons for the pretty low impact of OR are outlined as a set of problems specific to farmers and their systems and problems specific to computer use. One of the obvious problems in efficient application of OR/MS methods and techniques are in recruiting and training OR specialists for these specific fields of application. Generally, how important OR models are in decision making depends on several factors (Weintraub & Romero 2006):
—The quality of data,
—The competitiveness of markets,
—Ownership and
—The culture of the application area and peoples' understanding of OR's advantages.

There exists several ways for increasing OR impact in these areas: one is in training today's farmers (and, probably more important, future farmers) in an understanding of what computers can do and what models are available. There is a general lack of good flexible formulation of problems to be dealt with by OR techniques. A third problem is the need for much more efficient two-way communication and feedback between the developers of OR tools for agriculture and practical farmers. At present OR has connotations of being of little use to practical farmers, but of great value to academic enthusiasts who are unable and/or unwilling to transfer ideas into practicality.

3. APPLICATION OF LOCATION MODELS IN AGRICULTURE SECTOR

Location theory has found its use in agriculture since the early days of the field. The theory of spatial equilibrium and optimal location and the foundations of agricultural location theory are traced back to the classical work of von Thunen in 1826. He investigated the impact of the distance from the market on the use of agricultural land.

In agriculture, use of OR models is increasing with advances in hardware and software. The most commonly used OR techniques are LP models, simulation, risk programming, and multiple-criteria programming. People use models at two levels and for two purposes. They use them to improve decisions at the farm level, and they use them to help policy makers predict the impact of policy changes on farmers' behaviour (Weintraub & Romero 2006). Lucas and Chhajed (2004) give an overview of application of location analysis in field of agriculture and some selected applications of location analysis in agriculture are presented in table 1.

Table 1: Selected applications of location analysis in agriculture (adapted from Lucas and Chhajed (2004))

Authors	Problem description	Features
Grain storage in South Brazil (Borstein and de Casto Villela, 1990)	Optimal location of warehouses for grain storage, then location of service stations for technical assistance	Economies of scale Political, economic, and social aspects Partially funded by State Agency
Soybean-processing industry (D. Souza, 1988)	Optimal number, size, and location of soybean processing plants	Large size, with 57 regions US Economies of scale Multi-commodity (soybeans, then meal and oil) Consideration of two base periods 1977-1981 and predictions for 1999 and 2000
Cattle-slaughtering industry in Queensland, Australia (Brown and Drynan, 1986)	Selection of plant sites, sizes, throughputs and product flow	Economies of scale Marked seasonal and year-to-year variations Comparison of results form static and dynamic models

Authors	Problem description	Features
Post-harvest handling-chain operations in Northern Tahiland (Chu, 1989)	Optimal number and location of cooling facilities and assignment of production sites to those facilities	Large-size problem with 30 villages and 50 kinds of vegetable products, Problem decomposition, based on access road network and on locations of various extension stations Seasonality of production volumes and access road conditions Project supported by Government
Dairy industry in Ontario, Canada (Polley, 1994)	Changes in existing network (closing of several plants and warehouses) at Aults Foods – Canada's largest diary processor	Analyse the benefits of specializing each plants production mix and using multiple sources for shipping depots Sensitivity analysis with sales projection for 3, 5 and 10 year 30 plant production strategies
Brewing industry in Turkey (Koksalan, 1995)	Optimal locations of new breweries, and optimal distribution plans for malt and beer	Large-scale problem with 15 alternative cites and 300 customer zones High seasonality of beer demand, capacity constraints

Mladenović (2004) states common classification of location problems into (a) continual, (b) discrete, and (c) network models. Location problems in agriculture exhibit several features, such as their large scope and size, or the consideration of multiple and often conflicting objectives and, thus, demonstrate increased levels of complexity and realism. Common in agriculture are location– allocation problems, in which the number of facilities, their locations, and these interactions all become decision variables. Moreover, these location–allocation problems themselves are often complicated by routing decisions, leading to location–allocation-routing models.

Lucas and Chhajed (2004) presents six groups of location analysis application in agriculture: a cotton-ginning problem, the location of grain sub-terminals, the collection and processing of rubber, the fresh citrus packing industry, the cattle-slaughtering industry and The Bangladesh grain model. These applications of location analysis in agriculture do not consider solving of airfield location problems. Description and solution of one of the first problems regarding location models in agriculture aviation in Serbia can be found in Andrić Gušavac et al. 2013.

3.1 Simple and capacitated plant location problems

The simple plant-location problem (SPLP), also known as the uncapacitated facility-location problem, is one of the fundamental and most studied models in facility-location theory. The objective is to choose, from a set of potential facility-locations on a network, which ones to open to minimize the sum of opening (or fixed) costs and service (or variable) costs to satisfy the known demands from a set of customers. Although the origins of the plant-location problem go back to the pioneering work of Weber (1909), the actual of SPLP may be attributed to Stollsteimer (1963), Kuehn and Hamburger (1963), and Balinski (1965). In view of the size of facility-location problems that being tackled in practice today, ability to solve very large SPLPs is becoming more important. Mladenovic et al. (2006) develop a new methodology for solving the SPLP using variable neighbourhood search (VNS) to obtain a near-optimal solution, and they show that VNS with decomposition is a very powerful technique for large-scale problems, up to 15,000 facilities × 15000 users. Hansen et al. (2007) emphasized the fact that the SPLP is finding other applications in such areas as cluster analysis, computer and telecommunications network design, information retrieval, and data mining.

A basic CFLP model was formulated by Balinski (1961) and Manne (1964) for the simple plant location problem. This problem consists of locating plants and warehouses among a set of given locations in order to satisfy a given demand at minimum cost.

The assumption that all potential sites equally costly used like in maximal covering location problem, *p*-center, *p*-median problems, and location set covering problem is dropped in the simple plant location problem and its variant, the capacitated plant location problem (CPLP). Its objective is to locate an unspecified number of facilities and to meet all demand while minimizing the sum of site-related and transportation costs. The model makes a number of assumptions, the most important of which are as follows (Eiselt & Sandbloom, 2004):

- The facility can be supplied with unlimited resources whose prices do not vary by source;
- The transportation costs from factories to markets are linear, i.e., there are no economies of scale;
- The production costs at a facility are linear in a quantity produces once an initial fixed cost has been incurred;
- Demand in known and does not vary with changes in the delivered price;
- There is no capacity limitation on the quantity produced at a factory (for the SPLP);
- There is a fixed cost for purchasing and developing a site of selected for a facility.

Given the above assumptions we can define the following parameters. Denote by the fixed costs for opening facility , is the distribution cost for satisfying demand of user from facility . Then we need to define two sets of variables: is a binary variable equal to 1 if facility is in use and 0 otherwise; variable is the percentage of a satisfied demand of a user from facility . Now we can formulate the simple plant location problem as follows.

$$\min_{x,y} z_p = \sum_{i=1}^{m} f_i y_i + \sum_{i=1}^{m}\sum_{j=1}^{n} c_{ij} x_{ij} \qquad (1)$$

s.t.

$$\sum_{i=1}^{m} x_{ij} = 1, \quad \forall j \in I \qquad (2)$$

$$x_{ij} - y_i \le 0, \quad \forall i \in I, \forall j \in J \qquad (3)$$

$$y_i \in \{0,1\}, \quad \forall i \in I \qquad (4)$$

$$x_{ij} \ge 0, \quad \forall i \in I, \ \forall j \in J \qquad (5)$$

The placement of upper limits (that is, capacities) on supplies transforms an uncapacitated problem into a capacitated one. The CFLP is defined by introducing another type of constraints (6), which refers to the capacity of airfields. Denote by surface of fields in hectares and capacity of each airfield. Capacity of airfields is defined as total amount of fields in hectares which can be cultivated from every airfield.

$$\sum_{j=1}^{m} d_j x_{ij} \le Q_i y_i, \quad \forall i \in I \qquad (6)$$

CFLP has wide application for analysis of single-commodity location problems where capacity is an important consideration--that is, where management wishes to place a cap on the maximum output for any one facility.

4. CASE STUDY: AGRICULTURE

Simple plant location model is applied on large agriculture filed of company X which is situated near Belgrade (Andrić Gušavac et al. 2013). Company X is one of the leading companies in food production and production of this corporation is main base for meat and milk industry, industrial and other vegetables used in food industry. This company is considered as the premier supporter of the stable supply of high quality forage, fresh produce and dairy products to the local and regional markets. They own nine large agriculture fields with different crops: wheat, barley, corn seed, corn mercantile, soy etc. They use land mechanization and agriculture aviation for nutrition and protection of agricultural crops. This spring they processed 15000 ha of arable land with land mechanization and two aircrafts. Underground water represents great problem and limiting factor for successful fulfilment of agro technical deadlines. These deadlines are especially important in corn production, since corn is cultivated on 62.72% sawn area. Use of aircrafts in the technology of growing these crops would give better results in terms of yield and quality and also it will be necessary to use aircrafts due to underground water. (Jakovljević, 2006)

Subject of location models application is one of nine agriculture fields with approximately 9000 ha which is divided into 245 small fields and one part of land is unusable. Map of this part of land is presented in Figure 1. This part of land has nine airfields. Company had a problem to determine which of the airfields to activate, and how to allocate 245 fields to specific airfields. Each airfield is represented by a green node.

Figure 1. Map of arable land divided into fields (Andrić Gušavac et al. 2013)

Two groups of costs are summed up in the objective function (1). The first group represents the sum of costs f_i for opening airfield i, security and maintenance of that airfield. The second group of costs includes distribution costs c_{ij} for satisfying the demand of field j from airfield i, and these costs are proportional to distance between center of fields and airfields. In order to equalize units of two groups of variables in objective functions, model requires the conversion of the distances to distribution costs with unitary distribution cost of 1 EUR/km.

Distances between center of these fields (which have been earlier calculated) and airfields were calculated using Euclidean metric, where one distance unit represents 0,5 kilometers. Euclidean metric was used due to rectilinear aircraft movement.

The Euclidean distance between points p and q (7) is the length of the line segment connecting them ( ). If $p = (p_1, p_2,..., p_n)$ and $q = (q_1, q_2,..., q_n)$ are two points in Euclidean n-space, then the distance from p to q, or from q to p is given by:

$$d(p,q) = d(q,p) = \sqrt{(q_1 - p_1)^2 + (q_2 - p_2)^2 + \cdots + (q_n - p_n)^2} \quad (7)$$

Capacity of airfields is defined as total amount of fields in hectares which can be cultivated from every airfield. Capacity for each airfield is presented in table 1.

Table 2: Capacity of airfields

Airfield	1	2	3	4	5	6	7	8	9
Capacity [ha*100]	10	10	10	10	10	25	25	10	10

There is a slight difference between capacities of airfields. Airfields 6 and 7 were built as the first airfields in this area. These airfields were supposed to cultivate all of the arable land, and accordingly to this, the capacity of the chemical and gasoline storage were quite large. In the following period, it was obvious that these two airfields could not fulfil all of the needs of the arable fields. This resulted in setting up new lesser capacity airfields. Airfield area is calculated with the Heron's formula.

Table 3: Fixed costs for each airfield

Airfield	1	2	3	4	5	6	7	8	9
Fixed cost	70	70	70	70	70	100	100	70	70

Fixed costs are the same for each airfield – this is the case because all the airfields approximately are of the same size and capacity with same costs for opening – therefore the costs are the equal. Differences between these costs occur only for airfields 6 and 7 as a result of larger capacity.
Distribution costs between center of one example field (field 1) and every airfield are presented in table 2. Demand of each field refers to its surface in hectares (for example surface of the first airfield is 0,21ha^2).

Table 4: Distribution cost between center of field 1 and airfields

Airfield	1	2	3	4	5	6	7	8	9
Field 1	3,07472	4,34427	7,69806	9,86206	7,93396	6,27875	12,11549	13,63764	10,57403

The model was solved using GLPK software package. This package (GNU Linear Programming Kit) is intended for solving large-scale linear programming (LP), mixed integer programming (MIP), and other related problems. The GLPK package consists of several main components, including stand-alone LP/MIP solver - glpsol. The model was solved in order to suggest which airfields should be activated and used for cultivation. The solution also gives allocation of every field to specific airfield. Solution file from the solver has comprehensive insight in all the elements of the model solution:
1 objective: Total costs (=1093.17096)
2459 constraints:
Coverage
Allocation
Capacity
2214 integer variables
5 active airfields (1, 4, 6, 7, 8)

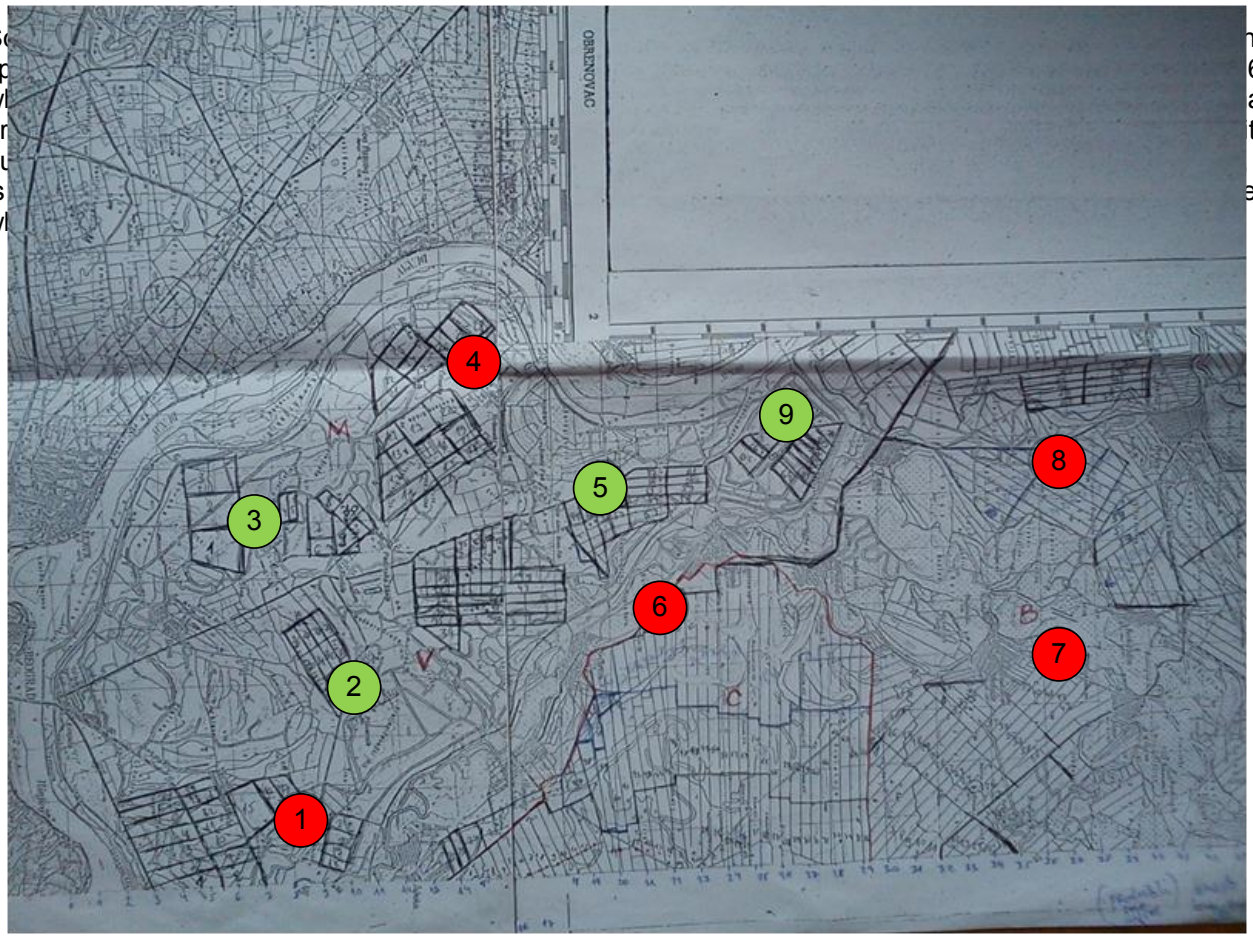

Figure 2. Map with chosen airfields

The number of fields allocated to the specific airfield is presented in the figure 3. Red nodes represent the activated airfields. This problem was firstly solved as a simple plant location problem, but there exist several factors which were not taken into consideration. One of these factors is a capacity of each airfield – defined as a total amount of hectares which can be cultivated from each airfield in a given period of time. This requires calculation of surface of each field in order to include this factor into model. Two solutions of the analyzed problem are presented in figure 3. Solution of the problem when simple plant location model is applied and the solution when a capacitated facility location problem is applied are presented in figure 3.

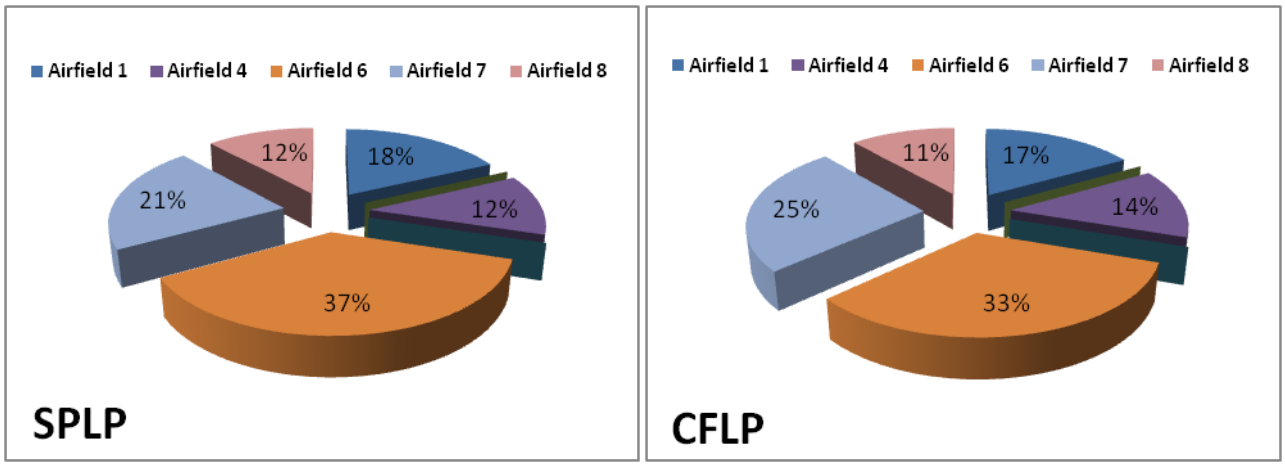

Figure 3. Solution of the problem - application of SPLP and CFLP

Figure 3 presents procentige of all fields which are cultivated from each activated airfield. There is a slight difference between result of SPLP and CFLP application which occurs as a result of a limited capacity of the airfields, but in the both cases the same airfields should be activated.

Table 5: Capacity utilization of airfields

Airfield	Maximum capacity of airfields [ha*100]	Capacity utilization [ha*100]
1	10	9.81110
4	10	9.39511
6	25	24.90626
7	25	19.96847
8	10	9.98313

Previous table shows a remarkable capacity utilization of airfield 1 (98%), airfield 4 (94%), airfield 6 (99%), airfield 7 (80%) and airfield 8 (99%).
Application of this solution enables the company to maximize use of capacities of the airfields. The remaining airfields can be closed and that area can be turned into arable land.

5. FUTURE RESEARCH

Application of a location model helps the management to orient their decision for airfields location rapidly and easily. Authors are convinced that a simple tool helps decision making and that the management should include the modeling results in business analysis including their possible preferences, so as to bridge the gap between measurability optimality and unpredictable and immeasurable compromises. Several more criteria should be taken into consideration for choosing airfield location, for example, proximity to the central airfield (main) or proximity to the important roads, etc. The results of this research could serve as an initial base for future optimization in agriculture aviation, where solutions could increase productivity and decrease energy supplying.

MULTIPLE CRITERIA APPROACH TO SELECTING SITES FOR PORTS OF NAUTICAL TOURISM

Mirjana Kovačić[1], Alen Jugović[2] Ana Perić Hadžić[3]
[1]University of Rijeka, Croatia, Faculty of Maritime Studies, E-mail – mirjana051@gmail.hr
[2] Faculty of Maritime Studies, E-mail – ajugovic@pfri.hr
[3] Faculty of Maritime Studies E-mail – ana@pfri.hr

***Abstract**: In this scientific paper the authors explore the issue of selecting a site for a nautical tourism port using the methodology of multi-criteria analysis (MCA). Given the huge importance of tourism, in particular, nautical tourism in most maritime countries, including the Republic of Croatia and its coastal counties, any help in resolving that issue would be of immense significance. In Croatia, the existing distribution of nautical tourism ports (NTPs), their capacities and the quality of their services are not fully suited to the spatial features. Often these ports fail to blend with their environment and provide no effective protection to natural assets. The distribution of capacities does not match actual spatial potential, while the quality and level of facilities and services varies greatly and is generally inadequate. Hence, the aim of this paper is to identify criteria for the location and development of NTPs in coastal areas. The paper applies the multi-criteria approach to selecting a site for NTPs in Split-Dalmatia County (SDC). Potential micro locations (35) in that region have been studied and criteria and sub-criteria for selecting sites for NTPs, identified.*

***Keywords**: criteria, multiple criteria analysis, site analysis, nautical tourism port, Croatia.*

1. INTRODUCTION

Site selection is a strategic problem addressed in many studies and by many authors whose scientific work have provided a better understanding of the importance of using the right methodology. Different issues are often united in a methodological approach involving the use of multiple criteria analysis (MCA). The reason for this is the fact that using MCA at the scientific level helps to expand the number of NTP sites and sites for accommodating vessels on land, thus resolving the problem of lack of space and the growing demand for berths by boaters.
This paper focuses on identifying the current state of nautical tourism in Croatia, specifically in Split-Dalmatia County (SDC), comparing it with Mediterranean trends, and analysing its spatial and environmental factors. Upon analysing existing and proposed NTP sites in SDC, the advantages and carrying capacities of marine areas are evaluated and criteria for selecting sites on the mainland and on islands are established.
Through research and analyses, the authors seek to accomplish the purpose of this paper which is to define spatial possibilities and constraints, and to propose criteria to ensure the selection of a location for NTPs. With regard to the research problem, the general and special goals set call for the application of MCA in selecting the criteria critical to determining the location for NTPs.

2. THEORETICAL DETERMINANTS AND NAUTICAL TOURISM DEVELOPMENT IN CROATIA

One of the most promising forms of tourism in Croatia, nautical tourism is a complex tourism and maritime concept and its pervasive connection with the sea and navigation makes it all the more difficult to define (Luck, 2007). Namely, the maritime component does not define nautical tourism in its entirety, although superficial analysis may make this seem so (Luković, 2007). Given the fact that both *tourism* and *nautical tourism* are derived concepts representing a set of activities adherent to them but which can change and be added to over time, the authors conclude that nautical tourism is a multidisciplinary phenomenon.

The Tourism Activities Act (Official Gazette 8/96, 19/96, 76/98) defines nautical tourism as "*the navigation and sojourn of tourists/boaters in vessels and in NTPs, for the purpose of recreation and entertainment*".
In the Croatian Adriatic, nautical tourism received powerful incentives and a strong identity in the mid-1980s through the construction of the ACI Marina system, which quickly became the leading nautical organization in the Mediterranean. However, due to various reasons, this role as a leader was lost during the two decades following Croatia's independence. During that period, France, Greece, Turkey, Italy, and other Mediterranean countries invested heavily in marina construction. Today the nautical tourism capacities of Italy are five-fold greater than those of Croatia. An analysis of the current state of nautical tourism in Croatia indicates that the assets of Croatia's Adriatic coast and islands have still not been valorised to any sufficient extent (Bošković et al, 2006). An analysis of statistical and other available data and the Development Strategy of Nautical Tourism in Croatia (2008) suggest that less than half of all vessels and yachts sailing the Croatian Adriatic in the summer season use berths in commercial marinas, while the majority of vessels and yachts are freely anchored in natural coves or moored in transient local harbours. The main reason for this is the shortage of marina capacities in the summer period, in particular, on the islands. Less than half of nautical tourism traffic (excluding small vessels that do not use marinas) in Croatia is encompassed in the organized accommodation of vessels, an activity which has an environmental protection function as well as an economic function. SDC is no exception; it accounts for a mere 13% of all available berths in Croatia. Considering that the existing offering of berths at sea and on land is lacking, many authors are of the opinion that it is necessary to plan sites for the organized accommodation of vessels.

Table 1: NTPs in Croatia and SDC, 2006 - 2012

Year	NTPs, total		Share of SDC in %	Indices	
	Croatia	SDC		Croatia	SDC
2006	95	11	11.6%	-	-
2007	94	11	11.7%	99	100
2008	97	11	11.3%	103.2	100
2009	98	13	13.3%	101	118.2
2010	98	13	13.3%	100	100
2011	98	13	13.3%	100	100
2012	98	13	13.3%	100	100

Source: the authors after CBS

Table 1 shows the number of NTPs in Croatia and SDC. The table demonstrates a continued growth in the number of NTPs in Croatia over the years, the greatest increase being in 2008. SDC also displays an upward trend, with the greatest boost being in 2009.

Table 2: Number of berths in Croatia and SDC, 2006-2012

Year	NTPs, total		Share of SDC in %	Indices	
	Croatia	SDC		Croatia	SDC
2006	15 973	1 591	9.9%	-	-
2007	15 834	1 581	9.9%	99.1	98.4
2008	16 403	1 576	9.6%	103.6	103.6
2009	16 848	1 789	10.6%	102.7	101.1
2010	16 913	1 792	10.6%	100.4	101.1
2011	17 059	1 913	11.2%	100.9	106.8
2012	17 454	2 238	12.8%	102.3	117

Source: the authors after CBS

Table 2 shows the number of berths in NTPs in Croatia and in SDC per year. Both Croatia and SDC display an obvious upward trend, with SDC accounting for about one-tenth of all berths in Croatia.

An analysis of the current state of NTPs in Croatia compared with the Mediterranean countries (Kovačić et al, 2012), together with an analysis of the existing state of infrastructure for accommodation of vessels in SDC, reveals there are:

- Sites which are established in existing plans
- Sites already being used for the purpose of nautical tourism although there is no organized accommodation of vessels at such sites and
- Sites which need to be included in new spatial plans.

Previous practice indicates that without the approval of the local community, the business policies of investors and the location of new NTPs come up against resistance as early as the initial phase of site preparation.
SDC spatial plans have identified sites for the construction of new NTPs, spurred by the growing demand for berths, the distinctiveness of the destination and the vicinity of outbound tourism regions. NTP capacities foreseen in plans are in accordance with the county's spatial potential and the interest of boaters. A large number of NTPs in SDC are used only during the summer season. The existing ports and harbour that do not have NTP status are exploited extensively and their marine areas are mostly occupied by small vessels, with no economic effect for the local community.
A survey conducted in SDC local government units points to poor communication (interaction) between towns/municipalities and NTPs, primarily as a result of imposed coexistence in a constrained area of two separate entities whose interests and goals apparently seem to differ:

- A port of nautical tourism – a marina, in particular – is a business entity focused on business efficiency, productivity, market competitiveness and development.
- A town/place/municipality, as a community of residents, is focused on promoting the well-being and quality of life of its citizens, and accordingly aspires to the environmental and visual assets and the expectations of people (residents).

From these diverging visions, conflicts may emerge bringing the physical and functional use of space into question (Kovačić et al, 2013). Hence, it is essential to involve the local government in the preparation phase of spatial planning, not only to gather opinions but also to communicate the socio-economic effects that the organized accommodation of vessels could bring (Favro et al, 2005).
The Development Strategy of Nautical Tourism (2008) is a fundamental document of the future development of nautical tourism in Croatia. It foresees the construction of NTPs as follows:

- Marinas in the vicinity of airports
- Marinas and moorings within urban centres
- The organization of transit berths at tourist moorings in traditional island ports
- The organization of a system of anchorages
- The construction of marinas for mega yachts.

3. BASIC FEATURES AND METHODOLOGY OF MCA

If conducted correctly (Nikolić and Borović, 2006), MCA requires the cooperation of all interested parties and the practical involvement in the decision process of all stakeholders to whom a problem applies, which, on the other hand, facilitates the realization of obtained priorities and eliminates any doubts concerning subjective decision making (Favro and Kovačić, 2010). The importance of building NTPs and using natural resources in contemporary conditions is particularly emphasized, as well as the number of parties interested in reaching a suitable solution (Jugović et al, 2011). The transparency of available data used in making analyses is highly important because it makes it possible to check whether parameters have been correctly evaluated. From a methodological perspective, MCA represents a systems approach, and in terms of methodology, it is the most effective and functional approach to problem resolution (Kovačić, 2010).
A systems approach to the problem of selecting sites for NTPs in SDC points to an unstructured problem which at strategic and tactical levels of decision making required a complex analysis of the goals set in this research. Problem structuredness or refinedness is the most important characteristic with regard to the decision-support methods and procedures available for a concrete problem (Brans and Vincke, 1985).
Before MCA methodology can be applied, it is necessary to establish whether the problem is characterized by alternative solutions. This was established for the problem of selecting sites for NTPs in SDC. It is also essential to ascertain whether all relevant criteria have been taken into consideration and have been properly evaluated, in particular parameters which are the product of expert judgements. Previous experience in evaluating the use value of space has justified the convenience of

using MCA because it makes it possible to understand and then evaluate all aspects of a problem across a variety of criteria.
A number of methods can be applied in resolving a problem, such as linear programming (Barković, 2002), AHP (Saaty, 1990), ELECTREE (Čupić et al, 1991), PROMETHEE (Brans et al, 1986, 2005), GAIA (Mareschal, 1988) and other methods. The experiences of authors in this field differ (Brans et al, 1984, 1986, Martić, 1992, Nikolić et al, 1996). In accordance with this paper's research problem, the PROMETHEE and GAIA methods have been applied.
PROMETHEE is an MCA method that makes it possible to express differences in the soundness of a particular site or part of the coastal zone. A mathematical procedure helps to objectivize the suitability of the selection of an NTP site.
The use of the GAIA software provides numerical results and charts that help decision-makers to understand the problem more clearly and gain better insight into the relations between criteria and activities.

4. METHODOLOGY FOR ASSESSING THE IMPORTANCE OF CRITERIA

Based on the research conducted and the results obtained from analysing the facts, the authors have identified the crucial criteria and ranked them in accordance to their importance. The weighting coefficient has been calculated for each criterion, and its preference level.
Any multiple criteria problem contains a number of different and, usually, conflicting criteria that can be of differing importance to decision makers. Most methods of multiple criteria decision-making (MCDM), require information on the relative importance of each criterion (Roubens, 1990). A number of methods can be applied in assessing the level of importance of criteria, each of which relies completely upon human judgement. The techniques in this category may pertain to individuals or to groups of people. Measuring opinions consists of a series of methods used to obtain information from an individual or to gather information from a certain number of people, mostly experts in a field relating to the given problem. The advantage of group opinion over individual opinion is that it provides a broader spectrum of information and brings expertise and experience to the analysis. However, there are certain problems related to the use of expert groups. An important aspect of assessing criteria importance is the fact that the involvement of a number of people will generally result in a varied ranking based on an individual judgement. So, methods are required that serve to synthesize these differing assessments. Relative criteria importance can be expressed in terms of priority or weight. Priority relates to cases in which criteria are listed in order of importance. In this, until a higher level (more important) criterion is taken under consideration, the next (less important) criterion may not be considered. On the other hand, weighting is used to numerically express (usually in percentages) the importance of a criterion or to distinguish between the relative importances of several criteria within the same priority. For the purpose of this research, group weighting methods have been used. These are: (Nikolić et al., 1996).
• **Ranking** – It is assumed that n criteria Aj (j = 1, 2, ..., n) need to be assessed and that l experts Ek (k = 1, 2, ..., l) are involved in this task. Each referee (expert) is required to rank all criteria according to their importance, by assigning the number $n-1$ to the most important criterion, the number $n-2$ to the second most important criterion and so on, down to the least important criterion that is assigned the number 0. This is a fairly simple method and requires little time to obtain the judgements of experts. Because only a set of whole numbers is obtained from each referee, there is no need for weighting the assessments of each individual referee. Instead, only the rankings of all experts are weighted.
• **Rating** – Each referee is presented with the criteria and asked to give a numerical rating to each criterion. Ratings are usually made on a given scale of, for example, 0 – 10 or 0 – 100. Each criterion is weighted separately as the sum of elements in a given line in the table. If these weights need to be normalised, this is done by dividing each criteria with the sum of all weights, which is equal to the number of referees.

5. APPLYING MCA IN SELECTING NTP SITES IN SDC

This chapter analyses SDC spatial and environmental factors and presents criteria and sub-criteria for selecting NTP sites.

5.1. ANALYSIS OF SDC SPATIAL AND ENVIRONMENTAL FACTORS

According to data of the Croatian Bureau of Statistics (2013), SDC is the largest Croatian county in terms of space. SDC has a total area of 14,045 km^2 of which, land accounts for 4,572 km^2 and 67.5% is sea (9,473 km²), (RiĐanović, 2002). The county is located in the central part of southern Croatia in the historical district of Dalmatia. It stretches from Vrlika in the north to the islands Vis and Palagruţa in the south, and from Marina in the west to Vrgorac and Gradac in the east. Its population numbers 455,242 people, of which 67% live in the coastal area; 7%, on the islands; and 26%, in the hinterland. SDC comprises 368 settlements organized in 16 towns and 39 municipalities.
Being the most populated and developed part of Dalmatia, the coastal zone of SDC has always played an important role in terms of traffic in this part of the Adriatic. This is where the traffic corridors running parallel to the coastline intersect with traffic corridors running vertical to the coast from the hinterland (neighbouring Bosnia and Herzegovina), and continue in the direction of the islands and across the Adriatic.
The island area comprises 74 islands and 57 rocks and reefs. The islands are poorly populated. Although economically more developed than the hinterland, the islands have experienced steady emigration due to a variety of circumstances. Four islands stand out in terms of size and population density: Šolta, Brač, Hvar and Vis. Six more islands are also populated: Veli Drvenik, Mali Drvenik, Sv. Klement, Šćedro, Biševo and Sv. Andrija. The islands have a pronounced Mediterranean climate and gentle relief.

Table 3: Spatial features of large SDC islands

Island	Area km^2	Length of coast (km)	Indentedness coefficient
Šolta	58.98	73.1	2.69
Brač	394.57	175.1	2.49
Hvar	299.66	254.2	4.14
Vis	90.26	76.6	2.88

Source: by the authors according to CBS data for 2012

SDC is within the zone of the Adriatic type of Mediterranean climate, the primary features of which are dry, hot summers and mild, humid winters (Filipčić, 1996). Mean annual temperatures drop from the islands towards the coastal zone and hinterland, while the amount of annual precipitation increases. The island area has a warm climate with abundant sunshine, temperatures that rarely drop below zero and little precipitation, unlike the climate of the hinterland where temperatures during the autumn and winter often fall below zero and there is much more precipitation.

5.2. ANALYSIS OF MCA INPUT PARAMETERS – CRITERIA AND SUB - CRITERIA

In resolving the problem of selecting NTP sites in SDC, factors relevant to site selection were previously analysed. The analysed factors were grouped according to their importance and parameters were identified that can be recognized as criteria for site selection. The importance of each criterion based on rating is defined by its weight or priority. Priority represents the importance of an individual criterion in a group of factors. These criteria, together with others identified during analysis, make up the information basis that enables decision makers to choose one solution from a number of proposed solutions. This is important with regard to management structure and the management level of the decision-makers.
Considering that an array of factors impacts the quality and suitability of a coastal area for NTP development, target analysis was used to separate those factors (criteria and sub-criteria) that have the greatest influence on the quality of specific sites and parts of the coastal zone. Elimination criteria were also needed to exclude those areas whose natural features would be substantially threatened by NTP construction.

Table 4: Criteria and sub-criteria for selecting an NTP site in SDC (with assigned weights and established min/max)

Criterion/sub-criteria		***weight***	***min/max***
Institutional and political	**A**	**10**	
Spatial plans of micro locations	**A1**	**8**	**max**
Regional tax and surtax system	**A2**	**2**	**max**

Natural and accommodation	**B**	**25**	
Geo-morphological features (relief of the coastal area, etc.)	**B1**	**5**	**max**
Hydrographic features of the site	**B2**	**7**	**max**
Oceanographic features of the micro location	**B3**	**6**	**max**
Micro climate features	**B4**	**7**	**max**
Environmental	**C**	**25**	
Ecological value and vulnerability of micro location to human activity	**C1**	**8**	**min**
Environmental impact assessment	**C2**	**8**	**min**
Amount of investment in environmental protection (5%-30%)	**C3**	**9**	**max**
Technical and technological	**D**	**15**	
Carrying capacity of micro location – size of vessels (yachts); assumed installed fleet	**D1**	**4**	**max**
Level of development of transport and other infrastructure, distance from airport, distance from Port of Split	**D2**	**3**	**max**
Distance from town cores	**D3**	**3**	**min**
Safety and sailing conditions at the micro location	**D4**	**5**	**max**
Economic	**E**	**15**	
Nautical services offering in the region (potential scope of market activity)	**E1**	**2**	**min**
Offering of providers in surrounding area	**E2**	**3**	**max**
Concession fee	**E3**	**3**	**min**
Investment amount	**E4**	**5**	**max**
Available personnel (professional ability)	**E5**	**2**	**max**
Socio-cultural	**F**	**10**	
Direct and indirect benefits	**F1**	**4**	**max**
Level of urban development and distinctiveness of micro location	**F2**	**3**	**max**
Improvement in quality of life of local community	**F3**	**3**	**max**

Source: the authors

For some (or all) criteria, corresponding qualitative ratings may be given which are translated into quantitative values using a linear scale of 0 – 10 and the ratings *poor*, *average* and *good*. Criteria have two characteristics:

- They can be of the maximization or minimization type.
- Most often they do not have the same importance and it is customary to assign weight coefficients. The sum of sub-criteria weights equals the global (total) weight of a criterion.

In the rating procedure, criteria weights were normalized by the total possible sum (100), which greatly facilitated further analysis.

The greatest weights were given to the Natural and Accommodation criterion and sub-criteria, and the Environmental criterion and sub-criteria. The importance of the Institutional and Political criterion and Socio-cultural criterion is relatively small. The Technical and Technological criterion and Economic criterion are of slightly less importance, which is understandable considering that the economic criterion is not necessarily crucial in selecting suitable sites and is dependent upon technological solutions. Distance from the town core, road and other infrastructure is not a crucial factor considering that research is focused on sites on islands which already have to deal with the problem of distance

and accessibility. When sub-criteria are analysed, it is evident that some sub-criteria have greater weights than others. For example, all three sub-criteria of the Environmental criterion have distinctly greater weights. Interestingly, sub-criteria A1- Spatial plan of micro location – has greater importance than most of the sub-criteria of the Technical and Technological criterion and the Economic criterion. This is because sub-criterion A1 could be a constraining factor in cases where a spatial plan has not been adopted or does not foresee a possible NTP site in a given micro location. Such cases require preliminary research to be carried out and the presentation at the local level of all benefits and advantages that an NTP built at a specific micro location could bring. Special attention should be called to the importance of safety and sailing conditions in selecting a site, as experts have rated this sub-criterion as important in ensuring the safety of boaters and their vessels. Considering the widespread trend in the Mediterranean and worldwide towards vessels exceeding ten metres in length, sea depth plays an important role in selecting sites for NTPs.

6. RESULTS ANALYSIS AND PROPOSED MEASURES FOR FURTHER RESEARCH

The ratings are the results of research based on available data and cartographic presentation of the Croatian Hydrographic Institute of Split for each individual location. Taking into consideration the collected data and the importance of factors for selecting sites for NTPs, the ratings for each group of criteria can be explained.

The Natural and Accommodation criterion is especially important and its sub-criteria were analysed for each individual location, where, for example, the depth of the marina area was established and assigned a certain value. All three sub-criteria were maximized. Criterion C – environmental factors – was rated on a 1-10 scale using five sub-criteria. While the importance and influence of some of these sub-criteria was maximized, in others (C1 and C2) it was minimized. Criterion D – technical and technological factors – consists of four basic sub-criteria rated on a 1-10 scale. Because of their importance, the value of these sub-criteria was mostly maximized. Sub-criteria D2 and D3 referring to the distance of an NTP to the Port of Split and the airport, and to the distance from the town core, respectively, were expressed in separate ratings based on the geographical position of each site. The distances from each site were calculated and a value in points assigned. Criterion E – economic factors – was broken down into five sub-criteria rated on a 1-10 scale, with the exception of sub-criterion E4 which was expressed in actual monetary value. It should be noted that an estimation of the costs of building NTPs in the selected sites is not possible without a comprehensive cost analysis of individual sites. Such an analysis involves the meteorological and hydrographic features of areas. The need to build a breakwater or set up a floating pontoon or sea-wall is determined based on the specific features of each site, considerably impacting construction cost. The availability of infrastructure and the condition of the shore (stone waterfront or a rocky shore full of shoal) also have a great impact on the NTP construction costs. The estimation involved the cost of building NTPs (with 50, 100, 150 or 200 berths). A preliminary cost estimation, which assumes the basic preconditions to building NTPs, was done for the sites included in MCA. This estimation represents the minimal investment required for constructing an NTP and while it may give a site a certain advantage in this phase of research, it is still not the deciding criterion or sub-criterion. The value of the overall investment increases depending on the facilities and services planned and the technological capacity of the nautical port. Criterion F – socio-cultural factors – consists of three sub-criteria, the importance of which has been maximized. The distinctiveness of a micro location contributes towards its selection and may bring direct and indirect benefits to residents. The rated criteria and sub-criteria and their maximization or minimization enable the presentation of the MCA procedure carried out.

The objective of research was to identify the criteria and sub-criteria required for selecting sites for NTPs in the SDC region. Research results point to six groups of criteria and 21 sub-criteria. Obtained by using the MCA method, these results may be used in the decision process to select sites for NTPs in SCD, which will be the subject of further research by the authors.

7. CONCLUSION

Great progress has been made in the Croatian Adriatic in the past 15 years through the development and construction of accommodation facilities for vessels, justifying the market orientation towards nautical tourism. The nautical tourism market is experiencing an upward trend in the Mediterranean and worldwide.

The paper examines the opportunities of developing NTPs in SDC from the viewpoint of proper spatial use and protection. The research conducted has accomplished the goals set out. Stress is placed on the correct selection of methodologies using the group weighting method and MCA, which can be applied in the decision process of selecting the optimum location and facilities for NTPs. The research results point groups of criteria and sub-criteria. In accordance with research problem, authors recomended the PROMETHEE and GAIA MCA methods and Visual PROMETHEE as very usefull software. Based on these insights, further progress can be made in research pertaining to the valuation and management of the marine domain and NTPs.
The criteria have been correctly chosen and are appropriate for the selection of NTP sites in SDC. Research results provide decision-makers with a scientific foundation on which to base further NTP development and site planning.

TRAVEL BEHAVIOUR OF TEENAGERS: KEY ATTRIBUTES IN CHOOSING TOURIST OFFER

Milena Vukic[1], Marija Kuzmanovic[2], Milica Kostić Stanković[2]
[1] Hospitality and Tourism School, Belgrade, milena.vukic12@gmail.com
[2] University of Belgrade, Faculty of Organizational Sciences, Belgrade

Abstract: *The aim of this paper is to investigate and quantify the preferences of teenagers' travel behaviour. For this purpose research conjoint analysis was used. The survey was conducted in Serbia in 2012 and refers to 163 teenage participants. The findings provided insights into how teenagers evaluate attributes of tourist offer. It has been shown that the price of tourist offer is the most important attribute on the aggregate level. Slightly less important were the following attributes: time of permanency, political stability and leisure offer, while the culture is the least important one. Preference-based segmentation was performed on the conjoint data to isolate homogeneous segments that possess similar preferences for tourist offer. Two segments of teenagers were isolated: Peace Ambassadors and Savers. The results of the study could further serves as a guideline for policy-makers to help them more effectively provide an appropriate tourist offer.*

Keywords*: Teenagers, preferences, conjoint analysis, preference-based segmentation.*

1. INTRODUCTION

Duty to synchronize both customers‟ desires and needs on the one hand and organization goals on the other, with a full social responsibility, create an obligation to approach teenagers as consumers with greater importance. The interest of companies is justified with greater purchasing power of this market although many of them are hoping to attract older consumers through this category.

Over half-billion global teens between the ages of 13 and 18 represent a dynamic opportunity for marketers who wish to grow their businesses and build consumer loyalty. Teens represent a primary market that purchases goods, an influential market that directs parental expenditures, and a future market for all retail products and services. Numerous businesses are targeting the attractive teen consumer market; however, few understand that new strategies are required to address teens‟ unique interests, choices and variety of experiences (Crutsinger et al. 2010).

Accurately defining adolescence is difficult because, like all life stages, it is a complex construct formed from socio-cultural, psychological, anatomical, legal and chronological components that may be spatially and temporally specific (Gullotta et al. 2000). This means the boundaries between adolescence and the stages that precede and follow it are fuzzy rather than distinct. As a result, there is no universally agreed definition of „adolescence‟. This research paper, however, will focus on teenagers from 15 to 19 years old although Coleman and Hendry (1999) define teenager as someone who is 12 to 17 years old.

In 2010 young travelers generated 165 billion US$ towards global tourism receipts, affirming their financial value to the global tourism industry and local economies. The last WYSE Travel Confederation New Horizons survey indicated that young travelers spent a total of US$2,600 on their main trip, compared with an average of US$950 per trip for international tourists as a whole. Since young people often take much longer trips than most other tourists, they end up spending more (UNWTO – WYSE, 2011). The importance of this market segment lies not only in the fact that their number is increasing, but also that they represent the market of the future. Compared to their older counterparts, young travelers are much more likely to revisit a tourist destination. Young travelers are very often pioneers; they like to discover new destinations. They also like their travelling to include some cultural content and they do not give up the destinations which are politically unstable or subject to natural catastrophes.

Spero and Stone (2004) suggest that teens need to be understood beyond traditional age classifications. Using a sophisticated segmentation strategy considering lifestyle variations and individual differences, marketers can reveal a more precise depiction of teens. Therefore, the purpose of this study is twofold: Firstly, to determine the preferences of teenagers while choosing a tourist offer, in order to understand tourist market better and to develop marketing strategies which suit this target segment. Secondly, to evaluate the usefulness of preference based segmentation in understanding travel-related behaviour among teenager consumers in Serbia. Specifically, the objectives of the study were to determine, first, whether teenagers could be grouped together based on similarities and differences in preferences for travelling; secondly, whether statistically significant differences existed between the resulting segments. In this regard, this study will profile the diversity of the market for a teen traveler, based on their distinctive preferences.

To elicit preferences of teenagers, in this paper we used conjoint analysis. Conjoint analysis is a consumer research technique developed to provide a method for determining the relative contributions of multiple factors to customer satisfaction. By using conjoint analysis it is possible to determine which attributes are important to certain customers, or market segments, in the selection of a travel destination.

2. KEY DRIVERS FOR TEENAGERS TRAVELING

Consuming is a complex social phenomenon especially with respect to adolescents (Benn, 2004) and teenagers can send messages through their consumption styles to illustrate commitment to different groups (peers), different lifestyles, and possibly even political or ecological affiliation (Miles, 1998). Children were first treated as consumers in the 1960s. The history of children"s consumer development dates back to the 1950s with the publication of a few isolated studies. After that, a considerable amount of literature has been published on children"s understanding of marketing and retail functions (John, 1999). Consumer socialization is a developmental process that proceeds through a series of stages as children mature into adult life. These changes take place through these series of stages helping the process of consumer socialization of children. Those wanting to do business with the teen market are motivated by three very practical reasons: (1) the estimated $175 billion (Hempel and Lehman, 2005; Wells, 2004) a year spent by this age group on product and services; (2) the amount of purchases and consumption experiences (e.g., movies, vacations, etc.) they influence among their families and friends; and (3) the possibility that, if done correctly, both brand name recognition and brand preferences can be influenced now to affect future purchases. Children of all ages influence an estimated $500 billion in family purchases (Moore, 2004). The teen market is both financially important to marketing professionals and a great source of product and market knowledge. The beginning of financial independence (access to part-time jobs, spending money, and debit/credit cards) is rooted in adolescence (Mangleburg and Brown, 1995) and may be related to adolescent consumption autonomy.

Furthermore, within the context of tourism, adolescents represent one of the largest markets for tour operators and other vacation service providers (Kang et al. 2003). This is why it is very important to understand what the key factors which motivate them to travel really are. Traveler"s motives represent a critical point in deciding on the purchase of a tourist product. Traditionally, tourism researchers argue that people go on vacation (1) in order to get away from everyday experience and (2) in search of new experiences.

Based on Maslow"s (Maslow, 1970) need hierarchy theory on motivation, Pearce"s Travel Career Ladder (TCL) „describes tourist motivation as consisting of five different levels: relaxation needs, safety/security needs, relationship needs, self-esteem and development needs, and self-actualization/ fulfilment needs" (Pearce, 2005). One of the best known typologies of tourist motives was proposed by Crompton (1979), who classifies motives into those which „push“ tourists to travel and motives which „pull“ tourists towards a tourist destination. In other words, people travel because they are "pushed" by their inner motives or because they are "pulled" by external factors of a tourist destination (Lam and Hsu, 2006).

Carr (2006) researched adolescent motivation in tourism. He made a list of 18 most important motives and listed them according to their significance: to relax; to be with friends/relatives; to get away from responsibilities; to see new things/places; to visit friends/relatives; to make new friends; to shop; to

party and dance; to engage in sport or exercise; to experience different cultures; to get a suntan; to visit heritage and historical sites; to enrich your education; in search of romance; to drink alcohol; in search of sex; to experiment with/use drugs. This list is very similar to Horner and Swarbrooke‟s (2004) stereotypical image of a North European teenager as someone who „loves beaches, sunbathing, and the idea of partying‟ in the holiday.

3. METHOD

3.1. Conjoint Analysis: Conceptual Framework

The conjoint measurement has psychometric origins as a theory, to decompose an ordinal scale of holistic judgment into interval scales for each component attribute. Originally developed by psychologist Luce and statistician Tukey (Luce and Tukey, 1964), conjoint analysis has attracted considerable attention in the field of mathematical psychology since the mid 70‟s, especially in marketing research, as a method that portrays consumers‟ decisions.

The conjoint analysis, sometimes called the „trade-off analysis‟, reveals how people make complex judgments. The technique is based on the assumption that complex decisions are made not based on a single factor or criterion, but on several factors CONsidered JOINTly, hence the term conjoint. Conjoint analysis enables the investigator to better understand the interrelationship of multiple factors as they contribute to preferences.

This approach has been broadly defined as “any decomposition method that estimates the structure of a consumer‟s preferences given his or her overall evaluations of a set of alternatives that are pre-specified in terms of levels of different attributes” (Green and Srinivasan, 1990). The basic assumption that underlies the decomposition approach is that customers evaluate the total utility of a product or service by combining the separate utilities to assess the attribute levels of that product/service.

3.2. Survey Procedure

There are several stages in the design and analysis of conjoint analysis studies (Ryan et al., 1998; Kuzmanovic, 2006): (1) Generating a list of key attributes and attributes levels; (2) Construction of the experimental design; (3) Survey implementation; (4) Data analysis; (5) Market simulations.

Generating a list of key attributes and attributes levels. The initial step is to identify the attributes of importance to the study question. We identified six key attributes based on literature review (Vukic et al. 2013; Lopes al. 2009), the previous work, and the pilot survey. In stage two, attribute levels have to be defined. The identified attributes and levels assigned to them are shown in Table 1.

Table 1: List of key attributes and their levels

Attributes	Description	Levels
Destination	Kind of tourist offer	Beach Mountain City
Time	Duration of stay at destination	2-3 days (Weekend) 4-7 days 8-12 days
Culture	Historical and cultural heritage	Rich Poor
Leisure	Level of tourist Leisure activities and Night fun	Rich Poor
Price	Price of tourist offer	Up to150€ 150-250€ 250-450€ > 450€
Stability	Political stability and safety of tourists	Stable Unstable

Construction of the experimental design. The next stage in the conjoint analysis study is to decide which scenarios to present to individuals, i.e. to generate an experimental design (Kuzmanovic,

2008). The attribute and levels in Table 1 gave rise to 288 possible scenarios ($4^1 \times 3^2 \times 2^3$). Since respondents could not realistically be expected to consider such a large number of different scenarios, a component of the statistical package SPSS (Orthoplan) was used to reduce the possible number of profiles to a manageable level, while still allowing the preferences to be inferred for all of the combinations of levels and attributes. The use of Orthoplan results in an orthogonal main effects design, thus ensuring the absence of multicollinearity between attributes. Through the use of this design, the 288 possible profiles were reduced to 16.

Survey implementation. Having established the experimental design, the next stage is to elicit preferences for the scenarios. In this study the rating approach was used. Respondents were presented with each of the 18 profile scenarios, 16 from the experimental design and 2 holdout tasks. Individuals were asked to state their level of preference for each scenario on a Likert's scale of 1 to 7, where 1 indicated "I certainly do not choose ", and 7 indicated "I certainly choose". Holdout cases are judged by the respondents but are not used to estimate utilities. They are used as a check on the validity of the estimated utilities.

Data were collected online through a web-based questionnaire. For that purpose we used social networks (Facebook, Twitter) and electronic mail. This method of data collection was chosen for several reasons: (1) Online surveys are less expensive than the traditional “paper and pencil”; (2) An online survey can be filled out simultaneously by a greater number of people; (3) The questionnaire is available to a greater number of people.

Conjoint model specification. Having collected the information on individual preference, the responses need to be analyzed. The simplest and most commonly used model is the linear additive model. This model assumes that the overall utility derived from any combination of attributes of a given good or service is obtained from the sum of the separate part-worths of the attributes. Thus, respondent *i*'s predicted conjoint utility for profile *j* can be specified as follows:

$$U_{ij} = \sum_{k=1}^{K} \sum_{l=1}^{L_k} \beta_{ikl} x_{jkl} + \varepsilon_{ij}, \qquad i = 1,...,I, \;\; j = 1,...,J, \tag{1}$$

where *K* is the number of attributes; L_k is the number of levels of attribute *k*. β_{ikl} is respondent *i*'s utility with respect to level *l* of attribute *k* (part-worths). x_{jkl} is such a (0,1) variable that it equals 1 if profile *j* has attribute *k* at level *l*, otherwise it equals 0. ε_{ij} is an error term.

The relative importance of each attribute is further calculated as the utility-range (difference between the highest and the lowest utility for that attribute) divided by the sum of utility ranges of all attributes:

$$FI_{ik} = \frac{\max_l\{\beta_{ikl}\} - \min_l\{\beta_{ikl}\}}{\sum_{k=1}^{K}\left(\max_l\{\beta_{ikl}\} - \min_l\{\beta_{ikl}\}\right)}, \; i = 1,...,I, k = 1,...,K, l = 1,...,L_k \tag{2}$$

The calculations are done separately for each respondent, and the results are then averaged to include all of the respondents.

Given that part-worth utilities are calculated at the individual level, the researcher can find preference heterogeneity if it is present. Therefore, part-worths can be used for preference-based segmentation. Respondents who place a similar value on various attribute levels will be grouped together into a segment, and the segmentation of conjoint part-worths produces true “benefit segments”. Part-worth utilities can be also used to obtain overall utility values for all possible combination of attribute levels, i.e. for all possible profiles (by inserting the appropriate part-worths into equation 1.) in order to conduct what-if analysis.

To estimate the part-worths as well as relative importance of attributes, the statistical package SPSS 16.0 (Conjoint procedure) was used. The parameters were estimated for each respondent in the sample individually, as well as for the total sample.

4. RESULTS AND DISCUSSIONS

In total 163 respondents, teenagers (from 14 to 19 years) completed questionnaires. The ratio between male and female examinees was roughly 1:3, actually, the number of male examinees was 40 (24.5 %), and female 123 (75.5 %). There were 30 respondents with income up to 100€ per household member, 55 from 100€ to 299€, 50 of them has income from 300€ to 499€, 19 people are between 500€ and 999€, and finally only 9 respondents have income higher than 1000€.

4.1. Aggregated Preferences and what-if analysis

The averaged results are shown in Table 2. The results suggest that the Price is the most important attribute (27.308%), then comes Time of permanency with importance of 20.171%. Slightly less importance on aggregate level has Political stability (19.926%). Relatively slightly important are attributes Kind of destination (13.212%) and Leisure offer and Night fun (10.121%), while Cultural offer is the least important attribute (9.263%).

The statistics for the estimated models are also presented in Table 2. A high value of the Pearson coefficient, 0.988, confirms the high level of significance of the obtained results. Similarly, a high value of the Kendall correlation coefficient, 0.900, indicates a high level of correlation between the input and the estimated preferences. The Kendall coefficient for two holdout profiles has a value of 1.000, which is an additional indicator of the high quality of the obtained data. The signs of the part-worths were all as expected, including the negative coefficient for the lowest levels of attributes. This is especially obvious for attributes with two levels, such as Political stability, Leisure offer and Night fun, Cultural offer (see Table 2).

Table 2: Aggregate level analysis (averaged results).

Attributes/levels	**Attributes' importance (%)**	**Part-worth utilities**	**Std. Error**
Destination	13.212		
Beach		0.034	0.123
Mountain		-0.046	0.145
City		0.012	0.145
Time	20.171		
2-3 days (Weekend)		-0.773	0.123
4-7 days		0.137	0.145
8-12 days		0.636	0.145
Culture	9.263		
High		0.263	0.092
Low		-0.263	0.092
Leisure	10.121		
High		0.321	0.092
Low		-0.321	0.092
Price	27.308		
Up to 150€		0.677	0.160
150-250€		0.558	0.160
250-450€		-0.191	0.160
> 450€		-1.044	0.160
Stability	19.926		
Stable		0.819	0.092
Unstable		-0.819	0.092
Constant=3.928			
Correlations between observed and estimated preferences			
	Value	**Sig.**	
Pearson's R	0.988	0.000	
Kendall's tau	0.900	0.000	
Kendall's tau for Holdouts	1.000		

As for the attribute Price, the first two levels: “up to 150€“ (0.677) and the level “from 150€ to 250€“ (0.558) increase the consumers‟ total preferences. As opposed to these, two next levels “from 250€ to 450€“ (-0.191) and “> 450€“ (-1.044) have negative values of part-worth so that they decrease consumers‟ total preferences. Considering the highly rated attribute Time of permanency, the respondents prefer the offer from 8 to 12 days. Although somewhat lower, positive preferences were

also given to the second level, that is, 4-7 days. Compared to these two levels, the 2-3 days offer decreases the total preferences (-0.773). The attribute Kind of destination, has a positive part-worth for the levels Beach (0.034) and City (0.012) and these two levels increase consumers‟ total preferences, whereas the last level Mountain with a part-worth of -0.046 decreases the total preferences (due to its negative value).

Considering the respondents‟ preferences at the aggregate level, the optimal tourist offer could be described as: 8-12 days on the beach, with rich cultural offer and night life, stable political region and the price as low as possible, up to 150 Euros. The total utility of such a scenario is 6.678.

If we offered participants mountains in exchange for the sea, and leave all other attributes on their highest levels, the total usefulness would be 6.598 (only 1.2% lower). It is such a small decrease because this attribute is not so important. On the other hand, if we looked at the most important attribute “Price” by raising the offer on the next level (from less to 150€ to price level from 150€ to 250€) the total usefulness would drop by 7%, while raising it even higher (on next price level from 250€ to 450€) we would have even higher decline of 15%. If travel deals offer a destination which is not politically stable on top of that, we would have a total usefulness drop of 35%.

Such an analysis is possible to be conducted for all the potential attribute combinations depending of requisitions that can emerge so we could have higher flexibility of tourism enterprises and anticipation of changes in customers' preferences. Such data can be further used in actual marketing scenarios as import parameters for positioning (prediction) of potential market share.

4.2. Preference Based Segmentation

A more detailed analysis of part-worths at the individual level revealed wide heterogeneity in consumer preferences. Therefore, a cluster analysis was performed to classify respondents into more homogeneous preference groups. These part-worths are then used as input for cluster analysis. This approach has been conducted by various researchers across industries, in order to determine customer segments based on distinct preference profiles (Lopez 2009; Kuzmanović et al. 2013).

The k-means cluster procedure in SPSS 16.0 was used to perform the segmentation. Based on the sample size, the solutions were searched in two and three clusters. A 2-cluster solution was chosen due to the size of the segments and statistical significance. An analysis of variance revealed that the segments in the 2-cluster solution differed significantly from each other, with respect to their part-worths (Table 3). Cluster level part-worths and attributes importance are also presented in Table 3.

Table 3. Cluster analysis results

Attributes and levels		**Attribute importance**		**Part-worths**		
		Cluster 1 (n=94)	**Cluster 2 (n=69)**	**Cluster 1**	**Cluster 2**	**Sig.**
Destination	Beach	1.54%	3.21%	-0.04	0.13	0.024
	Mountain			-0.01	-0.09	0.390
	City			0.05	-0.04	0.312
Time	2-3 days	20.52%	25.72%	-0.62	-0.99	0.000
	4-7 days			0.08	0.22	0.052
	8-12 days			0.54	0.77	0.003
Culture	High	13.39%	3.21%	0.38	0.11	0.000
	Low			-0.38	-0.11	0.000
Leisure	High	12.54%	8.19%	0.35	0.28	0.281
	Low			-0.35	-0.28	0.281
Price	up to 150€	17.01%	42.23%	0.26	1.24	0.000
	150-250€			0.35	0.84	0.000
	250-450€			-0.01	-0.44	0.000
	> 450€			-0.60	-1.64	0.000
Stability	Stable	35.00%	17.46%	0.98	0.60	0.000
	Unstable			-0.98	-0.60	0.000

The first segment, “Peace Ambassadors”, characteristics. The first segment includes 94 respondents, that is, 57.67% of the total sample. This group of tourists attaches the main importance to the attribute Political Stability (35.00%). The second level attribute by importance in tourist offer is “Time of Permanency” (20.52%), where the preferred duration of stay is from 8 to 12 days. Other

attributes have proved to be less important. The type of destination that they would most likely choose would be a metropolis, although that attribute had the smallest importance (importance only = 1.54%). The price level that they are willing to pay includes the first two levels of this attribute (up to 150€ and a price level from 150€ to 250€). The other two levels lower the total preferences.

The second segment, "Savers", characteristics. The second segment consists of 69 respondents, that is, 42.33% and is made up of the respondents to whom the price is by far the most important attribute in the choice of the tourist offer (42.23%) whereat they are willing to pay the price up to 150€, but they also consider acceptable the price level from 150€ to 250€ in which they are very similar to the first cluster group. A relatively higher importance has duration of stay (25.72%), which shows that this type of teenagers would most likely choose an offer for a vacation from 8 to 12 days. Next to last is "Leisure" attribute (8.19%). The least important attributes in this survey came out to be "Culture" and "Destination" with importance scores of just 3.21%. Although "Destination" is the least significant attribute (3.21%), we can see that this type of participants prefers the sea, while a mountain and a metropolis lower the total preferences.

Having in mind the segment size and customers‟ preferences toward tourist offer, it is possible to suggest adequate marketing strategies for tourist companies, in which we could underline attributes of higher importance and thereby gain a competitive advantage on the market. Tourist companies, in particular, would benefit from improving tourist products that could satisfy the needs and preferences of this segment by creating and delivering values that could lead to building long term relations with customers. By creating a tourist offer that can even satisfy the latent needs of teenagers as tourists, it opens up possibilities for building a future loyalty and it can even encourage consumers to pay a higher price for their dream vacation.

5. DISCUSSION AND CONCLUSIONS

Today teenagers are more and more sofisticated consumers who are more difficult to entertain than their parents. First of all, it is because teenagers are richer than ever thanks to getting higher and higher pocket money, and a bit older ones also earn money from part time jobs or sometimes household work.

Insted of common focusing on teenager-product relationship, this survey deals with their preferencies in tourism. More accurately, we used the conjoint analysis to determine the desirable features of tourist offers targeting this group in order to examine how teenagers in Serbia decide when choosing between travel deals. To our knowledge, this is the first study to use conjoint analysis to reveal teenagers‟ preferences towards tourist offer both in Serbia and abroad.

Results indicate that price was the most important atribute, as expected, considering the limited income of teenagers, which is also consistent with the results presented by Lopes (2009). Leisure offer and Night fun and Cultural offer came out as the least significant, which came as a suprise considering that we targeted teenagers, but we have to consider averaging of results. These findings differs from Swarbrooke‟s (2004) stereotypical image of a teenager as someone who who „loves beaches, sunbathing, and the idea of partying‟ in the holiday environment. For checking heterogenity of these teenage preferencies, we conducted a post hoc segmentation based on the conjoint data, which gave noticeable differencies. We segregated two clusters here: one that considered the price as the most important attribute - „Savers“ and one that most values political stability – „Peace Ambassadors“. We also concluded with this analysis that some attributes, such as Leisure offer and Night fun have a higher importancy than we concluded based on the average results, while the attribute Kind of destination which is very well ranked in average attribute importance evaluation, came out as almost insignificant.

What-if analysys can offer a good simulation of the change in preferencies if we change an attribute level. For example, the change of political stability of a destination would most likely affect travel deals with a drop of 35%. The posibility of anticipation of this kind of changes allows tourist enterprises more flexibility but also a chance to lower the percentage of 35% offering early booking or better terms of payment, like we had in the case of Serbian tourists traveling to Egypt and Tunisia in a situation when political stability in these countries was not on a high level.

Knowing these results as well as teenager desires and preferences that affect travel deals can help marketing a lot to target the market segment, to create values, to come out with new ways of

advertising, but also in promotional campaigns so that teenagers can be more convinced that there is a clear and an important difference between different tourist companies.

PREFERENCES TOWARDS ORGANIC VS. NON-ORGANIC FOOD: AN EMPIRICAL STUDY OF CONSUMERS IN SERBIA

Minja Marinović[1], Milena Popović[2], Marija Kuzmanović[3]
[1,2,3]University of Belgrade, Faculty of Organizational Sciences,
marinovic.minja@fon.bg.ac.rs; milenap@fon.bg.ac.rs; mari@fon.bg.ac.rs

Abstract: *Organic agriculture has become not only a significant public issue but also an important topic in academic research in the world. Because of importance and prospects of the organic agriculture, it is essential to elicit both the consumer preferences toward organic versus non-organic produced food and attitudes towards purchasing organic food. Therefore, the main objective of this paper is to analyze empirical determinants of organic food consumption by consumers from Serbia. For that purpose, we used conjoint analysis. The survey was conducted in Serbia, in January 2013. Results indicate that the price is the most important attribute for the entire population, and also that consumers have heterogeneous preferences when it comes to food origin and method of producing. It is shown that socioeconomic and demographic factors have important influence on customer behaviour in the process of buying. Based on the results of the study, it is possible to determine the optimal strategy for producers of organic products in Serbia.*
Keywords*: Organic food, consumers preferences, socioeconomic and demographic variables, conjoint analysis, segmentation*

1. INTRODUCTION

The main objective of organic agriculture production is to provide high quality food and sustainable agriculture development with the preservation of the ecosystem and maintaining and increasing soil fertility. It is obvious that maximum use of renewable energy sources is necessary, as well as maintaining genetic diversity of ecosystem and the environment. This will reduce all forms of pollution that may be the result of agricultural production in order to create the proper conditions for organic food production.

Since the organic food production in Serbia is a new trend, it is important to care about every single consumer. Although the most of the consumers have positive opinion about organic products, they don't behave consistently when purchasing them. Consumers trust in the product integrity is of crucial importance, in particular if the key attribute entails a price premium, as is the case with organic food. The organic food industry must better understand the variety of motives, perceptions, and attitudes consumers hold regarding organic food and their consumption in their own long-term interests.

In order to define effective strategic plans, research is of great importance – for understanding consumers' needs, life styles and decision making processes. The main objective of this paper is to analyze empirical determinants of organic food consumption using the data on sample of consumers from Serbia. Results obtained after this survey should help organic manufacturers, exploit development opportunities of Serbia in organic production. Survey is conducted to examine the preferences of the population towards the use of organic food. All the respondents answered questions and provided information about their patterns of consumption, ability and willingness to pay for organic food, their opinions on cultivation of organic food and demographic and sociodemographic information about their households.

To elicit consumers preferences toward organic food, conjoint analysis, one of the most widely used preference-based techniques, was applied in this study. The conjoint analysis is a consumer research technique developed for determining the relative contribution of multiple factors to consumer satisfaction.

The literature considers different issues related to the use of conjoint analysis in agriculture. Walisinghe and Gunaratne (2009) tried to determine consumer preferences for different quality attributes of rice. The appropriate attributes and levels were identified from a focus group discussion and subsequently a conjoint questionnaire was administered using a sample of 185 consumers under a fractional factorial design. Manalo (1990) in his paper illustrates the use of conjoint analysis in assessing consumer preferences for the attributes of an agricultural product (apple). The most important attribute was flavour instead of size, colour or price. Aizaki (2010) presented a paper whose purpose was to assemble topics related to agriculture that were treated using multi-attribute stated preference methods and conjoint analysis in Japan. Sydorovych and Wossink (2008) proposed a methodology that could be beneficial in aggregate sustainability assessment. They applied conjoint analysis to identify economic, social, and ecological attributes that are perceived as important for agricultural sustainability by different stakeholders and to assess their relative impact on the

overall sustainability measure. In USA author Evans (2008) conducted a survey in order to identify the influence certain consumer preferences have on watermelon purchasing behaviour.

2. MATERIALS AND METHOD

2.1. Conjoint analysis: Modeling of consumer preferences

Conjoint analysis is a multivariate method used to find the preferences of respondents for certain products and services (Hair, Anderson, Tatham and Black, 1999), and it is important to businesses that are evaluating new product or service attributes (Green and Srinivasan, 1978). Conjoint analysis is consistent with Lancaster's theory of utility maximization, where consumers demand attributes from a given product (Lancaster, 1971; Lusk and Hudson, 2004).

The Conjoint analysis is based on the idea that consumers evaluate the value of a product by combining the different amounts of value provided by each attribute. Thus, it is possible to elicit consumer preferences regarding the attributes of food characteristics, in this case organic products, among others. There are three main elicitation techniques: ranking (respondents rank alternative bundles from least favorite to most favorite), rating (respondents rate alternative bundles given a scale), and discrete choice (respondents are allowed to choose only one option). Ranking responses ostensibly provides more information than a single choice elicitation technique because it provides information for all profiles. A rating scale requires respondents to make judgments about the level of utility associated with each profile and assumes that this judgment directly transfers utility to the rating scale (Champ, Boyle and Brown, 2003).

The attraction of using conjoint analysis is that it asks the respondents to make choices between products defined by a unique set of product attributes in a way resembling what they normally do - by trading off features, one against the other. When asked which attributes they would like, most customers will choose everything on the wish list. Conjoint analysis can establish the relative values of particular attributes and identifies the trade-offs the customers are likely to make in choosing a product and service and the price they are willing to pay for it.

A conjoint analysis study includes the following key steps:
1. *Attribute List Formulation*. A business problem is defined and an attribute (features) list as well as their performance levels is developed to study the problem.
2. *Data collection.* Respondents are asked to express the trade-offs they are willing to make among product features by rating, sorting or choosing among hypothetical product concepts.
3. *Utility calculation*. A set of preference values (also called part worth utilities or part-worths) is derived from the interview data; they reflect the trade-offs each respondent made.
4. *Market Simulation*.

2.2. Research objective and design

The survey took place in Serbia, in January 2013. In total, 178 individuals completed the questionnaire in order to examine the preferences of the population in Serbia towards the use of organic food. Respondents provided information about their patterns of consumption, ability and willingness to pay for organic food, in this particular case – carrot, their attitudes toward the cultivation of organic food in Serbia and abroad, as well as demographic information about their households. Based on the results of this study, later it would be possible to determine the optimal organic food offer for the population in Serbia.

A list of key attributes is generated based on existing literature (Wang and Sun, 2003), market analysis and assumption that there is a correlation between them and consumers' behaviour. The attributes and levels assigned to them for the purpose of this study are: Production method and certification, Product origin, and Price. The attribute Production method and certification includes the modes of production and may be non-organic or organic, while organically produced food can be certified or without certificate. Certificate is the proof that food is controlled by those who are licensed by the state law. The Product origin represents a place of production, and refers to the fact that the food is produced in Serbia or abroad. The attribute Price represent current price of carrots in the market and has five levels: 50, 100, 150, 200 and 250 RSD/kg.

Once the attributes and their levels are defined, next step is to generate experimental design. Number of attributes (three) and the corresponding levels would lead to an unmanageable number of potential product profiles ($3\times2\times5=30$); therefore, it was necessary to generate a representative subset known as an efficient design. We generated near orthogonal and almost balanced experimental design with 18 profiles (Table 1). In order to elicit the preferences for the various profiles, in this study a rating approach was used. The

respondents expressed their preferences for a particular profile on a scale of 1 to 5, where 1 stands for definitely not buy, and 5 stands for buy for sure. The data was collected using social networks (Facebook, Twitter, www.ringeraja.rs, www.roditeljportal.com, www.kutak.forumotion.com, http://forum.b92.net/index.php) and by e-mail.

Table 1: Experimental design

ID	Production method and certification	Origin	Price
1	Non-organic production	Serbia	50 RSD/kg (0.5 €/kg)
2	Non-organic production	Serbia	100 RSD/kg (1 €/kg)
3	Non-organic production	Serbia	150 RSD/kg (1.5 €/kg)
4	Non-organic production	Abroad	50 RSD/kg (0.5 €/kg)
5	Non-organic production	Abroad	100 RSD/kg (1 €/kg)
6	Non-organic production	Abroad	150 RSD/kg (0.5 €/kg)
7	Non-certified organic production	Serbia	50 RSD/kg (0.5 €/kg)
8	Non-certified organic production	Serbia	100 RSD/kg (1 €/kg)
9	Non-certified organic production	Serbia	150 RSD/kg (1.5 €/kg)
10	Non-certified organic production	Abroad	150 RSD/kg (1.5 €/kg)
11	Non-certified organic production	Abroad	200 RSD/kg (2 €/kg)
12	Non-certified organic production	Abroad	250 RSD/kg (2.5 €/kg)
13	Certified organic production	Serbia	150 RSD/kg (1.5 €/kg)
14	Certified organic production	Serbia	200 RSD/kg (2 €/kg)
15	Certified organic production	Serbia	250 RSD/kg (2.5 €/kg)
16	Certified organic production	Abroad	150 RSD/kg (1.5 €/kg)
17	Certified organic production	Abroad	200 RSD/kg (2 €/kg)
18	Certified organic production	Abroad	250 RSD/kg (2.5 €/kg)

Conjoint analysis implies the assumption that the choice behaviour of consumers is guided by the maximization of utility. To determine the total utility, the additive model is commonly used. Considering the three attributes that are evaluated in this study, the econometric representation of the additive utility model is expressed as follows:

$$U_{ij} = \sum_{l_1=1}^{3} \beta_{i1l_1} x_{j1l_1} + \sum_{l_2=1}^{2} \beta_{i2l_1} x_{j2l_1} + \sum_{l_3=1}^{5} \beta_{i3l_1} x_{j3l_1} + \varepsilon_{ij}, \; i=1,...,I, \; j=1,...,18 \quad (1)$$

where U_{ij} represents respondent *i*'s predicted conjoint utility for profile *j*. $\beta_{i1l_1}, \beta_{i2l_2}, \beta_{i3l_3}$ are the coefficients (part-worth utilities) associated with the characteristics of each attribute, l_1 =production method (Non-organic production, certified organic production, and non-certified organic production), l_2 =product origin (Serbia and abroad), l_3 =price (50, 100, 150, 200 and 250 RSD/kg). $x_{j1l_1}, x_{j2l_2}, x_{j3l_3}$ are (0,1) variables that it equals 1 if profile *j* is characterized by corresponding attribute level, otherwise it equals 0. ε_{ij} is the error term

The relative importance of each attribute is further calculated as the utility-range (i.e. difference between the highest and the lowest utility for that attribute) divided by the sum of utility ranges of all attributes. The calculations are done separately for each respondent, and the results are then averaged to include all of the respondents.

The calculations were performed using the statistical package SPSS 16.0 (Conjoint procedure). The parameters were estimated for each respondent in the sample individually, as well as for the total sample (aggregated preferences).

3. RESULTS AND ANALYSIS

3.1. Socioeconomic and demographic variables influencing decisions on buying organic food

It has been proven that there is significant impact of some socioeconomic (education, income, and occupation) and demographic variables (gender and age) on the decisions on the buying organic food. Most studies report that "being female" positively affects purchase of organic food (Boccaletti, 2006; Rimal et al., 2001; Loureiro and McCluskey, 2001; Underhill and Figueroa, 1996).

In this study, the ratio between males and females was approximately 1:5. None of the male respondents do not buy organic food every day, and even 25% of them never buy organic food, while 4.1 % women buy organic food daily, but almost 40% of them never buy organic food (Figure 1). Those 40% of women that

never buy organic food mentioned that they often buy non-organic food on discounts in large supermarkets. There was no significant correlation between gender and frequency of buying organic products ($\chi^2(3) = 7.302, p = 0.063$).

Although, many empirical studies have found negative effect of age on probability of buying organic food (Boccaletti, 2006; Rimal et al., 2001; Wier and Calverley, 2002; Underhill and Figueroa, 1996), we found no statistically significant correlation between years and frequency of buying organic food. The interesting fact is that in the total sample, only 3.4% of respondents are aged over 46 years, have high incomes and buying organic food on a weekly basis. The age distribution of respondents was as follows: 18-25 years (18.1%), 26-35 years (55.7%), 36-45 years (22.8%), 46-66 years (3.4%).

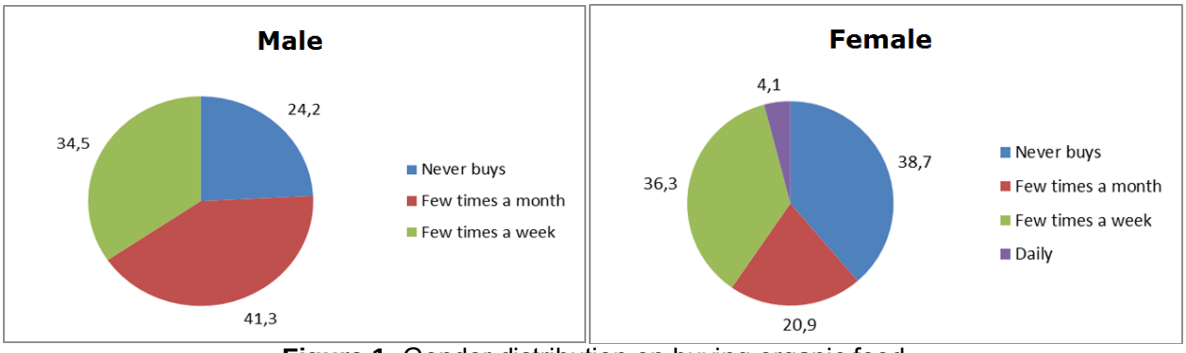

Figure 1: Gender distribution on buying organic food

Some of the studies have suggested negative effect of education on purchase of organic food (Thompson and Kidwell, 1998). Govindasamy and Italia (1999) suggested that less-educated consumers may exaggerate true risks of pesticide use, and/or higher educated respondents may have higher confidence in safety standards of non-organic production. On the other hand, some surveys have found often a positive correlation between higher education levels and increasing likelihood of purchasing organic products (Wandel and Bugge, 1997; O'Donovan, 2002). We didn't found any significant difference between education and buying organic products. We should mention that none of the respondents with primary and secondary school (24.1%) are not buying organic food on dally basis, or either consider that the use of it has positive influence on health.

Influence of income variables on buying organic food is definitely important. Some studies document that household income has positive impact on the purchase of organic food (Rimal et al., 2001) and that households with middle and higher income are more likely to purchase organic food. Verhoef (2005), Wier (2002), Thompson and Kidwell (1998), Zepeda and Li (2007) found that household income does not have necessarily significant effect on organic food purchase. However, willingness to pay price premium for organic food has been shown to rise with income (Stevens-Garmon, Chung and Biing-Hwan, 2007; Govindasamy and Italia, 1999). Table 2 represents monthly income per household member and willingness to pay for organic food of all respondents per product (1 Euro is app. 115 RSD).

Table 2: Monthly income per household member and willingness to pay for organic food

Characteristics	Description	(%)
Monthly income per household member	Less than 10.000 RSD	4.7%
	Between 10.000 and 20.000 RSD	18.1%
	Between 20.000 and 30.000 RSD	26.8%
	Over 30.000 RSD	50.3%
Willingness to pay for organic food	Up to 100 RSD	52.4%
	Between 101 and 200 RSD	40.3%
	More than 201 RSD	7.3%

It is shown that although more than half of the respondents have an income over the 30000 RSD, more than half respondents are still not willing to pay more than they usual pays for non-organic made product.

3.2. Consumers' preferences

Results from the conjoint analysis are shown in Table 3 and Figure 2. Table 3 presents the (averaged) part-worth utilities of each attribute level, while Figure 2 is the graph description of the attributes importance.

Table 3: Averaged results

Attribute	Attribute level	Part-worth utilities	Std. dev.
Production method	Non-organic production	-0.300	0.121
	Non-certified organic production	-0.340	0.097
	Certified organic production	0.640	0.121
Product origin	Serbia	0.220	0.072
	Abroad	-0.220	0.072
Price [RSD]	50 RSD/kg (0.5 €/kg)	-0.587	0.072
	100 RSD/kg (1 €/kg)	-1.174	0.145
	150 RSD/kg (1.5 €/kg)	-1.761	0.217
	200 RSD/kg (2 €/kg)	-2.348	0.290
	250 RSD/kg (2.5 €/kg)	-2.936	0.362
Constant		4.311	
Price Coefficient (β)		-0.012	
Correlations between observed and estimated preferences			
Pearson's R	*0.949*	*Significance = 0.000*	
Kendall's tau	*0.882*	*Significance = 0.000*	

The internal and predictive validity of the rating model was estimated by Pearson and Kendall's tau statistics. A high value of the Pearson coefficient, 0.949, confirms the high level of significance of the obtained results. Similarly, a high value of the Kendall's tau statistic, 0.882, indicates the strong correlation between the observed preferences and those estimated by the model. The β coefficient is related to the price attribute, because it is the only attribute defined as linear in SPSS software. This coefficient is always negative for the price and it represents the sensitivity of respondents' preferences on changes in price of products. Higher absolute value of the coefficient and steeper linear function means that respondents are more sensitive to changes in price, meaning that small increase in price leads to a sharp drop of preferences.

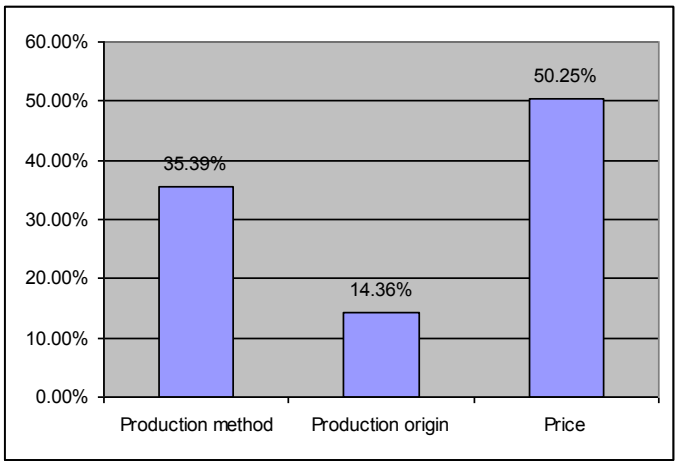

Figure 2: Relative importance of attributes

As Figure 2 shows, the most important attribute is Price, with an relative importance value of 50.25%. Than follows the attribute Production method (relative importance = 35.39%). Product origin (14.36%) is the least important attribute. Characteristics that describe „the most desirable carrot" are: Certified organic production, made in Serbia, at the price of 50 RSD/kg (0.5 €/kg).

3.3. Post hoc segmentation

A more detailed analysis of individual utilities revealed wide heterogeneity in preferences. Therefore, a cluster analysis was performed to classify respondents into more homogeneous preference groups. The part-worths are used as input for cluster analysis.

The K-means cluster procedure in SPSS 16.0 was used to perform the segmentation. A 2-cluster solution was chosen due to the size of the segments and statistical significance. An analysis of variance revealed that

the segments in the 2-cluster solution differed significantly from each other, with respect to their part-worths generated by the conjoint analysis (see Table 4 and Figure 3).

Table 4: Segment-level part-worth utilities

Attribute	Attribute level	Segment 1 (34.9%)	Segment 2 (65.1%)
		Part-worth utilities	Part-worth utilities
Production method	Non-organic production	0.11	-0.52
	Non-certified organic production	-0.24	-0.39
	Certified organic production	0.13	0.92
Product origin	Serbia	0.51	0.06
	Abroad	-0.51	-0.06
Price [RSD]	50 RSD/kg (0.5 €/kg)	-0.448	-0.661
	100 RSD/kg (1 €/kg)	-0.896	-1.323
	150 RSD/kg (1.5 €/kg)	-1.344	-1.984
	200 RSD/kg (2 €/kg)	-1.793	-2.646
	250 RSD/kg (2.5 €/kg)	-2.241	-3.307

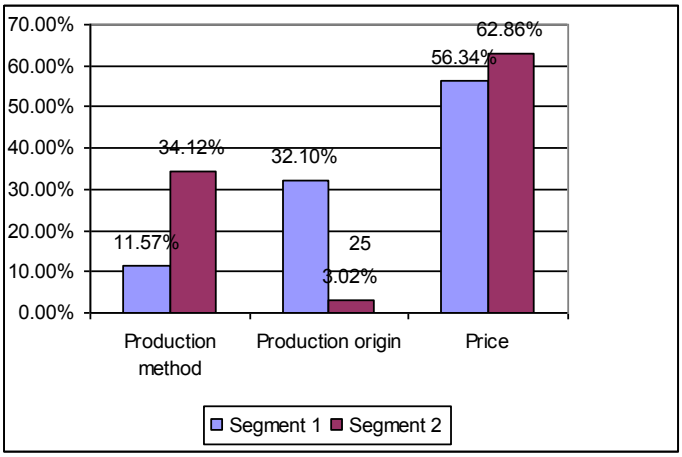

Figure 3: Segment-level attributes importance

As it is shown in Figure 3, price of the product is the most important attribute in both segments. Given the current situation and weak purchasing abilities in Serbia, as a result of the global economic crisis, it is expected that the price was determining factor when buying organically produced food (specifically carrots).

The first segment covers more than a third of the total number of respondents (34.9%). Respondents in this segment are equally important whether something is produced in non-organic or organic certified way, but this is an attribute that is not so important to them, and for that reason, they don`t find the difference between levels. On the other hand, the second segment was significantly larger (65.1%) and consists of respondents who are big supporters of organic food, which has an official certificate. The respondents from segment 2 find the origin as a lowest important attribute, and there is almost no difference whether food is produced in Serbia or abroad. Product origin almost does not affect the preferences of the members of this segment.

4. CONCLUSION

In a process of purchasing organic food, there is a significant number of factors that influence the final customer decision on purchasing organic products. Decision for purchasing is something that is evolving and maturing in customers mind and sometimes even the product itself is not main motive for decision.

The aim of this paper was to show that the production of organic food is a great development opportunity of Serbia in the future, so we explored preferences of consumers in Serbia towards the carrot. For this purpose we used conjoint analysis. The most important attribute of carrot is Price followed by attributes Production method and Product origin, which is to be expected given the current purchasing power in Serbia.

It is evident that on customers' behaviour socioeconomic and demographic variables has some influence. Faced with the dilemma of choice between organic and non-organic, consumers have different reactions. Female consumers are inherently more rational than male. Demographic results show that still a small number of respondents buy organic food. These results suggest that there is a small consumer base for

organic food and market potential is weak. We also came to conclusion that population is not familiar enough with the methods of production and the benefits of organic food.

In Serbia, above all, it is necessary to provide constant education on organic farming. From organic farming, everyone would have benefits. Our organic food can be exported to EU countries where it has already been observed that people who regularly use organic products improved their life quality. Organic farming essentially aims to save the environment along with high quality production, which is another important aspect. Successful economic development, preserved nature and healthier people - the only question is whether we will take advantage of these opportunities? But above all, the knowledge that we are eating really healthy food and still not destroying the land that feeds us, is in ourselves.

[1] Military Academy, University of Defence, brate@verat.net
[2] Military institution „Morovic", sudimnja@gmail.com
[3] Municipality „Ieastern Saraevo", Serbo Republic

Abstract: *In order to improve the economy of nutrition in the army of Serbia (hereinafter referred to as AS) there is a need to organize food surcharge during the working hours of professional members AS. Insufficient employment existing workforce and high overheads, the barriers are to reduce the amount of the total cost of food in AS. By using the software package LP Solve with multi-criteria analysis, based on nutritional value and biological food products (hereafter FP), their prices and food needs of professional members of the Army, leads to the development of a mathematical model of economic optimal eating plan for lunch.*

Keywords*: Multi-criteria analysis, LP Solve, energy value of foods, nutritional value of food, nutrition in the workplace, economically optimal nutrition, eating lunch.*

1. INTRODUCTION

Tests for food in AS[1] by many authors, such as B. Tesanovic and others point to the fact that nutrition can examine the qualitative and quantitative aspects. The qualitative aspect consists in the application of highly effective nutrition programs that provide health-safe and balanced diet of consumers. In this paper, the qualitative aspect of nutrition is analyzed primarily from the perspective of developing economically optimal eating plan of AS for lunch, as lunch is the meal by which in the course of the day brings the highest volume of energy and nutritive substances in the body.

2. NUTRITION IN THE WORKPLACE PAY IN SERBIAN ARMY

The consequences of malnutrition are very common throughout the world. Eating habits are conditioned by the greater number of factors: the need to enjoy food, real needs, scientific knowledge, and other economic factors. Under the eating habits of an individual involves the selection and preparation, the amount, time and manner of consumption of FP for a longer period (Pelva, 2010).

The main normative act that regulates food in AS the Ordinance on general and logistical needs of the Department of Defense (hereafter DoD) and AS (hereinafter referred to as the Ordinance). Ordinance regulating norms belonging to FP. Prescribed norms should provide nutrition based on scientific principles and align with the physical needs of AS and specific military requirements. In order to implement the provisions of the Regulations are made diet plans that are based on the statutory structure of FP , norms belonging and recipes for cooking in AS.

Abolition of compulsory military service (Jovic , 2013) the number of persons who are entitled to free meals, reduced to 4.000 persons. In order to develop the economy of nutrition, and increase the level of installed capacity employment military Restaurant (hereafter MR) there is a need to organize meals for a fee, which must meet the energy and nutritional needs in food.

Activities carried out by members of the AS can be classified as medium hard physical work, and to satisfy their daily energy needs should be provided daily meals (hereinafter referred to as d/m) feed containing about 14.700 KJ (Jokic, 1998). From that lunch should provide about 40% of the energy value of d/m food. According to the recommendations of the World Health Organization's share of nutrients in the total energy value of d/m is: for protein - 10 to 15 % ; the fat content - 15 to 30 % of carbohydrates, and - 55 to 75 %.

[1] According to the Regulations on general logistics needs of DoD and "nutrition personnel the task of the general logistic function, which is achieved on the basis of scientific knowledge, technological capabilities, experiences, habits and traditions in the diet of the population, in line with the psychological and physical stresses and demands concerted command and management as prescribed, regular health and proper way provides high quality and totally satisfying energy-biological needs of the professional members of AS. Nutrition in AS is planned, programmed and organized by the eating plan in AS."

Interest in nutrition surcharge in AS so far is small. Insufficient employment installed capacity of MR, the existing workforce and high overheads, the barriers are to reduce the amount of the total cost of providing food services at the workplace, thereby preventing an increase in the number of people who would be interested for this type of diet.

In order to provide all members of the MS one meal during the working time necessary to plan adequate funds to pay for it in the form of refunds from the approved budget allocations for food (Jovic, 2010). In order to achieve quality food, which is the economic aspect of production is acceptable, and which also meets the nutritional standards of quality, it is necessary to produce food that has an acceptable level of costs, and that is an acceptable range by members of the AS. It is necessary to create a proposal for a diet plan for lunch, which will ensure the proper and balanced diet for this meal, with the use of nutritional and economic criteria. This diet plan ought to include standardized menus , application menu cycle, plan expenditure of FP and an explanation of its use, but which are related to food during working hours and that includes just one meal instead of all day d/m food. Normative consumption of FP and food preparation should be adapted to the needs of the organism, since it would be realized only one meal, and that the remaining two lunch time staff consumed outside the workplace. The next section of the paper presents a general and then a special mathematical model diet surcharge in the Army, based on the study of optimal model diet plan for lunch.

3. DRAFT ANNUAL PLAN OF SERBIAN FOOD IN THE ARMY FOR LUNCH - GENERAL MATHEMATICAL MODEL

The main objective of the research in this paper is the Definition of diet plans for lunch, to establish a cost-effective nutrition surcharge ie. build a model that is optimal from an economic point of view, and that meets the predetermined energy and biological constraints and needs of the AS in the diet. Problem diet surcharge aims to making a diet plan for lunch, while minimizing the cost of food and meeting pre-defined energy and biological constraints and needs of the AS. For solving this problem affected by many factors, such as price FP, meals and menus, Percentage of different types of FP in nutrition and others.

Taking into account the limiting factors can be obtained as a result of Plan meals for lunch, which is the optimal solution from an economic point of view. The daily menus using the multi-criteria analysis, based on the analysis of energy and biological value of FP, FP prices and food needs of AS, leads to the development of combination dishes that. Daily menu for lunch. Each set contains: name of FP, quantity, energy value and amounts of nutrients. Determining the number of application of certain foods that are part of the handle defines a cycle of application meals. When preparing meals Cycle application, you need to meet several criteria: variety of food; appreciation of the seasonal character of FP; achieve the planned average energy-biological value lunch and planned expenditure FP. Price changes FP from the economic point of view is a significant limitation in the development cycle, the application meals.

In developing the model diet plan for lunch, as a starting point for the implementation recipes for making lunch, we used data from the eating plan in AS. In this diet plan defines the 133 recipes that can become part of lunch. By using the software package LP Solve, set the basic - a general mathematical model for the development of the Plan daily menus, with appropriate mathematical assumptions and limitations. Of the initial parameters for the development of a model diet plan are: FP, meal and menu. Based on these recipes for making lunch in the eating plan in AS and quantitative participation of FP, which are included in the prices of certain food dishes.

Mathematical assumptions are: a) the linearity of the objective function, b) linearity constraints, c) a finite number of constraints and d) additivity constraints and objective functions.

Based on these assumptions math was done setting the general mathematical model of cost-effective nutrition surcharge ie. build a model that will be the economic aspect of optimal, and that will meet predetermined energy and biological constraints and needs of the VS in the diet:

The criterion of optimality of linear objective function with respect to the restrictions:

$$F = \sum_{i=1}^{n} C_i X_i \rightarrow min \tag{1}$$

where: F (objective function), C (the coefficients of the variables in the objective function) and Xi (variable) .

Restrictions:
$a_{11}X_1 + a_{12}X_2 + ... + a_{1n}X_n \leq b_1$
$a_{21}X_1 + a_{22}X_2 + ... + a_{2n}X_n \leq b_2$
.....
$a_{m1}X_1 + a_{m2}X_2 + ... + a_{mn}X_n \leq b_m$

where: aij (the coefficients of the variables in constraints), C (coefficient restrictions) and Xi (variable).

On the basis of a general plan daily menus are made suggestions of specific models of the Plan daily menus for lunch.

4. PROPOSAL OF THE YEARLY DIET PLANS IN THE SERBIAN ARMY FOR LUNCH

In order to develop a specific model plan daily menus for lunch, it is necessary for a total of 83 main dishes, 11 types of soup (broth), 12 salads, 18 types of cakes and 9 species of fruit eating plan approved in AS find the frequency of each of them on an annual basis for 252 working days, taking into account the biological and energy constraints, to achieve the minimum total cost of the food. It is necessary to take into account that the number of cakes and fruit number of alternative variables, ie. that their sum total is 252 for lunch as part of the diet plan participates cake or fruit.

On the basis of standardized meals for lunch and preparation of statistical data on the average energy value and composition of nutrients shown to diet plans in the AS, and the price of individual FP forming part of the meal was made the budget share of proteins, fats and carbohydrates in each of dishes, as well as the price of food, which are used in the preparation of the handles. The above data are shown in Tables *1 – 5.*

Table 1. The percentage share of protein, fat and carbohydrate composition of the soup

Variable	Kind of soup	The energy value (Cal)	% Of the amount of food			Price in dinars
			Proteins	Fat	Carbohydrates	
X_{96}	Soup of the concentrate with stars	123,10	12,3	2,8	84,9	2,10
X_{97}	Beef soup with stars	177,32	9,7	24,3	66,0	1,77
X_{98}	Chicken soup with stars	318,95	23,7	39,6	36,7	6,39
X_{99}	Chicken soup	662,96	15,5	49,0	35,5	11,14
X_{100}	Beef soup	743,29	13,9	54,4	31,7	20,44
X_{101}	Cream of mushroom soup	567,17	10,7	44,3	45,0	13,46

Assuming that the total number of main dishes, salads, soups, cakes and fruit per annum equal to the number of working days, set limits are shown in Table 6.

Table 6. Frequency limits on the types of food for lunch

Type of food	Limitations
Entrees	$X_1+X_2+X_3+....+X_{81}+X_{82}+X_{83}= 252$
Salads	$X_{84}+X_{85}+X_{86}+X_{87}+X_{88}+X_{89}+X_{90}+X_{91}+X_{92}+X_{93}+X_{94}+X_{95}=252$
Soup-stew	$X_{96}+X_{97}+X_{98}+X_{99}+X_{100}+X_{101}+X_{102}+X_{103}+X_{104}+X_{105}+X_{106}=252$
Cakes and Fruit	$X_{107}+X_{108}+X_{109}+...+X_{131}+X_{132}+X_{133}=252$

Source: Authors' calculations

Due to the high cost of input points, and in relation to the need to meet the biological and energetic constraints placed additional restrictions on the minimum number of occurrences of certain cakes and dishes, presented in Table 7 and:

Table 7. The default limits the minimum number of occurrences of dishes

$X_{107}+X_{108}+X_{109}+X_{110}+X_{111}+X_{112}+X_{113}+X_{114}+X_{115}+X_{116}+X_{117}+X_{118}+X_{119}+X_{120}+X_{121}+X_{122}+X_{123}+X_{124}>=26$	
$X_{22}+X_{23}>=1$	$X_{24}+X_{25}>=1$
$X_{26}+X_{27}>=1$	$X_{48}+X_{64}+X_{65}+X_{73}+X_{74}>=1$

Taking into account that the composition of the meal for lunch has a larger number of components, ie. soup - soup, main course, salad and dessert or fruit, set the share of each of these dishes in the composition of the

handle on the quantitative amount of their shares, based on which further set linear constraints in relation to the biological requirements, as well as in relation to the demand:

a) For proteins:

By using the software package LP Solve the proposed model to obtain the optimal solution from an economic point of view, where food costs are minimized and met predetermined energy and biological constraints and needs of the AS, achieved with Fmin = 33.126,77 dinars annually, which represents optimal solution for lunch with the specified limits. Solving this set of model gives us important planning elements for the development of a plan for eating lunch, because as the output parameter data obtained on the number of frequencies dishes that are part of the handle annually.

The frequency of certain types of foods that are part of the lunch on an annual basis, which are shown in Table 9, satisfy criterion optimal combination of dishes for lunch with the economic aspects while satisfying energy and biological constraints and needs of AS.

Table 9. The frequency glavanih meals annually

$X_{1,3,8,18,20,21,38,39,41,49,63,71,72,75,76,80-83,}$=12	X_5=2	$X_{22,25-27,74}$=1
$X_{2,4,6,7,9-17,19,23,24,28-37,40,42-46,48,50-62,64,65,67-70,73,77-79,107-118,130}$=0	$X_{47,66}$=9	X_{84-95}=21
X_{96-106}=23; X_{124}=14	$X_{125-128}$=28	$X_{129-133}$=29

Source: Authors' calculations using the program LP Solve

Based on the defined share of certain types of food that are part of the handle, which is an optimal solution to The specified limitations, and can still access the development cycle, the application of food and the preparation of the Plan daily menus for lunch. From the above it can be seen that the cost of meals for lunch is 131,45 dinars on a daily basis, which is 285.55 dinars lower price than the price at AS.

5. CONCLUSION

Economic factors have a crucial impact on the eating habits of professional members AS. Abolition of compulsory military service, the number of persons who are entitled to free meals, reduced to 4.000 persons, which is imposed by the need to organize food for a fee, which must meet the energy and nutritional needs in food professional members AS.

By defining model diet plan for lunch, to establish cost-effective nutrition surcharge ie. build a model that is optimal from an economic point of view, and that meets the predetermined energy and biological constraints and needs of the AS in the diet contributes to increased economies of food in AS.

By using the software package LP Solve, set the basic - a general mathematical model, with appropriate mathematical assumptions and limitations, and then the specific model diet plan for lunch. Using 133 recipes suggested the frequency of application of each of them annually. By using the software package LP Solve the proposed model to obtain the optimal solution from an economic point of view, where food costs are minimized and met predetermined energy and biological constraints and the needs of the Army, achieved with Fmin = 33.126,77 dinars annually, which represents optimal solution for lunch with the specified limits, with price meals for lunch is 131,45 dinars on a daily basis, which is 285,55 dinars lower price than the price of lunch at AS.

Abstract: *Inventory management is one of the most important logistic tasks in the decision making process. Many companies are faced with problems of finding an optimal order policy when there are constraints on some operations. Problems of this type can become rather complicated, so we will illustrate some principles by looking at problems with constraints in inventory levels. This paper presents an inventory model where there is a limited amount of storage place. The research is based on data from the warehouse of a company in Strumica, Republic of Macedonia, which has a chain of supermarkets where there is a different kind of products. Our purpose in this paper is to calculate the optimal order quantities for different kinds of products which are determined by the capacity of warehouse place and also minimizing the total order costs and different inventory costs. In the research we use analytical and simulation methods and the results and suggested solutions will be discussed.*

Keywords*: inventory models with limited storage place, optimal order quantities, analytical methods, simulation, minimum total order cost, data analysis*

1. INTRODUCTION

Inventories are one of the main sources of costs within the companies. Therefore, the aim of inventory management is to keep inventories as much as possible on lower level, but always sufficient to meet the needs of customers. Waters (1949) discussed the reasons for holding inventories. He considered that there are several answers why organizations hold inventories, including: to allow demands that are larger than expected, or at unexpected times; to allow deliveries that are delayed or too small; to take advantage of price discounts on large orders; to avoid delays in passing products to customers; to make full loads for delivery and reduce transport costs; to give cover for emergencies etc. (p.8). Ravindran (2008) explained that keeping products in inventory causes certain costs. In this context, in the list of inventory costs he presented: the interest on the capital invested in the products retained, the cost of operating the physical warehousing facility where the items are held, the cost of obsolescence and spoilage, taxes that are based on the inventories on hand (p.305).

The excessive quantities of inventory causes unjustified high holding costs, while too low level of inventory initiate many problems, difficulties and negative effects on trade and distribution. Losses of inventory which take range to 1% of sales in retail trade are assessed as good, while in a lot of retail outlets they amount to more than 3% of sales. In this context, inventory management includes ensuring the optimal order quantity, storing it in an adequate way and also minimizing total order costs and other inventory costs. Thus are determined the basic decision variables in inventory models.

Waters (1949) considered the inventory cycle where he gave a picture for a typical use of inventory in a supermarket. He also listed the basic elements which are included in each inventory cycle (p.6).
Felea (2008) studied the importance of inventory in the supply chain. It was concluded that the changes in the inventory policies can lead to a dramatic alteration of the supply chain's efficiency and responsiveness (p.112). Roumiantsev and Netessine (2007) established that many of the predictions from classical inventory models extend beyond individual products to the more aggregate firm level; hence, these models can help with high-level strategic choices in addition to tactical decisions (p.421). Su and Lin (2013) established EPQ models concerning about the total relevant costs given in their study. In their research was determined the optimal order policy and the obtained results were practically used (p.10). Dukič, Sesar and Dukič (2007) gave an inventory model with storage limitation and simulated demand. They determined the optimal order quantities for different products with minimum holding costs using the Lagrange multiplier (p.223)

The subject of the research in this paper is an inventory model with possible constraints. In practice, there are many problems with constrains in inventory level and they mostly refer to capacity of the storage space, maximum acceptable investment in inventory holding, storage conditions, all the costs related to inventory etc.

We will analyze an example when there is a limited warehouse space in a supermarket where are ordered different kinds of products. In this case of many different products in the warehouse of the supermarket, we will calculate the optimal order quantities for each product with minimum total order costs and other inventory costs. It will also be given the amount of space occupied by one product from the available capacity of the warehouse. If it turns out that the storage space required for keeping the determined quantities of products is larger than available warehouse space, we keep decreasing simultaneously the initially determined values by changes in Lagrange multiplier (λ) until storage limitation is satisfied.

2. METHODOLOGY

Our research was conducted for a period of 1 month, including the time period when the supermarket makes an order for a different kind of products. During the research quantitative analysis was made which is based on quantitative optimization methods. Received data from the company that were processed are presented in a table below. The model will emphasize the capacity of the warehouse of the supermarket which is a constraining factor in this case. Therefore, the volume that occupies each product from the total available space was given in the table. The optimal order quantities for the products and minimum total order costs were calculated in Microsoft Office Excel 2007 and in determining the optimum quantity the Lagrange multiplier λ was decreased until the available storage place is used to the full. The results obtained from the research represent the optimal order quantity of all products and they are presented graphically.

3. RESULTS AND DISCUSSION

The inventory model with limited storage space is characterized by many assumptions**,** where the basic is that there are at least two different products with determined demand for a certain time period. We introduce the following parameters:

n - Number of products.
k_j - Demand rate per unit time of the j-th product.
c_1 - fixed costs of the company.
r_j - Storage costs of the j-th product expressed in percentage of the value of inventory per unit time.
a_j - Procurement costs per unit j-th product.
q_{j0} - Optimal order quantity of the j-th product.
v_j - Volume occupied by j-th product.
V - Total available storage place.

First, are determined the optimal order quantities for each j-th product in terms of minimum total order costs. To determine the optimum order quantity accompanied with minimum costs, the objective function must meet the condition (1):

$$\frac{\partial F(q_j)}{\partial q_j} = \frac{1}{2} r_j a_j - \frac{c_j}{{q_j}^2} k_j = 0 \qquad (1)$$

In this case we can calculate the optimal order quantity per product using the formula below:

$$q_{j0} = \sqrt{\frac{2c_j k_j}{r_j a_j}} \qquad (2)$$

The minimum total order costs of the model can be determined by the expression:

$$F(q_{j0}) = \sum_{j=1}^{n} \left[a_j k_j + \frac{c_j}{q_{j0}} k_j + \frac{r_j}{2} (a_j q_{j0} + c_j) \right] \qquad (3)$$

We will analyze an example where the constraining factor is the capacity of the storage space in a supermarket. So, in this case we introduce the following expression:

$\frac{q_j}{2} v_j$ – Space needed for average quantity of inventory for the j-th product.

The total required space for average inventory for all products is defined as follows:

$$\frac{1}{2}\sum_{j=1}^{n} v_j q_j \qquad (4)$$

In order to determine all optimal order quantities that will not exceed the available storage place, we will apply the Lagrange function defined in the expression (5):

$$F(q_j) = \sum_{j=1}^{n}\left[a_j k_j + \frac{c_j}{q_j} k_j + \frac{r_j}{2}(a_j q_j + c_j)\right] + \lambda\left(V - \frac{1}{2}\sum_{j=1}^{n} v_j q_j\right) \qquad (5)$$

The optimal order quantity for the j-th product using the Lagrange multiplier λcan be defined with the expression:

$$q_{j0} = \sqrt{\frac{2c_j k_j}{r_j a_j - \lambda v_j}} \qquad (6)$$

In the relation (6) it is very important to be made a quantification of the Lagrange multiplier λ. Tabular method was applied. Considering that $q_j > 0$, λ must meet the condition $r_j a_j - \lambda v_j > 0$, where λ is defined as follows $\lambda < \frac{r_j a_j}{v_j}$. But, $\lambda \leq 0$ because according to the existing problem the limited capacity of the storage space will affect the order quantity that will decrease, because otherwise the construction will be without impact on solving of the problem. Based on the relation for different values of λ , $\lambda \leq 0$are determined the order quantities for the products and the values of the expression (7) below:

$$\frac{1}{2}\sum_{j=1}^{n} v_j q_j \qquad (7)$$

Obtained values are presented in an appropriate table using the different values of Lagrange multiplier λ.

It was conducted a research in a supermarket and the received data from the company's storage are presented below. The results from the research are discussed.

In our research were taken 20 different products which are ordered every month by the supermarket. The optimal quantities are determinate according to the available storage space.

The Lagrange multiplier λ is taken as an appropriate for the values of q_{j0} if their common volume is closest to the constraint below:

$$\frac{1}{2}\sum_{j=1}^{n} v_j q_j \leq \mathrm{V}; \qquad q_j > 0, \qquad \mathrm{j} = 1,2,\dots,\mathrm{n} \tag{8}$$

Based on the processed data given in the Table 1 is calculated the optimal order quantity for the 20th different products of the supermarket for an available storage place of **5000 m^3** and the calculation is given in the Figure 2 in Microsoft Office Excel 2007.

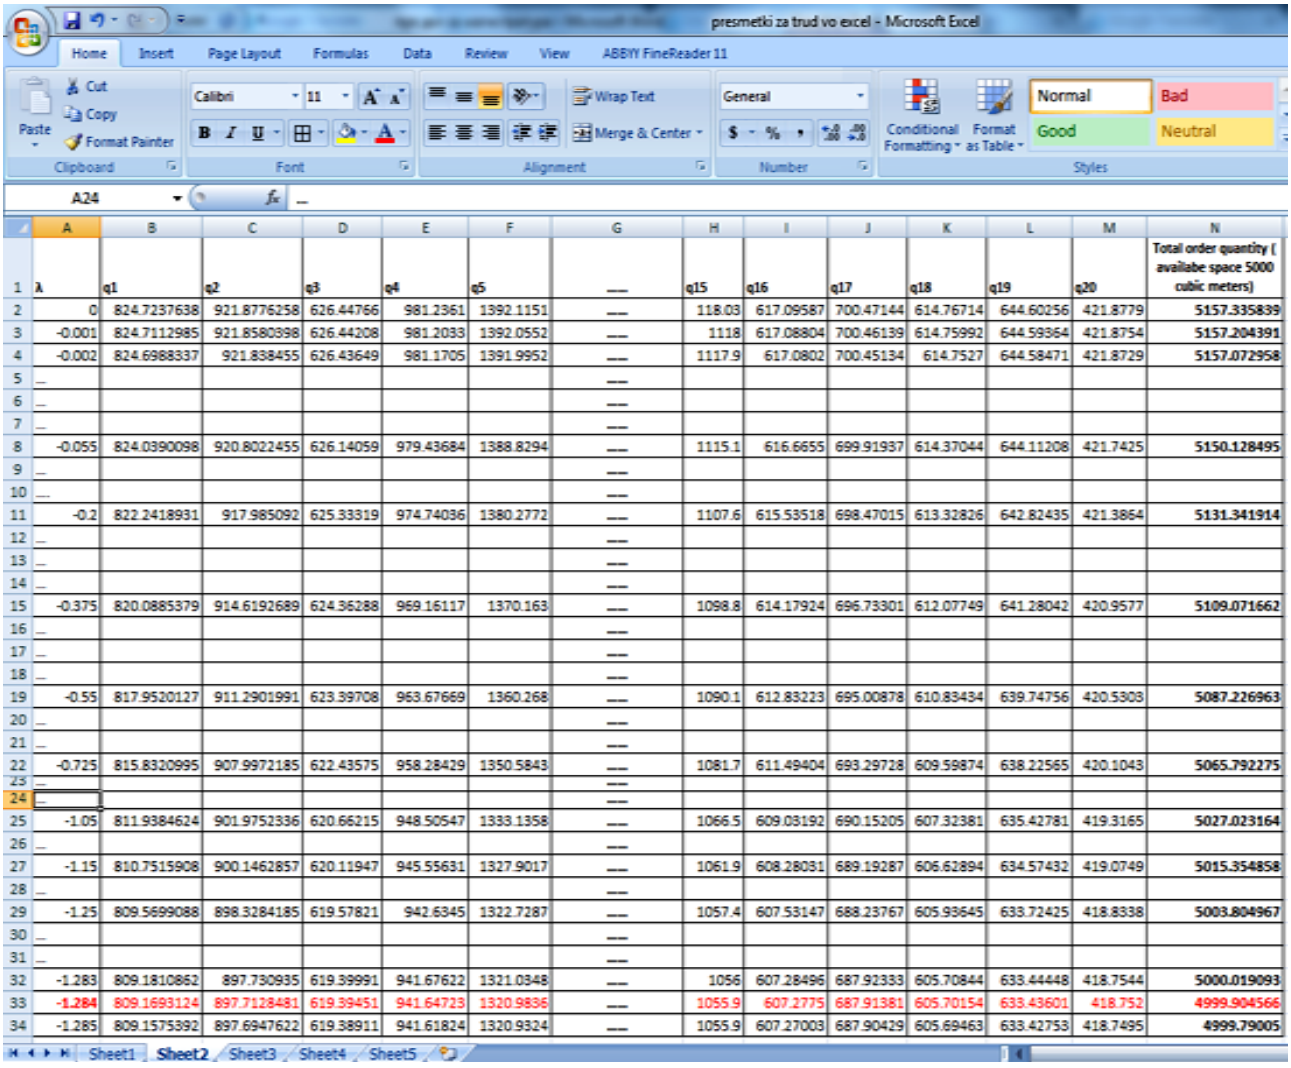

Figure 1: Calculation of optimal order quantity for 20 different products in a limited storage space

As the Figure 1 shows, based on assessments, we should calculate the values that are closing to the optimal quantity, which must be closest to the given available storage space of 5000 m^3.

In our case the optimal order quantity for each product is: q_1 =809.1693124; q_2 =897.7128481; q_3 =619.3945056; q_4 =941.6472309; q_5 =1320.983601; q_6 =1232.884922; q_7 =824.190598; q_8 =490.0917832; q_9 =555.4427822; q_{10} =1058.978488; q_{11} =528.768245; q_{12} =276.6579312; q_{13} =403.4453962; q_{14} =279.4117813; q_{15} =1055.909306; q_{16} =607.2774956; q_{17} =687.9138062; q_{18} =605.7015394; q_{19} =633.4360052; q_{20} =418.7519525.

Their common volume is **4999,904566 m^3** which not exceeds the available storage space of **5000 m^3**.

The results from the Figure 1 are graphically presented and it is given a comment based on the obtained values.

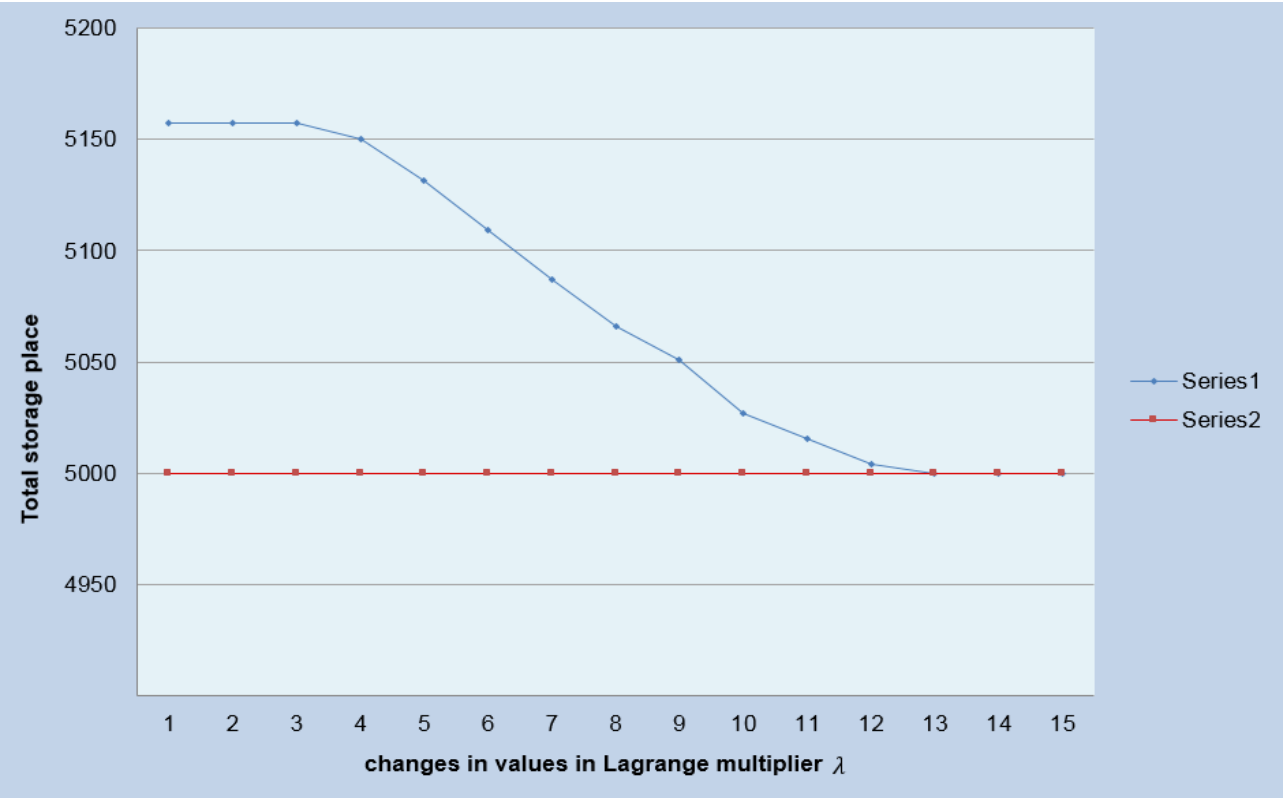

Figure 2: Graphic presentation of the optimal order quantity for determined values $\lambda \leq 0$

From the graphic presentation on Figure 2 is conclude that as much as is smaller the value of Lagrange multiplier ($\lambda \leq 0$), the total required space for average quantity of inventory for all 20 products is decreasing and is closer to 5000 m^3, which is the total available capacity of the storage of the supermarket.

The Series 1 show the total order quantity for all 20 products when there are changes in values in Lagrange multiplier when $\lambda \leq 0$ and Series 2 show the total available storage space of 5000 m^3.

As can be seen from the Figure 2 and Series 1 the order quantity for the first value for Lagrange multiplier ($\lambda = 0$) is 5157.335839. Than we took another value for the Lagrange multiplier ($\lambda = -0{,}001$) in order to decrease the occupied storage space and do not exceed the limited capacity of the warehouse of the supermarket. Next value for the Lagrange multiplier is $\lambda = -0{,}002$ where the order quantity decreases and amount 5157,072958. For $\lambda = -0{,}055$ the order quantity for all 20 products is 5150,128495. As the Lagrange multiplier decrease, so the order quantity is decreasing too. Therefore, our aim is to determine for which value of Lagrange multiplier the order quantity is optimal, so in our analysis the number of changed values for Lagrange multiplier (λ) was over 60 values. From the graphic presentation we can see that for the first few values of Lagrange multiplier, the order quantities are approximately same, until the order quantity decreases on a 5087,226963 for $\lambda = -0{,}55$.The last three values for Lagrange multiplier are very identical and all of them are very close to the amount of limited storage place. So, we calculated that for $\lambda = -1{,}284$, the order quantity is most suitable to the limited amount of storage space of 5000 m^3.

In this case, when the optimal order quantity is determinate by the results from research, the minimum total order costs were also calculated with the Lagrange function given in the expression (5).

$$F(q_{20}) = \sum_{j=1}^{n} \left[a_j k_j + \frac{c_j}{q_j} k_j + \frac{r_j}{2}(a_j q_j + c_j) \right] + \lambda \left(V - \frac{1}{2} \sum_{j=1}^{n} v_j q_j \right) \quad (9)$$

Thus, the amount of minimum total order costs is **125.133 797, 2 MKD.**

4. CONCLUSION

Optimal inventory management is very important for efficient working of the companies of the all industries. Inventories are one of the most expensive types of assets of the company, accounting for over 50% of the total invested capital. Inappropriate inventory management causes negative consequences, particularly high costs and big losses in profits of the companies.

There are many types of classification of inventory models. In this paper was elaborated the inventory model with constraints in capacity of the warehouse of a supermarket where there is a different kind of products. An important point of reference in this model is the estimate of the volume of storage space which is occupied by all products. Using this model the decision maker can easier determine the optimal order quantity which will have a volume that will not be larger than the available capacity, and will also result in a decreasing of total costs and setting them on minimum level.
Today, in reality, companies have very little scientific support for their operations, so with our researches we can help them to improve operations and achieve positive results. Our suggestion is in the future trade companies to apply merging of the process of trade operations with process of the modeling, because the models thus created may enable prediction of the total costs of operations and the same to be minimized.

OPTIMAL VEHICLE ROUTING IN THE OIL INDUSTRY

Jelena Golubović, Dragana Makajić-Nikolić, Nebojša Nikolić
University of Belgrade, Faculty of Organizational Sciences, gis@fon.bg.ac.rs

Abstract: *The vehicle routing problem (VRP) has been solved as an optimization problem for more than fifty years. However, any real problem of this type has its own characteristics that should be included in a specific mathematical model. In this paper, we observe the vehicle routing problem in the oil industry. Based on the characteristics of a real company, an original mathematical model for supplying gas stations from multi-depots has been formulated. The routing problem is observed as a set covering problem and is formulated as a mixed integer programming (MIP) problem. Based on real data, an analysis of the optimal routes for different company policies on the organization of gas stations fuel supply has been done.*

Keywords*: VRP, MIP, optimization, oil industry, multi-depot*

1. INTRODUCTION

The vehicle routing problem (VRP) involves the design of a set of minimum-cost vehicle routes, originating and terminating at a central depot, for a fleet of vehicles that services a set of customers with known demands (Giosa, Tansini, & Viera, 2002). The VRP is so widely studied because of its applicability and its importance in determining efficient strategies for reducing operational costs in distribution networks. Today, exact VRP methods have a size limit of 50 - 100 orders depending on the VRP variant and the time-response requirements. Consequently, current research concentrates on approximate algorithms that are capable of finding high quality solutions in limited time, in order to be applicable to real life problem instances that are characterized by large vehicle fleets and affect significantly logistics and distribution strategies (Kumar & Panneerselvam, 2012).

The pioneers of the VRP were Dantzig and Ramser. Their paper was concerned with the optimum routing of a fleet of gasoline delivery trucks between a bulk terminal and a large number of service stations supplied by the terminal. The shortest routes between any two points in the system were given and a demand for one or several products was specified for a number of stations within the distribution system. It was intended to find a way to assign stations to trucks in such a manner that station demands were satisfied and total mileage covered by the fleet was a minimum. A procedure based on a linear programming formulation was given for obtaining a near optimal solution (Dantzig & Ramser, 1959).

A few years later, Clark and Wright (Clarke & Wright, 1964) improved the Dantzig/Ramser approach by proposing a heuristic. Following these two papers, many researchers studied algorithms and models for different versions of the VRP.

Researchers are interested in studying the VRP for two reasons: its practical relevance and its difficulty. Lenstra and Rinnooy Kan (Lenstra & Rinnooy Kan, 1981) have analyzed the complexity of the VRP and concluded that practically all of the VRP problems are nondeterministic polynomial-time hard (NP-hard). VRP has many applications in real-world cases. Some applications are solidwaste collection, street cleaning, school bus routing, routing of salespeople and maintenance units, transportation of handicapped people, and so forth. The VRP can also be defined as the problem of designing least cost delivery routes from a depot to a set of geographically dispersed locations (customers) subject to a set of constraints (Daneshzand, 2011).

An important characteristic of VRP is the homogeneity of the fleet of vehicles (Baldacci, Battarra, & Vigo, 2008). In this paper, we observe the heterogeneous fleet of vehicles. Also, the number of depots makes great difference in modelling and solving VRP (Crevier, Cordeau, & Laporte, 2007). Our problem involves the multi-depot from which the demand could be met.

Fundamental components of the VRP are road network, customers, depots, vehicles, and drivers. To make different versions of VRP, different constraints and situations can be imposed on each component, and each of them can be supposed to achieve particular objectives (Toth & Vigo, 2002). Basic variants are capacitated VRP (CVRP), distance-constrained and capacitated VRP (DCVRP), VRP with time window (VRPTW), VRP with backhauls (VRPB), VRP with pickup and delivery (VRPPD), and any combination of these variants.

This paper is related to the problem of optimal vehicle routing of an oil company in the Republic of Serbia. In the oil industry, the delivery of petroleum products can be divided in two parts (Sear, 1993): the transport of the first type, which is done through pipelines or railway, that includes transportation from refineries to storage depots; and the transport of the second type that includes transportation from storage depots to gas stations, and is done mostly by tanks. The subject of this paper is the other type of transport that includes a network of gas stations, which are being supplied via tanks from several storage depots.

This paper consists of five parts. After the introductory part, in the section two, the characteristics of the observed routing problem in the oil industry will be described. In the third section, we present the original MIP mathematical model that includes the basic characteristics of the routing problem in the observed company, and in the fourth, the results of the experiments are presented. Concluding remarks and directions for further work are given in the section five.

2. PROBLEM DESCRIPTION

The observed oil company supplies a network of over 300 gas stations from multi-depots. Each of these stations has a specific demand for petroleum products, and the delivery is done once their level falls under a certain limit. In the depots, tanks are assigned to transport the designated derivative, and the speed of supplying the gas station with the missing quantity depends on the demand for it, the distance between the station and the storage depot, as well as on the driving speed of the assigned tank.

Vehicle routing problem in the oil industry has certain particularities. The demand for derivatives fluctuates depending on the season, so the companies have a number of vehicles at their disposal during longer periods, and during seasonal peaks they outsource the missing vehicles. At the same time, oil companies use their vehicles for third party deliveries in return for a certain compensation, and this further complicates the formulation of the problem. It is necessary to take into account the existence of a window of time during which it is possible or, however, prohibited to deliver petroleum products.

Considering the nature of the goods being transported, it is impossible to transport together two different types of products due to their physicochemical characteristics. Based on this fact, the types of vehicles in the oil companies have been classified. It is also important to mention a series of regulations related to the transportation of hazardous matters and their manipulation, which are specific compared to the traditional problems. Once we take into consideration numerous existing limitations and assumptions, this problem presents a challenge for every oil company primarily due to data collection problems, the creation of the model and its dimension, and finally because of the difficulties with the implementation of the solution and maintenance over time.

In this paper, only some of the characteristics of the routing problem in the observed company will be considered. Given that the capacity of the vehicles varies, multi-depot CVRP will be used in the paper, whereas the maximum capacity for each tank will be defined. It should be noted that the tanks are never completely filled which will also be taken into account when defining the maximum capacity of the vehicle. Only the most common derivatives at the gas stations will be considered, such as petrol and diesel, as well as the vehicles intended for their transport. The basic assumption was that the demand at a gas station is met entirely by only one vehicle, but later this assumption was extended by the possibility of supplying one gas station from multi-depots. Two depots were considered, as well as their respective gas stations, while some routes, which implicated that the demand of one gas station could be met by only one or both depots, were also predefined.

Therefore, the observed problem has the following characteristics:

- More storage depots; each of them owns a certain number of vehicles of different capacity at disposal;
- Large number of gas stations; some of them may be supplied from only one, while others may be supplied from a variety of storage depots;
- Limited maximum length of the route that complies with legal regulation and consists of time spent driving between storage depots and gas stations and the retention time at the gas station;
- Maximum and minimum capacities of the vehicle. Due to technical limitations, the gases that are produced during transport, etc., the vehicle cannot be filled to the brim but there is a minimum level of the tank that must be filled for the safety of the journey;

Thus, the routing problem observed in this paper is a multi-depot capacitated VRP with heterogeneous fleet of vehicles. For the problem described, an original MIP mathematical model has been formulated. For given

demands of gas stations, this model provides a set of routes and vehicles used for the routes in order to meet this demand with minimum total mileage.

3. MODEL FORMULATION

An approximate approach was chosen in the modelling of the observed problem, meaning that the routing problem was formulated as a set covering problem. It is more common in the literature that the routing problem is modelled as a set partitioning problem (Kumar & Panneerselvam, 2012). Nevertheless, in this paper, by introducing an additional variable, it was achieved that one gas station could belong to several optimal routes, and that the retention time at the station counts only for the route on which the vehicle supplies the gas station. Thus, the observed problem becomes a set covering problem. One of the advantages of the approach used in this paper is that fewer routes need to be predefined than in the set partitioning approach. More precisely, when one feasible route is defined in the set partitioning approach, it is also necessary to define its sub-routes in order to insure obtaining feasible solutions. In the set covering approach it is not necessary to define sub-routes. Another advantage is that this way it is possible to gain solutions by which one gas station can be supplied by several vehicles.

Once the vehicle routing problem is formulated as a set covering problem, we start from the predefined routes that could be used for supplying gas stations with petroleum. Among the predefined routes, those which cover all gas stations with demand and which have minimal total length (mileage) are chosen. The basic characteristic of this approach is that the quality of the obtained solution depends on the number and the quality of predefined routes. However, this approach allows faster solving, namely, less computational time needed for obtaining a solution.

The following notation was used to formulate a mathematical model:

Sets:

V - set of available vehicles in all depots
R - set of predefined routes that include all depots
B - set of gas stations

Parameters:

s_j - length of the *j-th* route in kilometers, $j \in R$,

p_k - the demand of the *k-th* gas station, $k \in B$,

$d_k = \begin{cases} 1 & \text{if } p_k > 0 \\ 0 & \text{if } p_k = 0 \end{cases}$ – parameter that defines whether there is a demand on the *k*-th gas station, $k \in B$

$a_{kj} = \begin{cases} 1 & \text{if the } k\text{-th gas station is on the } j\text{-th route} \\ 0 & \text{otherwise} \end{cases}$, $k \in B,\ j \in R$,

$m_{ij} = \begin{cases} 1 & \text{if the } i\text{-th vehicle belongs to the depot from which it departs on the } j\text{-th route} \\ 0 & \text{otherwise} \end{cases}$, $i \in V,\ j \in R$,

t_j - traveling duration on the *j-th* route in minutes, $j \in R$

z - vehicle retention time at the gas station in minutes

tr - maximum allowed retention time of the vehicle on route in minutes

$q_i^{\min}$ - minimum capacity of the *i-th* vehicle, $i \in V$

$q_i^{\max}$ - maximum capacity of the *i-th* vehicle, $i \in V$

Variables:

$$x_{ij} = \begin{cases} 1 & \text{if the } i\text{ - th vehicle is moving on the } j\text{ - th route} \\ 0 & \text{otherwise} \end{cases}, \; i \in V, \; j \in R$$

$$y_{ik} = \begin{cases} 1 & \text{if the } i\text{ - th vehicle supplies the } k\text{ - th gas station} \\ 0 & \text{otherwise} \end{cases}, \; i \in V, \; k \in B$$

Using the introduced notation, the following mathematical model was formulated:

$$(\min) \sum_{i \in V} \sum_{j \in R} s_j \cdot x_{ij} \tag{1}$$

s.t.

$$\sum_{j \in R} x_{ij} \leq 1, \quad i \in V \tag{2}$$

$$\sum_{i \in V} y_{ik} = d_k, \quad k \in B \tag{3}$$

$$\sum_{k \in B} p_k \cdot y_{ik} - q_i^{\min} \cdot \sum_{j \in R} x_{ij} \geq 0, \quad i \in V \tag{4}$$

$$\sum_{k \in B} p_k \cdot y_{ik} \leq q_i^{\max}, \quad i \in V \tag{5}$$

$$\sum_{j \in R} a_{kj} \cdot x_{ij} \cdot m_{ij} - y_{ik} \geq 0, \quad i \in V, k \in B \tag{6}$$

$$\sum_{k \in B} a_{kj} \cdot m_{ij} \cdot y_{ik} \cdot z + t_j - M(1 - x_{ij}) \leq tr, \quad j \in R, i \in V \tag{7}$$

The objective function (1) minimizes the total mileage that all the vehicles used for supplying will cross. The first constraint (2) provides that one vehicle uses at most one route, and the constraint (3) provides that the demand at each gas station be fully met. The constraints (4) and (5) refer to the minimum and maximum vehicle capacity that must be reached and must not be exceeded. The variables x_{ij} and y_{ik} are connected by constraints (6) and (7). Constraint (6) refers to the following: if there is a demand on the *k-th* gas station and if it is met by the *i-th* vehicle (i.e., if $y_{ik} = 1$), then it applies that the *i-th* vehicle needs to go along the *j-th* route (i.e., that $x_{ij} = 1$). The constraint (7) ensures that the total amount of time the vehicle will spend along the route will not be longer than the maximum time allowed, where parameter M is a very large number.

It is important to mention here that the manner in which the variable y_{ik} has been defined, that is, as a binary variable, implies that one gas station could only be supplied by one vehicle. If it is allowed that one gas station is supplied by several vehicles, the mathematical model remains the same while the variable y_{ik} needs to be defined as a continuous variable as follows:

y_{ik} – percentage of the *k-th* gas station demand that is met by the *i-th* vehicle, $0 \leq y_{ik} \leq 1, \; i \in V, \; k \in B$.

4. NUMERICAL RESULTS

The implementation of the mathematical model will be illustrated with a real example of an oil company. The observed problem involves two of the five depots which the company has at its disposal (depot I and the depot II). Depot I has 9 vehicles of different capacity, and depot II has 17 vehicles, also of different capacity. A total of 172 routes to 100 gas stations were predefined, out of which 99 routes start from depot I, and 73 routes from depot II. It is possible to transport fuel to 66 gas stations from depot I, and to 45 from depot II. In addition, it is possible to supply 11 gas stations from both depots.

In accordance with legal regulations, the maximum amount of time which a vehicle can spend on the route is limited to 9 hours. As it was already mentioned, this amount of time consists of the time spent on the road and the retention time. Based on the consultations with company's employees, it has been concluded that the average retention time at the gas station is 45 minutes: 30 minutes for fuel dispensing, and 15 minutes for filling in the documentation.

The other parameters of the problem, such as the names of gas stations, their demand and tank capacities, have not been revealed due to data confidentiality.

The following three scenarios have been analyzed:

Scenario 1: Each gas station must be fully supplied from one tank. The minimum tank capacity is limited to 25%.

Scenario 2: Gas stations must also be supplied from one tank. The minimum tank capacity is limited to 30%, which corresponds better with the real situation in the company.

Scenario 3: It is allowed that the gas station be supplied from multiple tanks, or more precisely, multiple routes. This is achieved once the variable y_{ik} becomes continuous. The minimum tank capacity is limited to 30%.

In all three scenarios there is a demand on 51 of 100 gas stations. The effective capacity was taken as the upper limit of the tank capacity, that is, the percentage of the tank capacity that must remain empty was subtracted from the total capacity.

Table 1 shows the results of all three scenarios. For each scenario the mathematical model has been implemented and solved using GNU Linear Programming Kit (GLPK), a software for solving MIP problems.

Table 1: Results of the optimization

Performances	Scenario 1	Scenario 2	Scenario 3
Total mileage (km)	3239.8	3242.2	3242.2
Number of routes from depot I	9	9	9
Number of routes from depot II	10	10	10
Capacity usage	25-98%	30-100%	30-100%
Total time on the routes	5542	5546	5636

The first row of the table 1 shows total mileage that all vehicles which participate in the supply of gas stations cross. The second and third rows refer to the number of routes, that is, the number of vehicles, from depot I and depot II. In the fourth row the range of capacity utilization of used tanks has been shown. The last row refers to the total time (in minutes) that all vehicles which participate in the supply spend on the routes (on the road and at gas stations).

Based on the total mileage, the number of vehicles (routes) and time spent on routes, scenario 1 is the most profitable one for the observed company. However, this solution can only be applied if the lower limit of the capacity utilization which is 25% is acceptable.

Optimal routes from scenario 2 differ from optimal routes in scenario 1, but the total number of routes is equal and the optimal value of the objective function is slightly inferior: the total mileage is only 2.4 kilometers longer. Total amount of time that vehicles spend on routes is only 4 minutes longer. Based on the obtained results, we can conclude that the company should not risk the loss by allowing that the vehicles be filled less than the safe limit of 30% tank capacity.

The optimal objective function value and the route in Scenario 3 are the same as in Scenario 2. However, by Scenario 3, two gas stations will be supplied by two vehicles. 44.5% of a gas station demand will be met by one vehicle that departs from the depot I and 55.5% by the second vehicle that also departs from depot I. In the case of another gas station, 25.6% of the demand will be met by one and 74.4% of demand by the other vehicle. In this case, both vehicles also depart from the depot I. The consequence of such satisfaction of the demand is that the total retention time on routes prolongs for 90 minutes because it includes two stops at the two gas stations. In further research, the retention time will be seen as a variable value that depends on the amount of fuel to be dispensed at the gas station.

For given input data, Scenario 3 proved to be the most inadequate supplying type. Nevertheless, in the general case, allowing one gas station to be supplied by several vehicles could provide a solution with fewer routes than when this is not enabled. Fewer routes mean hiring a reduced number of vehicles and drivers, hence the lower supply costs.

5. CONCLUSION

The subject of this paper was the vehicle routing problem in the oil industry. In addition to the theoretical focus, this paper provides an overview of current issue in real oil company and the characteristics of vehicle routing problem in the Petroleum Industry of Serbia. On that basis, and in accordance with the information, an original MIP mathematical model was created. Vehicle routing problem was observed as a set covering problem.

The aim of this paper was to present a solution for one part of the complex vehicle routing problem in the real oil company, which would set the basis for the introduction of scientific methods that would allow solving this problem in the company. And as a result of "what -if" analysis, guidelines should be derived that will indirectly lead to cost reductions in the chain of gas stations supply with petroleum products.

Abstract: *Higher education presents main engine of society's overall progress and development. The producers of the knowledge and future progressive force in all sectors of today's living are personified in the Universities. As generators of academic individuals, it is important to achieve high level of educated and qualified students/future employees that will be able to fit in the real sector and contribute to the collective/personal live. To accomplish that, resources investments are necessary to be made by the Universities. The question is how to organize the resources in order of efficient production of high qualified future academic individuals. Moreover, in cases of inefficiency detection, the question is what is necessary to be done for improvement. This paper shows concrete linear programming technique application called DEA (Data Envelopment Analysis), used for measuring the efficiency of the University study program, who through its real implementation represents a basic generator of knowledge.*
Keywords*: Linear Programming, Data Envelopment Analysis, Decision Making Units, Production levels, Composite units*

1. INTRODUCTION

One of the main issues that companies' and institutions' management deals with is permanent optimization and improvement of its main process or production. Given the fact that solving of one problem in many cases can be done in more ways, it is important to find and implement the optimal between them. According to the literature that deals with the system optimization in terms of overall efficiency improvement, especially complex for analysis are service oriented institutions/organizations. Considering the fact that Universities in its basis aim to offer a service called quality education to the consumers personified in students, they can be analyzed precisely in this constellation.

Mathematical programming is special mathematical approach of selecting the best/optimal from the set of possible alternatives towards solving the problem. It assumes that it is possible to represent the problem as a mathematical model that reflects certain production function (more precisely, mathematical function). In this direction, resolution of the problem of optimization converges to determination of the optimal (minimum or maximum, depending on the nature of the model) value of the production function, having in mind all the limitations of the model/environment, represented in the limitation equations. In general, mathematical optimization implies that the production function and the accompanying limitation equations can be linear or nonlinear equations and/or inequalities. If the production function and all limitation equalities are represented in linear form, the mathematical optimization takes form of linear programming modelling and solvation. Nevertheless, some mathematical models have high complexity level and cannot be solved through known mathematical optimization models. Then, not optimal, but "good enough" solution is the subject, using orientation and heuristic models [1].

In context of the previously stated, the starting point for this work is how to build a model that portrays the knowledge and skills delivery very real, taking into account the fact that Universities are the knowledge and skills generators, in order to detect its pros and cons and certain, to propose concrete ways of improvement of this process. For this purpose, DEA (Data Envelopment Analysis) technique is used, starting from the fact that it's nature of application offers very good possibility of model definition approach, as well as its mathematical processing and further discussion. Actually, this technique developed a new approach to the traditional cost / profit analysis and methods for efficiency measurement that enables policy-making through "learning from the best" and inducing theory from practice [2].

1.1. DEA (Data Envelopment Analysis)

There are several phases in LP appliance that have to be conducted:

- Definition of the problem and its mathematical formulation;

- Construction of the mathematical model;
- Finding the optimal solution of the model;
- Analysis of the results and sensitivity of the model, and
- Evaluation of the model and its implementation.

DEA as frontier analysis is designed for organization quality measurement and performance improvement, as main intention of the management. It is nonparametric non-statistical multi-criteria method that allows handling heterogeneous data. Based on LP, it operates with the term technological efficiency, defined as [3]:

$$\theta = \frac{Output}{Input} \tag{1}$$

where input is presented as sum of the resources invested and output is presented as sum of the outcomes of the entity which efficiency is measured. The efficiency is noted as pareto efficiency if allocation of the resources (input and output) is such that better performances are not possible for the entity analyzed. Pareto efficient subject is the subject (entity) with best possible allocation of the resources. Here, it is impossible to improve the output without worsening the input.

DEA declares as effective those entities that produce a certain or more output parameters with fixed inputs or use the same or a smaller quantity of inputs to produce a certain output, compared with the other subjects within the same group being analyzed. The set that is subject of measurement is consisted of entities called DMUs (Decision Making Units) and they have to be homogenous. All DMUs have same inputs and outputs in different quantities. DMU can be institution, bank, human, production line, vehicle, part of vehicle etc. In this work, the subject/course of a concrete University's study program is qualified as DMU.

The mathematical model of DEA, starting from the definition of the efficiency of the k-DMU, in set of n DMUs with m inputs and s outputs given by [4]:

$$\theta_k = \frac{u_1 y_{1k} + u_2 y_{2k} + \cdots + u_s y_{sk}}{v_1 x_{1k} + v_2 x_{2k} + \cdots + v_m x_{mk}} \tag{2}$$

Is defined as:

- Goal:

$$max\left(\theta_k = \frac{u_1 y_{1k} + u_2 y_{2k} + \cdots + u_s y_{sk}}{v_1 x_{1k} + v_2 x_{2k} + \cdots + v_m x_{mk}}\right) \tag{3}$$

- Given:

$$\frac{u_1 y_{11} + u_2 y_{21} + \cdots + u_s y_{s1}}{v_1 x_{11} + v_2 x_{21} + \cdots + v_m x_{m1}} = \frac{\sum_{i=1}^{s} u_i y_{i1}}{\sum_{j=1}^{m} v_j x_{j1}} \leq 1$$

$$\cdots$$

$$\frac{u_1 y_{1k} + u_2 y_{2k} + \cdots + u_s y_{sk}}{v_1 x_{1k} + v_2 x_{2k} + \cdots + v_m x_{mk}} = \frac{\sum_{i=1}^{s} u_i y_{ik}}{\sum_{j=1}^{m} v_j x_{jk}} \leq 1$$

$$\cdots$$

$$\frac{u_1 y_{1n} + u_2 y_{2n} + \cdots + u_s y_{sn}}{v_1 x_{1n} + v_2 x_{2n} + \cdots + v_m x_{mn}} = \frac{\sum_{i=1}^{s} u_i y_{in}}{\sum_{j=1}^{m} v_j x_{jn}} \leq 1 \tag{4}$$

$$v_1, \ldots, v_m \geq 0, u_1, \ldots, u_s \geq 0; \tag{5}$$

$$x_{jk} \geq 0, y_{ij} \geq 0; j = 1, \ldots, m; i = 1, \ldots, s; k = 1, \ldots, n \tag{6}$$

where x_{jk} is j-th input in k-th DMU, y_{ik} is i-th output of the k-th DMU, $v_1, \ldots, v_m$ are weights of the m inputs and $u_1, \ldots, u_s$ are weights of the s outputs, both of the k-th DMU. DEA sets weights in such way – best way, to maximize the efficiency of every single DMU. So, the frontier is consisted of efficient DMUs with efficiency equals to 1. Every other DMU with efficiency below 1 is considered to be inefficient. Often, as in this paper, the dual DEA CCR model is used. It is represented with following equations:

- Find $min\theta$;
- Having limitations:

$$\sum_{j=1}^{n} \lambda_j x_{ij} \leq \theta x_{i0}, \qquad i = 1, \ldots, m \tag{7}$$

$$\sum_{j=1}^{n} \lambda_j y_{rj} \geq y_{r0}, \qquad r = 1, \ldots, s \tag{8}$$

$$\lambda_j \geq 0, \qquad j = 1, \ldots, n \tag{9}$$

where index 0 represents each DMU that equations are solved for (in order to maximize its efficiency – observed DMU), lambdas are weighted coefficients that are used to represent the so-called composite DMU for each real DMU that will be located as inefficient. The composite DMU for each inefficient real DMU is consisted as sum of the ERS (efficiency reference set – efficient DMUs used for interpretation of the

composite DMU for the observed real DMU) multiplied with its lambda coefficients. If A and B are efficient DMUs (m inputs, s outputs) and define the ERS set of observed inefficient C DMU, the composite DMU of C → C' can be interpreted as:

$$\lambda_A \begin{bmatrix} y_{1A} \\ \dots \\ y_{sA} \\ x_{1A} \\ \dots \\ x_{mA} \end{bmatrix} + \lambda_B \begin{bmatrix} y_{1B} \\ \dots \\ y_{sB} \\ x_{1B} \\ \dots \\ x_{mB} \end{bmatrix} = \begin{bmatrix} y_{Composite} \\ \dots \\ y_{Composite} \\ x_{Composite} \\ \dots \\ x_{Composite} \end{bmatrix} = C' \quad (10)$$

2. MATHEMATICAL MODEL

The model built is based on the fact that the delivery of knowledge, skills and competencies of students is conducted through practical implementation of curricula or course components during the study. DEA is particularly applied to service-oriented institutions and requires existence of a basic entity whose efficiency will be measured, with defined constellation of input resources invested and output outcome. Universities can be understood as subjects that deal with knowledge, skills and abilities delivery (basic function). Bearing this in mind, a mathematical model is conducted based on the need of measuring the efficiency level of the financial and other structural resources allocation by the University, with consideration of the achieved results in the process of knowledge, skills and abilities delivery to the students through the courses within a specific academic program. The resources are invested for each course and each course produces knowledge, skills and abilities.

So, course / subject is the entity whose efficiency is measured, i.e. course as decision making unit (DMU):

- All inputs to the DMU are constellated so that their increase can reduce the efficiency of each study course individually. In this manner, all output are considered to represent the outcome of the study program or each course practical implementation so that their increase will influence the increase of the efficiency of each study program individually.
- Inputs of a single DMU are represented with:
  - Expenses and financial structure within each subject consumed on behalf of gross salaries for professors and assistants that were engaged in the study program processing during years. Expenses are calculated in terms of gross salaries / expenses, with consideration of three months length (12 working weeks) of the semester (period of knowledge delivery) and the percentage of load in terms of number of students of the observed course and all students that the concrete person (teacher or assistant) covered during those three months. All increases and salary / expenses fluctuations are considered also. This data is gathered using the finance and human resources modules in ERP platform of the Goce Delcev University in Stip;
  - Expenses and financial structure within each subject consumed on behalf of the equipment and inventory used for the concrete study program. This is done by calculation of the degree of utilization, i.e. the ratio of annual depreciation of computer equipment and inventory used, in accordance with their gross purchase price and the legislation. Percentage of load / utilization in terms of number of students of the observed course and all students that used the same equipment and inventory is considered, and
  - Number of classes held, having in mind that classes load, forming study groups, classes and schedule organization is very important part in the process of overall course organization;
- Outputs of a single DMU are represented with:
  - Index of the level of contribution of each course in skills, competencies and knowledge delivery, prescribed with the accreditation elaborate of the study program (IP-KKV). Massive survey was realized at representative sample of 28 (of total of 88 students graduated at the study program), that generated indexes' values, and
  - Index of the quality of skills, competencies and knowledge delivered (IPKS-KKV) through the study program. This parameter, represented by the average grade of each course is calculated using the reporting module of the student information system of Goce Delcev University, fully automated for students' e-administration.

The model is shown in figure 1:

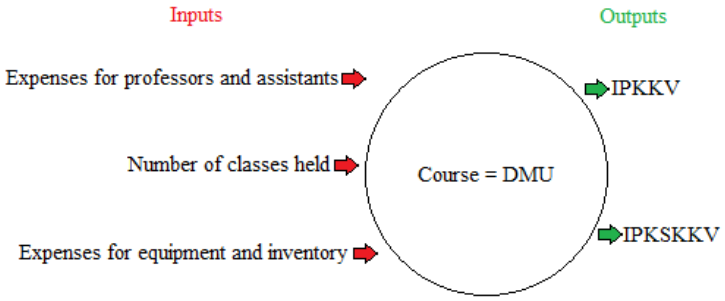

Figure 1. DEA Model: Course as DMU / Input = resources invested / Output = knowledge produced

3. CALCULATION, RESULTS AND DISCUSSION

Considering the above elaborated model and approach, table 1 shows the numerical side of it:

Table 1: Input / Output data

Number of classes held	Expenses for equipment and inventory	Expenses for professors and assistants	DMUs / Courses	IPKKV	IKPSKKV

The model has been applied on 24 subjects of the study program of Informatics at the Faculty of Computer Sciences, generation of students 2007/2008. The numerical model is processed in Open Source DEA software application (http://www.opensourcedea.org/index.php?title=Open_Source_DEA). The results of the subjects' efficiency measurement are given in table 2:

Table 2: Courses efficiency

DMU / Subject	Efficiency	DMU / Subject	Efficiency
English language 1	1	Data bases	0,856
English language 2	1 **(ERS=6)**	Digital logic	0,82
Probability and statistics	1 **(ERS=12)**	Multimedia	0,684

Internet programming	0,942	Software processes	0,487
Microprocessors	0,893	Computer architecture	0,375

Courses with efficiency = 1 are noted as relativly efficient courses and are set of representative courses for the courses with efficiency bellow 1, noted as inefficient courses. Most efficient courses are used in most of the cases of composite courses. In general, composite unit (in this case, the course) is the unit that DEA propose for each inefficient unit towards its optimization. Each inefficient unit has its own composite unit, as its example of best input / output allocation. The composite units are generated as the sum of the detected and specific (diferent for each inefficient DMU) ERS units and lambda corresponding coefficients, known as production levels. Courses that are bold in table 2 are noted as entities consisting Efficiency Reference Set – ERS, used in creating composite courses. ERS = X notes the number of times this course is used in creation of composite units for the inefficient detected courses. This defines **Graphics and visualization** and **Probability and statistics** as best efficient subjects, and **Software processes** and **Computer architecture** as subjects with worst resource invested and outcome results constellation.
Table 3 defines all inefficient courses in terms of definition of their composite DMUs (that are "on the frontier" and are what they "should be like").

Table 3. Production levels of inefficient DMUs

COMPOSITES	EFFICIENCY REFERENCE SET

Visual programming	0	0,189735113	0	0,598011357	0,296446308

Having this in mind, in order of inefficient DMUs to become efficient, they have to become as their efficient or composite DMUs. For example, most inefficient subject is **Computer architecture**. The composite course can be calculated as:

$$CA_{composite}\begin{bmatrix} ExpensesTeachers \\ ExpensesEquInv \\ NumberOfClasses \\ IPKKV \\ IKPSKKV \end{bmatrix} = 0.5322106 * EJ2\begin{bmatrix} 79832,87 \\ 25154,8 \\ 24 \\ 3,571428572 \\ 8,8160 \end{bmatrix} + 0,33862454 * GV\begin{bmatrix} 65273,13 \\ 128867,7 \\ 48 \\ 4,160714286 \\ 8,1704 \end{bmatrix} + 0,096534391 *$$

$$SPM\begin{bmatrix} 57935,99 \\ 7536,731 \\ 72 \\ 3,821428571 \\ 7,0113 \end{bmatrix} = \begin{bmatrix} 70183,79877 \\ 57752,97057 \\ 35,977508 \\ 3,678571429 \\ 7,1477 \end{bmatrix}$$

$$CA_{real}\begin{bmatrix} 187273,8 \\ 154104,2 \\ 96 \\ 3,678571429 \\ 7,1477 \end{bmatrix} : CA_{composite}\begin{bmatrix} 70183,79877 \\ 57752,97057 \\ 35,977508 \\ 3,678571429 \\ 7,1477 \end{bmatrix} = Deviation\begin{bmatrix} +166,83\% \\ +166,83\% \\ +166,83\% \\ +0\% \\ +0\% \end{bmatrix}$$

Discussion: The cost in terms of the teaching staff in terms of inventory and depreciation of computer equipment are 166.83 % higher than the potentially optimal constellation of parameters. This directly alludes to the fact that equally good results in the output, ie the same level of knowledge of the skills and competencies of the students with the same quality can be achieved mainly by reducing the cost of entry, and that means that the cost for teaching / associate staff and equipment costs . In addition, possible optimization may be required and reducing the number of classes that are realized in practice.

4. CONCLUSION

The purpose of this work is to review the system of delivery of knowledge, skills and abilities in a specific study program through the elaboration of the results achieved, as a result of the resources invested. The specific skills, knowledge and abilities are strictly defined in the official acts for study program accreditation. For its real processing, the University has to make efficient resource allocation (material and non-material), in order to deliver skills, knowledge and abilities at the expected level. Having this in mind, input oriented DEA model is used because it is assumed that the result (level of skills, knowledge and abilities, conducted through complex survey) is invariant and ask what can be done in order to decrease the resources investment for efficiency improvement.

The detection of inefficient courses in terms of inadequate allocation of input resources and / or achieved poor results proposes specific measures to optimize inefficient courses:

- Reduce the cost of engagement and collaboration of the teaching staff
    - Increasing the workload of the teacher
    - Reduction of gross salary

    - Option for freelance engagement of staff with less financial burden
- Reduce the cost of equipment and inventory
    - Purchase of equipment and inventory at a lower purchase price
    - Increasing utilization of the unit (in terms of number of students)
    - Increasing the rate of depreciation
- Reducing the number of realized lectures and tutorials
    - Reduction and convergence of matter in fewer lectures
    - Pipe classes for lectures and tutorials
    - Reducing the number of students' groups
    - Intervention within the study programs / change relevant parameters

For more accurate investigation, it is possible to do an extension of the model by increasing the parameters that are not taken into account in this case, according to the perception of the management of the University. DEA allows that in order of geenration even more appropriate and realistic model.

***Abstract**: Multi-Criteria Decision Making (MCDM) is one of the most prominent branches in decision-making process. It is applied in all those situations where there is a range of often conflicting criteria based on which an optimal decision is to be taken. It is the existence of a number of criteria that is a significant step towards the reality of problems that can be solved by applying MCDM methods. This paper presents a methodology of applying the AHP (Analytic Hierarchy Process) method in selecting the most competitive bank in the Montenegrin market. By reducing a complex decision making problem to comparing pairs of options and through a synthesis of obtained results, the AHP method enables reaching the most favorable decision.*

***Key words**: decision making, multi-criteria decision making, banks, AHP method*

1. INTRODUCTION

A transition process in Montenegro has instigated a reform of the financial sector. The reform has been aimed at providing security and stability of the financial system and boosting efficiency and profitability of the banking system. Reforms have yielded good results. New legislation has been passed, ownership transformation has been implemented, a new concept of bank management has been adopted and a supply of banking products has been increased.

Banks occupy a central position in a country's financial system, due to both the function they perform and the financial potential at their disposal. Contemporary banks are multiservice financial institutions which, in addition to their primary functions, offer a wide range of financial products and services to their customers. The nature of their business is such that banks are market-oriented enterprises operating on principles of liquidity, safety and profitability, aimed at maximizing profit.

The main institution in charge of supervision and oversight of the financial services sector in Montenegro is the Central Bank of Montenegro, founded in March 2001. As an independent institution, the Central Bank is responsible for monetary policy, establishing and maintaining a sound banking system and an efficient payment system. In 2010, a new Law on the Central Bank of Montenegro was passed, based on the new Constitution of Montenegro. Pursuant to that law, the Central Bank has assumed responsibility for providing stability of the financial system, including the promotion and maintenance of a sound banking system and a safe and efficient payment system.

2. BANKING SYSTEM IN MONTENEGRO

Since 2007, the banking sector of Montenegro has comprised 11 commercial banks and six micro-financing institutions that have a license issued by the Central Bank. Within the Central Bank, there is a special department for the control of banks. This department reports on financial indicators of each bank and ensures that each bank maintains a minimum share of capital equity in relation to total assets, as stipulated by law. As part of measures aimed to strengthen the financial system, special attention has been devoted to enhancement and maintenance of banking system stability. In order to achieve that, the Central Bank continuously monitors and analyzes, and if necessary, undertakes corrective measures to strengthen corporate governance and risk management and to ensure further implementation of internationally accepted standards and business principles (BTI 2014, Montenegro country report).

Since the beginning of transition, the banking sector has gone through a substantial change. As the privatization of state-owned banks was one of the main items of banking sector recovery, primarily through foreign capital inflow, a share of foreign capital has increased significantly. The crisis, which hit the world in 2008, affected Montenegro mostly as a lack of trust. Fearful that problems from the 1990s may reemerge, a certain number of people began to withdraw their deposits from the banking system. However, as the crisis spread to the real sector, an increasing number of companies became insolvent and they slowly started to

close and fall into bankruptcy. Since the second half of 2009, the situation has started to improve. Deposits have started to grow which is a sign of recovery and stability of a banking system. Profitability of the banking sector has made significant progress over the last decade. This is primarily due to a comprehensive reform of the banking sector, write-off of bad loans, privatization of state-owned banks, separation of commercial banks from the Central Bank, liberalization of interest rates, introduction of modern banking technology, expansion of loans etc., and opening banking sector to private and foreign units as well. Generally speaking, Montenegrin banking system has experienced a growing trend in profitability .

Stability of the banking system is, among other things, reflected in parameters of liquidity and solvency of banks, and at the end of 2013, these parameters were above the stipulated level. Growth of 4.9%, as compared to the end of the previous year, in total loans and other receivables in the first six months of 2013, is not only the result of an increase in newly approved loans but is also partly fostered by changes in regulations and implementation of IAS as well, and in view of this banks returned a part of written-off loans and other receivables from off-balance sheet items. However, in spite of the efforts banks have undertaken to reduce the level of non-performing loans[1] in the post-crisis period, continuity in growth of these loans has remained the biggest vulnerability of the banking sector and a potential source of risk to financial stability. Despite a moderate success attained by moving non-performing loans to parent banks' balance sheets or by selling and/or restructuring loans, their upward trend has continued. At the end of July this year, non-performing loans and other receivables accounted for 17.8% of total loans and other receivables. A key challenge in 2014, just like in previous years, will be a reduction in volume of non-performing loans. A so called "Podgorički model" for voluntary restructuring of non-performing loans has been developed, and this model has received a full support of the Central Bank, the Ministry of Finance and the World Bank. It is a very complex project whose implementation requires passing *lex specialis* for its enforcement in practice. The project is aimed at improving the performance of solvent legal entities – companies and entrepreneurs – that are dealing with temporary liquidity problems, and by doing that – at providing banks performance boost, since banks are a pillar of stability and support of banking system recovery. The project will, in the long term, prompt positive impulses for triggering economic activities and consolidating real economy.

Also encouraging is the fact that banks deposits grow, which leads to improved credit-to deposit-ratio. At the end of June 2013 the increase in deposits was 1.5%. Lending rates, both in 2012 and during 2013 were extremely high due to the high country risk premium, and thus more expensive fund sources, the upward trends of non-performing assets, risk rating and the general business climate. Due to limited access to resources, banks turned to domestic sources, secured by offering higher deposit rates, which resulted in higher interest margins.

Figure 1 (Source: Financial statements of banks in 2013) shows the proportion of Montenegrin banks in the banking system of Montenegro measured by total assets. The Montenegrin Commercial Bank has the largest share and accounts for 20% (of total assets), followed by the NLB Bank with 17% and the Societe General Bank of Montenegro with 12%. Other banks account for less than 10%.

Figure 2 (Source: Financial statements of banks in 2013) shows the share of banks in the banking sector in relation to the amount of loans given in 2013. The CKB (the Montenegrin Commercial Bank) comes first by this criterion as well with the share of 25%, followed suit by the NLB with 19% while the Societe General Montenegro is in the third place with 16%.

Bank performance has traditionally been measured based on an analysis of financial indicators. The most common way of performing analysis is based on the criteria of liquidity, profitability, capital efficiency and adequacy, whereby different models of multi-criteria analysis can be used. This paper has employed the AHP (Saaty, 1993) model for the ranking of Montenegrin banks.

[1] In compliance with the amended regulation, which came into force on January 1st 2013, a share of non-performing loans and other receivables is calculculated as a percentage of non-performing gross loans and other receivables, without interest and time limits, in total loans and other receivables.

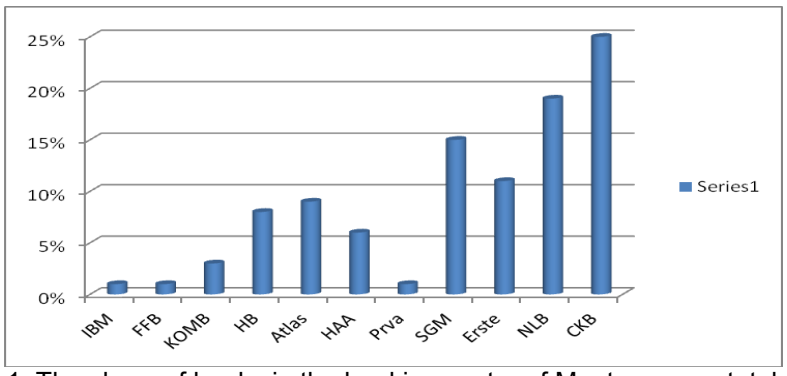

Figure 1. The share of banks in the banking sector of Montenegro – total assets

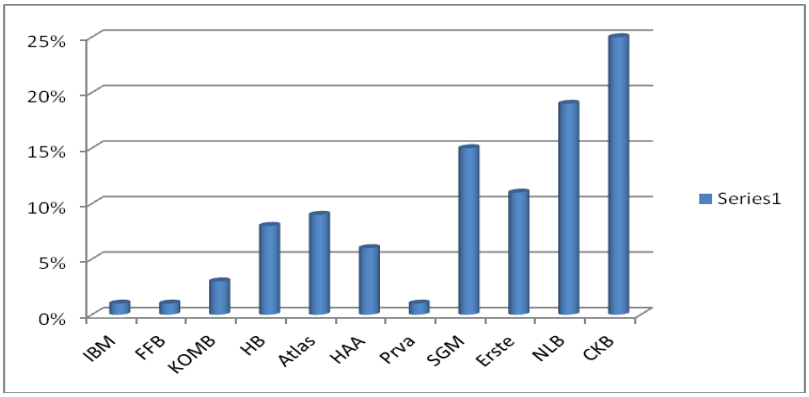

Figure 2.The share of banks in the banking sector of Montenegro – loans

3. AHP MODEL FOR BANK RANKING AND COMPARISON

In order to make an AHP model it is necessary to define the goal, criteria, sub-criteria and alternatives. The goal of this model is ranking of the banks in Montenegro from the best to the worst; the criteria have been divided into two groups – qualitative and quantitative. Quantitative criteria are financial ratios which display characteristics of certain bank performances. When choosing financial ratios in the model, the experience of many different experts in the field has been used (Yeh, 1996). Financial ratios are divided into four groups: liquidity, efficiency, profitability and capital adequacy. Within each group sub-criteria have also been defined. Liquidity sub-criteria are:

1) L1 = money + money equivalents + investments/total deposits;
2) L2 = total approved loans/total deposits;
3) L3 = Liquid assets/total assets

Efficiency sub-criteria are:

1) E1 = operational expenditures/operational income;
2) E2 = provision costs/net interest rate income;
3) E3 = operational income/total number of employees.

Profitability sub-criteria are:

1) P1 = Profit before tax/equity;
2) P2 = Profit before tax/total assets;
3) P3 = Profit before tax/operational income.

And for the last group – capital adequacy, the sub-criteria are:

1) C1 = total obligations/equity;
2) C2 = equity/total loans;
3) C3 = total deposits/equity.

Qualitative factors are owners' support, the importance of a bank in the financial system of Montenegro (significance), management and the bank maturity. These criteria could not be described by any of qualitative methods, so we use verbal descriptions. Alternatives are represented by 7 Montenegrin banks.

In order to use this model for bank ranking, we need to determine the weights of the main criteria and sub-criteria, and then for each criteria at the bottom level of the hierarchy structure to define the intensities for the evaluation of the relevant bank performances. The weights of criteria and sub-criteria are calculated by the

help of Super Decision software on the basis of the pairwise comparison of relative criteria and sub-criteria importance. For quantity criteria, the intensities are defined on the basis of the five-level scale of intensities (excellent, very good, good, satisfied, bad), which have been derived on the basis of the range in which their values have fluctuated.

As for the qualitative criteria, we have used the same evaluation as in CAMELS method, so the intensity scale for each category has been generated. For example, the scale for owners support is defined as: excellent, very good, good, satisfied and bad; the importance of the bank as: excellent, very good, good, satisfied and small; the management: excellent, very strong, strong, average, weak and, finally, the maturity of the bank is assessed as: more than 10 years, from 5 to 10 years, and less than 10 years. CAMELS method has 5 levels for each criteria, but due to the deficiency of precise and quality information, it has not been possible to recognize some subtler levels, as can be performed by the examiners for the bank monitoring who are entitled to have access to all the necessary information. Structure of the AHP model for bank ranking and comparison is presented in Figure 3.

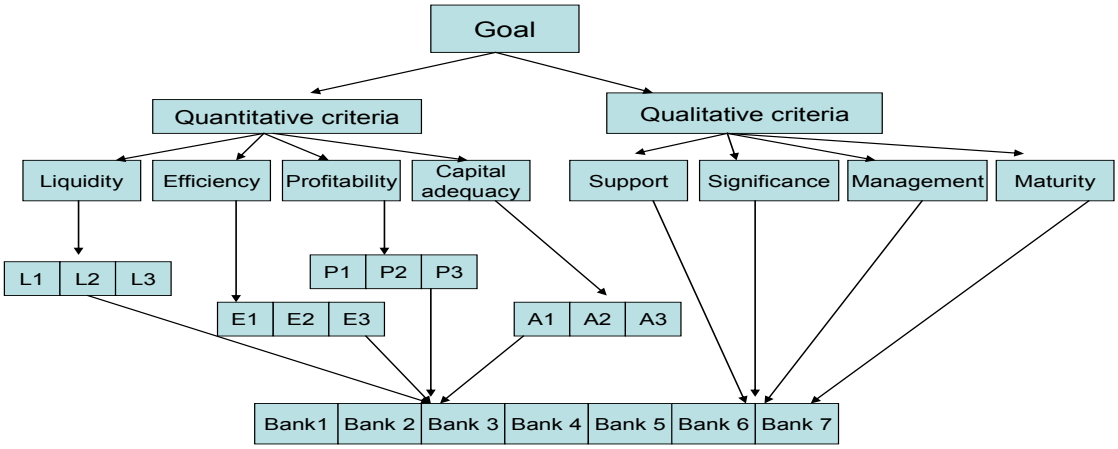

Figure 3. Structure of the AHP model for bank ranking and comparison

4. APPLICATION OF THE AHP METHOD FOR RANKING BANKS IN MONTENEGRO

The banking sector in Montenegro consists of 11 banks. For the purposes of this study, seven banks[2] with the largest market share have been analyzed. The data on the banks' financial indicators date from 2013 and have been obtained from the annual financial statements. The values of financial indicators are presented in Table 2 while the values of the intensity of the quantitative criteria are shown in Table 3. The weights of criteria and sub-criteria are calculated by the help of Super Decision software on the basis of the pairwise comparison of relative criteria and sub-criteria importance. For quantity criteria, the intensities are defined on the basis of the five-level scale of intensities (excellent, very good, good, satisfied, bad), which have been derived on the basis of the range in which their values have fluctuated (Table 3). For the qualitative criteria, we have used the same evaluation as in CAMELS method, so the intensity scale for each category has been generated.

Based on the data for the seven banks that were analyzed using the AHP model, a ranking list of banks has been obtained. A graphic illustration of the ranking list of banks is shown in Table 1 while Figure 4 shows the weights of certain quantitative and qualitative criteria.

Table 1. Graphical illustration of ranks

[2] Names of banks known to authors

Graphic	Ratings Alternatives	Total	Ideal	Normal	Ranking
	Banka1	0.6150	1.0000	0.1971	1
	Banka2	0.4148	0.6745	0.1329	4
	Banka3	0.5544	0.9015	0.1777	2
	Banka4	0.5317	0.8645	0.1704	3
	Banka5	0.3312	0.5386	0.1062	6
	Banka6	0.3259	0.5299	0.1045	7
	Banka7	0.3471	0.5643	0.1112	5

Figure 4. Weights for quantitative and qualitative criteria

Liquidity		0.41667
Efficiency		0.25000
Profitability		0.12500
Capital adequacy		0.20833
Owners' support		0.1601
Importance		0.2008
Management		0.0160
Maturity		0.1000

From Table 1 it can be seen which rank is taken by each selected bank all the given criteria taken into account. In fact, in the overall ranking the best bank in Montenegro is Bank 1, Bank 3 is the runner-up, followed by Bank 4 and Bank 7. The last and the second last place are taken by Bank 5 and Bank 6, respectively.

Bank ranks according to individual criteria (liquidity, efficiency, profitability, capital adequacy and qualitative criteria) have been calculated in a similar manner if the purpose of the analysis is to find the best bank in terms of a single criterion. The banks can be ranked separately on quantitative and qualitative criteria.

When taking into account only quantitative criteria, the analysis can be carried out separately according to individual quantitative criteria, such as the liquidity criterion (Table 4), the efficiency criterion (Table 5), the profitability criterion (Table 6) and the capital adequacy criterion (Table 7).These tables show that Bank 1, which is ranked best in the overall rating, according to these criteria usually occupies the sixth position (according to the criteria of liquidity and efficiency), i.e., the fourth according to the criterion of profitability and the second according to the criterion of capital adequacy. When you look at the table that shows the ranking of the banks according to qualitative criteria (Table 8), we can note that the leading bank is Bank 1. Thanks to qualitative criteria, as well as a good position according to capital adequacy criterion, the bank is the first in the overall ranking. This information may be of interest for those making decisions on the selection of the most competitive bank.

5. CONCLUSION

One of the options for finding a model to measure bank performance is the control of the banks performed by the Central Bank. The control is a common interest of the Central Bank, capital owners and users of banking services. The Central Bank, as the institution in charge of monetary policy, performs control over the banks in order to be able to promptly react to potential problems and protect the interests of citizens and the entire economic system. The owners of capital in banks are more and more interested in establishing an efficient and effective system of internal control in order to ensure better competitiveness through identifying the causes of their inefficiency and taking preventive action to avoid them. From the perspective of consumers – users of banking services, supervision over banks is important to avoid the risk of doing business with high-risk banks.

In the modern-day business world, in order to make optimal decisions, it is necessary to analyze the problem in terms of multiple criteria. In such cases, it is possible to use methods of multiple criteria decision-making. The choice of method depends on a particular case and the aim of the decision-maker. Some of the known methods are: ELECTRA, PROMETHEE, DEA, CAMELS, VIKOR and AHP. In this paper we employed the AHP method, in order to rank the banks in Montenegro, based on defined criteria. The advantages of the AHP method are in the possibility of inclusion of qualitative criteria and in the fact that apart from overall ranking, the alternatives can be ranked according to individual criteria and sub-criteria, which is an advantage that is often critical when decision-makers decide to use the AHP method. Montenegrin banks have been ranked applying the AHP method on the basis of quantitative and qualitative criteria, and with the help of a software package Super Decision. Banks have been ranked according to the criteria of liquidity, efficiency, profitability, capital adequacy, equity support, the importance for the financial market in Montenegro, management and maturity. In the overall ranking the best bank in Montenegro in 2013 is Bank 1. This practical example, accompanied by data from the financial statements, has shown the benefits of the AHP method, and helped in determining the most

competitive bank in Montenegro on the basis of several criteria relevant to the study, as well as in ranking the other banks.

Abstract: *This paper describes a risk management and it's evaluation procedures, in the operational planning process at the operational and tactical levels. Operational planning represents coordinated staff procedure in the work of the headquarters. Its purpose is to determine the best way to perform assigned missions and tasks, or to plan potential future tasks that might appear through the use of forces in the operations. The importance of risk management in the operational planning process has direct implications for the success of all types of operations performed by the Serbian Armed Forces. Emphasis is given to the management and risk assessment in all dimensions of the operational environment.*

Keywords*: operational planning, operational environment, risk management, SymOrg2014*

1. INTRODUCTION

Military operations are carried out within the framework of the complex factors of the area where the shape and nature have a significant impact on the effects of operations. It requires a broad understanding of the strategic and operational environment that is relevant to the completion of the mission.

Operational planning is a starting point of performing any operations, and also the element of the projection of future activities by which the operation is carried out, namely how is the complex mission carried out. Headquarter is conducting an assessment at the beginning of operational planning, in order to determine the best way to accomplish the mission. The assessment is carried out on the basis of established elements that comprise the factors of the operating environment. This assessment is a continuous process that includes the mission, enemy, time and land, its own strengths and total time available.

Observing the operating environment as a challenging environment for executing different operations, from combat to non-combat, military units must be capable and adaptable to successfully carry out the mission, no matter the conditions, particularly bearing in mind the different temperature, different land, fear, insecurity, confusion, fatigue and so on. All this combined with the human and physical dimensions takes the complexity that needs to be taken into account in operational planning. Operational environments are complex conditions, circumstances and influences that require from holders of operational planning to make the right decision. Operational planning refers to the executions of operations precisely in difficult conditions and with varying degrees of risk, which is manifested in certain trends of instability and lasting state of persistent conflict.

Risk management in the process of operational planning gets the central stage and it represents a complex approach, especially if one takes into account the operational environment that will remain dirty, the frightening, physically and emotionally exhausting ambient of environmental conditions in which the operation is performed .

2. THE OPERATIONAL ENVIROMENT

Military operations are conducted in a different range of environments characterized by complexity, uncertainty and constant change. The operational environment includes the physical components (air, land , maritime and cosmic space) and cyberspace. It also includes information to shape the conditions in these areas, including the enemy, friendly forces and neutral forces, relevant to the conduction of operations. Basic characteristics of the operating environment are complexity, variability and uncertainty.

The complexity and variability are the categories of operating environments that are constantly changing, and they manifest themselves in the complexity of the process and the situation that is made from a multitude of elements or components and their interactive relationship. Two operational environments that

are the same can not exist, especially bearing in mind that the operating environment is not static but it is constantly evolving. This evolution comes as a result from actions of a man who learns and is able to adapt. Therefore, the man influences the operating environment, and thus it changes. Some changes are expected, while others are not. Some changes are obvious and immediate, others are complex and hidden. The complexity and variability of the permanent nature of the operating environment makes the determination of the relationship between cause and effect very complex and contributes to the uncertainty of military operations, respectively contributing to the operations being exposed to certain risks. Uncertainty is what is unknown about a given situation or lack of understanding how the situation may evolve. In the process of operational planning, the commander accepts the implementation of operations in operating environments that are inherently uncertain. Within such situations, operational planning achieves a dimension of planning operations in the full range of influential factors.

3. OPERATIONAL PLANING

Operational planning is aligned staff process in the work of Command / HQ, whose purpose is to determine the best way to perform assigned missions and tasks or planning potential future tasks in the course of deployment of forces in operations (Instruction for operational planning and operation commands in the Serbian Armed Forces (SAM), 2014). At the same time, the system of operational planning enables the development of plans, which should be timely to respond to situations in which the SAM can be used. It is based on the development of goals and relationships with subordinate and superior levels, with clear and well defined responsibilities of individual organs of Command / HQ. (Instruction for operational planning and operation commands in SAM, 2014).

In the process of operational planning an essential prerequisite for the success of the operational plan and the success of the operation is an understanding of the operating environment" ... establishing an understanding of the conditions under which the power of the SAM is used. Armed forces are used in the operational environment governed by the certain conditions and they are changing during the course of the mission. By having full understanding of the operational environment, possible ways of solving problems are identified and the potential results of using own forces, enemy forces, and neutral participants are predicted." (Instruction for operational planning and operation commands in SAM, 2014).

According to the mentioned Instruction, operational planning at operational and tactical levels is implemented through seven stages : 1) initiation (receiving the task), 2) orientation (the study and understanding of the task) , 3) the development of variants of use (courses of action) , 4) analysis of variants use (course of action) , 5) comparison of variants of use (course of action) , 6) approval the use of variants (course of action) and the decision to perform the operation and 7) production of orders. For the operational planning process at the operational and tactical levels, the second phase is interesting - orientation, in which is risk assessments carried out and in a complex way goes on risk management as a whole. The second phase is characterized by seventeen steps, among which the seventh step is risk assessment.

Making reasonable estimates and conscious acceptance of risk is a fundamental issue for the performance of operational planning and execution of operations. Careful determination of risk, analysing and minimizing danger to an acceptable level and the executing the plan that provides that desired level, contributes to the success of the execution of the operation.

4. RISK MANAGEMENT

Risk management primarily refers to the process of identifying risks, its assessment and treatment. At the same time , risk management is a standard that defines risk as a combination of the probability of an event and its consequences. The way in which the risk is being managed depends on the likelihood that the risk will occur and what influence does its achievement has (Paul M. Collier, 2009) .

In the process of operational planning, HQ identifies potential hazards and begins doing initial assessments of the level of risk for each hazard. The commander, based on the assessment decides where, what type and how much risk can he accept for the realization of certain variants of use (course of action).

4.1. Definitions of risk

The term risk can be defined in a different ways. In most cases, the " risk " has one of the three meanings: 1) The possibility of loss or injury. This is the most commonly recognized concept which clearly states that

something is lost or can be lost through accident or other forms; 2) The potential for negative influence. This is a generic definition. Something could go wrong. The negative impact may be unclear and unknown, but it would also result in a negative outcome, and 3) Probability of adverse events. This moves us into the world of statistics and quantitative analysis. We see the risks on the horizon. What is the probability that it will achieve? What will be the impact if it does occur? Can you quantify the damage? What will be our best or worst case, if it happens? (John J. Hampton, 2009).

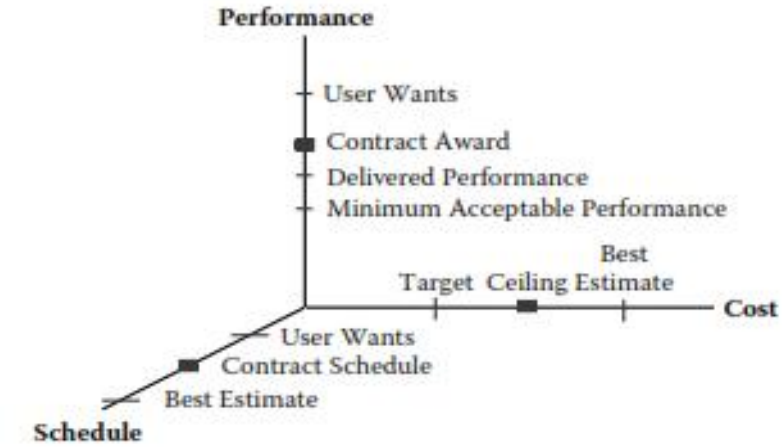
A broader definition is becoming the norm for the organization, namely becoming an imperative for operational planning process in a complex operating environment. Therefore, the risk is an occurrence which, if it occurs, adversely affects the ability of the project to achieve its objectives outcomes. (Paul R. Garvey, 2009). Hence, the risk of event has two aspects. The first is its probability of occurrence, and the other is its impact (or consequence) on the project.

Generally, this expression is given by the equation:

Risk = f (Probability, Impact) (1)
(1)

Uncertainty is the vagueness of the outcome of the situation. Uncertainty is analyzed to measure risk. Bearing in mind that the risk is potential event, the probability is used to express the chance that the event will occur. Often, the nature of such events is such that the analysis used to measure subjective probabilities instead of objectively derived measures.

Risk is present in every activity and is expressed in specific dimensions and to a large extent " pushes " what is technically or economically feasible. Managing risk exists within and across all these dimensions, as shown in Figure 1:



Scheme 1. Dimensions of risk management *(Paul R. Garvey, 2009)*

Risk management is a management method that focuses on the identification and control of events that have the potential to cause unwanted changes ... it is neither more nor less than an informed management." (TV Caver, 1985.). The objectives of risk management are early and continuous hazard identification and distribution of information on the results of risk. They should be such that the system fulfills its function within defined cost and meets customer needs.

Why is risk management in the operational planning important? It is important because risk management seeks to provide risk information relevant for the decision, namely a decision that will provide also the planning of forces in operation, in order to achieve the objective with respect to defined criteria.

In general, the risk management process consists of the steps that are shown in figure 2:

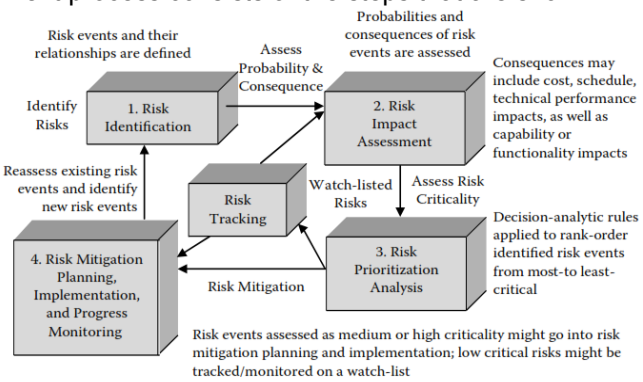


Figure 2: Steps common to a risk management process *(Garvey, P. R., 2009.)*

According to the Instruction for operational planning and operation commands in the Serbian Armed Forces, risk management involves identifying and controlling hazards to protect the forces and increase the chances for task execution. It applies to every task and operating environment and it is implemented through five steps: a) identification of the risk of adverse events specific situations; b) danger assessment; c) defining the measures to control the risk (decision on application); e) an estimate of the remaining (residual) risk; f) implementation and monitoring of the measures.

4.2. Identification of danger

Identifying dangers is a critical step in the risk management process . His goal is to timely and continuously identify dangers within the operational planning process, to list known risks and, thus ,identify risks that must be present for the commander and HQ in process of plan development. As a process, risk identification is a continuous activity that is regularly carried out in the operational planning of phase of orientation.

Danger represents such a condition that has the potential to cause a variety of injuries, illness or death of soldiers, damage or loss of equipment or property, or to prevent the execution of the mission. It may be a situation or event which may reduce the ability to perform the mission, or its failure .

Regardless of the used methods, the identification of risk requires a comprehensive understanding of the operational environment and the specific economic, legal and regulatory factors that are affecting the execution of the operation. Looking at the operational environment as a complex system where there are no clearly defined boundaries within its dimensions, require that during the operational planning, one should find solutions and successfully implement the operations with respect to balancede risk. (Paul R. Garvey , 2009).

In the process of identifying dangers, participation of certain specialists who are in command during the operational planning process, is necessary. All members of HQ can participate, especially if they have experience in planning operations.

Data for the process of identifying risks are coming from many different sources. Some sources are particularly relevant. Content in these sources and materials often provide the basis for risk and justifies why is a potential problem important for operational planning.

The risks can be identified and validated through systematic analysis of the operations, such as modeling and simulations, and through implementation of observation and experience. Risk identification includes efforts to analyse written materials and perform interviews with experts in specific areas of operation .

4.3. Assessment of danger

Assessment of danger includes events that may affect the success of the operation. Impacts are not limited to the above criteria only. Additional criteria such as political or economic consequences may also require consideration. Through assessment, it is necessary to include the probability of occurrence of each risk. This often involves the use of techniques of subjective probability estimates, especially when circumstances preclude a direct evaluation by objective methods (eg, modeling, simulation).

Subjective assessments of probability is mostly used in the process of operational planning. This allows access to information that can decide a course of action, or the alternatives, or need to assess the opportunities in the operational planning process.

An ordinal risk matrix is most commonly used in a method for analyzing risks in processes of operational planning at the operational and tactical level in terms of prioritization of risk and subjective assessment of probability of ranking.

Ordinal risk matrix is widely used for the determination of the risk event. Figure 3 is a classical 5 × 5 matrix of ordinal risk. Inline scale defines a matrix. These are measures of probability. Level along the vertical side of the matrix represents the probability level, while the level along the horizontal side of the matrix effect (consequences). (Paul R. Garvey, 2009).

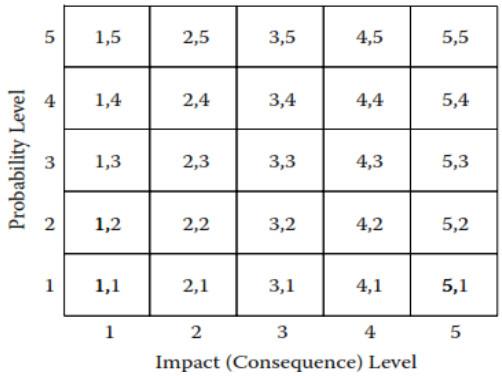

Figure 3. A traditional 5 × 5 ordinal risk matrix
(*Paul R. Garvey, 2009.)*

.
In the operation planning process, the matrix that is used to determine the level of risk is formed in the same way. It was created as a result of the practice and it was accepted in the American Army Manual (Headquarters Department of the Army, Washington, 2006). The final result of this analysis is the initial risk assessment for each identified danger, and it is expressed as very high, high, moderate or low. These categories were determined by using a standardized risk assessment matrix (Figure 4).

RISK ASSESSMENT MATRIX						
		Probability				
Severity		Frequent A	Likely B	Occasional C	Seldom D	Unlikely E
Catastrophic	I	E	E	H	H	M
Critical	II	E	H	H	M	L
Marginal	III	H	M	M	L	L
Negligible	IV	M	L	L	L	L
E – Extremely High		H – High		M – Moderate		L – Low

Figure 4: Risk Assessment Matrix

In this step, there are three sub-steps that are carried out, namely:

• Assessment of the probability of the event or occurrence,
• Assessment of the expected result of an event or occurrence and
• Determining the level of risk for a given probability and severity.

4.3.1. Assessing the probability of an event or occurrence

This is the first estimate based on known information, or information based on previous experiences. Probability is estimated based on the frequency of similar event. For the purposes of risk management in operational planning, according to the American Manual, FM 5-19 (Headquarters, Department of the Army, Washington, 2006), there are four levels of probability: often, probable, occasionall and rare. The meaning of the above probabilities is shown in table 2:

Levels	Definition/description
Often	Known as a regular occurrence. Expected to happen to someone for sure. Often examples are thermal injuries, collision of vehicles and similar.
Probable	Happens several times. Occurs habitually and will happen in a certain moment. Examples may include unintentional dropping weapons, unintentional firing a shot and similar.
Occasional	Happens sporadically but is not unusual. Examples may include unexploded agents elements or warfare against friendly units and similar.
Rare	Is supposed not to happen but is not impossible. Examples may include ammunition explosion during transport.

Table 2: Probability meanings

4.3.2. Assessment of expected event or occurrence result

The sensitivity of an assessment is expressed in the level of the the incident that will affect the operational capability or the success in accomplishing mission. The level of sensitivity is evaluated for every danger based on knowing the results of similar events that occurred, and they are graded as: catastrophic; critical; marginal and negligible.

Mark	Definition / description
Catastrophic	- the mission on the whole is endangered and cannot be accomplished, - death and permanent invalidity, - the loss of critical equipment for accomplishing mission, - dangerous environmental pollution, - security jeopardized mission and - unacceptable collateral damage.
Critical	- units' operational capability is seriously violated and so is the mission, , - permanent or partial invalidity or temporary incapability up to three months, - massive weapon and equipment damage - property and environment significant damage, - security failure and - significant collateral damage.
Marginal	- reduction of units operational capabilities or mission accomplishment, - minor damages of equipment, property or environment and - days lost due to injury or illness up to three months.
Negligible	- little or no negative influence on the units' operational capabilities and accomplishing mission, - first aid or minor medical treatment, - minor technique damage, but in function and reapaired and - minor or none environment damage.

Table 3: Level of sensitivity

4.3.3. Determining the level of risk

Using a standard risk assessment matrix (Figure 4) , the probability and severity of each identified danger is converted into a certain level of risk. Figure 4 is a classical 5 × 5 matrix of ordinal risk . Along the vertical side of the matrix the level of probability and impact is shown (consequences) along the horizontal side of the matrix.If the probability is higher, then the probability of the occurrence of risk events is higher, too. If the level of probability is lower, also is the lower of probability of risk events . A similar relationship stands for the consequences. A higher level of impact - the greater is the risk of the consequences of events on the operation or mission. The lower level of impact - less risk caused by events on the operation or mission. This matrix provides an assessment of the probability and severity expressed in terms of the standard risk level. Assessment is not absolute and can only be indicators but does not necessarily need to be, of the relative risk of a given work , activity or event. Levels of risk are listed in the lower left corner of the matrix. All accepted residual risks of the matrix must be approved at the appropriate level of command. Certain levels of risk and their implications in relation to the mission are shown in ordinal table 4:

Ordinal Scale Level (Score)	Definition/Context: Occurrence Probability
Extremely High Risk **(E)**	Loss of ability to accomplish the mission if hazards occur during mission. A frequent or likely probability of catastrophic loss (IA or IB) or frequent probability of critical loss (IIA) exists. This implies that the risk associated with this mission, activity, or event may have severe consequences beyond those as sociated with this specific operation or event. The decision to continue must be weighed carefully against the potential gain to be achieved by continuing this course of action (COA)
High **(H)**	Significant degradation of mission capabilities in terms of the required mission standard, inability to accomplish all parts of the mission, or inability to complete the mission to standard if hazards occur during the mission. Occasional to seldom probability of catastrophic loss (IC or ID) exists. A likely to occasional probability exists of a critical loss (IIB or IIC) occurring. Frequent probability of marginal losses (IIIA) exists. This implies that if a hazardous event occurs, serious consequences will occur. The decision to continue must be weighed carefully against the potential gain to be achieved by continuing this course of action (COA).
Moderate **(M)**	Expected degraded mission capabilities in terms of the required mission standard and will result in reduced mission capability if hazards occur during mission. An unlikely probability of catastrophic loss (IE) exists. The probability of a critical loss is seldom (IID). Marginal losses occur with a likely or occasional probability (IIIB or IIIC). A frequent probability of negligible (IVA) losses exists.
Low **(L)**	Expected losses have little or no impact on accomplishing the mission. The probability of critical loss is unlikely (IIE), while that of marginal loss is seldom (IIID) or unlikely (IIIE). The probability of a negligible loss is likely or less (IVB through (IVE). Expected losses have little or no impact on accomplishing the mission. Injury, damage, or illness are not expected, or may be minor and have no long term impact or effect.

Table 4: An Ordinal Scale for Occurrence Probability
(*Headquarters Department of the Army Washington (2006) FM 5-19 (p.1-3)*

4.4. Development of versions of use (courses of action)

In this step, a set of identified risk events, their assessment of the impact and probability of their occurrence are "treated" to get from the most to the least - critical rank - order the identified risks. The main objective of risk prioritising is to form the basis for the allocation of critical resources. These resources include the allocation of additional forces (if necessary), in order to focus on addressing the risks that are most critical in the process of operational planning.

Once when risks are identified, it is necessary to determine risk management instruments. It primarily depends on the type of risk, that needs to be solved to an acceptable level. For example, because of their nature, certain risks are usually managed by appropriate response measures.

4.5 . Defining measures to control risk (decision about application)

This step includes developing plans to mitigate risks, elimination or reduction of the risk and bringing it to an acceptable level. When the plan is implemented, it is the continuous monitoring and evaluation of specific solutions and re-correction of the courses of action if it is determined by the estimated level of risk. Making decisions is based on an estimate of residual risk and the process of the control development and review of risk control continues until an acceptable level of risk is achieved. Risks need to be reduced to a level that their activity is below potential benefits. This process is carried out in steps of development of courses of action, analysis of courses of action, comparing courses of action and their approval process defined in standard operating procedures of operational planning (Manual for operative planning and work of commands in the Serbian Armed Forces, 2014).

After assessing all dangers, commander exercise control that eliminates or reduces the risk (its probability). The primary function of control is manifested through: *training* (qualifications) *of the units*, *physical control and warning (avoidance)*. Control of training include elements that are typical for the process of training, and whether they achieved the performance standards defined in the training process. Segment of physical control is implemented through the physical security of certain places or placing certain warning signs. Finally, avoiding relates to the elimination of physical contact with the identified dangers.

According to the American manual for risk assessment (Headquarters, Department of the Army, Washington, 2006), for control to be effective, it must meet the following criteria: it is suitable , feasible and acceptable. The convenience of control is manifested through the removal or mitigation of risk of danger to an acceptable level. The feasibility of the control for a unit is that it can carry out control property, while the acceptability of control is expressed in subjective justification of the costs of time and resources through acquired use.

4.6. Evaluation of the remaining (residual) risk

A very important thing to keep in mind is that so-called residual, which remains after control also. The controls can not completely eliminate or reduce risks of certain danger. Total residual risk will be greater than or equal to the widest remainder of the identified risk. However, given the complexity of the remaining controls and potential synergy effects of all dangers, the commander can determine if the residual risk is high in the mission.

Decision making by itself is determination of what is an acceptable level of risk. The risk or potential loss should be adjusted according to the expected gains. It should be emphasized that all decisions, at every level of command, should be based on an adequate assessment of risk. (Karović , S. Radončić, H., Komazec N. , 2012.).

4.7 . Implementation and monitoring the measures

Taking into account the dynamics and complexity of the operational environment, in operational planning process we must expect different sources and levels of risk. Some risks can become more significant than others. Operational planning process is exposed to various sources of risk and it is necessary to consider all available parameters in order to be able to implement planned strategies for reduction or elimination of risks.

Supervision should be understood as a form of control measures and it is an integral part of risk management in the operational planning process. Supervision provides subordinates to understand how, when and where are controls implemented. This ensures prevention of unauthorized deviation from standards or violations of policy and risks control, that could jeopardize the mission. Evaluation (assessment) is done during all phases of operation, and also after the execution of an operation or its particular stage. The evaluation should: identify all the risks that were not identified as part of the initial assessment, to identify new danger that have appeared during the operation, or other activities, and to assess effectiveness in supporting operational goals and objectives.

These are the most important elements relating to the monitoring and evaluation of risk assessments. However, it is important to stress, in order to maintain continuity with the requirements of the mission and tasks, to implement process of complex risk management in a standardized way. Risk management can be adapted to use various tools to display information for the complex risk management. The paper is not about specific tools in the form of specific patterns that are used for specific assessment and this would represent a new paper that would include specific questions for the analysis and evaluation of certain danger. (Karović, S. Radončić, H. , Komazec , N. , 2012.) .

5. CONCLUSION

In the process of operational planning at operational and tactical levels for use of SAF, there are some clearly defined procedures and steps. A key segment in it is the operational environment and its assessment in all dimensions that characterize it. As a part of operational planning, an important part is risk management as an indispensable category that is crucial for making a decision on use of SAF in different types of operations.

The essence of risk management in the operational planning process is based on its identification as part of the operational environment, its ranking and bringing to an acceptable level, respectively taking measures to reduce its impact. Identifying risks in such circumstances is based on the experience of HQs that perform operational planning and it is oriented toward specific mission and the specific operational environment. Operational planning process is always carried out in conditions of uncertainty and limited time, which requires that risk assessment and methods that are used, must be very practical and adaptable to ambient of operational environment.

It may be noted that the previously presented method of risk management, presents the basis function in the operational planning at operational and tactical levels in consideration of the use of SAF in the operational environment. At the same time, it presents a very efficient method of determining the probability and level of risk, that is practically applicable. The implementation is very simple and provides efficient indicators that are essentially the best way to fast and effective action for the operational planning process and operational commands according to established procedures, particularly bearing in mind that most of the risk is based on the experience and records of various types of dangers in the operational environment.

A NEW CONSTRUCTIVE HEURISTICS FOR SOLVING THE MINIMUM FEEDBACK VERTEX SET PROBLEM

Milan Stanojević[1], Bogdana Stanojević[2]
[1]Faculty of Organizational Science, University of Belgrade, milans@fon.bg.ac.rs
[2]Mathematical Institute of the Serbian Academy of Sciences and Arts, bgdnpop@mi.sanu.ac.rs.com

Abstract: *In the present paper, we address the feedback vertex set problem, and propose a new heuristics to solve it. Our heuristics is a greedy constructive one, and is based on the vertices labeling. We tested our heuristics on random generated instances of various densities and number of vertices. We report the computational results as percentage of deviations of the approximate solutions obtained by our heuristics from the exact solutions of the instances or from the upper bounds, when we were not able to find the exact solution in a reasonable time by an exact algorithm.*

Keywords*: feedback vertex set, de-cycling, heuristics, un-oriented arcs, un-weighted vertices*

1. INTRODUCTION

The problem of finding a minimum feedback vertex set (FVS) in a graph is one of the classical *NP*-complete problems mentioned by Karp (1972) when he was researching the reducibility among combinatorial problems. A wide survey of the feedback set problems can be found in Festa *et. al* (2000), were it is emphasized that solving feedback vertex set problems is useful in combinatorial circuit design; deadlock prevention in operating systems; constraint satisfaction and Bayesian inference in artificial intelligence; and graph theory.

Festa *et al.* (2000) examined the relationship between the feedback vertex set (FVS) and the feedback arc set problems, described the applications of feedback vertex set problems, and showed new directions in feedback vertex set problem research. Moreover, the feedback vertex set problem has applications in VLSI chip design (see for instance the survey article published by Silberschatz *et. al* (2008)).

Different versions of the FVS problems exist. Xiao & Nagamochi (2013) defined four FVS problems, as there are oriented/un-oriented arcs/edges in the graph, and there are vertices or arcs/edges to be deleted in order to remove the cycles: Directed Feedback Vertex Set (DFVS), Undirected Feedback Vertex Set (UFVS), Directed Feedback Arc Set (DFAS), and Undirected Feedback Edge Set (DFES). UFES problem is equivalent to finding a maximum spanning tree in a graph, therefore, it can be solved in polynomial time. The other three problems are *NP*-hard, and UFVS and DFAS problems were included in Karp's (1972) list of *NP*-complete problems. Xiao & Nagamochi (2013) proposed an $1.7356^n n^{O(1)}$-time exact algorithm to solve UFVS, thus improving all previous published results.

Another version of FVS is obtained, when graph's vertices have associated weights and the feedback vertex set with minimum sum of weights is desired.

Chen *et. al* (2008) presented improved parameterized algorithms for the FVS problem on both un-weighted and weighted graphs. Their algorithms constructed a feedback vertex set of size at most *k* in a given graph *G* of *n* vertices, or report that no such feedback vertex set exists in *G*. In the weighted case, they determined the set of minimum weight among the feedback vertex sets of size at most *k*.

Fomin et. al (2008) presented a time $O\left(1.7548^n\right)$ algorithm for finding a minimum feedback vertex set in an undirected graph on *n* vertices. They also proved that a graph with *n* vertices can contain at most 1.8638^n minimal feedback vertex sets and that there exists an infinite family of graphs having 1.5926^n minimal feedback vertex sets.

Chen *et. al* (2012) showed that for every planar graph the minimum cardinality of a feedback vertex set is at most three times the maximum number of vertex disjoint cycles in the graph. Gasper & Mnich (2013) discussed some combinatorial and algorithmic questions around minimal feedback vertex sets in tournament graphs. Jiang *et. al* (2013) investigated the minimum weight FVS problem on tree convex bipartite graphs, which are generalizations to convex bipartite graphs and chordal bipartite graphs.

The rest of the paper is organized as follows: in Section 2, we explain the notation and terminology; Section 3 presents the mathematical models of a FVS problem and classic algorithms for solving FVS problems. In Section 4, we present our new heuristics. We report our computational results in Section 5. Section 6 contains some concluding remarks and ideas for future work.

2. NOTATION AND TERMINOLOGY

A feedback vertex set in an undirected graph $G=(V,E)$ is a set of vertices F, $F \subseteq V$ such that every cycle in graph G contains at least one vertex from F. A graph that contains no cycles is called forest. A forest that is connected is called tree, hence, a forest can be also defined as a collection of disjoint trees. In other words, a set F of vertices from G is a feedback vertex set of G if and only if $V \setminus F$ is a forest. The size of the feedback vertex set F is the number of vertices in F.

In the literature, three equivalent problems related to the feedback vertex set can be found under different names: minimum feedback vertex set, de-cycling (or minimum cut-set), and maximal forest. We insert below the definitions of those three problems.

Definition 1. Given a directed/undirected graph $G=(V,E)$, to solve the minimum **feedback vertex set** problem means to find a set $F \subset V$ with minimal cardinality such that each cycle from G contains at least one vertex from *F*.

Definition 2. Given a directed/undirected graph $G=(V,E)$, to solve the **de-cycling (minimum cut-set)** problem means to find a set $F \subset V$ with minimal cardinality such that the graph induced by $V \setminus F$ is acyclic.

Definition 3. Given an undirected graph $G=(V,E)$, to solve the **maximal forest** problem means to find a set $T \subset V$ with maximal cardinality such that induced graph $H=(T,E')$ of G is a forest.

Note that $F = V \setminus T$, where *F* is the minimum set found by solving the minimum feedback vertex set problem or the minimum cut-set problem and T is the maximum set found by solving the maximal forest problem.

One generalization of the FVS problem is the following: given a directed/undirected graph $G=(V,E)$, $V = A \cup B$ ($A \neq \phi$ - allowed, B - blackout), find a minimum set $F \subset A$ such that each cycle from G contains at least one vertex from F.

In this paper, we have considered un-weighted feedback vertex set problem on undirected graphs without blackout vertices (UFVS).

3. MATHEMATICAL MODELS AND CLASSIC SOLVING PROCEDURES FOR FVS PROBLEMS

Given an undirected graph $G=(V,E)$, Models (1)-(3) and (4)-(6) describe two possible mathematical formulations of the UFVS problem. Let C be the set of sets of vertices of all induced cycles of G. Model (1)-(3) refers to the vertices of the graph's induced cycles. In the final solution, the variable x_j is equal to 1 if the vertex v_j belongs to the feedback vertex set (or, in other words, it does not belong to the maximal forest), otherwise, it is equal to 0.

$$(\min) \quad \sum_{j \in V} x_j \tag{1}$$

$$\sum_{j \in c} x_j \geq 1 \quad \forall c \in C \tag{2}$$

$$x \in \{0,1\}^{|V|} \tag{3}$$

Let T be the set of sets of vertices of all induced trees of G. Model (4)-(6) refers to the vertices of the graph's induced trees. In the final solution, the variable y_t is equal to 1 if the tree t belongs to the maximal forest, otherwise y_t is equal to 0.

$$(\max) \quad \sum_{t \in T} |t| \, y_t \tag{4}$$

$$\sum_{t \in T : t \cap \{i,j\} \neq \phi} y_t \leq 1 \quad \forall (i,j) \in E \tag{5}$$

$$y \in \{0,1\}^{|T|} \tag{6}$$

The approaches for solving UFVS problems are split in exact algorithms and heuristics. The exact algorithms are sometimes polynomial, i.e. for the special cases defined by certain reducibility properties of the graph (e.g. majority of program flowcharts). In what follows, we present a simple Prim's algorithm like constructive heuristics, for solving the UFVS problem. This algorithm illustrates completely the nature of the problem we address.

- Input: $G = (V, E)$
- Set $T \leftarrow \phi$ and $F \leftarrow \phi$.
- Do
  Select an arbitrary vertex $i \in (V \setminus T) \setminus F$.
  If the sub-graph of G induced by the set $T \cup \{i\}$ is cycle free then $T \leftarrow T \cup \{i\}$
  else $F \leftarrow F \cup \{i\}$.
  While $(V \setminus T) \setminus F \neq \phi$.
- Output: the maximal forest induced by T, and the minimal feedback vertex set F.

We also implemented an exact algorithm that solves UFVS in order to find the optimal solutions to the randomly generated instances needed in our experiments. The algorithm is an iterative branch and bound which uses a relaxation of Model (1)-(3) in each step. It systematically adds constraints of type (2) until the solution does not contain any cycle. The main steps are presented below.

- Include in Model (1)-(3) only those constraints that correspond to the cycles of size 3.
- Solve to optimality the relaxed Model (1)-(3).
- While *Cycle_Found*
  Add new constraints to Model (1)-(3), those that correspond to the identified cycles.
  Solve to optimality the updated Model (1)-(3).

The number of iterations, needed to find the optimal solution, and the number of constraints, added to the relaxed Model (1)-(3) in any iteration, are inverse proportional. We implemented two versions of this exact algorithm: one with moderate constraints generation, and one with extensive constraints generation.

4. THE NEW CONSTRUCTIVE HEURISTICS

In this section, we propose a greedy constructive heuristics to solve the undirected feedback vertex set problem. The basic steps are inserted below.

- Input: $G = (V, E)$.
- Set $G^0 \leftarrow G$, $E^0 \leftarrow E$, $V^0 \leftarrow V$ and $k \leftarrow 0$.
- Do
  $v \leftarrow DetectCycle(G^k)$.
  If *Cycle_Found* then
  remove vertex v from V^k and all edges incident to v from E^k forming G^{k+1}.

$k \leftarrow k+1$.

While *Cycle_Found*.

- Output: the maximal forest $G^k = (V^k, E^k)$, and the minimal feedback vertex set $F = V \setminus V^k$.

The function $DetectCycle(G)$ detects a cycle in G, and returns the vertex from the cycle with the largest degree. The same function sets the global variable *Cycle-Found* to 'TRUE' if the graph G contains at least one cycle, or otherwise, to 'FALSE'. Removing the vertex with the largest degree favors breaking more cycles at once, but also makes the heuristics greedy.

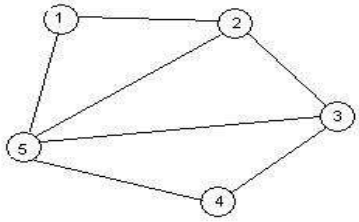

Figure 1: The graph used to describe how the procedure *DetectCycle()* works

A simple example of a graph and its minimal feedback vertex set is shown in Figure 1. Starting from the graph $G^0 = (V^0, E^0)$ where $V^0 = \{1,2,3,4,5\}$ and $E^0 = \{\{1,2\},\{1,5\},\{2,3\},\{2,5\},\{3,4\},\{3,5\},\{4,5\}\}$, the first detected cycle is 1-2-5. Further, the vertex 5, the vertex with the largest degree in the cycle, is returned by the function *DetectCycle()*. Then, vertex 5 is removed from the set of vertices together with all edges adjacent to it, i.e. $\{\{1,5\},\{2,5\},\{3,5\},\{4,5\}\}$. Thus, the graph $G^1 = (V^1, E^1)$ is defined, where $V^1 = \{1,2,3,4\}$ and $E^1 = \{\{1,2\},\{2,3\},\{3,4\}\}$. This graph is cycle free, hence the maximal forest is $G^1 = (V^1, E^1)$, and the minimum feedback vertex set is $F = \{5\}$.

The computational complexity of the cycle detection step is $O(|V^2|)$.

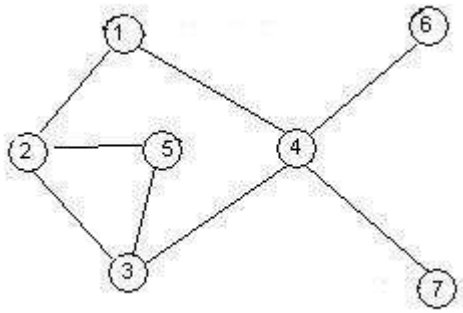

Figure 2: The graph used to show a situation when the new heuristic misses to find the exact solution

Running our heuristics for finding the minimum FVS of the graph presented in Figure 2, the following unfortunate situation appears: the detected cycle is 1-2-3-4; the vertex with the largest degree in the cycle is 4; the graph remains with cycles after eliminating 4 and its edges; the new graph after this step is $G^1 = (\{1,2,3,5,6,7\},\{\{1,2\},\{2,3\},\{2,5\},\{3,5\}\})$. The next detected cycle is 2-3-5; vertex 2 and its edges are eliminated; and the final FVS is $F = \{2,4\}$ and the final forest is $G^2 = (\{1,3,5,6,7\},\{\{3,5\}\})$. In fact, the minimum FVS contains one vertex and can be obtained in the first step, by removing the vertex 3 from the cycle 1-2-3-4.

5. COMPUTATIONAL RESULTS

For our experiments, we implemented the exact algorithm and the new heuristics that solve UFVS problems. We generated randomly 250 instances, and grouped them according to the number of vertices *v* (20, 30, 40, 50, and 60) and density *d* (10, 30, 50, 70, and 90).

Table 1: The results obtained by running the exact algorithm

Density	# vertices	# instances solved exactly	Average time (for instances solved exactly)	% Dev of LB from UB (for instances not solved exactly)
10	20	10	0	N/A
	30	10	0	N/A
	40	10	0.32	N/A
	50	10	75.07	N/A
	60	6	1934.50	3.27%
30	20	10	0.09	N/A
	30	10	22.89	N/A
	40	10	1433.96	N/A
	50	0	N/A	8.21%
	60	0	N/A	20.78%
50	20	10	0.97	N/A
	30	10	135.84	N/A
	40	3	6862.80	9.64%
	50	0	N/A	9.92%
	60	0	N/A	20.00%
70	20	10	2.05	N/A
	30	10	442.01	N/A
	40	8	4184.96	12.50%
	50	1	5888.30	13.58%
	60	0	N/A	17.65%
90	20	10	3.44	N/A
	30	10	173.19	N/A
	40	10	1605.88	N/A
	50	7	2934.14	16.67%
	60	4	2602.50	16.67%

For each pair of values *(v, d)* we generated 10 instances as follows: we arranged the edges into an array of size $\frac{v^2 - v}{2}$; following the uniform distribution, we randomly generated, *d* times, an index that refers to a component of the array. The first index was generated between 1 and v^2, the second index was generated between the first index and v^2, and so on; when we reached the component v^2, we started from the beginning.

Table 1 summarizes the computational results obtained by running the exact algorithm. For each group of instances, we reported how many instances out of 10 we solved exactly in less than 7200 seconds; the average time needed for exactly solved instances; and the average deviation of the lower bound from the upper bound in the case of instances that we did not solved exactly.

The computational results showed that the exact algorithm best performs when the density of the graph is either very small ($d = 10$) or very large ($d = 90$). In addition, for middle values of the density ($d = 30$, $d = 50$, and $d = 70$), the algorithm has a significant low performance when the number of vertices in the graph increases from 50 to 60.

In order to describe the performance of the new heuristics, we summarized our computational results in Table 2. For each group of instances, we reported the average percentage of the deviations of the size of the obtained forest from the size of the optimal forest (or, from the upper bound found for the size of the optimal forest, when we were not able to solve the instance exactly in less than 7200 seconds). In Table 2, d represents the density of the graphs that, together with the number of vertices, characterizes the groups of instances.

Table 2: The results obtained by running the heuristics (the percent of the deviation of the obtained forest size from the optimal solution or from the upper bound when the instance was not solved exactly in 7200s)

# vertices	$d = 10$	$d = 30$	$d = 50$	$d = 70$	$d = 90$
20	1.62%	3.36%	3.41%	6.15%	9.09%
30	2.39%	6.00%	4.90%	5.63%	10.00%
40	1.64%	5.81%	10.17%	5.00%	3.92%
50	3.43%	12.31%	14.50%	20.00%	8.77%
60	4.38%	21.65%	20.67%	19.61%	10.00%

Similar to the case of the exact algorithm, the experimental results showed a good performance of the new heuristics when the density of the graph was either very small or very large. Also, relatively good performance was noticed for the graphs with middle values of the density and number of vertices up to 50.

6. CONCLUSION AND FUTURE WORK

In this paper, we addressed the feedback vertex set problem, and proposed a new constructive heuristics to solve it. We tested our heuristics on random generated instances of various densities and number of vertices. We described the performance of our exact algorithm by counting the number of instances solved to optimality in a certain time, and the average difference between the lower and upper bounds, when the exact solution was not reached. Further, we reported the computational results as percentage of deviations of the approximate solutions from the exact solutions of the instances or from the upper bound, when we were not able to find the exact solution in reasonable time by the exact algorithm.

Our intention is to perform additional experiments in order to compare our heuristics to other constructive heuristics found in literature. Including some randomization steps, we can extend this heuristics to a GRASP procedure and/or a set-covering approach, thus improve its performance. Our intention is also to develop a meta-heuristics based on VNS to solve the FVS problems.

OPERATIONS MANAGEMENT

MATERIAL REQUIREMENT PLANNING FOR COMPLEX ASSEMBLY SYSTEMS UNDER ENVIRONMENTAL UNCERTAINTY

Abstract: *This paper presents basic settings of an original framework for optimizing the supply planning under environmental uncertainty in the assembly systems. A new dynamic inventory model with stochastic demand and stochastic lead times is formulated and incorporated within the framework. This notably strengthens the framework and makes it able to operate with real shortage costs of the final products within the optimization process and with more realistic assumptions about product demand. The use of the proposed framework is considered for single-level multi-product, multi-component assembly systems and, it is believed, that it can be generalized to a multi-level systems as well. The advantages of the proposed framework are confirmed through the experimental results, and the case in which multiple finished products share a common component bank is presented.*

Keywords: *shortage costs, backlogging, service level, component bank, BOM, dynamic programming*

1. INTRODUCTION

Effective management of inventory levels under environmental uncertainty is a complex and essential problem in production and operations management. The selection of no adequate replenishment policy leads to expensive inventories or increased penalty costs. The commonly accepted approach for replenishment planning in major companies is the Material Requirements Planning (MRP) under environmental uncertainties (Louly et al., 2008). Uncertainty in demand and supply creates the need for the optimizations procedures and almost all of them can be formulated as a trade-off between overstocking and stock out while minimizing the total cost. The inventory management is especially important for assembly systems, because for them a lack or excess of a component leads to increased holding and shortage costs related to the corresponding final product and components that assemble that final product. Therefore, the inventory level of a component depends on the stock levels of other components. Stock out for a component stops the assembly process, and so the stocks of other components and the corresponding holding costs increase.

In the available literature, there is a lack of works that can be effectively applied in practice in the cases of complex component's and final product's interdependencies in assembly systems. Traditional approaches should typically result in a large model that is difficult to solve and maintain. The assumptions made in known models tend to be restrictive for this kind of a problem, so the range of possible applications is significantly restricted. A serious drawback is that the obtained MRP is rather unrealistic, because it cannot take into account the real state of the production environment. Hence, the system cannot follow the large number of significant production events to make real-time decisions and it does not provide support to the manager to revise the unrealistic plans.

The assumption that, without a doubt, produces useless solutions for considered applications is that the shortage cost for an assembly component is known in advance. In assembly systems, shortage costs are related to a finished product, but the objective in a significant number of optimization procedures is to minimize the sum of average backlogging and holding component costs. As the stock out for a component can increase the holding costs for other components, it is clear that the holding costs also depend of the distribution of missing components. NP-hard character of this problem makes finding the proper solution to this problem very difficult. This is the main reason why researchers circumvented this problem, either by introducing backorders or by assuming that shortage component costs are known.

Another fact that further complicates the problem is that the demands for products are correlated in practice. This leads to a correlation between the demands for components, so incorporation of this into a model makes that model, due to its extreme complexity, practically unsolvable. However, as a holding cost, shortage cost and demand distribution are the three most important parameters on which optimization is performed, avoiding the real modeling leads to a completely useless solutions.

The paper deals with the management of inventory levels in a single-level multi-product, multi-component assembly system in a MRP environment under uncertainties. It presents basic settings of an original framework for optimizing the supply planning under environmental uncertainty in the complex assembly systems. A new dynamic inventory model with stochastic demand and stochastic lead times is formulated and incorporated within the framework. This contributes to determination of real costs and demand distributions in the considered environment. This is a significant improvement over the existing procedures, which, in real applications, due to the arbitrary and inaccurate defined input parameters, cannot give usable results, even for the simplest instances of the problem.

The remainder of the paper is organized as follows. The next section presents related works. The problem formulation is given in Section 3. Section 4 presents the basic settings of proposed framework, while Section 5 presents a detailed approach for the incorporation of total costs, incurred due to the lack of components into a known simple model for MRP under environmental uncertainty. The comparison of the proposed approach with the best known procedure (Proth et al. (1997)) is given in Section 6. Concluding remarks and directions of future research are given at the end of the paper.

2. LITERATURE REVIEW

The problem of supply planning in assembly systems in which multiple finished products share a common component bank, in its original form, has been given limited attention in literature. The extreme complexity of this problem can be one of the reasons for the lack of related works. The only paper that considers the incorporation of real shortage costs into the optimization procedure is the paper by Proth et al. (1997). This paper proposes an approximate assessment of components based on the arrangement of the final products. The production-volume policy states that it will be good to assemble as many type-1 products as possible, then as many type-2 products as possible, etc. Other published mathematical models of component inventory control for assembly systems cannot be directly applied when multiple finished products share a common component bank. Best replacement for the unit backlogging cost was with introduction of the service level or special control policies, and this does not solve the problem in a significant number of applications. The clear conclusion can be derived according to Louly and Dolgui (2008): “the obtained models show that the increased number of component types increases the optimal value of planned lead time”.

On the other side, the literature is rich in papers that consider optimization problems of MRP parameters, which is of great importance for the formulation of the problem. There are various approaches that optimize MRP parameters, like safety stocks, lot-sizing, planning horizons, planned lead times and other. Also, there are a number of exceptional works dealing with MRP parameterization under uncertainties and the comprehensive reviews of these models are given in Yeung et al. (1998), Dolgui et al. (2005) and Mula et al. (2006). It can be concluded that the analytical modeling approach was the most frequently encountered (Molinder (1997), de Kok and Visschers (1999), Yeung et al. (1999), Louly and Dolgui (2002), Gupta and Maranas (2003), Axsäter (2005, 2011), Arda and Hennet (2006), Dolgui and Prodhon (2007), Louly et al. (2008)). The dynamic programming models were mainly theoretical and they addressed only one type of uncertainty and assumed a simple structure of the problem. For problems with many different final products and more than one type of uncertainty, the analytical approach is replaced by procedures based on artificial intelligence (Hojati (2004), Samanta and Al-Araimi (2001), Petrovic (2001), Fox et al. (2000)) and simulation (Kadipasaoglu and Sridharan (1997), Xie et al. (2003)).

3. PROBLEM FORMULATION

Planning of multi-component supply for interrelated assembly systems with random lead times and random demands is impossible if the costs, which result from the lack of a certain amount of components, are not known. In defining the model on the basis of which the cost for an assembly system under environmental uncertainty is optimized, first task is to introduce variables that quantitatively determine the costs incurred if insufficient, or more than necessary components are available for assembling the finished product. In case of insufficient quantity, unified size is the shortage cost, while for the case where the amount is greater than the required, holding cost is considered.

In inventory management, holding costs include rent for the required space, labor to operate the inventory, interest on money invested in the inventory, cost for damaged and lost goods and other direct expenses. All of these factors can be introduced, on the basis of historical data and business analysis, into the aggregate holding cost of a certain component. How well the aggregate value reflects the real situation so the results of the optimization based on the applied model are more or less usable.

Cost, due to insufficient amounts of the components is, in the real world, far more complex than the holding cost. The shortage or penalty cost is the total of all costs per unit of not satisfying the order on its due date. It can be paid directly or it can be a chance of profit missed, which is called the opportunity cost. In assembly systems, first problem is that these costs are still tied for the finished product, but the optimization is always performed with regard to the components, because release of orders is always made for components, not for final products. In these systems, component shortages create additional cost in the form of holding cost for the other components which can't be assembled to the finished product. An additional complexity is the possibility that the same components can be used to assemble various finished products having different penalty costs. Most papers in the literature introduce the assumption which not only narrow the range of practical application, but in general provide useless solutions. The most common approximation in these papers is defining these parameters as deterministic constants related directly to the component, without any feedback to the other parameters of the model. As the holding cost and the shortage cost are an integral part of each of models and represents basic values of any optimization, application of this simplified model in practice usually gives inapplicable results. On the other hand, if these variables are presented in the model by real interdependence with other variables, obtained models, because of its enormous size would be also inapplicable in practice.

Problem can be formulated as an optimal assessment of unfinished final products according to the specific lack of components in a single-level assembly line. Once, the optimal assessment is determined, shortage cost for that assessment is uniquely defined. A procedure for solving described problem can be applied in two ways in the further optimization processes: it can be incorporated into a procedure for optimizing release orders and it can be used as a separate tool for the optimal assessment of unfinished final products.

In this paper we consider a multi-period planning horizon T having *n* periods of a cyclic assembly system for multiple finished products sharing a common component bank. Let index *i* denote the type of the finished product, $i = 1,...,ni$, where *ni* is the number of product types, index *k* denote the type of the component, $k = 1,...,nk$, where *nk* is the number of component types and $q_{i,k}$ denote quantity of component *k* needed to assemble the finished product *i*. Thus we can define the BOM matrix ***Q***,

$$Q = \begin{Vmatrix} q_{1,1} & \cdot & \cdot & \cdot & q_{1,nk} \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ q_{ni,1} & \cdot & \cdot & \cdot & q_{ni,nk} \end{Vmatrix}$$

which uniquely represents a BOM of a considered assembly system.

Following notations are used to describe the proposed model (upper script *j* denotes the period):

- h_k, the unit holding cost for component *k*;
- p_i, penalty cost charged for each finished product *i* short;
- p_k^*, *penalty cost charged for each component k being short.*
- L_k, the lead time for component *k*;
- d_i, demand for the final product *i*;
- dc_k^j, demand for component *k* in period *j*, $dc_k^j = \sum_{i=1}^{ni} q_{i,k} d_i$;
- $f_i^j(d) = P\{d_i^j = d\}$, probability mass function giving the demand for period *j* for finished product *i*;
- $fc_k^j(d) = P\{dc_k^j = d\}$, probability mass function giving the demand for period *j* for component *k*;
- x_k^j, $x_k^j = y_k^j - d_k^j$, random variable representing ending inventory for period *j* for component *k*;
- o_k, unit order cost for component *k*.
- y_k^j, available quantity of component *k* in period *j*;
- $\boldsymbol{X}^j[nk] = (x_1^j,...,x_k^j,...,x_{nk}^j)$, vector whose *k*-th element is x_k^j;

At the start of the *j*-th assembly cycle two decisions have to be made: how many type-*i* products to assemble in that cycle and how many components *k* to order in the same cycle. Ordering too many components results in excessive inventory costs and too few, in excessive costs related to product backlogging.

4. PROPOSED FRAMEWORK

The framework for optimizing the supply planning under environmental uncertainty in the assembly systems (SPF) enables incorporation of real costs into optimization procedures. SPF consists of four modules (Database, knowledge-based component - KBC, module OAMC and an arbitrary optimization procedure). In the Database, historical data about stochastic variables is stored. Also, dynamic data, produced in other modules is incorporated into database. The main task of KBC is to evaluate the probability distribution of stochastic variables and helps in optimizing the trade-off between the quality and efficiency of the optimization process. The module OAMC is used for optimal assessments of missing components.

In general case, the problem of optimal assessments of missing components is NP-hard. Danilovic and Vasiljevic (2014) have proven that OAMC could be reduced in linear time to the well known cutting stock problem which is known to be NP-hard. The advantage of the SPF is that OAMC can be mostly solved in preprocessing, so that the dynamic part of the procedure can be extremely efficient. The composition of the missing components (MC) determines the complexity of the optimization process, i.e., whether the procedure for solving OAMC should be hard or simple. Denote by *MCh*, a subset of *MC* with *"hard*" reductions and by *MCs*, a complement of *MCh* regarding to *MC*. As the cardinality of *MC* is limited in real applications, all *MCh* optimizations could be done in preprocessing and the resulting *OAMC*(*MCh*) could be stored in a database. In that way, the module that calculates the total costs of the current optimization state actually calculates the *optimized total costs* (OTC) for the current state of the missing components.

The SPF achieves a simple link to the KBC. The relational structure of the problem enables the use of relational programming for its implementation. This approach simplifies and speeds up the execution significantly and provides a simple and interactive processing. In practical applications, it is important to have all necessary calculations as close as possible to the database, obtaining a direct connection between the KBC and the decision system.

The outlook of the framework can be easily adapted for any arbitrary optimization approach. Figure 1 presents a framework that is used for a simple dynamic programming optimization. A well known stochastic dynamic programming procedure for identifying optimal decisions (Christou 2012) is used. The optimal decision at the start of any period depends on the inventory at the end of the previous period. Thus, using backwards recursion, the first step is to optimize the decision made in the final period, which minimizes the total future cost of that decision. This is a simple single-period problem to find the value of $\boldsymbol{Y^n}$ that minimizes the expected value of the cost function.

At the beginning of the optimization procedure, the *n*-th time period is considered. In each iteration, a required inventory level at the beginning of the current period is obtained. The optimization procedure has the bidirectional connection to the database (SQL Server database in Fig. 1) through the SQL procedures. Stochastic data (demand and lead times for the current time period) is obtained from KBC in the form of the correlated probability values. KBC interactively control OAMC through SQL procedures in order to optimize the trade-off between the quality of the solution and the efficiency of the calculations. For the current inventory level, module OAMC supply optimization procedure with the optimal assessment of missing components, so exact cost values can be calculated. Using calculated costs, optimization procedure defines best supply strategy for the first previous time period.

Optimization process is iterated recursively through the time periods, until the first period for which the inventory levels are known values. When *j* = 0, stored evaluation data from the database are used to release orders for components.

In the next Section, the detailed explanation of this example of dynamic MRP optimization is presented and in Section 6 the advantages of this approach are outlined through the experimental comparison with the best known results.

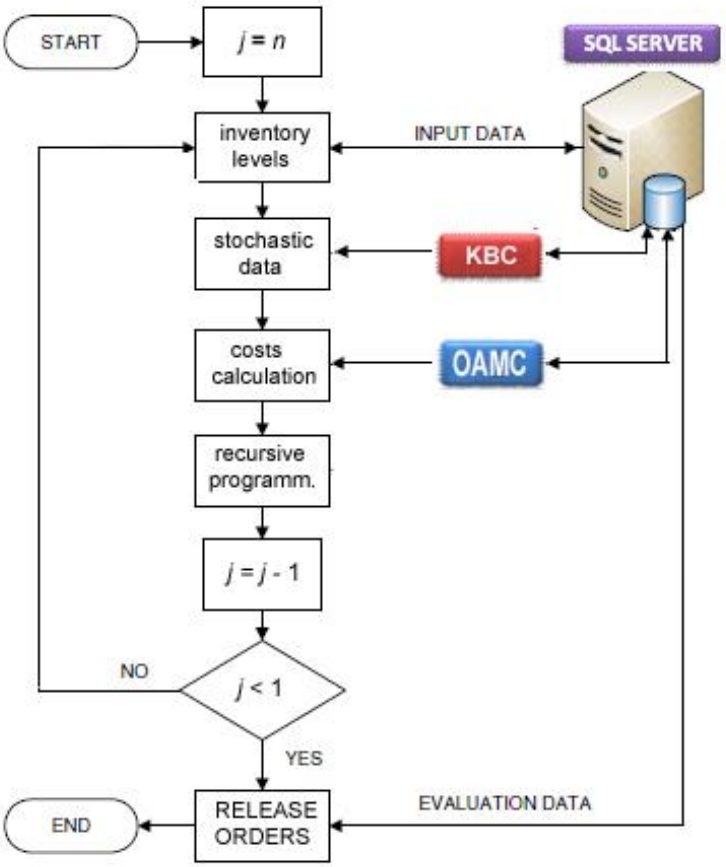

Figure 1: SPF for dynamic programming optimization

5. STOCHASTIC DYNAMIC MODEL

The stochastic inventory model involves the derivation of replenishment decisions over a discrete planning horizon consisting of a finite number of periods under stochastic demand and stochastic lead times. The demands and lead times for each period are usually sequences of random variables having arbitrary distributions. The objective is to determine the ordering quantities from period t = 1 to period $t = j - L$ so as to minimize the total expected ordering, holding and shortage costs. It is assumed in this example that order releases are at the end of the period and that the ordered inventory arrives immediately and is available at the beginning of the next period.

The stochastic process $\{x_k^0, \ldots, x_k^n\}$ is a Markov chain, so the first step is to optimize the decision made in the final period, that is, $\hat{\boldsymbol{Y}}^{\boldsymbol{n}}$, which minimizes total future cost, $W^n(\boldsymbol{X}^{\boldsymbol{n-1}})$ of that decision. The expected value of the cost function is

$$E[C(\boldsymbol{X}^{\boldsymbol{j-1}}, \boldsymbol{Y}^{\boldsymbol{j}})] = \sum_{k=1}^{nk} E[C(x_k^{j-1}, y_k^j)] = \sum_{k=1}^{nk} A + \sum_{k=1}^{nk} B,$$

where A is the expected value of the order component cost and B is the expected value of the sum of holding and shortage component costs:

$$A = o_k(y_k^j - x_k^{j-1}) \quad , y_k^j > x_k^{j-1};$$

$$B = E[C(y_k^j)] = \sum_{d=0}^{y_k^j - 1} h_k(y_k^j - d)\, fc_k^j(d) + \sum_{d=y_k^j+1}^{\infty} p_k^*(d - y_k^j)\, fc_k^j(d)$$

The major critique of this approach lies in it's inapplicability for the assembly systems where multiple finished products share a common component bank due to incorrectly defined variables p_k^* and $fc_k^j(d)$. The p_k^* is an abstract value which doesn't exists in the real environment. Only the value p_i for the finished product is known, and the estimation of p_k^* from p_i is impossible. On the other hand, the value $fc_k^j(d)$ must be calculated from expected demand of final products.

The following suggested approach more precisely defines this problem with the introduction of probability mass function of *nk* variables:

$$ff^j = f^j(d_1, d_2, ..., d_{nk}) = P\{dc_1^j = d_1 \wedge dc_2^j = d_2 \wedge ... \wedge dc_{nk}^j = d_{nk}\}.$$

The use of $ff^j(d_1, d_2, ..., d_{nk})$ enables efficient and simple inclusion of real costs into the model. The list of arguments $(d_1, d_2, ..., d_{nk})$ represents a specific sequence of component demand values. Therefore, KBC sets, for the *j*-th period, a set of sequences $\{\boldsymbol{\sigma}_r^j\}$, $r = 1, ..., rr$, where *rr* is the cardinality of the set and $\boldsymbol{\sigma}_r^j$ denotes the *r*-th sequence from a set. Denote by $\boldsymbol{\sigma}_r^j(k) = d_k^j$, the *k*-th element of the sequence $\boldsymbol{\sigma}_r^j$. Expected value of the cost function is then:

$$E[C(\boldsymbol{X}^{j-1}, \boldsymbol{Y}^j)] = \sum_{k=1}^{nk} A + \sum_{r=1}^{rr} \left[OTC(\boldsymbol{Y}^j, \boldsymbol{\sigma}_r^j) \cdot ff^j(r) \right],$$

noting that $OTC(\boldsymbol{Y}^j, \boldsymbol{\sigma}_r^j)$ is the optimal total cost for the current component quantities, obtained from the OAMC module. The data for $ff^j(r)$ can be stored as a data table in the database, and can be dynamically updated by KBC.

Using dynamic programming, value for $\hat{\boldsymbol{Y}}^n$ is obtained minimizing $E[C(\boldsymbol{X}^{n-1}, \boldsymbol{Y}^n)]$, so the total future cost is:

$$W^n(\boldsymbol{X}^{n-1}) = \min(E[C(\boldsymbol{X}^{n-1}, \boldsymbol{Y}^n)]).$$

Now, dynamic programming recursive function can be applied:

$$W^{n-1}(\boldsymbol{X}^{n-2}) = \min(E[C(\boldsymbol{X}^{n-2}, \boldsymbol{Y}^{n-1})] + E[W^n(\boldsymbol{X}^{n-1})]),$$

and the procedure can be proceeded until the first period, for which, the state of the inventory is a known value.

6. EXPERIMENTAL RESULTS

The aim of the experimental study is to outline the necessity for exact calculations of total costs for assembly systems, where final products share common component bank. In the literature, due to the complexity of the problem, no optimal assessments of missed components are considered. The only exception is the paper of Proth et al. (1997), which is an extended version of some previous works. Hereinafter their policy is denoted as PROTH. We will compare PROTH results with the results obtained with the proposed framework.

The PROTH policy introduces the sorting of product types in descending order according to their cost values, $p_i + \sum_{k=1}^{nk} q_{i,k} h_k$. Assembling of products is then performed according to this sorted list: we assemble as many products which type is the first element in the list, then products which type is the second element in the list, etc.

The example is described by the matrix *Q*, the vector ***p*** of product penalty costs and the vector ***h*** of component holding costs:

$$Q = \begin{Vmatrix} 3 & 1 & 2 & 3 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2 & 1 & 3 & 0 & 0 & 0 \\ 0 & 0 & 0 & 3 & 1 & 4 & 2 & 0 & 0 \\ 0 & 0 & 0 & 2 & 0 & 3 & 5 & 4 & 2 \end{Vmatrix}$$

$$\boldsymbol{h} = (2,3,1,3,2,5,3,5,2)\,,\quad \boldsymbol{p} = (200,150,200,150).$$

The demand for each product is d = 3 and the available quantity y_k of each component has value in (10, 12, 14). Proth's sorted order of products is (3,1,4,2). Table 1 presents randomly selected data from 19683 combinations of y_k values. Column O*i* presents the number of assembled *i*-type products when OTC is calculated and column P*i* presents the number of assembled *i*-type products when PROTH is applied. Column Δ holds absolute deviations in costs values for OTC and Proth, while column % shows relative deviations of the corresponding values.

Table 1: Comparison with PROTH assessment policy

y1	y2	y3	y4	y5	y6	y7	y8	y9	O1	O2	O3	O4	OTC	P1	P2	P3	P4	PROTH	Δ	%
10	10	10	14	10	12	10	10	10	2	2	0	2	1176	1	0	3	0	1451	275	23.38
10	10	10	14	10	10	10	10	10	3	0	1	1	1265	2	0	2	0	1458	193	15.26
10	10	12	12	10	10	10	10	10	2	1	0	2	1335	2	0	2	0	1454	119	8.91
14	14	12	14	14	10	14	14	14	3	0	1	1	1335	2	0	2	0	1528	193	14.46
12	10	10	12	10	14	12	10	10	1	1	1	2	1346	1	0	3	0	1465	119	8.84
12	12	14	12	10	10	10	10	10	2	1	0	2	1347	2	0	2	0	1466	119	8.83
12	10	12	12	10	14	12	10	10	1	1	1	2	1348	1	0	3	0	1467	119	8.83
10	12	12	12	14	12	10	10	10	2	1	0	2	1359	1	0	3	0	1461	102	7.51
14	14	12	10	12	12	12	10	14	1	0	1	2	1533	0	0	3	0	1699	166	10.83
10	12	12	10	14	14	10	14	14	2	0	0	2	1564	0	0	3	0	1713	149	9.53
14	14	12	10	14	14	14	14	14	0	0	2	2	1556	0	0	3	0	1739	183	11.76

From Table 1 it can be observed that, even for this simple example with only four final products, OTC and PROTH strategies result in entire different decisions about the assembling priority. The selected data in Table 1 represents the conclusions which are valid for the entire set of results. Costs, obtained by PROTH are always greater than OTC. For this particular example the relative deviation varies from 7% to more than 23%.

The proposed decisions for a certain planning period are now iterated through the dynamic recursion, so wrong decisions are multiplied through the iterations. The unambiguous conclusion is that algorithms with no optimal assessment policy cannot be applied to solve the MRP problem when multiple final products share common component bank.

7. CONCLUDING REMARKS

This paper presents an original framework that contains modules which are aimed at optimizing of supply planning under environmental uncertainty for complex assembly systems. As a detailed description of these modules is beyond the scope of a single paper, only the basic system settings are exposed here.

In cases where the cost, due to the lack of components, depends on the lack distribution, a multi-dimensional character of the problem causes exponential expansion of a feasible solution set. In the literature, the problem is avoided by introducing a service level, but this does not solve the problem in a significant number of applications. Additionally, correlated demand makes the problem even more complex.

The proposed framework has modules that serve for obtaining optimal assessments of missing components, for calculations of the optimal costs and incorporation of these costs into a known model. For the instances

having complex BOM structures, KBC and OAMC serve to reduce these structures to the level which is appropriate for the proposed procedures. The conclusion, which is common for all tested instances, is that it was always possible to reduce, even most complex BOM structures, to the structures that could efficiently be processed by the proposed procedures. The results, obtained on reduced networks, accurately reflected the real input variables of the problem. Experimental results at the end of this paper confirm the significant advantage of our proposed framework in comparison with the policy presented in Proth et al. (1997).

Limitations of the proposed approach are related to the depth of a corresponding network reduction, so future work on this problem has two possible directions: first, development of new modules for network reduction which would increase the number of instances that can be efficiently processed; next, determination of the most suitable stochastic procedures to treat multidimensional input variables.

Abstract: *This paper describes good practice of spreadsheet application in education. It enables operations management (OM) students to learn the logic behind software packages, to gain experience using a spreadsheet to model and solve real problems, to have a more clear view of the dynamics of business systems. We present modelling of operations management problems as discrete controlled object in spreadsheets. This concept allows clear separation between a discrete object (a low of behaviour and the control domain), a performance criterion, and a method used to find an optimal solution. Also, paper includes forecastig methods, developed in spreadsheets, as part of OM education. Benefit of approach, described in the paper, is in the easier understanding and solving of operations management problems for students. Approach is applied and tested in the education of operations managers at Faculty of Organizational Sciences, University of Belgrade. Primary purpose of paper is contribution to the development of spreadsheet models and spreadsheet applications in operations management education.*

Keywords*: operations management, education, spreadsheets, spreadsheet modeling, spreadsheet applications*

1. INTRODUCTION

In today business world, that is very competitive, spreadsheets play an important role as a business modelling, analysis, and decision support tool. Undergraduates from business, accountancy, information systems, economics, and social sciences schools, that doing internships in all business functional areas consider that Excel skills are invaluable and that corporate recruiters demand spreadsheet skills when hiring fresh graduates, as it is stated in Leong and Cheong (2008). It is therefore meaningful to examine how well spreadsheets are incorporated into management and engineering education and in what ways it can be improved. Most undergraduate programs on universities teach foundational courses in statistics, calculus, and computer programming. Their main purpose is to equip undergraduates with the ability to analyze and solve problems. Many students find learning such technical material dry and demanding and usually do not continue to apply those skills meaningfully beyond university course work. In order to facilitate acquiring of analytical skills for students, more professors that teaching these courses, and also teaching management science, have embraced spreadsheets as their primary computing and teaching tool, as it is stated in Liberatore and Nydick (1999),Winston (1996) and Winston (2004).

.

Research on spreadsheets in engineering education in the last few decades has placed great challenges on educators and other stakeholders to apply this computational tool both theoretically and practically towards improving the teaching process. These challenges have forced institutions of higher education to adapt spreadsheets for instructional purposes, with its enhancement tools as a means to improve the quality of engineering education, as it can be seen in Oke (2004). The need for high quality, learning-centred education has therefore made the application of spreadsheets important.

Spreadsheets are in accordance with active learning. Active learning allows students to discuss about problems, supports teamwork and problem solving activities. As it is described in Prince (2004) active learning is widely accepted as a far more effective mode of instruction than lecture alone.

This paper analyses spreadsheet models and application in education of operations managers. We organize paper as follows. In the introduction and second chapter, we briefly explained the need for spreadsheet application in education. Specifically, we base our review on operations management (OM) education. Chapter three describes concept of modelling business dynamics in spreadsheet as discrete controlled object. This chapter presents a low of behaviour, the control domain, a performance criterion, and a method used to find an optimal solution of operations management problems, modelled as discrete controlled object

in spreadsheets. Section four is dedicated to forecasting in a spreadsheet, as another example of learning the logic of operations management problems. Finally, we made general remarks and present future directions.

2. THE APPLICATION OF SPREADSHEETS IN OM EDUCATION

In the field of education, spreadsheets can be utilized in many different ways. Spreadsheets reduce the need for tedious calculations allowing greater attention to be focused on the subject itself. This feature of spreadsheets can be used in many disciplines across the curriculum. The distinction should be made between "content of the curriculum" which includes terms, facts, symbols, formulas, principles etc. and "process skills" which cover observing, measuring, inferring, communicating and experimenting. On the basis of this distinction, students should be given the opportunity to design and develop their own templates in each content area, and also to use the devices to solve problems and make decisions on the basis of quantified evidence. Spreadsheets are very useful for achievement of these objectives, since they are capable of solving different problems involving numbers or formulas, and are especially powerful if data are used repetitively and changing over time.

Using spreadsheet software in operations management courses can add relevance by enabling students to work on problems and data sets that are larger than textbook examples and similar in size to those they encounter in the real world, as it is presented in Gardner (2008). Having students build their own operations management software in a spreadsheet, takes students beyond the learning experience of using special purpose software by enabling them:

- to learn the logic behind software packages,
- to gain experience using a spreadsheet to solve real problems,
- to have a more transparent view of business systems dynamics, and
- to learn to organize and manage their work.

Lecturer can focus on the process logic, organizing the spreadsheet according to the logic while demonstrating the dynamics of business systems and processes, rather than teach spreadsheet mechanics. Spreadsheet projects are particularly good tools to use with hands-on learners and the charting capabilities make them effective with visual learners.

3. BUSINESS DYNAMICS IN SPREADSHEETS

Spreadsheet simulation is very appropriate for business dynamics understanding and modelling. One of convenient approaches for representing model of real operation management problems in spreadsheets is provided by discrete controlled object concept. This concept allows clear separation between a discrete object (a low of behaviour and the control domain), a performance criterion, and a method used to find an optimal solution. Spreadsheet structure, consisted of rows and columns, is appropriate for presenting different value of variables in time periods, as it is described in Kostic (2001). For example, dynamic discrete EOQ problem to find optimal number of replenishments in the fixed-order quantity system as a basic problem of optimal control can be modelled as discrete controlled object in spreadsheets, as it is showed in Kostic (2009). The decision environment is deterministic and the time horizon is finite. A discrete system consists of the law of dynamics, control domain and performance criterion. It is primarily a simulation model of business dynamics, but the performance criterion enables various order strategies to be compared. Model of discrete system control is both a simulation model of business dynamics and an optimization model which can give optimal control according to the defined performance criterion. This approach is appropriate for modelling and solving various types of operations management problems as:

- Minimizing costs of raw materials procurement;
- Production costs minimization;
- Route optimization;
- Production dynamics optimization;
- Business management financial aspects;
- Investment funds allocation;
- Transport cost minimization, etc.

The process that we follow in order to make students understand business dynamics and build their own model of discrete controlled object in a spreadsheet is:

1. Problem presenting and verbal description;
2. Problem analyzing:
    a. Time horizon and time intervals defining;
    b. System flows identification (actions and accumulations);
    c. Factors of influence identification (circumstances and control);

   d. Flow regulator relations development;
   e. Control domain constraints:
      - flow non negativity constraints;
      - available capacity constraints;
      - storage space constraints;
      - other constraints;
   f. Performance criterion formulation;
   g. Combined flows block diagram;
3. Optimal control problem:
   a. Transformation to basic problem form;
   b. Discrete object optimal control problem defining;
4. Spreadsheet simulation:
   a. Transformation of mathematical relations to spreadsheet formulas and functions;
   b. Tables, menus, reports and graphs organization;
   c. One admissible solution determination;
   d. Better solution determination;
5. Spreadsheet optimization (control domain searching);
6. Findings;

Students repeat described process for every new problem that is presented on the lectures. At the beginning of each class professor presents the underlying logic of problem for practice, using one or more examples in a lecture. Each student constructs spreadsheet model or application in a computer lab under the supervision of the instructor who may do a step-by-step demonstration. Over the course of the semester, as students gain experience with spreadsheet models, the detail level of instructions diminishes. This forces students to rely more and more on what they have learned from previous problems. At the end of course students have to model and solve assigned problems by themselves, with little or no help from the instructor because the goal is to teach students to work independently.

In the following of paper we will present simple example of transportation costs minimization problem, translated to discrete controlled object problem developed in spreadsheet, Kostić (2012). Problem is presented in order to describe learning process, which is created for better understanding and modeling of system dynamics.

Company has an obligation to deliver product X over next four periods in the dynamics defined in Table 1. There are three types of vehicles: P1, P2 and P3 that are available for transport. Capacity of vehicle represents number of containers in one period of time, and it is given in Table 2. Containers dimensions depend from vehicle type. Numbers of product X units that can be placed in containers are given in Table 3.

Table 1: Product delivery dynamics

Period	1	2	3	4
Quantity	290	215	200	390

Table 2: Capacity of vehicle

Vehicle	P1	P2	P3
Capacity	4	6	3

Table 3: No. of X units/cont.

Vehicle	P1	P2	P3
Capacity	50	45	65

Transportation cost is different for every type of vehicle, and also depends from time period, as it is shown in Table 4.

Table 4: Transportation cost/cont.

Vehicle	1	2	3	4
P1	3	2	3	2
P2	2	4	4	3
P3	4	3	2	4

Students have to define transportation plan that will satisfy given product delivery dynamic and to minimize total transportation costs.
In order to model problem in the spreadsheet, students have to identify flows of system. In this case, there are three material flows, where subject is product X, transported with particular type of vehicle. Phases of flows are:

vehicle 1 transport type
vehicle 2 transport type
vehicle 3 transport type
Yi
action

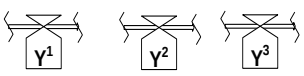

Figure 1: One phase flows

Phases of flow can be presented as it is shown in Figure 1, where Y_t^i represents transport of product X with transport vehicle i (i=1,2,3) in time period t.

Next step is influence factors identification. Influence factors are recognized in verbal description of problem.

p_t^1 - product X transport dynamics

p_t^{i+1} - available containers for transportation vehicle i (i=1,2,3)

p_t^{i+4} - container i capacity (i=1,2,3)

p_t^{i+7} - transportation cost for container i (i=1,2,3)

u_t^i - quantity of product X transported with vehicle i (i=1,2,3)

After problem flows and influence factors identification, students are familiar with problem. Now, they can start with mathematical modeling. In described problem, flow regulators equation development considers that for all vehicles transport is discrete, with stages on the beginning of time periods. Total of all previous delays of function rebound, when discrete quantity is created, is equal zero. Because of that, delay factors K_i (i=1,2,3) are also zero, and whole discrete quantity of flow $c_i = u_i$ (i=1,2,3) is realized in the same time period as its realization started.

$$Y_t^i = u_t^i \ , \ i = 1,2,3; \ t = 1,2,3,4 \tag{1}$$

Relations for constraints of available containers capacity, that has to be engaged for transport of u_i product X units, are following:

$$S_t^i = INT[\frac{u_t^i}{p_t^{i+4}}] + \delta_t^i \tag{2}$$

$$\delta_t^i = \begin{matrix} 1 \ za \ \frac{u_t^i}{p_t^{i+4}} - INT[\frac{u_t^i}{p_t^{i+4}}] > 0 \\ 0 \ za \ \frac{u_t^i}{p_t^{i+4}} - INT[\frac{u_t^i}{p_t^{i+4}}] = 0 \end{matrix} , \ i = 1,2,3; \ t = 1,2,3,4 \tag{3}$$

That number can't be greater than number of available containers for transport vehicle i.

$$S_t^i \le p_t^{i+1} \quad i = 1,2,3; \ t = 1,2,3,4$$

Realization of transportation plan, which will satisfy given product delivery dynamic, has to be included in control space relations.

$$p_t^1 = \sum_{i=1}^{3} u_t^i, \quad t = 1,2,3,4 \tag{4}$$

Goal function represents minimization of total transportation costs.

$$\min\{J = \sum_{t=1}^{4} \sum_{i=1}^{3} S_t^i \cdot p_t^{i+7}\} \tag{5}$$

Now, discrete control object is defined through the low of behavior

$$Y_t^i = u_t^i \ , \ i = 1,2,3; \ t = 1,2,3,4 \tag{6}$$

and control domain

$$0 \le p_t^{i+1} - S_t^i$$
$$0 = p_t^1 - \sum_{i=1}^{3} u_t^i, \quad i = 1,2,3;\ t = 1,2,3,4 \tag{7}$$

where

$$\delta_t^i = \begin{matrix} 1\ za\ \frac{u_t^i}{p_t^{i+4}} - INT[\frac{u_t^i}{p_t^{i+4}}] > 0 \\ 0\ za\ \frac{u_t^i}{p_t^{i+4}} - INT[\frac{u_t^i}{p_t^{i+4}}] = 0 \end{matrix}, \quad i = 1,2,3;\ t = 1,2,3,4 \tag{8}$$

$$S_t^i = INT[\frac{u_t^i}{p_t^{i+4}}] + \delta_t^i$$

Initial state is known $X_0^i = 0$ (i=1,2,3).

For defined object, admissible control should be chosen in accordance with circumstances dynamic p^s_t (s=1,2,...,10; t=1,2,3,4) for time periods T=4, in the way that will guide discrete object from known initial state X_0^i to the set of final phase states $X_4^i \in M_4$. For every t=1,2,3,4 control space constrains have to be satisfied and goal function J has to be minimized.

When mathematical model is created, students translate relations to spreadsheet model. Tables in worksheet are arranged in defined areas, for example:

- values for circumstances variables p are arranged in area D11:G20
- formulas for auxiliary variables δ are arranged in area D24:G26
- formulas for auxiliary variables S are arranged in area D30:G32
- control variables should be written in area D36:G38
- formulas for control space O are arranged in area D42:G46
- formulas for goal function are arranged in area D50:G50

Simulation model in spreadsheet is obtained when mathematical relations for discrete control object are translated in appropriate spreadsheet formulas and functions. Next paragraph presents spreadsheet formulas for time period t=1, in column D. These formulas should be copied in next three columns.

AUXILIARY VARIABLES δ
D24 =IF(D36/D15-TRUNC(D36/D15)>0;1;0)

Figure 2: Spreadsheet model of the problem

Careful selection of control variables values leads to admissible solution. Admissible solution provides non negativity of control space, arranged in area D42:G46. Negative values in control space are guide for admissible solution finding. Better solution is one that gives smaller value to goal function. When all described steps are realized, spreadsheet model for transportation costs minimization problem translated in discrete control object problem is created. This model is presented in the Figure 2.

4. FORECASTING IN SPREADSHEETS

Forecasting is another topic where students need to understand the underlying technique, but where textbook examples, that are small enough for hand computation, are too small to be realistic. As it is demonstrated in Gardner (2008) spreadsheets allow students:

- to understand mathematical concepts and techniques by enabling them to see the computation, without having to do the computation and get lost in the mechanics,
- to see the effects of changing parameters for various forecasting models,
- to learn to adapt forecasting models to special situations,
- to see the effects of data issues on forecasts,
- to use critical thinking skills to evaluate forecasting models, and
- to learn to organize their work.

Charting capabilities enhance the effectiveness of spreadsheets as a learning tool by providing visual images that enable students to observe the properties and limitations of the various forecasting techniques. This works particularly well for students who are visual learners.

Moving averages and exponential smoothing concepts (Holt and Winters forecasting methods) are much easier for understanding through copying formulas down a column in a spreadsheet, using data generated in the previous row. Data and formulas for the Holt forecasting procedure in spreadsheet are presented in the Figure 3.

	A	B	C	D	E	F	G	H	I	J
1	No.	Year	Actual demand X_t	Level L_t	Trend T_t	Forecast F_t	Mean squared error			
2	0	1999	3500	3200	1000			α=	1	
3	1	2000	4200	4200	1000	4200	0	β=	0	
4	2	2001	4800	4800	1000	5200	160000			
5	3	2002	5300	5300	1000	5800	250000			
6	4	2003	6700	6700	1000	6300	160000			
7	5	2004	8000	8000	1000	7700	90000			
8	6	2005	9200	9200	1000	9000	40000			
9	7	2006				10200				
10	8	2007				11200				
11	9	2008				12200				
12	10	2009				13200	116666,7	=MSE		
13	11	2010				14200				

=α*Xt+(1-α)*(Lt-1+Tt-1)

=β*(L_t-L_{t-1})+(1-β)*T_{t-1}

=L_t+T_t

=(X_t-F_t)^2

=L_t+n*T_t

Figure 3: The Holt forecasting procedure in spreadsheet

As it is presented in the Figure 3, students enter formulas for the first period and known initial values, and then copy them. For example, formulas needed to be entered in presented model are following:

LEVEL Lt
D3 =$I$2*C3+(1-$I$2)*(D2+E2)
TREND Tt
E3 =$I$3*(D3-D2)+(1-$I$3)*E2
FORECAST FOR ONE FUTURE PERIOD
F3 =D2+E2
FORECAST FOR n FUTURE PERIODS
F9 =$C$8+(A9-$A$8)*$E$8
MEAN SQUARED ERROR
G3 =(C3-F3)^2

The effect of changing parameters can be taught very effectively with a spreadsheet. In the case of exponential smoothing, smoothing constants can be maintained in cells that are referenced from the formulas so the constants can be easily changed and the formulas and charts updated automatically. By constructing the spreadsheet to accommodate multiple forecasts, the lagging and smoothing effects of different smoothing constants can be illustrated in a chart as in the Figure 4. This again allows the student to mentally connect the concepts of the parameter, the formula, and the visual image of the chart.

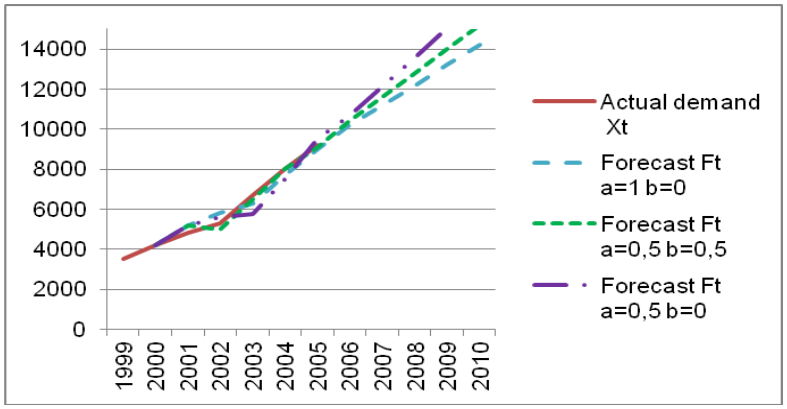

Figure 4: Comparison of Exponential Smoothing Parameters

5. CONCLUSION

Approach described in this paper is applied and tested in the education of operations managers at Faculty of Organizational Sciences, University of Belgrade, Serbia. This approach is used in education process, for students of the third and fourth year of undergraduate studies. As a result of this curriculum implementation in the classroom, we came to the conclusions that are given in the further of paper.

The final benefit of learning through spreadsheet approach is that students must learn to recognize problems in real world, describe noticed problems, translate them to mathematical and spreadsheet model, and try to find some satisfactory solution. Whole process teaches students to plan, organize, and assure quality in their work. In this way, students overcome usual fact that forecasting packages, ERP systems and other software packages appear to be black boxes that take data inputs and spit out answers without giving them any insight into the solution process. Students are learned to understand how the process behind the software works, to understand limitations and to recognize when data are missing or inappropriate for the application. Also, as employees, they are capable to model problem or create application by their own.

Most textbooks have spreadsheet models to accompany them, but that is not the case when some of the real projects should be implemented. Some texts, such as Barlow (2005) are actually spreadsheet-based. As it is proven in Gardner (2008), having students build their own operations management software in a spreadsheet enables improves and learning by allowing the instructor to tailor the software and the instructions for developing it:

- to the students' level of knowledge and ability,
- to any textbook, and
- to the instructor's teaching style and real-world experience.

Being able to adapt, rather than adopt, teaching materials can provide a more satisfying teaching and learning experience for both instructors and students.

As it is presented in the paper, dynamic discrete models are very appropriate for developing in spreadsheets because of the approach that takes as principal variable a discrete time t and separation of the law of dynamics, control domain, performance criterion and a method used to find an optimal solution. Spreadsheet structure of rows and columns is appropriate for developing this kind of model. Model set in spreadsheet in this way provide quality base for simulation, which is very useful for laboratory experiments in educational purposes. In this way students can understand the problem, develop mathematical model, translate it to spreadsheet model and run simulation.

One of directions for further elaboration of using spreadsheets in operations management education can be based on the integration of spreadsheet models and heuristic methods in order to solve different operations management problems modelled as discrete control systems. That approach could lead to the development of software applications, which would allow students to introduce and use searching methods, in order to achieve higher level of applied knowledge, which can be used for OM problems solving. Another possible application of spreadsheet in OM education is combination of Visual Basic for Application and spreadsheets, as very appropriate tool in problem solving. Usage of Visual Basic for Application and spreadsheets allow student to create own information system or software adjusted to exact problem. Even better, this kind of software is very quick to create, thanks to Visual Basic and spreadsheets characteristics. Also, any changes that should be implemented in model and application are easy to make.

omeja@fon.rs, atanasovn@fon.rs, zrakicevic@fon.rs

Abstract: ***The topic*** *of this paper was born out of the* ***pratical need for improving collaboration also within planning,*** *and it deals with synchronising a) constant improvement of Planning Systems (principles, concepts, processes, structure, software sulutions etc.) of the Supply Chain members (SCPS) and b) limited ability of the SC members (especially if they are of the small and medium enterprise type – SMEs) to maintain the required software solutions needed to support such a dynamic planning system in SC. Bearing in mind: a) the different types of SC and their members (big business and/or SME), b) the complexity of planning per se, c) the different ways of organising for planning in LS and d) the difficulty in applying software changes within SCPS (stress, waiting, cost etc.),* ***the problem*** *is how to ensure adequate, but not overly expensive software support (new or improved) in a timely fashion for the new SCPS concept. The initial* ***hypothesis*** *is that there is at least one way in which it is possible to develop SCPS and, at the same time maintain the adequacy of the software solution supporting it. The paper is* ***intended*** *for those who design and construct SCPS, as well as all users of it, with the intention to increase awareness of the necessity for constant development of that particular system and about the need for its flexibility, as well as the awareness of the significance and possibilities of planning system engineering. At the same time it is also intended for those who create SCPS software – so that they bear in mind that their software should be functional even if significant changes within SCPS occur. In this paper we have shown a SC model followed by the relevant problem areas (and related works): planning in SC, with the need for SCPS improvement, and the standard software solutions in SC planning/management. In the section about research and results, we have defined seven research questions; we have then* ***pointed out*** *the significant elements of participant collaboration complexity within SC, as well as the possibility for maintaining the adequacy (relevancy) of the software solutions whilst constantly imporving SCPS.*

Keywords: System Planning, Supply Chain (SC), Collaboration in SC, Software Solutions adequacy, SC Planning System Improvement

1. INTRODUCTION

Management of organizational systems, both individual and those associated in supply chains (SC), begins with planning. Planning is the process of defining goals and their decomposition to the level of operational objectives, defining the necessary operations for transforming objects of work and defining the associated resource requirements, as well as determining the total demand for resources and ensuring their availability (Omerbegovic-Bijelovic, 2010). This large task becomes even more complicated when connecting companies in SC (Fig. 1), because the planning for one company becomes the planning for a number of companies - related by management (including planning), but also by business, technological, economic, and formal - legal issues.

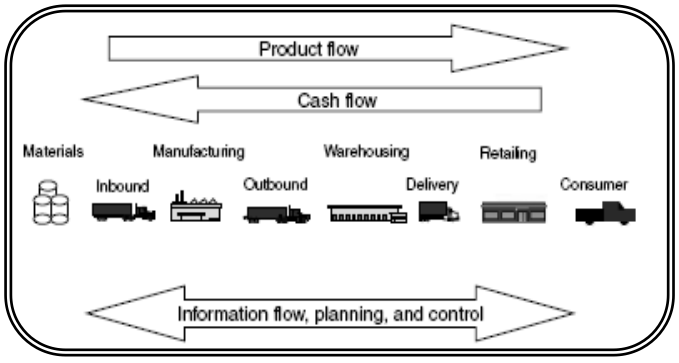

Figure 1: A classic view of the supply chain
Source: Schutt, 2004, p. 6.

Supply/value chain can be composed of two (buyer and seller, or resource supplier and manufacturers, or alike) or more consecutively positioned participants in the process of transformation of objects of work. Their predecessors and successors in the process (e.g. from those engaged in extracting ores, to those engaged in retail business of mixer bars) may also be members of SC. Carriers and others who provide various services to the other members (and thereby add value to the work of SC) are also SC participants/members, but are often omitted from consideration due to the simplicity of the model.

SC can be serial or divergent (Dominguez, 2014). As each participant in a SC may have more "input partners" and more "output partners," it is possible to generate more SCs (Fig. 2), and to plan for one or, more rarely, for more SCs, over the same set of partners.

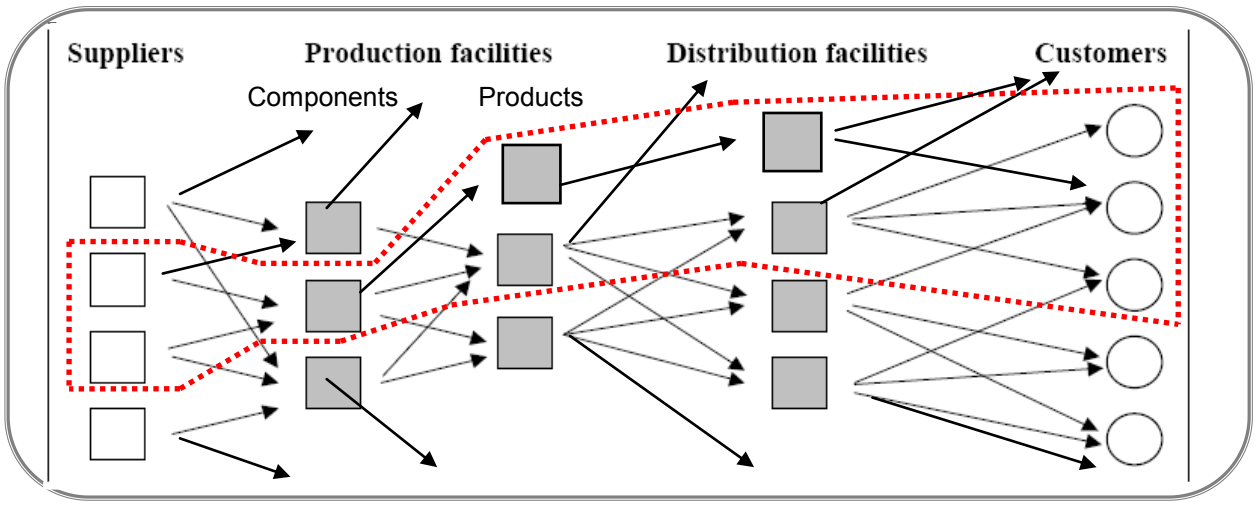

Figure 2. One possible supply chain in planning system network structure
Source: with adaptation from Dudek (2009), p. 26.

Planning in SC (as a system, SCPS) implies a shift from "individual" planning (successive and segregate) to collaborative planning in SC, wherein the collaborative planning approaches can be:
a) *Hierarchical planning approach* - with centralized guidance in planning in SC, with the inevitable use of modern software solutions, including using APS (*Advanced Planning and Scheduling*), models and methods of operations research and others.
b) *Non-hierarchical approach to planning* - essentially collaborative planning based on coordination between the selected areas of business planning ("*planning domain*") of participants in SC (Fig. 3). Thus it is possible to arrange that a supplier/manufacturer plans to supply a customer independently (VMI - *Vendor Managed Inventory*), to cooperate in the supply planning (CMI, Co-Managed Inventory) or to work together on planning, forecasting and supply (CPFR, Collaborative Planning, Forecasting and Replenishment).

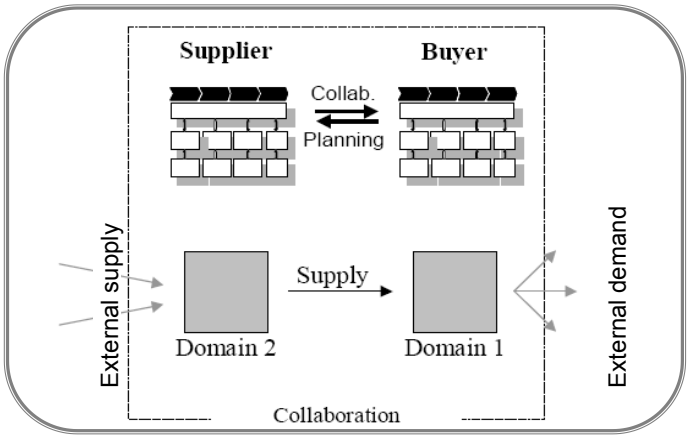

Figure 3: Two party collaborative planning
Source: Dudek, 2009, p. 58.

Due to the possibility of different interpretations of the term "collaborative planning", here it refers to: planning operations in SC, through the planning of operations of selected, contracted "*planning domain*". SC is planned according to time horizon (*far shorter than before*), and within a longer time horizon (in the corresponding number of iterations) it is planned for shorter periods. A long-term, medium-term and short-term plans still exist, and companies make "major" (master) plans for 12 (and/or 18) months - on a "rolling planning" principle. The principle implies also that plans relating to the shorter period give more reliable data. Typically, a master plan does not leave out the most important data (Table 1).

Table 1: Basic decisions of master planning, Source: Rohde / Wagner (2005), p.159.

N°	Decision type	Description
1	Procurement	Quantities of input materials purchased from external suppliers
2	Production / Material handling	Production and handling quantities, or output levels of other relevant operational processes
3	Inventories	Inventory levels at the end of planning periods
4	Customer shipments	Quantities supplied to customers and their origins
5	Transports	Transport quantities on all transport links considered

Besides on negotiation and contracts, the collaboration between members of a SC is based on the fulfillment of the contracted issues and on building the trust among SC participants. Therefore, collaboration is

established in multiple phases (Kilger and Reuter, 2005, p. 271): Domain planning, Data exchange, Negotiation&Exception handling, Execution, Performance measurement.

When it comes to the realization of the planning process, it is done by a pull principle: first the outputs from SC are determined, then predecessors' operations, upstream. At each stage (for each participant in SC) firstly the type and quantity of its output are determined, and then - based on consumption norms - the necessary amount of resources (which should be obtained from the predecessor in SC). The neighbours in SC cooperate on the level of "planning domain" (Fig. 4).

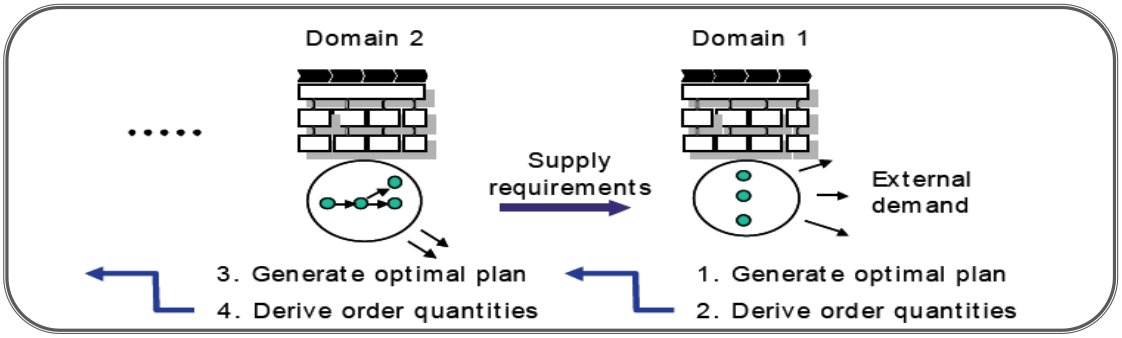

Figure 4: Upstream planning scheme
Source: Dudek (2009), p. 47.

The above suggests the complexity of the problems of planning systems in SC (SCPS). The complexity increases when we take into consideration the development of SCPS. As the system implies a process (processes) and structure, here the "organization to plan," as well as appropriate meta-managerial tools (Omerbegovic - Bijelovic, 1998) such as concepts / models, methods, technical means and organizational tools (including software), their development even more/ further multiplies the complexity of SCPS.
This paper is written based on the following structure: Section 2 explains the conceptual framework and gives the problem description; in Section 3 survey results are presented, and Section 4 summarizes some concluding remarks and suggestions for further studies.

2. PROBLEM DESCRIPTION AND LITERATURE REVIEW

Working within SC demands serious activities and resources for synchronising the varied interests and operations of its members. Synchronising the SC functioning starts with planning (SCPS), which, in time, changes (as a rule: improves). Planning in SC has, for decades, been impossible without software support. That support needs to change together with the changes within SCPS. SC members, not only within the SME category – which have “evidently of limited capacity” (Sitompul, 2012), and can therefore seem like a serious if not insurpountable problem – especially if the changes are very frequent. This is why some members of SC, unable to follow developments, decide on ceasing to be in SC altogether or find other solutions for keeping the relevancy of their software planning solutions.

2.1. Planning in supply chains

Schut (2004, p. 219) states that planning (including SC) covers the following areas: Sales Forecasting, Quantitative support for Sales & Operations Planning, Integrated Supply Chain Tactical Planning, Production requirements calculation from distribution network requirements, Master Scheduling of production, Detailed scheduling of production, Inventory deployment planning in a distribution network and Short-range transportation planning and load building. By Zamarripa et al. (2012), “the typical scope of the **SC planning problem** is to determine the optimal production levels, inventories and product distribution in an organized network of production sites, distribution centers, consumers, etc., taking care of the constraints associated to products and raw materials availability, storage limits, etc. in such network nodes.”

All of these areas (and others relevant to SCPS) are based on mathematical modelling and programming, which is an argument in favour of claims that there is no modern planning without software support. (*Of course, sometimes, in special circumstances and only for the limited scope of issues / narrow fields, even today it is possible to obtain an acceptable solution without software support.*) But the business system is so complex that it is impossible (and certainly not profitable) to operate without adequate software support in the conditions of contemporary competition.

2.1.1. Planning of one participant in a supply chain

Participants in SC can retain a tendency to "individualistic" or "disconnected" planning in SC (DSC), reffering to planning without involving other parties and without "spreading" the scope of the information based on which the planning is done. Moreover, within a single company so called "Functional silos" may appear

where there is a lack of cooperation between different functions within a company. In the same way we can define the ”planners' silos” in SC, where the planning is done without taking into consideration the attitudes/knowledge of other participants in SC who are also involved in the planning (planning "within the closed box"). This planning approach implies that a company plans only internal activities (procurement, production, sales) that are directly related to the supply/demand of the first predecessor/successor in SC. Companies that aim to integrate the entire supply chain tend to eliminate "functional-" and "planning silos" and create inter-functional processes.

2.1.2. Cooperation between neighbouring participants in SC in production and inventory planning

Cooperation between neighbouring participants in SC in the area of production and inventory planning in different participants in SC has been studied by many authors. Prominent authors in this area (Lee, Padmanabhan and Whang, 1997; Barratt and Oliveira, 2001) agree that the presentation of sales data from retail outlets is useful information for manufacturing companies that are planning the production in line with demand forecasts. Raghunathan (1999) claims that a manufacturer reduces its costs to a different extent, depending on the number (percentage share) of retailers who share their sales forecasts with a manufacturer, as well as that the cooperation in forecasting helps to reduce the cost of the retail chain which shares its forecasts with a manufacturer.
Paiva et al. (2014) suggest that supply planning and trust-based relationship within buyers and suppliers are positively related and both influence supply integration and operational performance. They claim that “integration with suppliers is the means by which companies work with suppliers seeking mutual objectives, sharing ideas, information, knowledge, risks, rewards and solutions to common problems”.

2.1.3. The cooperation of the entire supply chain in production and inventory planning

It is assumed that some of the members of SC (e.g. retail) have limited interest in participating in the exchange of information and cooperation in SCPS . The key reason for cooperation can be identified by the fact that SCPS is a prerequisite for the efficient supply of all the members of SC.
Cao and Zhang (2011) consider collaborative relationships and find that they “can help firms share risks, access complementary resources, reduce transaction costs and enhance productivity, and enhance profit performance and competitive advantage over time”. Collaboration concerns with the alignment of decisions and actions amongst SC members - in their planning and inventory management. This alignment is enabled by the exchange of information in the SC (Stadtler 2009).

The availability of relevant information provides a manufacturer with better production planning, especially for products with a high variation in demand. As production plans are developed under the direct influence of identified demand, this means the possibility of creating a detailed and reliable delivery and supply schedule, using simulations in defining future orders, for example. A manufacturer is enabled to create its own delivery plan that is probably different from that of the customer's orders, with the adjustment of production plans to the real market needs. Considering research studies, according to Småros (2007), it is possible to draw a general conclusion that the availability of sales data from customers' facilities to the end user is a very significant potential for improving business of manufacturing enterprises. Studies show that by a combination of reports on orders of retail outlets and reports on the flow of goods in distribution centers of retail chains (which are governed by the concept of VMI), a production company can benefit even when only a handful of the total number of customers and retailers is involved in the collaboration system. The greater part (%) of its sales is "covered" by including into the VMI system, the better for all participants in SC.

2.2. Application software in supply chain planning

The general trend of the software manufacturers is the integration of supply chain components into existing software packages (ERP) in order to offer customers a complete solution designed for the overall needs of companies in SC. According to (Yen, Chou and Chang, 2002), in most cases, softwares for SC management (SCM software) are software solutions specifically developed for the needs of companies of a certain type (production, storage, distribution, trade). Some of the major software vendors have tried to combine different and specific software solutions for SC in a single software solution. According to (Yen, Chou and Chang, 2002), the best solution for the success of SC is the development of SCM software in two ways: a) The solutions that support the planning of participants in SC (Supply Chain Planning Software), and b) Software solutions that support the operational functioning of SC (Supply Chain Execution Software). *Softwares used for planning in SCs* are based on mathematical algorithms whose implementation optimize the flow of information and goods, enhance the efficiency of the SCs and optimize inventories. These software solutions are completely dependent on the available information and its reliability (precision). Software for planning in SC provides the support for these most important functions of SC; the greatest contribution is realized in the demand planning, which is the initial plan for all other activities in the chain - based on which further plans are created. *Software intended to support the operational functioning of SC* is designed for automation of SC

specific needs (e.g. vehicle route optimization in distribution or automatic ordering in accordance with predefined signal inventories/re-order point).

2.2.1. Software packages for production and inventory planning of one participant in SC

Software used for planning in SC allows SC members to manage inventory in line with sales and demand forecasts. As part of the SCM in general, a software solution for SC planning (S&OP - Sales and Operations Planning) plays an important role in reducing costs and improving the profitability of a company. Using software for SC planning (such as Modules for demand planning or S&OP modules), based on historical data and along with the expected activities to improve sales, companies can simulate the potential demand and, in line with expectations, harmonize inventories of finished goods and raw materials.

In some cases the software components required to manage SC represent solutions that are fully integrated into the standard ERP, while in the others they represent separate modules or fully independent software solutions for the management of SC. According to (Kumar, 2001), software solutions for the SCM have a very large impact on the performance of the entire company, which has been recognized by leading software manufacturers. Major producers of software (SAP and Oracle) are dedicated to the further development of software for SCSP; this resulted in the creation of advanced software modules aimed at "complex" planning in SC (Chang and Makatsoris, 2001).

Current software solutions for planning in SC enable cooperation between a manufacturer and buyer through the exchange of information on the available stock and realized sales, in order to perform mutual optimization of inventories. According to the recommendation made by Software AdviceTM (www.softwaradvice.com), in accordance with the cost of software, the number of implementation and success in optimizing inventory, the following software packages are recommended: JD Edwards, WISERoyal, SCP 4.0, SAP-SCM, PackManagerNulogy's, iTracker Hosted 3PL, MachSix, IBS Enterprise Manufacturers, POOL4TOOL and Quintiq's Supply Chain Planning & Optimization.

SC aims to integrate all the key business processes. In practice, it happens that the key processes in SC individually do not have uniformed adequacy of software support, which implies a reduction of compatibility and causes missed business results.

Standard business softwares (ERP) are primarily focused on providing software support to internal operations (production planning, inventory records of raw materials and finished goods, material and financial records - accounting, etc.). In contrast to standard ERP solutions, software solutions designed for SC are focused both on internal business activities and on external processes among participants in SC. According to (Buxmann, von Ahsen, Díaz and Wolf, 2004), the largest number of Supply Chain Management Software packages support SCPS (all SC members who cooperate in planning), while standard ERP solutions provide automation and support in the implementation of operational plans.

The most common system of advanced planning, APS, provides immediate response to customer requirements providing timely and reliable information from the business system of a production company. APS system is a concept on which the software for SCM is based. The basic structure of APS concept ensures the creation of software that consists of the following planning modules and sub-modules: Strategic Network Planning, Demand Fulfilment & ATP, Production Planning and Scheduling, Transportation Planning and Distribution Planning.

2.2.2. Software support to production and inventory planning with the cooperation of neighboring participants in SC

From the perspective of the cooperation in the SC planning, one of the most important goals is to achieve harmonized interpretation of: 1) the problems that exist in all participants, 2) the functioning system of observed supply chain, and 3) the approach to decision making. The key to success is the adoption of comprehensive optimal decisions based on the collective knowledge of participants in SCPS.

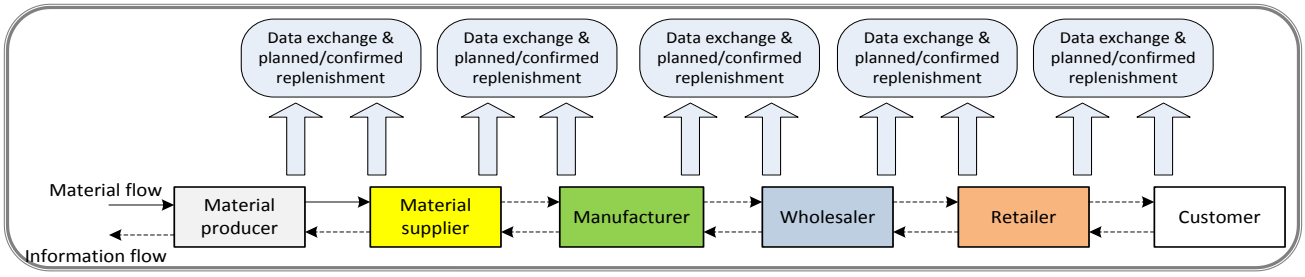

Figure 5. Model of cooperation of neighbouring participants in SC planning

The model of cooperation of neighboring participants in planning in SC is shown in Figure 5. Software tools that provide cooperation in planning in supply chains should be clear and "user friendly" for all members of

SC, transparent (and to show valid and accurate information), provide monitoring of performance indicators of all participants in the SC planning, as well as enable compatibility with different software (ERP solutions) used by participants in the SC.

In their studies (Stadler and Kilger, 2005) presented (by APS matrix) the list of software manufacturers that base their software solutions on the APS. The survey by the SCM Competence & Transfer, published in (Laakmann et al., 2003) included 23 APS software solutions. Stadler and Kilger (2005) summarized the results of the survey and presented the complemented results by APS matrix (**Table 2**). Some of the most important comprehensive software solutions for SCM, based on the APS, are i2 Technologies, PeopleSoft and SAP (with *Advanced Planner and Optimizer* (APO)). In these comprehensive solutions it is possible to use only a specific module, in case of limited need.

i2 Technologies offers the solution from i2 software modules, mostly directly connected with the planning in SC: SC Strategist, Demand Manager, Supply Chain Planner, Factory Planner, Production Scheduler, Demand Fulfilment, Enterprise Project Planner and Transportation Modeler, Optimizer and Manager.

Table 2. The planning process in SC and APS

PeopleSoft as part of Oracle's Advanced Supply Chain Planning (ASCP) provides companies with the ability to plan in the entire supply chain through a "holistic planning, scheduling and optimization". ASCP is a simultaneous approach to planning for all members of the SC - suppliers, manufacturers and distribution centres, both in short and in long terms. The concept of APS in this software is implemented through the following modules: Strategic Network Optimization, Production & Distribution Planning (PDP) and Vehicle Loading, Demand Management (Demand Forecasting and Demand Consensus, Production Scheduling Process (PSP), Production Scheduling and Discrete Order Promising.

SAP AG offers the SAP APO (based on APS). APO is a fully integrated APS solution, which is accessed through the application of Supply Chain Cockpit. It contains the modules: Demand Planning, Supply Network Planning, Global ATP, Production Planning and Detailed Scheduling, Deployment and Transport Load Builder, Transportation Plan-ning and Vehicle Scheduling, Purchasing, Workbench.

2.2.3. Software support to production and inventory planning with the cooperation of all participants in SC

Software solutions for cooperation in planning in supply chains are a combination of ERP solutions, software for project management and software on whose concept different social networks are functioning. The main advantage of this software is that it allows decentralization of control and responsibility in the planning of activities in the whole SC. All participants in the SCPS have access to the software in accordance with the position in which they work and the relevant responsibilities. The concept of the functioning of the software is based on the regular exchange of information between participants, so it is imperative that all stakeholders are aware of the responsibilities of regular updates of progress and change in the status of the activities for which they are responsible. Unlike the traditional software designed for planning in SC which optimize plans and simplify the planning process, these software solutions allow "discussion" i.e. the exchange of information between participants on a particular topic.

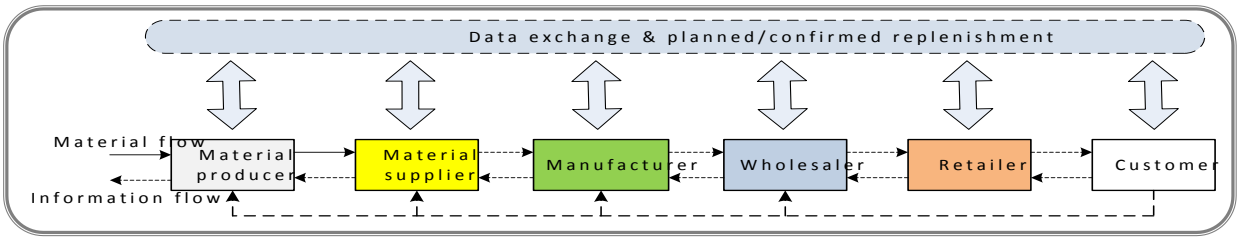

Figure 6. Model of a full cooperation in planning in SC

The cooperation of the participants in planning in SC can be full or limited. Full co-operation (Fig. 6) is achieved if all participants in SC cooperate fully (transparent) and use the appropriate software for collaboration in planning in SC. The basic concept of cooperation is presented in Lecic-Cvetkovic et al. (2012).

Limited co-operation (Fig. 7) is a modification of the full cooperation model; it occurs when the cooperation of the participants in SC is limited, where each participant cooperates with the first predecessor and successor in the SC, whilst concurrently cooperating with the final buyer. It is believed that the cooperation with the buyer is most easily attainable, because the buyer i.e. retail store, aims to ensure the availability of products to consumers and thus "retain" them, while the other SC members have the opportunity to find alternative channels of product placement.

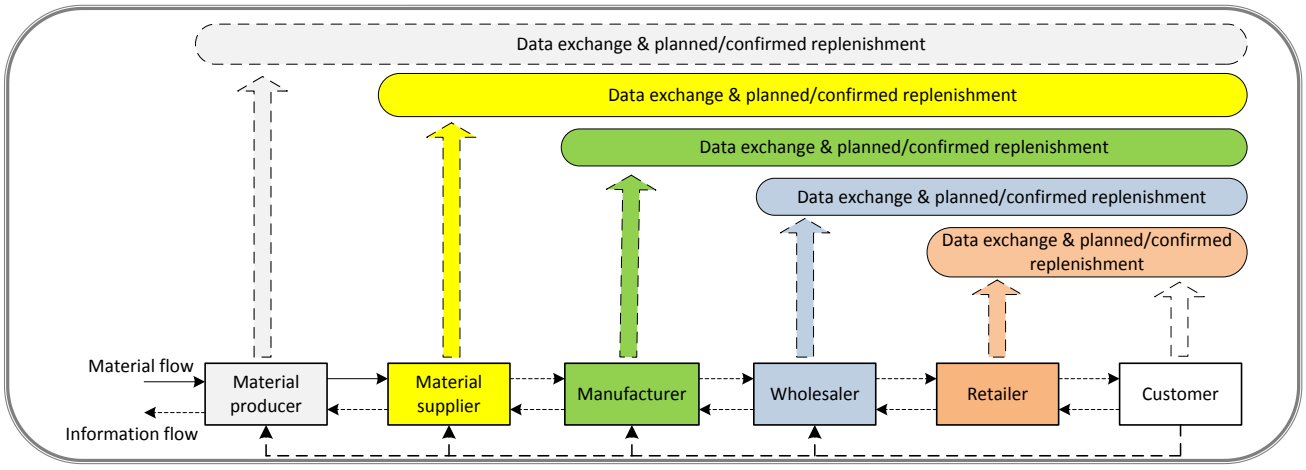

Figure 7. Model of limited cooperation between the participants in SC planning

Collaborative planning, forecasting and replenishment (CPFR) software from „Demand Solutions“ which is "cloud-based" concept, provides reliable information on the demand and the need for replenishment of the stock through the coordination of material and informational flow between multiple participants in the SC, between different locations and different companies. *Demand Solution software* allows defining priorities in meeting the demand (through *Demand Solutions Dashboards*), as well as different levels of aggregate considerations of demand and the available stock. Cooperation is achieved through the following additional features: Exchange calendar event (production, delivery, receipt), Support for XML and EDI in order to facilitate the exchange of information, full access to the entire SC from the perspective of each member. Cooperation in planning in SC is also provided by software „Voyager Collaborate“, whose main advantage is Module Logility Voyager Collaborate with providing effective communication in decision-making, contributes to the identification of potential problems and preventive action. JDA CPFR, created by JDA Software Group, is a direct upgrade by creators of VICS CPFR ® standard, through the module that allows planning by the application "alerts" and the work with flexible planning horizon. NeoGrid CPFR is a software solution for collaboration in planning in SC which is derived from the solutions intended for aligning inventory levels between the SC members, i.e. between multiple storage positions.

3. RESEARCH AND RESULTS

By Paiva et al. (2014), “Some studies about supply chain planning have focussed on mathematical models to reduce losses due to mismatches, while other studies have focussed on antecedents that lead to improvements in supply chain planning, for example, the use of electronic marketplaces, advanced planning systems, information technologies use and supply chain flexibility. Here we draw attention to the improvement of planning in LS and the need to maintain the software support for such, new planning.

Contemporary SC cannot operate without adequate software support (which effectively and efficiently serve SCPS, i.e. which can be applied, and, at the same time, provides the benefit for SCPS), and the adequacy of software support reduces with the accumulation of changes in the concept of SCPS (because every change of SCPS requires appropriate, new or updated software). Hence the need to replace the software with a new, more adequate one. But the downsides of the replacement are: replacement costs, changing time, and stress (training for new software for planning in SC, adjustments of experts in planning in SC etc.).

Hence SCPS must be improved, and the adequacy of its software support must be maintained, i.e. must not be reduced. Therefore, this paper seeks answers to questions (RQ1-RQ7):
RQ1: What is the "chosen problem" in SCPS?
RQ2: Why is it necessary to have a software support for SCPS?

RQ3: What changes with the improvement of SCPS?
RQ4: What is happening with the SC planning software with the improvement of SCPS?
RQ5: Is it possible to "keep" the adequacy of the software for SCPS?
RQ6: Who can "keep" the adequacy of the software for SCPS?
RQ7: How to "keep" the adequacy of the software for SCPS?

"Selected problem" (RQ1) refers to maintaining the adequacy (or at least the usability and usefulness) of not too expensive, new or improved, software solutions to support the SC planning system (SCPS), in circumstances when SCPS maintains its topicality, i.e. it improves in accordance with the progress of the environment. "*The adequacy of software support for SCPS*" (Software Support Adequacy for Supply Chain Planning System, SSA4SCPS) as one of the key performance indicators of "quality software solutions for SCPS", means that software solutions suit all the needs of SCPS, that this support is effective and efficient, is on the same "level of modernity" as the SCPS, is usable (accomplishes its goals well enough) and is useful. Indicator SSA4SCPS, similarly to other quality indicators of any product/service, must be measurable/comparable, its functional dependence on certain variables should be described, standards for measures of their changes should be defined for the measurement system and the maintenance of the desired values, etc. The question is what happens when the SCPS software support loses its function, i.e. is it possible to do business without this support? Examples from the past show that it is (was) possible, but the contemporary practice says that it is not possible. Modern business involves a significant level of availability and reliability of data, accessibility, and the use of software tools for decision making, quick decision making, and dislocation of the participants in the decision-making system and in the complete management, etc. The cooperation of the participants in SC without software support for SCPS is now virtually impossible. Therefore, it is necessary to maintain the highest possible (or at least acceptable) indicator levels of SSA4SCPS.

When considering the SC planning system, it is interesting to investigate what is the function of software support (RQ2), i.e. which business activities in SC cannot be planned if there is no adequate software support. It is already said (Tab. 1) what "basic decisions of master planning" are. But that is only part of the function of a complex planning system in general as well as in SC. Practically, there is no area or object of planning where the software support does not facilitate obtaining a solution of a higher quality (more reliable, more accurate, faster, etc.).

When asked why the SCPS is complex, the best response is to remember at least some of the dimensions of the business system (Omerbegović-Bijelović, 2005): processes, resources, organizational components/parts, inputs and outputs, the relationship between inputs and outputs, changes, property, environment, expectations and goals, constraints, and so on. When this is viewed as an object of development in SC, exponential growth in a number of potential problems can be identified. For managers (owners and managers), this complexity would be insurmountable without a software support - for planning and for all other managerial activities.

Enhancement/improvement of the SC planning system (RQ3) can be symbolic and "painless", but a radical change (concepts, principles, data supply and software support, together with function and location of parts of the planning system in the SC organizational structure) is an important, complex, and unavoidable task. The cause of these changes is the need to maintain the competitiveness of SC and its members while the motives may be different - depending on the perceived problems and the capacity to address them, but always with setting a certain priority/objective: maximizing the satisfaction of customer requirements (Lecic - Cvetkovic et al., 2010). Often the Bullwhip Effect phenomenon (BWE) is used as an excuse to change the SC planning system. For example, instead of founding their plans on communicating with their immediate neighbours, the SC members may decide that each member of the SC should plans it output according to the last member in SC (usually a retail), using the same reasoning mechanism and taking into account its own historical data (Lecic - Cvetkovic et al., 2012).

The often cause of SCPS changes is the necessity to improve the SCM system (in order to improve the quality of plans, eliminate conflicts, increase the level of communication within the SC and with the environment), or the application or changes of meta-managerial tools, reducing costs, reducing the duration of production and business cycles, improving decision-making (by introducing higher mathematics and related disciplines), introduction of APS and the like. Along with the improvement of SCPS, it is necessary to adapt its software support (RQ4). Only together they perform their function in the SCM.

If the software is not flexible, if there is no automatism in its adaptation to changes in SC and in its planning system, the question of the adequacy of such software support arises. SSA4SCPS indicator should signal the need for software updates. Maintenance of the adequacy of the software is important for all participants in the SC; in several ways: as a sign that SC is uniformly developed and remains competitive, but also as an incentive to occasionally check whether at least one element from the set {"*Planning system in SC*" * "*Software support to SCPS*"} has been improved (and caused the improvement of the other one) in the given period. Practice shows that the improvement of the planning system in the SC is inevitable, even desirable,

but that it is also necessary to keep the adequacy of the planning software in SC (RQ5). It is not difficult to keep SSA4SCPS within the limits of admissibility - if there are necessary resources (e.g., money, time, staff readiness for change).

Given the importance and the task of SCPS imrovement, including the importance, and the task of maintaining the adequacy of the software (SSA4SCPS), the question is who has a role in fulfilling these tasks (RQ6). Among the resposabile and interested are: a) Those who conceived, designed, devised the SCPS, b) Those who "produce" software support to SC planning, and c) Companies - participants in SC.

Some of the ways to keep the adequacy of the software for SCPS within the limits of acceptability (RQ7) are proposed: application of planning system engineering (processes and organizational structures) and the design of a flexible planning system for SC; the use of flexible, adaptable software solutions for planning in SC (modules and the possibility of accepting the "upgrade" - tailored to the changes in the SCPS); replacement of SCPS software (especially if it is possible to substitute it on the "old to new" principle with software provider); automatic updating of software solutions; timely defining principles for the change of software and allocation of related costs; that, from the moment of establishing SC, all participans define and agree on not only SCPS, but also the principles of its development; timely creation of a body for improving SC planning/management; the fund for improvement of SC planning/management settings; miscellaneous.

4. CONCLUSION

The paper points at the necessity of improving the planning system in supply chains (SCPS), and the need and ability to maintain the adequacy of the software to support the SC planning even when the planning improves and promotes/develops. Today, a complex planning system (planning, organizational structure in which the process takes place and the cooperation among the participants in SC) cannot function without a software support. Given the variety ranges of SC in which modern businesses operate, the complexity of planning is still growing. The competition between enterprises and their association's increases, and therefore SCs need to increase their competitiveness, i.e. to develop. Consequently, it urges the planning systems in enterprises in SC to improve, innovate, change, including the whole SC.

Due to the development of the principles and concepts of organization and functioning of SCPS, a reduction of the adequacy of existing software support occurs, and this leads to the need to provide the software that is not too expensive, which is (new or improved) adequate for the new SCPS. Therefore, the problem of maintaining the adequacy (usability, usefulness) of software packages that need to support the operation and development of the SCPS is noticed.

In addition to identifying the needs for maintaining the adequacy (or at least usability) of software support to SCPS, this paper also pointed at some possibilities to extend the duration, usefulness and/or appropriateness of software for planning in supply chains. Different aspects of cooperation/collaboration in planning in SC are presented by authors (as shown on Fig.5, Fig.6 and Fig.7) clearly showing the respective information flows between one or more participants in SC planning, with extension of closed loop for feedback/backward data collection. Some ways of keeping the SCPS software support adequacy within acceptable boundaries are also suggested.

Regarding further study on this subject, authors would like to suggest examining the scale of the software support adequacy and/or measuring its influence on business results.

Abstract: *Bullwhip effect in supply chains is a topic of interest of many authors, but research has mainly been done on operational causes and only some of them. This paper gives an overview of all operational and behavioral causes of the bullwhip effect, as well as modes of overcoming them.*

Keywords*: supply chain, bullwhip effect, operational and behavioral causes*

1. INTRODUCTION

Coordination of supply chains operates well if all the participants in a supply chain (suppliers, manufacturers, distributers, wholesalers, retailers) consider how their actions affect other participants and the entire chain. Lack of information and coordination can cause the bullwhip effect, which implies a distortion of information within the supply chain because different stages in the supply chain have different demand forecasts, so that demand increasingly varies from retailer to manufacturer. Bullwhip effect was first identified by Forrester (1958). Later, the causes of the bullwhip effect were defined as “players’ systematic irrational behavior” or as a “misperception of feedback” (Sterman, 1989, Goodwin 1994). The retailer interprets small variations in customer demand as a growth trend, which leads him to increase his order. Further up the chain, the size of the orders increases. Also, retail sales may increase an order due to planned promotions. If the manufacturer interprets this increase in demand as a permanent increase, and orders from the supplier accordingly, he will have the problem of surplus stock by the end of the promotional period. Croson et al. (2004) have classified the causes of the bullwhip effect as operational and behavioral. Most authors deal with operational causes and mainly only some of them, while behavioral causes are seen as important, but insufficient research has been done. This paper provides an overview of all operational and behavioral causes of the bullwhip effect, and modes of overcoming them.

2. OPERATIONAL CAUSES OF THE BULLWHIP EFFECT

Lee et al. (1997a, 1997b) found that the information on the size of orders distort more as they move up the supply chain, thus leading to the bullwhip effect. The causes they list are: 1. processing a signal that there is demand, i.e. that it is necessary to order, 2. rationing game - when the manufacturer has limited capacities and the available quantity produced must be divide among all consumers, consumers start to order more, because they think that there will be a shortage and that they will get a certain percentage from the order, 3. determining the size of the orders, 4. price variations.

Aly (2007) showed that increasing the lead time, the time between two deliveries and the time during which an average amount of stock is consumed leads to an increase in the bullwhip effect. On the other hand, increasing the prediction frame (the number of previous weeks when demand is monitored and used to forecast future demand) leads to a reduction of the bullwhip effect

Buchmeister et al. (2008) list the factors:

- forecast errors,
- overreaction to backlog,
- lead time variability,
- no communication and no coordination up and down the supply chain,
- delay times for information and material flow,
- batch ordering (larger orders result in more variance),
- rationing and shortage gaming,
- price fluctuations,
- product promotions,
- free return of goods policy,
- inflated orders.

Chopra and Meindl (2001) list the following as obstacles to coordination in the supply chain and as operational causes of the bullwhip effect:

- **Incentive obstacles** – Incentives for the participants to purchase more, in case this leads to an increase in demand variability which is not followed by a change in demand from end buyers, decrease the supply chain profit. These include incentives for a participant's local activity, and do not increase the overall supply chain profit.
- **Information processing obstacles** – Information about demand is distorted as it moves from the retailer to the manufacturer or if the demand forecast is based on orders, instead of customer demand.
- **Operational obstacles** – If a company orders larger quantities of a product than it can sell, due to the economy of scale or the discount on purchase price, and the supplier identifies the current rise as a trend and includes it in the plan for the forthcoming period, he will have surplus stock. The longer the lead time, the higher the error.
- **Pricing obstacles** – Promotions and other short-term discounts from a manufacturer result in forward buy, where retail and wholesale buy large quantities during the promotion period to cover the needs for a longer period of time, which is followed by a decrease in orders. During the promotion period, orders are larger than sale, so after this period the orders are lower so as to sell the delivered stock.

Decreasing the Influence of Operational Causes of Bullwhip Effect

It is possible to decrease the bullwhip effect by affecting its causes. Numerous authors have dealt with this problem, and the solutions can be divided into six categories.

1. **Information sharing** is usually seen as a "remedy" for the bullwhip effect and it is generally acknowledged that it can optimize supply chain performance (Forrester, 1958, Lee et al., 1997a and 1997b, Simchi-Levi et al., 2000, Chen et al., 2000, Carlsson and Fuller, 2002, Gangopadhyay and Huang, 2004, Vujošević, 2004, Vujošević and Panić, 2004). However, some authors show that the value of information sharing varies depending on the scenario. Variation in manufacturer demand is lower when the demand is filtered through a distribution centre, than when a retailer orders directly from the producer (Baganha and Cohen, 1998). When all supply chain participants replenish stocks on the same day, information sharing has no effect on stocks (Bourland et al., 1996). Some participants find that information sharing could disclose confidential information of a company, which would lead to loss of competitiveness. To prevent abuse of information sharing, the chain participants determine the minimum amount of information which should be shared to gain benefit and not risk abuse. In addition, it has been determined that the more the participants evaluate information as useful, the more often they share and forward them. However, the participants underestimate the usefulness of information for other participants when compared to the estimated value of the information for them. The less the usefulness of the information is evaluated to be, the less they are prepared to forward this information (Nienhaus, 2006). The most common is either the type of information shared (horizontal perspective) or the number of trading partners involved in information sharing (vertical perspective). According to the type of information shared, they can be classified as (Gangopadhyay and Huang, 2004): 1. product information, 2. inventory level and consumer transaction information and 3. decision models. In this case, it is possible to share all information, share partial information or share no information. It is important that trading partners see why and which information should be shared. Li et al. (2006) differentiate three levels of information sharing: transactional, operational and strategic. Transactional information sharing includes the quantity of order, prices, sales level, product specifications, quality and delivery specifications. Operational information sharing includes an exchange of information on the level of stock, expenses, production and transport capacities and lead time. Strategic information include information on retail centers, demand in real time, understanding of market trends, what customers value most and product design. The companies that are closer to the end user have a better view of the demand and should forward this information upstream to companies who are further away from consumers. On the other hand, information that is forwarded downstream should be the information on order status, storage utilization, production schedule and inventory level. Table 1 shows the type of information which can be shared in the supply chain and why (Lee and Whang, 2000).

   Miler (1996) underlines the importance of information quality and suggests the following characteristics of information: relevance, accuracy, timeliness, completeness, coherence, format, accessibility, compatibility, security and validity.

   In addition to the type and quality of information, the mode of information sharing is also important. There are a number of variations between non-sharing and complete sharing of information. Lee and Whang (2000) propose three ways of sharing information: the information transfer model, where one partner forwards information to the other who maintains the decision-making database, the third party model

where the third partner maintains the database and gathers information and *the information hub model*, where the third partner is the system.

Table 1: Type of information shared and the aim of sharing

type of information	**aim of sharing**
inventory level	avoid double storage of safety stock (with both participants)
sale level	decrease bullwhip effect
order status	enable buyer to know where the order currently is
sale forecast	decrease safety stock of participants who are further away from the end user
production and delivery schedule	provide customer with a specific delivery time
performances (product quality, lead time, waiting time)	identify where bottleneck is
capacity	avoid rationalizations

2. **Improvement of information flow** can decrease the bullwhip effect. Since the only demand that needs to be met is the demand of the end user for the final product, all participants in the supply chain should have information about this and plan accordingly (Chopra and Meindl, 2001). Also, replenishment and delivery time for the whole supply chain must be collaboratively controlled. The most common models of replenishment which enable information sharing are: *Continuous Replenishment Programs - CRP* (Chopra and Meindl, 2001), *Manufacturing Resource Planning - MRP* II (Renko, 2011), *Enterprise Resource Planning - ERP* (Chopra and Meindl, 2001, Renko, 2011), *Advanced Planning Systems - APS* (Renko, 2011) *Vendor-Managed Inventories - VMI* (Chopra and Meindl, 2001, Renko, 2011), *Collaborative Planning, Forecasting and Replenishing Processes - CPFR* (Jovanović and Vasiljević, 2008, Renko, 2011, BLANCHARD, 2010).

3. **Collaborative observation of goals** decreases the bullwhip effect by making the decisions regarding transport, information and inventory based on their influence on profitability, and not based on the total price and particularly not the local prices of individual participants in the chain (Chopra and Meindl, 2001, Vujošević, 2004).

4. **Collaborative demand forecast and making decisions about orders** decreases the variations of orders (Chen et al., 2000, Wu and Katok, 2006). The bullwhip effect can be decreased by analyzing demand patterns and by applying appropriate demand forecast methods. Buchmeister (2008) proposes the method of moving average for demand forecast.

5. **Flexibility** of the supply chain includes process and logistics flexibility (April and Garavelli, 2007). Process flexibility refers to the number of product types produced, and logistics flexibility refers to different logistics strategies applied. Flexibility of the supply chain and the improvement of operations decrease the bullwhip effect caused by undetermined (stochastic) lead time or production capacity (Chopra and Meindl, 2001, Aprile and Garavelli, 2007). Improvement of operations includes (Chopra and Meindl, 2001): decrease in lead time and the quantity of order i.e. decrease stock. Safety stock should be decreased as we move up the supply chain and maximum stock level should be limitied (Buchmeister, 2008). By decreasing the replenishment lead time, uncertainty of demand can be decreased, and this is achieved by increasing manufacturer flexibility and electronic exchange of information (Chopra and Meindl, 2001). A decrease in quantity of goods ordered, decreases demand variance between specific supply chain phases. The main obstacle for this decrease is the transport cost, if the cost is fixed for a vehicle. The solution is to load the vehicles with smaller quantities of products, if they can be transported together. This increases the cost of delivery, but it can be regulated by implementing a technology which simplifies the delivery process. One of the convenient ways for decreasing transport costs is the so called *milk runs,* which means that one vehicle transports a smaller quantity of a product for more retailers. Another way of having smaller orders are incentives for customers when ordering, so that demand is leveled in time (Chopra and Meindl, 2001).

6. **Strategic pricing and stabilization of orders** encourage retailers to order goods in smaller quantities and thus reduce the forward buy. If they are offered a discount on the total amount of goods purchased within a certain longer period, this will reduce the size of orders at shorter intervals. It is possible to completely eliminate promotions and charge every day low prices (*EDLP - Every Day Low Price*), limit the amount of goods that may be ordered or bound the size of promotions offered to retail to the amount sold to the end user.

3. BEHAVIOURAL CAUSES OF THE BULLWHIP EFFECT AND DECRESAING THE EFFECT OF BEHAVIOURAL CAUSES OF THE BULLWHIP EFFECT

The second category of the causes for the bullwhip effect are behavioral causes, which refer to a bounded rationality of the decision maker, particularly on wrong account of feedback and time delays, and can be classified into five groups.

1. The causes of imbalance can be external, such as change in customer demand which is not timely forecasted. However, if the decision makers doubt that their suppliers and customers would make wrong decisions, they may drop the balance strategy to provide stocks for the case of non-optimal behavior of partners. These are internal causes. Uncertainty caused by internal actions of partners in a supply chain can be labeled as **coordination risk** (Croson et al., 2004).

2. If the participants cannot predict how other supply chain partners would act, because they have limited knowledge or insufficient trust in the motives or cognitive abilities of the partners, variance in demand arises (Croson et al., 2004). This is not only the **distrust** that other participants would obey the rules; it is the distrust that they would know how to implement a rule. Lack of trust leads to work doubling. The more important the available information is, the more likely it is that it has not been shared or that it is ignored, because it is not trusted (Chopra and Meindl, 2001).

3. Sterman (1989a) and Croson and Donohue (2006) have shown that the supply chain partners behave as if there are oscillations in demand even when there are none, thus causing the bullwhip effect, which indicates **cognitive limitations** of the participants in causing the bullwhip effect. People find it difficult to simultaneously monitor and reflect on their inventory, inventories in progress, how much has been ordered, what the unmet demand is and how much to order. The way in which the participants are presented with the simulation game can affect their way of thinking. They think more about movement, changes and differences than stock. If the participants' calculations in a way emphasize lead time, for example, the participant takes the time into calculations more often and shows better results (Schaffernicht, 2006). Participants perceive their actions locally and cannot see the impact of their actions on others. Thus, a participant does not learn from their own actions, because the consequences of certain actions are best reflected elsewhere (Chopra and Meindl, 2001).

4. People often order based on the shortage between the target and current stock levels, ignoring the amount they have ordered, which has not yet arrived. If the system is out of balance, rational decision makers will try to restore the system back into balance, but if they apply sub-optimal decision making rules based on inadequate mental models, they can increase the imbalance and get into an infinite loop. Various authors (Sterman 1987, Kampmann, 1992, Diehl and Sterman, 1995, Croson and Donohue, 2006) showed that even when all participants know what the optimal ordering policy is and when demand is constant and known to all, still the majority of participants **underweight the supply line**. This proves that the bullwhip effect is partly a behavioral phenomenon. Participants react to the current local situation, before identifying the problem model for the whole chain (Chopra and Meindl, 2001).

5. Some **personality traits** may influence the decision-making process. Ruel at all. (2006) examined the extent to which risk taking, ambiguity, self-efficiency and locus of control may influence decision-making and performance. Self-efficiency can be described as a person's belief in their ability to perform a task. Locus of control is a tendency of people to attribute the causes of their behavior either to themselves (internal) or to environmental factors (external). People with an internal locus of control believe that they can control their results, and people with external locus find that their results are a product of circumstances that are beyond their power. People who are prone to risk have higher backorder costs than those who are moderately or highly prone to risk. The authors believe that such persons are cautious when placing orders, and it happens that they have insufficient stock. Only the manufacturers had positive stocks, but they also had a lower level of stock than manufacturers who are more prone to risk. Retailers who are less prone to risk place larger orders on average when compared to people who are more prone to risk on the same position. It is highly probable that people, who are less prone to risk, react more slowly to changes in demand, but when they respond, they place larger orders. As a result of this behavior, retailers who are not prone to risk cause a greater bullwhip effect and incur higher costs. In contrast, wholesalers, distributors and manufacturers who are not prone to risk and behave the same way, cause a smaller bullwhip effect and have lower costs, because in these positions it is better to react more slowly to changes in demand. People who perceive themselves as less efficient, have higher costs due to lack in stocks, but lower storage costs in comparison to the people who see themselves as more efficient. People prone to risk react more quickly, which proved to be good in the position of a retailer, but bad in other positions. People who prefer unambiguous situations have higher costs due to shortage in stocks, probably because people who like ambiguity feel better in ambiguous situations. The level of

orders is higher as people are less inclined to ambiguous situations. People who have an external locus of control were making larger storage costs and placed larger orders. Participants blame each other for the variability of demand (Chopra and Meindl, 2001). Nienhaus et al. (2006) and Nienhaus (2002) have identified two extreme types of behavior called “safe harbor” and “panic”. “Safe harbor” means that people order more than they need to ensure the level of safety stock. This increases their stock, but forces their suppliers to either increase their orders or to pay for unmet demand. “Panic” means that a participant just forwards the orders placed, and empties their warehouse at the beginning. Initially, it does not affect other participants, but if the end-user demand increases, a participant behaving this way must order more than a participant with safety stocks would. This is when this strategy is having the same negative effect as the previous one. The authors have showed that the optimal value is attainable only if a player is a computer. The more people participate in the simulation, i.e. as more people take part, rather than a computer, the result is worse. If a player chooses the “panic” strategy, they pay high penalty, and if the strategy “safe harbor” is played, they pay high storage costs (Nienhaus, 2006).

Decreasing the Influence of Behavioral Causes of the Bullwhip Effect

Croson and Donohue (2006) showed that, after the common knowledge and trust that everyone will make optimal decisions has been established, providing additional stocks does not eliminate the risk of coordination, but reduces order oscillations that could occur due to internal risk of wrong decision making. Therefore, the authors introduce the concept of coordination stocks. Unlike safety stock, which protect against external uncertainty, coordination stocks provide protection from non-optimal decisions of the participants in the chain. In addition, to overcome the coordination risk, a common knowledge about optimal orders should be created, to reduce the effects of suboptimal activities (Croson et al., 2004).

Long-term relations between the participants in a supply chain change the supply chain performance (Chen et al., 2012). Belavina and Girotra (2001) showed that in the case of one-off sales, a centralized supply chain generates higher gross profit, and individual participants generate higher profits in a centralized supply chain. If the sale is repeated, as long as the participants behave in the agreed manner, balance is maintained. If a participant disturbs the balance by deviating from planned actions, other participants also deviate, i.e. take punitive action, as they have strategic memory which influences decisions in subsequent periods if the sales repeat (Belavina and Girotra, 2001). If the sale is repeated, a decentralized supply chain generates higher profit than a centralized.

All of these actions are much more successful if there is trust and strategic partnerships within the supply chain. This ensures more successful information sharing and the reduction of prices between phases of the supply chain. Successful cooperation is beneficial when executing a specific task around which partners work together, but also improves the quality of the relationship between the partners. The highest value of better relations between a supplier and its customer is a satisfied end user. The basic purpose of cooperation between the participants in a supply chain is the reduction of costs and the possibility to give the customer a better offer, so that supply chains compete, rather than companies within a supply chain. Collaboration means that two or more companies share responsibility for the exchange of mutual information on planning, management, execution and performance measurement. There are two types of collaboration in a supply chain (Barratt, 2004 in Van de Vijver, 2009): vertical, between different levels of a supply chain and horizontal, between participants on the same level, but from a different supply chain. The elements necessary for successful collaboration are (Barratt, 2004 in Van de Vijver, 2009):

- Trust – reliance on an exchange with a partner who we trust
- Mutuality – mutual benefit and risk sharing
- Information sharing – transparency and quality of information flows
- Communication and understanding – clear lines of communication
- Openness and honesty – results in high level of trust, respect and devotion.

A research conducted by Mentzer, in Poirier (2002) identified enablers, impediments and benefits from collaboration in supply chains. Enablers are:

- Common interest and clear expectations – All participants should take part in the results of collaboration in order to achieve long-term cooperation. Everyone should have a clear understanding of what is expected from them.
- Openness and trust – For a partnership to be functional, all participants should speak openly about their practices. This sometimes means sharing confidential information and it is necessary for the partners to be responsible and ethical.
- Acknowledging who and what is important – The participants and activates that bring most benefit should be selected.
- Leadership – A leader who supports collaboration is essential.

- Cooperation, non-punishment – When things do not go as planned, punitive actions sometimes help, but an appropriate approach for good cooperation is collaborative problem solving.
- Benefit sharing – Partners should share both benefit and damage.

Impediments, i.e. obstacles to collaboration and their consequences are (Van de Vijver, 2009):
- Lack of mutual commitment – partners are not motivated to cooperate with each other
- Unclear roles and responsibilities – partners are dissatisfied with relations, because they feel the other partner is not meeting the responsibilities
- Insufficient information on the added value of collaboration – partners are insufficiently interested in collaboration
- Opportunistic behavior of partners – partners lose trust.

Based on the experiences of 20 professionals in managing supply chains from various sectors and industries, Quinn (2000) concludes that collaboration in supply chains can bring benefits if the enablers are in the right place and if the impediments can be overcome. Enablers have more to do with the style of management and interpersonal relationships, than with technology. Collaboration is a process which evolves through three stages (Lapid et al. 2002):
- Initial level of collaboration, where chain members exchange information to complete day-to-day transactions
- Cooperative collaboration, where chain members have simultaneous access to information needed
- Cognitive collaboration, where chain members share information to collaboratively increase the level of knowledge and make decisions - “win-win” partnership.

Relations within a supply chain can be based on either power or trust. If the relations are based on power, in the long term it leads to increased profits of one participant at the expense of others, and others are seeking alternative ways to survive. If the balance is once disturbed, unjust division may be detrimental to the company. The more powerful party has greater control and the ability to profit at the expense of the weak. Relations should be beneficial for both parties. The stronger party must accept its responsibility for partner profitability. Relationships based on trust imply that every participant is interested in the welfare of others and that they will not act without taking into account the impact of their actions on others. Trust can be based on retention or built through various formal contracts, or based on a process where trust is built over time as a result of long-term cooperation between two or more groups. It is most common to start with the trust based on a contract, which then evolves into process trust.

The ways companies can have a positive influence on the development of partnerships are (Van de Vijver (2009): transparency with the aim of avoiding suspicion, teams whose members are from two/more companies working in the same office on solving a common problem, defining the common key performance indicators, face to face meetings.

Chopra and Meindl (2001) propose the following activities for successful coordination:
- Measuring the bullwhip effect
- Devotion to coordination on the part of top management
- Allocation of resources to coordination
- Focus on communication with other phases
- Tendency to achieve coordination in the whole supply chain
- Use of technology for improving connections and communication within the chain
- Division of benefit from just coordination

As for interpersonal aspects of collaboration, three aspects are mainly discussed: 1. the influence of emotions (Andersen and Kumar, 2006, Hutt et al., 2000, Bagozzi 2006), 2. the role of trust (Jap and Anderson, 2003, 2005, Jeffries and Reed, 2000) and 3. the importance of maintaining relationships (Welling and Kamann, 2001, Ulaga, 2003). Interpersonal trust has the most positive effect when opportunism is low. However, if the inclination to opportunism is high, confidence can be harmful and show its “dark side” and even induce opportunistic behavior on one side. One of the ways of increasing trust and improving relationships is socialization, which represents “interactions and communication between participants and between organizations, whose aim is to build rapport and improve communication and problem solving”. It was found that there was a significant positive impact of socialization on supply chain performance; however, if there is a previous bad experience with partners, socialization does not give expected results (Van de Vijver, 2009).

4. CONCLUSION

The paper gives an overview of the causes of the bullwhip effect, both operational and behavioral, as well as modes of overcoming them. Although the authors agree that the bullwhip effect is to some extent a behavioral phenomenon, behavioral causes are rarely investigated. Therefore, further research could take this course. Since supply chain management and the reduction of the bullwhip effect emphasize the importance of cooperation, further research could examine the impact of cooperation between participants in a supply chain on the bullwhip effect.

MAINTENANCE MANAGEMENT MODELS – A COMPARATIVE ANALYSIS

Viktorija Paunović [1], Jelena Popović[2], Jovana Popović[3]
[1] Faculty of organizational sciences wiktory91@hotmail.com
[2]Faculty of organizational sciences p.jelena@yahoo.com
[3] Faculty of organizational sciences popovicjovana0@gmail.com

Abstract: *This article deals with three concepts of maintenance management: (i) Total Productive Maintenance (TPM), (ii) Reliability Centered Maintenance (RCM) and (iii) Life Cycle Cost (LCC). The article is based on the works of prominent and distinguished authors in the field of maintenance concepts. The purpose of the article is to compare these concepts: their goals, methods they are based on, system reliability, system failure, their costs, advantages and disadvantages and other characteristics. The original result achieved through this analysis is a systematic representation of the three concepts with their main advantages and disadvantages, which should be useful to maintenance managers and anyone who is engaged in maintenance management.*

Keywords*: Total Productive Maintenance, Reliability Centered Maintenance, Life Cycle Cost, advantages, disadvantages, criteria*

1. INTRODUCTION

Subject of this work are management models, total productive maintenance, reliability centered maintenance and terotechnology (product economic lifecycle) and their analysis.

The goal of the research is a comparative analysis of management models with the aim of determining advantages and shortcomings of each model, as well as possibilities of their integration to achieve maximal performances of technical systems.

In the second chapter of this paper the theoretical background is given. An overview of the chosen models is given in third, fourth and fifth chapter, while the sixth chapter, named Comparative analysis, shows tabular review of the mentioned models comparison. This chapter considers resemblances and differences between the models and potential for their integration in order to attain minimal maintenance costs. In the final, seventh chapter the authors' conclusion and suggestion about further analysis are given.

2. THEORETICAL BACKGROUND

Literature shows that manufacturing organizations worldwide are faced with numerous challenges in trying to operate successfully in today's competitive environment. Modern production requires organizations to have effective and efficient maintenance in order to be successful.

During the past two decades, manufacturing organizations used different approaches in order to improve maintenance effectiveness as said in Roup, J. (1999), (p. 5-32). One approach for improvement of maintenance activities is implementation and development of Total Productive Maintenance (hereinafter: TPM) strategies. Moore, R. (1997), (p.88-90) said that implementation of TPM enables organizations to substantially transform their factories by integration of culture, process and technology, .

TPM concept originated from the Japanese production industry (adopted in Japan in 1951). It was initially aimed at elimination of production loss due to limitations in JIT (*just in time*) process in production. Seiichi Nakajima, the vice president of Japanese Institute of Plant Engineering, promoted TPM in Japan and became known as the father of TPM. Contemporary equipment management was started by preventive maintenance and developed into productive maintenance. TPM is based on teamwork and inclusion of all levels and functions in an organization, from the top management to the manufacturing workers.

Numerous researchers emphasized the importance of TPM implementation, both in production environment Ahmed, S., Hassan, M.H. & Taha, Z. (2005) and Ahuja, I.P.S. & Khamba, J.S. (2007), and service sector Patra, N.K., Tripathy, J.K. & Choudhary, B.K. (2005) and Pramod, V.R., Devadasan, S.R., Muthu, S., Jagathyraj, V.P. & Moorthy, G.D. (2006). TPM is considered to be a Japanese response to American approach to Preventive maintenance as it said in Wal, R.W.E. & Lynn, D. (2002). It is widely recognized as a strategic tool for improvement of production performances by boosting effectiveness of production plants Dwyer, J. (1999) and Dossenbach, T. (2006) and it was accepted as the most perspective strategy for maintenance improvement, aimed to achieve success at high-demanding market in Nakajima, S. (1988). It is a proven production strategy, which has been successfully applied worldwide in the past three decades for

reaching organizational goals related to achievement of essential competence in competitive environment like it was discussed in Ahuja, I.P.S., Singh, T.P., Sushil, M. & Wadood, A. (2004) (p. 422-426)

Problems with Reliability Centered Maintenance have been studied for a long time by numerous scientists and experts in this field. Best known works regarding reliability centered maintenance are: Heap, F. H., & Nowlan, F. S. (1978) and Moubray, J. (1997) and there is also a large number of works dealing with this issue. All these works are more focused on maintenance than reliability. Prominent author Smith, A. M. (1993) said: "(…) How to introduce RCM model depends on experience of owner and employees."

Back in December 1978, Heap, F. H., & Nowlan, F. S. (1978), have published the report "Reliability Centered Maintenance". The report was the result of a multi-annual work aimed at finding a new, cost-effective model for maintenance of complex systems. It was named Reliability Centered Maintenance (RCM) because it was focused on safety and reliability of equipment and minimization of costs. Until then, managers usually practiced repair of all machines as a way to prevent failures. Gradual development of RCM model in American aviation industry has lead to the application of this approach in other industries. If proper tools and procedures are applied, RCM model is simple to apply and reduces the costs and risks in a system.

According to Gibbons, P., & Friis, J. (2013) RCM is: "Approach using reactive, proactive and preventive maintenance and strategies in integrated manner, in order to increase probability that machine or component will operate in demanded mode during its overall economic life, with minimal maintenance. In Technical Manual (2006) (p. 4), it is written that savings after introduction of RCM model at annual level are between 30 and 50%.

The Oxford Dictionary Oxford Dictionary website – 2013 defines ***terotechnology*** as "the branch of technology and engineering concerned with the installation and maintenance of equipment" (downloaded from The Oxford Dictionary website, 2013). However, this definition does not explain the essence of the term – there are other concepts concerned with sustainability (such as RCM and TPM), while terotechnology is just one of them. The main idea behind terotechnology is that the domain of sustainability management should not only include the period of system technological use, but also the whole system life cycle. In other words, as defined by the British Standard BS:3811, terotechnology is "A combination of management, financial, engineering, building and other practices applied to physical assets in pursuit of economic life-cycle costs." (downloaded from the website www.plaint-maintenance.com, 2013).

The term *terotechnology* first appeared in 1971 when the *Supplement to Radio and Electronic Engineer* published the article "Terotechnology – A New Approach to An Old Problem*"* by professor Leonard Atkinson*.* Atkinson claimed that sustainability system, which was in use at that time, is set up too narrowly and that a lot of savings could be achieved by taking into account the system life cycle cost (downloaded from the IeeeXplore website, 2013).

Today, the term *terotechnology* is mainly obsolete, and replaced with the term *life cycle cost (LCC)*. Therefore, the term *life cycle costs* will be used in this article, along with the references concerning the LCC analysis. It is important however, to stress that LCC approach as known today, in addition to its implementation in the field of sustainability management, could also be used in project management, product analysis and other areas. Ralph Horne, Tim Grant and Karl Verghese (2009) in their book "*Life Cycle Assessment: Principles, practice and Prospects"*, claim that the LCC concept is created with a new generation of energy technologies in the post-World War 2 era. As more complex nuclear technologies were developed, more researches were conducted in order to answer questions such as whether a given nuclear technology produced more energy than it consumed as well as analyses of uranium mining, waste management, and transportation impact. Further, such researchers followed to development, marketing and service management sectors, i.e. to all LCC costs related to nuclear power plant"s management and usage. In time, this approach started to be applied in other fields, such as maintenance management. (p.2)

3. TOTAL PRODUCTIVE MAINTENANCE

As it was noted in Suzuki, T. (1994) Total productive maintenance can be regarded as a machine medicine. It is a maintenance program which includes a new definition of the concept for plants and equipment maintenance. The goal of this program, particularly emphasizing maintenance, is to significantly increase production and simultaneously raise employees moral and job satisfaction and to reduce urgent and unscheduled maintenance to the minimum.

Japan Institute of Plant Maintenance defines TPM as:

- T = Total – Inclusion of all employees at each level of organization
- P= Productive – Efficient use of all resources
- M = Maintenance – Maintenance of Staff/Machines/Materials in optimal condition

TPM is an innovative Japanese maintenance concept. Its roots go back to 1951 when preventive maintenance concept, accepted from USA, was introduced for the first time in Japan. *Nippondenso* was the first company introducing preventive maintenance in 1960. Combination of Preventive Maintenance concept, Prevention of Maintenance concept and Improving Maintenance concept resulted in Productive maintenance concept as it was stated in Venkatesh, J. (2007). The goal of productive maintenance was maximal effectiveness of plants and equipment:

1. Achieve minimum 90% OEE (Overall Equipment Effectiveness);
2. Machine should work during breaks as well (Breaks are for staff, not for machines);
3. Run business with no complaints of consumers;
4. Reduce production expenses by 30%;
5. Achieve 100% success in goods delivery in accordance with buyers" demands;
6. Keep working environment safe;
7. Increase by three times employees suggestions for improvements and in this way develop multi-skilled and flexible workers.

The main system of measurement connected to TPM is Overall Equipment Effectiveness (OEE) which was originally developed in Japan in the 70"s as a system for determining production effectiveness. It includes three basic indicators of equipment performances and reliability like it was said in Gupta, A.K., & Dr. Garg, R.K., (2012), (p.1-2). Hence, OEE is function of three following factors:

1. Availability or readiness (deadlocks; scheduled and unscheduled, replacement of tools, service of tools, change of work)
2. Equipment effect ratio (real capacity compared to the incorporated one)
3. Participation of accurate products in overall number of products (malfunctions and reproduction)

TPM reminds of Total Quality Management – TQM concept. Many of tools, such as encouraging employees to take active part in increasing effectiveness process and benchmarking, used in TQM concept are also included in TPM concept.

4. RELIABILITY CENTERED MAINTENANCE

According to Rausand, M., & Vatn, J. (1998), (p.1-26) main goal of RCM model is to provide effective and applicable maintenance, taking into consideration four factors: safety of staff, impact to environment, production capacities of company and material losses (costs). Effective maintenance requires an increase of reliability in order to provide better safety of staff and, in so doing, to ensure better production capacity. By increasing production capacities, costs are reduced, as well as losses due to failures. By applying contemporary methods and appliances in the production process, harmful effects to environment are reduced and reliability of systems is increased. The conclusion is that the main goals are maximal reliability and minimal costs, which contributes to increased safety of staff and productivity.

RCM model determines conditions that must be fulfilled so that a physical device, in its operating context, could continue to work in a way that consumers expect. Smith, A. M. (1993) stated that RCM approach has four key features. Each of these is defined and discussed here.

The most important feature of RCM is maintenance of continual equipment functionality of overall system. The fact is that equipment functionality has to be provided so that overall system could be effective, but RCM approach starts from the desired output, as a primary task. The basic idea is to establish necessary functions for creation of the final product and then provide equipment functionality which performs these functions.

The next feature is based on functionality failure, in other words, loss of system function. It is necessary to study all potential in the state of equipment, in order to determine possible deadlocks and failures. The main goal is to identify possible failures in equipment components, which could potentially endanger system functionality.

The third feature of the RCM approach means defining priorities as a basis for establishing the distribution of resources and budget. Here, the goal is to define which failures have more importance and, according to defined priorities, to remedy them. Distribution of priorities is based on „"decision tree"" method.

Previously mentioned features help to establish location of failure occurrence, cause of occurrence, as well as priority for taking measures to remedy these failures. The next step (i.e. the fourth feature of RCM) is to apply appropriate methods for failures removal, which must be applicable and effective. The idea is to carry out only applicable methods for failures removal which are the most convenient as well. By doing so, we can prevent removal of failures with minor priority, in order to prevent unnecessary waste of limited resources.

RCM approach combines different models such as preventive, proactive maintenance, „"work until failure"" and uses advantages of each model to provide equipment effectiveness and functionality at lowest costs.

Advantages achieved by application of this approach have already been proved in numerous industries: military industry, aviation, navy, chemical industry, oil industry, small and middle size companies, as well as in hospitals, railroads, ships, wind turbines. According to Smith, A. M. (1993) key advantages are: improvement of system performances, lower maintenance costs, longer economic life of equipment, simple database maintenance, minimization of repairs, risks included in analysis, better staff motivation, teamwork. Shortcomings of this model are mentioned on the website Energy.Gov (2013) and they are: high costs for staff training and teaching, as well as longer necessary time frame to achieve results through return of investments.

From the text above it can be concluded that RCM approach has four basic tasks:

- Machine maintenance
- Indentifying possible causes of machine failures
- Lowering costs
- Extending the life cycle of machines

5. LIFE CYCLE COST

The core idea of the LCC approach is usually presented with the famous “tip of the iceberg” metaphor. When a company purchases expensive installations and systems, it is a big mistake to take into account only acquisition costs. They are the *tip of the iceberg*. In the effort to minimize costs, a company often focuses on activities that will reduce its short-term costs, which could have a very negative effect on its long-term costs. Therefore, when a company considers the acquisition of some equipment, it should also take into account the labor costs, operating costs, scheduled maintenance costs, unscheduled maintenance costs and conversion/decommission costs. Paul Barringer (2007) in his article *Life Cycle Cost & Reliability for Process Equipment* state that these are the key elements of the LCC structure which should be assessed prior to purchase of equipment, as well as for product pricing calculation (p.6).

The object of LCC analysis is to choose the most cost-effective approach from a number of alternatives so that the least long term cost of ownership is achieved. LCC analysis helps engineers to justify equipment and process selection based on total costs, rather than making decision on the initial equipment/services purchase price only. Furthermore, the LCC could be used for the system effectiveness calculation. System effectiveness is derived from the relationship between LCC and technical effectiveness. This relationship can also be used as a benchmark, i.e. as a basis for the two systems comparison. This is also a statement claimed by Paul Barringer (2008) in his article *Life Cycle Cost And Good Practices* (p.7).

Christer Idhammar, Reliability and Maintenance Management Consultant and Vice President of IDCON said that the concept of Life Cycle Cost is not properly practiced in many organizations because management is often focused on short-term cost reductions instead on what drives the cost. He gives two main examples to illustrate the importance of understanding the total amount of costs in a company. One example is about a preventive maintenance program. A good preventive maintenance program reduces final costs, but it costs money to be implemented in mid-term. Although some effects could be seen after a year, significant results emerge only after three to five years. Due to staff turnover, it often happens that the management team that carried out LCC implementation left the company and could not claim the results. Selection of equipment based on Life Cycle Cost is another example. The proper equipment might cost more, but cost of ownership is lower. Therefore, understanding the whole picture, in the process of equipment or system acquisition is the key issue of the LCC approach (downloaded from the website www.idcon.com, 2013).

6. COMPARATIVE ANALYSIS

One of the essential criteria in comparison of these three models is their focus, i.e. a particular field affected by the models to achieve their goal. These criteria make substantial difference between the three models. It is also significant to point out the origin of each model in order to make it easier to understand the concepts they are based on. The approach to employees is one of the criteria giving insight into the models and it shows that they are applied in organizations in approximately the same manner, which suggests the possibility of combining them to achieve the desired objective. The comparative analysis can be seen in Table 1 shown below. The table and the comparative analysis is the result of the work of the authors.

Basically, TPM approach is more focused on management, while RCM approach is more focused on engineering. LCC approach implies use of accounting methods and exercising different analyses to determine various costs, their bearers and position of costs. It would be wrong to say that these three approaches are not compatible, bearing in mind that they achieve the same goals in different manners.

Table 1: Comparative analysis

Criteria	Total productive maintenance	Reliability centered maintenance	Economic Life cycles costs
Origin	Japan-car factory	USA-military aircraft industry	USA and Great Britain – nuclear technology and aircraft industry
Focus	Equipment (system input and causes of failure occurrence)	Reliability of system and equipment	Reduction of overall costs of economic life cycle of equipment
Applicability	Car industry, microelectronics, movies, plastic, administration	Military industry, energetic, aviation, nuclear plants, wind turbines, small and middle size companies	Energetics, nuclear plants, aviation, big companies and supply chains
Costs	Reduced (30-50%)	Reduced (30-50%)	Reduced up to 80-90%
System reliability	Increased (10-250%)	Increased (40-70%)	/
Failure occurrence	Reduced	Reduced	Reduced
Methods based	Preventive, productive, improvement of maintenance, prevention of maintenance	Preventive, proactive, conditions centered maintenance, „work until failure“	Preventive, proactive maintenance, accounting methods of costs conversion and , statistical methods of risk estimation and probability related to certain costs, long-term approach
Goals	-Increase OEE to 90% -Consumer's satisfaction -Reduction of production costs for 30% -Safe working environment	-Safety of staff -Reduced impact to environment -Increase of production capacities -Costs reduction	-Reduction of overall costs of system or equipment economic life cycle -Calculation of price for customer -Support in making decisions (selection among more equipment alternatives considering all costs)
Advantages	-Increase of equipment and machine effectiveness -Increase of production quality -Reduction of losses when production starts -Reduction of maintenance time and costs	-Increase of performances -Increase of staff and system safety -Lower costs -Longer economic life of equipment -Minimization of repairs -Motivated staff and team work	Minimization of overall equipment economic life cycle costs by long-term and comprehensive approach and analysis of all costs
Shortcomings	-High cost for staff training who to deal with equipment maintenance	- High costs for staff training and teaching and equipment - Potential savings are not easy to achieve	-Effects of application are noticeable after 3-5 years the least -It requires collection and processing of large number of information from different company departments - It requires close cooperation and team work of the employees from different company

			departments, which might be difficult to achieve - Inconsistency in information processing and application of different accounting methods in different fields make results invalid
Approach to employees	-Staff practise self-maintenance -Inclusion of all employees -Staff development -Inclusion of top management in early stage -Circles of employees	-Expert team for introduction of RCM model -Introducing model to all employees -Association of employees from different departments	LCC approach requires team work and cooperation of employees from different departments in order to collect all necessary information about overall costs

In a technical system it is necessary to establish priorities on what is the first to be repaired or improved. It could be the purity of a system, inclusion of employees, preventive maintenance or environment issues. When every problem of one system is defined and when priorities are assigned, there is decision to be made regarding the maintenance type to be applied, with the possibility of combining RCM and TPM model. According to Moore, R. (1997) (p.88-90) RCM approach is based on establishing standards of preventive maintenance, and TPM approach carries out further improvement within the overall system. This is so called integrated system, aiming to take the best of each model in accordance with the company"s goals. There is no conflict as long as powers of TPM approach supplement weaknesses of RCM approach and vice versa.

LCC approach enables consideration of the bigger picture. Each maintenance concept used in some system implies certain costs and resources, necessary for its application. LCC approach puts the scheduler in a position to assess costs of each maintenance model. Costs of maintenance models determined in this manner constitute the basis for their comparison. It is significant to mention that during comparison of different models only their distinguishing aspects are taken in consideration.

As a conclusion of this comparative analysis arises the viewpoint that TPM and RCM concepts could and should be combined, while LCC approach presents a tool for their costs comparison and independent method providing complete consideration of different systems.

7. CONCLUSION

The present work arrives at the conclusion that total productive maintenance is an approach that is primarily based on inclusion of all employees into the maintenance process, thus accomplishing minimum costs and optimal engagement of each individual in a company. As for reliability centered maintenance, it can be concluded that it is primarily a preventive model, aimed at improving the reliability of the overall technical system, through maintenance of critical components. By so doing, maintenance costs are reduced and economic life of equipment is extended, which leads to the increase of functionality and productivity of the overall system. The essence of the third model, LCC, is to provide significant support in decision making. It"s vital feature and main advantage is in providing consideration of the bigger picture, in terms of time and value. Each of these models has its advantages and shortcomings and different approaches in the maintenance process. However, the possible conclusion is that the main goal of these models is minimization of costs in a technical system. According to the accomplished analysis, we can conclude that these models are mutually compatible, capable of being successfully combined within one technical system, in order to achieve minimal costs and maximal productivity.

Abstract: *In the literature, as in practice, there are number of models and frameworks that provide guidelines for the performance measurement system development and review performance measurement problems from different perspectives. In the paper, some of the most important performance measurement models are considered, and it is noticed that the majority of models takes into account the strategy or goals while determining performance, most of them don't specify performance indicators, but give an indication for their determination and none of them link directly organizational goals and performance indicators. In other words, none of them specify their interdependence, which would allow model flexibility. Furthermore, the novel approach to business process performance measurement is proposed, which starts from business system goals, decompose them on the lower level objectives and link them to the key processes of business system. Suggested approach allows interconnection between organization's top level goals and key process performance indicators, by using lower level objectives, which enable model flexibility.*

Keywords*: process performance measurement model, objectives, performance indicator, flexibility*

1. INTRODUCTION

Business processes performance measurement has began in the early 20th century, when, among the others, Frank and Lilian Gilbreth formally related performance measures to processes (Towers, 2005, p.10). Although much has changed in the meantime, the business process performance measurement practice of is becoming increasingly important. According to Antonucci at al. (2009, p. 11), it is the performance of the business processes, not the organizational functional units or a set of assets, that has to be manager's central focus in order to gain true benefits of a performance management initiative. Through performance measurement, managers receive the information for defining, improving and managing the key business processes.

Nowadays, there are a number of performance measurement models that include or strongly rely on performance planning, job design, performance measures determination and monitoring, and on the reward system definition (Sikavica and Hernaus, 2011, p.433). Those frameworks assist in this performance measurement system building process by clarifying boundaries, specifying dimensions or views and may also provide initial intuitions into relationships among the performance dimensions (Rouse and Putterill, 2003, p.792).

In the paper, some of the most important performance measurement models are briefly described, as the results of their comparative analysis. After that, a new performance measurement approach is proposed, which overcomes some of the shortcomings of existing models. At the end, some conclusions are drawn, and direction of future research is proposed.

2. THEORETICAL BACKGROUND

Performance measurement systems models may be considered as a means of reaching performance objectives (Lisiecka and Czyż-Gwiazda, 2013). In the literature, as in practice, there are number of models and frameworks that provide guidelines for the performance measurement system development. The objective for such models is to help organizations to define a set of measures that reflects their objectives and assesses their performance appropriately (Kennerly and Neely, 2002, p. 146). Those models are multidimensional, balancing financial and nonfinancial measures. Some of them are:

- *Activity Based Costing (ABC)*, developed by R. Cooper and R.S Kaplan (1991), has been promoted and adopted as a basis for making strategic decisions and for improving profit performance (Cagwin and Bouwman, 2002, p.1). ABC model assigns more accurately than traditional instruments, the costs of an organization's activities to its products and processes (Kueng, 2000, p.69). ABC has emerged as a tremendously useful guide to management action that can translate directly into higher profits Because

ABC reveals the links between performing particular activities and the demands those activities make on the organization's resources it can give managers a clear picture of how products brands, customers, facilities, regions, or distribution channels both generate revenues and consume resources (Cooper and Kaplan, 1991, p.130).

- *Brown's performance measurement concept* (Brown,1996) shows links between five stages in a business process and their performance measures. These stages are defined as inputs, processing system, outputs, outcomes, and goals respectively. The model demonstrates how inputs to the organization affect the performance of processing systems and ultimately the top-level objectives of the organization (Kennerly and Neely, 2002, p. 147)
- *Balanced Scorecard* proposed by Kaplan and Norton (1993) is a strategic management instrument: (1) to clarify and translate vision and strategy; (2) to communicate and link strategic objectives and measures; (3) to plan, set targets and align strategic initiatives; and (4) to enhance strategic feedback and learning (Kaplan and Norton, 1996, p. 10). The method looks at four interconnected perspectives: Financial, Customer, Internal business process and Learning and Growth. Customer satisfaction drives financial success; effective and efficient business processes ensure high levels of customer satisfaction; and sustained, continuous improvement enhances the organization's operational performance (Franceschini at al, 2007, p.124)
- *Business System Design Decomposition framework* (Taticchi at al, 2010), offers a holistic approach to performance measurement, identifies cause-effects relationships in business processes, measures the performance versus stakeholders and offers interlinking between performance indicators. BSDD is based on strengths of the Axiomatic Design and Analytic Hierarchy Process techniques. (Taticchi at al, 2010, p.229).
- *Data envelopment analysis (DEA)* (Charnes at al, 1978), is a mathematical programming model applied to observational data which provides a new way of obtaining empirical estimates of external relations – such as the production functions and/or efficient production possibility surfaces that are a cornerstone of modern economics (Adler at al, 2002, p.250). DEA enables measuring the level of efficiency of non-frontier units, and to identify benchmarks against which such inefficient units can be compared (Cook and Seiford, 2009, p.2)
- *Demand to measure model* (Ljungberg, 2002), classifies process measures in to main groups: process/activity measures and resource measures. Interrelating of this two groups of measures facilitate evaluation of efficiency and productivity (Ljungberg, 2002, p.267). Purpose of this seven-step method is to identify and derive proactive process measures.
- *DOE/NV model*, proposed by U.S. Department of Energy Nevada Operations Office (Bellman at al, 1994), is standardized approach to developing and implementing performance measurement systems. Performance measurement process has been separated into 11 discrete steps. Those steps present a guideline, intended to show the process generically. Different organizations who have vast knowledge of their own internal processes should feel free to adapt the guidelines where necessary to best fit within their operations (Bellman at al, 1994., p. 9)
- *EFQM model*, proposed by European Foundation for Quality Management (EFQM), is used to assess an organization's progress towards excellence, independently of the organization's type, size, structure, and maturity. The model is based on nine criteria. Five of these are classified as "Enablers" (cover what an organization does) and four as "Results" (cover what an organization achieves) (Franceschini at al, 2007, p.131).
- *Kanji Business Excellence Measurement System* (Kanji, 2002), based upon Kanji's Business Excellence Model and Kanji's Business Scorecard (KBS), These are made up of several criteria that correspond to the Critical Success Factors, i.e. the areas that must perform well if an organization is to succeed. They form, respectively, Part A and Part B of the Performance Measurement System and should be applied simultaneously, since they form a single and complementary view of organizational performance (Kanji, 2002, p. 718).
- *Tableau de Bord* (de Guerny at al, 1990) establishes a hierarchy of interrelated measures and cascading measures to different organizational levels, forcing functions and divisions of an organization to position themselves in the context of the company's overall strategy (Kennerly & Neely, 2002, p. 148). This concept is designed to help the personnel pilot the organization by identifying key success factors, especially those that can be represented as indicators (Franceschini at al, 2007, p.127)
- *Performance measurement matrix* (Keegan at al, 1989) categorizes performance measures as "external" or "internal" and "cost" or "non cost". This is a simple and flexible framework, and whilst it does not reflect all attributes of measures that are increasingly considered necessary, the matrix is capable of accommodating any measure of performance (Neely at al, 1995, p. 97). However, the matrix does not make explicit the links between the different dimensions of business performance (Anderson & McAdam, 2004, p. 469).
- *Performance pyramid* (Judson, 1990; Lynch and Cross, 1991), ties together the hierarchical view of business performance measurement with the process view. It cascades measures down the organization so that measures at department and work-center level reflect the corporate vision as well as internal

business unit objectives. This strategic measurement and reporting technique also supports the need to include internally and externally focused measures of performance (Neely at al, 2007, p.146)

- *Performance Prism* (Kennerly & Neely, 2002, p. 151) reflects the growing importance of satisfying stakeholder requirements, considering five distinct but linked perspectives of performance: stakeholder satisfaction, strategies, processes, capabilities and stakeholder contribution. In this framework, results (stakeholder satisfaction) are function of determinants (the other prism, facets) (Neely at al, 2007, p.156)
- *Framework of results and determinants* (Fitzgerald at al, 1991) is based on the premise that there are two basic types of performance measure in any organization, those that relate to results (competitiveness and financial performance) and measures that focus on the determinants of those results (quality, flexibility, resource utilization and innovation). Framework highlights the fact that the results obtained are function of past business performance with regard to specific determinants (Neely at al, 2000, p.1122).
- *Supply Chain Operations Reference (SCOR) model,* developed in 1997 by Supply Chain Council is business process reference model that contains all supply chain activities from supplier's supplier to a customer's customer. SCOR contains four levels of process detail. SCOR also includes methodology that enables companies to analyze and improve their supply chain operations by helping them to communicate supply chain information across the enterprise, measure performance objectively, identify supply chain performance gaps and improvement objectives (Scheer at al, 2002, p.50)
- *Theory of Constraints* (Goldratt, 1984) offers a systematic and focused process that organizations use to pursue ongoing improvement successfully. Within the TOC three global performance measures are used for assessing a business organization's ability to obtain the goal (i.e. making money). These global measures are net profit, ROI and cash flow (Tangen, 2004, p.732).
- *TQM performance measurement model* (Sinclair & Zairi, 1995) is based on concept of Total Quality Management and is designed to integrate measurement within the overall management process. The model consists of five levels: strategy development and goal deployment; process management and measurement; performance appraisal and management; break-point performance assessment; and reward and recognition systems concept.

Mentioned models consider performance measurement issues from different perspectives. Besides tendency to link operations and processes to strategic goals, they integrate financial and non-financial measures, and focus all business activities on customer requirements (Lynch & Cross, 1995, p.6). Nevertheless, these different approaches have led to numerous definitions of a performance measurement system, but still, there is little consensus regarding its main components and characteristics. (Dumond, 1994, p.17).

3. COMPARATIVE ANALYSIS OF EXISTING MODELS OF PERFORMANCE MEASUREMENT - THE RESULTS

Each of these performance measurement models suggests that it is unique and comprehensive. However, each model offers a different perspective on performance. Based on this, the following questions arise: Which process performance measurement model should be selected and applied? Which model is appropriate? When to use a certain performance measurement model?
To respond to those and similar questions, a comparative analysis of above mentioned models was done according to ten selected criteria. Those criteria are:

- Model purpose
- The basis for performance measures determination
- Performance measures (categories)
- The interconnections between performance measures
- Specificity of indicators to be measured
- Complexity
- Stakeholders, considered within the model
- System improvements incorporation
- Possibility to compare with competition
- Interdependency between process indicators and organizational goals

Comparation of models according to cited criteria is described in the paper „Process performance measurement models" (Simeunović at al, 2013, p.226). The results of comparative analysis show that all models consider performance from different perspectives, and that they are designed for different purposes. Analysis also show that the majority of models takes into account the strategy or goals while determining performance, which isn't surprising since this is the way to ensure obtaining reliable information about achieving of strategic goals, and taking corrective action , if necessary.

It should be noted that most of the studied models doesn't specify performance indicators, but gives an indication for their determination, because the indicators are viewed as too specific to each individual company.

However, what is most notable is that none of these models link directly organizational goals and performance indicators, in other words, they don't specify their interdependence, which would allow model flexibility. This is important because the environment is dynamically evolving, and goals, as well as the organization's strategy should be changed in time and when they change, some of performance indicators also have to be changed. Therefore, there is the need for performance measurement system flexibility. According to Franceschini at al (2007, p.55), one of the most critical aspects in operations management is "translating" a firm's goals into performance indicators. Those remarks are not surprising since even two decades ago numerous authors espoused the need for reflection on measures to ensure that they are updated to reflect these continuous changes (Meyer & Gupta, 1994; Ghalayini & Noble, 1996; Dixon et al., 1990; Wisner & Fawcett, 1991).
So, the crucial question is: How to enable flexibility in measuring performance, i.e. how to respond quickly to changes of the business system goals, and adapt performance indicators, so the performance measurement results are kept up to date and provide timely and accurate information?

4. PROCESS PERFORMANCE MEASUREMENT MODEL BASED OF OBJECTIVE-INDICATORS LINKAGE

In order to overcome mentioned shortcomings of performance measurement models, and, particularly, to enable flexibility in measuring performance, the novel approach was proposed. This approach allows direct linking of organizational goals and process performance indicators. In order to apply this approach, it is necessary for an organization to have well-designed process model, that is the base for process management. Graphical interpretation of creation the foundation for processes management, and, therefore, for performance measurement is shown in Figure 1.

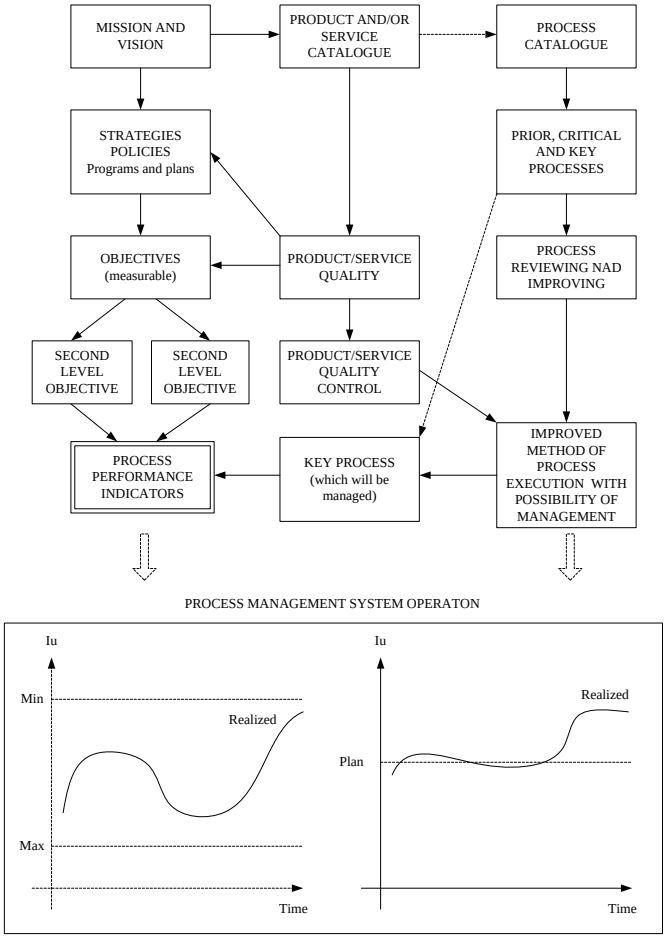

Figure 1: Establishing foundation for process management (adapted from Radović at al, 2012a, p. 611)

The first step in establishing process-oriented performance measurement system (figure 1) is the development of mission and vision statement. The mission can be seen as the far goal that may never be reached. It should describe what the organization is in business to do. The vision is where the company wants to go, the ideal future state of the organization (Radović at al, 2009). Well-defined mission statement should facilitate product/service identification, on the one hand, and identification of stakeholders, and their requirements, on the other hand, vision statement, along with identified stakeholders, are the basis for defining those product/service quality features by which the organization meets the requirements of stakeholders. Considering the importance of stakeholders for the success of the organization, their requirements should be than incorporated into the strategy and translated into measurable organizational goals. Those goals have to be defined according to stakeholders needs. Furthermore, company should decompose those organizational goals to lower level objectives of organizational units. At the same time, according to mission, the basic product/service (or more basic products/services) should be identified, and the product/service catalogue should be created, which is the basis for business process identification, i.e process model design. Next step is to identify those processes and activities that (from process model) lead to achievement of organizational goals, and whose performance indicators should be measured. However, since it is impossible to simultaneously improve all processes, or to measure performances of all processes, due to limited resources and time, considering that all performances are not equally important, efforts should be focused on measuring the performances of those processes whose execution contributes to achievement of the organizational goals or stakeholders requirements. So, the list of prior, critical and key processes should be created, whereby the key processes are those processes through which the specificity of business system can be recognized and which contribute to business system goals realization. Given the above mentioned, it is necessary to select the key processes that will be measured and managed.
The final step is to translate the top level goals into key process performance indicators which lead to the achievement of these goals. The degree to which goals, as a mission, are met is determined by measuring and comparing process performance with a defined goal.
Goal translation into key process performance indicators should enable determination of their interdependency. This would allow achieving of performance measurement system flexibility, i.e. possibility of rapid adaption of performance indicators according to changes in organizational goals and strategies. Translation process is performed as follows.
When the goals at the highest level of organization are defined based on the requirements and expectations of customers, shareholders, employees, the state, local communities, and other stakeholders, it is necessary to determine what an organization needs to do for achieving those goals. Therefore, the strategic goals of the organization, aligned with the requirements of stakeholders, are decomposed into the lower level objectives, i.e. objectives of the business system units. If an organization achieves objectives of its organizational units, the top level goals will be achieved too. The goals of organization units are considered as second level objectives, and they should be defined according to SMART principles. In this step, it's necessary to define the units of measurement, reference values (values that are required for goal achieving), the method of measuring these goals, and to describe how (in which interval) the trend of achieving these goals will be followed. Next step is to determine which processes in organization should be performed in order to achieve those second level goals. Those are the key processes, and performance of these processes should be measured, since they contribute to defined goals realization.
The logic and procedure for translating the business system's goals in process performance indicators are shown in Figure 2.

Starting from the procedure described above, interdependencies between business system's goals and organizational unit's objectives can be identified, as the interdependencies between organizational unit's objectives and key process performance indicators, and therefore the direct linkage between business system's goals and process performance indicators

The proposed approach for measuring performance has been applied in over 30 companies in Serbia in the period from 2010 to the present, and the preliminary results show the satisfactory success in measuring business performances in these companies.

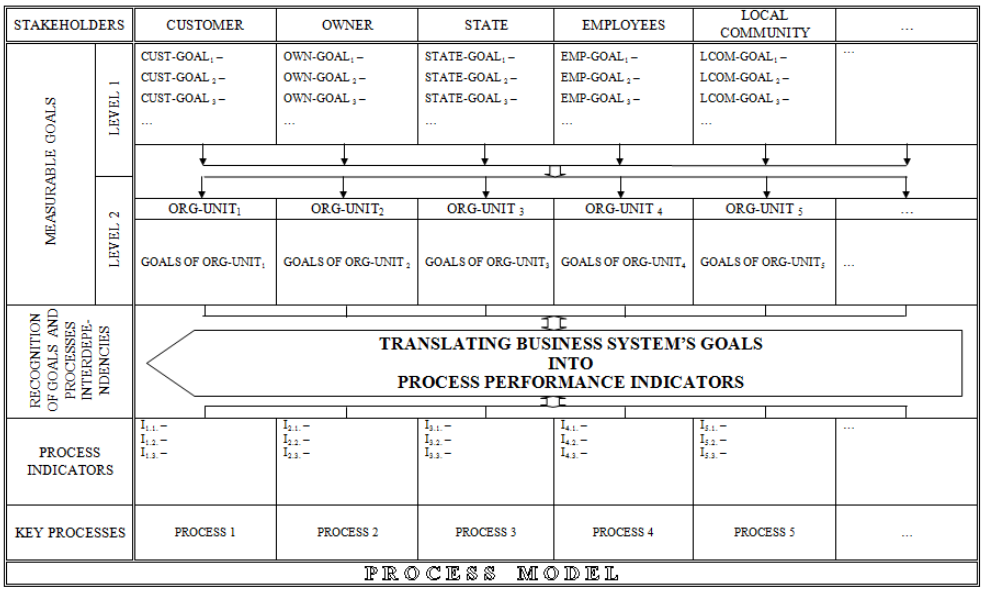

Figure 2. Procedure for translating the business system's goals in process performance indicators (Radović at al, 2012b, p.129)

5. CONCLUSIONS AND FURTHER RESEARCH

It is well-known that the performance measurement is vital for business system success and development. In the literature, there are number of process performance measurement models and frameworks. In this paper, some of those models are briefly described, and the results of their comparative analysis are shown. According to those results, each of the models has a purpose in the practice, and none of them can be selected as the best or the most successful model.

Generally, those various models and frameworks have a clear academic grounding, and are "philosophically" sound – they do provide guidance on how a company should design its unique performance measurement system, but they rarely help with the practical realization of specific measures at an operational level. The measurement practitioner still has to translate the framework into practical measures. (Tangen, 2004, p.736). However, what is most notable is that none of those models link directly organizational goals and performance indicators, in other words, they don't specify their interdependency which would allow model flexibility.

Accordingly, the novel process performance measurement approach is suggested, which starts from business system goals, decompose them on the lower level objectives and link them to the key processes of business system. Suggested approach allows interconnection between organization's top level goals and key process performance indicators, by using lower level objectives. This should enable model flexibility, i.e. rapid adaption of performance indicators according to organizational goals changes.

The next step would be, according to linkages between goals and process indicators that are identified in companies in which this approach has been applied, to define the general set of business system's goals and process performance indicators, and to determine their direct relationships, which would be applicable in all companies. This would be further research direction of authors.

[3] University of Belgrade, Faculty of Organizational Sciences, tisma@fon.bg.ac.rs

Abstract: *The purpose of this paper is to compare business process management and business process improvement practice in Serbia from study in 2012 and 2014 in order to notice if there is any progress in implementation of those practices or companies process maturity level according to CMMI model, and whether there are changes in problems and challenges that companies in Serbia encounter while trying to implement process change initiatives. Questionnaire was sent to approximately 500 companies in Serbia based on the similar research in 2012 and response rate was higher. Results of the comparison study show that process maturity level increased over a two years period, that the main business driver for process change is need for cost reduction and main challenge is lack of interest within top management. This paper suggests steps for further efforts in process management and improvement practice and can be useful for practioners and researchers on this field in similar economies.*

Keywords*: Business process management, Process improvements, Serbian industry*

1. INTRODUCTION

Today, there is declining number of customers who make the decision solely on price, and cost, quality, delivery speed and reliability play a decisive role in selecting product and/or service. (Simeunović et.al, 2012) Stojanovic et.al. (2012a) stated that “constant intensification of global competition and increasing of market demands, force all business systems, to find new ways of preserving and improving its competence and achieve advantage on market in terms of prices, deadlines, quality goods and services”. (p.205) Madison (2005) considers that 85% of all problems in the company can be attributed to the processes, and 15% to people, and solving problems in processes may lead to customer satisfaction improvement, cost and cycle time reduction (p. 3). Radović et.al. (2012) describes processes as elements of business system structure, which increasingly gaining the importance, because they are entity which can be used for the best establishing of new business systems, analyzing, improving and developing of existing business systems and managing of his parts and system in the whole. (p.4)

Business Process Management (BPM) has emerged as a concept in literature and practice in the last two decades. So, many associations of process professionals like BPTrends or Process Excellence Network analyze and monitor development of BPM practice in the world for several years (Wolf and Harmon, 2012; Process Excellence Network, 2012). First research of this kind was conducted in Serbia two years ago. The motivation to repeat the similar study after two years was to notice if there is any progress in process work in Serbia and to create a picture of what process management programs might look like in the following period. In the research, authors used questionnaire which was sent to 500 companies which operate in Serbia via e-mail and LinkedIn professional network.

After an introduction, a brief literature review will be given about business process management and improvement. Chapter three will present research methodology that was used for the purpose of this paper, and the main results of the research will be given in chapter 4. These results will be discussed in chapter 5, and the conclusion and future implications will be given afterwards.

2. THEORETICAL BACKGROUND

“Processes are vital for any organization, and they constitute a business system and things that it does, so it can be said that any business system can be managed by managing its processes”. (Stojanović, 2012c, p.1374) Lientz and Rea (2001) stated that “company profitability depends on processes”. (p.15) Business process management and process improvement are important themes for researchers and practitioners, because process improvement represents bottom-line of business enhancement. (Siha & Saad, 2008, p.778). Jeston and Nelis (2006) defined BPM as “achievement of organizational objectives, through the

improvement, management and control of essential business processes", and emphasized that the "process management is an integrated part of "normal" management" (p.11) Therefore, the first part of the research is dedicated to ways in which companies understand BPM and how they describe level of interest for process improvements.

In order to recognize the level of adoption of process management practice in Serbia, authors used CMMI model, which contains five level of process maturity (initial, repeatable, defined, managed, optimizing). Stojanović et.al. (2012c) stated that "key assumption of the model is that immature companies cannot provide the consistency of their performance, while mature companies make quality products at effective and consistent manner", and key point of the model is to understand where the organization is today and where it wants to get. (p.1374)

Skalle et.al. (2009) emphasized that one of the areas that are in focus of BPM is business process design and improvement in order to fulfil or exceed customer expectation, while achieving organizational goals. Work on process improvements is one of the important parts of BPM and is recognized as one of the main priorities of companies according to Gartner survey from 2009. (Zellner, 2011) Business process improvement was one of the sources of competitive advantage, but now is a necessity for surviving on the market. (Stojanovic, 2012b, p.281) Also, one of the shortcomings of BPM is long duration of implementation and companies cannot wait long to see the results, so they need to define improvement projects which will achieve and show results quickly and these projects can be a key drivers for successful BPM deployment. One part of the survey is dedicated to process improvements as part of the BPM in order to comprehend success factors for process improvements so as BPM.

The main goal of this research is to evaluate level of adoption of process practice and to investigate what are drivers, challenges and trends for process work in Serbia in the following period, and to propose further efforts in process management and improvement practice which can be useful for practitioners and researchers on this field.

3. RESEARCH METHODOLOGY

The purpose of this study is to determine if there are any changes in the extent to which companies in Serbia have adopted process management and improvement practices, whether their process maturity level is higher or lower according to CMMI model, and what are the problems and challenges that companies in Serbia encounters while trying to implement process change initiatives. Besides that, it would be interesting to see:

1. What are factors for success in process improvement and management?
2. What is next for process management is Serbia?

In order to compare results, similar survey instrument to the one used in 2012 research was used, with additional questions concerning business process improvement (BPI) practice. Questionnaire included 28 questions divided into three groups: the first group are general questions about company and respondents, second group are questions about process maturity and third group of questions refers to business process improvement practice. The questions required single or multiple choices and some of them included an open form in case when offered answers couldn't reflect the views of the respondents.

The research instrument was mailed to general managers, CEOs, process analysts at a random sample of 500 manufacturing and service organizations in the Serbia. A total of 89 usable responses were returned, resulting in a response rate of 17,60 percent. The 300 of 500 companies were included in previous research. In 2012 research instrument was sent to 300 companies and response rate was 13,66 percent. This year, authors also used social professional network group LinkedIn to contact potential respondents. All of these responses were included in the results presented in this paper.

After the questioners were filled by the participants, the statistical package SPSS was used for calculation of frequencies and X^2 test (with significance set to 0.05) and Man-Whitney U test (with asymptotic significance value set to 0.05). In order to see is there any difference between results from 2012 and 2014, Z test was used.

4. RESULTS

Among 89 respondents in the research, 10,1% were general managers, 7,9% were executive officers, 22,5% were business function/department managers, 13,5% were business analyst, 14,6% were process analyst, 12,4% were consultants, 9% were researchers, while 10,1% of respondents stated that their position was something else. In comparison with previous research, new job title is defined – process specialist/analyst, because authors assumed that BPM practice is developed from 2012 and that this job title is present in

companies in Serbia. Majority of the companies included in the research were large companies (46,1%) with more than 250 employees. Also, majority of companies were service oriented 60,7%, 20,2% were manufacturing companies, while 19,1% were operating both in service and manufacturing industry.

Most companies were domestically owned (66,3%), about a third of them have foreign owners (24,7%), and with the rest (9%) the ownership was shared between domestic and foreign owners.

Figure 1 presents the comparison of the way the respondents understand the term Business process management

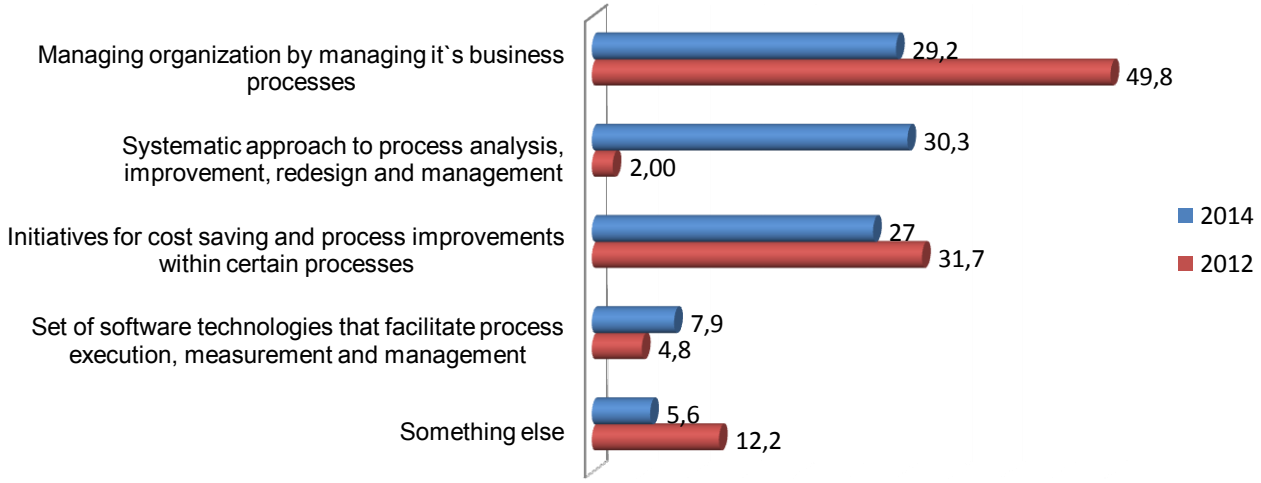

Figure 1: Companies' understanding of Business process management concepts in 2012 and 2014

Figure shows that respondents mostly indicated that their organizations understand BPM as systematic approach to process analysis, improvement, redesign and management (30,3%) or managing organization by managing its business processes (29,2%). Initiative for cost saving and process improvement of certain processes is also represented in 27%.

The participants were asked to explicitly position their company at one of the levels offered by CCMI maturity model. The results are shown in Figure 2.

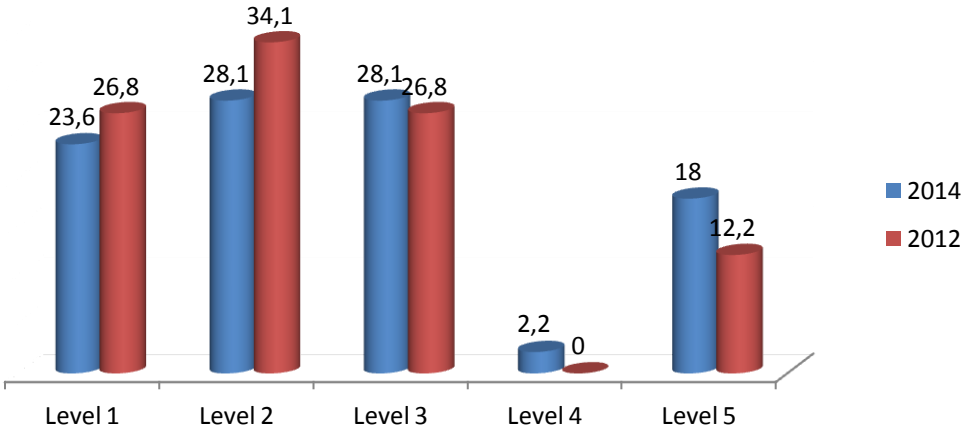

Figure 2: Levels of CMMI process maturity of companies in Serbia in 2012 and 2014

In 2014, most of the companies are on second or third level of process maturity (28,1%), and there's increasing number of companies which are on the Level 4 or 5. None of the respondents placed it's company's processes on Level 4 in 2012 and only 12,2% (5 of them) were at level 5, but in 2014, 2,2% (2 companies) are at level 4 and 18% (6 companies) are at the highest level of process maturity.

Table 1 shows that in 2012 and 2014, majority of the companies stated that they are undertaking activities concerning process maturity "in some cases" or "always" . Also, in 2014 percent of companies that answered "never" is much lower than 2012, and on the other side there is higher number of companies that gave answer "always" than in 2012.

Table 1: Questions concerning process maturity in 2012 and 2014

	2014	2012	2014	2012	2014	2012
Questions concerning process maturity	Never		In some cases		Always	
Business processes documented and updated	6.8	12.2	53.9	63.4	39.3	24.4
Business processes measured and monitored	11.2	14.6	48.3	46.3	40.4	39
Core business process models include activities of suppliers and partners	25.8	30	57.3	51.2	16.9	9.8
IT support in accordance with business processes	8.9	9.8	58.4	70.7	32.6	19.5
Skills needed for activities are defined and documented	12.6	12.2	58.4	75.7	29.2	12.2
Managers are trained for analysis, design and business process management	17.9	19.6	56.2	68.3	28.9	12.2
Process managers use data about performances in order to manage processes	16.8	17.1	59.6	65.9	23.6	17.1

In 2012, only 2,4% of the respondents stated that process improvement initiatives are always being able to identify and remove problems and inconstancies, while 82,9% stated that problems are frequently solved by process improvement initiatives. On the other side, in 2014, 15,7% said that that process improvement initiatives are always being able to identify and remove problems, and 73% stated that problems are frequently solved by process improvement initiatives. Difference between these results is confirmed with Z test (Z=-2.2041, p=0.027)).

In 2014, 58,4% of the companies stated that they don't have formal group for process management, while in 2012 that number was 39%, or if they have formal process management group, location is within their executive management (18%), while in 2012 24,4% of the companies stated the same (Z test also confirmed that there is significant difference between results for the companies which do not have formal group (Z=-2.0581, p=0.039).

Comparison of main drivers behind business process change initiatives identified among companies operating in Serbia are given in figure 3 (multiple answers were allowed).

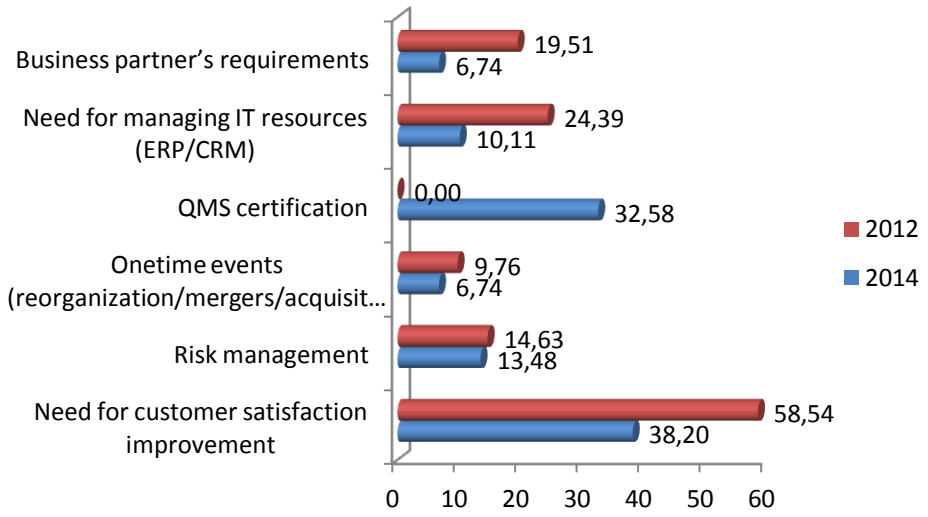

Figure 3. Main drivers for business process change initiatives

Main driver for business process change in 2012 were need for customer satisfaction (58,54%), need for managing IT resources (19,51%) and business partner`s requirements (19,51%). In 2014, need for customer satisfaction was also main driver for 38,2% companies, but other drivers were changed. QMS certification was the second driver with 32,58%, and the others drivers have approximately the same percent. Z test also confirmed significant difference between results for "need for customer satisfaction improvement" (Z=2.1672, p=0.03) and QMS certification (Z=-4.1467, p=0.00).

With regard to process initiatives that companies have undertaken so far, new answers were added in 2014, in accordance with development of process improvement practice: Modeling/documenting processes

Redesign of processes with reference models, Lean Six Sigma improvement projects and Process excellence concepts. Comparison of the results is given in table 2 (multiple answers were allowed)

Table 2: Comparison of the process initiatives that companies have undertaken so far

Business process initiatives undertaken so far	2014 %	2012 %
Business process architecture development	51,69	41,46
Business process measurement system development	53,93	58,54
Modeling/documenting processes	65,17	-
Business Process management	58,43	56,10
Process managers training for process analysis/redesign	14,61	26,83
Core processes redesign	35,96	17,07
Redesign of processes with reference models	3,37	-
Six Sigma improvement projects	3,37	4,88
Lean improvement projects	8,99	12,20
Lean Six sigma improvement projects	4,49	-
Continuous process improvement projects/KAIZEN	12,36	19,51
Process automation projects	35,96	34,15
Process excellence concepts	5,62	-

Z test shows that there is significant difference in the application of core processes redesign ($Z=-2.183$, $p=0.029$).

Challenges and resistances encountered while trying to broaden business process initiatives differ from previous study. The main challenges in 2012 were that multiple process change projects require same resources and management doesn't want to invest in process change projects at this time. In 2014, main challenge is lack of interest within top management and also management doesn't want to invest in process change projects at this time. But, five companies stated that they haven't encountered any type of resistance. Results are given in table 3 (multiple answers were allowed)

Table 3: Comparison of challenges and resistances encountered while trying to broaden business process initiatives

Challenges encountered	2014 No. of companies	2012 No. of companies
Lack of interest within top management	31	8
Management doesn't want to invest in process change projects at this time	24	11
Multiple process change projects require same resources	18	11
Previous process improvement projects were unsuccessful	13	0
Management requires ROI that is not achievable	7	2
No resistance	5	1
Something else	2	17

Table 4 present which process initiatives companies plan to undertake in the following period.

Table 4: Process initiatives that companies plan to undertake in the following period

Business process initiatives undertaken so far	No. of companies
Core processes redesign	32
Business Process management	24
Process managers training for process analysis/redesign	22
Business process measurement system development	22
Modeling/documenting processes	20
Business process architecture development	19
Process automation projects	17
Redesign of processes with reference models	13
Continuous process improvement projects/KAIZEN	12
Lean improvement projects	11
Lean Six sigma improvement projects	10
Six Sigma improvement projects	9
Process excellence concepts	6

The third part of the survey consisted of questions regarding business process improvement. A majority of companies reported that process improvement is part of normal work environment (50,6%), and 30,3% stated that interest in process improvement was expanding. Companies that reported expanding interest for process improvement were so far engaged in following business process initiatives: Modelling/documenting

processes (14 companies), Business process architecture development (11 companies) and Business process management (11 companies). These companies plan to implement Business process management (13 companies), and will continue to work on process modelling and business process measurement system development. Companies with expanding interest in BPI also have core process redesign in their plans. Companies in which process improvement is a part of normal work environment have so far implemented following initiatives: Business process management (36 companies), Business process measurement system development (35 companies), and Business process architecture development (33 companies).

More than one third of companies stated that they were engaged in business process improvement for more than two years (36%), and one third of companies reported that they work more than five years on process improvements (34,8%). The focus of business process improvement initiatives is mainly on production/operations (28 companies), IT business unit (27 companies) and sales (24 companies) or customer service (23 companies). According to the survey, 22 companies reported that they apply business process improvement methodologies in the whole company. In accordance with expansion of application of BPI in companies, majority of the respondents had enterprise-wide improvement projects (34,8%). Companies stated that their process improvement project length is 6-12 months (19,1%), while 15,7% reported that average project length is less than three months. Companies whose process improvement project length is 3-6 months account for 15,7%. Survey shows that 44,9% of the companies expect that number of employees dedicated to process improvement will increase, and 42,7% stated that number of employees will remain the same. Only 12,4% said that this number will decrease in the future. The same situation is with budget for process improvement program. Among the companies that have deployed business process improvement initiatives, 32,9% reported that their BPI program was successful, and 20% rate their programs as unsuccessful. Survey shows that 25 of 26 companies which report that they were successful in BPI program were engaged with the program for more than two years..

Chi-square and Mann-Whitney test were used in order to test whether interdependence between the basic parameters of the company, drivers and challenges with process management and improvement practice in companies in Serbia exists. The main driver for business process change in manufacturing companies is QMS certification (X^2=7.535, df=2, p=0.025), while service companies listed QMS certification as the main driver to a much lesser extent. Large companies are increasingly facing with challenge of lack of interest within top management, while in the small companies that challenge is much less frequent (X^2=11.419, df=2, p=0.002). Companies that have not yet started with process improvement initiatives reported that the main reason was lack of interest within top management (X^2=8.111, df=3, p=0.04). On the other side, companies that work longer than 5 years on process improvement state that the main challenge for widening BPM initiatives across the company is that multiple project compete for the same resources (X^2=7.696, df=3, p=0.04). Service companies are more oriented to process improvement deployment in IT sector, while none of the manufacturing companies report any initiative within this sector (X^2=12.049, df=2, p=0.000). Small companies implement more BPI methodologies more in sales and marketing business unit than large companies (X^2=5.935, df=2, p=0.04). Large companies are mostly oriented to enterprise wide deployment of BPI (X^2=5.928, df=2, p=0.037). Mann-Whitney U test shows that companies faced with lack of interest within top management were unsuccessful in their process excellence program (U=540,00, Z=-3,336, p=0,001), and that companies which do not have a formal group for BPI are less successful in their improvement programs (U=702,50, Z=-2,331, p=0,02).

4. DISCUSSION

Majority of respondents are functional/department managers as in previous study, but also significant percent of respondents are process analyst. Respondents job title preliminary show that companies are aware of business process importance. Respondents' understanding of BPM is different in 2014 compared to 2012, but not significantly. Companies are more oriented to process improvement in order to reduce costs, but respondents also understand that BPM enables managing whole organization through business process management, like in previous study. In 2012 study, majority of the companies were at Level 1 or 2 of CMMI process maturity, while in 2014, there is growing percent of companies which are on the Level 4 or 5. Still, the majority of the companies are at Level 2 or 3, which is in accordance with companies in the world (Wolf and Harmon, 2012). Other answers to the questions concerning process maturity are in accordance to these results (see table 1). This can be a consequence of the greater business process awareness in companies.

The number of respondents who reported that process improvement initiatives are always being able to identify are remove problems is higher in 2014, compared to 2012 study. This corresponds with higher process maturity level, which implies that processes are well documented, monitored and measured. with this situation, it is significantly easier to detect errors when they happen, as well as to react in short time and with greater accuracy, thus making problem solving more efficient.

Companies in Serbia still do not have formal group for process work, and this can be a future task for our companies, especially because Chi-square test shows that companies which do not have formal BPI group are less successful in their process improvement program.

Regarding the main driver for business process change, there is significant difference between results, since companies are less oriented on improving customer satisfaction, and more on cost reduction and QMS certification. Chi-square test shows that QMS certification as driver for process change is more typical for manufacturing companies than services. The number of companies engaged in core process redesign increased in 2014, while number of companies engaged in incremental improvement activities, such as Lean, Six Sigma, or Kaizen, decreased.

Situation that might concern practitioners is growing lack of interest within top management for process improvements, especially in large companies. This is the main obstacle in starting with process improvement initiatives. The main cause of unsuccessfulness of BPI program is also lack of interest within top management. Companies in Serbia are also facing with the problem that management doesn't want to invest in process change projects at this time, which can be attributed to different priorities in transitional economies. Companies that work longer than 5 years on process improvement have a problem with lack of resources for realisation of multiple projects. It is encouraging that 5 companies stated that they do not have resistance at all, and that majority of companies reported that process improvement is part of normal work environment or that interest in process improvements was expanding.

The results show that more companies were engaged with business process architecture development, process modeling, and process measurement. This contributes to the higher overall level of process maturity in companies operating in Serbia. These projects established a foundation for future business process initiatives, which is why it is not surprising that these companies are expecting for process improvement to become everyday effort. This is why these companies, encouraged with positive results obtained at a lower level of process improvement, are ready to tackle greater projects regarding process improvement, such as core process redesign.

Continuous process improvement is traditionally focused on operations. However, there's a trend of shifting continuous process improvement practices toward service sector. By combining continuous improvement practices with IT knowledge, new process improvement concepts, such as Lean IT and agile programming, emerged. This new body of knowledge made IT sector very appealing for process improvement initiatives, especially within service industry.

Majority of the companies had enterprise-wide deployments of process improvement work, what is reflective of the fact that majority of companies worked on those improvements more than 2 years. Average length of process improvement project is less than six months, which indicates that quick wins are necessary in order for bigger process improvement initiatives to gain acceptance.
Survey shows that 25 of 26 companies which report that they were successful in BPI program deployed longer than two years BPI, so it can be concluded that past experience with process improvement projects plays a significant role in the success of improvement initiatives. Large companies are more oriented to enterprise wide deployment of BPI, while small companies implement BPI methodologies in specific business units (frequently marketing and sales).

5. CONCLUSION

Considering the results obtained from the comparison study, it can be concluded that companies in Serbia have greater process awareness now than in 2012, when this research was conducted for the first time. Companies in Serbia are at greater level of process maturity which is now closer to the leading global companies. In favour of this fact is that process specialists are able to solve the problems in companies. This higher level of process maturity helps companies to focus their process improvement efforts, thus making problems more manageable, and problem solving more efficient.
Although quick wins are essential for maintaining the momentum of process improvement efforts, more companies recognize the need to advance to a higher level of business process management. This includes establishing enterprise-wide system for process measurement and management, as well as redesign of core processes.

Formal process groups are a major process improvement success factor, which is why one of first steps in embracing process improvement practice should be the formation of specialized process teams, dedicated solely to business process management promotion.

Challenges for process improvement are also new, with lack of interest within top management being the most significant of them all. Top management should be the driving force behind all change initiatives, which is why their support is of the outmost importance. In order to obtain this support, an aggressive education policy is needed, in order to present all benefits that business process management might bring to companies strengthening business-academia connections should be one of key steps in this effort.

Abstract: *First systematic operations management research agenda emerged in 1980, with subsequent updates and additions in 1981, 1987, 1989, and 1999. Since no similar research has been conducted in 2000's, we believe it is time to assess operations management research in the 21st century. In this paper, we have studied the operations management output from eight academic journals in 4 years period (2009-2012), and compared the results with similar research conducted in the 1980's and 1990's, in regard to topics covered in operations management articles, and methodology used in operations management related research. The results show that there's a significant difference in topical coverage of operations management research being performed in the 2000's vs. the 1990's and the 1980's. Growth of interest in strategy is evident from the results, while modelling still stays dominant method in operations management research. However, a certain shift towards empirical research methodologies is present.*

Keywords*: Operations management, research topics, methodology, literature*

1. INTRODUCTION

Operations management (OM) can be defined as a design, operation, and improvement of the systems that create and deliver company's primary products and services (Chase et al., 2006) (p.9). The field of OM has been evolving for decades now, trying to distinct itself from the fields of operations research, management science, and industrial engineering by establishing its own body of knowledge and literature (Buffa, 1980; Meredith et al, 1989; Pilkington and Liston-Heyes, 1999). Operations management academics have researched OM related academic journals (Buffa, 1980; Chase, 1980; Miller and Graham, 1981; Hill et al., 1987; Amoako-Gyampah and Meredith, 1989; Meredith et al., 1989; Pennirselvam et al., 1999) in an attempt to establish a research agenda that will be in accordance with the needs of the industry.

In order to test if the proposed agendas have been followed, we've conducted the analysis of OM themed articles published in a four years period, from 2009 to 2012. The main goal was to study current trends regarding topical and methodological coverage of OM output, and compare it to trends and directions proposed in previous research. In order to compare the results of our research to research conducted in the 1980's and 1990's, we have modelled our study after the ones done by Amoako-Gyampah and Meredith (1989) and Pennirselvam et al. (1999).

The remainder of the paper is organized as follows: after the short review of similar research conducted in the past, methodology used in this study will be presented; after that, the results of the study will be presented; our results will be compared to the results from similar research performed in the 1980's and the 1990's; discussion and conclusions will follow.

2. LITERATURE REVIEW

The literature review will mainly be focused on studies similar to ours. Buffa (1980) proposed a first systematic OM research agenda. His agenda was aimed at solving real life problems in operations, and his predictions were that OM would move away from mathematical modelling. Buffa considered OM research to be narrow, based mostly on single-criterion quantitative models. He emphasized the importance of strategic planning decisions, and identified main topics to be manufacturing strategy and technological choice, job design, capacity planning, and facility location choice. Buffa also identified operations planning and control as an important topic to be addressed in the future, as well as operations in service systems.

Chase (1980) classified and evaluated OM research prior to 1980's. His results show that inventory control and scheduling are two most frequent subjects in OM research, and that research was mainly oriented towards solving problems on a micro level. He identified the evident lack of integrative component of the research, which he thought was bad for the field. Model formulation and mathematical/computer manipulation of the model were identified as dominant research strategies, thus rendering OM research

rather abstract, and making it technique oriented instead of knowledge oriented. Chase also observed that operations management does not draw upon management theory, which he found to be very unfortunate, since managerial issues such as organizational structure might be constraining factors for OM application.

Miller et al. (1981) used Delphi-like procedure among researchers and practitioners in order to generate discussion of potential agenda for operations management. The authors identified four main areas of operations management research: operations policy, operations control, service systems, and productivity and technology. Miller et al. (1981) state that more application work and field based research is needed, but that the peer review process and time constraints stand as an obstacle to action oriented research. The authors also emphasize the need for more human and organizational oriented research.

Hill et al. (1987) analyzed if Miller et al. (1981) agenda was being followed by surveying dissertations in Business Administration and Management completed in the U.S.A. during the period 1980–1986. Their research reports that inventory control and scheduling are still most popular research topics. They also report the increase in popularity of process design, strategy and quality. Hill et al. (1987) identified the need for new research methodologies to address more managerial and macro-level issues.

Meredith et al. (1989) summarized previous research, and concluded that OM research failed at being integrative and useful to operations managers and practitioners. Authors proposed a framework for research methods, and applied the framework to operations management research. They have identified quality management and technology implementation as fertile areas for future research.

Amoako-Gyampah and Meredith (1989) analyzed articles in the field of operations management appearing in ten journals for the time period of 1982-1987. The authors compared their findings to pre 1980's OM research, and concluded that work measurement significantly lost in popularity compared to previous research, while process design gained in popularity. Their research shows that inventory control has held high popularity in research topics. Amoako-Gyampah and Meredith (1989) also surveyed the proceedings of Decision Sciences Institute for 1986 and 1987, in order to compare published research with pipeline research. Inventory control and scheduling remained the most popular topics in pipeline research, while service system research has shown increase in popularity in pipeline research (14% of articles in pipeline research vs. 6% of articles in published research). The authors also surveyed the research approaches used in OM research, and the results show that modelling and simulation have been predominantly used as research methods.

Pennirselvam et al. (1999) compared the results of their study with the ones presented by Amoako-Gyampah and Meredith (1989). Their findings show significant changes in the kind of research being performed in the 1990's compared to the research in the 1980's, with greater interest in strategy and quality. The authors state the OM research is more integrative in nature in the 1990's. Modelling is still dominant methodology used in research, while the expected increase in case study research was not met. The authors also conducted a study of pipeline research, and identified quality as most popular topic.

3. RESEARCH METHODOLOGY

In order to compare the results of our study with the ones presented by Amoako-Gyampah and Meredith (1989) and Pennirselvam et al. (1999), we analyzed the same journals covered in their studies. Impact factors analysis and journal categorization show that these journals are still relevant in the field of OM. Research that analyzes the relative importance of journals used in operations management back up this claim (Theoharakis et al., 2007; Machucha et al., 2007; Barman et al., 2001; Soteriou et al., 1999;). We have surveyed original seven journals covered in Pennirselvam et al. (1999) research: International Journal of Operations and Production Management (IJOPM), International Journal of Production Research (IJOPR), Journal of Operations Management (JOM), Production and Operations Management (POM), Decision Sciences (DS), Management Science (MS), and IIE Transactions (IIET). We added International Journal of Production Economics (IJPE) to our study, since it is perceived by OM academics as a high quality OM-related journal.

We classified the articles from the selected journals by topic areas and by research methodologies. The topic areas chosen were those used in similar research (Chase, 1980; Amoako-Gyampah and Meredith, 1989; Pennirselvam et al., 1999). This allowed us to compare our results to previous findings. First step in article analysis was to determine whether the article in question was and OM article or not. If the article is an OM article, OM topics areas were analyzed, as well as methodology used in the article. All doubts regarding OM/not OM classification, topic and method coverage were resolved by consensus between authors. Emerging topics, such as supply chain management, role of operations in sustainability, performance measurement and management, lean/agile operations, and new product/service design/development were

identified, and fitting those articles into one of 17 OM topics category was quite a challenge. Some of the articles surveyed address more than one OM topic. In such cases, we counted each of the topics that were addressed because the objective of this research was to identify the current topics of interest. We also kept track of the type of topics that are studied in combination and the frequency of topic combination occurrences to look for trends in integrative research in OM. Also, multiple research methods were used in some articles. We have identified single methods, as well as combinations of methods.

4. RESULTS OF TOPIC/METHODS ANALYSIS

The following sections will cover the analysis of topical coverage and methodology used in OM output analyzed in this study.

4.1 Topical coverage

We have analyzed 4318 articles published between 2009 and 2012, and identified 2802 as OM articles. Total number of counted OM topics is given in Table 1.

Table 1: Total number of OM topics counted

No of articles	No of topics	Topics counted
2324	1	2324
456	2	912
22	3	66
Total OM topics counted		3302

Table 2 presents the coverage of OM topics by journals. It shows that's strategy has gained in popularity in recent years, accounting for 18.63%. Inventory control and scheduling are still positioned high, accounting for 17.84% and 15.35% respectively. Process design and quality are also positioned in the top part of the table, accounting for 9.96% and 8.03% respectively.

Last two columns in Table 2 show percentages of topics for periods 2009-2010 and 2011-2012. The results show that topics have held their positions for both time periods, although there was a decrease in percentage for strategy in 2011-2012 period, as well as a slight increase in percentage for scheduling for the same period. It can also be seen that topics occupy same positions in two-year time periods and in four year (cumulative) time period.

In order to look for integrative research in operations management, we have analyzed types of topics that are studied in combination, as well as the frequencies of their occurrence. The results show that most popular combination is inventory and control and scheduling, accounting for 7.11%. Combination of strategy and process design follows with 4.18%, followed by distribution and inventory control, and forecasting and inventory control with 3.14% for each combination. Besides combinations mentioned above, there are 142 more, but most of them have total count of 1 or 2.

During the study, we have also identified emerging topics in operations management, which were not covered by the original list of OM topics described by Chase (1980), and Amoako-Gyampah and Meredith (1989). Supply chain management (SCM) is by far the most common emerging topic, with total count of 573 (47.95%) occurrences. SCM is not that new of a field in OM research, but since it was not included in the original 17 topics, we have decided to count it as an emerging topic. SCM is followed by Role of operations in sustainability with total count of 100 (8.37%) occurrences, Performance measurement and management with total count of 99 (8.28%) occurrences, Lean/agile operations with total count of 91 (7.62%) of occurrences, and New product/service design/development with total count of 78 (6.52%) of occurrences. All other emerging topics comprise remaining 21.26%.

4.2 Research methods

Table 3 presents a matrix of methods used in OM research by journals. The matrix consists of single methods used in research, as well as combination of methods that we have encountered in our study. Methods are sorted by frequency of occurrence. The results in the table show that modeling is still used the most in OM research, with the account of 43.61% in total. The percentages are similar in periods 2009-2010 and 2011-2012, as can be seen from last two columns of the table.

Table 2: Topical coverage of operations management research

Article percentage	1.25	1.03	3.14	2.78	3.21	3.68	14.24	18.27	15.42	24.02	1.75	2.46	2.39	1.93	1.96	2.46	100			

It is interesting to note that case study is second most popular method used in OM research, accounted for 12.03%, which is a significant increase in popularity compared to study performed by Pennirselvam et al. (1999). Survey is very close, accounting for 11.99%, while simulation decreased from 17.84% in 1999 to 7.46%. Modelling is mostly used in inventory control and scheduling research, which in accordance with results from previous studies. Empirical methods, namely case study and survey, are predominantly used in research that is dealing with strategic issues of operations management. All other research methodologies account for less than 8%.

Modeling and simulation is the most popular combination used in OM research, accounting for 3.28%. It is also interesting to note the number of times a "hard" methodology, such as modeling or simulation, is backed up with "soft", empirical methodology, namely case study, field study, or survey. The results show that a total number of combinations of "hard" and "soft" research methods accounts for mere 3.53%.

5. COMPARISON WITH PREVIOUS STUDIES AND DISCUSSION

Our main goal was to study research topics and methodology used in operations management research, and to compare it with previous studies of similar type, in order to see whether the established research agendas are being followed, and to see if new trends arose in the 21st century. Table 4 shows comparison of findings from our study, with findings presented by Amoako-Gyampah and Meredith (1989), and Pennirselvam et al. (1999) in their studies.

Table 4: Comparison of OM topics in 1980's, 1990's, and 2000's

Topics	Amoako-Gyampah and Meredith study		Pennirselvam et al. study		Our Study	
	Ranking	%	Ranking	%	Ranking	%
Inventory control	1	28.15	2	16.19	2	17.84
Scheduling	2	16.89	1	25.54	3	15.35
Process design	3	15.23	4	11.29	4	9.96
Aggregate planning	4	11.26	15	0.66	11	2.30
Services	5	6.29	8	2.71	9	3.03
Quality	6	3.97	3	11.34	5	8.03
Strategy	7	3.64	5	10.88	1	18.63
Project management	8	3.31	12	1.74	15	1.15
Capacity planning	9	2.98	9	2.09	8	3.63
Maintenance	10	2.65	10	2.04	10	2.54
Purchasing	11	1.66	11	1.99	7	5.06
Facility layout	12	1.66	6	7.61	12	2.09
Forecasting	13	1.32	14	1.02	13	2.00
Quality of work life	14	0.33	17	0.20	16	0.51
Facility location	15	0.33	13	1.07	14	1.61
Distribution	16	0.33	7	3.12	6	5.91
Work mesurement	17	0.00	16	0.51	17	0.36
Total		100.00		100.00		100.00

In order to test the proportions obtained from our research with the ones given by Amoako-Gyampah and Meredith (1989), and Pennirselvam et al. (1999), we have performed a chi-square test, and hypothesized that relative proportions from all three studies are the same. The results from the chi-square test indicate that the differences between the proportions from all three studies are significant, at an alpha level of 0.01.

The topic that contributes the most to the difference between the proportions is strategy. Our study shows that strategy is the most popular OM research topic, while it was ranked as 5th and 7th topic in Amoako-Gyampah and Meredith (1989), and Pennirselvam et al. (1999) studies, respectively. This rise in popularity was predicted by Amoako-Gyampah and Meredith (1989), and confirmed by Pennirselvam et al. (1999) study, as well as in our study. It is interested to note that growth in popularity of strategy corresponds to the growth of popularity of emerging topics. To test this, we have analyzed further the relationship of emerging topics with the traditional OM topics, and found out that in most of the cases emerging topics were included under strategy, where more than 50% of articles about supply chain management were dealing with strategic issues of operations management. The situation is even more indicative with lean/agile operations, where nearly 70% of the articles were included under strategy. Inventory control and scheduling are still positioned high on the list (2nd and 3rd place), as was the case with previous research. Inventory control and scheduling are two topics that are traditionally combined one with another, but what is interesting is the rise of combinations of inventory control with other OM topics, especially the ones that are dealing with logistical aspects of operations, namely purchasing and distribution. This is an encouraging fact, showing a sign of

integrative approach of current OM research. Process design is also positioned high on the list, as was the case with previous research. It is frequently combined with strategy, which was also shown in Pennirselvam et al. (1999), but there's an increase of process design/quality combinations compared with the mentioned study.

As far as methodology goes, modeling is still number one choice among OM researchers. This fact is unsettling, because it contributes to the fact that OM is perceived as an artificial discipline, detached from real-life problems, since modeling is still utilized more than empirical research. What gives hope is the fact that the results show the increase of survey and case study utilization in OM research. This corresponds to the rise of interest in strategic issues of operations, since survey and modeling are methods mostly used in strategy research. This deflection from artificial and axiomatic research is also noted by Craighead and Meredith (2008), but it is not enough to make a paradigm shift in operations management research. Although it wasn't addressed explicitly in this study, action based research is still not used enough in OM research, whiles many scholar stress the importance of action oriented research, since it can contribute to knowledge as well as to practice (Coughlan and Coghlan, 2002; Näslund et al., 2010; Sheikhzadeh and Heidari, 2012). The popularity of modeling can be attributed to one of two factors. Firstly, high level of rigor is required in top-ranked scientific journals, which puts reviewers in a tough position. Reviewers are often unable to recognize the work properly executed with less-of-a-standard methodologies, while some reviewers perceiving case and action-based methodologies as less structured than traditional analytical modeling (Barratt et al., 2011). Secondly, in today's "publish or perish" environment, the authors are forced to walk the tested paths, and use "proven" methods in their research. This saves their time, since they don't have to spend months (or even years) in a real life environment trying to solve concrete problems, and grants them a better starting position in a review process, since they too are aware that a high level of rigor can more easily be followed by utilizing traditional research methods, such as mathematical optimization or simulation.

Pennirselvam et al. (1999) stated in their study that a new, more relevant list of OM topics might be needed, having in mind the rise of popularity of supply chain management and new product/service development/design. We concur with this point, as our study also shows the popularity of supply chain management, as well as other topics, such as lean/agile operations and performance measurement and management.

6. CONCLUSIONS AND FURTHER RESEARCH

The main goal of this study was to compare the current state of operations management research (topic- and methodology-wise) with similar research conducted in the past. The results have confirmed some conclusions from the past research, and have backed up some predictions regarding topical coverage of OM research. Two main problems still are the lack of integrative approach to OM research, and detachment of OM research from real-life problems. Although some advancement has been made, the number of articles which combine several topics in one research is still relatively small. Mathematical modelling is still dominant methodology used in OM research, although case study and survey gained in popularity. This gain is in correlation with the rise of popularity of strategic topics, since these two methodologies are most frequently used in this type of research.

An update of OM topics list is definitely needed, since it is hard to categorise some articles that are OM in nature by using the existing topic list. Some new topics have been noted in earlier research, such as supply management, new product development, and sustainability and environmental concerns. In the meantime, more topics have emerged, such as lean/agile operations and performance measurement and management.

Previous studies compared published research to pipeline research, and the result show differences both in topical coverage and in methodologies being utilized. The future of our research would be to cover more years with published research, and also to analyze conference proceedings in order to see if anything has changed regarding the relationship between published and pipeline research. It would also be interesting to see if new research methodologies are being used with the emerging topics, and to devote a special study to action-based research, and the way it is represented in top-tier OM related journals. Since action research is advocated by many OM scholars, we think that a separate study on action research in operations management is needed.

ORGANIZATION OF BUSINESS SYSTEMS

COMPARISON OF DIFFERENT QUANTITATIVE APPROACHES TO ASSESMENT OF ORGANIZATIONAL CULTURE

Abstract: *Different authors point out that the organizational culture is a very important aspect of every organizational system. They all agree that it is usually influenced by various factors and that their combinations generate different types of culture. However, if its elements are managed properly, organizational culture can present valuable competitive advantage and the source of organizational development. It is crucial for management of every organization to adequately deal with the cultural issues, to continuously project the desired condition of culture and to put the efforts on reaching it. In order to define necessary steps for improving the culture, current state of culture should be specified first, and then compared to the designed one. It means that organizational culture needs to be measured somehow. This article will provide two approaches for measuring and comparing the culture among individuals and organizations. Two models, developed by different researchers, but with significant similarities, will provide the method not only for quantifying the organizational culture, but also for developing certain factors that determine it, in order to improve the organizational performance. The results can present the managerial guidelines for leading organizational development through implementing changes in the culture.*

Keywords*: Organizational culture, behavior styles, quantitative approach, measuring, organizational change*

1. INTRODUCTION

The appearance of culture as a concept which is substantial for organizations has generated numerous questions and unresolved issues for the organizational design and development. Opened questions remain concerning the content of culture, the influence on organizational results, the possibility of measuring the culture and the feasibility of cultural change. It is generally accepted that the organizational culture is an important element of all organizations and an integral part of the organizational development (Waterman Jr., Peters, & Phillips, 1980).

Culture has been treated by organizational researchers as a set of cognitions shared by members of a social unit (O'Reilly, Chatman & Caldwell, 1991). These cognitions are developed through social interaction and process of socialization when individuals are in connection with different elements of culture. Professor Geert Hofstede defines national culture “as the collective programming of the human mind that distinguishes one group or category of people from another” (Hofstede, Hofstede, & Minkov, 2010). The "category" can refer to nations, regions within or across nations, ethnicities, religions, occupations, organizations or genders. At organizational level, he defines culture “as the collective programming of the minds of group members by which one group distinguishes itself from other groups”. According to Hofstede, differences between nations are on the deepest level of culture, on the level of values, as presented on Figure 1.

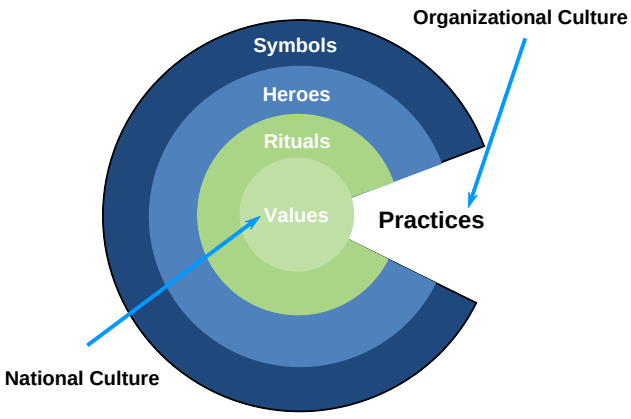

Figure 1: Different levels of culture (Hofstede, Hofstede, & Minkov, 2010)

Organizations that exist within the same national culture differ among themselves on a higher level of culture, the levels called practice (organizational rituals, heroes and symbols). It is level of practice which provides the information about the appropriateness of behaviors. Practice reinforces ways of thinking and behaving of individuals. It strengthens the connection between features in the environment and an individual's responses. There is an interpretation that individuals in organizations develop appropriate behaviors to reduce ambiguity and uncertainty of different events.

Different views on organizational culture and its components will be described in section 2 of this article. As presented on Figure 1, organizational culture can be layered. Each segment of the culture can be compared for different individuals, groups, nations, organizations etc. In order to compare any two features, they must be measured first. In section 3 of this article will be presented two tools for measuring the organizational culture. Each of them focuses on different elements of this phenomenon. However, the results that they provide have numerous similarities, which will be pointed out in the discussion part. Finally, certain conclusions and directions for future research will be given in section 5 of this paper.

2. THEORETICAL BACKGROUND OF ORGANIZATIONAL CULTURE

Relationships among people are recognized as a very important component in different organizational models (Jevtić, 2013). Waterman Jr. et al. (1980) propose *Stuff* as one of the elements in their 7S model. *People* are important part of Star model (Kates & Galbraith, 2007). Harold Leavitt (1965) also recognizes *People* as an organizational factor in his Diamond model. Such relations between members of an organization, together with their thoughts and perceptions, can be described as organizational culture. Different authors have different understandings and approaches to organizational culture.

Charles Handy (1976) describes four types of organizational culture: power culture, role culture, task culture and person culture. A *Power culture* characterizes influence that comes from a one person of group of people. Other members of organization, in which this culture is dominated, are as powerful as their possibility to freely get in touch with the supreme authority and with as few intermediaries as possible. Quick decision making and little bureaucracy are also characteristics of this culture. A *Role culture* characterizes highly defined structure and bureaucracy. In this culture, influence derives from a position in organizational structure, but not from expertise of employees. Role culture increases by procedures, job descriptions and role definitions. A *Task culture* characterize by the structuring of employees within teams. Power derives from expertise as long as a team requires expertise. This culture often exists within the matrix structure. *A Person culture* characterizes situations in which individuals are more important than the organization itself. This culture is appropriate for some professional partnerships, where each partner brings specific expertise to the organization.

Deal and Kennedy (1982) defined organizational culture as *the way things get done around here.* They differentiate four types of cultures: work-hard, play-hard culture, tough-guy macho culture, process culture and bet-the company culture. Those four types of cultures differ on how quickly the organization receives feedback, the way members are rewarded, and level of risks taken.

Cooke and Rousseau (1988) define culture as the behaviors that members believe, are required to fit in and meet their expectations, within their organization. Twelve behavioral norms are grouped into three general types of cultures. *Constructive cultures* characterize interactions among members and approach tasks in ways that help them meet their higher-order needs. *Passive-defensive cultures* characterize interactions among members in ways that will not threaten their own security. *Aggressive-defensive cultures* characterize interactions among members in forceful ways to protect their status and security.

Edgar Schein`s (1992) model of organizational culture has three levels. At the first level are organizational attributes that can be seen, felt and heard – known as *artifacts*. At this level of organizational culture we can see visible items, such as dress code, office design, furniture, rewards and recognition to employees, but also elements as logo and slogan of the company, mission statement and other elements. At the next level of organizational culture are values which represent preferences of individuals regarding certain aspects of business performance (i.e. loyalty and quality of provided services to consumers). Examining this level of organizational structure is mostly realized by interviewing members of the organization and by using questionnaires to obtain information regarding attitudes of employees. According to Schein, the lowest level of organizational structure assumes organizational assumptions. These are the elements of culture that are unseen and not cognitively identified in everyday interactions between organizational members. Surveys and interviews cannot be used for collecting data related to these characteristics of the organization.

Robert Quinn and Kim Cameron (2011) researched what makes organizations effective and successful. Their model of organizational culture distinguishes four culture types. Competing values produce polarities like: flexibility versus stability and internal versus external focus. These two polarities construct the quadrant with four types of culture. A c*lan culture* describes friendly workplace where leaders act like father figures. Clan culture organizations have internal focus and flexible structure. An *adhocracy culture* describes dynamic workplace with leaders that stimulate innovation. Adhocracy culture organizations have external focus and flexible structure. A *market culture* describes competitive workplace with leaders like hard drivers. Market culture organizations have external focus and high level of control. A *hierarchy culture* describes a structured and formalized workplace where leaders act like coordinators. Hierarchy culture organizations have internal focus and high level of control.

3. MEASURING THE ORGANIZATIONAL CULTURE

The study of organizational culture comes from qualitative research methods in the field of organizational behavior (Janićijević, 2011). This was expected, if we take into consideration that the main fields of interests of researchers from that area were social interaction, socialization, behavior and other areas which are typical for qualitative research. On the other hand, qualitative and quantitative methods are complementary approaches in studying organizations and their elements. Qualitative researches are useful in early phases of process of developing a concept (such as organizational culture) when there is no developed terminology used to describe phenomena and when there is a lack of information. The advantages of quantitative methods in examining the attributes of organizations also include the possibility of comparing the results between the organizations, cross-sectional comparisons, possibility of repeating the research in different organizations performed by different researchers, as well as objective interpretation of the obtained results. Two quantitative methods for measuring the organizational culture will be described in further text.

3.1. Organizational Culture Inventory

Inventory which was developed by Robert A. Cooke is one of the quantitative approaches to the assessment of a specific aspect of organizational culture – the shared norms and expectations that guide the think and behavior of members (Cooke & Rousseau, 1988). Rather than measuring organizational culture directly, Organizational Culture Inventory (OCI) focuses on the behavioral norms and expectations associated with the shared beliefs and values held by organizational members (Cooke & Szumal, 1993). Thus, inventory connects the aspects of culture that have the greatest impact on the activities of member and outcomes of the organization. Statements in the inventory describe some of the thinking and behavioral "styles" which members of an organization might be expected to adopt in carrying out their work and interacting with others. These statements measure 12 different cultural styles.

OCI measure more global aspects of culture such as shared beliefs and values and this is what differentiate the OCI from other tools for measuring organizational culture. Although the beliefs and values influence the behavior of people, in the case of norms and expectations, this impact is more direct. By measuring norms and expectations, the OCI makes the concept of culture somewhat less abstract and easier for understanding. The 12 styles of behavior are visualized on "Circumplex", researched and developed by Robert A. Cooke and Clayton Lafferty, in the period from 1973 to 2009, which shows the results for all styles and represents a cultural profile of the respondent's organization, as presented on Figure 2.

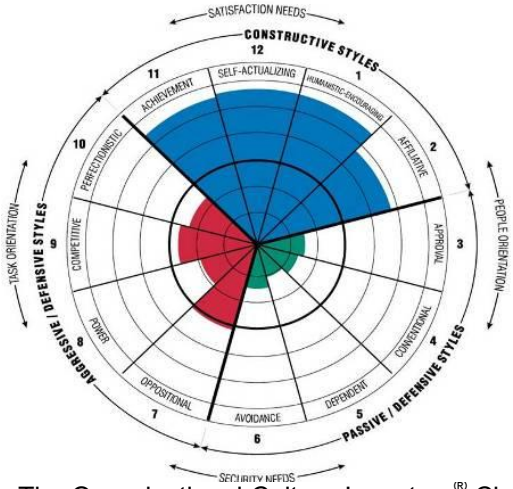

Figure 2: The Organizational Culture Inventory® Circumplex

According to these 12 types of norms we can make distinction between three general clusters:

1) **Constructive cultures** expect their members to interact with people and perform their tasks from the perspective of satisfying the higher-order needs (Self-Actualizing, Achievement, Humanistic-Encouraging and Affiliative norms).

2) **Passive/Defensive cultures** direct members of organization to interact with people in ways that will not jeopardize their own security (Approval, Conventional, Dependent, and Avoidance norms).

3) **Aggressive/Defensive cultures** encourage that the approach to tasks is directed towards protecting their status and security (Oppositional, Power, Competitive, and Perfectionistic norms).

The **Constructive** cluster considers norms of culture which are promoting the needs which has the higher-order of satisfaction and satisfaction behaviors. Constructive cultural norms are:

- (**11 o'clock** position) *Achievement culture.* This culture is typical for organizations which appreciate members who set and accomplish their own goals. These goals are ambitious but realistic. In realizing these goals, employees set up plans for reaching the goals, and **enthusiastically** pursue them. Organizations with achievement culture are effective and solve problems in a proper way. Their clients and customers are well-served, and organizations' and their members' orientation is healthy.

- (**12 o'clock** position) *Self-Actualizing culture.* Valuing creativity, quality and growth of an individual in cooperation with his task accomplishment are characteristics of this culture. In self-**actualizing** cultures employees are pushed towards personal development and enjoy in their work. Although these organizations are challenging for control, they attract outstanding employees and provide high-quality outputs with high level of innovativeness.

- (**1 o'clock** position) *Humanistic-Encouraging culture*. For these organizations it is typical to have person-center management with high level of employees' participation. Employees are pushed to be constructive and supportive which should lead towards effective organizational performance. Members of these organizations are highly satisfied **because** they have provided professional growth and active involvement in organizations' functioning and are highly committed to the organization.

- (**2 o'clock** position) *Affiliative culture.* Affiliative organizations have the constructive **interpersonal** relationships as the top priority. Loyalty, good cooperation and open communication in the work group is typical for these kind of organizations. Employees in affiliative organizations are sensitive to the satisfaction of their co-workers, friendly and open.

Cultural norms of **Passive/Defensive** cluster promote self-protective behavior in interactions with people. Passive/Defensive norms are:

- (**3 o'clock** position) *Approval culture*. Characteristic of these organizations is that they avoid conflict (mostly artificially) in interpersonal relationships. Employees are pushed to be liked by others and agree with all the decisions without giving their own opinion. Although the work atmosphere might be pleasant, effectiveness of these organizations is minimized because of limited "open-mindedness" of employees which are not giving constructive ideas.

- (**4 o'clock** position) *Conventional culture*. Traditional, bureaucratically organized and conservative organizations are typical example for conventional culture. Employees are conformists, they follow the rules, which is limiting innovation and suppressing the level of the organization's ability to adopt the changes occurred in its environment.

- (**5 o'clock** position) *Dependent culture.* If an organization has high level of hierarchical control and low level of employees' participation, we classify it as organization with dependent culture. Members of these organizations are highly limited with centralized decision of their superiors and they actions are highly directed by management. In dependent cultures, performance is not efficient because of low flexibility, no possibility to take initiative and long decision making process.

- (**6 o'clock** position) *Avoidance culture.* Organizations which do not highlight accomplishments but focusing on made mistakes are characterized with culture of avoidance. In these cultures, employees avoid responsibilities because of the negative reward system. Because the members of these organizations are not willing to take actions and make initiative, their survival is questionable.

Cluster of **Aggressive/Defensive** has norms which are oriented towards self-protective behavior and it values the way that members approach tasks. In Aggressive/Defensive cluster, norms are:

- (**7 o'clock** position) *Oppositional culture.* Prevailing negativism and confrontation is the most suitable for describing highly oppositional organizations. These organizations have employees which gain their status by high level of criticism and opposing the new ideas which enables safe decision making process. Unneeded conflicts and issues with problem solving are characteristics of oppositional cultures.

- (**8 o'clock** position) *Power culture.* When there is no participation and the functioning of the organization is based on the authority of the superiors, we have organization with power culture. In these organizational cultures, members have high control of subordinates because they believe they will be rewarded for that behavior. Low effectiveness is typical for these organizations, but members are mostly not aware of it, because subordinate they control are holding back the information and not interesting in giving the contributions.

- (**9 o'clock** position) *Competitive culture.* Competitive-oriented culture mostly values winning and employees are directed toward competing with each other. They believe their colleagues are their opponents and perceive their actions through a "win" or "lose" outcome. Because of limited interest in cooperating and highly set standards these organizations might be poorly effective.

- (**10 o'clock** position) *Perfectionistic culture.* Mostly preferred values in organizations with this culture are persistence, hard work and, of course, perfectionism. Making mistakes in these organizations is not acceptable and precisely defined goals which demand long working hours are not questionable. Although lower level of perfectionism is wanted, going to the extreme level can cause loosing the sight of the goal and becoming lost in details.

3.2. Hofstede model

Another approach to measuring organizational culture, which will be discussed here, was developed by Professor Geert Hofstede. He defines organizational culture as "the way in which members of an organization relate to each other, to their work and to the outside world that distinguishes them from other organizations" (Hofstede & Pedersen, 2002).

The questionnaire was aimed at collecting information on the same four types of manifestations of culture as covered in the interview checklist: symbols, heroes, rituals, and values. The first three are subsumed under the common label "practices" (Figure 1). Values items describe what the respondent feels "should be", practices items what she or he feels "is".

If we talk about dimensions for measuring organizational culture by using Hofstede model, we diversify two main groups of dimensions:

1) Autonomous group of dimensions
2) Semi-autonomous group of dimensions

Autonomous group includes six dimensions**:** organizational effectiveness, customer orientation, control, focus, approachability and management philosophy. On the other hand, group of **semi-autonomous group** has two dimensions: degree of acceptance of leadership style and degree of identification with the organization. In further text will be given the description of every dimension from Hofstede model.

First dimension is *Organizational effectiveness*. This dimension is closely connected with the effectiveness of the organization, and that connection is the closest among all the others. Organizational effectiveness distinguishes means and goal oriented cultures. Means oriented cultures focus on the way of performing work (the key question is "how"), while in the goal oriented cultures employees are primarily achieving internal goals (the key question is "what"), as shown on Figure 3. People from **very means** oriented culture are avoiding risks and giving limited effort at the workplace in reverse to **very goal** oriented culture.

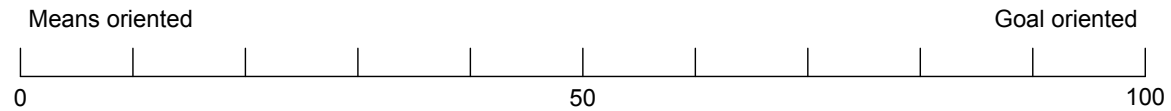

Figure 3: First dimension scale – Organizational effectiveness

Second dimension is *Customer orientation*. In comparison to the first dimension, this one is oriented towards the satisfaction of the customer or other interested parties. According to this dimension we separate internally driven and externally driven, as presented on Figure 4. In a case of **very internally** driven cultures business ethics and honesty are the most important and they work in favor of customer ant the world at large. Employees perceive that their most important task is to meet the customer's requirements in **very externally** driven cultures, and the ethical side of their performance is not in the focus. This dimension also shows how much is the organization's relations with surrounding programmed in advance.

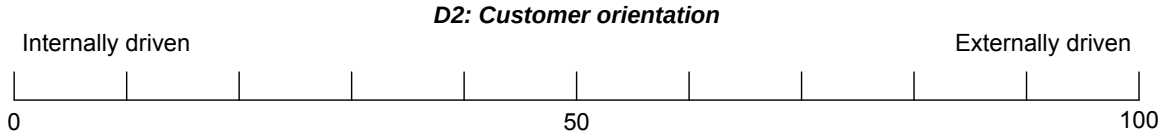

Figure 4: Second dimension scale – Customer orientation

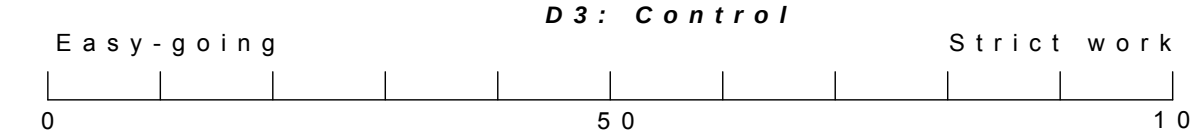
Control, the **third** dimension of this model focuses on measuring the internal structure, control and discipline. As shown on Figure 5, this dimension classifies organizations as **easy-going cultures** if internal structure is loose, with little control and discipline and a lack of predictability, and if it has a lot of improvisation which provokes employees to think out of the box. On the other hand this dimension claims that the organization has very strict work discipline if people are prompt, cost conscious and serious. In difference to the second dimension, this dimension describes the predictability of internal functioning.



.

Figure 5: Third dimension scale – Control

Fourth dimension is *Focus*. According to the focus dimension organizations are diversified by the influence of internal social norm, as presented on Figure 6. In that way, organizations are considered as **local companies** if employees identify with the boss and/or the business unit they belong to, and, the other possibility is to be a **professional company** if the identity of an employee is shaped by his profession and the content of his job. It is important to emphasize that this dimension is not related to the identification with the company as a whole, but the parts of it. The dimension related to the total organization will be explained hereinafter. Also, this dimension suggests that cultures which are classified as **very local** are short term directed and internally focused, and their characteristic is that an employee tends to be like everyone else in the organization.

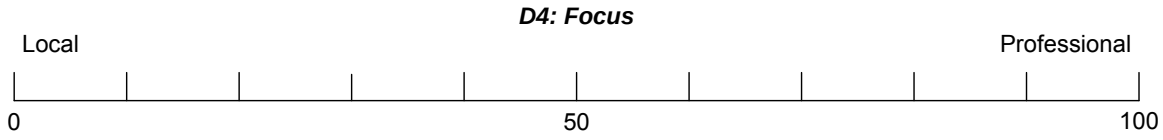


Figure 6: Fourth dimension scale – Focus

Fifth dimension is *Approachability*, presented on Figure 7. In terms of the accessibility of an organization Hofstede defined the fifth dimension, approachability. This dimension separate **open systems,** in which newcomers are immediately accepted, wheatear they are considered as outsiders or insiders. In these kinds of organizations everyone could fit in, while on the opposite side we have **closed systems** in which the situation is reversed. Also, we can mention that, from the aspect of satisfaction, employees' favorite preference is the open culture.

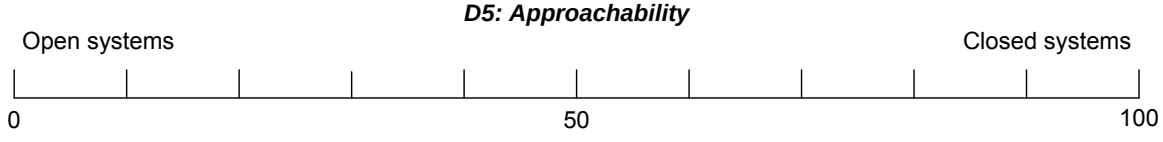

Figure 7: Fifth dimension scale – Approachability

Sixth dimension is *Management philosophy*. Management philosophy diversifies cultures to employee oriented cultures and work oriented cultures, as shown on Figure 8. **Employee oriented** organizations consider that people are more important than completing the job, no matter how high the price might be. Very employee oriented cultures take personal problems of staff into account, contrary to very **work oriented** organizations with a high pressure of performing the task if it harms employees.

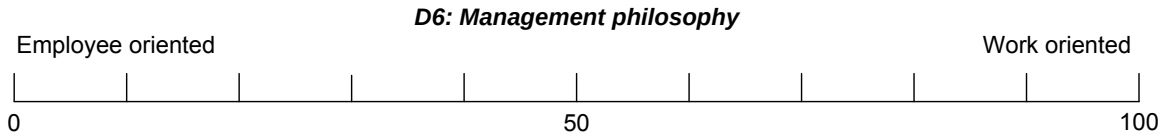

Figure 8: Sixth dimension scale – Management philosophy

Seventh dimension is *Degree of acceptance of leadership style*. In this dimensions difference is made by the answers of respondents give to the questions related to the comparison of true leadership style of their boss versus the leadership style they prefer, as presented on Figure 9. This dimension is different than the previous six, because there is no referent value, just the level of agreement with the preference of the respondents, and the value is correlated with the Power Distance Index of the 5-D Model.

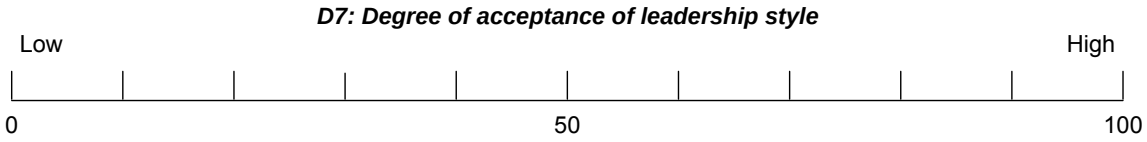

Figure 9: Seventh dimension scale – Degree of acceptance of leadership style

Eighth dimension, shown on Figure 10, is *Degree of identification with the organization*. In describing the fourth dimension, focus, we mentioned that it is not related to the identification with the company as a whole. For the information about the degree of cohesion between of the company Hofstede uses this, eight dimension. Results provided from this dimensions give us the answers about the homogeneity of the culture. As well as the previous dimension, this is also semi-autonomous dimension. We can also mention that scores achieved on this dimension has a certain degree of correlation with the scores on the second dimension, when the more internally driven organizations (low score of D2) most likely identify with the organization overall opposite to identification with stakeholders.

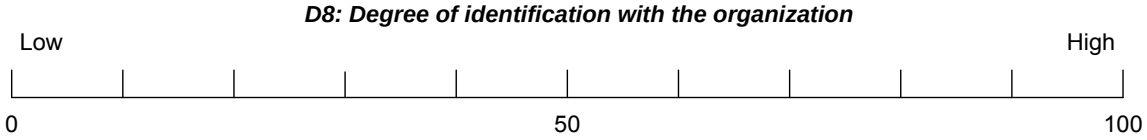

Figure 10: Eighth dimension scale – Degree of identification with the organization

All eight dimensions of Hofstede model are described in brief in Table 1.

Table 1: Overview of Hofstede model dimensions

Group of dimensions	Dimension	Dimension name	Low score	High score
Autonomous dimensions	**D1**	Organizational effectiveness	Means oriented	Goal oriented
	D2	Customer orientation	Internally driven	Externally driven
	D3	Control	Easy-going	Strict work discipline
	D4	Focus	Local	Professional
	D5	Approachability	Open systems	Closed systems
	D6	Management philosophy	Employee oriented	Work oriented
Semi-autonomous dimensions	**D7**	Degree of acceptance of leadership style	Low degree	High degree
	D8	Degree of identification with the organization	Low degree	High degree

4. DISCUSSION

Through parallel analysis of two presented models, certain resemblances can be identified. First of all, their authors have similar view on organizational culture. Both authors define the culture as the approach of the employees to their work, their mutual behavior and interaction, and their attitude towards the organization, its goals and their tasks.

Second, if the definitions of Robert Cook's behavior styles and Geert Hofstede's dimensions are analyzed, certain parallels can also be found. One of them is related to D6 dimension from Hofstede model, *Management philosophy*, and a group of Cook's behavior styles. *Work oriented* side of D6 is the combination of styles from the left hemisphere of the "Circumplex" (*Oppositional, Power, Competitive, Perfectionistic* and *Achievement*), while behavior styles from its right hemisphere (*Humanistic-Encouraging, Affiliative, Approval, Conventional* and *Dependent*) match the reverse, *Employee oriented* philosophy of D6.

Next, opposite values of D3 dimension, *Easy-going* and *Strict work discipline*, mostly correspond to contrary behavior styles, *Power* and *Affiliative*, respectively, but also to all the styles from the top hemisphere (*Easy-going*) and the bottom hemisphere (*Strict work discipline*) of "Circumplex". *Easy-going* cultures are characterized by little control and discipline, and a lack of predictability, and they have a lot of improvisation which provokes employees to think out of the box. Described behavior matches the styles which are oriented towards higher needs and self-actualization, such as *Self-Actualizing*, *Humanistic-Encouraging* or *Affiliative*. The organizations with *Strict work discipline* culture are those with people who are prompt, cost conscious and serious. Those behavior resemble the styles from bottom of the "Circumplex", like *Conventional*, *Dependent*, *Avoidance* and *Oppositional*.

Additionally, dimension D5 from Hofstede, *Approachability,* separates the organizations or organizational units in which newcomers are immediately accepted. Such behaviors are in OCI described by *Humanistic-Encouraging* and *Affiliative* styles. Contrariwise to open systems, closed systems are not friendly and do not support new members or new practices, which corresponds to *Conventional* and partly to *Dependent* behavior style.

Furthermore, reverse cultures of D1 from Hofstede model match the styles on 11 o'clock and 5 o'clock positions on "Circumplex", *Achievement* and *Dependent*. *Goal oriented* side of D1 is described as the culture where employees are focused on achieving realistic and reachable goals, and the accent in their reaching is on "what?" question. It resembles the behavior style described as *Achievement*. Reverse to that, *Means oriented* culture is oriented towards "how?" question and is looking for the answers to the same questions as those which are characteristic for behavior that belongs to *Dependent* style.

Various similarities among behavior styles from one model and cultural dimensions from other can also be recognized when different groups or combinations of styles and dimensions are analyzed.

5. CONCLUSION

Presented models of organizational culture and quantitative approach to their analysis provide multiple benefits. Both models are widely accepted as tools for organizational development. Different organizations have different organizational cultures, even though their members are of the same nationality and come from the communities where similar values are appreciated. As described in other models of organizational culture, all of the styles or dimensions are related to (and result from) organizational structural variables, reward system, leadership and managerial styles and other factors. Norms and expectations are shaped by numerous factors, most of which are controlled by the organization and its leaders. These factors are usually called the levers of organizational change and can be influenced during projects of organizational development.

Both methods for measuring organizational culture that are presented in this paper can be integrated into wider model of organizational change. Their components, behavioral norms in OCI and dimensions in Hofstede, are connected to the organizational change levers. Organizational change models enable the overview of the priorities and the definition of the initiatives which will reduce the gap among current and targeted organizational culture. The priorities are determined by the correlation analysis between organizational change levers and elements of organizational culture. This means that organizational development can be conducted through adequate improvement of different components of organizational culture (behavior styles or cultural dimensions).

In the same way, both analyzed models indicate that behavioral norms or dimensions measured by defined questionnaires are associated with important outcomes at the individual, group and organizational levels. The most immediate outcomes are motivation, inspiration, satisfaction, quality of work-life, teamwork, cooperation etc.

Described tools are widely accepted in organizational science, but there is no data that indicate that they have been used in organizations in Serbia. Such approach could be very useful for Serbian public enterprises, where dominant defensive behavior is the legacy of previous regime and inadequate organizational forms (Todorović et al., 2013). For this reason, future research should determine whether these models are applicable in local cultural values, in terms of providing adequate directions and support for successful organizational development.

Abstract: *One of the burning issues currently in Serbia is the reform of public sector. Present organizational model is the legacy of previous government system and disables public companies to adapt to the changes in environment. Total number of employees in public entities is extremely high, comparing to EU countries, so downsizing is one of the necessary measures and cannot be avoided. In order to successfully complete the EU integrations, Serbian government needs to propose sustainable solutions for public sector organization and management at state and local level. In many cities worldwide local governments recognized network organization as possible solution for increasing the efficiency of public enterprises and upgrading the quality of public service at the same time. Such concept is based on centralization of certain non-core functions which appear in multiple public companies, in order to secure better allocation of human resources and improve their performance. This research aims to show how centralization of adequate jobs can provide the base for reducing the number of employees in public companies, using the City of Belgrade as an example. The findings can be practically used as the guidelines for the city authorities in Belgrade during the following process of public sector restructuring.*

Keywords*: Downsizing, restructuring, public sector, public company, public enterprise, centralization, network organizational model, Belgrade*

1. INTRODUCTION

Public sector functioning is topic of many studies all over the world. Most of that studies conclude, that public spending could be much smaller and more efficient than today (Alfonso, Schuknecht & Tanzi, 2010). On the other hand, the role of local public enterprises within public sector of one country is growing with the development of that country. Industrialized countries typically spend 50% or more of public sector resources to fund local public services (IDG Policy, 2013). Explanation is that the additional services which improve the life quality are demanded, not just communal (Longo & Cristofoli, 2008). In order to adapt to new trends, public sector leaders often widen the scope of public services (Indihar, Stemberger & Jaklic, 2007) For this reasons, performance of public enterprises has become persistent topic in organizational analysis (Aharoni, 2000).

Considering public spending, situation in Republic of Serbia is more dramatic due to several factors. The first one is high overall unemployment rate of 24.1% (Statistical Office of the Republic of Serbia, 2013). That caused excessive employment in local governments, public agencies and public enterprises, usually helped by politicians. Structural reforms promoted by new Serbian government include, as one of the mayor goals, reducing public sector size and scope. This paper proposes one of the possible ways for reducing public sector scope of services, and consequently, its size, in the City of Belgrade.

Today, local public enterprises in City of Belgrade are highly specialized, and with clearly defined jurisdiction. (Todorović, Komazec & Jevtić, 2012). All enterprises are functionally organized, legally and essentially fully independent of each other, although all of them are claiming funds from city budget. This non-cooperation forces local public companies to form similar non-core organizational units, in order to provide support to primary activities and improve the output quality (Jaško, Krivokapić & Čudanov 2010). Besides increased independence of each public company, this led to growth of growth of its size, in term of number of employees (Čudanov, Jaško & Săvoiu, 2012). Large number of employees is just one of the reasons for pure performance, and former studies have shown that there is no public company in Belgrade that is without any reserves in term of number of employees (Todorović, Komazec & Jevtić, 2012).

Many of these problems could be solved by implementation of network organizational model in public sector (Todorović, Komazec & Čudanov, 2013). Network organization, through better coordination, increases the efficiency of resources allocation, brings more flexibility, enables organizational learning, improves planning process and upgrades the quality of services (Jaško, Jaško & Čudanov, 2010). Network organization of

public sector also enables wide spectrum of internal services that companies can provide to each other (Komazec, Todorović & Krivokapić, 2012). Precondition for forming a network is focusing on core business and outsourcing most of the non-core activities (Popović, Jaško & Prokić, 2010). For this reason, the basis for the successful implementation of network model in public sector is the determination of non-core activities in each public company, so some of them could be centralized at network level. This centralization will consequently emphasize double activities and a number of employees that are engaged on them at the level of whole City of Belgrade.

The purpose of this article is to analyze all the functions which exist in Belgrade public enterprises, to separate non-core from core functions, to identify the functions which appear in multiple public companies and to propose the centralization of certain non-core functions. In the second paragraph will be presented the methodology for gathering the necessary data. The third section will describe the process of identifying the functions that are adequate for centralization, and the fourth will deal with the scope of centralization. Number of employees covered by centralization and possible economic effects will be discussed in the fifth paragraph, while conclusions, limitations and directions for future research will be presented in the sixth section of this paper.

2. METHODOLOGY

All the directions for public sector downsizing through centralization that will be presented in this paper appeared during our engagement as business consultants on projects of restructuring public sector in the City of Belgrade. Our analysis included 28 public enterprises, with 21.023 employees, which provide different communal or public services to city residents.

First step was to get insight in all the activities that are performed in individual companies, for every analyzed public company, in order to classify the activities to core and non-core and to select those that could be centralized. Those activities were derived from job descriptions and later categorized to core and non-core and grouped into unique jobs and functions for all 28 companies.

Second step was to calculate total number of employees for each function. For this purpose, we analyzed the content of formal documents in every company. From systematization documentation, existing organizational structures and job classifications we managed to create the list of positions in every public company. Through salary reports we were able to relate each employee with single position from the list, and to calculate total number of employees on every position. Their sum is equal to the total number of employees in public sector. Since every position is followed by job description, we managed to link the positions to previously mentioned functions, and to determine total number of employees for each function.

Based on this, we were able to conclude whether certain non-core functions were executed in multiple enterprises and to calculate the exact number of employees for each function. These two parameters represent the main inputs for the decision making process concerning centralization of non-core functions which will be described in this paper.

3. IDENTIFYING THE FUNCTIONS THAT ARE ADEQUATE FOR CENTRALIZATION

In order to determine which functions are suitable for centralization, unique catalogue of all functions that are performed in public sector is requested to be created first. However, in order not to lose data, the catalogue ought to have two levels, which means that each function will have a list of jobs included. After that, each job from the catalogue should be assigned “1: MANY” relation with the list of public enterprises.

In order to achieve this, various positions from different public companies need to be standardized (Krivokapić, Todorović & Komazec, 2013). For example, same positions, according to job descriptions, may be named differently in two enterprises. As a consequence, all job descriptions need to be analyzed separately in order to perform job standardization. The result is the list of standardized positions, which is in “1: MANY” correlation with actual list of positions that can be found in the official documentation. Now each standardized position can be “1:1” connected to the job from the catalogue.

Finally, since every function is related to the job, standardized position, which is correlated to the actual positions in the companies, as presented on Figure 1, it is possible to conclude which functions are performed in more than one public company.

This way, not only precise number of different public enterprises for each function where it is identified can be determined, but also the exact total number of employees on each function can be calculated, since every actual position has number of employees as an attribute.

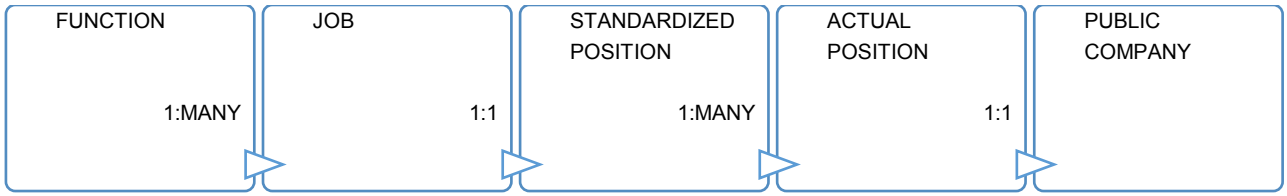

Figure 1: Process of identifying the functions which exist in multiple public companies

Complete catalogue contains 294 different jobs that are performed in Belgrade public sector. Less than 20%, 49 jobs, are performed in more than one public company. Possible explanations are highly specialized core activities in most public enterprises, which are characteristic only for the company which is providing relevant public service.

At first sight, it may seem that these 20% of jobs do not offer plenty of space for centralization. Without deeper analysis, it can be explained by the necessity for some supportive activities, such as cleaning, fire protection or IT support, which are present in almost all companies. Nevertheless, total number of employees on these jobs is 5.645, which is about 27% of total number of employees in Belgrade public sector. If only jobs which exist in 5 or more public companies are analyzed, number of examined jobs is reduced from 49 to 26, but total number of engaged employees still remains over 5.000, 5.088 to be precise, or 25% of total workforce. Same way, if the list is shortened to 21 jobs which are identified in 10 or more Belgrade public enterprises, calculated number of people that are hired just for their execution is 4.405, which is more than 20% of total number of employees in complete public sector.

Considering all of the above, the list of all functions and jobs which should be centralized in Belgrade public sector for the purpose of increasing their efficiency on city level is derived from the catalogue and presented in Table 1.

Table 1: Functions and jobs proposed for centralization in Belgrade public sector

Function	Job
Safety, security and health at work	Safety and health at work
	Security at work
	Firefighting
Finance	Finance
IT support	IT support
Internal transportation	Internal transportation (C, D and E category)
	Internal transportation (B category)
Public procurement	Public procurement
Marketing and public relations	Marketing and public relations
Vehicle maintenance	Administrative support
	Vehicle and mechanization maintenance
	Vehicle repair and maintenance services (C, D and E category)
	Technical inspection of vehicles
	Car washing
Maintenance, Hygiene, Sanitation and Cleanliness	Maintenance, Hygiene, Sanitation and Cleanliness
Legal	Legal
Media space selling	Media space selling
Registration, insurance and car washing	Technical inspection of vehicles
	Car washing
Inbound logistics	Car maintenance
Human resources	Human resources

Several jobs from the catalogue are present in all or almost all enterprises. In some cases it is expected, since certain non-core functions are necessary for normal operations in any enterprise. For the purpose of securing regular workflow, some of those jobs simply need to remain decentralized and to continue performing on company level. For example, centralization of complete storage jobs would be rather inefficient, because it would consider that every time when any office supplies are needed, centralized

warehouse should deliver paper, toner, paperclips etc. Such centralization would have a negative effect on normal, everyday operations in every public company.

Same way, there are jobs which should remain in every company due to their specificities. Accounting is an example. Although it is theoretically done by the same rules in every public enterprise, certain specificities of core business demand the adoption period for accountants, in order to achieve maximal efficiency. If the accountants were integrated and started serving 28 different companies, most of their work time would be spent on analyzing business activities and learning new accounting principles. Since their current job routine would be lost, such jobs ought to be left decentralized.

Centralization considers grouping of employees engaged on same jobs into unique organizational units (Jaško, Čudanov, Jevtić & Krivokapić, 2013). However, since some of the jobs from Table 1 have very large number of employees, next important decision that should be made concerns the scope of centralization. It ought to be determined whether all the employees on same job will be organizationally moved to centralized unit, or some of them will continue working in their current companies.

4. DEFINING THE SCOPE OF CENTRALIZATION

As already explained, introduction of network organizational model and centralization of certain non-core functions in Belgrade public sector can lead towards improved management, more efficient planning, better allocation of public resources and reduction of overheads. However, the scope of centralization cannot be the same for all functions and jobs that were marked as suitable for centralization.

IT support is one of the functions proposed for centralization on city level. Nevertheless, it does not indicate that all IT employees should be locational moved to centralized organizational unit. If that was the case, other employees in Belgrade public enterprises would be left to wait for the arrival of IT support from centralized unit every time they have even smallest technical issues with IT equipment. Described organization would disturb normal operating of individual companies. On the other hand, employees on certain IT jobs, such as software developing or database administration, can be locational centralized without any organizational barriers, since their presence in individual enterprises is not demanded constantly. In these cases, centralization increases their efficiency, but also allows better usage of public sector intellectual capacity and expertise, since functional silos will be eliminated and knowledge transfer enabled (Todorović, Čudanov, Komazec & Krivokapić, 2013).

Another example of function that is proposed to be centralized partially is HR. Same as in previous case, part of employees, those who perform everyday HR activities such as presence recording, sick benefits, holidays etc. should remain in individual companies, while employees on strategic HR jobs such as selections or trainings could be more efficient if they were moved to single centralized organizational unit.

Opposite example are public procurements. Employees on these activities are among those with the lowest performance in Belgrade public sector (Todorović, Komazec & Jevtić, 2012). At first sight it can be explained by too many employees. However, when the real needs of each company in terms of public procurement are identified, it can be concluded that most of the employees who carry out these tasks are really necessary. Underutilization of the capacity occurs due to the nature of this business. The procurement is not something that happens every day. When there are active procedures, all available resources are deployed, often even overtime. The problem is that when there are no active processes, these employees literally have nothing to do. Therefore, their average performance is low.

The solution to this problem is the complete centralization of public procurement at the city level, so the employees on these activities could serve multiple companies. Since on city level at least one procurement procedure is active almost every day, their average performance would significantly increase. Of course, this would mean that the new organizational unit does not require all the employees who are currently performing activities related to public procurements. The savings that could be achieved by reducing the number of employees on these jobs could be used for hiring new people on jobs with lack of available capacity, for expanding the scope of activities under the auspices of Belgrade public sector, or for the development of public service in another respect.

Public procurement is just one of the jobs that can be completely centralized in the network model. Other examples are marketing, vehicle maintenance etc. In certain EU countries maintenance of public equipment is specific activity under the jurisdiction of local public enterprises (Crediop, 2004), which can be guidance and encouragement for centralizing these activities in Belgrade.

As previously described, jobs and functions need to be categorized by the centralization scope criterion, to full centralization and partial centralization proposals, as shown in Table 2.

Table 2: Proposed scope of centralization for all functions and jobs

Scope	Function	Job
Full centralization	Marketing and public relations	Marketing and public relations
	Public procurement	Public procurement
	Vehicle maintenance	Technical inspection of vehicles
	Media space selling	Media space selling
	Registration, insurance and car washing	Technical inspection of vehicles
		Car washing
Partial centralization	Safety and health at work	Safety and health at work
		Firefighting
		Security at work
	Finance	Finance
	IT support	IT support
	Legal	Legal
	Internal transportation	Internal transportation (C, D i E category)
		Internal transportation (B category)
	Maintenance, Hygiene, Sanitation and Cleanliness	Maintenance, Hygiene, Sanitation and Cleanliness
	Vehicle maintenance	Administrative support
		Vehicle and mechanization maintenance
		Vehicle repair and maintenance services (C, D i E category)
		Car washing
	Inbound logistics	Car maintenance
	Human resources	Human resources

After defining centralization scope, it is possible to analyze the number of employees affected by each type of centralization, possibilities for downsizing and economic effects on the city budget.

5. DISCUSSION

In order to get full view of the size and effects of proposed centralization, we need to analyze total number of employees in Belgrade public sector who will be affected if the proposals are accepted. The results are presented in Table 3.

Table 3: Number of employees per scope of centralization, per public company and total

Public company	Full centralization	Partial centralization	No change	Total
Public company 1	2	2	34	38
Public company 2	1	13	44	58
Public company 3	11	240	1327	1578
Public company 4	12	249	2021	2282
Public company 5	42	372	2749	3163
Public company 6	12	386	1637	2035
Public company 7	6	32	184	222
Public company 8	35	2263	4201	6499
Public company 9	4	33	159	196
Public company 10	10	14	145	169
Public company 11	31	256	778	1065
Public company 12	3	48	401	452
Public company 13	9	77	1118	1204
Public company 14	2	10	93	105
Public company 15	1	5	18	24
Public company 16	2	52	257	311
Public company 17	13	28	170	211
Public company 18	1	5	53	59
Public company 19	2	20	124	146
Public company 20	1	8	245	254
Public company 21	/	22	130	152

Public company 22	5	19	169	193
Public company 23	3	13	151	167
Public company 24	/	2	14	16
Public company 25	2	26	139	167
Public company 26	/	5	34	39
Public company 27	2	13	158	173
Public company 28	1	10	34	45
Total:	**213**	**4223**	**16587**	**21023**

Table 3 shows that in each of the 28 analyzed companies are identified the employees who should be included in any of the two proposed forms of centralization. They can be deployed in new centralized organizational units, but also in a completely new public companies, if the amount of work indicates that there exists real need for their formation. In order to gain a clear insight into the extent of the jobs that need to be centralized, it is important to determine the number of employees involved in each of the jobs for which the centralization is proposed, at the entire public sector level. These data is shown in Table 4.

Table 4: Number of employees per scope of centralization, per function and job

Function	Job	No. of employees
Safety, security and health at work	Safety and health at work	39
	Security at work	356
	Firefighting	180
Finance	Finance	357
IT support	IT support	203
Internal transportation	Internal transportation (C, D and E category)	137
	Internal transportation (B category)	61
Public procurement	Public procurement	85
Marketing and public relations	Marketing and public relations	92
Vehicle maintenance	Administrative support	67
	Vehicle and mechanization maintenance	399
	Vehicle repair and maintenance services (C, D and E category)	1721
	Technical inspection of vehicles	4
	Car washing	50
Maintenance, Hygiene, Sanitation and Cleanliness	Maintenance, Hygiene, Sanitation and Cleanliness	412
Legal	Legal	130
Media space selling	Media space selling	9
Registration, insurance and car washing	Technical inspection of vehicles	14
	Car washing	9
Inbound logistics	Car maintenance	21
Human resources	Human resources	90

It can be noticed that the majority of these employees works on the vehicle maintenance. Therefore, the formation of an entirely new public enterprise that would deal with the maintenance of public equipment can be considered. As mentioned above, there are examples of such enterprises owned by local governments in EU countries. Using the same principle, the City of Belgrade may found its own security company, software engineering enterprise, marketing and PR agency, company for maintenance, hygiene, sanitation and cleanliness etc.

A key question that emerges after the centralization is the financing of this new company. Namely, if the local government continue to finance the salaries of all employees who still work on maintenance of public vehicles, there is no progress. It is, therefore, necessary to determine the market value of the services that are provided by the new company for other members of the network (other public companies). This way the transferring prices can be defined, so public funds can be shift to the account of the new company in accordance with the extent of the work and defined transferring prices. These funds will certainly be lower comparing to the total gross value currently allocated for the salaries of employees involved in these jobs. In this manner, the city budget will be significantly relieved.

On the other hand, the management of the new company will be able to make appropriate decisions independently. Either will they reduce the number of employees and adapt to the real needs of other public companies, or will promote their service and offer it to other market participants. Second option would lead to

the utilization of all available resources, but also to the occurrence of additional sources of funding that would cover the costs of the new company, at the same time.

However, jobs like public procurement, human resources, finance, legal etc. can be performed within centralized organizational units. In these cases also it is crucial to adjust the number of employees to the actual needs of public companies which use such services, since they are still financed from the city budget, so any unnecessary expenses should be avoided.

In both situations, total number of employees in Belgrade public sector can be significantly reduced, which is followed by less appropriations for salaries on city level. This way the pressure on the city budget can be considerably diminished, that is one of the main goals of public sector restructuring in the City of Belgrade. Finally, public sector downsizing is achieved without endangering the functionality of public enterprises nor the quality of public service.

Some of the non-core functions may be opened for private capital after the centralization, regardless their organizational form (new public company or centralized organizational unit). In general, studies in this scientific field conclude that in order to improve public sector governments should adopt better institutions and should transfer many non-core activities to the private sector (Alfonso, Schuknecht & Tanzi, 2010). Transferring those activities to private sector could represent acceptable model for additional downsizing, in terms of corporate social responsibility, followed by improved quality of public service due to competition.

6. CONCLUSION

In this paper we have shown that some non-core functions appear in multiple public companies in Belgrade and that number of employees involved in them has significant share in total number of employees in Belgrade public sector. The centralization of certain non-core functions at the city level can highlight the appropriate number of employees, considering the real needs, since the employees on non-core functions will be able to serve more than one public company. In such way, the results of this research can help the city authorities with finding the appropriate model for downsizing public sector in Belgrade, but also to provide useful guidelines for other local governments in Serbia, since the number of employees in public companies is one of the most important issues in the process of EU integrations.

Consequently, the centralization of adequate non-core activities will lead to the reduction of total labour cost and reduced pressure on the city budget in Belgrade, as described in this article.

After identifying the functions that should be centralized in public sector, the next task is to define centralization priorities, since not all functions can be centralized at once. This can be the topic of some future article. Future research should also analyze possible institutional alternatives for implementing network organization in public sector and propose the concrete procedure for introducing such organizational and institutional model, with the centralization of non-core functions as one of the steps.

ORGANIZATIONAL ANALYSIS AND DIAGNOSIS: TRACKING DOWN PROCESSES AND STRUCTURE

Ivan Stefanovic[1], Marina Momcilovic[2]
[1] M&I Systems, Co. Group, stefanovic_i@yahoo.com
[2] NIS a.d. Novi Sad, marina.momcilovic@nis.eu

Abstract: *Processes and structure are two inextricably intertwined components that must be taken into consideration while designing organization. The aim of this paper is to depict the overall methodology for analyzing and diagnozing processes and structure that can be applied to every industry with some small adjustments. The motive for undertaking its writing is the improvement of existing process and organization structure design practice. It synthesizes and systematizes existing theoretical knowledge that has been refined and proven in practice through implementation of numerous projects within one big vertically integrated profit organization operating in Serbia. The paper starts with an overview of techniques and tools for processes and structure analyses, continues with the manner in which a diagnosis report may be presented, and ends by describing its limitations and providing a recommendation for practitioners. The expected outcome of this paper is contribution to organizational performances increase of all organizations operating in Serbia and the region. In order for this to happen, managers must become aware of the importance of gaining an in-depth knowledge about the processes and organization structure. They ought to realize that this knowledge will enable them to continually improve the manner in which their organizations operate. Therefore, methodology insight provided in this paper is highly beneficial for managers and other practitioners in terms of development of their organizations' competitive advantage, which is a necessity in environment subjected to frequent changes.*

Key words: *organization, organizational analysis, organizational diagnosis, process, structure, organization design.*

1. INTRODUCTION

Quality of organization design has become accepted as one of the major factors of competitive advantage in contemporary environment, even though numerous researchers began investigating this topic back in the 1960s and 1970s (cf. Chandler, 1962; Lawrence & Lorsch, 1967; Greiner, 1972; Galbraith, 1973; Khandwalla, 1973; Mintzberg, 1979). Organization design may be regarded as an outcome of shaping and aligning all the components of an organization toward the achievement of an agreed mission and objectives (Stanford, 2007), which ultimately makes organizations actively practicing organization design high-performing systems ready to adapt to almost any shift in its environment. Since contemporary organizations are facing the unpredictable and more complex environment than ever before, in effect paying attention to a much larger number of variables in the environment and their dynamics than was the case earlier (Stefanović, Prokić & Vujović, 2012), significance of organization design for on-going operations as well as for long-term viability of organizations is obvious.

Each organization design project rests on the chosen organization design model. The organization design model is a model of an organization that identifies its main components and relations between them for the purpose of understanding the organization as a dynamic entity. The most widely used models are the following: (1) Weisbord's Six-Box Model (Weisbord, 1976), (2) Nadler-Tushman Congruence Model (Nadler & Tushman, 1980), (3) McKinsey 7S Model (Pascale & Athos, 1981; Peters and Waterman, 1982), (4) Model of Organizational Performance and Change (Burke & Litwin, 1992) and (5) Galbraith's Star Model (Galbraith, 1995; Kates & Galbraith, 2007). These models are being used because researchers dealing with organizations are unable to treat the organization in all its diversity and multidimensionality, or it is simply not practical, so they, therefore, choose one perspective, or "portion" of the reality and observe the organization through it (Morgan, 1990). Therefore, the main role of organization design models is to provide an understanding of the organization and the effects that specific actions might have within it by simplifying the reality (Janićijević, 2010). The choice of the model depends on the resources available to the organization, as well as required complexity of the organization design project, i.e. the required level of detail.

Two crucial components that are inextricably intertwined and must be taken into consideration in each organization design effort, no matter what organization design model is used, are processes and organization structure. "A process is simply a structured set of activities designed to produce a specified output for a particular customer or market. It has a beginning, an end, and clearly identified inputs and

outputs. A process is... a structure for action, for how work is done... [Business] processes are therefore the structure by which an organization does what is necessary to produce value for its customers" (Davenport, 1994, pp. 134-135). On the other hand, organization structure can be defined as "the sum total of the ways in which its labor is divided into distinct tasks and then its coordination is achieved among these tasks" (Mintzberg, 1983, p. 2).

Processes and structure are at the core of each operational effectiveness analysis that is being undertaken in order to increase the overall effectiveness and efficiency of the organization. Importance of process and structure analysis and diagnosis for in-depth understanding of the manner in which organizations are structured and the way they operate is the reason for which a profound insight on a contemporary methodology for analyzing and diagnosing these two components is presented in this paper.

The reminder of this paper is organized as follows. The next section is focused on process and structure analyses, i.e. techniques and tools for conducting these analyses. After that, an overview of process and structure diagnosis is given, as well as the tool for presenting diagnosis results to the stakeholders. Finally, in the conclusion section, limitations of the paper and a recommendation for practitioners are given.

2. PROCESS AND STRUCTURE ANALYSIS

Before tracking down processes and structure takes place, some preparations ought to be done. The most important preparations include activities such as: stakeholder identification and mapping, development of communication plan with them in order to get their support for the project, as well as early risk identification and making risk management plan. These activities will not be elaborated in this paper because it is out of its scope, but only after they are done properly, process and structure analyses can start.

In-depth knowledge about the processes and structure is necessary for each organization if it seeks to maximize effectiveness and efficiency of its operations. In order to learn about the processes and structure, and how the overall organization works, the first step that management of an organization ought to take is to acquire specific data and perform a set of analyses. The goal is to examine organization from multiple perspectives, after which these perspectives ought to be merged into one snapshot of an organization. In this section, these analyses are listed and depicted.

Process identification and classification. In order to successfully manage an organization, management needs to be familiar with the manner in which organization operate its day-to-day activities. In other words, business processes are the driving force of any organization (Hammer & Champy, 1993), which is why gaining an in-depth knowledge about them has become a necessity.

Therefore, the first step in getting to know the processes is to make a list of them. The result is a process register with the main processes or process areas. These processes are then being decomposed until the level of individual activities is reached. Since processes always achieve a certain result or output, process identification is recommended to start with identification of results or outputs, after which the task of identifying the processes that lead to them becomes a lot easier.

In the second step, identified processes are classified using one of the mostly used and accepted process classifications. Probably the most known process classification concept is the one developed by Michael Porter (Porter, 1985). Porter's value chain in which processes are classified into one of the following two groups: primary processes (processes that directly transform inputs into outputs, i.e. inbound and outbound logistics, operations, sales and marketing, and services) and support processes (those that provide support to the primary processes, i.e. infrastructure, human resources, technological development, and procurement). The other well-known process classification concept has been developed by Jay Galbraith (Galbraith, 1998). He has divided all processes into three groups. Processes at the back of the value chain include all the processes that are related to production, technology, product development, etc. Processes at the front of the value chain are those that have a direct user – external consumer. Processes in the middle of the value chain are the so-called infrastructure processes that have internal users, and that serve as a support to processes at the back and at the front of the value chain. Process classification ought to provide guidelines for further work with the processes, i.e. the sequence in which processes will be mapped, analyzed, and improved.

Process mapping and analysis. After the process classification is completed and priorities in working with processes are defined, the next step is to depict processes by mapping them out. Process mapping is an act of acquiring data about the process in order to make a graphical representation of all the activities and their sequence within the process flow in the regular situation, as well as alternative activities if some sort of

deviation occurs (Stefanović, Milovanov & Momčilović, 2013). The tool for process mapping is shown in Figure 1. Graphical representation of the process flow is given in Figure 2.

Process number	Process name	Process phase	Activity name	Activity description	Alternate scenario	Input/output documents	Duration (days)	FTEs

Figure 1: Process mapping template

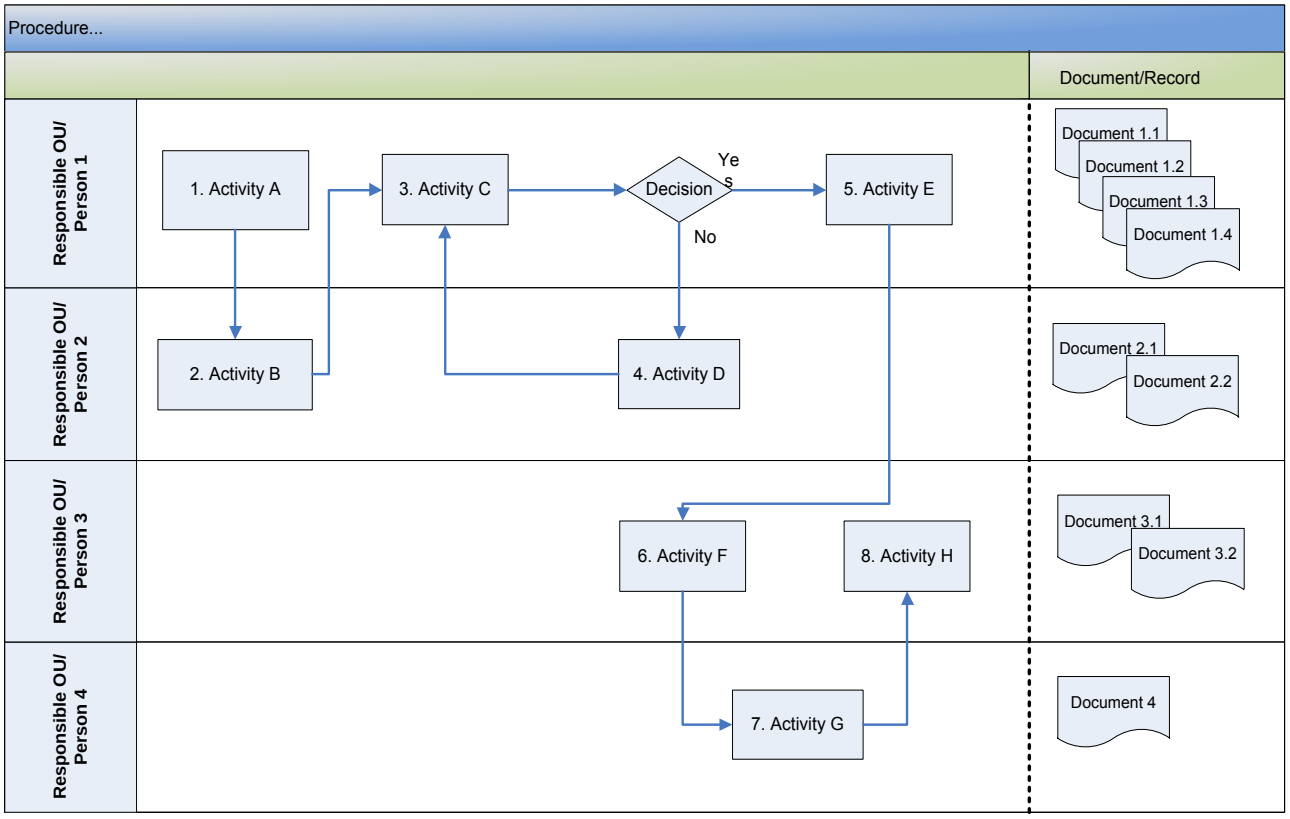

Figure 2: Process flow diagram

Obtained graphical process representation is a basis for performing several types of analyses. These analyses are expected to result in identification of the following: (1) process owner and other process participants, (2) key performance indicators (KPIs), (3) necessary competences for running the process, (4) value being added by the process, and (5) weak points and barriers.

Process/organization structure relationship mapping. Processes are not being performed by themselves, but rather by dedicated employees who are organized in a certain manner that ought to support maximization of the process performances. In other words, organization structure ought to be in the function of supporting the processes, no matter whether it is deliberately shaped or formed in an ad hoc manner. “Structures happen to be there, or, if not ready at hand, they are the outcome of the artful recombination of what is at hand under specific circumstances” (Ciborra, 1996, p. 111).

Therefore, the next step is to determine the part of the organization structure in charge for the process that is being observed, i.e. it is necessary to map the process flow through the organization structure. This kind of process representation provides additional information about weak points and barriers. Figure 3 provides an insight into the process/organization structure relationship mapping.

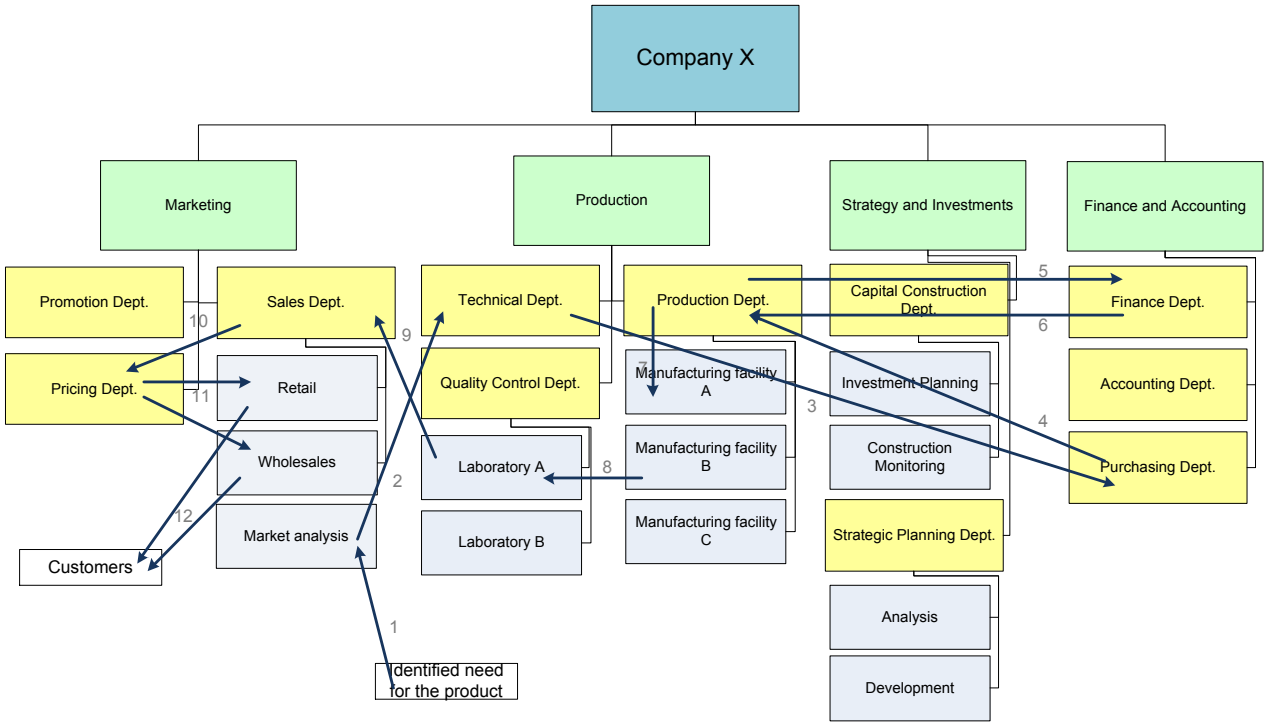

Figure 3: Process/organization structure relationship mapping

Organizational unit scope of work mapping. In this step, the researcher is taking a somewhat different perspective. Instead of tracking down the processes, the focus is now being turned toward the organization structure, i.e. organizational units in particular. The goal of this step is to determine which parts of identified processes are being performed by an organizational unit that is being observed. Therefore, while previous analysis shows the flow of one or more end-to-end processes through the organizational structure, this one is concerned with the sum of all parts of the processes (all activities) being performed by one or more organizational units. The tool for organizational unit scope of work mapping is exhibited in Figure 4.

Processes/ Activities	Market Analysis Dept.	Wholesales Dept.	Retail Dept.	Technical Dept.	Production Dept.	Organizational Dept. N
Activity A1	X	X				X
Activity A2	X		X			
Activity M					X	

Figure 4: Template for organizational unit scope of work mapping

Upon the completion of identifying all the activities being perform by one organizational unit, its scope of work is determined. If the sum of all organizational units' scope of work contains all the activities of all the processes that have been identified and mapped in the previous steps, it means that the researcher has done a superb job: the process mapping and process/organization structure relationship mapping are done in an appropriate manner. In other words, using both process and structure perspective, represent a control mechanism that checks whether all processes are identified and their flow through the structure is precisely depicted.

Structure of activity and workload per position analysis. Once when the processes and their precise flow through the structure are known, the research focus switches to each position in the organization individually. This level of analysis provides an understanding of micro level structure, i.e. the manner in which labor is divided into distinct tasks and then coordinated in order to achieve specified objectives. Two most commonly used techniques for analyzing activities being done and workload per each position are functional analysis and DILO (Day in the life of) analysis.

Functional analysis is based on collecting data related to the activities carried out by an employee in a specified position. The time frame for which these data are being collected may vary significantly, but it is usually a one year period. As far as data being collected concerns, they are usually as follows: (1) activity

name, (2) measurement unit, (3) time required for execution of a measurement unit, (4) number of measurement units for a designated period, (5) total workload in minutes or hours for the designated period, which may be obtained by multiplying (3) and (4). These data result in charts that show the time distribution per each activity, distribution of value added activities versus non-value added ones, existing bottlenecks in the processes, and whether a specified position requires more or less employees. Functional analysis may be done in two ways: by sending functional analysis template to an employee or employees occupying specified position in order to fill it in, or by interviewing the same employees. In each case, statements and figures in the template ought to be supported by hard evidence. Functional analysis template is shown in Figure 5.

Position/Organizational unit		**Name of an employee:**			
Number of activity	**Activity**	**Unit of measurement (UM) of the observed activity**	**Time needed for 1 UM in min**	**Workload from (start date) until (end date) in UM**	**Workload from (start date) until (end date) in min**
1					
1.1.					
1.2.					
2					
3					

Figure 5: Functional analysis template

DILO is an observational record of each activity performed by an individual during one working day or full shift including observations, quotes and comments. It provides the following information and benefits (Celerant Consulting, 2007): (1) a detailed understanding of how the activities are being performed, (2) insights into the issues and problems that arise on a day-to-day basis and how both of these are being managed, (3) distribution between value added and non-value added activities, as well as types, quantity and causes of non-value added activities, (4) understanding workload and the complete environment within which activities are being performed, (5) understanding of an organizational culture, and (6) builds credibility and relationship with employees being observed. Table 1 provides an insight into typical value added and non-value added activities.

Table 1: Typical value added and non-value added activities

Value added activities	Non-value added activities
- Working on a job - Working in a workshop - Receiving directions/coaching from supervisor - Safety required job preparation - Filling documentation into system/entering required data into computer system	- Waiting for work (no work allocated or between tasks) - Unofficial/excessive breaks (late start, over run on breaks, early finish) - Unnecessary movement - Pacing inappropriate (actual time to historical average or best demonstrated to quantify pacing) - Waiting time (for colleagues, permits, etc.) - Rework (job not completed correctly first time, repair job, extra time required, not using correct tools, etc.)

Headcount, spans of control and hierarchy analysis. These parameters are a direct consequence of an organization size. They ought to indicate whether the size and shape of the organizational structure are aligned with other organizational components.

Headcount may imply the overall remuneration costs, organization inertia/flexibility, necessary coordinating mechanisms, etc. This parameter is also a fertile ground for making various ratios that can be used in order to determine an appropriate size of some parts of the structure, as well as benchmarks against the competitors. Some of the ratios that may be taken into account are (Irwin i Cichocki, 2011): (1) number of employees in support function to total headcount, (2) number of billable employees to number of non-billable employees, (3) revenue per employee, (4) number of employees to new customer orders, (5) number of employees to number of customers, etc. The importance of having a proper headcount may not be

overstated. Having the right number of people enables an organization to get the work done in a most efficient manner.

Span of control affects the width of an organization. It is the number of employees reporting to one manager, thus making an organizational unit. Span of control refers to the amount of information coming to the manager from his direct subordinates. Contemporary organizations often have higher spans of control than was the case in the past. There are many reasons for this (Irwin & Cichocki, 2011): (1) the workforce is generally better educated, (2) managers are also better educated, (3) production technology makes it easier to apply consistent standards to work, (4) development of information and communication technology makes coordination and knowledge-sharing much easier, etc.

Hierarchy represents the height of an organization, i.e. the number of organizational levels. Hierarchy directly affects the responsiveness of an organization to the stimuli coming from its environment, as well as the P/A ratio (number of employees that directly create value to number of administrative workers). In organizations with tall structures (more organizational levels), it usually takes more time for an information to reach a relevant decision-maker, especially if he is located near the top of hierarchy and the source of information is at the bottom. This time lag causes slower response to the information, which reduces the overall responsiveness of organization. In addition, tall structures are characterized by low P/A ratio, which usually means that organization is highly bureaucratic and has high overhead costs. The following table (Table 2) provides a comparison between tall and flat structures.

Table 2: Tall and narrow versus broad and flat organizations (Irwin & Cichocki, 2011)

Organization structure shape	Advantages	Disadvantages
Tall and narrow	- Allows manager to communicate quickly with immediate staff - Allows close supervision and direct control - Feedback of ideas between immediate supervisors and staff is more effective - The fewer the staff, the lesser the management skills required	- Many levels of management mean higher cost of management staff - Large distance between top management and staff, poor executive communication and visibility - Less independence and decision authority for staff
Broad and flat	- Staff has better communication with top management - Costs less as organization employs fewer managers - Flat organizations are associated with higher level of employee morale and productivity - Encourages empowerment through delegation of authority and decision making	- Creates more supervisory responsibility for relatively few managers - Overloaded management leads to loss of control

Coordination mechanisms analysis. This analysis aims to highlight the existing coordinating mechanisms between employees, as well as their suitability. It starts by identifying liaisons between employees, which can be extracted from the process flow diagram or process/organizational structure relationship map. In the second step, prioritization of obtained liaisons is being done based on their impact on organizational performances. The list of prioritized liaisons represents the sequence in which a researcher ought to identify and analyze coordination mechanisms and their historical problems, starting from the most important liaison.

In order to analyze current coordination mechanisms and determine the gap between them and the actual requirements, it is necessary to do the following analysis for each identified liaison (Recardo, 2008):

- Importance. This is done by determining how critical each liaison is to the organization (this was done in the previous step in order to make a list of liaison priorities).
- Complexity. Greater complexity requires more sophisticated coordination mechanisms.
- Task uncertainty. The scale for assessing task uncertainty is 1 for predictable and repeatable task, while 10 is for ambiguous and unpredictable one.
- Interdependence. The scale for assessing interdependence is 1 for pooled interdependence (groups are relatively independent of each other, but contribute to the overall goals of the organization), 5 for sequential interdependence (outputs of one group become the input of the other group), and 10 for

reciprocal interdependence (certain outputs of each group become an input for the other group; collaboration needs to occur in both directions).

Figure 6 exhibits the manner in which coordination mechanisms are analyzed.

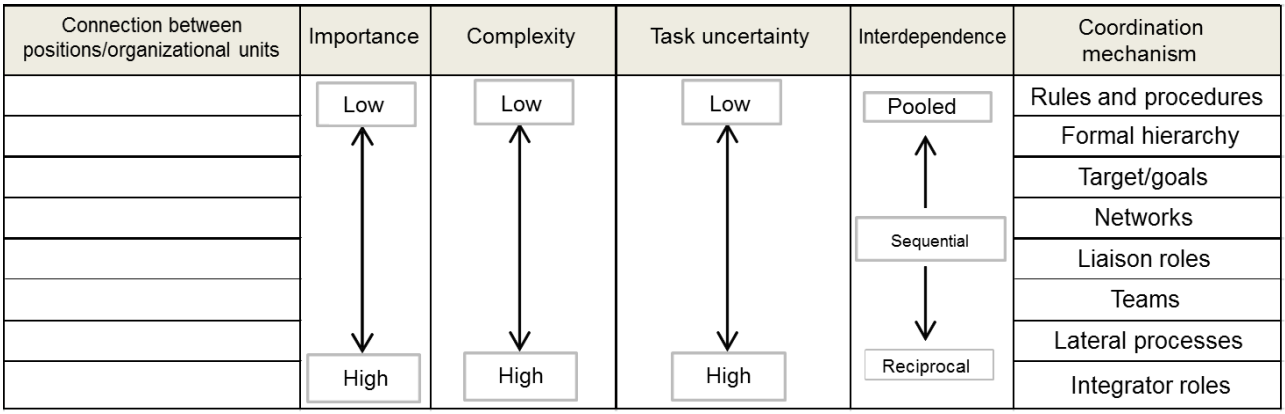

Figure 6: Coordination mechanisms identification table (Recardo, 2008)

Employee structure analysis. This analysis indicates the ability of the existing human resources within an organization to secure that on-going operations are run smoothly, and take part in the overall organizational development at the same time, in order for organization to seize new market opportunities and thrive in the long run. In other words, this analysis provides an insight into the human potential of an organization. It highlights the strengths and weaknesses in this domain, which is, without any doubt, the most important one. Indicators that explicitly or implicitly show human resources characteristics within an organization are the following: (1) age distribution, (2) qualification distribution, (3) quality of recruitment and selection process, (4) quality of training and development process, (5) reward and incentives system, (6) absenteeism, (7) employee turnover, and (8) remunerations (base salary and other monetary or non-monetary benefits that employees receive).

In addition to these, it is possible to perform a number of other analyses, while some of them may be done by a combination of some of the above. The choice of the analyses to be performed depends on the situation specifics.

3. PROCESS AND STRUCTURE DIAGNOSIS

Process and structure diagnosis is a step following the completion of analyses discussed in the previous section of this paper. After the results of each of the presented analyses are known and placed together, a researcher can start analyzing the relations between them. In the next step, all the results are being summarized (a synthesis of the obtained analysis results is being made) and again analyzed, but this time the analysis is being done in a holistic manner, for all the elements combined. Thus, the sum of these analyses results in the processes and organization structure snapshot that, after being subjected to a critical review, makes a process and structure diagnosis. In other words, process and structure diagnosis is a critical review of the state of processes and structure at a particular point of time.

Table 3: Diagnosis report example

Diagnosis parameters	Weak points	Actions to be taken	Benefits expected
Process (1... X)			
Organizational unit (1... Y)			
Position (1... Z)			
Headcount			
Spans of control			
Hierarchy			
Employee structure			

Process and structure diagnosis is a report that shows all the existing problems related to processes and structure, as well as the potential problems that may occur unless some actions are taken. After that, guidelines for actions are provided with the expected benefits. On the other hand, diagnosis may highlight positive aspects as well, depending on the desired effect of presentation. Therefore, the diagnosis report usually shows weaknesses (sometimes even strengths), actions to be taken, and benefits expected as a

result of these actions. The manner in which it will be presented may be customized to best fit the purpose. An example of the diagnosis report is exhibited in Table 3.

Process and structure diagnosis report is a starting point for process and organization structure design, i.e. for the first step in this process, which is the development of design principles and metrics. Diagnosis report broadly defines a domain in which alternative process and structure designs ought to be found. In other words, diagnosis report provides guidelines for making specific design decisions.

4. CONCLUSION

Process and organization structure play a very important role in creating a competitive advantage of an organization. On the other hand, since these two components cannot be observed and analyzed isolated from the other organizational components (e.g. strategy, human resources, organizational culture, etc.), but only through a network of complex interactions with them, it is quite clear that process and organization structure design efforts depend on these other components, but also have a profound effect on them. Therefore, it can be concluded that tracking down processes and structure is a very complex matter that does not consist of a simple series of sequentially related steps leading up to a predetermined goal. Process and organization structure design is much more than that. It is a process with logical sequence of decisions and actions that ought to be followed, but it also involves a great deal of intuition when it comes to searching for available solutions determined by the dynamic environment and internal factors specific to each organization.

What further complicates this process is the fact that there is no ideal solution for the processes and organization structure. It requires constant comparison between positive and negative traits of each solution and making a compromise. The aim is to achieve the closest approximation to an optimal solution as possible taking into account all the circumstances. However, a typical problem that arises while making a decision about the solution to be implemented is the lack of a proper feedback. This is due to the fact that effects of process and organization design typically have a delayed effect, which means that the results of chosen solution may be evaluated only after certain period of time passes from the full implementation of new processes and structure. This is usually measured in months or even years.

Even though authors are hoping that this paper presents a solid methodological foundation suitable for practitioners in order to develop their plans for tracking down processes and structures in various organizations, some limitations it suffers from are recognized. First, this paper does not provide all the techniques and tools available to the practitioner while performing process and organization structure analyses. However, the reader ought to keep in mind the complexity of this process and the limited length of this paper. Second, process and organization structure methodology presented in this paper is aiming at large and perhaps some medium-sized organizations. As such, it can be applied to small organizations, but with certain adjustments being made, which are not discussed in this paper. Finally, methodology presented here ought to be incrementally adapted to the circumstances specific for each organization. The manner in which the methodology ought to be modified is not the topic of this paper.

One general recommendation for practitioners can be extracted from this paper. It concerns general awareness about the importance of the topic presented here. Therefore, it is essential to communicate with the managers in all kinds of organizations about the importance of gaining an in-depth knowledge about the processes and organization structure. They ought to realize that this knowledge will enable them to continually improve the manner in which their organizations operate, which will affect strengthening of their competitive position in the market. Managers also need to know that tracking down processes and structure is not a one-time action, but rather a permanent process of monitoring the changes in the environment and other organizational components, as well as their effects on processes and structure. Only if they keep on tracking processes and structure inside of their organizations, they will enable them to continually increase effectiveness and efficiency of its operations, thus providing them at least a chance to thrive in this age of technological and market discontinuity.

Abstract: *Researchers have often used constructs such as routines, operational capability, dynamic capability, absorptive capacity, etc., to explain various organizational phenomena, especially a competitive advantage of firms. As a consequence of their frequent use in different contexts, these constructs have become extremely broad and blurred, thus making a void in strategic management literature. In this paper we attempt to bring a sense of holistic perspective on these constructs by briefly reviewing the current state of the research and presenting a conceptual model that provides an explanation for the causal relationships between them. Authors hope that findings in this paper may serve as a foundation for other research endeavours related to the topic of how firms achieve competitive advantage and thrive in their environments.*

Keywords*: absorptive capacity, dynamic capability, operational capability, routines, inertia.*

1. INTRODUCTION

Field of strategic management is primarily concerned with the question of how firms develop strategies and thrive in their respective environments. In this quest, strategic management has developed theories and concepts that examine the environment and look inside the firm (Herrmann, 2005). Its goal is to explain underlying mechanisms and depict actions that ought to help firms in satisfying the needs of its stakeholders and outpacing the competition.

In the past few decades, the focus of the research has been partially shifted toward some specific internal aspects of firms, such as routines (Nelson and Winter, 1982; Cohen et al., 1996; Zollo and Winter, 2002; Feldman and Pentland, 2003; Becker, 2004), operational capability (Amit and Shoemaker, 1993; Winter, 2000; Schreyögg and Kliesch-Eberl, 2007; Helfat and Winter, 2011), dynamic capability (Teece et al., 1997; Gilbert, 2006; Schreyögg & Kliesch-Eberl, 2007; Helfat and Winter, 2011), absorptive capacity (Cohen and Levinthal, 1990; Kim, 1997a; 1997b; Van den Bosch et al., 1999; Zahra and George, 2002), etc., in order to explain the creation and retention of their competitive advantage. Even though these constructs were initially used to explain different aspects of organizational dynamics and competitiveness, in time they started to become extremely broad and less concise, as a consequence of their frequent use in different contexts. These days, the field of strategic management lacks clear understanding and differentiation between these constructs, as well as clear linkages joining them.

The identified gap in the strategic management literature has been the rationale for writing this paper. The effort was undertaken in order to precisely define these constructs based on literature review, make a clear boundary between them, and finally, since all of them are inseparable from the field of strategic management, make a clear connection between them. Thus the two primary goals of this paper are: (i) to review the most influential papers in strategy management literature in order to crystallize the meaning of the following constructs - routine, operational capability, dynamic capability, and absorptive capacity; and (ii) to reconceptualise their connections by integrating them into a conceptual model extracted from a literature review.

2. CONCEPTUAL FRAMEWORK

For a firm to be successful in the contemporary environment, it must maintain continuity of its on-going operations, while fostering innovations and change at the same time. Continuity and change come together when stability, hierarchy, specialization, formalization and centralization are coupled with attributes such as speed, flexibility and responsiveness (Graetz & Smith, 2008). In order to achieve a competitive advantage and growth, a firm must be capable to continuously reconfigure its resources and capabilities in order to adapt to changes in the environment (Argyris, 1996), but without

compromising the stability of its operations. This is especially true in a situation in which the management of a firm ought to pay attention to a much larger number of variables in the environment and their dynamics than was the case before (Stefanovic et al., 2011; 2012).

The ability to change continuously while keeping the efficiency is a core capability of successful firms, especially in the highly competitive, high-velocity oligopolies in which many contemporary firms compete (Brown and Eisenhardt, 1997). In other words, "a system has to develop boundaries, identities, procedures, practices, and competencies that bring about institutionalizing effects (replicability, inertia, selectivity, etc.) likely to damage the system"s adaptability and flexibility. Responding to those inevitable tendencies (trade-offs), an organization has to find ways to handle this risk of inherent dysfunctional flips and rigidity" (Schreyögg and Sydow, 2010, p. 1258).

In this paper we provide a review and propose a reconceptualization of several constructs that represent antecedents of competitive advantage of firms by achieving efficiency through stability and continuity, and at the same time, effectiveness through instability and adaptability.

2.1. Routines

"As companies grow, they develop structures and systems to handle the increased complexity of the work. These structures and systems are interlinked so that proposed changes become more difficult, more costly, and require more time to implement, especially if they are more than small, incremental modifications. This result in structural inertia – a resistance to change rooted in the size, complexity, and interdependence in the organization"s structures, systems, procedures, and processes... Quite different and significantly more pervasive than structural inertia is the cultural inertia that comes from age and success. As organizations get older, part of their learning is embedded in the shared expectations about how things are to be done. These are sometimes seen in the informal norms, values, social networks, and in myths, stories, and heroes that have evolved over time. The more successful an organization has been, the more institutionalized or ingrained these norms, values and lessons become. The more institutionalized these norms, values, and stories are, the greater the cultural inertia – the greater the organizational complacency and arrogance" (Tushman and O"Reilly, 1996, p. 18).

In order to discuss the concept of routines, we will adopt the approach of Nelson and Winter (1982), who begin their analysis of routines from the notion of skill, which they define as "… a capability for a smooth sequence of coordinated behaviour that is ordinarily effective relative to its objectives, given the context in which it normally occurs" (p. 73). Skill is a basic trait that determines the quality of work performed and things to be done. As far as routine concerns, although the term has been in circulation for decades, we are just beginning to understand its nature (Pentland and Feldman, 2005). Routine represents a general way of doing things, that is, a stable pattern of behaviour that characterizes organizational reaction to a specific internal or external stimulus (Zollo and Winter, 2002).

Historically, the term „routines" clearly referred to reccurent interaction patterns, that is, collective recurrent activity patterns (Becker, 2004). It is "an executable capability for repeated performance in some context that has been learned by an organization" (Cohen et al., 1996, p. 683). In a revision of the extent literature, Becker (2004) identified the following characteristics associated to the routine construct: (1) patterns, (2) recurrence, (3) collective nature, (4) realm of consciousness (mindlessness vs. effortful accomplishment), (5) processual nature, (6) context-dependence, embeddedness and specificity, (7) path dependence and (8) triggered.

When viewed from a distance, any particular organizational routine can exhibit a great deal of continuity over time, which leads some theorists to emphasize their role in organizational inertia and stability (Nelson and Winter, 1982). This stability-providing effect of routines is important for organizational learning, as well as for organizational efficiency increase. However, sometimes the stability-providing effect of routines does develop into a pathology. Repetition of specific activities takes place, even though there are no obvious evidence of benefits for this kind of behaviour. In other words, routines may lead to inertia (Becker, 2004).

Gilbert (2005) argues that two basic types of inertia are resource and routine rigidity. Resource rigidity stems from resource dependency, i.e. blinders created by resource dependence, and incumbent reinvestment incentives, i.e. a desire to preserve market power. Resource dependency means that

firm"s external resource providers, i.e. capital markets and customer markets, shape and constrain its internal decision-making process (c.f., Pfeffer and Salancik, 1978). Incumbent reinvestment incentives are found to exist in situations in which firms cannot acquire new technology, and therefore they increase investments in their current market positions (Gilbert & Newberry, 1982). On the other hand, routine rigidity may influence inflexibility of firm routines as well. In this view, routines are seen as repeated patterns of response that become reinforced through repeated use. Routines are self-reinforcing by nature and are not built to change. Gilbert (2005) explains that both resource and routine rigidity constrain adaptation, but they have different underlying causal mechanisms. "Data show that resource rigidity stems from unwillingness to invest, while routine rigidity stems from an inability to change the patterns and logic that underlie those investments. The first relates to the motivation to respond, the second to the structure of that response... By analogy, resource rigidity is concerned with movement along a line, while routine rigidity deals with the trajectory of the line... Threat decreases resource rigidity but increases routine rigidity" (Gilbert, 2005, p. 757). One of his main findings is that the response to discontinuous change in environment requires more than just commitment of resources. The underlying organizational routines that use those resources must also adapt accordingly. Therefore:

Proposition 1: *Resources and routines, if not questioned and re-examined periodically, have a tendency to become rigid due to the force of inertia.*

Having this in mind, the question that practically imposes itself is whether routines exhibit only continuity and repetition, or there is some other trait invisible when viewed from distance. Closer observation of routines reveals their different kind of nature, the one that is opposite to continuity and repetition. Viewed up close, routines change. They change continuously and endogenously, which leads various academics to emphasize their role in flexibility and change (Pentland and Reuter, 1994). In response to these apparently contradictory empirical findings, Pentland and Feldman (2005) argue that routines are continuously emerging systems with internal structures and dynamics. The internal structure of a routine can produce a wide range of different outcomes on the continuum between „very stable" and „constantly changing", depending on circumstances.

The stability and instability of routines are both desirable. This presents a paradox that continually challenges organizations to balance the two objectives (Poole and Van de Ven, 1989). Anand et al. (2012) argue that routines go through alternating cycles of intended stability in terms of adherence to the established procedures, and intended instability in terms of improvisation and change in these procedures. In other words, operational routines go through regular phases of renewal through organizational learning. In the absence of a renewal, adherence to routines tends to decay, leading to a state of higher entropy over time. The preceding arguments suggest the following proposition:

Proposition 2: *The greater the extent to which firms foster organizational learning, the greater the likelihood they will establish empirically proven routines that will be subjected to renewal as circumstances dictate.*

2.2. Organizational (operational) capability

The capabilities refer to a firm"s capacity to deploy and coordinate different resources, usually in combination, using organizational processes, to affect a desired end (Amit and Shoemaker, 1993). Hence, resource and capability represent two different conceptual levels. A firm's resources at a given time could be defined as those (tangible and intangible) assets which are tied semipermanently to the firm (Wernefelt, 1984). On the other hand, capabilities are focused on the combination and linking of resources, that is, capability represents a distinctive and superior way of allocating resources (Schreyögg and Kliesch-Eberl, 2007), and each firm gradually develops its approach to selecting and using specific resources (Schreyögg and Kliesch-Eberl, 2007), which is why it is also called organizational capability, or even operational capability. All these terms are treated as synonyms in this paper.

Organizational capability may also be regarded as a firm"s capacity to perform a specific activity or interrelated set of activities in a reliable and at least minimally satisfactory manner (Helfat and Winter, 2011). "Operational capability enables a firm to perform an activity on an on-going basis using more or less the same techniques on the same scale to support existing products and services for the same customer population." (Helfat and Winter, 2011, p. 1244) According to Winter (2000), an organizational capability is "a high level routine (or collection of routines) that, together with its

implementing input flows, confers upon an organization‟s management a set of decision options for producing significant outputs of a particular type" (p. 983). Hence:

Proposition 3: *Firms that incorporate appropriate routines on the selected resources during their operations will have a greater chance to create more effective organizational (operational) capabilities.*

As already implied in the section covering routines, organizational capabilities may fall into trap of becoming needless routines if their underlying logic is not subjected to continuous re-examination and evaluation. "Any capability therefore contains an inherent risk, that is, the risk of rigidity and helplessness in the face of fundamentally changing conditions. As a consequence, organizations are confronted with a dilemma: on the one side, they have to develop reliable patterns of selecting and linking resources in order to attain superior performance and competitive advantages and on the other side this endeavour constitutes – at least in volatile markets – a considerable risk of becoming locked into exactly these capabilities" (Schreyögg and Kliesch-Eberl, 2007, p. 919). Based on the aforementioned:

Proposition 4: *Organizational (operational) capabilities, if not questioned and re-examined periodically, have a tendency to become rigid due to the force of inertia.*

An organizational capability is the result of an organizational learning process (Schreyögg and Kliesch-Eberl, 2007). Organization learning is a form of informational updating through which decision makers develop an understanding of relationships between organization actions and outcomes (Levitt and March, 1988). Thus, the factors that define an organization‟s capabilities evolve over time: they start with resources, then move to processes and values, and finally end with culture (Christensen and Overdorf, 2000). Seen through these lenses, it is not surprising that creating outstanding organizational capability has a synergistic effect, i.e., it enables the company as a whole to be more valuable than the sum of its parts (Brockbank and Ulrich, 2009). Therefore:

Proposition 5: *The greater the extent to which firms foster organizational learning, the greater the likelihood they will establish adequate organizational (operational) capabilities.*

2.3. Dynamic capability

In an environment where technological, regulatory, and competitive conditions are subjected to rapid change, persistence in the same operating routines quickly becomes hazardous. If the change is not only rapid but also unpredictable and variable in direction, operational capabilities and even the higher-order learning approaches will need to be updated repeatedly. Failure to do so turns core competencies into core rigidities (Leonard-Barton, 1992). Thus, established organizational capabilities ought to be changed as quickly and frequently as environment changes. In other words, a firm must adapt its operational capabilities fast enough in order to cope with the environment dynamics.

Firm‟s ability to thrive over time lies in its ability to integrate and build upon its current competencies while simultaneously developing fundamentally new capabilities. This is called a „dynamic capability‟. According to Teece et al. (1997), dynamic capabilities may be regarded as "the firm‟s ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments" (p. 516). In other words, organizations must develop dynamic capabilities in order to survive in the contemporary environment.

Dynamic capabilities are those that promote a seemingly radical change in how a firm makes a living (Helfat and Winter, 2011) on the basis of its existing (operational) capabilities. They refer to the capacity to renew competencies (Teece et al.,, 1997). When change in the environment is discontinuous, residual fit usually remains between the already established firm‟s capabilities and some portion of the environment, which means that established capabilities as well as new ones must coexist for some period of time. This is what dynamic capabilities really mean: moving from one competency configuration to another, and maintaining multiple competencies that address inconsistent contexts simultaneously (Gilbert, 2006). "Dynamic capabilities in this sense build different types of capabilities, which amount to experiential, improvisational, and highly fragile processes of reconfiguration, integration, and acquisition of resources. They make use of real-time information, simultaneously explore multiple alternatives, rely on quickly created new knowledge, are governed by very few simple rules, do not get stored in the organizational memory, and thus do not produce

predictable outcomes. Their strength no longer flows from architecture but rather from its ability to continuously produce new constellations and solutions" (Schreyögg & Kliesch-Eberl, 2007, p. 919). The foregoing literature review suggests the following proposition:

Proposition 6: *The greater the extent to which firms develop various organizational (operational) capabilities, no matter whether in a successive or simultaneous manner, the greater dynamic capabilities they possess.*

Thus, an organization"s dynamic capabilities depend on simultaneously exploiting current technologies and resources to secure efficiency benefits and creating variation through exploratory innovation. Maintaining an appropriate balance between exploitation and exploration is critical for firm survival and prosperity (March, 1991; Teece et al., 1997). This is not to say that dynamic capabilities are supposed to replace operational capabilities, but rather that, as Graetz and Smith (2008) argue, the key characteristic of duality thinking that organizations must achieve if they are to exploit and explore, is the bidirectional partnership between continuity (efficiency through operational capabilities) and change (flexibility and responsiveness through dynamic capabilities).

Therefore, aligning organizations to simultaneous exploitation and exploration is a task of dynamic, rather than static alignment (Raisch and Birkinshaw, 2008), and the firm"s capability to manage this alignment is called organizational ambidexterity (Duncan, 1976; March, 1991). Even though organizations need both types of capabilities (exploration and exploitation), organizational ambidexterity can be viewed as an organization-level dynamic capability (Jansen et al., 2009), but only if management can repeatedly and intentionally orchestrate firm assets and resources (O"Reilly and Tushman, 2007). "As a dynamic capability, ambidexterity embodies a complex set of routines including decentralization, differentiation, targeted integration, and the ability of senior leadership to orchestrate the complex trade-offs that the simultaneous pursuit of exploration and exploitation requires. Developing these dynamic capabilities is a central task of executive leadership" (O"Reilly & Tushman, 2011, p. 6).

Cao et al. (2009) have shown that ambidexterity is fostered by close interrelations between existing and new knowledge. They argue that synergistic effect can be achieved by allowing existing resources to be more fully employed to acquire new capabilities, while at the same time permitting new knowledge to be more fully integrated into the existing pool of resources. Therefore, since organizational ambidexterity is a dynamic capability, it can be concluded that dynamic capabilities must be developed through learning. Zollo and Winter (2002) focused on organizational learning as a source of dynamic capability, which they defined as "a learned and stable pattern of collective activity through which the organization systematically generates and modifies its operating routines in pursuit of improved effectiveness" (p. 340). They argue that dynamic capabilities emerge from the co-evolution of tacit experience accumulation processes with explicit knowledge articulation and codification activities. It thus follows:

Proposition 7: *The greater the extent to which firms foster organizational learning, the greater the likelihood they will establish dynamic capabilities.*

2.4. Absorptive capacity

An absorptive capacity is the ability of a firm to identify, assimilate and apply useful external knowledge (Cohen and Levinthal, 1990). It can also be acknowledged as the capacity to learn and solve problems (Kim, 1997a; 1997b). In order to identify, assimilate and exploit new knowledge, a firm must possess prior related knowledge. The prior knowledge allows assimilation of new knowledge only if some portion of it is closely related to the new knowledge (Cohen and Levinthal, 1990). An absorptive capacity tends to confine a firm to operate in a specific technological domain (Cohen and Levinthal, 1990), which may eventually lead to the pattern of inertia (Nelson and Winter, 1982). Hence, two propositions follow:

Proposition 8: *The greater the extent to which firms foster organizational learning, the greater the likelihood they will have effective absorptive capacity.*

Proposition 9: *Absorptive capacity, if not questioned and re-examined periodically, has a tendency to become rigid due to the force of inertia.*

"Absorptive capacity is more likely to be developed and maintained as a byproduct of routine activity when the knowledge domain that the firm wishes to exploit is closely related to its current knowledge base. When, however, a firm wishes to acquire and use knowledge that is unrelated to its ongoing activity, then the firm must dedicate effort exclusively to creating absorptive capacity (i.e., absorptive capacity is not a byproduct)." (Cohen and Levinthal, 1990, pp. 149-150) Creative utilization of new knowledge will be permitted if some part of the prior knowledge is fairly diverse, although still related (Cohen and Levinthal, 1990).

Van den Bosch et al. (1999) argued that Cohen and Levinthal"s (1990) implicit feedback loop (absorptive capacity→ learning → new absorptive capacity) is mediated by the environment in which the firm competes and its success in coping with it. Firms facing stable or turbulent environments tend to organize themselves differently and emphasize different ways of combining knowledge (Lane et al., 2002).

On the other side, Zahra and George (2002) have established a conceptual link between absorptive capacity, organizational (operational) capability and dynamic capability by defining absorptive capacity as "a set of organizational routines and processes by which firms acquire, assimilate, transform, and exploit knowledge to produce a dynamic organizational capability." (p. 186) According to them, acquisition, assimilation, transformation and exploitation are organizational capabilities that build on each other to yield absorptive capacity. In this way, absorptive capacity may actually be seen as a dynamic capability that enable firms to create and deploy the knowledge necessary to build other organizational capabilities, that is, production, marketing, sales, etc. (Zahra and George, 2002). Therefore, two propositions are extracted from the foregoing claims:

Proposition 10: *Absorptive capability is a dynamic capability*.

Proposition 11: *The greater the absorptive capacity/dynamic capabilities that firms possess, the greater the possibility they will develop various organizational (operational) capabilities.*

Based on a thematic analysis of the literature, Lane et al. (2002) found that organizational learning and absorptive capacity coevolve with each influencing the other. However, they concluded that little attention has been given to the implications of exploitative versus exploratory learning for absorptive capacity development. Thus, Lane et al. (2006) suggested a more detailed definition of absorptive capacity as a firm"s ability to utilize externally held knowledge through three sequential processes: (1) recognizing and understanding potentially valuable new knowledge outside the firm through exploratory learning, (2) assimilating valuable new knowledge through transformative learning, and (3) using the assimilated knowledge to create new knowledge and commercial outputs through exploitative learning. Hence:

Proposition 12: *The greater the extent to which firms have established absorptive capacity/dynamic capabilities, the greater the likelihood they will foster organizational learning.*

3. CONCEPTUAL MODEL

The propositions extracted from the literature review of the constructs in this paper determine connections between them, thus making a conceptual model depicted in Figure 1.

The first trait of the proposed model that ought to be emphasized is the relationship between dynamic capabilities and absorptive capacity. The literature review began by considering them as two separate constructs, but ended with the premise of them actually being one construct. The second obvious trait of the model is positioning of operational capabilities as a central construct inextricably intertwined with all the other constructs.

Resources and routines, as well as operational and dynamic capabilities, if not questioned and re-examined periodically, have a tendency to become rigid due to the force of inertia. The explanation for this statement lies in the velocity of the contemporary environment in which majority of firms operate (Stefanovic et al, 2012). In the ever-changing environment, sustainable competitive advantage is a thing of the past. Contemporary environment has shifted the focus towards the temporary competitive advantage (D"Aveni et al, 2010), because the true sustainable competitive advantage is rare and declining in duration (Ruefli and Wiggins, 2002). Long-term survival ought to be embedded in new

variations, internal selection that correctly reflects external selection pressures and top management"s capacity for recognizing and retaining viable strategic initiatives (Burgelman, 1994).

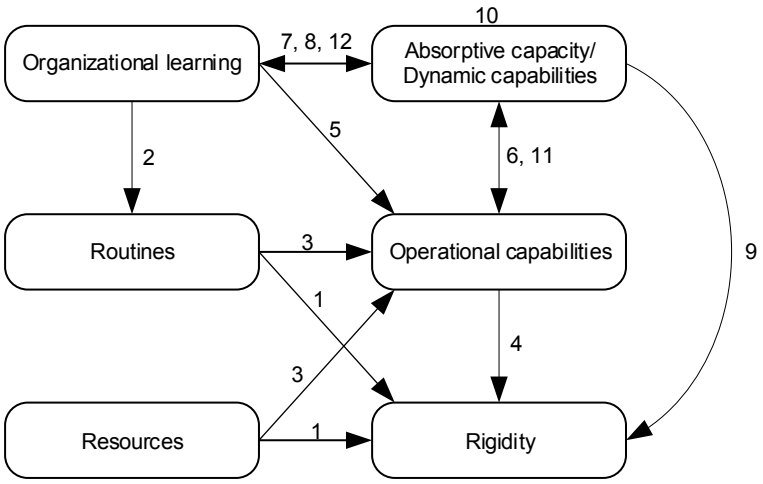

Figure 1: Conceptual model of routines, capabilities, and absorptive capacity interplay

In other words, firms ought to engage in the process of continuous organizational learning in order to cope with the changes and surprises arising from the environment. Fostering organizational learning within firms increases the likelihood of establishing empirically proven routines that will be subjected to renewal as circumstances dictate. Firms that learn how to incorporate these routines on the selected resources during their operations will have a greater chance to create more effective operational capabilities suitable for the specific situation. Therefore, widespread organizational learning increases the likelihood of creating adequate operational capabilities, but also plays an important role in establishing dynamic capabilities/absorptive capacity. Nevertheless, there is also a direct causal relationship between operational and dynamic capabilities. Thus, the greater the extent to which firms develop various operational capabilities, no matter whether in a successive or simultaneous manner, the greater dynamic capabilities they possess. Finally, the greater the extent to which firms have established dynamic capabilities/absorptive capacity, the greater the likelihood they will foster organizational learning and develop needed operational capabilities.

4. CONCLUSION

The constructs of routines, operational capabilities and dynamic capabilities/absorptive capacity have been applied to a wide variety of phenomena in recent years. Their growing appeal is a reflection of their versatility, but this versatility carries the risk of a lack of clarity in meaning and differentiation between these constructs, as well as clear linkages joining them. In this paper, we attempt to bring a sense of holistic perspective by briefly reviewing the current state of the research and highlighting what is known about the topic. After that, the conceptual model is provided based on the propositions extracted from the literature review of the constructs.

Even though this paper provides a reconceptualization of causal relationships between routines, operational capabilities and dynamic capabilities/absorptive capacity, and may present a small contribution to the holistic perspective on how firms achieve competitive advantage and thrive in their respective environments, authors are fully aware of its limitations. First and foremost, this paper presents a theoretical review and reconceptualization based on this review. In other words, the conceptual model presented in this paper has no direct empirical confirmation. It is simply a synthesis of various research papers, which is why its approval in an empirical setting is needed. Second limitation concerns the scope of the literature reviewed. Even though some of the most influential articles on the topics of interest are covered, and they share practically the same underlying logic, maybe some less-known articles would indicate other aspect of the gap in the strategic management literature we are trying to bridge. Thus, a review that covers a broader scope of articles covering these topics is needed.

We hope that this paper encourages future research on the dimensions, causal relationships linking them and contributions of the constructs. It is reassuring that researchers in diverse organizational disciplines have recognized the explanatory power of routines, operational capabilities as well as

dynamic capabilities/absorptive capacity, and we hope that their future uses of this concept will show greater recognition of its multiple dimensions and their links to create and sustain a competitive advantage of firms.

DEVELOPMENT OF PROCESS MODEL OF ENTERPRISE ORGANIZATION

Branko Matić[1]
[1]VIPOS – Valjevo, branko.matic@gmail.com

Abstract: *This paper examines the emergence and development of process model of the enterprise. Here are given the early contributions of authors who have indicated the occurrence of the process model. Basic theoretical models are given, ranging from Deming`s flowchart and Porter's value chain model over Davenport`s model, horizontal organizations: Rumler and Branch, John Byrns and Ostroff, to the reengineering of Hammer and Harmons organizational models and processes. In particular, a model of quality management systems and model thin horizontal structures are shown. Based on them, the basic model of process organized company is given and its main characteristics are described.*

Keywords: *model, process, development, structure, horizontal organization*

1. INTRODUCTION

Process approach to the organization of companies that emerged at the end of the twentieth century is not at the same time brought the establishment of a general process model of the enterprise. Some authors in their papers describe their models, but none of them was good enough to become generally accepted - universal (general). Each of them contained the individual "process" elements but was not universal, and today there is no single model that would be in the science of the organization ranked next to well-known model of organizational structure: functional, multidivisional, project and matrix, but there are more, originating from a variety of authors and institutions. Such a single model can be reached by a critical analysis of the known models and by the results of process approach researches published so far, and the integration of the knowledge thus obtained.

2. THE START OF THE DEVELOPMENT OF PROCESS MODEL

The process model has a long course of development, which began in the early years of the twentieth century, and its fundamental shaping was achieved in the nineties. In a period of about 80 years, a number of practitioners and scholars have contributed to the emergence and development of the process model.

Gant created Gantt chart at the beginning of the twentieth century - a graphical way to view the flow of production through a series of horizontal segments, showing the duration of the manufacturing operations and their relationship. By these diagrams Gant became unconsciously the originator of the process model.

Fifty years later the Network planning was designed - graphical and quantitative methods for the analysis of complex enterprise, consisting of a large number of interconnected horizontal activities. Two techniques were developed: 1) CPM (Critical Path Method), and 2) PERT (Program Evaluation and Review Technique). Although they were methods of planning and management, they paved the way for the arrival of process model by the horizontal propagation of events.

A significant shift towards a process model was brought by the emergence of the theory of the system - the system approach of the mid-twentieth century, as it has begun studying a whole composed of parts - as a whole system. The system is defined as a set of related elements (entities) and their properties, integrated relationships between themselves and these properties. (Berrtalanffy, 1951.) Is a graphic system shown as a box with a horizontal structure - general qualitatively defined and relatively stable ranking of relationships between elements of the system - subsystem and horizontal inputs and outputs. Each system can be seen as part of the - a subsystem of a higher system, and it can also have its subsystems.

A significant contribution to the research enterprise as a system given by the 60s of XX century, Forrester, who was a pioneer of industrial dynamics - a mathematical approach to the study of the forces at work in the company and moving to one of his causes. To study the dynamics of the industry, it is used for simulation, which is specially developed methodology graphical and mathematical modelling of the functioning of the company as a whole, consisting of horizontal associated elements of state and change of state elements.

According to Forrester, the business system is a complex organization and functioning of the various states and flows controlled flashback coupled circuits. In his operation on the target-oriented, and only operation is the result of the incorporation of various activities. Business system is a subsystem of broader and more complex systems, and participates in the exchange of goods, energy, information, etc., the transformation of the lower usability in more, their exchange and consumption. Specific environment and structure of parts of the system as well as their mutual coupling significantly affect the behavior and performance achieved. (Forrester, 1963, by Rajkov, 1977.)

All these results have created a solid theoretical framework and some practical experience on which several authors in the second half of the twentieth century, published his models to generate a process approach.

3. PREVIOUS THEORETICAL MODELS

3.1. Deming Flowchart

One of the first process model given by Deming, even in 1950 at the commencement of his famous lectures in Japan. The model shown on figure 1, he used to explain to Japanese managers the interplay of individual parts of the system quality. Deming described it as "a network of independent components that work together to achieve the objectives of the system".

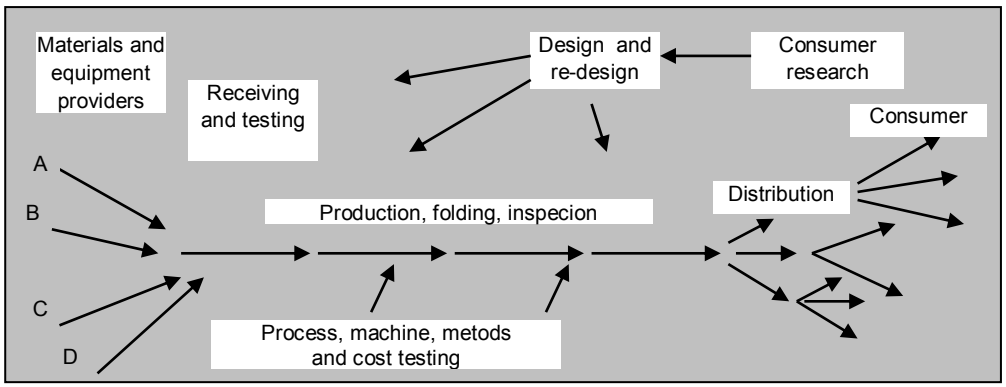

Figure 1: Production shown as a system (Deming, 1996.)

Deming has already used Flowchart - graphical display system components in a horizontal range of activities necessary for the creation and distribution of products.

3.2. Porter`s model of the chain of values

For further development of the process model, the fundamental importance of the Port`s value chain model, (published in 1985.), which contributes to the achievement of competitive advantage. "Competitive advantage can not be understood if the company is not seen as a whole. For analysis of the sources of competitive advantage, it is necessary systematic examination of all activities performed by firms, and their interactions. Every company has a set of activities that are performed in order to design, manufacture, marketing, delivery and support of its products. All of these activities are shown on figure 2 value chain of each company consists of nine generic categories of activities that are characteristic way related to each other." (Porter, 2007).

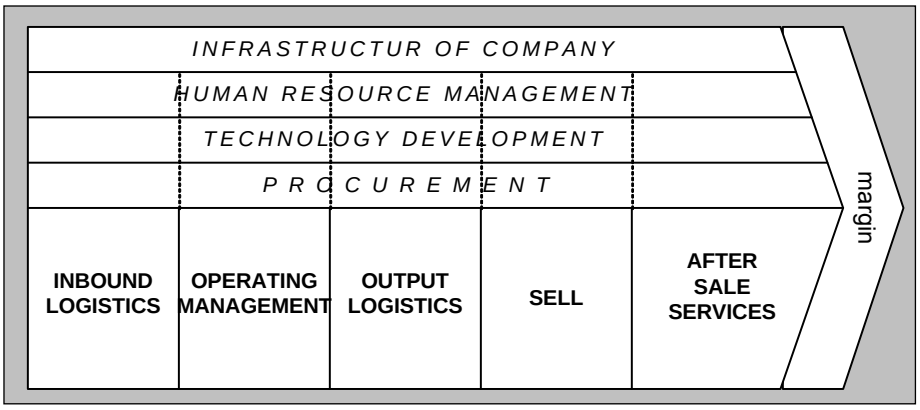

Figure 2: Porter's value chain (Adapted from Porter, 2007.)

Porter then viewed the company as a whole (process), which consists of two groups of horizontal activities (sub-processes): 1. PRIMARY - contribute to the creation of new values of the company through five generic activities: Inbound logistics, Operations, Output logistics, Sales and Service After Sales and Service and 2. *AUXILIARY*, which provide basic support, but also to each other, by providing: Inputs, Technology, Human resources and Other functions at the firm level.

3.3. Horizontal organization Rumler and Brache

Rumler and Brache (Rummler, Brache, 1990). assume that organizations behave as adaptive processing systems, which convert various input resources into outputs of goods and services, which supply the market. These organizations are based on, to processes for, structures, measures, rewards, and resources.

People within a working, functional silos, focus on what is best for a given function, often to the detriment of other functions. Rumler and Brache among the first propose the organization of activities, structures, measures and rewards, around horizontal processes.

3.4. Horizontal organization John Byrne

Byrne in 1993. popularized the term "Horizontal organization" and gave the definition of the model oriented towards business processes. Horizontal organization is described as the removal of both functional as well as the hierarchical boundaries. They all work together, within multidisciplinary teams, conducting key processes such as product development.

Byrne described horizontal organization model which contains the following elements:
1. A company is built on about three to five key processes, not tasks, with specific goals and each executive process is given to the "owner of process".
2. Hierarchy is flattened, shallow. Supervision (supervision) is reduced, fragmented tasks are combined, work that brings value was eliminated, the number of activities of the process is reduced to a minimum the number of teams in the implementation process is as small as possible.
3. Teams manage everything. The teams are the main building blocks of the masonry, with limited supervision, because they themselves manage them. They are responsible for the executive measurable goals.
4. Contacts with suppliers and customers are direct.
5. All employees are informed and trained.
6. Customer satisfaction, rather than a capital increase or profitability is a primary driver, and performance measures. Profit will come and capital will grow, if the customers are satisfied.
7. Performance team is rewarded. The review and payment, reward effects, the results of the whole team and not just the individual. (Byrne, 1993.)

3.5. Davenport's model of integrated company

Davenport (Davenport, 1993.) was among the first focused on the improvement and process improvement in this regard stressed the crucial importance of information technology. Model integration of an enterprise (figure 3), which was established as part of the improvement of its processes, can be considered as the first practically usable process model company. However, it is quite a general view of the processes in the company, and Davenport has not focused his attention to its further improvement. Still visible is its horizontal flow, the main processes and their relationship and taking into account the customers and retailers. Unusual is the unification Engineering and Marketing.

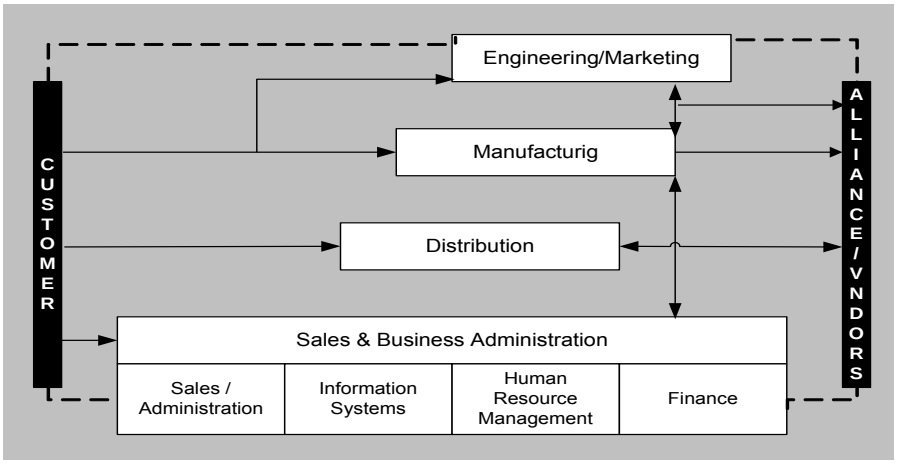

Figure 3: Davenport`s model integration off enterprises (Adapted from Davenport, 1993)

3.6. Horizontal organization Frank Ostroff

Ostroff 1999. offers the first viable concept map the horizontal arrangements under which explains what the horizontal organization, what it looks like, why it is important, as it leads to performance improvement, where appropriate, to introduce and how to develop. He explained the twelve primary key principles for the formation of horizontal organization. The five principles relate to:
1. organizing around basic cross-functional process, not about the tasks or functions;
2. setting process owner or manager who will take responsibility for the main process;
3. the formation of teams, not individuals, as the foundation of organizational design and performance;
4. reducing hierarchy by eliminating jobs that do not create value;
5. integration with customers and suppliers.
The other seven principles relate to institutional changes:
6. allowing employees to make decisions important to the team's performance;
7. use of information technology to assist people to reach performance goals and deliver proper value to the customer;
8. highlight multiple competencies and train people to solve problems and work productively in cross-functional areas within the new organization;
9. promote multiple skills, abilities, creative thinking and flexible response to the new challenges that arise in business performing teams;
10. teaching people trained primarily in specific functions or departments to work in partnership with others;
11. measuring target output process performance such as customer satisfaction, employee satisfaction financial contributions;
12. building a corporate culture of openness, cooperation and collaboration, which focuses on continuous improvement of performance and evaluate accountability, well-being and empowerment of employees. (Ostroff, 1999.)

With these principles Ostroff gave a graphical representation of the model, but it only shows the position of teams within the classical vertical structure and not widely usable.

3.7. Process reengineering by Hammer and Champy

A decisive contribution to the implementation of the process approach in practice achieved reengineering processes since 2001. firmly suggested Hammer and Champy. "It is no longer necessary or desirable to companies organize their work around the division of labor Adam Smith. Jobs oriented task in today's world, customers, competition and change the date. Instead, companies must be organized around business processes." (Hammer, Champy, 2004). According to them, it means the next ten changes in the company:
1) Work units change - from functional departments to process teams.
2) Jobs change - from simple tasks to multidimensional work.
3) The role of the people is changing - from controlled to authorized decision-making.
4) Shall be prepared for the job - the practice of education.
5) The focus of enforcement measures and compensation shifts - from financial results.
6) Changes to the criteria for promotion - from the productivity capabilities.
7) Values change - from patronizing the creative.
8) Managers change - from supervisors become coaches.
9) Changes to organizational structure - from hierarchical to flat.
10) The Executive Directors are changing - from the counter points to the leader.

These changes represent the essence of reengineering, which is described as follows: "Reengineering is the fundamental rethinking and radical redesign of business processes to achieve dramatic improvement in contemporary critical success criteria such as cost, quality, service and speed." (Hammer, Champy, 2004.)

3.8. Harmon`s model of organization and process

Harmon (Harmon, 2003) says we should leave the organizational chart because under it we do not know which organizational unit is responsible for a process. He used the name of an organization chart which shows the three main processes: R&D, Sales and Marketing, Manufacturing and Order Fulfillment group and Auxiliary processes. Each of these processes consists of several sub-processes, and the processes are divided into activities. To view the process Harmon uses rectangles with rounded corners to distinguish the organizational units (departments) showing by rectangles with normal angles. View the processes of enterprises with the help of an organization chart is important because "department don`t produce profits; value chains and processes produce profits." Therefore, "organizations need to focus on the flows and relationships that actually add value and produce product for customers." (Harmon, 2003.)

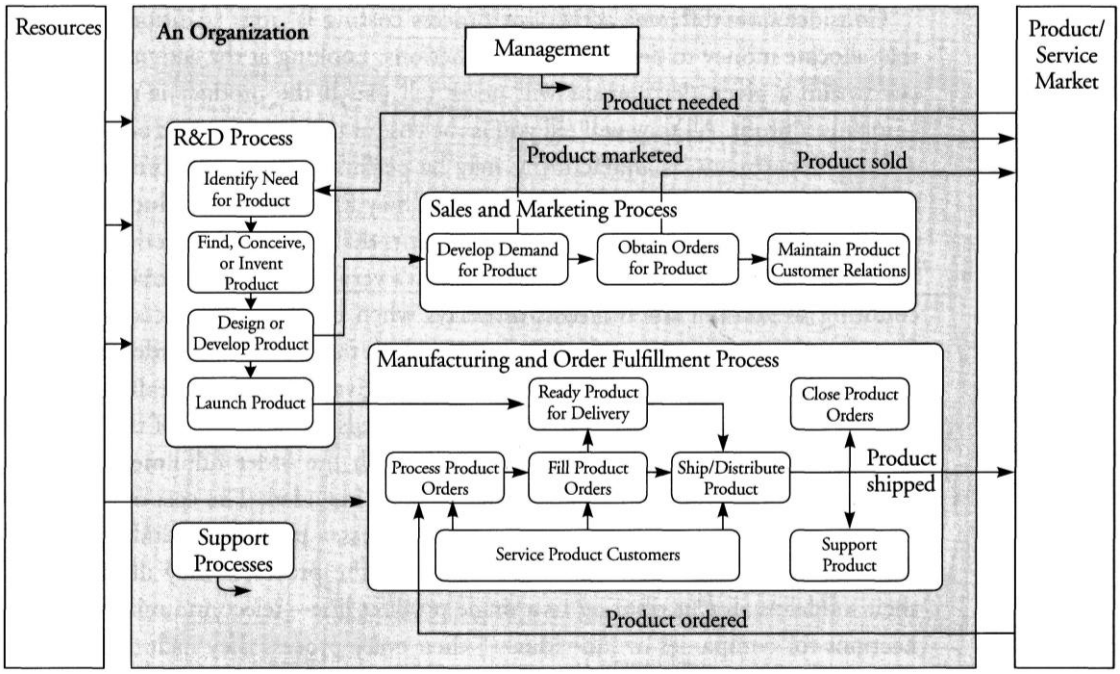

Figure 4: Harmon`s organization chart (Harmon, 2003) (On basis General Elseivier permission)

3.9. Model of anatomical structure of the business system

A group of autors at FOS developed a model of anatomical structure of the business system (Radović, 2008.) with four processes: Research and Development, Production, Business and Management, which consists of ten subsystems: 1) The basic activity, 2) Marketing, 3) Supply, 4) Sale, 5) Economics, 6) Finance, 7) Personnel, 8) Legal-normative, 9) Control) and 10) Development. For this model a detailed process approach of the 12 steps was developed, among them a central place occupies 5. Identification and classification process. This approach - engineering process is carried out in a number of organizations.

4. QUALITY MANAGEMENT MODEL

ISO 9000 published in 1984. developed rapidly, so that the version of the year 2000. was based on the process approach. For an organization to function effectively, it must determine the number of related activities and to carry out their management. Activities or groups of activities, using resources, and managed in order to enable the transformation of inputs into outputs, can be considered as a process. Often the output element from one process directly forms the input element to the next. Application of processes within an organization, together with the identification and interaction of these processes, and the management of them, to obtain the desired results, it can be called a "process approach".

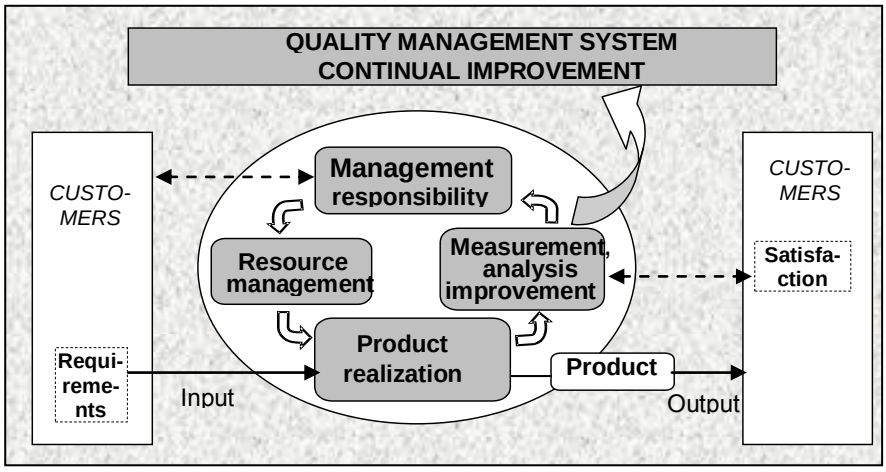

Figure 5: Model of quality management system based on processes (Adapted from SRPS ISO 9000:2005)

Model quality management system based on processes (Figure 5) shows that customers play a significant role in defining requirements as inputs and monitor their satisfaction which is determined by how the

organization meets their requirements. The model is fully consistent with systems theory, a control uses a feedback mechanism, which consists of the measurement and analysis of data collected for the purpose of continuous improvement.

5. MODEL THIN HORIZONTAL PROCESS STRUCTURE

The idea of tanks - flattened horizontal structure was quickly accepted as a way of achieving a process approach in organizations. It particularly applies to the logistic and operational aspects of business. One of the models of tanks is shown on figure 6.

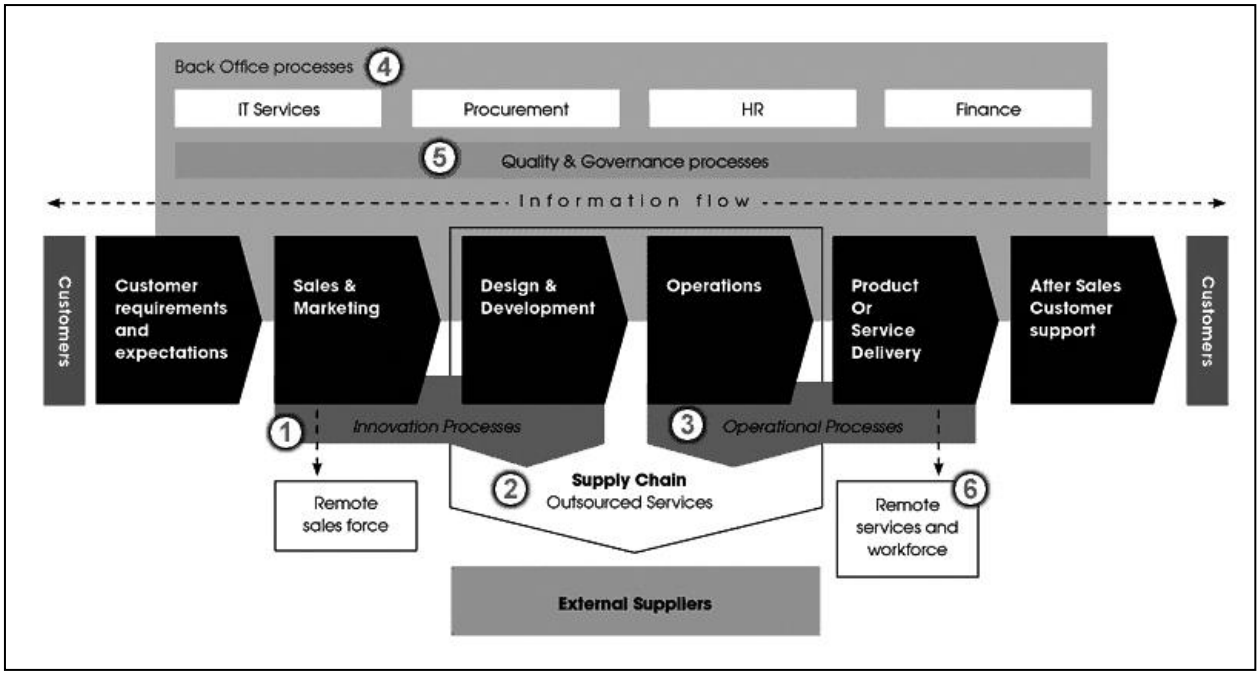

Figure 6: Model thin horizontal process structure (With Lean Business Thinking permission)

In this model, it was pointed out that there are six key process groups:
1. Innovation Processes - Development processes usually involve transforming customer's requirements and information along the value stream.
2. Lean Supply Chain Development - It is important to recognize that outsourcing can provide lean levers for improvement.
3. Lean Operations - Sales, Procurement and Manufacturing.
4. Lean Back Office - Within your organization there are a series of non customer facing, but business critical processes.
5. Quality Lean - Lean techniques signpost a different role for the Quality organization.
6. Service - Lean thinking is directly applicable to service industries. It is important for service delivery teams to have a clear understanding of the characteristics of service (value) that the customer cares about.
Company Lean Business Thinking using this model as a starting point in the acknowledgments of consulting services for process improvement.

6. BASIC MODEL OF PROCESS ORGANIZED COMPANY

Based on the characteristics previously described models can form a general - a universal model, which can be used as a starting point in the application process approach in each company. How it is used as a basis for the design process on the folder might be called the basic process model of enterprises, and its essential one feature are:
1) The model assumes that the company operates in an environment with market principles of business, making sure there is the process of marketing management (MM) and customer relationship management (CRM) through which establishes relationships with customers that defines their requirements and monitor the achievement of satisfaction.
2) The model also implies that the main objective of business enterprise economic efficiency - profit making, which is why there is a process of financial management (FM).
3) The products and services of the company is in the process of devising their own research and development (R&D), but are used and the results of R&D and others.

4) The company's activity is achieved in the process of operations management (OM), supported by the process of supply chain management (SCM).
5) Needed quality of products, services and business processes is realized by QM and appropriate integrated management system standards: quality, environmental protection and employee safety.
6) People are creative factor in business and management, and they can engage in teamwork - teams and managing established through the owner of the process, which is under the process of human resource management (HRM).
7) The structure of the model is made by the listed horizontally oriented processes, which are shown by arrows, and their informational links that are indicated by dashed lines, which establishes an IT process (IP). It is organized as an information system ERP type and should provide support to the management and processing teams and achieve integration process.
8) Top management in collaboration with the owners determine the strategic framework - vision, mission, objectives, strategies and policies.

The elements of the process model of enterprises and their relationship are shown on figure 7. As you can see, the display processes and sub-processes using the horizontal arrow, which reflects the nature of the process: the horizontal orientation of the flow of converting inputs into outputs.

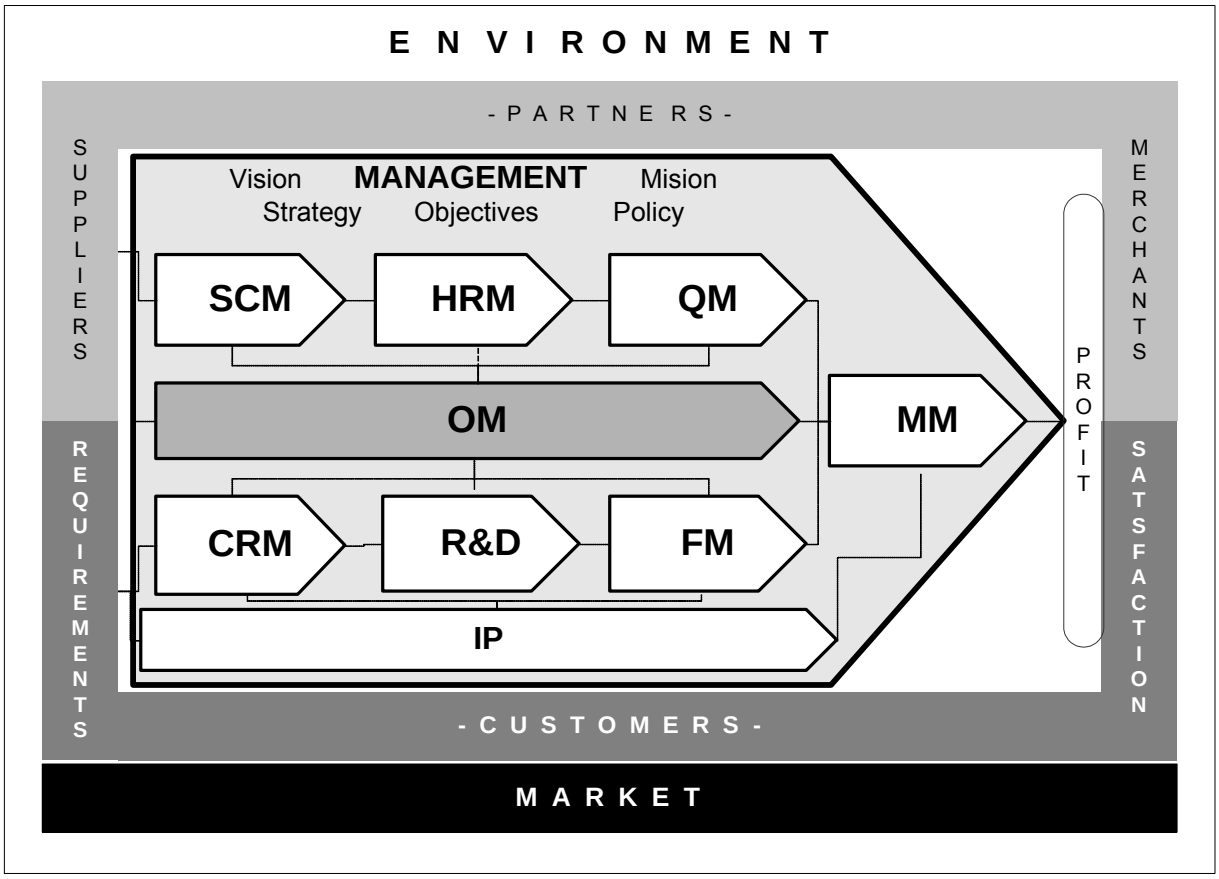

Figure 7: The basic model of a process of organized enterprises

Dashed lines connecting subprocesses indicate that the model involves multiple interconnectivity process. In the model is clearly visible role of top management to integrate processes and direct corporate performance by defining a framework of business factors. The model clearly shows that the final users are the main reason for the company's operations, the good organization of its processes, realized profit, operating in partnership with its suppliers and distributors.

7. MAP OF PROCESSES AND ITS CREATION AND PRESENTATION

These models reflect the views of their authors by the process approach. When implementing these models in practice for any particular company it is needed to create a process map, which describes in detail a process organization. To view maps of the process there are many different methods (standard) and software tools such as Method Integrated Definition (IDEF), Workflow Management (WfM), Unified Modeling Language (UML), Business Process Modeling Notation (BPMN), Business Process Modeling Language

(BPML) and so on. (Comparative analysis of the most important methods - standards have been published in: Ryan,K.L.Ko, Stephen,S.G.Lee, Eng Wah Lee (2009) and Recker,J., Indulska,M., Rosemann,M., Green, P., (2009). It is important to note that the process creates a special folder for each company, and that the process model is unique for all companies, except that adapts to each individual case.It is also important to distinguish between the process model as a general view of the processes in the company from a folder process that gives a detailed view.

8. CONCLUSION

The process model of the company has evolved over several decades of the twentieth century. A significant contribution to its development was given by several authors, for which there are several models. Analytical approach separates their main features, and it is given in their graphical representation. Due to the complex nature of the process approach integrating a feature of all of these models can come to one basic process model that clearly and unambiguously determines the way of the company. It is general enough to be applied to all companies and specific enough to be clearly different from other models of organizational structure. Further, the proposed model includes all the processes that exist in modern enterprises. Therefore, when working on the implementation of the process approach in every enterprise it can be used as a starting point for understanding the processes of the company and determine its process structure. Then it should be used as the basis for creating detailed maps of its processes using a variety of methods, standards and procedures to identify, describe and improve process.

[2] Faculty of Organizational Sciences, Belgrade, Serbia, jasko@fon.bg.ac.rs

Abstract: *This paper will present causal relationship between entrepreneurial ventures and the business environment in which such activities are initiated. Academic research in this direction emerged in last few decades, and they point to the undoubted importance of this topic for economic development at the national and global level. Many authors have indicated the complexity of relations and interactions between entrepreneurship and the environment, and have emphasized the importance of certain factors that simultaneously represent potentials and threats for these businesses. Also, although it is clear that the environment influences the encouragement of entrepreneurship and its success, the influence in the other direction should not be neglected, since these ventures largely affect the business environment, especially if they are numerous and significant for other companies.*

Keywords*: Entrepreneurship, environment, Porter's structural analysis, Population ecology theory, Resource dependence theory*

1. INTRODUCTION

Although entrepreneurship has its roots in changes and development of the society, it has become a subject of studies only in the last few decades (Fayolle, 2008). For a long time it has been held that entrepreneurship is not something that should be paid attention on in academic circles. However, we witness the fact that the modern economy is actually based on entrepreneurial ventures in different stages of development of the societies. Special attention was devoted to this concept during the last decade of the twentieth century, as evidenced by many indicators such as number of researchers involved in these issues, number of published scientific papers with the topics related to entrepreneurship, number of scientific papers with this problem presented, and so on. In many countries, especially in Europe, entrepreneurship provides solutions for many economic problems, and improves national economies.

Entrepreneurship can be, and often is motivated by the situation observed on some specific market, but this relation can be observed in the opposite direction, and then we can say that entrepreneurship in some way creates a market or its activities. This paper will present the relationship between entrepreneurship and the business environment, regarding the changes that occur in the environment as a result of the existence or non-existence of entrepreneurial consciousness and activities. In developed countries, entrepreneurship is usually on an extremely high level, and therefore allows the economies of these countries to develop much faster than it is the case in developing countries. This, however, does not mean that encouraging entrepreneurship is an easy task, but the fact is that it is necessary to work on it, because that opens up new possibilities, provides space for innovation, and, in the end increases degree of competition, leading to the various qualitative and quantitative benefits for many participants on the relevant market.

2. OVERVIEW OF ENTREPRENEURSHIP THROUGH STRUCTURAL ANALYSIS

Terms "*entrepreneur*" and "*entrepreneurship*" in different societies have different interpretations. Thus, in the United States entrepreneur is a person who runs his *own*, *new* and *small business* (Drucker, 2007). However, this should be considered with caution, since it is assumed that not every new business is an entrepreneurial venture. In Germany these terms are associated with the concepts of power and property, so entrepreneur (*Unternehmer*) is considered to be the one who owns, but at the same time runs his business. In each case, regardless of whether it is a new business, or an own business, or a combination of both of these conditions, the importance of innovation is usually emphasized (Drucker, 1984).

Although there are different points of view, generally, none of them denies the claim that entrepreneurship is based on economic and social foundations of the community in which it occurs and persists. Also, entrepreneurship is almost always associated with a risk, especially when it is related to some kind of innovation. Indeed, the practice shows that many entrepreneurial ventures have ended infamously, and it is believed that the main causes for this outcome are actually the entrepreneurs themselves, that is those of them who start such businesses, but are unaware of what is engaging, so they are not prepared for

challenges that are in front of them. This especially applies to the activities that are closely related to high technology, for example. Consequently, we might say that entrepreneurship involves a combination of creativity, planning, and risk-taking (Kuratko, 2013).

The market position of the company depends on a number of factors. Also, the market itself is created and developed in accordance with the appearance and operations of new subjects. This means that there is a strong causal relationship among all these elements. That way enterprises affect the business environment in which they survive and develop.

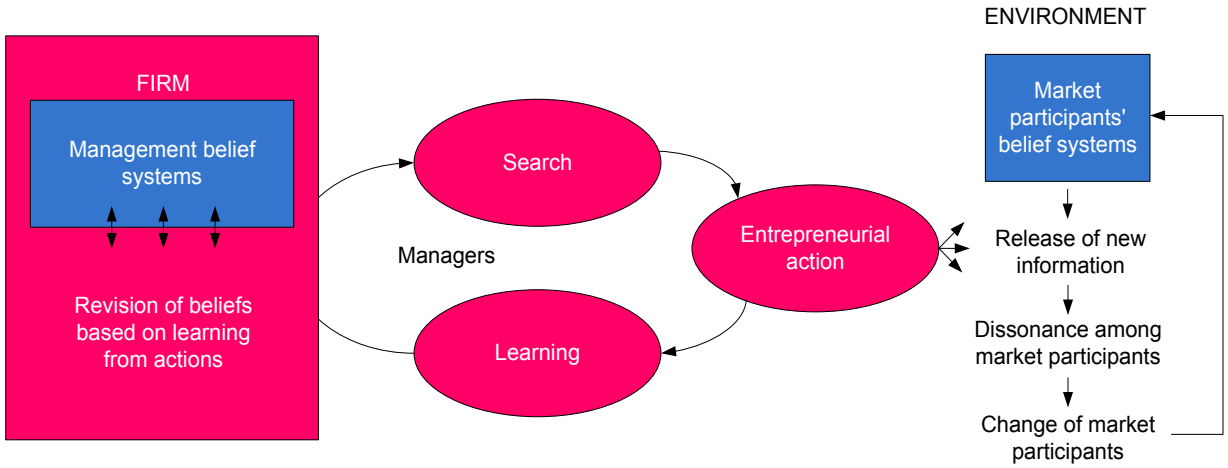

Figure 1: Entrepreneurial perspective on the firm-environment relationship (Smith & Cao, 2007)

Many studies have been conducted in order to analyze the complexity of these relationships. It is clear that in the first step environment imposes certain restrictions, but also provides certain opportunities for the individual enterprise. An important role is often played by the strategy that the company uses. Strategy can be seen as an integrative result of all the other aspects of the organization, so it needs to include internal aspects of the structure, procedures, people, culture, as well as all environmental processes (Jaško et al., 2013a).

Michael Porter notes that not all industries offer equal opportunities for the sustainable profitability, and not all organizations use equally the opportunities offered by the industries (Porter, 2008). He believes that enterprises through a selection of strategy clearly affect the improvement or worsening of their positions in the industry.

As a basis for the analysis of the environment, Porter suggests a structural analysis, which emphasizes five basic factors that describe the attractiveness of an industry:

1. Threat of New Entrants
2. Rivalry Among Existing Competitors
3. Bargaining Power of Buyers
4. Bargaining Power of Suppliers
5. Threat of Substitute Products or Services

The threat of new entrants in an industry is one of the key indicators of competitiveness. From the standpoint of individual enterprises, higher barriers for entry reduce the threat of new competition and ensure the position of existing companies. This means that the threat of new entrants depend on barriers to entry and the reactions of existing companies who expect this new company (Jaško et al., 2013b).

Rivalry among existing competitors involves various forms of price competition, the struggle for better promotion, bigger and better after-sales service, and includes a number of competitors that determine the degree of concentration, degree of product differentiation and barriers to entry.

Bargaining power of buyers means that the stronger buyer is in a better position to influence the reduction of prices, higher quality of products and services, and thus contribute to the achievement of profitability of the industry. Buyers are stronger and their impact on producers is higher in case where they are concentrated, when they have large individual purchases, when they possess a lot of information about products or services, when there are substitutes for the main product and when products or services are not differentiated.

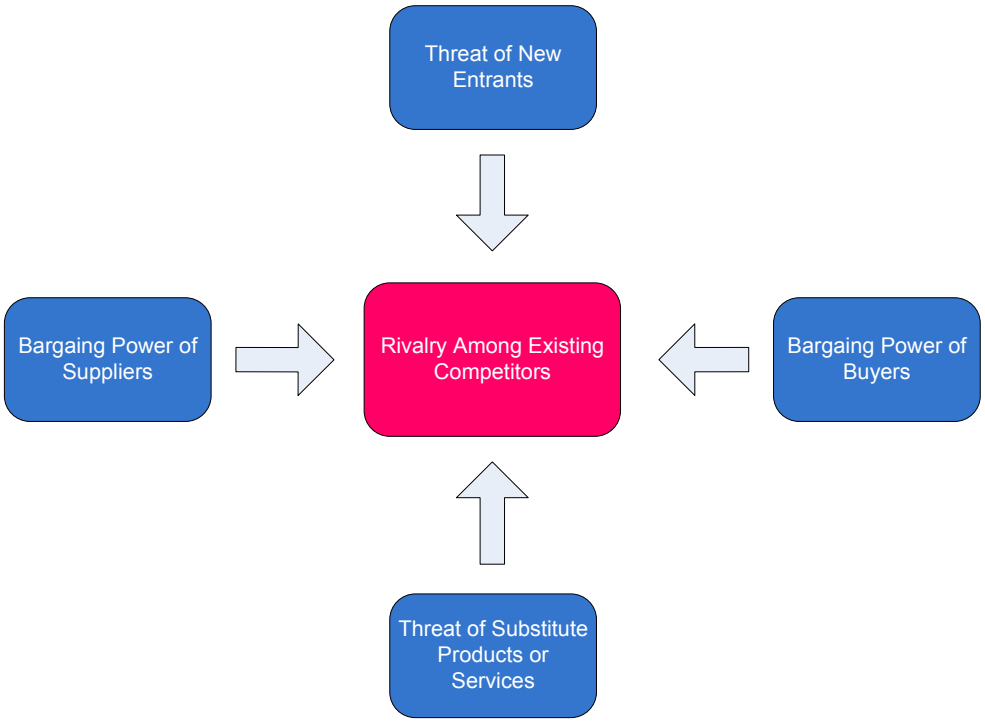

Figure 2: The five competitive forces that shape strategy (Porter, 2008)

Suppliers may also affect business results through the influence on the price, terms of sale, the quality and availability of the required raw materials. They are stronger and their bargaining power is greater in cases where there are no substitutes for the necessary inputs, when these inputs are important for the production of a specific product, when there are only a few suppliers of necessary inputs, when there are more buyers of its product, etc. Otherwise, the supplier is in a position to protect his only customer through reasonable prices and good quality.

The existence of substitute product significantly affects the demand for a particular product. Its sale is restricted in case where consumers can buy a similar product, the product of the same quality, or the product that has the same utility value. Danger of substitutes is higher when there is no exclusive consumer loyalty to the original product. An enterprise can minimize the risk of substitutes through good-differentiation of its products or if it achieves significant cost advantages over competitors (which will make the price of its products more attractive to the customer).

If Porter's considerations are observed through the prism of entrepreneurship, then we can come to conclusions that clearly show the importance of entrepreneurship in creating the image of the business environment. In fact, each of these factors significantly defines the entrepreneurial potential in a particular area or in a particular industry, but also depends on the existing entrepreneurial structure. Let us consider the example of manufacturers of certain components or semi-finished products. They are stronger if there are only few of them, so they have excellent position that allows them to dictate the terms of dealing with other business entities. On the other hand, manufacturers in the next phase of process want to acquire these necessary resources at better conditions. Accordingly, they are willing to somehow motivate entrepreneurs to start up businesses of common interest, in order to provide what they need at a lower price than the one that is already offered. The similar story is with the products substitutes. Often, it is practically impossible to obtain a specific product (component, semi-finished product) or the product is simply not acceptable from the point of the spending power of the local population. In this situation entrepreneurial spirit comes to the fore, and this is the chance for these producers that make a product that has similar characteristics and meet same needs, but is more accessible than "the original one".

However, the lack of entrepreneurial initiatives can scare potential foreign investors. Generally speaking, in developing countries production is significantly cheaper than in developed countries, and therefore the world's major companies often try to relocate at least part of their production in order to reduce their own costs. That way, through contracts with local companies, they switch production on potentially more profitable base. This trend is especially prevalent since the beginning of twenty-first century, in various industries. Besides the benefits for these companies, a chance is seen by the local governments, but also by the manufacturers or suppliers of parts and components that should be incorporated in the final products.

Global companies are counting on these local entrepreneurs, because they hope to get what they need at a lower price than it would have been if production is located somewhere else. Of course, the proper quality must be achieved, because these companies cannot afford to make final products of poor quality due to the lower cost, since it would affect their credibility, and that is the last thing they want to happen.

3. MODERN APPROACHES TO THE RELATIONS BETWEEN BUSINESS ENVIRONMENT AND ORGANIZATIONS

The importance of entrepreneurship in the contemporary business environment can be seen in different ways. One of the important concepts that follows the creation and development of new business is the *Population ecology theory*. This concept was created some forty years ago. Hannan and Freeman noted that during the observation of mutual influence and interaction with the environment it is much easier to group and classify organizations in certain categories (Grundstén, 2004). Those organizations are observed as organisms in the process of natural selection, and therefore special attention should be paid to the birth of the organizations, their growth and development, and death. Authors believe that the behaviour and results depend on several factors associated with a particular organization, and these factors are (Hannan & Freeman, 1993):

- niche width,
- inertia and change,
- density dependence,
- age dependence,
- resource partitioning.

Although this concept initially was not focused on entrepreneurial ventures, it is spotted its great applicability in this context over time. Accordingly, Aldrich believes that the theory of entrepreneurial behaviour should (Grundstén, 2004):

1. pay more attention to the capacities provided by the environment;
2. notice the importance of other organizations that are part of the environment that affects the new company;
3. consider interdependence of organizations;
4. take into account the sequence of events associated with organizational foundings;
5. pay special attention to the unique strategies used by companies that are specialized in different industries or populations in the early years of life;
6. work together in teams to build longitudinal community-based samples of organizational populations; and
7. develop comprehensive studies of entrepreneurial behaviour over time.

In the context of taking entrepreneurial action, the emphasis will be placed on the market niche that organizations occupy. Organizations are actually founded due to entrepreneurial initiatives, appearance or creation of new consumer needs, changes in market conditions, government regulations, but there is a great variation in their population. If the niche is relatively new, a number of organizations will collapse in the selection process, because they are not compatible with the environment. Those that survive will make a relatively stable population, with very similar characteristics. Once stabilized, this population will have a relatively stable structure due to internal and external constraints (Jaško et al., 2013a).

According to this theory, the organizations arise ("are born") and disappear ("die") depending on the density of the population in a particular niche. If the niche has a small number of organizations, it gives a strong impulse for entrepreneurial activity and the establishment of new organizations, and reduces the likelihood that the organization will go bankrupt. On the other hand, if the niche has too many organizations, high rivalry will increase the probability of organization bankruptcy, and reduce the attractiveness of the branches for the establishment of new organizations. Dynamics of organizational populations within a niche occurs in the manner that was presented on the previous picture.

The practical application of the population ecology theory is reflected in the observation of organizations considering them as specialists or generalists. Organizations generalists focus on a broad niche - they offer a wide range of products and services and meet the needs of many different groups in the market. Specialists focus on a smaller number of products and services, and meet needs of a small number of groups or even just a group of clients (who still numerically may include a large number of members). Depending on the ambition and the capacity of the entrepreneur, his new ventures will be directed precisely to one of these two categories.

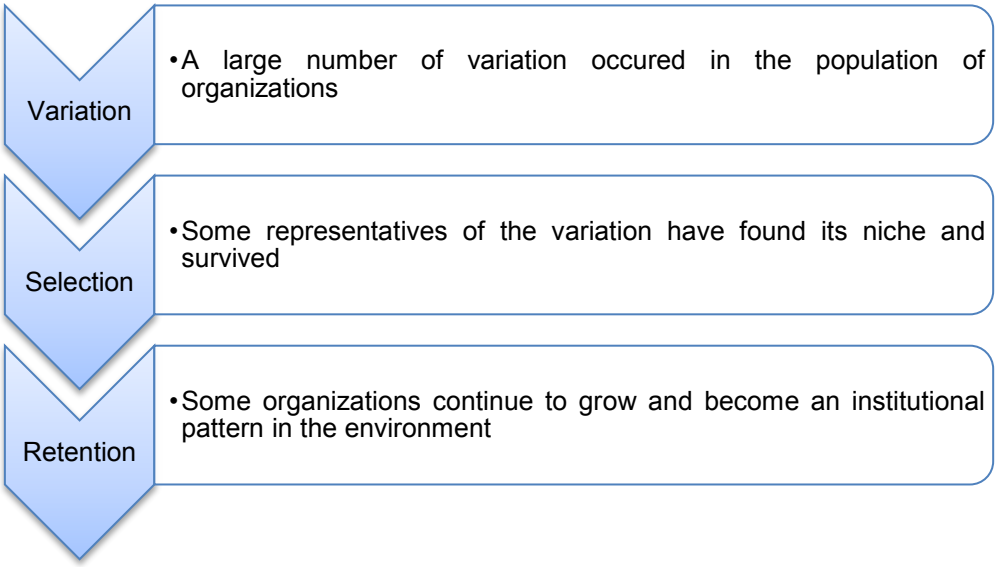

Figure 3: Dynamics of organizational forms in population ecology (Jaško et al., 2013a)

Certainly, one cannot say that one type is better or worse than the other - it depends on a number of factors, but it is possible to make some conclusions that are based on practice and logical judgment. Thus, specialists are generally more capable in business in the narrow area in which their operations coincide with companies generalists because they react faster, they are more flexible and better adapted to the specific conditions of these market segments. However, they are still more sensitive on changes in business environment because they do not have the sufficient size and business insurance in case that the environment negatively affects them. If specialists have problems in their performing, there is no some other activity that can compensate their efforts. On the other hand, generalists have a wider area in which they operate, which makes them some way protected from changes in the environment, and that reduces the risk of their existence. Demand in some areas may decline, but it is unlikely that the combined problems arise in all businesses, because these segments are substantially different. Specialists do not have that kind of security. In accordance with that, generalists can perform partitioning of resources. They can strategically allocate resources from one segment to another, and therefore provide more stable capital flows and cash flows compared to generalists.

If we look at the width of these niches, we can conclude that the broad niches are more appropriate for generalists, while narrow niches are more suited to companies specialists, because they better achieve their advantages in such environments respectively. Changes in niches also affect the chosen strategy of organizations. If the environment is stable, specialists have the advantage. However, if there is a change in the environment, the nature of that change should be considered. Rapid changes favour organizations generalists, since they have enough resources to survive and adapt to the new environment. On the other hand, changes which do not come up with major quakes favour specialists because they are generally faster and they better adapt to new conditions. Since these changes do not carry too much of quakes, they do not need any significant resources in order to survive.

Thus, the theory of population ecology is one new way to explain the organizational dynamics. Many phenomena, such as creation and deterioration of small organizations, structural similarity of organizations in similar environments, dynamics of disappearance and changes in organizations are explained by this approach. However, the disadvantage of this theory is that it looks at the environment as the only significant impact on the organization, ignoring the internal factors, and sees the choice of strategy with the positioning in organizational niches as the only factor of success, but that does not have fully justification in the environment. Therefore, it is advisable to take into account other relevant factors, or combine the theory with additional approaches.

Another concept that discusses this issue is the *Resource dependence theory*. According to this theory, as the name might suggest, organizations depend on the availability of certain resources, and as such, in many situations they need to interact with other market participants in order to provide them. In this way, they become dependent on the environment (Grundstén, 2004). The authors of this theory, Pfeffer and Salancik believe that it is necessary to focus on the interaction of the basic six dimensions, which are (Pfeffer & Salancik, 2003):

1. Concentration - the degree of dispersion of power and authority in the environment;

2. Munificence - the availability of critical resources;
3. Interconnectedness - the number and types of relations between the participating organizations;
4. Conflict - disagreement regarding the objectives:
5. Interdependence - the degree to which one organization influences the other;
6. Environmental uncertainty - the impossibility to predict future accurately.

These elements interact in a specific manner, which is presented by the next scheme:

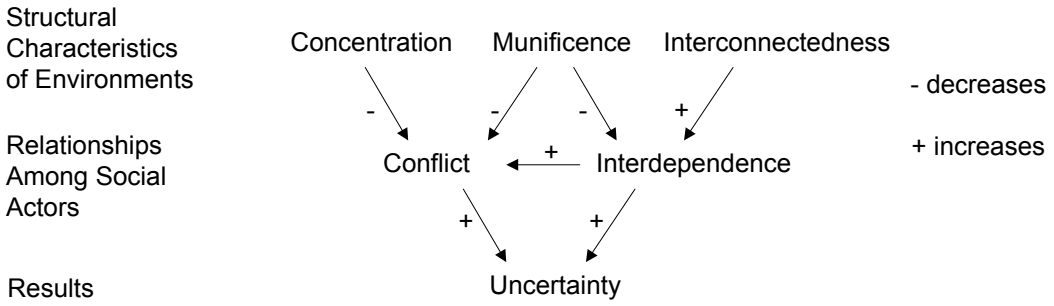

Figure 4: Relationships among dimensions of organizational environments (Grundstén, 2004)

Similar to the population ecology theory, it is possible to make conclusions concerning the relationship between environment and entrepreneurship. It is clear that the availability of resources has large positive impact on the establishment of new businesses, but it is not the only factor that should be taken into consideration. Since these relationships are extremely complex, it is necessary to observe all these elements in interaction in order to gain an objective picture of the potentials for taking entrepreneurial activities. These two theories still differ to some extent, mainly due to the fact that the population ecology theory holds that organizations are reactive and passive, and believes that they will survive if the environment allows them to, while according to the resource dependence theory, organizations are active, able to fight for their position every time the environment changes. These differences are presented in the following table:

Table 1: Two frameworks for entrepreneurial environments (Grundstén, 2004)

Population ecology theory	Resource dependence theory
Acts of the entrepreneur are predominantly deterministic.	Acts of the entrepreneur are primarily volitional.
The entrepreneur's choice are predicated and molded by the industry.	The entrepreneur makes strategic choices to secure the best transactions with the environment.
The environment is a set of influences which selectively permit some ventures to survive.	The environment is a pool of resources which the entrepreneur selects and acquires to establish his venture.
The entrepreneur is an exponent of environment and an instrument of economic development.	The entrepreneur masters fate and makes strategic choices to minimize threats and exploit opportunities.

Regardless the fact that these approaches observe organizations and entrepreneurs from different aspects, there is no doubt that both concepts have their foundation in practice, and that, as such, they have great significance. All authors who have considered this issue agree that there is a mutual causal relationship between organizations and environment, but that in each case the relation is specific and based on a number of factors. Therefore conclusions regarding this relationship can only generalize and represent a broader view of the problem that is a cornerstone, but cannot be precise guidance for behaviour in specific situations.

4. CONCLUSION

Although entrepreneurship is one of the bases of economic development and has undeniable role and importance throughout history, academic researches concerning this issue appeared in the last couple of decades. These researches warn that entrepreneurship is not something that can be planned to the end, and that the success of these efforts depends on many factors, both internal and external. The impacts of these factors manifest different on different markets, so many ventures failed although they had strong financial or technological support. The reason for failure often lies in the fact that these jobs are taken in inadequate business environment. Considerations of relevant authors who have studied this issue have confirmed that there are some environmental factors that simply encourage entrepreneurial activity. However, they believe that it is not possible to find a pattern of behaviour that will guarantee success. Many of them actually observe entrepreneurship as an art, due to the lack of such a pattern that would surely lead to success or avoid failure, at least.

Considering the specificity of entrepreneurial ventures and their dependence on the specific conditions and situations, each one of them should be considered separately in one particular context. Although the environment provides the potentials for success, it also imposes restrictions, so all these factors should be carefully considered and their interaction should be examined, in order to gain previously set goals. In accordance with that, special attention should be paid to the relationships with other participants, especially if they are big or strong, because they affect, directly or indirectly, the results of all these ventures.

The organization will focus on specific market segments and try to make success. In doing so, due to the dynamism and instability of the environment, it should be remembered that once established mode of behaviour is something that might be changed, since the organization must continuously follow possible changes in the environment. In accordance with that, given the fact that in most cases these changes come as a result of actions of other participants or the occurrence of certain objective circumstances, it is necessary to adapt them in order to make further development possible. That way, by changing themselves, organizations are also changing their business environment, in continuously repeated iterations. Some of them will be in a position to influence these changes more than others, and that will bring them a competitive advantage.

[3]SHARE Foundation-SHARE Defense, goran@sharedefense.org

Abstract: *The protection of personal data is an integral part of the basic human right of privacy. All data operators, including companies, need to comply with the principles of protection of personal data, in a line with positive legislation. This paper focuses on the importance of abiding by the rules on protection of personal data in the companies' operation in Serbia, especially in the business sector based on information technologies (hereinafter: IT). In addition to this, a presentation of the study on compliance of IT companies in Serbia with the regulations in the field personal data protection is given. The paper also points to the techniques through which the companies can synchronise their operation policies with the appropriate legislation.*

Key words*: Personal data, privacy, IT sector, e-commerce, internet, operators, legal framework*

1. INTRODUCTION

Personal data have become the new currency which is already used on the global market along with other goods. As shocking as this may be, the data shows that the value of personal data in 2011 was circa 315 billion Euros, with a potential growth to 1 trillion Euros until 2020 (Financial Times, 2013). Companies, among which most belong to the IT sector, because of the nature of their businesses often come in contact with personal data that they gather, process, exchange and intersect. This advantage of the IT companies entails a huge responsibility in regard to protection of personal data. Bearing in mind that protection of personal data is an aspect of the right of privacy, and an integral part of human rights in general, it is of vital importance to explore and determine which companies provide the necessary level of protection of personal data.

The first part of the paper is consisted of a review of the national and international legislation that deals with protection of personal data. In the second part, the focus is on the companies' obligations regarding the protection of human rights. In the third part there is a representation of the results of the research of the protection of personal data in 30 companies in Serbia. Finally, in the last part recommendations are given, so that companies can improve their operation in the field.

2. LEGAL FRAMEWORK FOR PROTECTION OF PERSONAL DATA IN THE NATIONAL AND INTERNATIONAL LEGISLATION

The Constitution of the Republic of Serbia ("Official Gazette of the Republic of Serbia" no. 98/2006, article 42, paragraph 2) states that the protection of personal data is regulated exclusively by a law. In this sense, a Law on personal data protection which comprehensively regulates the matter was adopted. However, as the technological development rapidly surpasses and easily bypasses the established regulations, there is already a necessity for amending the existing law in a way that it would prevent the possible violations of the right on protection of personal data.

The existing framework regulates the requirements for gathering and processing personal data, and obliges the companies which legally defined as data operators, that before processing any personal data they obtain consent from the person whose data is being processed, to inform them about the processing of the data and future changes. Basically, data operators are obliged to enable their customers to exercise their rights, to access, to a copy, to correct, modify, update or delete data (Law on personal data protection (hereinafter:LPDP), "Official Gazette of the Republic of Serbia", no. 97/2008, 104/2009 - other law, 68/2012 -,

article 3). Data operators are also obliged to report any collection of personal data to the Central register's database within the jurisdiction of the Commissioner for Data Protection (in further text: Commissioner) (LPDP, article 52)

The international legislation in this field has integrated the right of protection of personal data into the core of the basic human rights, as a segment of the right of privacy. The UN has adopted a resolution which deals with privacy and binds the member states to protect the privacy of their citizens against mass surveillance and data gathering (GAUN, 2013). In addition to this, Serbia also signed and ratified the Convention number 108 of the Council of Europe which defines the protection of people in regard to the automated personal data processing, and the additional Protocol of the Convention number 108 related to the monitoring institutions and cross border data flow. The Directive of the European Parliament and the Council of the EU 95/46/EC from 24.10.1995, deals with the protection of the citizens from the processing of personal data and freedom of movement of such data and obliges the member states to protect the basic human rights and freedoms of their citizens, emphasising their right of privacy in regard to the processing of personal data.

3. PROTECTION OF PERSONAL DATA FROM THE PERSPECTIVE OF THE BUSINESS SECTOR

The problem of personal data is multi - layered one because it's been noticed that individuals do not have a mechanism to protect their data from the continuous requests from the state organs to the companies that possess most of their users' data. To make thing worse, individuals cannot expect protection from the state organs because of the improper handling of their data by the companies. The reason for this being the lack of capacity and resources of the countries which are mandatory for effective control over the operation of the companies in this field. Additionally, the fact that the companies mostly operate in several different legal systems brings to collisions between the laws of several different instances.

Being aware of the reality, and with the aim to protect their own reputation and assure uninterrupted operation, companies have begun to adopt internal procedures for data protection, in the form of technical standards ISO 27001 and other that regulate some of the issues regarding retained and processed data (International Standardisation Organisation, 2005) as well as employing officials who would have only one specialisation i.e. providing higher level of personal data protection.

An example of good practise for establishing a "pact" between the consumers and the companies with the civil society organisations as mediators is the project titled Global Network Initiative (GNI, http://globalnetworkinitiative.org/). GNI seeks to implement a legal framework based on the internationally accepted standards that would ensure responsible operation within the IT sector, enable inclusion in the process of making self-regulatory rules and mutual exchange of ideas and experiences. This organisation has adopted the Principles for freedom of expression and privacy (GNI, 2008), Guidelines for implementation of the Principles (GNI, 2008). The members of this association in order to protect the data of their clients are taking active part in public debates on the reforms of the systems for surveillance that the states have.

4. METHODOLOGY OF RESEARCH ON THE LEVEL OF PERSONAL DATA PROTECTION BY IT BUSINESS SECTOR IN SERBIA

The first step of defining the research methodology of the IT business sector in Serbia compliance with the data protection legal framework was consisted of the process of selecting and determining a research target group with regard to the relevance in the field of data protection. In that sense, 30 IT companies were divided into three groups - cellular and landline operators, Internet providers and e-commerce companies, with 10 representatives from each group. After that, the predefined number of companies was selected. Each of them, because of the nature of their business, is in position to collect much personal data from their customers. Furthermore, in each group 5 of the companies were selected on the basis of market share significance, while other 5 were selected randomly.

In the next step, criteria that empowered the determination of the level of data protection were formed. Further explanation of the criteria will be given in the next chapter. The web pages of the selected companies were analysed with the goal to obtain relevant documents that contain answers for fulfilment of the mentioned criteria. In order to confirm the found answers, after the analyses of the obtained documents, questionnaires for the companies were prepared and distributed to all of the 30 companies with a request to provide the missing answers or verify the answers that were defined in the documents on their web sites. Qualitative legal analyses and intersection of the findings followed as well as a draft of the recommendations that could enable companies to improve their operation in regard to data protection.

It is important to notice, that this research did not deal with the question if the companies are operating in compliance with the developed criteria in practice, yet the research results are only based on the analysis of the available documents on the companies' web sites and based on the verification answers that were provided by the companies as well as on the insight to the online Central data file register that kept by the Commissioner. It should be noted that out of 30 companies only 3 replied to the questionnaires they were sent, therefore the results of the preliminary research are verified in accordance with their answers. The findings from the other companies are relying solely on the analyses of the companies' documents available online, precisely Terms of services, Privacy policies and Contracts that are companies closing with their clients.

The aim of this research, which is first of this kind in Serbia, was to indicate the activities of the in the IT sector in Serbia and provide recommendations that could improve this field of work. On the other hand, the data protection security level remained out of scope of the research, since the focus was on the analyses of the available legal documents which are enabling users to get to know the level of protection of their personal data.

5. EXPLANATION OF THE DEFINED CRITERIA - INDICATORS OF THE BUSINESS COMPLIANCE WITH THE DATA PROTECTION LEGAL FRAMEWORK

As already mentioned, the research methodology included the development of criteria i.e. indicators of the level of protection of personal data, after the legal analysis of the legal framework on data protection and based on the later. In that context, the criteria was modeled by a similar research that was conducted by the organization Electronic Frontier Foundation (EFF, https://www.eff.org/), were created. The criteria are based on whether each and every of the companies:

1. Requests a court order to access the personal data - state bodies can gain access to the personal data only on the grounds of a court order which is afterwards submitted to the companies that are obliged to act upon it. (Law on criminal procedure ("Official Gazette RS", 45/2013) - art.167. Law on Military security agency and Military intelligence agency ("Official Gazette RS", no. 17/2013)- art. 13a, Law on security-information agency ("Official Gazette RS", 111/2009), art. 13 and 14, Law on electronic communications ("Official Gazette RS", no. 60/2013 – Constitutional Court Decision), art. 126)

2. Informs the user about the request for access to personal data - the mentioned laws do not strictly bind companies to inform their user, but at the same time it is not forbidden. Therefore, companies that are protecting the privacy of their clients and their reputation should inform them about the request for access to personal data, if it is not in accordance with a court order (i.e. if the court order contains gag order).

3. Delivers the personal data when ceding the company's claim - companies are allowed to cede their claims together with the necessary personal data of their clients to third parties in accordance with the article 436 of the Law on contracts and torts ("Official Gazette of Serbia and Montenegro" no. 1/2003 – Constitutional Charter). This means that a third party that is not included in the contract can gain access to the personal data. According to the law, the client's consent for ceding the claim is not required, but must be notified.

4. Notifies the clients about data processing - pursuant to the article 15, par. 1, line 1-8 of LPDP, companies are bound to publish a Notification letter about the processing of personal data. This Notification letter must contain the following: primary information about the company, purpose of data processing (e.g. register of users, number of post-paid users), the manner in which data will be used (e.g. to inform users about new services), the identity or categories of persons who will use the data (e.g. only employees in the sector of date security) then the voluntary nature of data provision and processing and legal grounds (e.g. only on the basis of voluntary given consent) including the data subject's rights: to access, to a copy, to correct, modify, update or delete data, as well as to a stay and suspension of processing. Also, companies should notify the client about other circumstances the withholding of which from a data subject or a third party would be contrary to conscientious treatment.

5. Notifies the user of any modifications of Notification of data processing - if in any moment the company decides to modify the Notification of data processing, the company is bound to provide the user with a notification of such a modification. It is not in accordance with the Law on data protection to request from the users to inform themselves on these modifications by visiting the official website of the company (LPDP, art.15, par.6)

6. Publishes the internal acts on Privacy policy and data protection - this criteria reflects on the practice of drafting and publishing internal acts on Privacy policy and data protection that define in a comprehensive way the following issues: types of data that the company collects and for what purpose, notification of data processing and modifications of Privacy policy, means of data protection, information on ceding of claims and personal data, including the implemented procedure in regard to the request of state bodies for the access to personal data etc. This is not defined by Law, but presents good practice that should be accepted.

7. Keeps a database in the Central register in jurisdiction of the Commissioner - when collecting and processing personal data, companies are obliged to register their data sets in the Central registry according to article 52 of LPDP.

5.1. Defining the target research group - operators, internet providers (ISP), e-commerce companies

An operator is a legal entity that conducts or is authorized to conduct activities of electronic communications (Law on electronic communications, article 4, par.2). The research embraced the 5 largest and most well-known operators (Telekom Srbija, Telenor, VIP Mobile, Orion Telekom i SBB) as well as 5 companies selected randomly (Ikom, Radijus Vektor, Kopernikus, Targo Telekom i Katel Network).

Internet service providers are defined as entities that offer access to the Internet with no regard to whether it is ADSL, Dial-up, cable, etc. The selection of Internet providers was conducted based on their media and public presence (Beotelnet, Veratnet, EUnet, Beonet, Pošta net), while other 5 were selected randomly (SRBnet, Teledot, Netpro, Bluenet, Tippnet).

.

The Law on electronic commerce ("Official Gazette of the Republic of Serbia", no. 95/2013) defines that commerce of goods and services online is a form of remote commerce in sense of the law that regulates commerce (article 4, par.2). According to the data of the company "Limundo" around 900 000 people shopped online in 2013. In this research, the 10 e - commerce companies were divided in two groups: the first group is comprised of companies that mediate in the trade (Limundo, Kupujem prodajem, Kupi me, Popusti), in the second group are the companies that participate actively in the e-commerce i.e. online shops (Hoću to, Planeta shop, Tehnomanija, Tako lako, Knjižara Vulkan, Non stop shop).

6. PROTECTION OF PERSONAL DATA IN IT BUSINESS SECTOR IN SERBIA RESEARCH RESULTS

It is noteworthy that 9 out of 30 companies did not pass any of the criteria: Ikom, Radijus Vektor, Kopernikus, Katel Network (operators); SRB Net, Teledot, Beotelnet, Bluenet, Netpro (ISP).

Regarding the first criteria, i.e. requesting a court order to access users' data, 10 companies in total allow access to their users' data only with a valid court order, i.e. 4 out of 10 operators (Telekom Serbia, Telenor, Orion Telekom, Targo Telekom), as well as 6 out of 10 e-commerce companies (Limundo, Kupujem Prodajem, Kupi Me, Popusti, Hoću To, Knjižara Vulkan). Not a single of the Internet providers that were part of this research requests a court order for accessing data.

In regards to the second criteria, informing users about the court order, bearing in mind that giving this information is not a legal obligation, none of the operators inform their users, neither do 9 ISP's, or e-commerce companies. Only Verat Net (Internet provider) and Limundo (e-commerce) contact their users when there is a court order for accessing their data.

The analysis of the practice of companies in which they cede their claim (that is user's debt) to third parties, the results show that 4 operators (Telenor, VIP Mobile, Orion Telekom, Targo Telekom) deal with this problematic, and this information are provided as part of the Terms of Service, which are an integral part of the user contract. None of the e-commerce companies deal with ceding, which is probably because 5 out of 10 e-commerce companies in this research, merely meditate in the sales, which implies that buyers, don't have any direct debt towards them. Three ISP's explicitly stated that they do not act in such a manner, precisely, they don't cede their claims to third parties (Tipp Net, Verat Net, EU Net).

The Notifications of data processing that were analysed as part of the fourth criterion are publicly available on the websites of 4 operators (Telenor, VIP Mobile, Orion Telekom, Targo Telekom) and only 2 ISP's (Pošta Net and Verat Net), even though that is required by law. All of the 10 e-commerce companies have publicly available Notifications on their web pages.

The Notification for data processing, which is also required by LPDP, is only actively practised by 3 operators, but their Terms of Services, which include the Notification of data processing, provide that the users shall be notified by the "authorised dealer and the official website". Only two ISP's (Pošta Net and Verat Net) act in accordance with the law, except for Pošta Net, which acts like the operators do, while only Verat Net regulates this matter in their Privacy Policy, but they also publish the changes on their website. Article 15 of the LPDP explicitly states that companies must personally notify their users about data

processing, as well as about the modifications of the Notification. Only 3 e-commerce companies act in such a way (Limundo, Planeta shop and Tehnomanija), while Nonstop Shop, Popusti and Kupi Me notify their users about the changes through their official websites.

Table 1: Protection of personal data in IT business sector in Serbia research results

Operators	Telekom Srbija	Telenor	VIP Mobile	Orion Telekom	SBB	Ikom	Radijus Vektor	Kopernikus	Targo Telekom	Katel Network
Request court order for the access to personal data	Yes	Yes		Yes					Yes	
Inform users about requests for access	No	No								
Cede claims to third parties	No	Yes	Yes	Yes					Yes	
Notify users of data processing	No	Yes	Yes	Yes					Yes	
Inform users of the modifications of the Notification of data processing	No	Yes	Yes	Yes						
Have internal privacy policies	No	Yes		No					Yes	
Registered database in the Central Registry	Yes	Yes	Yes	Yes	Yes	No	No	No	Yes	No
ISP	Pošta Net	BeoNet	TippNet	SRBNet	Teledot	VeratNet	BeotelNet	BlueNet	EUnet	Netpro
Request court order for access to personal data										
Inform users about requests for access						Yes				
Cede claims to third parties			No			No			No	
Notify users of data processing	Yes					Yes				
Inform users of the modifications of the Notification of data processing	Yes	Yes				Yes				
Have internal privacy policies	Yes	Yes				Yes				
Registered database in the Central Registry	No	No	No	No	No	No	No	No	Yes	No
E-Commerce	Limundo	Kupujem prodajem	Kupime	Popusti	Non stop shop	Tako lako	Hoću to	Planeta shop	Tehnomanija	Knjižara Vulkan
Request court order for access to personal data	Yes	Yes	Yes	Yes			Yes			Yes
Inform users about requests for access	Yes									
Cede claims to third parties										
Notify users of data processing	Yes	Yes	Yes	Yes	Yes		Yes	Yes	Yes	Yes
Inform users of the modifications to the Notification of data processing	Yes		Yes	Yes	Yes			Yes	Yes	
Have Internal privacy policy	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No	Yes
Have a registered database in the Central Registry	Yes	No	Yes	No	No	No	No	No	No	No

When it comes to adopting and publishing internal Privacy policy acts that would comprehensively regulate the companies operations in the field of users' privacy protection, only 2 operators (Telenor and Targo

Telekom) operate in accordance with this good practice, as well as 2 ISPs (Beonet and Verat Net). Unlike them, only Tehnomanija hasn't yet published such an act, while all the other e-commerce companies have it (Limundo, Kupujem prodajem, Kupi me, Popusti, Nonstop shop, Tako lako, Hoću to, Planeta shop i Knjižara Vulkan).

With respect to the practice of registering the database in the Central Register of the Commissioner, which is defined in the seventh criterion, 6 operators have registered databases (Telekom Serbia, Telenor, VIP, Orion Telekom, SBB and Targo Telekom), and only one Internet provider (EU Net). At the same time, only 2 e-commerce companies have registered databases (Limundo and Kupi Me). In this way companies commit misdemeanour (Law on personal data protection, Article 57, Paragraph 1, Line 13) and can be fined.

7. CROSS EXAMINED RESULTS AND ANALYSIS

Based on the analysis of the published documents it can be concluded that none of the Internet providers request a court order for the access to personal data, nor do half of the operators. Furthermore, the provider EU Net clearly stated in its Terms of Services that: "...the Provider has a right to provide User's data and his misconduct to interested parties." (EUnet, 2011). Unlike operators and Internet providers, most e-commerce companies demand a court order for the access of personal data of users.

Telekom Serbia didn't have a publicly available answer to any of the developed criteria in our research. However, after we sent them questionnaire, the company replied that is has implemented the ISO 27001 standard and in that way has provided a high level of personal data protection security, adopting certain internal acts which regulate the procedures for data management. Notwithstanding this, after analysing these acts (General policy for data management security, IT security and protection for employees policy) an explicit Notification of data processing and its data modification was not found, but it's clearly stated that data is provided only with a court order. In any case, when adopting the ISO standard companies give a clear signal that personal data is, from a technical point of view, well protected.

As it has been previously stated, companies in most cases do not inform users on governmental requests to access data. However, Verat Net and Limundo do inform users about requests, with the exception that Verat Net doesn't have explicitly stated that it requests a court order to enable access to the state bodies to the personal data, which is surprising. Verat Net is the only Internet provider that has a positive answer on all other criteria and, as such, represents a good example which should be followed by other companies.

When it comes to the Notification on data processing, the content of this Notification is defined by law, and not complying with the law is financially punishable (LPDP, art. 57, par. 1, line 4). Regardless of this obligation, Internet providers do not consider that it is necessary to make this Notification available to users, so 8 providers do not have any Notification, and neither do 6 of the operators. However, the situation is different when it comes to e-commerce companies, which all but one sends the Notification whose content is fully in compliance with the aforementioned law.

A modification of the Notification of data processing is also regulated by LPDP, and it obliges companies that they inform the users about every modification personally. Out of all of the analyzed companies, only 3 (Limundo, Planeta shop and Tehnomanija) act in such a manner that they inform their users personally, while others do so through their website. Most users do not visit the official website of their operators and providers, so there is little chance that they will acquaint themselves with the modifications. Furthermore, most operators and Internet providers do not have a clear stipulation on the modifications of the Notification of data processing, but do so through the Terms of Services which include the Notification of data processing. As an example of good practice in this field we can name the company Limundo, which sends an e-mail of notification to all registered users with every modification of the Notification of data processing and publishes the new version on its webpage at least 8 days before it takes effect.

It is encouraging that almost all e-commerce companies that were a part of this research, have internal acts on privacy and personal data protection. This practice should be followed by operators and ISPs, which in most cases do not have any internal documents in regard to data collection and data processing. It is especially troubling that some of the more successful companies in this field, such as SBB and Ikom, do not have publicly available documents that regulate the matters of data collection and personal data protection of their users.

One of the interesting results of the research refers to the ceding of data to third parties in order to collect claims. Telenor, Orion Telekom, Targo Telekom and VIP Mobile envisage the possibility of ceding data to

third parties in order to collect claims. However, what concerns the most is the fact that terms that provide for such a possibility are not linked to relevant articles of the law, which oblige companies to notify users on every ceding, but that, solely by signing the contract, the users consent to the ceding of claims to third parties, and at the same time to the ceding of their personal data. Two companies do not envisage such a possibility, namely TippNet and EUnet.

This research has shown that e-commerce companies take the importance of personal data protection of users much more seriously and that 9 out of 10 issue a Notification of data processing and an published Internal privacy policy. Unfortunately, the situation is dramatically different when it comes to operators and Internet providers, who have only published Terms of Services on their websites, which in most cases does not include a Notification on data processing and a Procedure for acting in regard to requests for access to personal data. The aforementioned Terms of Service are mostly aimed at regulating the terms under which service is provided, as well as the users' obligations, and only touch upon data protection.

8. RECOMMENDATIONS FOR THE IMPROVEMENT OF THE PROTECTION OF PERSONAL DATA IN IT BUSINESS SECTOR IN SERBIA

Furthermore, on the basis of the research results, recommendations for the improvement of compliance of the companies from the IT sector with the data protection regulations will be presented. These recommendations are not directed only to the companies that were part of this research, but to the entire IT industry and those who are interested to conduct their business in this field.

First of all, companies should get acquainted with the legal framework of the Republic of Serbia, primarily the Law on personal data protection, but also the Law on electronic communications (article 126), the Law on criminal procedures (article 167), the Law on the security-information agency (article 13-14), as well as the Law on the military security agency and military intelligence agency (article 13a), that are all explicitly defining that in order to enforce any measures that tackle personal data, it is indispensable for the state bodies to obtain a court order. Therefore, only companies that are respecting these regulations and procedures can be seen as ones that plead for the privacy protection of their users, and consequently they can expect trust and loyalty of their users.

In case the court order does not contain a gag order, companies should inform user on that order. This practice was implemented only by Limundo (e-commerce company) and Verat net (Internet provider) since these companies already understand the advantage of the relationship of the mutual confidence can bring to the market.

Regarding the ceding of their claims, companies should inform their users in each case, while consent of the user is not mandatory in accordance with the article 436 of Law on contracts and torts. Based on the analysis of the available documents of the companies, this matter can be improved by sending notification to each user when his/her claim, together with their personal data, was ceded.

In order to have a legal basis to collect and process data, which is the precondition for conducting their primary activity of offering IT services, which cannot be imagined without proceeding of personal data, companies are bound to publish easily understandable and accessible Notifications of processing of the personal data, which was omitted by 17 companies included in the research. The fundament of data protection is the existence of consent for the processing and the Notification of processing of data that are both fully defined by the Law on personal data protection (article 19). Therefore, the essential recommendations for all companies is to publish online the Notification of the processing in compliance with the aforementioned Law, in shortest time possible, following the good practices of companies that were already mentioned.

Equally important is to personally inform each user on the modifications of the Notification of the processing that is also regulated by the LPDP. Only two out of 30 companies act in this manner, which clearly demonstrates ignorance of the companies. Moreover, this also indicates that our IT business sector has not yet acknowledged the advantages of relationship tailored to each user's needs. Also, it is important to build a two-way communication with the user and this presents a good possibility to do so.

Internal privacy policy documents that are publicly available present a good and easy way to inform users on companies conduct under all criteria that were developed for the purpose of this research. Largest segment of the companies that were included in the research (17) did not make this document publicly available, making it more complicated for the users to get acquainted with the data protection procedures while at the

same time often regulating these sensitive issues of data protection through unreadable and unclear Terms of service.

Bearing in mind that state bodies lack the internal capacity to fully control companies in this field, companies from the IT sector could adopt guidelines for conducting operations in this area through the process of collaboration and joint investments, following the global initiatives such as GNI, and in this manner ensure security in conducting business, and at the same time simplify the work of state bodies.

The fact that the users in Serbia will sooner or later realize that their personal data and privacy are important, as was the case in other countries, and that it is not all the same if one or the other operator provides them services and has direct control over their data. This also represents the possibility for smaller companies to prove that they care about privacy and that privacy of their users is an important market value and advantage in comparison to other “players”, as well as that they need to use these advantages.

The new EU Draft Regulation on data protection (European Union, 2013) provides higher penalties for misdemeanour- up to 2 percent of the annual global profit of the company. Since Serbia is a candidate for joining the EU, during the process of accession it will need to improve the standards on data protection to comply with this Regulation, which will also pertain to companies. What this means is that, companies, on their own or under the pressure of sanctions, will need to improve their business in this area, and in return will be able to expect more clients and higher profit.

PERFORMANCE MANAGEMENT

PERFORMANCE MANAGEMENT METHODOLOGY: INTEGRATIVE APPROACH

Tijana Obradović[1], Veljko Dmitrović[2], Milica Latinović[3]
[1]Faculty of Organizational Sciences, tijana@fon.rs
[2]Faculty of Organizational Sciences, dmitrovicv@fon.rs
[3]Faculty of Organizational Sciences, latinovicm@fon.rs

Abstract: *Performance management is not a new methodology. In fact, there is no unique performance management methodology. It is an integrated concept comprised of many separated methodologies. Those individual methodologies should and must be integrated, linked and applied together, since this is the only way they can achieve its own full performance. More importantly, their integration and enhancement achieved through the performance management methodology provides the synergy that creates superior business performance as a whole. This paper will present the most important methodologies that represent an integral part of performance management methodology.*

Keywords*: performance management, methodology, performance indicators*

1. INTRODUCTION

There is no unique performance management methodology: performance management goes through the whole process of managerial planning, executing and control. Performance management is not new methodology; it is approach that tightly integrates business improvements and analytical methodologies already known to management and employees. It involves methodologies, metrics, processes, software tools and systems that manage the performance of an organization as a whole. Performance management can be seen as an umbrella concept that integrates business and financial information into unique support framework for planning and decision-making. It includes strategic mapping, balanced scorecard, managerial accounting, customer chain value, cost management, budgeting, forecasting and planning. These methodologies inspire other key solutions, such as supply chains management, risk management, human resources system management, lean management and six sigma (Cokins, 2009).

Performance management integrates methodologies and their support systems in order to provide synergy that would not exist if they would be implemented isolated one from another (Cokins, 2009). It is holistic model in which all parts must be combined and connected in order to realize organizational strategy in a sensible and coherent way (Hope & Player, 2012). The more those methodologies are integrated, unified and enriched with all kind of analyses, the more powerful performance management will be. Integrated methodologies, combined with analytics, represent a key for completing full vision of performance management framework (Cokins, 2009).

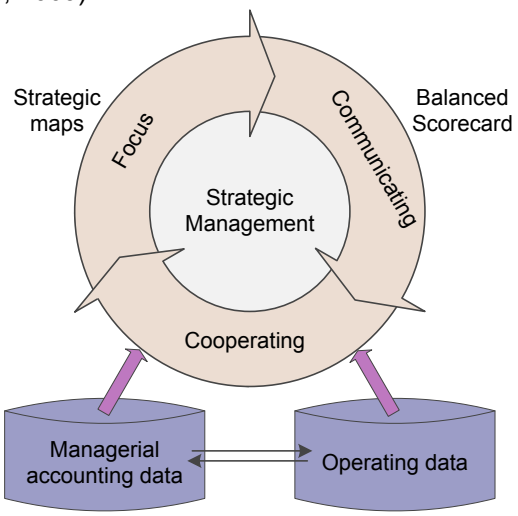

Figure 1. Performance management integrative cycle (Cokins, 2004)

The implementation of performance management is tightly connected with these managerial approaches (Hagos & Pal, 2010): Sigma Strategy, Balanced Scorecard, Activity Based Costing, Total Quality

Management, Economic Value Added (Economic Profit), Integrated Strategic Measurement, Theory of Constrains. Figure 2. illustrates independent methodologies that make performance management.

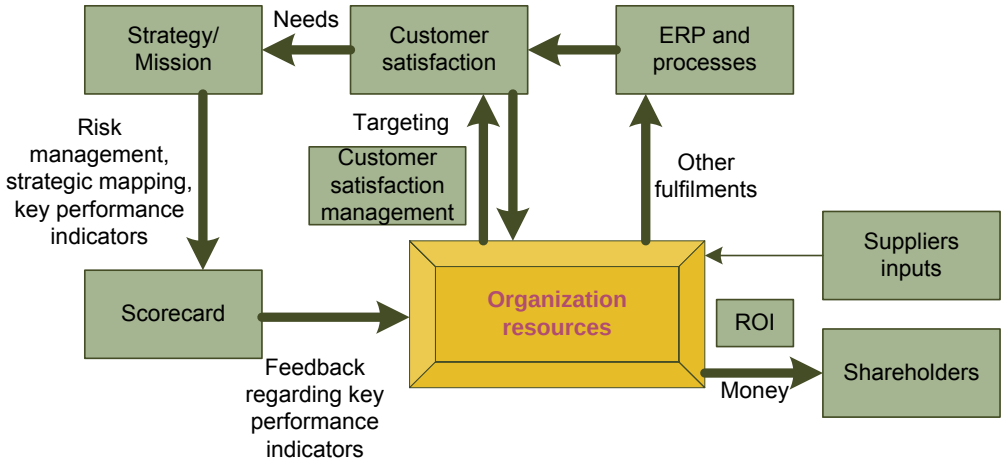

Figure 2. Linked performance management methodologies (Cokins, 2009)

Many performance management components exists for decades now, while some of them are only recently became popular. Some of these components are already partially or completely implemented in many organizations, while performance management is simply enriches them in order to be more harmonized with other components (Cokins, 2004).

2. KEY PERFORMANCE INDICATORS

Key performance indicators are key management instruments used by managers in order to understand if their organization is seeking in the right direction or is turning from the road of company progress (Marr, 2012). Key performance indicators represent results or outcomes identified as key for archiving high performance and they provide baseline for goals setting and performance measurement (Armstrong, 2009). They measure things that are of strategic importance for organization, therefore it is necessary to define strategy first and afterwards to define and link indicator to it. Key performance indicator is indicator that is really meaningful, since everything and anything can be measured. If all indicators are considered to be the key ones, than none of them will standout and get the attention it deserves (Schiff, 2008). The proper set of indicators will put the light on the performances and emphasize areas that need special attention (Marr, 2012). The number of key performance indicators depends on the type of organization, but usually organizations have six to twelve key indicators and potentially dozen others that support the key ones (Armstrong, 2009).

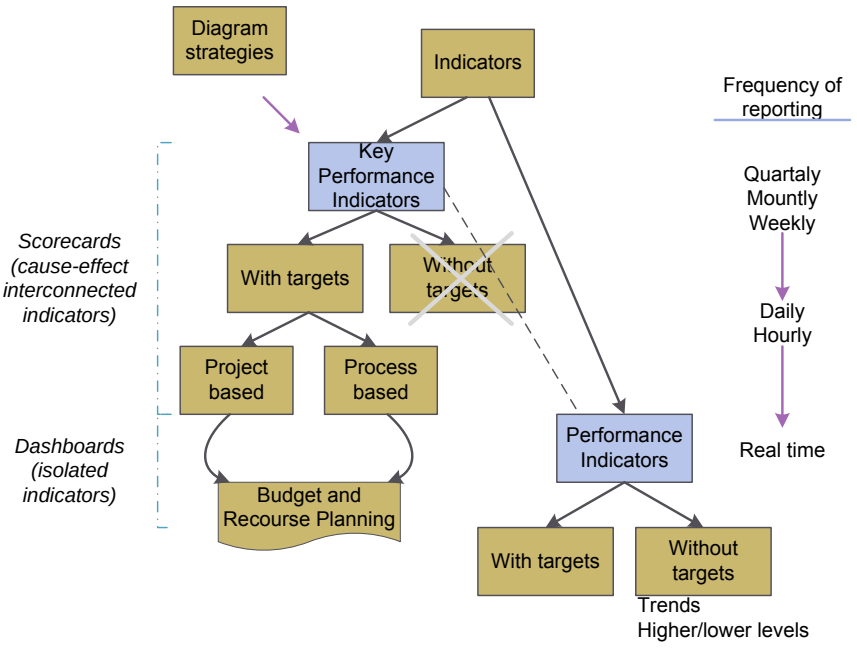

Figure 3. Key performance indicators, scorecards and dashboards (Cokins, 2009)

Sets of key performance indicators are presented on the scorecards, which report on organizational performances (Armstrong, 2009). When putting performances of scorecards, one should not be carried away

in trying to include as many indicators as possible. Unwritten rule is that it is often enough to have six to ten key performance indicators (Dagan, 2007). Integrated key performance indicator framework is shown on Figure 3. Performance frameworks, dashboards or scorecards are often in use for grouping key performance indicators into displays or reports so they can represent immediate insight into business performance (Marr, 2012).

It is important that key performance indicators provide information and answer about what company needs to know, therefore it is necessary to determine information needed and questions that need to be answered, first. Marr (2012) developed key performance questions (KPQs), where key performance question precisely says exactly what manager needs to know. In that way key performance questions represents guide for selection of meaningful indicators (Marr, 2012).

3. BALANCED SCORECARD

Balanced scorecard is widely accepted performance management methodology, and many companies use it for measuring their performances (Hagos & Pal, 2010). Balanced scorecard basically uses integral performance management in order to follow and adjust business strategy (ten Have, ten Have, & Stevens, 2003). The managers often use it for goal clarification, monitoring and structuring mechanisms for initiating interventions. These are the same steps that performance management applies, which results in using balanced scorecard as a basis for performance management activities in organization (Hagos & Pal, 2010).

Traditionally, dashboards seek to focus solely on financial performance indicators (Armstrong, 2009), while the inclusion of nonfinancial information into financial ones is become known as a balanced scorecard (Avis, 2009). The goal of balanced scorecard was to battle the tendency of focusing to short-term financial reports only, because business success needs balanced usage of financial and operational indicators (Kaplan & Norton, 1992) (Kaplan & Norton, 1996).

Organizations are trying to find a ways for observing performance indicator from the perspective of business as a whole, since they must be able to measure financial as well as nonfinancial performances (Hagos & Pal, 2010). Understanding the connection between short-term work of employer with the long-term organizational goals is a key for successful performance management. Balanced scorecard transforms the vision of an organization into understandable goals on every organizational level (Jones, 1999). Balanced scorecard is the way to present former, present and future goals with the easily understandable set of performance indicators (Horngren, Sundem, Stratton, Burgstahler, & Schatzberg, 2008). Balanced scorecard was developed to measure performance toward organizational goals, serving as an indicator of the overall organizational efficiency (Hagos & Pal, 2010).

Kaplan and Norton believe that balanced scorecard approach focuses attention on the vision and strategy, rather than control (Kaplan & Norton, 1992). They imply that this approach can help in harmonization of individual performances with overall strategy, since it motivates people to engage themselves in communication and education, goals setting process and links rewards with performance indicators (Kaplan & Norton, 1996). The original Kaplan and Norton concept asks managers to answer four basic questions, which means observing four connected perspectives (Kaplan & Norton, 1996). Beside usual financial perspective, balanced scorecard motivates managers to incorporate customer's perspective, operations and organizational innovation and learning capabilities (ten Have, ten Have, & Stevens, 2003).

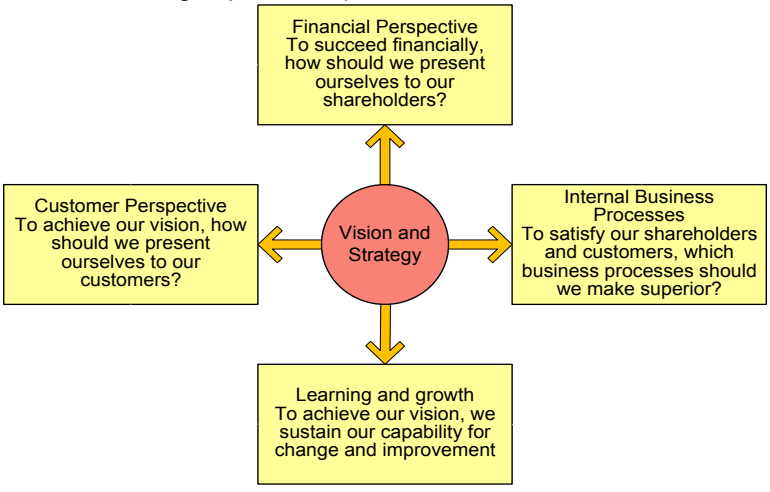

Figure 4. Four perspectives of vision and strategy conversion (Kaplan & Norton, 1996)

Balanced scorecard provides answer to four main questions (ten Have, ten Have, & Stevens, 2003):

- What is important for company shareholders?
- How do customers perceive company?
- Which internal processes can add value?
- Is company innovative and ready for the future?

The balance is a key word. Each area is equally important and each should have no more than four to five indicators. These indicators should reflect the organizational culture. (Jones, 1999). Basically, balanced scorecard is a selection of adequate indicators; if key performance indicators are wrong, than behavior, priorities and employers decisions will not be harmonized with the vision and the strategy of the organization (Cokins, 2009). Balanced scorecard indicators depend on the nature of the company (ten Have, ten Have, & Stevens, 2003). They must not be just a tool for control of behavior and evaluation of past performances, but should be the basis for management system that communicate the strategy, harmonize individuals and teams with the strategy, set long-term strategic goals, allocate short-term and long-term resources and provide feedback and learning about strategy (Armstrong, 2009).

Balanced scorecard methodology, developed by Kaplan and Norton (1996), recognized faults of focusing on short-term financial results. It improves organizational performances by moving attention from financial indicator toward nonfinancial business indicators that reflect customers, internal processes, innovation, learning and growth (Cokins, 2009). And, in return, these indicators lead to better financial results. Balanced scorecard provides insight into aggregate financial consequences of nonfinancial indicators (ten Have, ten Have, & Stevens, 2003).

It is important to stress than none individual methodology, including balanced scorecard cannot achieve results if it is not integrated with other performance management methodologies. Implementation of balanced scorecard often does not succeed in providing projected benefits purely because it is not integrated with performance management processes, especially with those used on operational level (Cokins, 2004). It is believed that 80 % of companies than do not integrate balanced scorecard with performance management methods and tools will give up on it and go back to less organized and less effective set of metrics (Leahy, 2003).

4. STRATEGIC MAPS

Strategic maps in a term of strategy are often compared to financial analysis: in the same way that financial analysis explains company's financial health, the strategic maps explain strategic health of a company. Strategic maps represent a tool that help in defining strategy and facilitate keeping organization on the right track by altering and modifying strategy if it is necessary to change that track (Cokins, 2004).

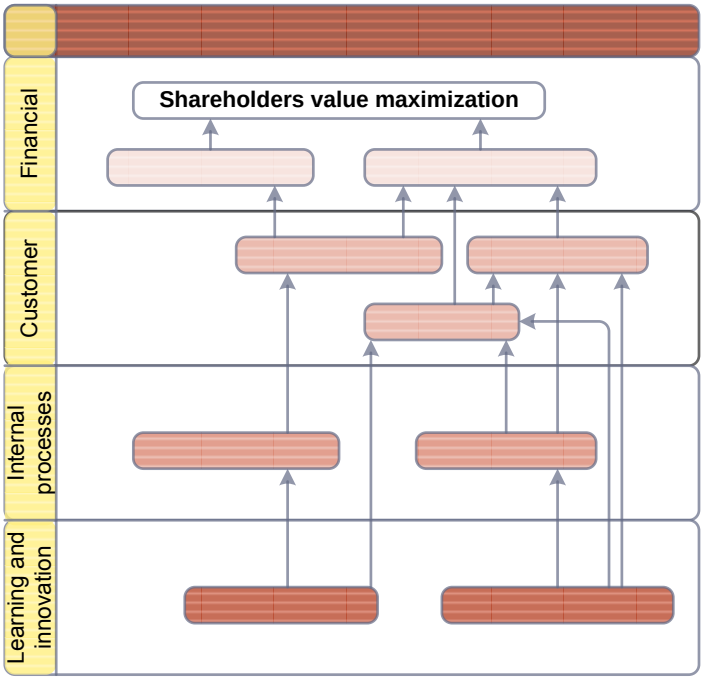

Figure 5. Generic strategic map (Cokins, 2009)

Strategic maps are actually diagrams that show logic of the way that organizations interact in creation of overall performance (Bourne, Franco, & Wilkes, 2003). These maps show connection between cause and effect by which certain improvements create desired results. They are means for description of the elements of organizational system and connections between them. In that way they become guide mark for system improvements that leads to performance improvements. Furthermore, strategic maps provide employers with clear connection between their work and overall goal and give visual insight into critical goals of organization and their relations that run organizational performances (Armstrong, 2009).

5. DASHBOARDS

Dashboards are graphical presentations designed to transfer key performance indicators from intranet systems of organization to a broader audience so that they can assimilate with them and act accordingly simply and quickly (Armstrong, 2009).

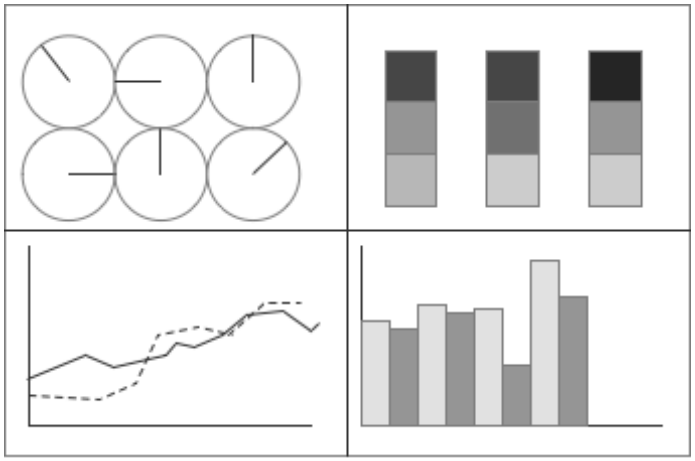

Figure 6. Examples of charts on the dashboards (Armstrong, 2009)

Dashboards can be described as “delivery vehicles” (Dover, 2004), since they make performance information available when it is needed, where it is needed (Armstrong, 2009).

Dashboards enable fast and convenient way for monitoring progress by referencing to an adequate indicator, enabling fast corrective action if it is needed (Dagan, 2007). They can be complemented by drawings, traffic lights, charts and tables, but they should not be overcrowded and in that way hide important indicators (Armstrong, 2009).

6. ACTIVITY BASED COSTING

Performance management is considerably supported with richer information provided by ABC – Activity Based Costing (Cokins, 2004). Traditional costing models allocate indirect costs according to the volume. As a result, product costs with high volume become overvalued, while products with low volume become undervalued. On the contrary, activity based costing calculates real costs of products, customers or services by adding indirect costs according to the activity performed instead of volume (ten Have, ten Have, & Stevens, 2003).

Activity based costing is not solely accounting system. Also, it is much more than accounting management information system. It shifts managerial accounting into managerial economics and represents change management tool. It is socio-technique tool and its main value is irrefutable information based on facts that can be used by employees and managers in order to build business situations and quickly recognize business opportunities and challenges (Cokins, 2004).

The principles of activity based costing must not be applied only to products, but to different distribution channels and customers. The goal is to apply direct cost to any consumer recourse. As for shared recourses, they should be tracked by using measurable drivers that reflects consumption rate instead of arbitrary cost allocation (Cokins, 2009). The starting point for activity based costing is that activities cause costs, not the products or consumers. As different products need different activities, while each of them uses different recourses in different amounts, the cost allocation must be pondered in accordance with that (ten Have, ten Have, & Stevens, 2003).

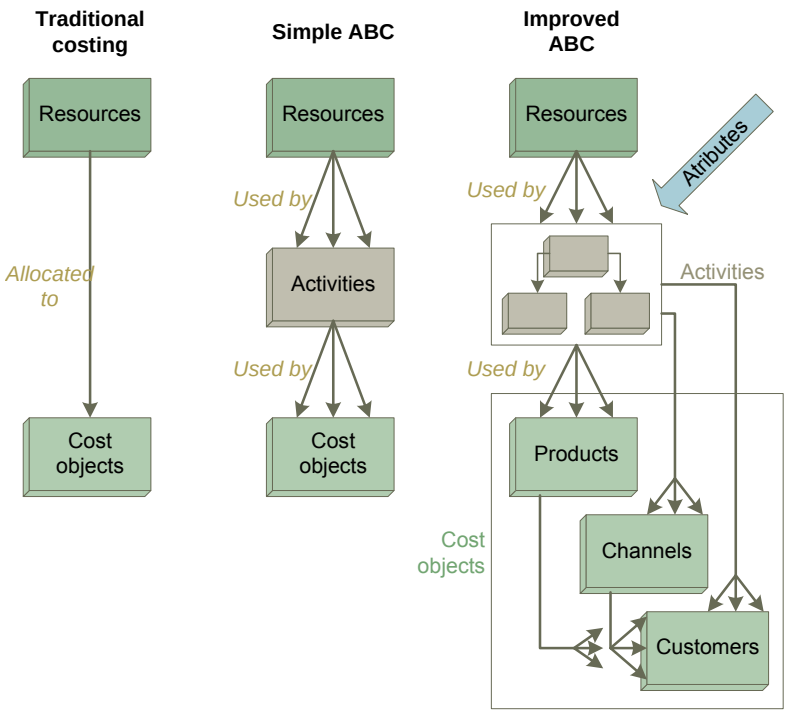

Figure 7. Comparative overview of costing systems (Cokins, 2009)

ABC analyses can be applied through following steps (ten Have, ten Have, & Stevens, 2003):

- Defining cost objects, indirect activities and recourses used for indirect activities.
- Assessing costs by indirect activity.
- Identifying cost drivers for each recourse.
- Calculating total indirect costs of product for the type of cost object.
- Dividing total costs with indirect cost volume by individual cost object.

Recently, Time-Driven Activity-Based Costing – TDABC is becoming the more advanced managerial accounting technique. When it is possible that considerable part of resources consumption exists in repetitive process, activity drivers from ABC model can be replaced with average (standard) time necessary for each activity (Kaplan & Anderson, 2004).

The difference between TDABC and ABC system in in fact that Time-Driven Activity-Based Costing is capacity sensitive and calculates standard activity cost by using standard rates. On the other hand, ABC system is not capacity sensitive and calculates activity cost of each period as real cost. Time-Driven Activity-Based Costing requires investment in measuring event times and to constantly maintain them. ABC simply requires amounts regarding activities that are exported form operational systems (Cokins, 2009).

7. ECONOMIC VALUE ADDED

Economic Value Added – EVA is a method for company's financial performance measurement (ten Have, ten Have, & Stevens, 2003) (Hann, 2011). The concept conceived in New York consulting company Stern-Stewart, assesses economic profit of a company (Marr, 2012). Economic value added measures real economic profit instead of accounting profit, that is the level in which company earnings exceeds shareholder's and creditor's rate of return, with assumption of comparative risk (Hann, 2011). Economic value added measures real profit after deducting all capital expenditures (Hagos & Pal, 2010).

Economic Value Added is unique because it focuses on measuring value, as well as performance (ten Have, ten Have, & Stevens, 2003). It measures economic profit achieved during certain period and is equal to net operative profit after tax adjusted for the price of capital employed (Elliott & Elliott, 2006). It can be calculated using following formula:

$$\textit{Economic value added} = \textit{Net operating profit after tax} - \textit{Price of capital employed after tax} \times \textit{Average capital employed} \quad (1)$$

It can be seen that economic value added measures economic profit, that is excess profit after deduction of earnings necessary for company to maintain capital and it indicates if company really created wealth. The

calculation uses net operating profit after tax (NOPAT) because it reflects profit available from operations, and not accounting profit. The other part of formula means that capital employed, which has its own price (weighted average cost of capital WACC (Marr, 2012)), should be seen as cost of maintaining capital that must be deducted in order to get economic profit (Hann, 2011). Positive economic value added means that during certain time period, value has been created (Elliott & Elliott, 2006).

Economic value added measures economic profit that exceeds expectations of investors and represents performance indicator that, by removing accounting anomalies, enables direct comparison of companies with similar risk profile (Marr, 2012). Adjustment of net operating profit after tax is performed by modification of operating profit by capitalization of some costs that should be seen as assets in economic sense, such as leasing expenses, and than deducting real cash outflows (paid tax instead of calculated tax) (Hann, 2011). Also, when calculating economic value added, research and development and training costs are investments and should be treated in that way (Marr, 2012).

Economic value added is adequate indicator for setting goals, evaluation of performance, defining bonuses, communicating with investors, capital budgeting and valuation (ten Have, ten Have, & Stevens, 2003). It can be increased by (Hagos & Pal, 2010):

- Increasing revenues,
- Minimization of operating costs,
- Production of the same products and services using less capital,
- Investing only in productive projects,
- Decreasing costs of capital.

For adequate application of economic value added four main areas can be perceived: measuring, management, motivation and state of mind, as shown in Figure (ten Have, ten Have, & Stevens, 2003).

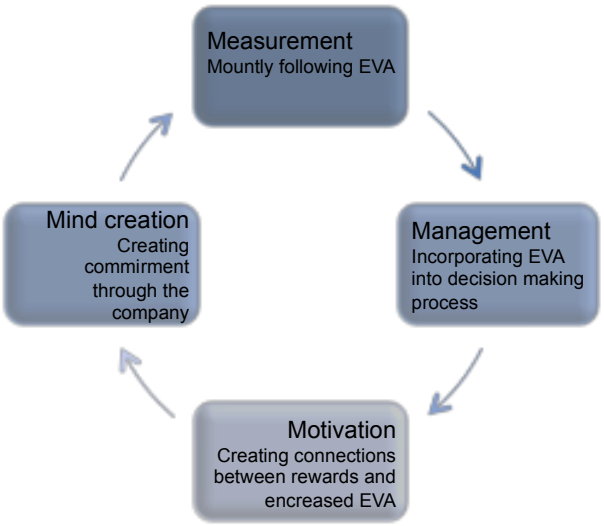

Figure 8. Key areas of EVA implementation (ten Have, ten Have, & Stevens, 2003)

The main challenge in use of economic value added is in calculation of real cost of capital, since that requires deciding about how many and which anomalies will be considered (there are over 150 of them) (ten Have, ten Have, & Stevens, 2003). Stern suggests that only the most important factors should be considered and use roughly defined cost of capital (Stern & Shiely, 2001).

The implementation of economic value added is more about cultural than financial change. Organizations must create culture where performance is more important than simply profit or loss (Marr, 2012).

8. CUSTOMER RELATION MANAGEMENT

Customers are more valuable for the company than the current sales amount. If a company can successfully identify the most valuable customers, gain them, keep them and increase its purchases, it will generate greater value than if all the customer were treated in the same way (ten Have, ten Have, & Stevens, 2003).

The key issue in customer relation management is to give to a customer perception that he or she is recognized and served immediately in a certain way through multiply integrated interface. This requires strategic management of all interactions with customers through marketing strategy customer led from outside to the inside, superior operations, systems and procedures that support customer interface and values and a customer focused culture (ten Have, ten Have, & Stevens, 2003).

Figure 9. Customer managemet piramide (ten Have, ten Have, & Stevens, 2003)

When it is defined what the potentially most valuable customers are, the company should be following next steps (ten Have, ten Have, & Stevens, 2003):

- Gathering as mush as possible relevant information about (potential) customers.
- Analysis of information with redefinition of information needs over time.
- Setting goals regarding the way in company wants to be perceived as provider of products, services or experience.
- Selection of media, systems and content of communication and interaction with customers.
- Development of engagement rules and special service packages for each customer.
- Incorporation of a customer guided culture.
- Warehousing and analysis of data about customers.
- Development of customer management system through learning.

9. CONCLUSION

Performance management is not comprised of several unconnected parts that can be improved separately from one another (Hope & Player, 2012). Individually, these methodologies cannot provide complete solution for performance management needs. The integration with fundamental processes of performance management is necessary (Hagos & Pal, 2010). There is significant interdependence between numerous methodologies and systems for improvements and therefore, change in one area can influence performance elsewhere (Cokins, 2009). Performance management system is nor linear nor sequential process. It is dynamic process that evolves over time. In order for performance management to function, it is necessary to include all of its parts. If only one part is neglected, the system will not work (Bacal, 2012).

Cokins remarkably illustrates performance management framework by comparing it with gorgeous villa, called “Performance Management Villa” (Cokins, 2009) in which all chambers are equipped with strategic maps who establish the routes given from executive teem. In each chamber information and analytical tools are provided so that people can determine the way for accomplishing strategy. Balanced scorecard instrument tables for feedback exist in each chamber so that everyone knows how well his job is done. Villa has unique information platform. People are encouraged to make decisions quickly because there is less and less time for asking superiors for answers. In this way, managers do not manage villa, they enhance it.

Abstract: *Performance management in defence is very important for the process of managing the defence and is fully integrated with all of its aspects. This paper presents a system of defence performance management, and it is based on the concept of Balanced Scorecard. The solutions presented in this paper are the authors vision as a possible solution for the continuous improvement of defence performance, in terms of dynamic changes. This paper may be useful for the development of military science, as well as practical solutions for management in public sector organizations.*

Keywords*: defence system, performance, management, balanced scorecard, key indicators*

1. INTRODUCTION

Contemporary public sector organizations, as well as private sector organizations, operate and achieve their activity in different political, economic, security, social, demographic and other conditions. Dynamic changes in these conditions raise new and complex demands to organization management. Results achieved in a short period of time become obsolete and unusable. Public sector organizations are faced with the problem of constantly increasing demands of stakeholders, as well as maintaining the quality of activities for general interest.

For defence system, as a specific public sector organization, an activity of general interest is the protection of the defence interests. In this regard, the defence system develops capabilities necessary to perform basic activities. That development processes are realized with a significant role of performance management.

Performance management in defence require a lot of information about the strengths, abilities, budget, organization, etc., which should be in balance. Based on that, it is necessary to create a system of performance evaluation which will be followed through different categories of indicators - perspectives. One of the useful tools to synthetically measure organizational performance is the Balanced Scorecard.

The concept of the Balanced Scorecard allows measuring of performance through multiply perspectives, management of organizational performance and presentation of balanced scorecard. It is applied in modern organizations, but also in some countries armed forces.

Armed forces are developing their own system for defence performance management that is based on the concept of Balanced Scorecard, with respect of defence specifics. Process of defence Balanced Scorecard development is consisted of strategy map drafting, measure of key performance indicators and present results of measurements.

2. PERFORMANCE MANAGEMENT IN THE DEFENCE SYSTEM

The defence system is a subsystem of the public sector whose mission is to protect the national security and national interests. Performance management is very important for developing of defence capabilities that are necessary for protection of national security and national interests.

Performance management in the defence system is a dynamic and iterative process. On figure 1 is shown an example of a cyclic model of defence performance management.

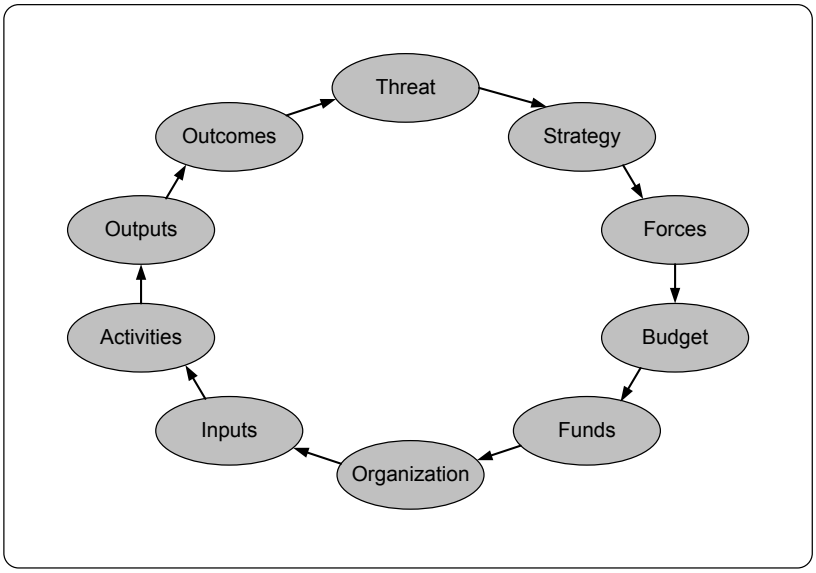

Figure 1: Model of defence performance management. (Angelis and Webb, 2009)

According to state security threats and based on an environment estimate, the government develops policy and strategy. In the next step the plan of the necessary forces development are prepared in order to implement policies and strategies. Also, it is necessary to provide adequate resources and prepare budgets for personnel, equipment, and other inputs needed to provide defence activities.

The approved budget is allocated through defence force structure and the costs types. Each defence organization provides specific inputs (staff, equipment, infrastructure, etc.) necessary to perform assigned missions and tasks. The output values are created as a result of combining inputs and activities.

Efficiency is the quality of being able to do a task successfully, without wasting reliable resources (time, money or energy). It is reflected in the „inputs activities outputs" part of the model. Rather than focusing on budgeting processes, efficiency requires understanding the outputs. Efficiency answers the question, *are we doing things right*?

Effectiveness comes from the „outputs to outcomes" part of the model. It describes how well the defence outputs performed relative to the strategies or high-level goals that the organization set out to achieve. Effectiveness also answers the question, *are we doing the right things*?

Outcomes are results, consequences, effects, or impacts of direct importance to stakeholders. Outcomes depend on the generated output and on the interaction of the output with the environment and the interpretation of stakeholders as to the success of that interaction. There are many measures, each with some utility for a particular audience and none fully measuring the „success" of the goal of providing national security (Stojkovic, Stojanovic, 2012).

It is obvious that defence performance management needs a lot of information about capabilities, budget, organization, et cetera. They must be in balance, because decisions making process based on only one type of information can have a negative impact on the defence system functioning, and probably here will be no success to provide national security and protection of national interests.

3. BALANCED SCORECARD CONCEPT

Modern organizations carry out their activities in changeable and complex conditions. Such conditions require a focus for continuous improvement of performance and implementation of strategic objectives. In this sense, many organizations devote considerable attention to performance measurement. In the process of performance measurement there are a lot of shortcomings. One of them is the foundation of the financial and material indicators.

However, such a method of measurement is not appropriate for modern organizations. In organizations there are intangible assets as employee knowledge, customer loyalty, innovative culture et cetera. The late twentieth century Kaplan and Davis Norton have created a new performance measurement system. The system, named Balanced Scorecard, is based on the performance measurement of the following perspectives: customers, internal business processes, learning and growth and financial (Figure 2).

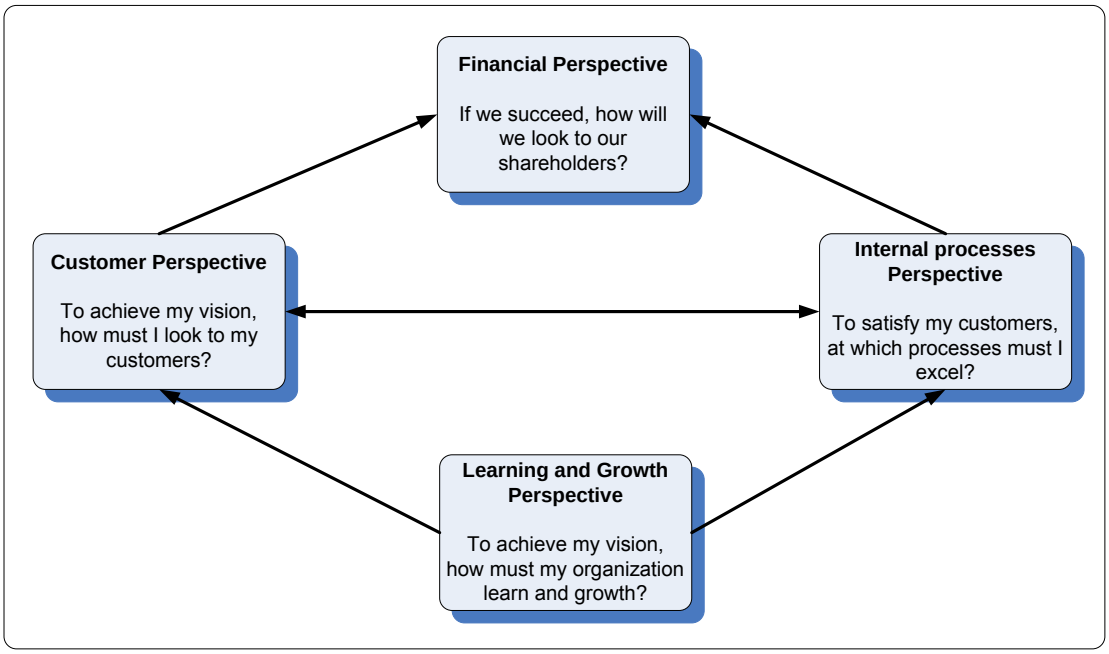

Figure 2: Perspectives of the Balanced Scorecard (Kaplan and Norton, 2001, adopted)

Essentially, the Balanced Scorecard can be viewed in three ways: communication tool, measurement system and strategic management system (Niven, 2008).

Stakeholders should to know what it needs to be done to implement the strategy. This allows the strategy map in complex conditions. The strategy map is a communication tool that shows the paths from the beginning to the end of implementation the strategy. It shows causal paths through perspectives and leads us to the implementation of strategy.

The strategy map is the basis for the development of measurement system. The Balanced Scorecard system allows an organization to translate its vision and strategies by providing a new framework — one that tells the story of the organizations strategy through the objectives of the strategy map and measures chosen to represent those objectives on the Balanced Scorecard. The strategy map and measurement system are inseparable.

The Balanced Scorecard evolved from the measurement system to the strategic management system. It harmonizes short-term activities and the strategy. The Balanced Scorecard overcomes the following obstacles: vision, people and resources. On figure 3 is shown a number of possible reasons for launching a Balanced Scorecard program.

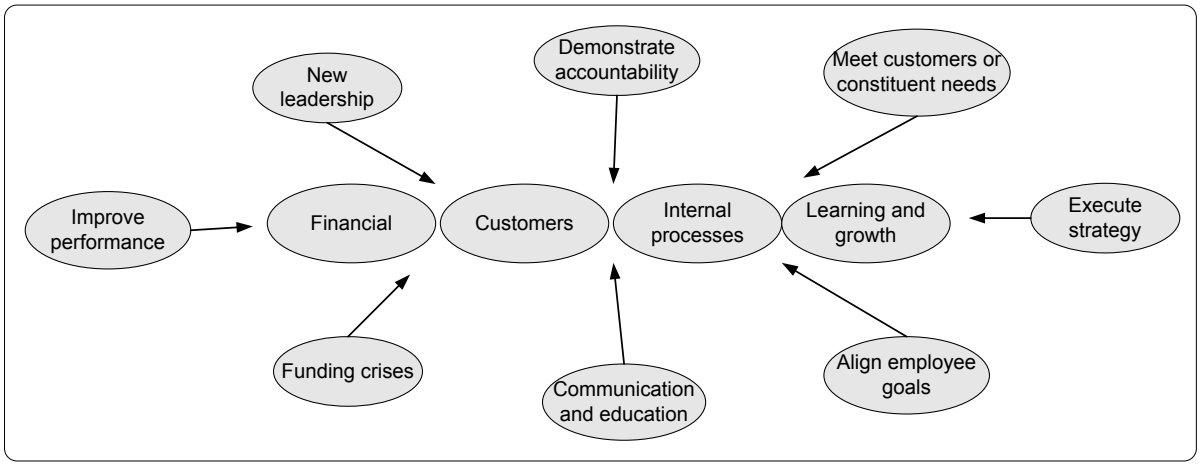

Figure 3: Arguments for BSC (Niven, 2008)

In order to realize real benefits from the Balanced Scorecard, organization should determine their specific justification for launching this implementation.

4. BALANCED SCORECARD IN DEFENCE SYSTEM

The Balanced Scorecard concept is used in modern organizations, but also in some armed forces. However, armed forces are developing their own performance management system based on the Balanced Scorecard concept, which were adopted and adjusted to the defence specifics.

The defence performance may be monitored through the following four perspectives:

- „Outcomes" provides information on the current fulfillment of tasks and the defence readiness comparing to the future challenges;
- „Resources" provides information about resources available to the defence;
- „Processes" provide information about the quality of the key processes in the defence and
- „Development" provides information about the possibility of continuous improvement and value creation of the defence.

Perspective determination and performance selection are realized in the process of defence strategy map developing (Figure 4). Due to the complexity of the defence as a system, the selection of performance is not easy. It is necessary to select the performance of which the realization of the vision and mission depends on, as well as the realization of long-term defence goals.

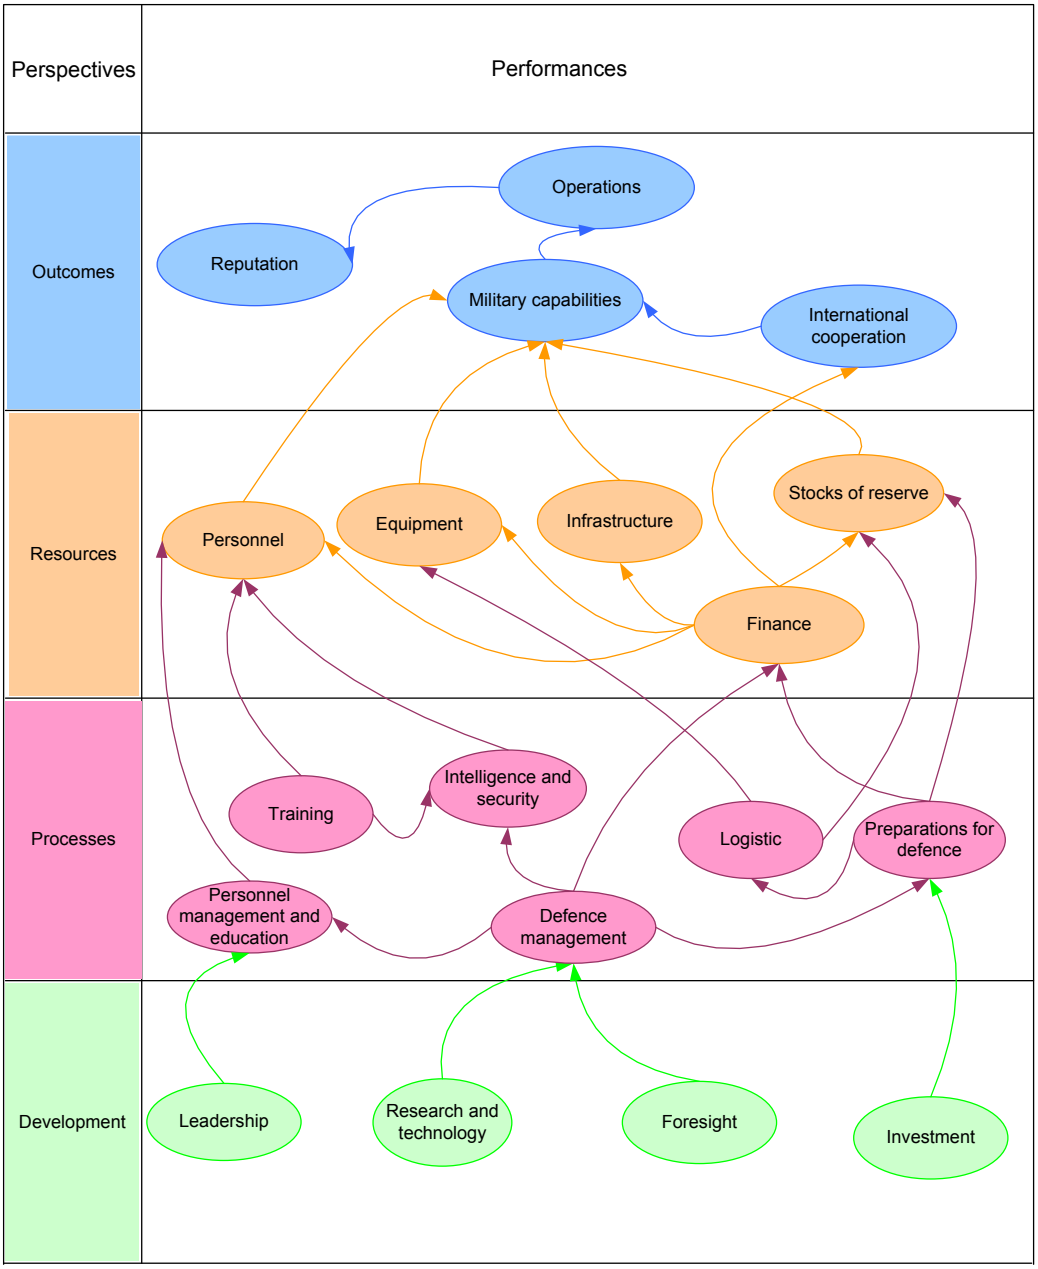

Figure 4: Defence strategy map

However, the functioning of the defence system does not depend on all performances equally. Some performances are more important, but some performances are less significant for the defence system. In this regard, in the defence system, weights for each performance within the perspectives are determined using expert choice method and software Expert Choice.

One of the main ways to obtain data on the quantity and quality of performance is their measurement. Performance measurement is the process of developing indicators for assessing specific goals and execution of measurement (Dictionary of Business and Management, Fourth edition 2006, Oxford, page 396).

There are dozens or hundreds of performance indicators to measure performance. However, it is necessary to select only the indicators that will show the real quantity and quality of performance. Performance indicators are directly related to defence objectives indicators.

The present method of measuring performance indicators allows simultaneous monitoring the implementation of the medium-term objectives and the defence performance.

Making defence strategy map and performance measure are complex processes. Due to the complexity of these processes the most expert people in the defence establishment must be engaged.

Based on the measurement results, identification of the performance shortcomings and the defence key problems are performed. The measurement results and the defence key problems are presented to the Ministry of Defence leadership, as well as proposed measures to eliminate shortcomings and resolve key issues.

In order to present the results of measurements defence dashboard are made, that graphically displays the current status and future trends of performances and perspectives (Figure 5).

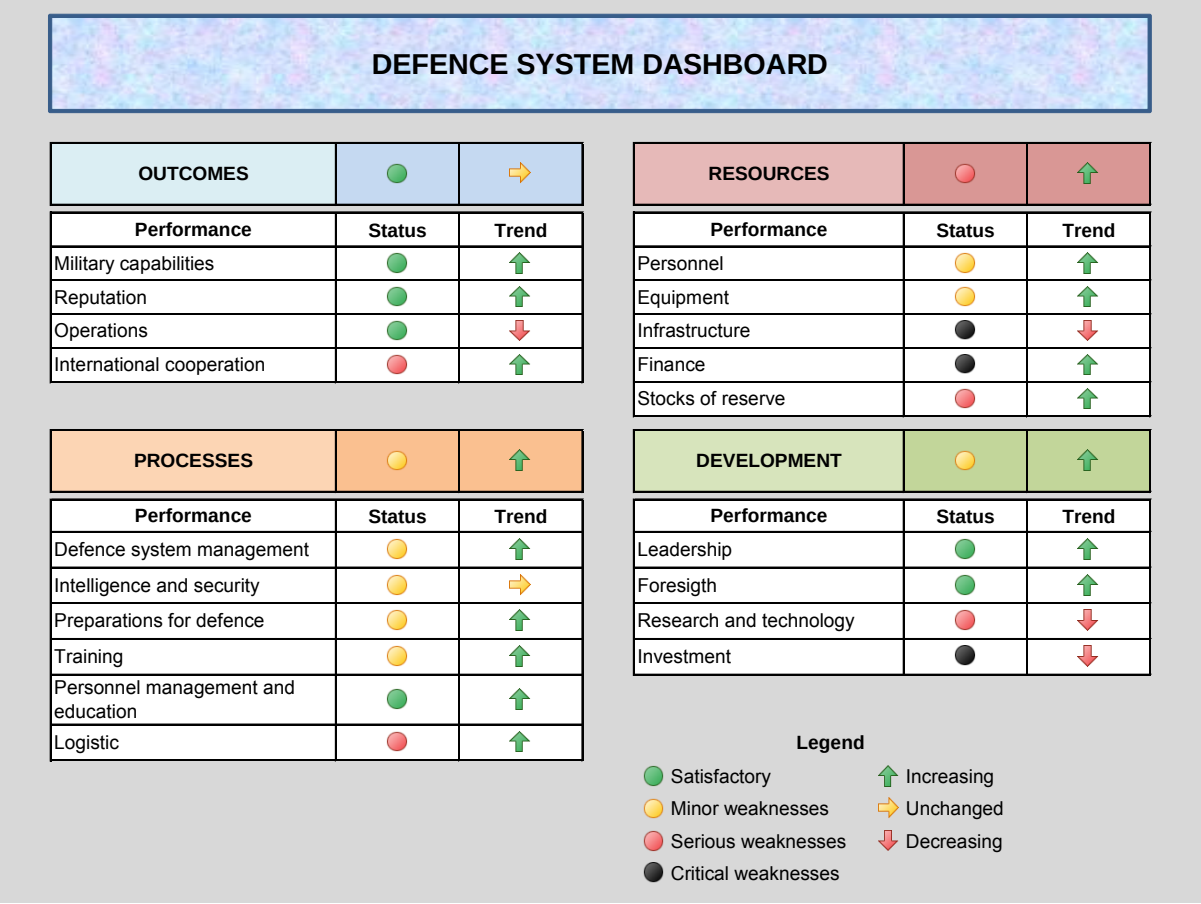

Figure 5: Defence system dashboard

Displaying the defence performance in such a way helps in understanding the entirety state of the defence, easily spotting key issues and quickly makes decisions about corrective action.

5. CONCLUSION

Performance management supports strategic planning in organizations using measurable indicators and better information enables managers to recognize success, identify problem areas and develop actions in order to provide better service to society.

The Balanced Scorecard concept enables to monitor organizational performance through more different categories of indicators. Defence performance management is based on the Balanced Scorecard concept with respect of the defence system specificities.

Appliance of the presented model of the defence performance management enables to achieve different effects:

- monitoring the performance necessary to achieve the defence system objectives;
- quick identification of key issues;
- simple and understandable presentation of the defence system state;
- defence planning based on objective indicators;
- corrective action.

The presented model may be applied in military organizations, as well as in public sector organizations. However, application of the presented model requires its adjustment in accordance the specification of the particular system.

AKNOWLEDGMENT

The results presented in this paper are made within project No III47029 financed by Ministry of Science and Technology Development of the Republic of Serbia.

Abstract: *In recent times, the role of transfer pricing has become especially important in complex holding companies on an international level. Due to the trade between the parent company and subsidiaries located in different countries, the tax implications of transfer pricing is expressive. Therefore, the harmonization of relations between multinational companies and governments of some countries is becoming increasingly important issue. In this regard, the paper will discuss the role of transfer pricing in multinational companies, as well as their influence on the governments of the host countries. Bearing this in mind, the main objective of this paper consists in analyzing the importance of transfer pricing in order successfully manage the multinational companies performance. By adequate application of theoretical concepts and chosen research methods, the work is expected to extend domestic writings in this field and to introduce our economic publicity with the role of transfer pricing in the operations of multinational companies.*

Key words*: transfer pricing, multinational companies, tax implication*

1.INTRODUCTION

The last decade of the twentieth century was marked by increasing globalization and internalization of international business. In terms of trans-nationalization of most economies in the world, multinational companies have become the central organizers of economic activity and the main actors in shaping the international division of labor. They achieve this role through foreign direct investment, and a number of non-equity arrangements with the enterprises in the host country.

Transfer price is the cash basis for quantifying the internal transfer of products / services. It is determined for an adequate and fair determination of participation of each participant in this transfer and measurement of its effectiveness. The specificity of transfer pricing in relation to the external market price is reflected in the fact that they condition performance of the unit that buys and units that sells intermediate product / service, but also the company as a whole.

Transfer pricing has become one of the most important elements in the operations of multinational companies. Internal transfer is a potentially serious and complex economic phenomenon in relation to the external exchange of products / services, that is performed relatively without a problem due to the effects of market rules.

The role of transfer pricing in the creation of tax benefits for multinational companies became more pronounced. The ultimate effect of the tax consequences of the profit of multinational companies significantly exceed the effect of other factors, such as reduced risk of monetary disturbances, keeping the preferred dividend policy or achieve competitive advantage through finding cheap capital.

2. THE GROWING IMPORTANCE OF MULTINATIONAL COMPANIES IN THE WORLD ECONOMY

The term multinational corporation was first used in 1960. The term was apparently “coined by David E. Lilienthal, director of Tennessee Valley Authority under President Roosevelt and the Atomic Energy Commission during the Truman... His report at the Carnegie Institute of Technology from the 1960s, hich was then published in Development and Resources Corporation has a title: The Multinational Corporation. The title was then taken over by Business Week in a separate report of Multinational Companies in the issue of April 20 in 1963” (Svetličić, 1986). In fact, it seems that the multinational corporations occurred with the use of the term that indicate the feature which can by no means be considered new. However, “the features can not bear with the names they receive, but they form through a long process, filled with contradictions and struggles of various factors, which ultimately lead to the prevalence of certain characteristics. And this may be expressing something qualitatively new in relation to the old features or just be a new form” (Svetličić, 1986).

Multinational companies are very difficult to define, given that among them there are many differences observed in terms of form and concentration of ownership, the volume of capital and scope of operations, geographic dispersion of activities, degree of differentiation and integration, the structure of the internal organization and management system. The lack of a comprehensive definition of multinational companies is probably the result of applying a number of criteria that cannot be avoided during the time of their definition. With this in mind, the literature can meet various definitions of multinational companies.

Dunning defines a multinational company as a company that undertakes foreign direct investment (FDI) and owns or has the right of control over the activities of more than one country. According to this definition, a multinational company has two characteristics. First, they coordinate production between a numbers of different companies and internalize this coordination problem within a single organizational structure. Second, a significant part of economic transactions associated with this coordination activity is achieved outside of the national economy. According to these characteristics multinational companies are different than other companies. On the one hand, a large number of companies control and coordinate production between the various companies and while many other companies have taken economic transactions across borders. On the other hand, multinational companies are the only companies that coordinate and internalize their economic activities beyond the borders of the national economy.

Hood and Young point as important elements of the multinational companies following (Svetličić, 1986):

- direct investments (unlike previous portfolio investments),
- transmission resources in the package,
- property ownership abroad that bring income in various countries.

According to the management criteria, it is believed that a multinational company is that whose control central has a multinational character, i.e. the management of a given multinational companies (the leadership includes representatives of all branches of multinational companies) is multinational.

Numerous and different views of given phenomena suggest that comprehensive definition of multinational corporations must include the following elements: multinational corporations represent the major economic organizations that only part of its activities performed outside of the national economy and to this end establish affiliates abroad, their central administration is in the hands of citizens of the exporting capital country and ownership structure of the corporation may, but need not have a multinational character.

It must be recognized that difficulties in the precise definition of multinational companies, as the dominant actors in shaping global economic trends in the contemporary conditions, represent a reflection of their complexity and the fact that they are in fact “mixed formations, because on the one hand, they are a reflection of the competition, and on the other, negation of the competition, a reflection of the concentration and centralization of capital and state intervention. These companies are polyvalent, and national and transnational (multinational), and market and anti-market, they are factor of the development of the productive forces, but also the limiting factor of this development, they are a factor of the integration also and disintegration of the world market and the national economies” (Svetličić, 1986).

However, "in the broadest sense of the word multinational company we can be defined as a company that produces goods and sells its services in more than one country. In the strict sense of the word, multinational company can be defined as a company that, through foreign direct investments, controls and manages affiliates in foreign countries” (Held et al., 2001).

Specific features of multinational companies are reflected in the large geographical coverage, significant organizational interdependence and capabilities of coherent integration of activities implemented in different countries. In terms of revenues, profits, capital and resources, these companies represent the true giants, and their economic power is often greater than the potential and performance of many countries.

Their great power based on the enormous size and activities on a global scale, especially in the social influence that stems from it; internationalization of all phases of operations; centralization of decision-making; monopoly control of the world's raw materials and energy; as well as the great potential of scientific and technical development, including the ability to attract and engage a number of scientific staff from around the world. Thus, MNC’s are still the most important factor in the world economy, which controls more than 70 % of world trade and 80% of the world's financial potential. The most dynamic sectors of the economy are broadly transnational and have an interest in maintaining an open international economic system. The expansion of MNC’s has led to the growing integration of the world economy in which their business is increasingly limited by national boundaries, so that the factors of production and goods to move freely, which allows for the reproduction cycle of global capital freely fertilization.

It is characteristic that, for example, the Japanese company „Toyota" one-third of the total production generates from its 25 companies located in America, Europe and Asia. Exports about 45 % of its production realized in Japan. Through its regional network of Asian imports diesel engines from Thailand, the Philippines transformers, heaters, etc. from Malaysia. American company „IBM" in the field of information technology, 41 % of its sales realized in the North American market, 30 % in Europe and 9 % in Asia. „Canon" is realized 30 % of its production in North America, 29 % in Europe and 37 % in Asia. For companies that have a relatively small domestic market, such as the giant Dutch electronics industry „Philips" or Swiss food colossus of industry „something", it is crucial exit out of the national market and the expansion of its activities on the planet. For this reason, MNC's locate their center of activity everywhere that can realize the most effective combination of technology, capital and labor to produce the most profitable and launch their products. They are trying to infiltrate in the periphery of the world economy, the interest of the city to spatially decentralized production operations, seeking more profits and lower wages. As a consequence, the emergence of transnational unwieldy empire whose business scope often exceeds the gross national product of many countries.

On the basis of the content of MNC is a strategy that foreign investment is being made, rather than in the form of the loan capital in the form of capital and entrepreneurial business to be managed mainly from the country of origin of the company. Foreign direct investment in modern developmental stages functions as a key development factors and the international trade and technological progress have become the main mechanism for the global economy. Common modes of transmission activities of MNC's in other countries, in addition to FDI as the most important ways as: exports of goods, sales of licenses, portfolio investments, joint ventures, contractual arrangements and know-how. In such circumstances, the companies strive to become a global, primarily due to the inclusion in the global market of material goods and services, to oppose competition in the domestic market, hedging and cost per unit of product. In addition, the development of productive forces, as a result of the scientific and technical revolution, led to the fact that in some industries it is impossible to organize the production of which would be profitable, if it only works for the national market. To be effective, corporations seek to ensure good market position, increasingly insist on quality, technological innovation, with particular attention to attach a global strategy and development. In the struggle for dominance in the market, they are not shy to use various non-economic, even illegal activity, that they an effective and fast way to provide global dominance.

Power, available knowledge and accumulated experience of multinational companies are coming to full expression in situations where they use favorable conditions and comparative advantages offered by a specific geographical location and when they integrate these separate locations in the multinational network of research and development, production and sales, and marketing (Milićević, 2003).

In the circumstances of a complex organizational structure, instability of exchange rate movements and possible political upheaval in the host countries, companies has as tasks-coordination, control, resource allocation, performance measurement and currency management becomes more complex.

3. TRANSFER PRICING - A FORM OF MULTINATIONAL COMPANIES POWER EXPRESSION

Power of multinational companies is not expressed only through competitive advantages in a number of countries in the world. These companies have a significant influence on the government of the host countries. The power derives from their ability to influence the macroeconomic policies of local governments and set up rules to suit themselves. The most obvious example of the expression of this type can represent transfer prices.

As for the group at the international level, the transfer of goods and services between the parent company and subsidiaries is carried out by transfer pricing. Thus, for example, if the parent company that manufactures equipment and subsidiaries installes that equipment in another country, transfer pricing implies a level of profit and tax profit of parent company and subsidiaries. Established equipment transfer pricing imply in this case the cost of the branch of subsidiaries and at the same time the income of the parent. That is, regardless of how they are formed, transfer prices significantly affect the profitability of each entity within the complex group. Transfer prices affect the decision making process of the input and output. These decisions directly affect profits, rates of return on investment as well as on taxation in the case of complex organizations at the international level.

Transfers of products and services among subsidiaries that are located in different countries represent a very important segment of the multinationals. In support of this conclusion is the fact that internal transfers between subsidiaries account for between 30 and 50% of the total annual income of multinational companies. The prices at which these transfers take place based either on cost or estimated market prices

for the products or services that are subject to internal trade. In both cases, these prices are considered administrative or management cost, given that they do not provide the economic value of internal transfers. Accordingly, the transfer price can be a significant source of multinational companies' benefits as the central management successfully manages them (Radebaugh & Gray, 1997).

If transfer prices are implemented incorrectly, a company increases its exposure to double taxation, penalties, and high legal costs. This results in an increase in the total cost of ownership as a short term money saving decision may finally cause an overall higher cost. Thus, the increased total cost of ownership makes the corporation less profitable. Transfer pricing was found to be an important part of maximizing operating performance (Kumar & Sosnoski, 2011).

Transfer pricing at multinational groups level have multiple effects. They directly affect the amount of business results of the group members in the supply chain. For multinational companies with global supply chains, increased awareness of transfer pricing–related issues is leading to the acknowledgments that changes in an operational structure often demand appropriate changes to the tax and legal structure to align business models (Balachandran et al., 2010). This result has a different level of corporate taxation and taxation of distributed profit of group members in different countries. By the transfer pricing, profit is transferred from countries with high tax rates in countries with lower tax rates. They directly influence the increase in profits in countries with lower rates of income tax. On the other hand, transfer price may have a control part. Thus, or example, if the parent wants to receive dividends from its subsidiaries, which is not possible because of legal restrictions, then the parent will artificially increase their profits and reduce profit of subsidiaries.

Therefore, the main benefit, which could result in the effective management of transfer pricing is reflected in minimizing global tax liabilities, reducing the risk of monetary disturbances, maintaining desirable dividend policy, finding cheap capital, and the like. Tax consequences arising out of the utilization of different transfer prices can be easily quantified, and the final effects of the profit of multinational companies significantly beyond the effects of other factors. Transfer pricing is the movement of money from one country to another. Almost correctly, it can save a company millions of dollars, if not done accurately, transfer pricing can place global companies at considerable risk for audits, interest and penalties, even result in double or triple taxation (Tully, 2012).

Tax legislation and tax incentives vary from country to country and range of moves performed by multinational companies in order to achieve tax savings very large . In the period since 1980 till 1990 in the U.S. there was a big expansion of multinational companies whose asset value almost tripled and climbed up to the amount of 1.8 trillion dollars, while the amount of taxes paid in the same period hardly changed. Than 36,800 foreign companies, more than half did not report any taxable income. U.S. Treasury Department has estimated that 36 multinational companies in this period to avoid paying more than 100 billion dollars in taxes, of which two-thirds related to Japanese companies. Particularly outstanding was the example of Toyota, which was accused that by excessively high transfer prices of cars and parts in the U.S. carried out the transfer of profits in Japan, where tax rates were much lower. Later the company still paid the entire trillion dollar tax.

In order that such cases would not be repeated in the early 90s, many countries have begun to incorporate into their tax legislation the different ways of calculating of transfer pricing for multinational companies that do business with them. A large number of multinational companies in the world has imposed the need to address the problem of calculating transfer prices at the global level in what they include and organizations such as *The Organisation for Economic Co-operation and Development - OECD* and *United Nations - UN*, and the final solution was a principle "arm's - length transaction," which included the recognition of transfer prices, for internal deliveries between the parent company and the foreign subsidiary, on level comparable prices applicable to unrelated entities. This means that the tax base includes the difference between this particular transfer pricing and internal established transfer prices. When transfer prices do not reflect market relations and the arm's-length principle, can lead to distortion in terms of tax liabilities of related entities and the tax revenues of the host countries. Therefore, the profit of related entities can be corrected to the extent necessary to correct such distortions and ensure the application of the principle of arm's length. OECD member countries are considered that appropriate alignment is achieved by establishing requirements for commercial and financial relations between unrelated entities in comparable transactions under comparable conditions (OECD Guidelines, 2010).

Although this approach limits the possiblility for transfer prices manipulation, it is difficult to apply. The problem is that the transfer prices are essentially administrative cost, and used for evaluation of internal financial flows that cannot be traced through the flow of goods or services. Even in situations where the primary cost of unfinished products can be accurately defined, there is always the opportunity to "discover" a

new service whose cost accounting system recognizes. Thus, expenditures on behalf of mutual advisory services, insurance services, general management, research and development, phone calls, loans, and others, can still be included in the calculation as costs by choice. Moreover, in many countries a firm's legal structure and ownership structure define respective accounting requirements. For instance, disclosure requirements may vary with factors such as size, number of owners, liability regimes, and so forth (Martini et al., 2012).

Multinational companies have the ability to easily and quickly reallocate their profits, and that the governments of the countries puts at a disadvantage. By threat of closure of their factory, and thus by the loss of jobs for many people, by a bad image of the host country to other investors as well as by weakening of political support for elected governments of these countries by the local population, multinational companies are pressuring the government policies of host countries.

For these reasons, many countries are introducing benign procedure for the control of transfer pricing of multinational companies. In order to keep or attract large companies, they offer a number of tax benefits, benefits in the area of production, such as cheap or free land for the construction of production facilities, subsidies and financial assistance in times of crisis in order to maintain or increase employment.

4.CONCLUSION

Multinational companies provide a powerful process of international integration and the emergence of the global economy, whose essence is the realization of national interests and economic expansion, primarily to home countries. Power, available knowledge and accumulated experience of multinational companies are coming to full expression in situations where they use favorable conditions and comparative advantages offered by a specific geographical location and when integrate these separate locations in the multinational network of research and development, production and sales, and marketing.

Transfer prices are an important instrument for planning and controlling of business performance at the level of multinational companies. The effect of transfer pricing is best seen in terms of a high degree of independence of the organizational units of businesses. Recently, by transfer pricing profits is transferred from countries with higher tax rates in countries with lower tax rates. Law in developed countries successfully discover such an effect of transfer pricing at the level of individual complex groups and, therefore, possess adequate tax regulations.

Financial flows and income distribution of multinationals must be controlled by the governments of the host countries. On the other hand, starting with the economic and political power of multinational companies, local governments must sometimes directly intervene by way of tax incentives or through benefits in production.

We conclude that the alignment of the relationship between multinationals and the governments of certain countries is associated with the distribution of wealth and the control of production. This relationship is much more than a successful creation of tax legislation.

Abstract: *Expenditure on research and development (R&D) is one of the most widely used measures of innovation inputs. Governments in modern economies devote much attention to enhancing productivity and emphasizing its drivers such as investment in R&D. So far, there are no existing frameworks that perform ranking based on R&D. The aim of our paper is to present an I-distance methodology that gives a new perspective on the measurement of R&D. In addition, we aim to compare it to the list of the OECD countries by R&D expenditure, and to point out improvements that our methodology provides. As a case study we analyzed a dataset of 41 OECD countries, with the latest available data of 2013. One of the contributions lies in the application of an I-distance method which can easily integrate R&D variables with different measurement units into one composite indicator. Using the I-distance method, the obtained results suggest that following indicators are very significant for ranking countries: GERD as a percentage of GDP, Business Enterprise Expenditure on R&D as a percentage of GDP, Percentage of GERD financed by industry and GERD per capita population. In addition, applying the I-distance method we were able to overcome the problems concerning the aggregation of composite indicator that uses presumably biased weighting factors. Moreover, our approach could be a foundation for an appropriate framework of R&D ranking countries which would be unbiased i.e. independent from subjectively formed weighting factors.*

Keywords*: research and development (R&D), I-distance method, ranking of countries, OECD countries*

1. INTRODUCTION

As a branch of economics that focuses on improving the economies of developing countries, development economics considers how to promote economic growth in such countries by improving factors like health, education, working conditions, domestic and international policies and market conditions (Cracolici et al.2010) It examines both macroeconomic and microeconomic factors relating to the structure of a developing economy and how that economy can create effective domestic and international growth. It seeks to determine how poor countries can be transformed into prosperous ones (UNDP 2008). Strategies for transforming a developing economy tend to be unique, because the social and political background of countries can vary dramatically (Petrosillo et al.2013). Today, more than ever before, innovation, enterprise and intellectual assets drive economic growth and increase standards of living (D'Acci 2011). Innovation is instrumental in creating new jobs, providing higher incomes, offering investment opportunities, solving social problems, curing disease, safeguarding the environment, and protecting our security. To help achieve these objectives, governments must create appropriate incentives for continued growth in innovation and technology development and embrace sound policies for assuring broad social diffusion and access to key scientific and technological advances that enable us, as Newton first observed, *~~to~~ stand on the shoulders of geniuses*" (Business and Industry Advisory Committee to the OECD, CREATIVITY, INNOVATION AND ECONOMIC GROWTH IN THE 21st CENTURY).

It is not uncommon that the countries refer to the best rank in one criterion, while the other criteria (which are also important) are below average. In order to enhance and improve ranking and conclusion we focused on the application of the composite index (Amdt et al.2013; Guttorp and Kim 2013; Saisana et al.2011). Composite indicators as tools to compare country performance are increasingly common (Saisana and Tarantola 2002; Saisana and D'Hombres 2008). Simplistically a composite indicator synthesizes the information included in a selected set of indicators and variables (Paruolo et al.2013) The output of a composite indicator is a set of scores indicating the relative performance of a country within a set of countries (Brügermann and Patil 2011). A composite is thus a measure of similarity (Saltelli 2007; Paruolo et al.2013). The main virtue of composite indicators is their usefulness for policy analysis in that they can summarise complex and sometimes elusive issues in wide ranging fields, e.g., environment, economy, society or technological development. Composites often seem easier to interpret than finding a common trend in many separate indicators and have proven useful in benchmarking country performance.

There are many problems we experience when applying composite indicators (Diener and Suh 1997;Moffat 2000). Some of them are: imputation of missing data, multivariate analysis, normalization, weighting and aggregation, uncertainty and sensitivity analysis. For each of them methods how to overcome it (Dobbie and Dail 2012; Soo 2013;Tarantola and Saltelli 2007) are applicable. We will explain those three we find most important for this work. First problem is with data selection and missing data - the most common problem at all. Indicators should be selected on the basis of their analytical soundness, measurability, country coverage, relevance to the phenomenon being measured and relationship to each other. The use of proxy variables should be considered when data are scarce. Imputation of missing data is needed in order to provide a complete dataset (e.g. by means of single or multiple imputation). Consideration should be given to different approaches for imputing missing values (Handbook on constructing composite indicators: methodology and user guide). For example extreme values should be examined as they can become unintended benchmarks. Multivariate analysis is an exploratory analysis which should investigate the overall structure of the indicators, assess the suitability of the data set and explain the methodological choices, e.g. weighting, aggregation. Another most common problem with getting one dimensional variable by observing more dimensions is normalization. Normalization should be carried out to render the variables comparables well as indicators. Attention needs to be paid to extreme values and skewed data, because they may influence subsequent steps in the process of building a composite indicator.

The aim of our paper is to present an I-distance methodology that holds a new perspective on the measurement of R&D. In addition, we aim to compare it to the list of OECD countries by Expenditure on R&D (% of GDP) available from the World Bank data, and to point out improvements that our methodology provides. We will try to discuss several topics. We will incorporate expenditure R&D indicators into the evaluation framework of countries (OECD Factbook 2013). A simple definition of R&D intensity is *"the ratio of expenditures by a firm on research and development to the firm's sales".* Generally speaking, R&D is the main driver of innovation, and R&D expenditure and intensity are two of the key indicators used to monitor resources devoted to science and technology worldwide (Economic Glossary). R&D intensity for a country is defined as the R&D expenditure as a percentage of Gross Domestic Product (GDP) (Eurostat). The main aggregate used for international comparisons is gross domestic expenditure on R&D (GERD). This consists of the total expenditure (current and capital) on R&D carried out by all resident companies, research institutes, university and government labour (OECD Factbook 2013). The GERD is an indicator of science and technology (S&T) activities; it is appropriately used as a summary of R&D activities and the basic flow of funds (Griffith, R., Huergo, E., Mairesse, J., P, B., : Innovation and productivity across four European countries).

The aim of this work is to provide a framework for introducing the necessity of evaluating countries by composite indicators. Our paper will employ a statistical I-distance method which can easily overcome the problem of subjectively chosen weighting factors. In addition, it can integrate variables with different measurement units into one value which is thereafter considered as a rank of a certain country. Besides the analyze of influence of each one indicator , we will compare the results of I-distance method with other method and we were able to provide detailed data on how each observed indicator contributes to the final rank and point out the crucial indicators of countries. In addition, we compared ranks obtained by I-distance method with ranks based on the Expenditure R&D (% of GDP).

2. METHODOLOGY

The common case with different ranking methods is that their bias and subjectivity can affect the measurements and evaluation to a great extent. This problem can be somewhat overcome by the use of the I-distance method, a metric distance in an n-dimensional space, which has recently made a significant breakthrough (Jeremic et al. 2011a; Radojicic and Jeremic 2012; Jeremic et al. 2012; Dobrota et al. 2012). It was originally defined by Ivanovic (Ivanovic 1977), who devised this method to rank countries according to their level of development based on several indicators, where the main issue was how to use all of them in order to calculate a single synthetic indicator, which will afterwards represent the rank.

For a selected set of variables $X^T = X_1, X_2, \ldots X_k$ chosen to characterize the entities, the I-distance between the two entities and $e_r = x_{1r}, x_{2r}, \ldots x_{kr}$ and $e_s = x_{1s}, x_{2s}, \ldots x_{ks}$ is defined as

$$D(r,s) = \sum_{i=1}^{k} \frac{\left| d_i \;\; r,s \right|}{\sigma_i} \prod_{j=1}^{i-1} 1 - r_{ji.12\ldots j-1} \qquad (1)$$

where $d_i(r,s)$ is the distance between the values of variable X_i for e_r and e_s, e.g. the discriminate effect,

$$d_i(r,s) = x_{ir} - x_{is} \quad i \in \{1, \dots k\} \tag{2}$$

σ_i the standard deviation of X_i, and $r_{ji.12\dots j-1}$ is a partial coefficient of the correlation between X_i and X_j, $j < i$ (Radojicic et al. 2012; Jeremic et al. 2013).

To overcome the problem of negative coefficient of partial correlation, which can occur when it is not possible to achieve the same direction of variables, it is suitable to use the square I-distance (Jeremic et al. 2011b). It is given as:

$$D^2(r,s) = \sum_{i=1}^{k} \frac{d_i^2(r,s)}{\sigma_i^2} \prod_{j=1}^{i-1} 1 - r_{ji.12\dots j-1}^2 \tag{3}$$

The I-distance measurement is based on calculating the mutual distances between the entities being processed, whereupon they are compared to one another so as to create a rank (Seke et al. 2013). It is necessary to fix one entity as a reference in the observed set using the I-distance methodology. The ranking of entities in the set is based on the calculated distance from the referent entity (Jovanovic et al. 2012).

3. ANALYSYS – CASE STUDY

The results of the I-distance method, as well as a comparison of the I-distance and the Expenditure R&D (% of GDP) ranking, are presented in Table 1. A total of 41 countries have been included in the analysis. As can be seen from Table 1, Korea, Japan and Switzerland are the countries that top the I-distance method list. Korea, which comes in first for the I-distance method, takes third place in the Expenditure R&D rank, and, while Israel tops the Expenditure R&D rank, it takes eighth place in the I-distance rankings. A very interesting finding is that several countries show major oscillations in ranks methods, far more than other countries.

Table 1: I^2-distance rank, Expenditure R&D rank and Rank change

Country	I^2-distance	Rank I^2-Distance	Expenditure R&D (% of GDP)	Rank Expenditure R&D	Change
Korea	31,986	1	3,74	3	-2
Japan	29,848	2	3,36	6	-4
Switzerland	26,621	3	3,37	4	-1
United States	25,419	4	2,77	10	-6
Finland	25,309	5	3,78	2	3
Denmark	23,513	6	3,09	7	-1
Sweden	23,318	7	3,37	5	2
Israel	22,704	8	4,39	1	7
Chinese Taipei	19,486	9	1,84	19	-10
.	.	.	.	.	.
.	.	.	.	.	.
.	.	.	.	.	.
Russia	1,654	39	1,12	33	6
Romania	1,562	40	0,48	39	1
Mexico	1,529	41	0,46	40	1

For the past six years, the R&D funding for the top ten countries have remained mostly the same. There has been dramatic change however, in the extent of globalization involved in research, as well as shifts in the way funds are spent. While 2013 R&D investment growth was minimal in the U.S. and Europe, growth in most Asian countries, especially China continued. Asian R&D investment growth rates are expected to return to their pre 2013 levels in 2014 and 2015. The exception to this outlook may be Japan, which is more correlated with trends in the U.S. and Europe than with neighbouring Asian countries (Grueber and Studt 2013). Thus, implementing this concept in the I-distance framework is of great significance, because the results confirmed this order and such predictions.

As has been previously implied, one of the main objectives this paper is to present the relevance of R&D indicators. Namely, the I-distance method uses ten indicators and places them into a specific order of importance. This allows for a better understanding of the ranking results of the I-distance method, as well as for a better comprehension of the differences between the I-distance and Expenditure R&D ranking. In that, it is essential to establish an order of importance for the indicators since it provides an answer to the question: "What *are the variables that are the most relevant for measuring the R&D level of countries?*" Accordingly, a Pearson correlation coefficient of each variable with the I-distance value has been calculated as to determine the significance of input variables. These correlations are presented in Table 2.

Table 2: Variable importance as measured by correlation with I-distance

Variables	Correlation with I-distance
GERD as a percentage of GDP	0,869
Business Enterprise Expenditure on R&D (BERD) as a percentage of GDP	0,828
GERD per capita population (current PPP $)	0,712
Percentage of GERD financed by industry	0,588
Basic research expenditure as a percentage of GDP	0,536
Total researchers per thousand total employment	0,480
Total R&D personnel per thousand total employment	0,466
Higher Education Expenditure on R&D (HERD) as a percentage of GDP	0,398
Number of patent applications to the PCT (priority year)	0,254
Higher Education researchers as a percentage of national total	0,168

The results show that the first three variables are significantly correlated to the I-distance measurement values. According to the results of our research, the most significant variable for determining R&D level appears to be *GERD as a percentage of GDP*, where r =0,869, p<0,001. Very high relevant positions are taken by the three important variables: *GERD as a percentage of GDP, Business Enterprise Expenditure on R&D (BERD) as a percentage of GDP, GERD per capita population*. It is essential for lower-ranked countries to improve these most significant R&D indicators in order to improve their overall position in the ranking process.

The most important indicator in composite index, which is used to enhancing R&D indicators of OECD countries, is *GERD as a percentage of GDP*, with r^2=0,869 (p<0,01). In addition, *Business Enterprise Expenditure on R&D (BERD) as a percentage of GDP* have an almost identical contribution to the composite index, with r^2=0,828 (p<0,01). It should also be noted that *GERD per capita population (current PPP $)* plays a significant role in composite index, with r^2= 0,712 (p<0,01) (Isljamovic et al.2013).

Table 3: Overview of the most significant R&D indicators for the top 4 high placed countries and other 4 with the highest change in rank

Country	GERD as a percentage of GDP	BERD as a percentage of GDP	GERD per capita population
Korea	4,36	3,09	1307,77
Japan	3,34	2,61	1190,44
Switzerland	2,87	2,17	1364,96
United States	2,79	1,95	1443,13
Israel	4,20	3,54	1231,44
Chinese Taipei	3,07	2,28	1178,06
Russia	1,12	0,65	264,61
Slovakia	0,82	0,34	212,77

Table 3. presents the results of the three most significant indicators for the first four countries and those that have had the greatest change in rank respectively. We have previously seen that in the first place is situated Korea. Progress of two positions is explained by the fact that Korea has the best results for the three most important variables which leads to the first place in the I-distance ranking. Second place belongs to Japan. By achieving 2,61% *BERD as a percentage of GDP*, as one of the key indicators, Japan has progressed for

four places. As Japan is one of the leading economic powers, this result is not so surprising. Good results by all indicators, without major oscillations bring Switzerland in third place. This represents an improvement of one position. A very interesting progress from ten to fourth place achieved United States. Although there is an average *BERD as a percentage of GDP* for that position, what stands out and leads to a high position is the most accomplished *GERD per capita population* of 1443,13. In I-distance ranking Korea, Switzerland and Finland have kept a place in the top five countries. The most significant decline was recorded by Israel, having fallen from first to eighth position. Although it has good results in key indicators, very bad *Percentage of GERD financed by industry* has proven to be crucial stumbling point. By observing the poor ranking of countries, we noticed two great progresses of China and Slovakia for nine and ten position respectively. As you can see in the table 3, the reason for this rise of Chinese Taipei is located in very good results in all major indicators, while other indicators have larger oscillations. From all observed, we concluded that the use of I-distance method realized a more reliable ranking, since including far more R&D indicators than previous methodologies This has helped to clear up image, which countries such as Chinese Taipei and Slovakia have taken a much greater position than they previously had. We have noted that in addition to Finland, Switzerland and Korea which took the top five countries, have found also Japan and United States, although they had previously significant the lower positions. All other countries have had a slight change in the ranks.

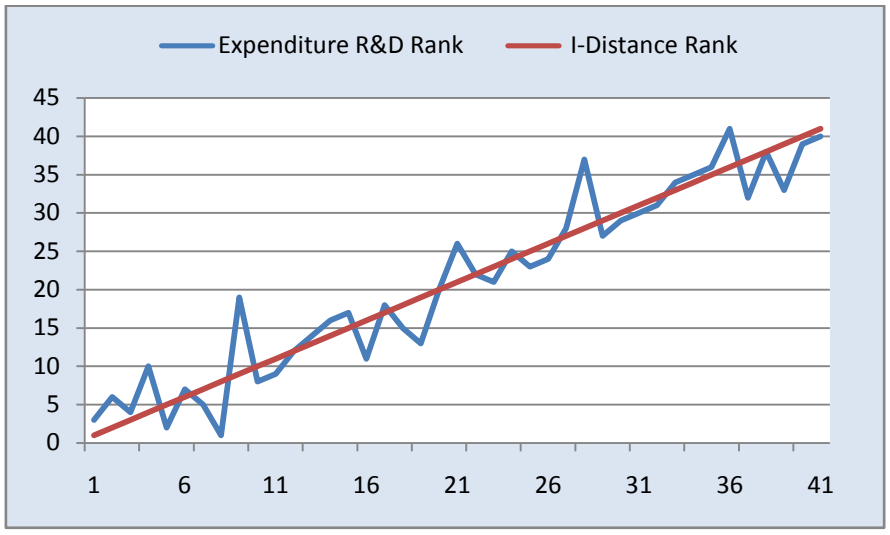

Figure 1: I-distance ranks and Expenditure R&D ranks

What we can see on the Figure 1. is the existence of several peaks, which are located below the red line, representing I-distance rank. These peaks represent Expenditure R&D rank, regarding a decline in the number of ranking positions to the I-distance rank. With the other hand we have two peaks one at the beginning which is a ascent Chinese Taipei from the 19th to the 9th position and another Slovak Republic from 37th to 28th position. However, the chart provides a better look at the relationship I-distance rank and Expenditure R&D rank.

4. CONCLUSION

Broadly speaking, innovation has become foundation for human progress. In today's world, ~~"~~We owe our existence to innovation. We owe our prosperity to innovation… We owe our future to innovation… Innovation isn't a fad—it's the real deal, the only deal. Our future no less than our past depends on innovation." (Hamel 2012)

So, a common indicator used to measure R&D investments across countries is represented by GERD: Gross Domestic Expenditures on Research and Development as a percentage of Gross Domestic Product (GDP) (R. Griffith, E. Huergo, J. Mairesse, B. Peters 2006). In this paper we have also showed the other crucial indicators for the relevant findings. False, incomplete or vague information causes confusion and mistaken investment decisions. If the governments want to improve the country rank, they need to invest in crucial variables.

Since the integration of R&D indicators into general development is an obvious necessity, we proposed the I-distance framework for evaluating and potentially enhancing R&D indicators of OECD countries. Our results emphasized the importance of Expenditure on R&D by incorporating the *GERD as a percentage of GDP*, *Business Enterprise Expenditure on R&D (BERD) as a percentage of GDP* and *GERD per capita population*.

Precisely those variables proved to be essential part of the I-distance framework for enhancing R&D indicators.

In I-distance ranking Korea, Switzerland and Finland have kept a place in the top five countries. As previously mentioned, while 2013 R&D investment growth was minimal in the U.S. and Europe, growth in most Asian countries, especially China, continued. The exception to this outlook may be Japan, which is more correlated with trends in the U.S. and Europe. Thus, implementing this concept in the I-distance framework is of great significance, because the results confirmed this order and such predictions. In addition to Finland, Switzerland and Korea which took the top five countries, have found Japan and United States, although they had previously significant the lower positions, which also shows the quality of our model.

In order to create a real, objective index of R&D indicators, we use the I-distance method which can easily integrate variables with different measurement units into one composite indicator. Moreover, our approach could be a foundation for an appropriate framework for evaluation and enhancing R&D indicators which might be in every way independent from subjectively formed weighting factors. We would also like to point out that the I-distance method proved to be quite useful in the first phases of research and that it emphasized important variables and provided us with the foundations for further elaboration of R&D indicators.

[2]Faculty of Organizational Sciences, University of Belgrade, ivan.todorovic@fon.bg.ac.rs

Abstract: *This paper deals with the relation of the level of GDP per capita and the total revenue in four major sport leagues in USA as the most developed sport market in the world. Business linked with sport is one of the most important and profitable parts of developed economy. Sport as an average individual perceives it today is a modern phenomenon of sophisticated approaches in marketing on the one and the expectances of profits from the investors on the other side. In this paper we prove there is a relation between the change of GDP per capita and total revenues in four major USA leagues. The results of this study show new insights to the perception of sport and can be a good indicator for further researches on that field.*

Keywords*: Sport industry, GDP per capita, economy, entrepreneurship, marketing, USA sport league*

1. INTRODUCTION

The main purpose of this paper was to illustrate the connection between sport industry and economy today. Current research focuses on the American sport market because the concept of private ownership reflects in their sport industry the most, relative to other countries. In other parts of the world government is much more involved in the ownership of sport entities but private investors are interested in commercially attractive sports. Other reason for choosing USA sport market is the fact the sport business is the most developed in there. Further, based on Forbes (2014) American sport companies have been found as one of the most valuable brands worldwide in 2013:

- 1. Nike Brand Value: $ 17,3 billion,
- 2. ESPN Brand Value $ 15 billion,
- 5. Under Armour Brand Value $3,7 billion etc.

The relationship between sports and the economy dates back to the first antique Olympic Games when athletes were compensated in either goods or species (Andreff, 2008). Then after sport was not very common phenomenon for some time. According to Ratten (2011) the entrepreneurship and sport management disciplines have grown significantly again in the past decade and further, entrepreneurship is an integral part of sports management and creates a competitive advantage for people and organizations involved in sport. This is somehow not surprising since in recent years renewed attention has been given to the role of entrepreneurship in economic development (Wennekers and Thurik, 1999) or as Ball (2005) argued it has become 'flavour of the month' both in practice and in the development of policy in political, industrial, educational and other setting. It is further recognized that the entrepreneurial process should lead to economic growth with the creation of successful growing companies like Microsoft, Intel and Sun Microsystems among others (Acs and Varga, 2005). From that view entrepreneurship is a necessary condition for economic growth and development (Cucculelli, 2012; Guloglu and Tekin, 2012; Audretsch et al., 2008). In this paper entrepreneurship is concerned as an interest of the individuals and groups in financing sport business in order to make a profit for investors.

This is an exciting time for sport industry around the globe. Not only sport is a multibillion dollar industry (many times over and still growing), but research that examines the management of sport in its various forms is expanding (Parent and Slack, 2007). Sport-related research can now be found in numerous subdisciplines within economics, including industrial organization, labor economics, and public finance (Kahane, et al. 2013). According to Humphreys and Ruseski (2008) several frameworks for defining the sports industry have been proposed; much of this research emerged from Europe, where government policymakers took an interest in estimating the overall economic importance of sport several decades ago:

- Gratton (1998) discusses a general method for estimating the economic scope of the sports industry, and points out that economic interest in sport extends well beyond the boundaries of professional sports. Gratton's (1998) approach uses existing national income and product accounting methods, essentially combing through existing national accounts data to identify sport-related sub-industries and aggregating across them;
- Davies (2002a, 2002b) adopts one national accounts approach, value added, to estimate the contribution of sport to the local economy in Sheffield, England.

In the course of time, sports industry started to grow and has become an important part in the business environment, thus inducing the interest of enterprises and investors. They saw in the sports industry a potential for growth and an opportunity for profits. Economics and finance adopt an instrumentalist notion of rationality in which the allocation of resources is the means (i.e., inputs) by which individuals and organizations seek to attain the end of maximizing their economic well-being (i.e., outputs) (Parent and Slack, 2007).

The most interested parts in financing the sports business are direct investors as also entrepreneurs that distribute and manufacture services and equipment related to professional or recreational sport. Further an interest in organizing sport events is seen also in governments that candidate for different challenges, from Olympic Games to World championships. According to Andreff (2008) the most features of the sports economy today are represented by: (1) sport shows and (2) sports mega-events. Indeed, it is impossible to separate the growth of corporate and government interest in the hosting of mega-events and the media discourse on place competitiveness from the commercialization of sport on a global scale and advances in communication technology (Whitson, 1998; Barney et al., 2002; Coles, 2003; Hall, 2006). Local, national, and international events have molded the sport industry into a shape not seen before (Hums, 2010).

Based on our literature review there seems to be, on the one hand an interest for many scholars for studying sport (e.g. Nicolau, 2011; Staurowsky et al. 2013; Taylor and McGraw 2006) and on the other hand for studying economic growth (e.g. Lewis, 2013; Kilian and Hicks, 2013; Kim and Kim, 2014) but the relation between sport industry income and economic growth measured as a change of GDP per capita till this research stayed an unexplored topic. Since Reynolds et al. (2000) claimed there is a correlation between the level of entrepreneurship (we propose that investors in sport business are mostly entrepreneurs) and between the growth of economy this paper tried to fill a literature gap on the field of GDP per capita and growth of sport business in USA.

There exists very little literature that uses the sports industry to study teammate effects in firms (Kahane, et al. 2013). So current study examines revenues of franchises in four most important sport leagues in USA; NBA, NHL, NFL, and MLB. We compared and examined the correlation between the growth of GDP p.c. and the revenue of franchises total income (gate revenues, sponsors, advertising, sale of merchandise etc.). The purpose of the paper was to examine the relation between the growth of economy, measured as GDP per capita with the growth of sport franchises measured as total revenue and set a theoretical platform for the further research.

2. THE DEVELOPMENT OF SPORT

Professional sports have emerged as a lucrative business, with many opportunities for sports marketers to flourish (Mason, 1999). Today sport as a whole concept is a business which affects us, even if we are not active athletes. For instance, many people buy clothes from sports companies that have transparent logos on the most visible places, computer games (FIFA, NBA live, Formula 1, etc), equipment, watches, and other products. As a condition for that, professional sports leagues provide a unique environment for marketing decisions and processes to occur, in a number of markets and at a number of levels, and should continue to be a growing segment within the broader, global, entertainment industry (Mason, 1999).

Organized sport has become an inevitable part of modern life. There are many definitions of sport; Westenbeek and Smith (2003) give following characteristics of sport:

- it has defined rules,
- it has complex organizational structure,
- it has a physical component included in the game,
- equipment and an appropriate playground are necessary,
- uncertainty is always present – there is always a chance of victory and defeat,
- modern sport demands cooperation and opposition.

Because of many specifics that are related to sport today, there is also another well-known definition of sport according to Parks et al. (1998) who defined sport as activity, experience or enterprise that is in correlation to fitness, recreation, professional sport or free time. Sport is very broad phenomenon. It can be on the one hand dance or jogging and on the other hand wrestling or chess. The sports industry's core sources of revenue can be divided into three main categories: broadcast rights, sponsorships (including licensing and merchandising), and ticketing and hospitality (such as entertainment and catering in sports venues) (Forbes, 2014). Nations, regions, cities and corporations have used mega-events to promote a favorable image in the international tourist, migration and business marketplace (Ritchie and Beliveau, 1974; Law, 2000; Malecki, 2004; Hall, 2006).

Professional sport industry is more regulated than recreational sport industry and has a different income structure. Income in professional sport comes from advertising, sponsorships, broadcasting rights, licenses, etc. It has become an industry which has the same »rules« as other industries. There must be multiple factors which can enable growth. Hardy (1986) defined three key factors of professional sport development:

- Sport product;
- Role of entrepreneurs and investors in product development;
- Types of different organizations and networks created by entrepreneurs.

An important role in the development of sport had also banks. Mandell (1984) stated that banks in USA played an important role in growth of sport industry by being flexible enough to finance new and poorly known industry. Beside this fact, which is true mostly in the later phases of sport industry development, the main credit for the success of sport industry is accorded to individuals who had a vision and saw an opportunity in investing in sport. Banks and other institutions played a more important role by financing franchises and enterprises and in this way accelerated the growth and enlarged the part of sport industry in the overall economy.

Profit seeking promoters and investors over-ran »hobby« investors and their organization became dominant in some sport (Hardy 1986). Sooner or later various leagues in the same sport merged in order to achieve larger market. Regardless of whether we observe NBA, MBL, NHL or NFL, they all have one thing in common; they were created by individuals (or group of individuals) who saw a business opportunity in sport. However, with increasing corporate involvement, an American model of private ownership is now influencing professional sport throughout the world (Nauright and Phillips, 1997).

2.1 Sport industry

There are several factors that potentially distinguish professional sports from other businesses, including stadium lease arrangements, monopolistic bargaining for broadcasting rights, territorial rights in predetermined geographic markets, and the capital depreciation of player contracts (Daly, 1977; Noll, 1974; Zorn, 1994). Based on development of sport organization we separate countries on four categories (Westerbeek and Smith, 2003):

- Highly developed: USA;
- Developed: West and middle Europe, Canada, Japan, Australia;
- In the process of development: South America, east Europe, China, India, and some South Africans countries;
- Undeveloped: Economically undeveloped countries, Africa, Asia.

Sport in general is a mix of different determinants as are equipment for practicing sports, related services (from services related to equipment to food services), sponsorship services (communication with potential buyers), promotion of health life and fair play etc.

3 ECONOMY AND SPORT

3.1 GDP per capita

Gross domestic product (GDP) is the monetary, market value of all final goods and services produced in a country over a period of a year and thus implicitly, and often even explicitly, identified with social welfare – witness the common substituting phrase ‘standard of living’ (van den Bergh, 2007). The real GDP (Gross domestic product) per capita is concerned as the most used indicator in defining the position of one economy over time or relative to that of other countries.

Guest and McDonald (2007) point out that the share in global GDP of a region is of interest because it indicates, to some extent, the economic, political and cultural importance of that region. Nevertheless, GDP deserves its special status because it represents an important bottom line: how much the market economy produces, and what it is worth (Boyd, 2007). In this study a GDB per capita purchasing power index was used. The objective behind a calculation of GDP per capita is to quantify the average amount of goods and services available to each person in an economy (Angeles, 2008).

3.2 Sport business

Entrepreneurship is a driver of change, innovation and employment in these industries and is crucial to meeting the rapidly changing demands of hospitality, leisure, sports and tourism consumers (Ball, 2005). Entrepreneurship is an important force behind success in any industry so in that manner also in sport.

According to Schumpeter's definition of an entrepreneur as an innovator, we could define James Naismith as an entrepreneur. In the 1892 he »invented« basketball – a basic product being a game, which nowadays involves a multi-billion industry. Money in that industry is generated by selling tickets, sport equipment, broadcasting rights, advertising, etc. on the one hand the invention itself it is not enough, for becoming an industry it needs to be organized, it needs promotion, league, rules and other definitions on the other hand. Then certain sport becomes a product which can be sold. A sport that can be sold in a form of a game ticket, broadcasting right, advertising space, and the name of the club becomes a brand with a value and can be sold to investors.

At one point the club owners and promoters noticed that people are prepared to pay for watching the game. The point where a spectator is prepared to pay for watching the game is the point where sport becomes a product (Hardy, 1986). This means that people are willing to trade money for their participation and satisfaction of their needs.

In this research we chose four major leagues in USA because they are the most prominent in the world, there play the best players from the entire world and these leagues are the most commercialized worldwide. The definitions of these leagues according to the data from their official websites are:

- MLB - Major League Baseball is the highest level of play of baseball in northern North America. It consists of the National League (founded in 1876) and the American League (founded in 1901).
- NBA - The National Basketball Association is the premier basketball league. It was founded as the Basketball Association of America in 1946, and adopted its current name in 1949, when the BAA partially absorbed the rival National Basketball League.
- NFL - The National Football League was founded in 1920 as a combination of various teams from regional leagues such as the Ohio League, the New York Pro Football League, and the Chicago circuit. The NFL partially absorbed the All-America Football Conference in 1949 and merged with the American Football League in 1970.
- NHL - The National Hockey League was founded in 1917 as a breakaway league from the Canadian National Hockey Association (founded 1909), taking all but one of the NHA's teams. The NHL partially absorbed the rival World Hockey Association in 1979. There are 30 teams, with 23 in the U.S. and 7 in Canada.

4. METODOLOGY

Based on the upper theory the following hypotheses were formulated:

H1: Total revenue in MLB is positively related to GDP p. c. in USA.
H2: Total revenue in NBA is positively related to GDP p. c. in USA.
H3: Total revenue in NFL is positively related to GDP p. c. in USA.
H4: Total revenue in NHL is positively related to GDP p. c. in USA.

The selected period for research was chosen for nine years from 2004 to 2012. The data for a research were gathered from an online free public bases. The data for GDP per capita p.p. in USA were gathered on the web site of the CIA (2014). This data show GDP on a purchasing power parity basis divided by population as of 1 July for the same year.

Table 1: GDP p.c. in USD in 10^3

Year	GDP p.c. in USD in 10^3
2004	40,1
2005	41,6
2006	44,0
2007	45,8
2008	46,9
2009	46,0
2010	47,2
2011	49,0
2012	52,4

The data for total revenue for four major leagues in USA were gathered on Forbes (2014). Forbes is an American business magazine owned by Forbes, Inc. published biweekly and it features original articles on finance, industry, investing, and marketing topics. When the data were not available on Forbes we gather the data from the official web sites of four major leagues in USA (MLB, NBA, NFL, NHL, 2014).

Table 2: Total revenue in four major leagues in USA in 10^9 USD

League/Year	2004	2005	2006	2007	2008	2009	2010	2011	2012
MLB	4,3	4,7	5,1	5,5	5,8	6,6	7	7,2	7,5
NBA	2,9	4,2	3,4	3,6	3,8	4	4,7	4,9	5
NFL	6	6,2	6,5	7,1	7,6	8,5	9,3	9,4	9,5
NHL	2,2	2,2*	2,3	2,4	2,7	2,7	2,9	3,2	3,3
Sum	15,4	17,4	17,3	18,6	19,9	21,8	23,9	24,7	25,3

**due to a strike in NHL in 2005 we took the arithmetic mean of 2004 and 2006 values*

5. RESULTS

A regression analysis was used to determine the strength of the relationship between the independent variable GDP p.c. and other dependent variables (total revenues in four major USA leagues) in statistical analytical program SPSS for Windows.

Table 3: Statistics for variables

		GDP p.c.	MLB	NBA	NFL	NHL	SUM
N	Valid	9	9	9	9	9	9
	Missing	0	0	0	0	0	0
Mean		45,8889	5,9667	4,0556	7,7889	2,6556	20,4778
Median		46,0000	5,8000	4,0000	7,6000	2,7000	19,9000
Mode		40,10[a]	4,30[a]	2,90[a]	6,00[a]	2,20[a]	15,40[a]
Std. Deviation		3,71330	1,15758	,71434	1,42342	,41567	3,60131

The frequencies for the variables are shown in Table 3. The highest mean value among four major leagues in USA has NFL (7,78 in 10^9 USD) and the lowest NHL (2,65 10^9 USD).

Table 4: Regression Model Summary

Model	League	Adjusted R Square	Standardized Coefficients Beta	t	Sig.
1 (constant) GDP p.c.	MLB	,837	,926	6,481	,000
	NBA	,565	,787	3,378	,012
	NFL	,765	,891	5,201	,001
	NHL	,856	,935	6,976	,000

The results of the regression analysis show that all four hypotheses were confirmed.

H1: Total revenue in MLB is positively related to GDP p. c. in USA.
The relationship was found positive, high and significant (stand. coefficient 0. 926), with variance explained of 83,7%. T- test value was found as good (t = 6,481) and show that the relation is statistically significant at Sig. = 0,000.

H2: Total revenue in NBA is positively related to GDP p. c. in USA..
The relationship was found positive, high and significant (stand. coefficient 0. 787), with variance explained of 56,5 %. T- test value was found as good (t = 3,378) and show that the relation is statistically significant at Sig. = 0,012.

H3: Total revenue in NFL is positively related to GDP p. c. in USA.
The relationship was found positive, high and significant (stand. coefficient 0. 891), with variance explained of 76,5 %. T- test value was found as good (t = 5,201) and show that the relation is statistically significant at Sig. = 0,001.

H4: Total revenue in NHL is positively related to GDP p. c. in USA.

The relationship was found positive, high and significant (stand. coefficient 0. 935), with variance explained of 85,6 %. T- test value was found as good (t = 6,976) and show that the relation is statistically significant at Sig. = 0,000.

The results show that the relation between the growth of GDP per capita and total revenues of franchises in four largest US sport leagues is positive and very strong.

5. CONCLUSION

Sport is a dynamic business which changes constantly. On the one side the sport business tries to fulfill the needs on the market and satisfy expectations from the crowds. Thus on the other site inventors or the leading individuals in certain sport invent new games, new rules and new products or services related to that sport. When people follow new game it has a potential to become a promising business. In the frames of increasing the volume of sport industry, marketing and world known sport stars contribute to the revenue of sport organizations and realization of the aims. Entrepreneurial approach is crucial for development, promotion and commercialization of new sport. Sport and the story behind have big impact on people. Not only that people spend hours watching their favorite team or an individual but they are also prepared to invest their money to be a part of the story.

In current study we showed that the total revenue in four major leagues in USA is dependent from GDP per capita. This is not surprising since more money will people have the more will be able to spend also for sport.

Like every study, this one also has some limitations. One of them could be the fact that in current statistical analysis we used total revenue from four major USA leagues. It would make sense to develop the model with all incomes from all sport business in one country and compare it with GDP p.c. Another limitation could be the fact that this study could not be applied to all countries because of different popularity of different sport (e.g. soccer is popular in Europe vs. baseball is popular in USA). But these limitations present further research opportunities. Next research should be done with the integration of sport industry as a whole business and the comparison of the situations on different markets.

AIRPORT CHARGES AND DISCOUNTS: IMPLICATIONS FOR AIRLINES OPERATED AT AIRPORTS IN SOUTHEAST EUROPE

Milica Kalić[1]; Jovana Kuljanin[2]
[1]University of Belgrade – Faculty of Transport and Traffic Engeneering, m.kalic@sf.bg.ac.rs
[2]University of Belgrade – Faculty of Transport and Traffic Engeneering, j.kuljanin@sf.bg.ac.rs

Abstract: *Deregulation and liberalization processes during 1990s have led to tremendous changes in airline industry forcing all participants, primarily airlines and airports, to actively tailor their business strategy. In order to sustain profit in highly competitive market, a number of airports across Europe offer variety of airport incentives schemes which rely on airport charges discounts as a part of financial incentives as well as on other incentives. This paper illustrates the airport charges systems at several airports in the region of Southeast Europe. Moreover, paper aims to discover the impact of discounts within specific airport charges systems on airline financial performance.*

Keywords*: Airport charges, Financial incentive schemes, Airport charges discount, Airlines*

1. INTRODUCTION

The completion of the three liberalization packages in the European Union in mid-1992 has significantly increased the competition among the existing airlines, but has also led to penetration of new rivals on the market. The advent of low-cost carriers (LCC) has become one of the most important occurrences bringing a number of innovations in air transport industry. Liberalization and the entrance of LCC which offer significantly lower fares have forced the traditional flag carriers to compete for the first time (ELFAA, 2004). Prior to this event, the flag carriers were protected by governments who have even been closely involved with their daily operation and fares that were set through bilateral agreements between states. The aim of the liberalization process was to remove the regulatory protection that most of the airlines had received in the past. This led to serious financial problems at various European air carriers while some of them could not survive in the new environment and went bankrupt.

In order to retain market share and sustain profit growth, traditional airlines had to develop their own strategies which aim to reduce labour costs or increase productivity within the mainline airline operation. Mergers between traditional network airlines across national border, as well as establishing alliances comprising large number of carriers, have been deemed an appropriate response to the challenges imposed by fierce competition on the European market. Some airlines even set up a low-cost carrier subsidiary, while some others transfer services to regional partners.

However, liberalization has also a positive impact on the increased competition between airports bringing lower charges and more efficient services. IATA (2012) argues that a vast majority of European airports evolved from merely infrastructure providers into fully fledged businesses in their own right due to the deregulation and liberalisation of the European aviation industry during 1990s. Therefore, a number of airports in Europe tries to attract new airlines to start operating their services or stimulate existing airlines to expand their offers mainly through discounts on airport charges or/and other financial and non-financial incentives. These arrangements are very well known in the literature as Airport Incentive Scheme. The core strategy of majority incentives schemes considers the reduction of airport charges which are levied on aircraft operators for using airport facilities and services. Classification of airport charges is not standardized across European airports, but some of them are common and charged by almost each airport (landing charges, passenger charges and parking charges). Having in mind that around 3.5% to 5% of an airline's total costs are directly related to airport charges, it is not surprising that many airlines will seek those airports that can provide a variety of discounts.

The goal of the paper is to investigate the different types of incentive scheme employed by several airports situated in region of Southeast Europe (SEE), as well as financial implication that these

incentives may have on airline performance. The special attention is paid to discounts on airport charges since they represent a marketing tool used by airports that aim to increase traffic.

The paper is organizes as follows. Section 2provides an overview of airport charges on several airports situated in region of Southeast Europe (SEE). The essential indicators of current air transport market in the region of SEE are presented in Section 3. Section 5 investigates the different types of incentive scheme employed by specific airport from the sample, as well as their financial implication that these incentives may have on airline performance. Conclusion is given in Section 6.

2. AIRPORT CHARGES

Airport charges are charged to airport users for the use of airport facilities (EC, 2014). In other words, airlines that operate from specific airport are obliged to pay certain amount of money to cover the airport's costs for providing facilities and service. It is clear that these charges are indirectly paid by passengers and freight customers via the ticket price or freight forwarding fee. Nowadays, there is no straightforward classification of airport charges in Europe. Rather, airports adopt classification of airport charges that is the most suitable for them, although they may slightly vary one from another. However, airport charges systems have to comply with regulatory requirements set by authorities. Despite large combinations of different types and methods existing in practice, vast majority of airport charges systems display common elements. According to the ICAO (2009), airport charges contain several elements:

- landing charges based on aircraft weight formula,
- parking and hangar charges depending on aircraft attributes (weight, dimensions)and length of stay,
- passenger service charges levied through the aircraft operators where practicable,
- security charges,
- noise-related charges,
- emissions-related aircraft charges to address local air quality (LAQ) problems at or around airports.

Terms 'fees' and 'charges' are used interchangeably in this paper. Landing fees are very often levied as take-off fees, or fees per landing and take-off, the calculation of which is based on aircraft weight. These charges are sometimes called runway charges. Some airports use different calculation of landing charges for airlines operating domestic or international routes. Majority of airports considered in this paper levied landing charges based on Maximum Take-Off Mass(MTOM) either giving the price of service per ton or in the intervals of aircraft mass.

Passenger fees are commonly charged by the airport per on-board departing passenger and therefore represent a variable cost for airlines. These charges are normally billed to the airline, which then passes the cost onto the passenger. Airport often imposed different charges for passengers who fly international routes and those who fly domestic ones. Passenger fees can very often be combined with security service fees, which is a common practice especially at airports in Europe.

Aircraft parking fees are related to leaving an aircraft stationary at an airport. Parking charges are normally levied on a time basis, but can also be levied by weight or size of aircraft.

Ground-handling fees normally consist of the costs for handling of aircraft, passengers, baggage in arrival and departure. They are often levied on aircraft weight basis and given in interval prices for most airports from the set.

Moreover, in last few years a number of airports, especially those congested, charges airlines for noise they produce in the vicinity of the airport. These fees are levied by aircraft types that are categorised each according to their relative impact. More recently, some airports have also introduced emissions charges, aiming at an improvement of the local air quality at the airport and its surroundings. Noise charges, as well as emission charges, have not yet been introduced into charges systems of airports investigated in this paper. All the above-mentioned charges can be subject to modification to a certain level since they represent the essential part of incentives schemes developed by the large number of airports across Europe.
Although wide varieties of financial and non-financial incentives are currently available at a number of airports, the focus of this research is on financial incentive, particularly the part thereof that deals with

different discounts on airport charges. In addition to discounts on airport charges, financial incentives also encompass direct payments to airlines and different types of risk sharing arrangements. Reduced charges in Europe often cover passenger charges and landing fees in an all inclusive per passenger charge.

3. OVERVIEW OF SOUTHEAST EUROPE AIR TRANSPORT MARKET

The paper investigates the structure of airport charges at airports situated in following countries of Southeast Europe: Serbia, Montenegro, Croatia, Macedonia, Bosnia and Herzegovina and Albania.

Table 1: Air transport market indicators in 2012

	Serbia	Montenegro	Croatia	Macedonia	Bosnia & Herzegovina	Albania
Population	7.1 million	0.6 million	4.4 million	2.1 million	3.8 million	3.2 million
GDP per capita	5190 US$	7041 US$	13879 US$	4565 US$	4556 US$	4000 US$
Total air pax (million)	3.39	1.35	5.96	0.91	0.67	1.66
Number of airports	2	2	8	2	4	1
Primary airport	Belgrade	Podgorica	Zagreb	Skopje	Sarajevo	Tirana
IATA code of prim. a/p	BEG	TGD	ZAG	SKP	SJJ	TIA
No. of paxat prim. a/p (million)	3.36	0.64	2.34	0.83	0.58	1.66
Flag carrier	JAT Airways, from 2014 Air Serbia	Montenegro Airlines	Croatia Airlines	-	B&H Airlines	-
Other a/p (more than 0.5 mil.pax)	-	Tivat (TIV)	Split (SPU), Dubrovnik (DBV)	-	-	-
Other a/p (0.3 - 0.5 mil.pax)	-	-	Zadar (ZAD), Pula (PUY)	-	-	-
Other a/p (0.05 - 0.3 mil.pax)	-	-	Rijeka (RJK)	Ohrid (OHD)	Mostar (OMO)	-
Other a/p (less than 50 000pax)	-	-	Osijek (OSI), Bol (BWK)	-	Banja Luka (BNX), Tuzla (TZL)	-

Table 1 provides an overview of air transport market indicators in respective countries. It is evident that Serbia has the largest population with around 7.1 million passengers, followed by others the population of which ranges from 4.4 million (Croatia) to 0.6 million (Montenegro). On the other hand, Croatia has the highest value of GDP per capita (in current US dollars) which is also considered as a key driver of air travel demand. Tourism highly contributes to the country's overall GDP because of the seacoast and large number of islands which need regular air transport service for passenger mobility all year round and especially during the summer season. Montenegro has also developed summer tourism due to Adriatic coast. It has to be emphasized that all countries considered, except Croatia, have no domestic air traffic. However, the major common denominator for all selected countries is that they are all emerging markets recently passed (or still passing) through the process of transition.

4. AIRPORT CHARGES AND DISCOUNTS AT AIRPORTS IN SOUTHEAST EUROPE

Certain airport charges can significantly vary at different airports. Therefore, it is more useful to analyze total amount of charges levied rather than compare specific airport charges within airport

charges system. Graham (2008) shows that the total amount of airport charges and fees for A319 aircraft varies in the range of 6:1, thus amounting to less than EUR 1000 at Mumbai and Dubai airports, but reaching EUR 5000at Boston and London Heathrow airports.

This paper illustrates the airport charges imposed by different airports located in Southeast Europe, as well as their respective financial incentive schemes within airport charges systems. In order to enable the comparison across the airport set, several hypothetical premises were introduced. Firstly, all flights are operated by Airbus 319, with capacity of 156 seats and MTOM which equals 75.5 tones. Secondly, the assumed average load factor will be 80%, which means that total number of passengers per flight accounts for 125. Finally, an airline operates three flights on a daily basis, which accounts for 1095 flights annually.

Table 2: Prices of airport charges

Airport	Landing	Lighting	Handling+ Centralizedinfrastructure + Use of Air Bridge	Parking	Pax int. service + Security charge (per pax)
BEG	8.1€/t	2.46€/t	(602.64 +335.36 +185) €	1.8 €/t	(12 (T1) + 3.3)€ (16.5 (T2) + 3.3)€
INI	8.5 €/t	2.1 €/t	(902 + 0 + 0)€	-	14 €
SJJ	14 €/t	40% Price of Landing	1388 €	2.55 €/t	18 €
ZAG	6.5 €/t	-	900 € + (1.5 €/t + 1.3 €/pax) +0	1.5 €/t	(15 + 6.5) €
SPU	8.5 €/t	-	939 € + (0.9 €/t + 0.5 €/pax) +0	4 €/t	(10 + 2) €
DBV	12.70 €/t	-	964 € + (96.40 € + 1 €/pax) +0	3.3 €/t	(11 + 2) €
ZAD	11.70 €/t	25% Price of Landing	(927 + 51.78+0) €	4 €/t	12 €
TGD	9.5 €/t	25% Price of Landing	775 €	2 €/t	15 €
TIV	9.5 €/t	25% Price of Landing	1100 €	2.5 €/t	15 €
SKP	7.6694 €/t	25% Price of Landing	(995 + 0 + 40) €	1.6 €/t	(11.50 +6) €
OHD	7.6694 €/t	25% Price of Landing	760 €	1.6 €/t	(10.20 +6) €
TIA	650 €	540 €	1320 €	140 €	(12.50 + 2) €

Table 2 shows a comparative analysis of different charges within specific airport charges systems in SEE. All data used in the research are based on the information published by respective airports and listed in the References. It has to be mentioned that calculation of landing fees, parking fees and lighting and part of centralized infrastructure (but only in some cases) are based on MTOM so that every part of a started ton is calculated as a whole ton. Lighting fees are levied in several cases: adverse weather conditions, during the night and on pilot request which will be the subject of Air Traffic Control (ATC) decision. All airports in the set calculate handling fees according to the categories based on MTOM by defining the price of each, although these categories may vary across the airports. For example, Macedonian airports and Belgrade Airport provide a list of handling fees with fifteen categories, airports in Montenegro and Croatia have thirteen, while Tirana Airport has only eleven. Concerning parking fees, airlines are granted first four hours free of charge at all airports considered. Passenger fees shown in Table 2 consider only passengers on international routes. It can be seen that some airports do not charge security fees. Total amount of passenger and security fees ranges from EUR 12 (Zadar Airport) to EUR 21.5 (Zagreb Airport).

Figure 1 presents the total amount of airport charges which an airline has to pay for a single flight operated from specific airport. The minimum amount which an airline will have to pay for using airport facilities and service is EUR 3216 (Split Airport), while the maximum amount is EUR 4652 (Sarajevo Airport). Average value of airport charges is EUR 3758 with standard deviation of EUR 480.

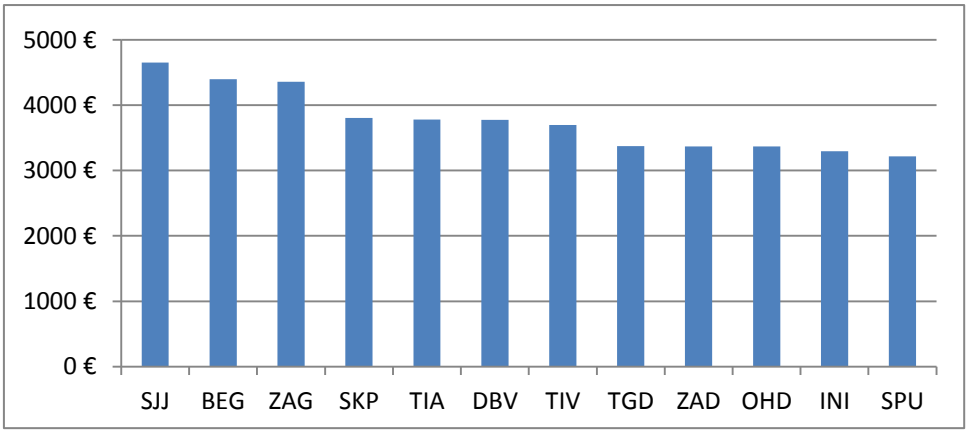

Figure 1: Total airport charges per one flight

Among the charges indicated above, passenger fees together with ground handling fees comprised the large proportion of aeronautical revenue that most airports in the region of SEE received from their users. As observed from Fig 2, the proportion of passenger service fees is 62% in the case of Zagreb Airport and 43% in the case of Dubrovnik Airport.

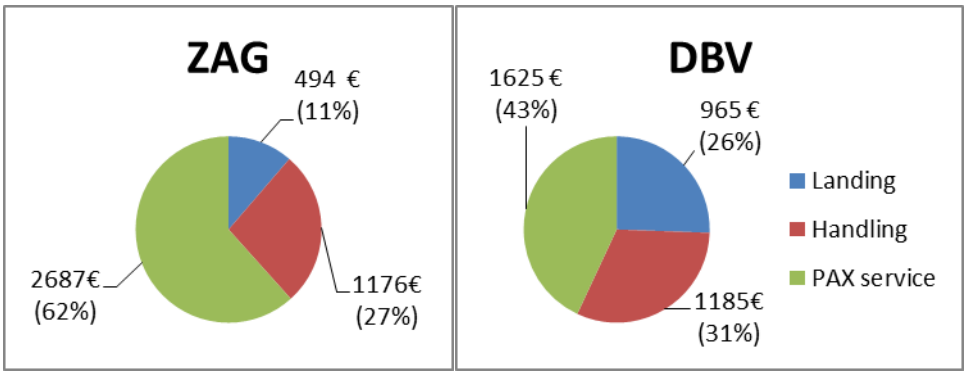

Figure 2: Share of landing, handling and passenger service fees in total airport charges

The amount of total airport charges levied on an annual basis for all flights carried by one aircraft and schedule of three flights per day is given in Fig 3. The average value of total airport charges for all airports is EUR 4.2 million.

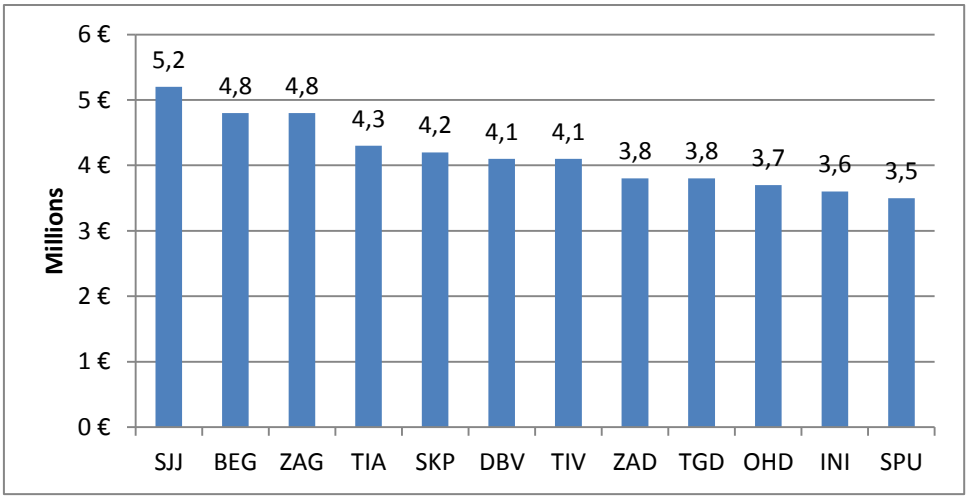

Figure 3: Total annual airport chargesfor all flights

The analysis of the airport incentive schemes operated by airports in SEE tends to display a few distinct characteristics, although some similarities with current practice in Europe may also be observed. The majority of airports investigated in this study suffer from transparency of their financial incentive schemes which an airline can obtain by flying from specific airport, although there are indications that these airports have developed financial schemes.

Among airports observed, Tirana Airport provides the most detailed information on financial incentive scheme offered to airlines. These discounts are published on its website and applicable to each airline which meets the imposed criteria. For airlines that operate or planning to operate from Tirana Airport the following incentives are available: new route incentive for scheduled traffic, additional frequency incentive for scheduled traffic, new route incentive for charter traffic, off-peak discount, non-satisfactory load factors, larger aircraft incentive, airport growth financial support, support for transit traffic and financial support on prepayment. For example, the airport offers the following two year scheme for introducing a new scheduled route: 100% reduction of the published landing, parking and lighting fees in the first twelve months and 10% reduction of ground handling fee, while for the subsequent twelve months 50% reduction of the published landing, parking and lighting fees is offered.

The airports from the set situated in Croatia, Zagreb Airport and Split Airport, have the same mechanism of calculating the reduction in charges (handling charges) based on total number of passengers carried in the previous year, although the percentages of reduction are not consistent. These two airports have transparent discounts on airport charges published on their Internet sites. Additionally, Zagreb Airport offers special anniversary discounts on handling charges for airlines which operate from this airport for a defined period of time.

Two Macedonian airports, Skopje Airport and Ohrid Airport, are operated by *TAV Airports Holding*. There are evident indices about the existing airport scheme, which are not fully published on respective airports' Internet sites. However, it is found that Ohrid Airport offers a reduction in the landing fee if an airline has more than fifty landing within one month.

Airports of Montenegro, namely Podgorica and Tivat airport, provide only partial information about conditions upon which an airline could obtain certain level of reduction in airport charges. Depending on the number of aircraft movements carried, these two airports provide reduction of up to 20% for handling charges. Moreover, airlines are also granted a promotional discount for new destination up to 30% in landing and handling fees for the period up to three years.

Finally, to the best of our knowledge, Belgrade Airport, Sarajevo Airport, Dubrovnik Airport and Zadar Airport do not provide any public information about potential financial incentive offered to airlines.

Table 3: Discounts on airport charges

	SPU	ZAG	OHD	TIV	TGD
Discount on	Handling	Handling	Landing	Handling	Handling
Criteria	Number of passengers in last year	Number of passengers in last year	Number of aircraft movements in one month	Number of aircraft movements	Number of aircraft movements
Number of carried pax or number of movements	136875	136875	90	1095	1095
Discount	55%	6%	25%	20%	20%
Price without discount (annually)	1028205 €	985500 €	638248 €	1204500€	848625 €
Total discount	565513 €	59130 €	159562 €	240900 €	169725 €
Price with discount (annually)	462692 €	926370 €	478686 €	963600 €	678900 €

Table 3 illustrates the discounts offered by respective airports with their implications to possible savings for an airline. It has to be emphasized once again that all calculations are based on the generic examples: airline operating with one aircraft (A319 with 156 seats) and a schedule which assumes three flights per day.

The discounts offered to airlines operated from the airports considered range from approximately EUR 60000 to more than EUR 0.5. It can be observed that the largest amount of savings can be achievedwith discount provided by Split Airport, while the smallest discount is offered by Zagreb Airport.

5. CONCLUSION

Revolutionary changes introduced in air transport industry as a result of deregulation and liberalization during 1990s have evolved intense competition not only between airlines, but also between airports. In such circumstances, most European airports were transformed from passive providers of infrastructure to commercially oriented companies. In order to stimulate the traffic growth which ensuressufficient revenue, a vast majority of airports have recently implemented incentive schemes for airlines within their airport charging system. On the other hand, airlines that strive to increase profit margins have seen these incentives as a suitable tool for additional cutting of their costs.

This paper provides classifications of airport charges levied at several airports situated in Southeast Europe. Additionally, a broad investigation of financial incentive, especially of those parts related to discounts on airport charges, has been conducted. The resultsshowfinancial discounts imposed by specific airport and their implications to airlines. The investigation also reveals that many airports from this sample suffer from the transparency of incentives schemes. Since the European Commission requires the principle of transparency and non-discrimination, the airports in this region should invest significant efforts to achieve this goal in the future.

PROJECT MANAGEMENT

CHALLENGES OF IT PROJECT PORTFOLIO SELECTION*

Dejan Petrović, Marko Mihić, Vladimir Obradović
Faculty of Organisational Sciences, Belgrade

Abstract: *This paper presents possible challenges in the process of IT project portfolio selection. The paper begins with explanation IT project portfolio management. IT project portfolio management needs to ensure that the group of IT projects support achievement of the goals of the corporate strategy. The paper considers key aspects of IT selection process and introduces organizational support for IT project portfolio selection. An established PMO that is actively supported at the executive level can help solve problems with project selection and initiative approval.*

Key words: *project management, project portfolio management, project selection, IT project, portfolio management office*

1. INTRODUCTION

The task of the IT project portfolio management is to ensure a consistent approach to the classification, selection, prioritization and planning of the right IT projects and programmes in the company (Reyck, Grushka-Cockayne, Lockett, Calderini, Moura, & Sloper, 2005). The aims of IT project portfolio management are as follows:

- optimization of IT project portfolio results (not an individual project or portfolio);
- harmonization of IT projects and programmes with the company's strategy;
- selection of IT projects and programmes to be realized;
- defining IT projects and programmes priorities;
- discontinuing or stopping IT projects or programmes;
- coordination of internal and external resources for IT projects and programmes; and
- organizational learning between IT projects and programmes.

2. IT PROJECT PORTFOLIO MANAGEMENT

An efficient realisation of an IT project is said to be a key factor of the company's business success. This is, however, only partly true. The achieved competitive advantage is not the result of efficient work on a project only. The fact that companies conduct real IT projects is important. IT project portfolio management is meant to ensure a successful execution of the company's strategy through the most effective and most efficient execution of respective IT projects possible (Verhoef, 2002). It is closely related to the role of the top management in the company and with the key decision makers in creating the environment in which set goals can be achieved.

According to Cooper, Edgett and Kleinschmidt (1997), works dealing with the issues of project portfolio have appeared since 1970. In these works, elements such as "selection of research-developmental projects", "resource allocation in research-developmental projects", "project prioritization"and "portfolio management" are analysed.

The majority of works on this topic deal with the problem of portfolio management by defining the optimization methods and techniques (Cooper, Edgett, & Kleinschmidt, 1998). According to these works, the portfolio management problem appears to be a limited optimization in the conditions of uncertainty: multiproject and multilevel model of decision making should be achieved by means of mathematical programming. The starting models for the selection of projects were mathematically oriented and they used techniques such as linear, dynamic and full number programming. The aim was to develop a portfolio of new and existing projects to maximize some function goals (e.g., the expected profit) as the issue of setting resource limitation.

The application of these methods immediately revealed some difficulties in solving the problems of IT portfolio management (Verhoef, 2002). Contrary to the many methods developed in an early stage of the

* The paper is a result of research within the framework of Project No.179081, named: "Researching contemporary tendencies of strategic management using specialized management disciplines in function of competitiveness of Serbian economy", which is supported by the Ministry of Education and Science of the Republic of Serbia

approach to this problem, none of these could be adequately implemented in the IT project portfolio management.

The IT projects are recognized as a vital fact for any company. The influence of the IT projects upon the future of any company is certainly strong since they are related to all the important events and processes in the company, be it the development of a new product, the implementation of a new service process, the change in organizational structure or the launching of a new business (Russell, 2003). The IT project portfolio is a collection of projects which together with other projects make the strategy of the company's investments.

The project portfolio management means the implementation of knowledge, skills, methods and techniques upon a set of projects in order that the needs and expectations of the company's investment should be attained and even exceeded (Dye & Pennypacker, 1999). This calls for a balance to be made between strategic and tactical requirements. The IT project portfolio management usually requires that a definition should be made of what is possible and what is necessary. Balancing between the possibilities and the needs generally results in finding the best possible solution within limited resources.

There is a gap today between a majority of management models and the environment in which the IT projects are executed. These models emerged in the circumstances in which it was possible to predict the consequences of certain decisions and the project's impact upon the company and the community in general. A successful IT project portfolio in the project environment nowadays is characterised by a number of non-economic features, uses an iterative budgeting process and what appears to be the best decision for an organization may not be viewed as such for all its stakeholders. Today's the IT project environment is much more complex compared to a majority of management models, and such a complexity must be taken into account in defining „the best" IT project portfolio to be executed.

The IT project portfolio management focuses upon a clear definition of the values the projects bring to the company (Kaplan, 2001). The IT project portfolio management is applied to all projects, to making decisions as regards the selection and prioritization, which is in accord with the strategic goals and the development of the company.

Alongside decision making on the IT projects execution within a portfolio, there is another process of the final approval of the very beginning and of some specific phases in the IT project execution underway. There certainly must exist a lower level of decision making that takes place in the real time of the IT project execution. Decisions within the IT portfolio are made during the given time intervals, all the projects being discussed together, whereas at a lower level decisions are made on individual IT projects at any moment the project passes from one execution phase into another. All this may cause conflicts between the two levels of decision making, since in decision making processes we most frequently deal with different people, even different criteria.

Decision making at the portfolio level, although taking all the IT projects together and making a comparison among them, does not pay enough attention to individual projects (Levine, 1999). On the other hand, the lower level of decision making focuses upon only one IT project, leaving out all the other IT projects. It is of great importance for the company that these two different decision making processes be integrated and harmonized. The dominance of either of the two is unwelcome in any company.

The weakness of the IT portfolio model appears to be insufficient accuracy or relevance of the facts on the basis of which the processing, the analysis, and the conclusion procedures are conveyed and then a final decision is made. The models used in IT portfolio decision making are by far more advanced compared to the input data. Financial indicators, criteria and the processing and presentation methods themselves may be well created and functional for making the final decision. However, all these calculations and use of the seemingly appropriate criteria may lead to a wrong decision, if the data used are incorrect, inaccurate or unreliable (Morris, 1997). If we wish to enhance the success of an IT portfolio decision making process, we must ensure that we have as high a quality of input data.

In their research Cooper, Edgett and Kleinschmidt (1997) have found that the main problems the companies encounter in the project selection and portfolio management are the following:

1. The project portfolio does not reflect the strategy of the company;
2. The portfolio quality is poor;
3. The checking procedures and the decision making procedures at check points are inefficient;
4. Scarce resources and lack of focus;
5. Simplification of the product development projects.

The issue raised in the companies that apply the project-oriented organization concept is whether the undergoing IT projects should be discontinued or deprioritized in favour of certain better quality projects that we become acquainted with. On one hand, we should try to keep the resources engaged in IT projects flexible and capable of shifting from one project to another, as the need may be. The reason for such an attitude is found in the need that the company's management be granted an opportunity to allocate resources in a best possible way, regardless of their current use. On the other hand, there are attitudes that the resources involved should remain in the project all along, regardless of whether there is a more attractive project in sight. Here the issues of continuity and the morale of the project team and the project manager appear to be considerably more important than an optimal allocation of resources. Such a view resulted from the attitude that discontinuing and restarting the project would mean a substantial loss of resources and time, that a shift from one project to another would by all means affect the projects and that a launch and discontinuation or a final suspension of a project would all need additional time and costs (Wysocki, 2004).

The new IT projects always appear better than those under way, therefore the resources in the projects that are in the final phases are usually transferred as a support to new projects. Such support sometimes results in the projects deprived of resources in this way being never completed (Thomas, 1993). The far-reaching consequences and damages for the company fail to be perceived in that moment.

There is no universal rule on how we should act or set the company policy in such cases (Norton & Kaplan, 2003). It is certain that the long-term IT projects call for a continuity in order that satisfactory results should be obtained. On the other hand, there is a need that the company responds to changes in the market by introducing a flexible model of resources distribution. Many companies find that using only financial methods and criteria in giving priorities to IT projects prove inappropriate. The reasons most frequently lie in the financial simplification, which results into an unreliable image of the project, especially prior to the launching of the project, when the prioritizing is most necessary, but also, during the execution of the project. Analyses carried out upon executions of projects have shown that the evaluations of key parameters on the bases of which decisions are made were significantly incorrect.

Statistical implications of the portfolio choice are complex and varied. They include the analysis of both internal and external factors of the company, the company's market position, the strengths and weaknesses of the company. These analyses may be used to create a wide perspective of strategic directions as well as specific initiatives for achieving competitive advantage (Cleland, 1999). Such a procedure may be used in developing focused goals of the IT project portfolio and determining the necessary resources for its support. In estimating the strategic position of the company a portfolio matrix is used, where the different criteria for the company positioning are presented in one or more graphs within two description dimensions. A decision maker may use such a presentation to estimate the current position as well as the position the company wishes to occupy in the future. It is clear that the company's strategic direction must be defined prior to the analysis of the individual projects for the IT project portfolio. Successful organizations conduct a broad strategy preparation and planning before individual projects are analysed.

Upon determining the strategic direction, it is necessary that IT projects be selected and resources allocated. The IT projects selection includes the identification of opportunities, the estimate of organizational fitting, the cost analysis, the cost and risk analysis, the forming and the selection of the portfolio. The success of the IT project portfolio depends on the readiness and the support of the company's management (Verhoef, 2002). This is more important, sometimes even crucial, than just the selection of the method to be used in project selection.

A periodical review of IT project portfolio is absolutely necessary (Bridges, 1999). This means that each active project should be checked, those on the waiting list as well, and should be compared to another. The aim of this check is to find out whether there is the right set of active projects and whether these projects are still in accord with the strategic goals of the company.

To aid the decision making process it is necessary that general criteria are established, as well as the evaluation of each IT project related to those criteria. Since a majority of decisions are based on multiple factors, it is necessary to evaluate each criterion in order to establish a relative importance of each of them. Thus we could identify what is most important for the company, and every project could be measured as regards the criteria that are defined as important (George et al., 2005).

The company must establish an unbiased mechanism of monitoring and control of IT projects (Reyck, Grushka-Cockayne, Lockett, Calderini, Moura, & Sloper, 2005). Measuring may be based on the revenue from the project in relation to the resources invested; then there is measuring of a number of projects within the project portfolio and a continual adjustment to the overall goals of the company. It is very important that there exists an agreement from the start on the process of authority determination. Only when the company

defines its overall goals and the investment strategy into the IT projects, will it be able to create an optimal group of projects or an IT project mix to implement its strategy and achieve goals.

In order to achieve a respective relation between the risk and the extent of revenue from the investment into IT projects, it is necessary that each project be evaluated on the basis of its two characteristics: technical difficulties and added value. The secret of a successful IT project management is in understanding critical relations between the probability of success and the values the project will earn if successful. This provides a good basis for quality decision making on the input portfolio of IT projects.

A majority of portfolio decisions is aggravated by a long time horizon, high level of uncertainty and a large number of variables affecting each project (Ghasemzadeh & Archer, 1999). The tools most commonly used in developing a business model that would predict a potential project value are a learning diagram, a sensitivity analysis and a decision tree.

The purpose of the decisions related to the IT project portfolio is not only the selection of right projects; it is also the inclusion and strengthening of appropriate personalities and their groups who are to realize these decisions efficiently and effectively. Creating an adequate level of participation between cross-functional teams allows for a constructive dialogue between decision makers and those who are in charge of enacting them, which leads to coordination of ultimate actions to be conducted (Englund, Graham, & Dinsmore, 2003).

The portfolio analyses and deals with the future events and possibilities where the majority of information necessary in the selection of projects is at best uncertain, and at worst is largely unreliable. The decision making environment is dynamic, and the status and the perspective of the IT projects in a portfolio constantly change in accordance with the inflow of new information and technologies. The IT projects in a portfolio are in different phases of execution and compete for available resources. However, the comparison among the IT projects is made with varied quantities and reliability of information. The resources distributed among the projects are limited, which is to say that the decision on resource allocation to one project means depriving another project of resources, and the transfer of resources from one project to another usually leaves deep scars.

3. SELECTION OF IT PROJECT PORTFOLIO

The selection of IT project portfolio is one of the crucial steps in the portfolio management process. It is a periodical activity of choosing one portfolio among the available project propositions and projects which are underway, and which achieve the defined organizational goals in a desired way, without exceeding the resources available or breaking other limitations (Archer & Ghasemzadeh, 1996). IT projects selecting directly guides and adjusts business activities to the strategic guidelines of the company. It is within this process that decisions are made on the future execution of IT projects as well as on any vital aspects of their realization.

By undertaking a proactive approach to the IT project selection and real performance management the companies significantly enhance the achievement of IT project goals as regards time, quality and costs, as well as making sure that these projects will facilitate the overall business success. Using quality principles in decision making on evaluation and management of IT project portfolio profitability and productivity may be significantly improved. The IT projects, however, include factors that account for the complexity in the process of project portfolio harmonization. One of the most important among them is the interaction of the projects within the portfolio (Mantel & Meredith, 1999). IT projects are not independent, they overlap and are related to each other by depending critically on each other, in different ways.

Although there are numerous methodologies to be used in selecting an IT portfolio, so far the consensus on which one is most effective has not been reached (Reyck, Grushka-Cockayne, Lockett, Calderini, Moura, & Sloper, 2005). As a consequence, every company tends to choose a methodology that corresponds to the existing organizational culture and allows for the analysis of project attributes it considers the most essential.

The conventional methods of measuring IT values, the estimation of what is easily measurable – costs – and the expectation that an automatic cost saving or cost avoiding practice will pay the investment off do not, in fact, represent the real value IT earns to the company. The problem is reflected in the IT professionals' inability to establish a link to the business value of the proposed IT solution which consequently fail to get the manager's support until it is too late. The problem of inadequate communication is often largely based on the fact that IT managers do not have an effective access to the data they need in order to approach the benefits of a certain IT initiative.

Numerous IT managers estimate IT investments solely on the basis of IT costs saving. While this approach is valid in case the critical factors of success are directed towards reducing exploitation costs in time, it may prove problematic when it is necessary to take into consideration the overall value created by an innovative application of information technologies in business (Sommer, 1999).

As a consequence, the strategic role of investments in new IT initiatives that may lead towards new business opportunities for an organization is neither recognized nor measured. One of the key problems in the total cost scenario implementation is the lack of communication between business activities and technology management, when decision making on implementing new information technologies and the resulting specific business benefits are concerned.

Without the knowledge of where and how IT earns value for the organization, it is impossible to measure this value in concrete quantitative terms. Also, without financial guidelines in defining the value of increased business flexibility, it is difficult to develop a meaningful proposition of values to invest in any IT initiative.

In preparing the input data for the portfolio selection it is necessary to analyse whether the project is worth the risk undertaken (Cooper, Edgett, & Kleinschmidt, 1998). This means conducting an overall identification of potential risks, risk estimation, the analysis on the impact the risk may have on the project, a discussion on the moves to reduce risk and estimation as to whether the project is still justified after the risk reduction costs are added.

The input information for portfolio selection is to allow for (Levine, 1999):

- finding out which of the projects proposed bears the greatest value for the company, so that the priorities in resource allocation may be defined.
- an estimation of the projects proposed in view of their importance for the overall portfolio, especially as regards the availability of resources and the realization of other projects.
- identifying projects which lag behind the planned terms by 25 percent or more and analysing influences upon the entire portfolio in case these projects are discontinued (depending on the availability of resources and the realization of other projects).

The choice of the method to be used in the project estimate depends on the purpose of the project. The most frequently used methods of project estimate of individual IT projects are the following:

- economic revenue – net current value, internal profit-making rate, return on capital, pay off terms, expected value
- benefit-cost techniques – include the calculation of the benefit-cost ratio, where the inputs represent the total value of all benefits and costs
- risk analysis – a combination of the probability of events (usually undesired events) and consequences related to the event. Every project carries a certain risk of failure to reach the desired goals
- potential project success – specific measuring of the probability of project success
- degree of acquaintance with the organizational strategy
- degree of acquaintance with the activities of competition
- degree of acquaintance with the organizational financial goals.

Individual projects may be estimated as good, however, they may be negative from the point of view of the company (Kerzner, 2003). Therefore it is essential that the project be analysed not only from the aspect of its success, but from the aspect of its contribution to the overall goal of the company as well. The project must not endanger the existing benefits and advantages the company has. No decision on the project requires all the analyses possible, nor is every element equally important.

Strategic decisions affecting the IT portfolio focus should be executed in a broad context that takes into account both external and internal business factors, and before the project portfolio is selected. The frame of the project selection should be flexible enough to allow for prior selecting of individual techniques and methodologies that are adequate for the relevant data analysis and decision making on the selection in a certain type of projects (Markowitz, 1991).

The project portfolio selection and adjustment is an iterative process (Meta Group, 2002). The existing projects require resources from the set available therefore the time of execution and resources are interdependent and affect new projects. It is a general practice that the review of the estimate of the project key elements is conducted at the end of each phase, in order to determine whether the project is eligible to be continued.

As regards the plan and the input information we have when we enter the decision making and the project execution processes, further execution may change many things. The best project may prove to be only average, and sometimes it is necessary to discontinue the project since it does not promise satisfactory results (Ghasemzadeh & Archer, 1999). During the execution stage it is therefore necessary that requireded adjustments be made, in accordance with the changes that appeared in the process.

The current IT projects that reached a certain key event should be reviewed again at the same time when new projects are analysed to be selected into the IT project portfolio. Thus it is possible to, in accordance with the resources available, generate a combined portfolio in regular intervals, and this is defined by:

- project completion or project abandoning
- new project proposition
- changes in strategic focus
- review of available resources
- changes in the environment

Problems related to the project failure and project discontinuation may be reduced if those working on the project approval are better organized and more careful in the decision making process. Within the IT project portfolio the scopes of performances for each project must be identified. It is necessary that certain acceptable values that would serve as an alarm tool within the IT project portfolio management system should be defined in advance.

4. PORTFOLIO MANAGEMENT OFFICE AS ORGANIZATIONAL SUPPORT FOR IT PORTFOLIO PROJECT SELECTION

Companies usually have a large number of different projects within their portfolio and the more these differ, the more complex their management process becomes (Englund, Graham, & Dinsmore, 2003). In order that a successful execution of an individual IT project be supported and its compliance with the goals of other projects and with the overall organizational strategy be ensured, there must exist a specific integrative structure, e.g., strategic centre, expert group, centre for competence in project management or a portfolio office (Block & Frame, 2001; Bolles, 2002; Dinsmore, 1993; Miranda, 2003). Some of these may be virtual organizational units (Gareis & Huemann, 2000; Seltzer, 1999).

The hierarchically highest level is the Portfolio Management Office. The Portfolio Management Office defines projects and programmes in accordance to the general organizational strategy and goals. Its basic role is managerial and is related to the project portfolio management process phases, from defining the portfolio and categories of projects (such as IT projects) to the control and periodical review of the existing priorities and plans. The Office can also be viewed as the director or managing board headquarters, with an impact upon the strategy and a general direction of the company's development. Though primarily engaged in the activities on the strategic management level, it works together with the members of the Project Management Office on the operational jobs related to coordination of project activities, developing and spreading the project management principles throughout the company in certain situations (changes in plans, radically changed business conditions, delay caused by lack of resources, etc.).

The strategic role of the PMO is primarily concerned with the project portfolio development and management and its coordination with the organizational strategic goals. Hence the PMO provides the basis for a quantitative estimate of the portfolio management success in the organization and promotes the awareness of the portfolio management value.

The PMO provides numerous benefits for the organization that implements it, in view of the portfolio management process standardization, project execution improvement, professionalism building, improvement of organizational performances, etc. However, the other part of the PMO implementation has negative aspects that diminish the importance of the benefits listed above. Its significant weaknesses are: implementation costs, stress and conflicts, dualism in decision making, lack of clearly defined responsibilities, delays in execution, etc.

In a large number of organizations the implementation of the PMO remains, unfortunately, at the operational level, therefore the support of modern PM concepts in strategic planning and management is minimized. The management of such an organization will have to make additional efforts towards restructuring, changing the business methods and improving the PM competence level in their employees in order to position the PMO on a strategic level, that is, on project management as a basic competence of the company. Only in this way will the advantages of corporate project management be fully visible.

5. CONCLUSION

Modern companies rely on their IT to a large extent and this cannot be denied. It is almost impossible nowadays or in future to imagine a successful business without an equally successful IT. On the other hand, the link among these structures is often not strong enough so as to make this relation useful for new investments and joint projects. In order to understand why some organizations earn greater financial value from implementing the same information technologies compared to some others, numerous research have been conducted. Among the best practices certainly is the joint vision of valuable opportunities that exist both in the IT and in business units, quality business planning for any initiative and an effective linking of projects and programmes. The basis of all these is the portfolio management with its process of work.

In the project-oriented organization, strategic management is implemented by way of project portfolio management. Classification, selection, prioritization, planning, monitoring and control of programmes and projects are defined and analysed as basic elements of project management. The IT project portfolio management is to allow for a consistent approach to classification, selection, prioritization, planning and execution of the right IT projects and programmes in the company. The IT project portfolio management is characterised by uncertainty as well as by changing information, dynamic possibilities, manifold goals, strategic analyses, interdependence of projects, manifold decision making and group decision making. Defining and managing the IT portfolio is today one of the most demanding processes in modern business.

The development and selection of the IT project portfolio is a process which helps optimize a set of IT projects, not just one project. The approaches in IT portfolio development vary from simple ranking, based on a cost reduction rate, to very complex methodologies that take into consideration the interrelations among the projects. Organizations tend to select a methodology appropriate to their organizational identity and allowing for the analysis of project attributes they consider the most essential. Regardless of the model chosen, the goals should be related to the portfolio optimization, not only the optimization of individual projects. The choice of IT project portfolio mostly depends on the company's strategic direction, its capabilities, limitations and the complexity of the project.

Abstract: *This paper discusses the current situation in project management in the energy sector in Serbia, by analyzing the results of the project management maturity research. The research was conducted on a relevant sample of project managers and members of project teams implementing energy projects in more than 70 organizations in Serbia. Firstly, the paper presents an overview of the generic project maturity model, followed by the presentation of data on current and projected situation in energy sector in Serbia, with the aim of understanding the context of the research. Secondly, it moves on to presenting the results of research and the analysis of results obtained. Finally, the paper offers recommendations for improvement of specific aspects of project maturity, as an answer to the challenges that the Serbian energy sector is likely to face in the years and decades to come.*

Keywords*: energy sector companies, projects, project management maturity*

1. INTRODUCTION

At the beginning of the second decade of the twenty-first century, Serbia has been facing numerous problems in the energy sector. Great dependence on import of oil and natural gas, which constitute as much as 17.4% of the total national import volume (Statistical office of the Republic of Serbia, 2013), obsolete electrical and energy capacities, low energy efficiency in almost all sectors (Oka et al.), represent only several among many problems affecting the country's development. As an attempt to solve some of these problems, Serbia has adopted The Energy Sector Development Strategy of the Republic of Serbia by 2015 (MMERS, 2005). The Strategy lists the following five energy policy priority programs in the forthcoming period (MMERS, 2005):

- Priority of continuous technological modernization of the existing energy facilities/systems/sources in the following sectors: oil, natural gas, coal including strip mining and underground mining, power sector, production facilities – thermal power plants and hydro power plants, distribution systems, thermal energy sector – district heating companies and industrial power plants.
- Priority of economical use of quality energy products and increase in energy efficiency in production, distribution and utilization of energy by end consumers of energy services.
- Priority of use of new renewable energy sources and new, more energy efficient and environmentally acceptable energy technologies and installations/equipment for energy utilization.
- Priority for extraordinary/urgent investments in new power sources with new gas technologies (combined gas-steam thermal energy installations).
- Priority of constructing new energy infrastructure facilities and electric and thermal power sources within the energy sectors of Serbia, as well as capital-intensive infrastructure, within the frameworks of regional pan-European infrastructure systems connected with Serbian systems.

Aiming to implement the priority programs and encourage the development of energy sector, the strategy has envisioned investments of up to EUR 8 billion between 2008 and 2015 (MMERS, 2005). Given the overall workload anticipated over the mentioned period, the emerging imperative is the need to establish an efficient system of project management in energy sector.

2. PROJECT MANAGEMENT MATURITY ANALYSIS OF ENERGY PROJECTS

Maturity models can be implemented in almost all processes in an organization, including quality management maturity, energy management maturity, human resource management maturity, overall organizational maturity model, etc. Recognizing the significance of project management in achieving organizational strategic goals, it was to be expected that the organizations would develop the need for

* *Supported by MPN Republic of Serbia, project OI 179081*

assessing the project management maturity (Cooke-Davis and Arzymanov, 2003). The key reasons for the growing interest and significance of these models underline the fact that many organizations implementing project management principles were unable to measure the success of implementation, or to compare their own practices with those of other organizations. Additionally, these models enable the identification of phases critical to the process of advancing of project management practices and achieving higher performance levels (Mihic, 2010). Maturity models identify strengths and weaknesses of the organizations and provide data used for benchmarking (Judgev and Thomas, 2002).

Project maturity can be viewed as a capacity of an organization to successfully implement its projects and programs. Analysis of the project maturity allows for evaluation of achievement of strategic goals through implementation of project management principles. The research conducted by Loader (2006), indicates the existence of a strong link between organizational project maturity and the success of the projects it implements. Organizations at a higher project maturity level are also more successful in implementation of their projects, whereas those at lower project maturity levels often encounter problems such as failing to achieve project objectives, exceeding deadlines and budget, underachieve client requirements, etc.

Analysis of some of the best known project maturity models, such as CMM, PMMM, OPM3, PRINCE2, EFQM, IPMA project excellence award model, etc, helps define a generic project maturity model consisting of five levels: initial, repeatable, managed, distributed and continual improvement level (Mihic, 2010). The level of project maturity can be determined by means of standardized questionnaires containing key elements of project maturity in an organization (Crawford, 2006). The elements of project maturity have been derived from knowledge areas defined by Project Management Institute (PMI, 1996).

The energy sectors of most countries are facing numerous challenges, most of which represent the results of multi-decade global orientation towards fossil fuels as the main generators of economic growth. Such orientation is contrary to the sustainable development principles, which, in relatively close future, can lead to serious environmental, economic, social and political consequences on a global level (UN, 1987). In addition, the accelerated economic growth of certain countries or regions contributes to an increase in the overall energy consumption worldwide (Zhang and Wang, 2011). Therefore, projects in the field of energy tend to focus more on the development of energy efficiency, construction of facilities for producing energy from renewable sources and electrification in developing countries.

Several general characteristics of the projects in this area can be identified in accordance with the established practices of implementation of energy projects and Flyvbjerg and Flyvbjerg's research (2004). The characteristics are as follows:

- Energy projects are classified as capital investment projects and often require substantial financial investments.
- Inherent to these projects are numerous risks that come as a result of the inability to forecast all threats in the process of long-term planning.
- Implementation of these projects is complex and often includes hundreds (or thousands) of activities.
- Implementation of these projects does not employ standardized technology.
- Decision making and planning involves a number of stakeholders who may have conflicting interests at times.
- Workload may significantly differ at times.
- Project budgets are often set without contingency reserves for funds and time, which leads to exceeding budget or time boundaries, often resulting in exceeding the deadlines and costs or in underachieving of forecasted benefits in the majority of projects.

Organizations in energy sector operate in a very dynamic environment with significant risk exposure; in addition, these risks have escalated since the beginning of the global downturn. The mentioned environment, being prone to frequent fluctuations, affects the regular operations of energy companies, and also influences project management in this field. Nevertheless, the problems such as delayed implementation or exceeded budgets are not exclusive characteristics of energy projects; rather, they are a reflection of project management shortcomings connected with an organization's deficient project maturity. Improving project maturity may result in improved project success.

3. OVERVIEW OF THE EMPIRICAL RESERCH

Empirical research of the project maturity in the energy sector in Serbia was conducted in 2013 on a sample of 75 respondents from 75 organizations. The respondents were expected to answer a questionnaire built around key aspects of project maturity. Five questions were defined for each of the aspects. The

questionnaire also featured questions important for appreciation of the strategic aspect of project management analysis. To ensure the collection of high-quality data important for understanding and verifying the obtained results, focus groups and interviews included key management personnel from selected organizations. The data was processed using the software package SPSS ver.16.0.

Data about a broad span of characteristics of organizations and projects that were researched, speak in favor of relevance of the questionnaire. The research encompassed some of the largest and most prominent organizations from the Serbian energy sector, as well as smaller organizations that provide goods and services to the energy companies. The average number of participants in projects covered by this research was 84.61; falling within the interval ranging from 5 to 240. The average duration of the projects was 19.98 months, with the duration ranging between 2 and 90 months. Average project budget was EUR 7.452.367, i.e. ranging between EUR 30.000 to EUR 55 million. The research included 10 program managers/directors, 27 project managers and 38 members of project teams. The majority of projects in organizations covered by this research were implemented in Serbia, whereas only a few were executed abroad (in ex-Yugoslav states). Based on the data about the characteristics of the sample, it can be concluded that the research presented herein is consistent with the trends in the area of project management in the energy sector in Serbia and can, therefore, be taken as a foundation for assessing the actual state of matters in project management in the organizations observed, as well as for the formulation of recommendations for further improvement. Furthermore, it is useful to point out that there are no statistically relevant dependencies between the success of the implementation and the number of people hired for the projects, the duration of project implementation and project budgets. Therefore, the sample constitutes an adequate basis for further research of project maturity in the Serbian energy sector.

The principles of examination of project maturity in individual organizations were used as a starting point for analysis of project maturity in Serbian energy sector. Inclusion of the majority of energy companies in Serbia in this research facilitated the identification of common characteristics of project management practices in this sector nationwide.

The research presented herein was envisaged so as to incorporate all questions and elements of project maturity most pertinent to the successful implementation of this type of projects, not necessarily adhering to the format of any of the existing project maturity models mentioned in the second chapter. The research of the project maturity in energy sector, presented in this paper, is the first of this kind in Serbia. The results obtained in this research, as well as the recommendations for further improvement, may largely contribute to the more efficient implementation of energy projects.

Analysis of the results obtained should be complemented with the results of the statistical testing relating to the existence of statistically relevant dependencies between certain categories in the research conducted and statistical differences in maturity between strategic and operational levels of management of observed projects.

According to Andersen and Jessen (2003), the concept of maturity indicates that there might be a development from one level of capability to a higher one. One of the goals of this research is to establish whether there is a statistically important difference in maturity between managing the project as a whole and managing individual activities within it. For this purpose, we have compared 2 groups of answers relating to the questions that directly correspond to different levels of project management: the level of project/program and the level of activities. The value of paired t-test equals 4.143, with statistical relevance at 0, which means that there is statistically important difference in project maturity on the level of project/program on one side and project activities on the other. In addition, according to statistical data, we can conclude that energy projects in Serbia are better managed on the level of entire program/project than on the level of individual activities.

4. ANALYSIS OF RESEARCH RESULTS AND DISCUSSION

Analysis of gathered results relating to various aspects of project maturity and individual questions has shed the light on some of the obvious problems in the area of managing energy projects in Serbia. Some of these problems are as follows:

- Project management office is not adequately developed;
- IT systems are not sufficiently used;
- Poor risk management;
- Poor planning, particularly in the segment concerning the use of methods, techniques and mechanisms for monitoring project implementation;

- Poor results in the area of planning and implementation of benefits, etc.

Furthermore, certain positive examples of project maturity can be identified in individual elements or questions, such as:

- Clearly defined responsibilities and roles of project managers an project staff;
- Relatively efficient financial management;
- Largely successful identification and alignment of benefits;
- Relatively sound communications management, etc.

The results relating to project maturity elements or questions should not be observed independently from other elements or questions. Discerning correlations between different processes of project management provides for appropriate examination of the project maturity and enables us to determine the true nature of any deficiencies, and implement the appropriate improvement measures accordingly.

The results relating to the existence of well-defined responsibilities of project managers and project staff can be considered satisfactory. Given that the clearly defined roles and responsibilities of project management and staff are one of the prerequisites for successful project communication, it is understandable that positive results in this segment reflect positively on solid results in communications management. However, fairly low results were recorded in the segments concerning the existence of project management office (42.7% positive answers and as much as 32% negative answers). The main functions of project management office (PMO) are: risk management; communications management; use of software tools in project management, and stakeholder management (Mihic, 2010). Also the PMO plays an important role in project monitoring and coordination. Despite the fact that relatively good results were achieved in some segments of communications management and monitoring of project costs, underdeveloped PMO largely contributed to the poor research results in the area of risk management, IT support and stakeholder management. Absence of a fully functioning PMO or its partial existence in many organizations has a profoundly adverse effect on the existence of efficient mechanisms for project monitoring and coordination among projects/activities with the purpose of transferring surplus resources to those projects or activities that need them. The conclusion is that energy companies in Serbia need to establish PMOs as functional units that would strive to efficiently contribute to the implementation of the organizational strategy. The manager of PMO would have complete responsibility for achieving the project goals of an organization. Based on the results of dependency analysis, it is possible to conclude that the PMO is particularly essential in organizations involved in the implementation of multiple projects involving a vast number of participants, long duration and a sizable budget.

Analysis of planning of the projects/programs points to certain discrepancies between the processes of planning and implementation of projects/programs. Namely, the results of monitoring of the course of projects are in collision with the results relating to resource allocation planning and establishing efficient mechanisms for monitoring project implementation. Given that energy projects often imply considerable funding, and that, as a result of long duration, frequent changes take place in the course of implementation, it is important to monitor the course of the project on a regular basis. Consequently, it is understandable that over 90% of the organizations partially or fully monitor the use of resources and changes in cost structure. However, in order for the monitoring to be efficient, it is important to clearly define and implement a system for monitoring the course of project. This system should largely be supported by information technologies, i.e. appropriate software solutions. Poor results in these segments are the result of an inadequate structure and level of development of the PMO, as mentioned earlier in this paper. Fairly low implementation of project planning methods and techniques (such as WBS diagrams, milestones, schedule analysis, etc.) are rather easy to identify in the segment of planning of projects/programs. The use of these methods largely contributes to the success of project implementation as it forms the basis for risk analysis, assessing the duration of the project, its budget, number of participants in the project, etc. Taking all of the above into account, the conclusion is that the organizations operating in the energy sector in Serbia are in need of efficient mechanisms for measuring project progress indicators. These systems should be supported by appropriate software solutions and should be implemented both on the level of individual activities and on the level of programs. Likewise, there is a need for consistent use of methods and techniques of project planning, which, in turn, can contribute to the improvement of other elements of project maturity and improve projects' success rate. This finding was confirmed by analysis of dependencies.

Results of research relating to the identification and alignment of all benefits that the project/program should produce can be regarded as positive (68% positive answers, and only 6.7% negative answers). However, other aspects of benefits management show serious deficiencies, primarily in areas of planning, monitoring and securing the benefits. More often than not energy projects produce direct benefits that are fairly easily identifiable. They mainly consist in improving the energy balance of the country or region, growth of employment in the energy sector, securing procurements for energy industry, increased certainty of energy

supply to consumers, etc. (Mihic et al. 2011, 2012a, 2012b). However, poor results relating to planning, monitoring and securing the benefits, primarily stem from the complexity of this type of projects (several hundreds or thousands of activities, long implementation periods, unforeseen events…) and identified deficiencies in use of project planning methods and techniques. Analysis of dependencies has proven that efficient benefits management is critical for the success of any project.

Risk management is of the weakest aspects of project maturity. It has already been pointed out that energy projects often encounter problems such as exceeding deadlines and budgets. The root cause of these lies in the project/program planning phase. The planning phase in energy projects is often affected by varied stakeholder interests in terms of time or cost constraints. The budget is often set according to estimated costs, and it often does not include contingency reserves. The situation is similar in the case of overall project duration. Since the budget and the timeframe are preset, the need for thorough risk analysis seems to disappear. This analysis would, however, cover a detailed identification of risks, assessing the likelihood of their occurrence, and defining the procedures for risk avoidance, reduction or addressing the consequences. This is the reason why risk analysis is taken somewhat more seriously on the level of entire project/program, whereas on the level of activities only key risks and the likelihood of their occurrence, reduction procedures and response plans are identified.

In terms of the strategic aspect of project management in Serbian energy sector, the gathered results indicate the need for improvement of the implementation of strategic management in observed organizations. To be precise, 61.3% of managers in the surveyed organizations have recognized the need for strategic management and 72% of the organizations have a strategic plan in place. This in itself is a positive result. However these results are inconsistent with the much less positive results of the examination of well-defined phases in strategic management and the existence of the department for planning and (strategic) analysis. Likewise, positive results were recorded in relation to the examination of central coordination of resources in an organization (62.7% positive answers), but these were also inconsistent with the identified deficiencies of project management office, efficient coordination of multiple projects and the existence of professional mechanisms for project monitoring. The results obtained lead to the conclusion that Serbian energy sector is in need of further strengthening of the links between strategic and project management, in order for the strategic goals of an organization, as well as of the entire country, to be achieved. The links between an organization and project management should be strengthened trough the development of strategic plans specifying the roles and responsibilities of both the functional units and the PMO in the attainment of an organization's strategic goals during the course of project implementation.

Having in mind the previously described characteristics of project maturity in Serbian energy sector, it is necessary to define measures aimed at removing deficiencies in project management and at encouraging a faster development of the energy sector. The proposed measures are presented in Table 1.

Table 1: Summary of recommendations for improving project management maturity in Serbian energy sector

Area	Recommendations
General	• A more detailed project planning and management, most of all on the level of individual activities; • Education of project managers relating to the implementation of project management methods and techniques, as well as to the use of relevant software tools.
Program/project management	• Establishing of PMO in organizations implementing a numerous large-scale projects; • Establishing efficient mechanisms for monitoring project progress; • A more intensive implementation of project planning methods and techniques supported by adequate software tools; • Establishing an efficient system for coordinating parts of a project.
Benefits from the program/project	• Definition of plans and responsibilities relating to project benefits.
Risk and quality management	• Definition of risk management procedures on the level of project phases and activities within a project. • Establishing a special service in charge of project quality management; • Certification of quality management system; • Definition and consistent implementation of quality plans in all projects.
IT support	• Implementation of project management software and adequate training of project staff.

5. CONCLUSION

The research of project management maturity in the energy sector was conducted in Serbia in 2013. It featured a questionnaire divided into nine areas of project maturity. The research has shown that organizations in this industry are not fully prepared for numerous, dynamic, large-scale changes expected in the forthcoming period. Energy projects, their complexity and inherent risks, as well as the fast-paced changes characterizing the contemporary market and world in general, impose an obligatory improvement of nearly all project management processes in organizations. An integrated analysis of results from the entire questionnaire confirmed that managers lack proper training for leading energy projects, stressing the need to implement extensive measures aimed at professional and specialized trainings. An analysis relying on the elements of project maturity detected several critical points relating to project management in Serbian energy sector. Key areas that, according to the results, require immediate improvements are: establishing of a functional PMO; utilization of risk management tools; use of software solutions for planning and monitoring project implementation; improved communication with stakeholders, etc. The statistical analysis of gathered answers confirmed that an adequate implementation of project management methods and techniques is necessary in projects requiring substantial investments, involving long duration and numerous staff, because it contributes to a higher success rate of projects. In addition, a statistical analysis confirmed that project management teams focus more on projects than on individual activities within them. This also stresses the need for a more intensive implementation of project management methods and techniques in energy projects implemented in Serbia.

Energy sector in Serbia faces considerable challenges. Investments expected in this area over the years to come can potentially generate immense benefits to the society. Nevertheless, in order for these benefits to be generated, it is important to manage the projects in this area efficiently. Application of the project management maturity model facilitates assessment of the current capacities of Serbian organizations to successfully implement energy projects, and offers a set of recommendations aimed at improving project management processes. Only a consistent implementation of project management concepts in the energy sector will lead to the achievement of strategic goals of, not only the energy companies, but also the Republic of Serbia, as defined in the national development strategies.

[2]University of Belgrade, Faculty of Organizational Sciences, dejanp@fon.bg.ac.rs
[3]University of Belgrade, Faculty of Organizational Sciences, milicaristic@hotmail.com

Abstract: *Emotional intelligence is not a new concept. However it is not applied to modern management in an adequate manner. This paper tries to examine whether this personal characteristic is needed competence for successful project manager. For this purpose, substantial theory review was conducted and two surveys were analyzed. Results show that there is correlation between success of project managers and their competence. Also it is clearly shown that project managers do need to have emotional intelligence in order to run successful projects and move forward in their careers.*

Keywords*: emotional, intelligence, competence, project, manager*

„Emotional intelligence, more than any other factor,
more than intelligence, or expertise, counts 85% to 90% success on the job...
Intelligence is the limit.
You need but it, but it cannot make you a star.
Emotional intelligence can.“
Warren Bennis

1. INTRODUCTION

Project managers should understand that the people involved in it represent a heart and a soul of every single project - their relationships, skills and ability to function as a compact entity. Skilled project managers from the first day of the project focus their attention on the understanding of human dynamics and predict possible human interaction along the project. Human Dynamics is based on researches originated back from 1979, which involved more than 40,000 people from 25 different cultures. They identify and document the inherent differences in the functioning of the people as a part of a system. Generally, team dynamic is defined as a motivating and driving force that "pushes" the team members towards achieving their goal or mission. It is a social process in which people interact and behave in accordance with environment of the group they belong to.

The starting point for the use of emotional intelligence is when you realize that project management refers to the work with other people. Project manager's success depends on the other people involved in the project. In order to achieve what was important, it is necessary to work at the team level. Big and important projects generally require big and effective project team, as well as an effective project manager. Efficient project teams do not just happen, they are carefully prepared by a group of highly qualified (in terms of skills and abilities) and motivated individuals who have a clear picture of their own goals and receive a clear and tangible evidence of their accomplishments.

People do not realize the importance of emotions in general, and today especially they do not understand their key role in the doing business. In terms of project management, emotional intelligence can be crucial to the success of the project. It is essential that the project manager becomes aware of his own feelings, learn to trust them and accept them as a source of information. If he or she properly recognize and regulate its own emotions and the emotions of the team members, this will be helpful in carrying out the project activities, resolving potential problematic issues, becoming a better leader and will create a "dream team", which will be, thanks to the good atmosphere and the energy, more productive and achieve a better performance.

2. EMOTIONAL INTELLIGENCE

Intelligence comes from the Latin word *inteligere*, which means understand, comprehend. Many definitions do not currently define it as mental function. Certain authors state that intelligence is the ability to solve new problems and cope with new situations, and some believe that it includes the capacity for abstract thought,

understanding the causes and consequences of a problem, the ability to distinguish important from unimportant, ability to learn and to adapt to a given goal. Other authors focus on intelligence as the ability of small and rapid learning and acquiring new skills.

David Wechsler defines intelligence as a global concept of an individual to act with intention, think rationally and effectively deal with its environment (Wechsler, 1958).

Numerous studies of intelligence, lead to the conclusion that intelligence has its own categories, and this model is called model of multiple intelligences defined for the first time by Howard Gardner (Gardner , 1983). He named the six categories of intelligence that involves the abstract (symbiotic reasoning, mathematics and formal logic), social (understanding the social context and addressing the people), practical (common sense), emotional (awareness and managing own emotions), aesthetic (sense of form, design, music, art and literature), and kinesthetic intelligence (skills of the whole body including sports, dance, music). After him, Sternberg gave a little clearer and more accepted image of intelligence by defining its aspects, so-called aspects of successfulness. The concept of multiple intelligences (MI model) is based on the idea that human beings are equipped with the whole range of mental abilities, not just IQ and is now widely accepted in business and in education. MI model radically changes the view of intelligence as a genetic predisposition, an innate ability that never changes and makes it clear that the "intelligence" is capabilities that can be learned and developed. Intelligence is now divided into seven intelligences as follows:

- Analytical Intelligence - refers to the resolution of problems which means that clearly defined problem has only one solution;
- Creative intelligence - a new situation creates new ideas;
- Practical intelligence - involves the lack of clear, common situations with multiple solutions;
- Social intelligence - is successful navigation the complex social situations;
- Emotional intelligence - observation, expression, understanding and regulation of emotions;
- Moral Intelligence - involves understanding and judgment, righteousness;
- Existential intelligence - raises questions about the meaning, life, and death.

Project Management Institute has published research on the intelligence in the project environment. The research shows that intelligence is a factor of success in almost all projects, and has an incredibly large impact on the achievement of project objectives. The project team, led by project manager must possess the competence of not only cognitive intelligence, but also many other competencies that are based on the individual capability as well as the ability to establish positive relationships between all members of the project team. PMI lists the following types of intelligence in the project:

- Professional Intelligence - the ability to master and control the knowledge, information and skills within a given project professional environment;
- Rational intelligence - the ability to solve logical problems in the project environment;
- Physical Intelligence - the ability to learn and master the physical skills;
- Creative intelligence - the ability to produce new and original ideas;
- Emotional intelligence - a productive personal interaction of team members (self-confidence, self-control, self-motivation and empathy);
- Social intelligence - the ability to accomplish complex social skills such as teamwork, communication, conflict resolution, harmony, achievement of consensus, multiculturalism; and
- Leadership Intelligence - the ability to express leadership skills such as leadership, motivation, negotiation, influence and control.

Recent research after 90s have confirmed that there is an emotional brain - a place called the limbic system, where our emotions reside. This place is separate from the rational part of the brain (the neocortex), but they are certainly linked and developed together. This means that our power of reasoning and our feelings are intended to be used together. Because of the design of the brain, all the information go first to our emotional center, and then in the center of our thinking. Emotions come before thoughts and behavior. What scientists have confirmed is that we badly need our emotions, our feelings which "turn on the engines" that produce energy and creativity. As a result of these studies, it has become important to understand what we feel, what other people feel, how to manage our own emotions and how to manage relationships with other people. This is the essence of emotional intelligence - terms used to describe the complexity of regulating our impulses, connecting with other people, and resilience in the face of difficulties. Because of this, emotional intelligence is the product of a number of information exchanges between the rational and the emotional center of the brain (Mackin, 2006).

Among researchers there is a lot of indecisions when it comes to emotions. While most agree in their basic set, their opinions differ when it comes to less well-known emotions. One of the most common definitions of emotions explains that emotions are a mental condition that often arises spontaneously rather than through

conscious effort and are often accompanied by physiological changes, feelings - feelings of joy, sadness, respect, love and hate (The American Heritage Dictionary of the English Language, 2006).

Founders of emotional intelligence are two psychologists Peter Salovey and John D. Mayer who, with their definition of emotional intelligence pushed psychological concept forward, who received the most attention in the academic and practical literature ever since (Salovey & Mayer, 1990). According to them, emotional intelligence is the "ability of monitoring our own emotions and feelings, and emotions and feelings of others, the ability to create discrimination among them and the use of this information for the management of our own thoughts and actions."

Their model includes and identifies five main areas: understanding own and other people's emotions, managing emotions, self-motivation, recognizing emotions in others, and relationship management. After Salovey and Mayer's research, interest in emotional intelligence has begun to grow significantly, and many authors have begun to explore this concept. Each of them gave their own "stamp" to emotional intelligence, by changing certain competencies it covers, but basically, it all finally came down to research Salovey and Mayer's. It is a great pity that the two of them did not called the concept of emotional intelligence using something that is characteristic for them, say "SaloMayer principle" because in future studies this term was used as a global term.

In 1995, Daniel Goleman wrote the book "Emotional Intelligence - why it can matter more than IQ?", which rapidly became a bestseller. After that, he wrote more books on this subject, linking emotional intelligence with a successful business and this book became synonymous for this concept. His definition, perhaps the most general of all, states: "The ability to recognize our own and others' emotions, self-motivation and managing emotions in ourselves and our relationships with other people. (Goleman, Emotional Intelligence: Why It Can Matter More Than IQ, 1995)"

Goleman adapted by Salovey and Mayer's model as a basis for its discussion on the theory of emotional intelligence and its impact on life, including the business world. He adapted the model of emotional intelligence to develop four emotional competences and this is one of the most accepted and most widely used approach in the development of emotional intelligence in humans. He lists the following competencies:

1. Self-awareness. High emotional intelligence is associated with high self-awareness, which means recognizing and interpretation of emotional signals in ourselves and others, and the impact of emotions on the other. Once a person becomes aware of its own thoughts and feelings, he or she can use them as positive thoughts and feelings - the instructions. A high level of self-awareness leads to self-confidence, realistic self-assessment and a sense of humor. He stated that the skills associated with self-awareness include:
    - Emotional self-awareness – recognition of our own emotions and their effects (recognition of emotions, connecting feelings with actions, words and thoughts, understanding the impact of emotions on performance, possessing leading awareness of personal values and goals).
    - Accurate self-assessment - knowledge of our own strengths and limitations (awareness of personal strengths and weaknesses, ability to learn from experience, open to sincere feedback, new perspectives and personal development, the ability of showing a sense of humor and own perspectives).
    - Self-confidence - honest belief in ourselves (the ability to have the confidence and "presence", demonstration of views that are different and/or unpopular, determination and decisions making despite uncertainty).
2. Self-management. The ability to use awareness of our own emotions in order to provide flexibility and direct and positive behavior. Self-management is a strategy to change our own mood, a tendency not to judge other people and to think before acting. Emotions affect the personal performance, and the performance of the other. Emotions are contagious. People with self-management skills tend to show integrity and reliability, are open to change and are comfortable with ambiguity. Self-management skills help people to overcome the perspective of "victims" and reframe stressful situations into a challenge, in addition to becoming more than feasible. Knowing and managing our own "emotional triggers" is critical for self-management. It includes the following components:
    - Self-control - managing disruptive emotions and impulses (managing impulsive feelings and stressful emotions, staying calm and positive even in difficult times, thinking clearly and stay focused under pressure).
    - Trust - maintaining standards of honesty and integrity (to act ethically and above complaint even in the face of conflicting emotions, to build trust through reliability and authenticity, admit mistakes and deal with the actions of others).

- Conscientiousness - taking responsibility for personal performance (to learn about the obligations and keep promises, to be responsibility to the goals).
- Adaptability - flexibility in managing change (smoothly managing various demands, changing priorities and rapid introduction of change, flexibility of views on situations and events).

3. Social consciousness. Once a person becomes aware of his own emotions honestly and with the intention of understanding them, it's time to look around itself. Emotional intelligence is reflected in the inclusion of our own feelings and the feelings of people around us. A key component of social consciousness is empathy, which is basically the ability to see the world from another's perspective. It begins by listening. Individuals who do not have the skills of empathy are more focused on their own needs and problems and do not pay attention to anyone else. They do not build positive relationships with others. Social awareness involves the development of positive and effective relationships with people in the environment and the ability to communicate in order to prevent conflict, achieve higher consciousness and light distribution of the basic tension that can accumulate and have a negative impact on work relations. These relationships encourage cooperation and teamwork. Research shows that people when they get to know the other person, within 3-5 seconds determine whether they like him or her and if he or she can be trusted. This is how much it takes for the emotional part of the brain to form a first impression. The rational part of the brain does not have time to engage, and it deliver an intellectual proof later on. Components of social consciousness are as follows :
   - Empathy - feeling other people's emotions and perspectives and demonstrating an active interest in other people's problems and concerns (paying attention to the emotional signs and good listening, showing sensitivity and understanding of others' perspectives, providing assistance on the basis of understanding of others' needs and feelings).
   - Orientation - predicting, identifying and meeting the people needs (answering to their needs, finding ways to increase satisfaction and loyalty of others, offering appropriate assistance).
   - Political awareness - identifying current and potential emotional relationship of the group (accurately identifying key relationships, detecting crucial social networks, understanding the forces that shape the attitudes, views and actions, "reading" the situation accurately).

4. Relationship management. Relationship management involves mastering the skills of self-awareness, self-management and social awareness that paves the way for more effective relationships. It refers to the interaction with people and skills in managing others' emotions. Relationship management includes:
   - Impact - the use of effective negotiation tactics (skillful persuasion, the use of complex strategies like indirect influence to obtain consensus and support, management of dramatic events to effectively highlight some key points).
   - Communication - sending clear and convincing messages (efficiency of sending and receiving emotional signals, openly dealing with difficult issues, good listening, mutual understanding and full exchange of information, fostering open communication and humility in accepting the bad news).
   - Conflict management - negotiation and resolving misunderstandings (dealing with difficult people and tense situations diplomatically and tactfully, identifying potential conflicts, disagreements and bringing them to light, encouraging debate and open discussion, providing win-win solutions.
   - Collaboration and cooperation - functioning with the others towards common goals (directing focus on duties with special emphasis on relationships, free sharing plans, information and resources to promote friendly, cooperative climate, nurturing the opportunities for collaboration).

Matthews, Zeidner and Roberts (Matthews, 2007) published their research and make a distinction between two concepts of emotional intelligence - the capabilities model of emotional intelligence and attributes model of emotional intelligence.

The first model explains emotional intelligence as the ability similar to cognitive abilities and measure it through tests based on performance. It is seen as another legitimate form of intelligence. This model is also known as emotional cognitive capabilities or emotionally intelligent information processing. This model uses Salovey-Mayer's definition and explains that emotional intelligence is divided into four branches. The first relates to the emotional identification, perception and expression – it deals with the ability of accurate perception of emotions in verbal and nonverbal behavior of others. The second one relates to the emotional relief - the ability to use emotions to assist thinking and problem solving. Third, emotional understanding is the ability to analyze feelings, discrimination of emotions and thinking about the results. Finally, emotion management deals with the possibilities of reflection and change of feelings.

The second model, a model of emotional intelligence attributes, perceive it in relation to personality and self-reporting. In this model, emotional intelligence is defined as a set of cognitive skills, competencies and skills that influence one's ability to successfully struggle with the demands and pressures of the environment.

This model uses the broadest definition of emotional intelligence. Capabilities such as perception of emotions are usually combined with non-cognitive competencies, abilities and personality attributes. This model measures the five wide factors and fifteen aspects, namely:

- Intrapersonal - emotional self-awareness, self-confidence, independence, own meaning and self-actualization;
- Interpersonal - empathy, social responsibility, and interpersonal relationships;
- Stress management - stress tolerance and impulse control;
- Adaptability - reality testing, flexibility and problem solving;
- General mood - optimism and happiness.

There are conceptual and methodological issues related to research of emotional intelligence with this mixed model, mainly due to the ambiguous definition and very broad content of the model.

Hendrie Weisinger said: "People are born with the ability to regulate emotions, like a thermostat, but rather to nurture skills, most people walk around them, like mercury in a thermometer, only as a response to what is visible around them. (Weisinger, 2000)" He believes that whenever people blame someone else for the way they feel or behave, they gave up control over their emotions and behavior and handed control to the people around them. Also, according to managers, leaders or people with a high coefficient of emotional intelligence understand that people need to be valued and appreciated, that they need a sense of belonging, a real future, a future full of hope, and the basic organization of their lives.

Bruce Cryer and Lew Childre added to the above Goleman's definition that emotional intelligence improves through the internal quality management (Bruce & Lew , 2004). They say that it is about a genuine increase in the internal coherence and balance in person, and that there is not any doubt that emotional conditions of people affected by the brain and its ability to process information.

We can conclude that all the research on emotional intelligence and its definition can be reduced to four, what we can call - components:

- Self-awareness,
- Social awareness,
- Relationship management and
- Managing emotions.

These components can be viewed through two dimensions related to social and personal skills. Personal competencies include self-awareness and self-management, i.e. own emotions, and the social skills relate to social awareness and relationship management.

3. PROJECT MANAGERS AND EMOTIONAL INTELLIGENCE

If you take a look at list of the competences successful project manager should have, even though there are numerous competences, most of the authors dot mention emotional intelligence as a necessary one. Having that in mind we have conducted several researches trying to establish whether that is important or not.

One of the researches was focused on identification of correlation between project managers' emotional intelligence and educational and business success. A sample of 75 project managers had to show are there any correlation between emotional intelligence and success. One of the standardized test was used. Results show (Figure 1.) that Project managers on top management level have an average EI of 4.33, on executive management level 4.09, on middle management level 3.68 and on operational management level 3.71 (Obradović, Jovanović, Petrović, Mihić, & Mitrović, 2013).

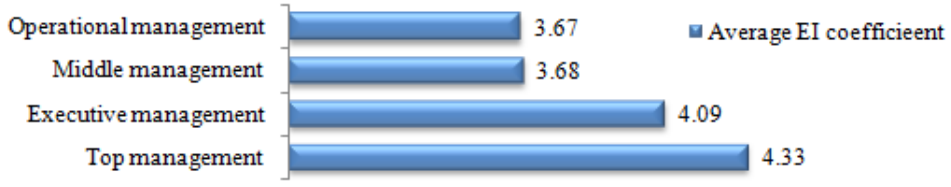

Figure 1. Coefficient of EI in relation with position in organizational hierarchy

Another research conducted had slightly different focus. It aimed to all managers in the organization, not only project managers and to establish is there any correlation with type of manager and emotional intelligence. Results show that highest level of emotional intelligence have middle managers which are actually project managers since the survey was conducted in a project based organization.

Table 1. Emotional intelligence levels on various managerial positions

Managerial level	Average emotional intelligence
Operational management	3.90
Middle management	4.25
Executive management	4.06
Top management	4.19

One can see that results show different results in these two researches, implying that there are differences in emotional intelligence among various managerial levels, but also among different types of managers.

4. CONCLUSION

We came to the conclusion that emotional intelligence is defined by mixed set of capabilities that allow a person to manage themselves and others. This definition can be more accurate if it is accompanied with frequency with which an individual shows itself or use constituent skills or competencies inherent to emotional intelligence that determines the way in which certain persons deals with itself, life and, other people. Decades of research of the effects of psychotherapy, cognitive behavioral therapy, training and education programs have shown that people can change their behavior, mood and self-image (Goleman, 2001).

The current conceptualization of emotional intelligence raises a challenging question: Can a person change their capabilities in a set of competencies that makes emotional intelligence, and that has been proven to bring great results in many occupations, including project management? Series of studies conducted on this topic, confirm that people can change in relation to the competencies of emotional intelligence, usually within two to five years (Weatherhead School of Management (WSOM) of Case Western Reserve University).

Daniel Goleman states that there are three reasons why a person may wish to develop their emotional intelligence. The first is to increase the effectiveness of the work or to increase of the potential for improvement. The reason could be called career development objective or professional development. Another reason is that a certain person wants to become a better person, which is connected with the goal of personal development. Third, people may want to help other people to develop emotional intelligence. All these reasons lead to the simple conclusion that people definitely need to work on their personal development in terms of emotional intelligence competencies, and a starting point for this development and self-change is actually finding out who we really are and who we want to become.

Exploring this theme we have proved that an improvement in emotional intelligence assist project managers in developing their careers and the impact of this concept on the success of the project manager is really great.

Anhtony Mersin states that while working with project managers he realized that they really understand the emotional intelligence at a concept level (Mersin, 2006). The challenge for them is that they lack the tools to use this concept in project management. Ultimately, how you use emotional intelligence in project management?

In life, it is clear that the smartest people are not always those who are the most successful and most fulfilled. There are people who have excellent academic background, but who are socially unsuccessful in work or in their personal relationships. Emotional intelligence affects the following:

- Success on work
- Physical health
- Mental health
- Connections and relationships with other people

All information come into our brain through our senses, and when the information is too stressful or emotional, instinct can take over the ability of behavior. In order to have access to a wide choice and the ability to make good decisions, primarily we need to be able to balance the emotions that arise. It is clear that in order to enhance emotional intelligence primarily we need to understand and learn to manage our own

emotions. This can be achieved by developing key skills for the control and management of overwhelming stress and effective communication. Each skill is build on the lessons learned from the past and by practicing following (Segal & Smith, 2014):

1. Quick reduce of stress at different times;
2. Recognizing own emotions and keeping away from indulging them;
3. Emotional bonding with other people through the use of non-verbal communication;
4. Using healthy humor and a connections in challenging situations;
5. Resolving conflicts in a positive manner and with trust.

By emphasizing the importance of emotional intelligence for project management, as well as in relation to the above-mentioned quote, we conclude that the impact of emotional intelligence on the performance of project managers is extremely high. Emotional intelligence of the project manager can make a different and much needed "star" in every modern organization.

Open expression of thoughts, feelings, and intentions allows people to really see each other for what they are and encourages confidence and building of positive social relationships. These managers are freed from prejudice and very clear and real in observing current relationships and situations. Knowing yourself and having the ability of making good choices when it comes to relationships, fosters a climate in which even the most diverse and difficult issues can be discussed. Self-conscious project manager is at all times ready to undertake concrete actions and absolutely sure about decisions he or she made, displaying at the same time a clear opinion on issues related to the implementation of projects.

What are the possibilities of a project manager who has a strong sense of empathy? People believe that others are really interested in their feelings, intentions, problems and deepest hopes. The project manager must take the time for the members of his team in order to understand exactly what they feel and think. This kind of relationship creates authentic and close relationships between people and assist managers to cooperate with people from their project team much easier.

What are the possibilities of achieving the objectives of the projects being run by a project manager who has the perspective to see the needs and interests of all members of the team? Such manager, even in difficult and dangerous situations reflect careful and firm presence. It is clear that people with this brilliant ability to influence other people are respected and valued for their vision and the possibility of transforming people through building relationships of trust. The possibilities are simply immeasurable.

Emotional intelligence coefficient of various managerial levels are different. It turned out that mid-level managers that are project managers have an extremely high coefficient of emotional intelligence, and therefore a greater awareness of this concept. We certainly believe that in the short time they will become very successful senior level project managers who will be able to manage the most complex projects in a very simple way.

Since this is a concept that will become more and more popular in a future, a concept necessary for any job interview, and certainly for a daily life, it is important to begin a general rise of awareness about emotional intelligence and its competences. For the new generation, a work on this concept will be required in early childhood, and emotional intelligence will be introduced in the education system. We hope that the importance of self-awareness, social awareness, emotions and relationships management will be fully recognized.

Abstract: *This paper proposes a method for ranking candidates according their past performance and their qualitative personal qualifications for managing a project. The rank allows selecting the best candidate to be the project manager. The method also allows evaluation of the past performance of project managers. The proposed method combines between two common methodologies: the Data Envelopment Analysis (DEA), the Analytical Hierarchical Process (AHP) and ranking methods via DEA. The method is especially useful for the assignment of project manager for an important project.*

Keywords*: Project Management (PM), Analytical Hierarchical Process (AHP), Data Envelopment Analysis (DEA), Ranking Methods (RM).*

1. INTRODUCTION

Experts for organizations and human resources managers are constantly busy in searching ways to examine the performance of workers and managers. The evaluation of past performance of the employees can be made according to quantitative and/or quality parameters. The evaluation allows to establish a comparison between the workers and to rank them according to their performance. The rank allows selecting the best candidate for a specific job. This paper proposes a method to rank candidates for managing a project. The method also allows evaluation of the past performance of project managers.

A project success is depended on several critical success factors. One important factor is a competent project manager with proven leadership skills (Fortune & White, 2006). In the selection of the project manager his/her past performance should be considered and his/her personal and professional skills. If there are several candidates for managing an important project, it is a common practice to select the best candidate on the basis of several criteria. Some of the criteria are qualitative/subjective (for example, leadership, technical skills and teamwork ability) and others are quantitative/objective related to previous projects (for example, completion time, completion cost and meeting the technical requirements). In order to evaluate the past performance of candidates to be the selected project manager their completed projects should be examined. Many criteria can be used to compare the relative performance success of completed projects. Asosheh et al. (2010) discussed about 30 criteria reviewed in six papers they surveyed concerning IT project management.

The project manager selection process has been widely discussed in the literature. Hadad et al. (2013) surveyed several papers of this topic, here some of them in brief. Zavadskas et al. (2008) proposed a set of criteria for the selection of construction managers. El-Sabaa (2001) conducted a survey concerning the skills of successful project managers. Hauschildt et al. (2000) identified five types of project managers. They calculated the prevalence of each type and examined the success levels of project managers classified to each type. Muller & Turner (2007) claimed that project managers' past performance depends on their competence, particularly their leadership. It can be concluded that the criteria most often taken into consideration are the candidate's personal skills, project management skills, and experience in similar projects. Cheng et al. (2005) concluded that task competencies are specific to a given project. However, when selecting a project manager one must consider both: the past performances of the candidates as well as their suitability for the specific project. Eilat et al. (2006) stated that project performance evaluation is a multiple-criteria problem. The criteria and their weights must be determined and weighted according to the organization's preferences.

In order for project managers to successfully and effectively perform all of their functions, they must be experienced, knowledgeable and skilled - in other words, they must possess competence, and personal competence is proven through certification (Uhlir, 2013). Of course, a certificate cannot guarantee an individual's success, but Uhlir (2013) claimed that a certification is a significant indicator and tool for differentiation between project managers. In this paper we propose we assume that there is a group of certified project managers. The aim is to rank the managers according their past success and according to their qualitative personal criteria and then to select one of them for managing a specific project.

This paper is expansion of the decision-making support system (DMSS) which proposed by Hadad et al. (2013). The DMSS of Hadad et al. (2013) used only objective criteria in order to rank a group of candidates. This paper proposes to use the scores that each project obtains by the previous DMSS as input to a revised

DMSS, and with other qualitative/subjective criteria to obtain a full rank of the candidates. The revised DMSS combines two well-known methodologies: Data Envelopment Analysis (DEA) (Charnes et al., 1978) and the Analytical Hierarchical Process (AHP) (Saaty, 1980). Moreover, the DMSS uses ranking method in the contest of the DEA (see, Adler et al. 2002, Hadad & Hanani, 2011). Combining AHP with DEA can be found for example in: Sinuany-Stern et al. (2000); Hadad & Hanani (2011); Hadad et al. (2013); Yang & Kuo (2003) and others.

2. LITERATURE REVIEW

This section introduces the two well-known methodologies that are at the basis of the proposed model, the Data Envelopment Analysis (DEA) and the Analytical Hierarchical Process (AHP). The DEA evaluates the relative efficiency of Decision-Making Units (DMUs) and the AHP converts qualitative evaluations into quantitative criteria. Furthermore, this section introduces ranking methods in the DEA context that can be used to rank the project managers.

2.1 DATA ENVELOPMENT ANALYSIS (DEA)

The DEA (CCR model) was first developed by Charnes et al. (1978). The DEA is a non-parametric method to evaluate the relative efficiency of DMUs based on multiple inputs and multiple outputs, even if the production function was unknown. The DEA provides a mechanism for measuring a DMU efficiency (in our case project), compared with other DMUs. The DEA methodology solves a linear programing (LP) formulation per DMU and the weights assigned to each linear aggregation are the results of the corresponding LP (Adler et al., 2002). The DEA has become a useful tool for operations researchers (Emrouznejad, et al., 2008 report on over 4000 references on DEA; see also Tavares, 2002 and Seiford, 1996), its use by economists is limited (5%). There are also many papers that use the DEA for comparing project efficiency (for example, Vitner et al., 2006; Eilat et al., 2006; Mahmood et al., 1996, Hadad et al, ,2013, Hadad & Keren, 2013).
The DEA finds different weights for each DMU, such that any DMU in the objective function with the optimal weights will receive a maximal efficiency score. In the DEA, the weights of the inputs and outputs vary from DMU to DMU. Moreover, DEA can distinguish only between efficient and inefficient DMUs (dichotomic classification). Therefore all the efficient units have the same ordering score and it is difficult to rank according to the DEA score. The DEA measures the relative efficiency score as a ratio between the weighted output and the weighted input. DEA calculates for each DMU *k* the ideal weights for each output- U_r^k $\left(r=1,2,..,s\right)$ and the ideal weights for each input-V_i^k $\left(i=1,2,..,m\right)$ that maximizing its relative efficiency score under the restriction that this score is bound by 100% efficiency. If a DMU with its ideal weights receives an efficiency score of 100% - it is efficient, while a score of less than 100% is considered inefficient.
Consider *n* projects, where each project *j* (*j*=1,…,*n*) is characterized by *m* kind of inputs $\vec{X}_j=\left(X_{1j},X_{2j},.....,X_{mj}\right)^T>0$ and by *S* kind of outputs $\vec{Y}_j=\left(Y_{1j},Y_{2j},.....,Y_{sj}\right)^T>0$. The CCR model (output-maximized) for project *k* is formulated as follows:

$$
\begin{aligned}
& h_k = Max \sum_{r=1}^{s} U_r^k \times Y_{rk} \\
& s.t \\
& \sum_{i=1}^{m} V_i^k \times X_{ik} = 1 \\
& \sum_{r=1}^{s} U_r^k \times Y_{rj} - \sum_{i=1}^{m} V_i^k \times X_{ij} \le 0 \quad j=1,....,n \\
& U_r^k \ge \varepsilon > 0 \quad \mathrm{r}=1,2,..,\mathrm{s} \\
& V_i^k \ge \varepsilon > 0 \quad \mathrm{i}=1,2,..,\mathrm{m}
\end{aligned}
\qquad (1)
$$

where ε is an infinitesimal number.
The CCR model assumes that the production function exhibits Constant Returns To Scale (CRTS). The results of the CCR output-maximized formulation are identical to the CCR input-minimized results (Adler et al., 2002).

2.2 ANALYTICAL HIERARCHICAL PROCESS

The Analytical Hierarchical Process (AHP) methodology was developed by Saaty (1980). AHP is methodology to quantify the value of the qualitative/subjective criteria. AHP has been widely used in real-life applications (see a survey in Zahedi 1986, Vaidya & Kumar 2006, Hadad and Hanani, 2011). The AHP is designed for subjective evaluation of a set of alternatives (elements or units in our case) based on multiple criteria, organized in a hierarchical structure. At the top level, the criteria are evaluated and at the lower levels, the alternatives are evaluated by each criterion. The decision maker assesses his evaluation separately for each level and sublevel subjectively. He creates a pairwise comparison matrix in which his subjective evaluation for every pair of items is assessed (Sinuany-Stern et. al., 2000). While AHP has been widely used in real-life applications, there have been some reservations regarding its lack of axiomatic foundations on the utility preferences of the decision maker (see Dyer, 1990 and response Saaty, 1986; Winkler, 1990; Barzilai et al., 1987).

In our case each project manager is evaluated according to several criteria, not all quantitative. The output of AHP is numeric scores of each project manager in each qualitative/subjective criterion. In input of the AHP is a pairwise comparison matrix for every pair of project managers for each qualitative criterion that is created by the decision makers. A common scale of values for pairwise comparison is ranging from 1 (indifference) to 9 (extreme preference). Note that in AHP, the pairwise comparison matrix $A=\left(a_{i,j}\right)_{n\times n}$ on the diagonal has a rank of 1 $\left(a_{i,i}=1\right)$ and the elements $a_{i,j}$ reflect the evaluation of i over j, $a_{i,j}=1/a_{j,i}$ and each element in the matrix is strictly positive - $a_{i,j}>0,\ i=1,2,...,n,\ j=1,2,...,n$ .If $a_{i,j}<1$, it means that i is evaluated less than j .

For *n* project managers and *m* criteria the number of comparisons to be carried out is:

$$m(n^2-n)/2+m(m-1)/2.$$

According to Saaty's definition, the eigenvector $\vec{N}$ of the maximal eigenvalue λ_{max} of each pairwise comparison matrix is utilized for ranking the project managers. For more detail about the AHP methodology see Saaty (1980, 1986, 1990). AHP has been widely used in real-life applications (see a survey in Hadad & Hanani, 2011).

Saaty (1980) defined a statistical measure to test the consistency of the respondent. The statistical measure of the consistency index (CI) is:

$$CI=\mu=\frac{\lambda_{max}-n}{n-1}$$

and the Consistency Ratio (*CR*) is given by:

$$CR=\left(\frac{CI}{RI}\right)100\%.$$

where:

λ_{max} - is the maximal eigenvalue of the matrix,

n - is the number of rows/columns of the matrix,

RI - is the random index. It is the average of the CI for a large number of randomly generated matrices. The values of RI can be found in the table that developed by Saaty (1980, p.51).

The consistency of the decision makers can be checked by the value of CR. Generally, if the CR is 10% or less, the respondent is considered consistent, acceptable, and the computed comparison matrix can be used (Saaty, 1980). If $CR>10\%$, the respondent is not consistent and he/she must correct his/her pairwise estimations.

2.3 RANKING METHODS

There are many different methods for ranking DMUs within the DEA context (for reviews see Adler et al., 2002, Hadad & Hanani, 2011). This sub-section presents two of them.

2.3.1 THE SUPER EFFICIENCY METHOD

One drawback of the DEA methodology is that it does not rank efficient DMUs (those with efficiency scores of 1). To overcome this drawback Anderson & Peterson (A&P) (1993) proposed the Super efficiency ranking method. They suggest allowing the efficient DMUs to receive a score greater than 1 by dropping the constraint that bounds the score of the evaluated the efficient DMU to 1. The A&P formulation for the DMU *k* is follows:

$$
\begin{aligned}
& h_k = Max \sum_{r=1}^{s} U_r^k \times Y_{rk} \\
& s.t. \\
& \sum_{r=1}^{s} U_r^k \times Y_{rj} - \sum_{i=1}^{m} V_i^k \times X_{ij} \le 0 \quad for\ j = 1,2,..,n,\ j \ne k \\
& \sum_{i=1}^{m} V_i^k \times X_{ik} = 1 \\
& U_r^k \ge \varepsilon > 0 \qquad r = 1,2,..,s \\
& V_i^k \ge \varepsilon > 0 \qquad i = 1,2,...,m
\end{aligned}
\tag{2}
$$

2.3.2 THE CROSS EFFICIENCY METHOD

Other drawback of the DEA methodology is that it does not use common weights while evaluating the efficiency of DMUs. To overcome this drawback Sexton et al. (1986) proposed the Cross Efficiency (CE) ranking method. This subsection presents the steps for setting the score of each DMU by the CE.

Step 1 – Find the optimal weights $u_r^k \ \left(r = 1,2,...,s;\ k = 1,2,...,n\right)$ and $v_i^k \ \left(i = 1,2,...,m;\ k = 1,2,...,n\right)$ by the CCR model.

Step 2 – Calculate the elements of the cross-evaluation matrix as follows:

$$
h_{k,j} = \frac{\sum_{r=1}^{S} u_r^k \times Y_{r,j}}{\sum_{i=1}^{m} v_i^k \times X_{r,j}},\ k = 1,2,...,n,\ j = 1,2,...,n\ .
$$

Thus, $h_{k,j}$ represents the efficiency given to DMU j in the CCR run of DMU k (the efficiency of DMU j by the optimal weights of DMU k).

Step 3 - Calculate the score for each DMU j as follows:

$$
\bar{h}_j = \frac{\sum_{j=1}^{n} h_{k,j}}{n} \tag{3}
$$

Step 4 – Rank the DMUs according to the scores $\bar{h}_j$, $j = 1,2,...,n$. The DMU with the highest score will be ranked first and so on.

2.4 INPUTS AND OUTPUTS FOR RANKING PROJECTS

Many quantitative criteria can be used to compare the relative performance success of completed projects. The decision makers must determine the appropriate criteria for projects evaluation and how they can be measured. The criteria should reflect the organization's objectives and the projects type. In order to use ranking method in the DEA context the criteria must be classified into inputs and outputs. Hadad et al. (2013) proposed the following inputs and outputs:

Input 1- The cost stabilization coefficient of project i .

$$
X_{1,i} = \frac{E(C_i)}{\sigma(C_i)} \tag{4}
$$

Where

$E(C_i)$ - the i-th project's expected cost.

$\sigma(C_i)$ - the i-th project's standard deviation cost.

$X_{1,i}$ - the coefficient of variation (Levy and Sarnat, 1995).

Input 2- The completion time stabilization coefficient of project i.

$$X_{2,i} = \frac{E(T_i)}{\sigma(T_i)} \tag{5}$$

Input 3- The reciprocal of the intensity of project i.

$$X_{3,i} = \frac{E(T_i)}{E(C_i)} \tag{6}$$

Output 1- The ratio between the expected cost and the actual cost of project i.

$$Y_{1,i} = \frac{E(C_i)}{e(C_i)} \tag{7}$$

Where $e(C_i)$ is the i-th project's implementation expenses.

Output 2- The ratio between the expected and the actual completion time of project i.

$$Y_{2,i} = \frac{E(T_i)}{e(T_i)} \tag{8}$$

Output 3- The ratio between the actual cost, excluding implementation expenses, and the implementation expenses of project i.

$$Y_{3,i} = \frac{e(C_i)}{l(C_i)} \tag{9}$$

where $l(C_i)$ is the i-th project's implementation expenses.

Output 4- The ratio between the actual completion time, excluding the implementation duration, and the implementation duration of project i.

$$Y_{4,i} = \frac{e(T_i)}{l(T_i)} \tag{10}$$

3. CANDIDATES RANKING

This section presents the steps of the proposed method that allows full rank of the candidates. The rank is carried out according to the average scores of the projects that each project manager performed in the past, and according to the scores of his personal qualitative criteria.

Step 1: Define the candidates to be evaluated. For each candidate k, $k = 1,2,...,K$, determine the projects that will be used for candidate ranking $l = 1,2,...,L_k$. L_k is the number of the projects that according to them candidate k will be evaluated.

Step 2: Calculate for each project k,l the input and output values according to equations $(4),...,(10)$, respectively.

Step 3: Select one of the ranking methods (section 2.3) and compute the level of performance, $F_{k,l}$, for all the projects k,l, $k = 1,2,...,K;\ \ l = 1,2...,L_k$. For A&P ranking method use equation (2) to compute $F_{k,l}$. For the CE ranking method use equation (2) to calculate the optimal weights and then compute $F_{k,l}$ via equation (3).

Step 4: The average level of past performance of candidate k is calculated as follows:

$$F_k = \frac{1}{L_k} \sum_{l=1}^{L_k} F_{k,l} \quad (11)$$

Step 5: Determine the qualitative personal criteria that according to them the candidates will be evaluated. For each criterion t, $t = 1,2,...,T$ perform pairwise comparison according to AHP methodology and create a pairwise comparison matrix A_t. Calculate for these matrixes $\lambda_{t,max}$ and the consistency ratio CR_t. If $CR_t \leq 10\%$, go to the next step. If not, the pairwise comparison must be modified.

Step 6: Calculate the normalized eigenvector $\vec{N}_t$ $(t = 1,2,...,T)$ of the maximal eigenvalue $\lambda_{t,max}$. The elements of this vector, $P_{k,t}$, represent the score of candidate k in criterion t.

Step 7: Determine the relative weights, W_t $(t = 1,2,...,T,T+1)$ for all the criteria (qualitative and quantitative). Note that there are T criteria that represent the qualitative attributes of the candidate and one quantitative criterion that represents his/her past performance level. The relative weights can be set directly by the decision makers, or subjectively by AHP or objectively by DEA.

Step 8: The final score of each candidate, S_k, is the weighted score he/she obtained in all the criteria. This score is calculated as follows:

$$S_k = \sum_{t=1}^{T} W_t \times P_{k,t} + W_{T+1} \times F_k$$

Step 9: Rank all the candidates by S_k. The candidate with the highest S_k is ranked first and so on.

4. CONCLUSIONS

This paper proposes a method that uses DEA, AHP methodologies and ranking method for selecting the best candidate for a managing a project. The proposed method allows calculating the weighted score and the rank of each candidate according to quantitative and qualitative criteria. It is important to select the appropriate criteria for the ranking because the selected criteria have influence on the final rank. The values of the criteria (quantitative and qualitative) are based on the past performance of the candidates. Therefore it is applicable only for experienced candidates. The proposed method can be used in project oriented organizations such as building companies and software companies, where all the projects have similar characters.

Abstract: *This paper reviews ranking indexes of project activities for project management tasks. The ranking of project activities in one project is applicable for focusing the project manager attention on the important activities. The selection of the appropriate ranking indexes should be done according to the managerial purpose: 1) Paying attention to activities throughout the execution phase and in the resources allocation process in order meet the determined qualities, and to deliver the project on time and within budget, i.e., to accomplish the project within the "iron triangle" 2) Setting priority in order to share the managerial care and control among the activities. The paper proposes to use multi-criteria ranking methods in order to rank the activities in a case where several ranking indexes are selected.*

Keywords*: Project Management (PM), Ranking Indexes (RI), Multi-Criteria Ranking Method (MCRM), Analytical Hierarchical Process* (AHP).

1. INTRODUCTION

Project is a complicated task that requires coordinated efforts to achieve a set of goals. These goals are typically: meeting the determined qualities, delivering the project on time and within budget (the iron triangle). Other goals can be performing the project according to the organization culture and rules and minimizing the interruptions to other activities. Keren and Cohen (2012) developed a formulation that reflects a triangular trade-off structure between the project objectives: time, budget, and quality. The major challenge of the project manager is carrying out a balanced distribution of his managerial efforts between various project tasks, activities and objectives (Hadad and Keren, 2013).

The project program should be prepared initially, taking into consideration the set of the project activities with their precedence priorities and the possible execution modes of each activity (Laslo & Gurevich, 2013a). The planning of the project includes optimization allocation of the project activities' budgeting, i.e., minimization of the total budget subject to on time accomplishment of the project. Such optimizations of multi-mode optimization problems are performed via the Critical Path Method (CPM) time-cost tradeoffs procedure (Kelley & Walker, 1959; Kelley, 1961) when deterministic duration of all project activities is considered. In a case of project with stochastic durations, a semi-stochastic time-cost tradeoffs procedure (Golenko-Ginzburg, 1993) or a stochastic time-cost procedure (Laslo & Gurevich, 2013b) are performed. Recently, many heuristics for multi-mode resource-constrained scheduling optimization problems have been tested on sets of benchmark instances from the PSPLIB library (Kolisch & Padman, 2001; Kolish & Hartman, 2006)). However, the uncertainty throughout the project's lifecycles disables following the initial timetable, and thus, the practice requires a dynamic scheduling routine where in cases of resource shortages during the project execution decisions should be reconsidered and taken via dispatching. When the decision-making is based on the deterministic approach, the MINSLACK dispatching was found very effective for the reestablishment of the project's time target (Davis & Patterson, 1975). Considering uncertain durations of project activities, Laslo (2010) introduced for this purpose a heuristic pairwise dispatching that raises the probability confidence of accomplishing the project on time. The dynamic scheduling determines which of the project activities is in process at each point during the execution of the project.

When several activities are processed simultaneity, it is important to rank the activities according to their relative importance in keeping the project performances within the iron triangle. Such rank enables the project manager to focus his/her managerial efforts and control in the most important activities and by that to increase the probability for a project success. This paper reviews several ranking indexes that help to rank the project activities in process by their importance for attaining the project targets. By selecting an appropriate ranking index a project manager can rank all these activities. If the project manager prefers to use several ranking indexes, he/she must set relative weights for each selected index. The most important activities would be managed by the project manager himself/herself (similar to the Pareto principle). The values of the relative weights can be determined by subjective methods such as: Analytical Hierarchical Process (AHP) (Satty, 1980); ELECTRE (Roy 1989, 1990); Simple Multi-Attribute Technique (SMART) (Edwards 1977, Edwards and Barron 1994) or by the decision makers. The values of the relative weights can be determined by objective methods via Data Envelopment Analysis (DEA) (Charnes et al., 1978) such as the Super Efficiency (Anderson and Peterson, 1993); Canonical Correlation Analysis (Friedman and

Sinuany-Stern, 1997); Global Efficiency Method (Ganley and Cubbin,1992); Cross Efficiency Method (Sexton et al., 1986). For reviews see Adler et al. (2002), Hadad and Hanani (2011).
Ranking of the project activities can be done for two distinguished goals. The first goal is for setting priority for performing the activities and for resources allocation in order to meet the due date. The second goal is for setting priority in order to share the managerial care and control among activities. Ranking indexes that important for meeting the due date are the minimum slack (the difference between the latest and earliest start time of the activity) in a deterministic case and the Significance Index (SI) (Williams, 1992); Activity Criticality Index (ACI) (Van Slyke ,1963, Martin, 1965); Cruciality Index (CRI) (Williams, 1992, Elmaghraby, 2000); time–cost tradeoffs under uncertainty (Laslo and Gurevich, 2013) and others in a stochastic case. These indexes are presented in the next section. Ranking indexes that useful for sharing the managerial care and control are related to the cost, duration and risk of an activity. Several indexes of this type are also presented in the next section.
Furthermore, the importance of the activities is dynamic and can be changed during the project execution. Therefore in every major mile stone the project manager must recalculates the ranking indexes taking into account the current status of the project. In other words, when several activities have been completed – the ranking of the uncompleted activities should be carried out again. Milestones are events in a project that divide the project into stages for monitoring and measurement of work performance. These events typically indicate a completion of a major deliverables of a project.

2. RANKING INDEXES FOR PROJECT ACTIVITIES

The Critical Path Method (CPM) is developed in the 1950's. It represents a project as an activity network as a graph that consists a set of nodes $N=\{1,\ 2,\ \ldots,\ n\}$ and a set of arcs $A=\{(i,\ j\ )\,|\,i,\ j\in N\}$. The nodes represent project activities whereas the arcs that connect the nodes represent precedence relationships. Each activity j has either deterministic activity duration t_i or a stochastic duration. Each activity can start after all its predecessors have completed. CPM uses an early-start schedule in which activities are scheduled to start as soon as possible. However, most projects are not deterministic since they are subject to risk and uncertainties due to external factors, technical complexity, shifting objectives/scopes, and poor management. In practice, project risk management includes the process of risk identification, analysis, and handling (Gray and Larson, 2005).
Ranking indexes enable the ranking of project activities based on the impact they have on project objectives (Creemers et al., 2010, 2011, 2014). This section presents the ranking indexes that will be used for calculating the scores of each project activity. The first indexes are related to the duration of the project and to the duration risks (2.2), and the rest are related to the cost and to the managerial care.

2.1 NOTATIONS

This sub-section presents the notations that are used for determined the ranking indexes.
$\mu(t_i)$ - The expected duration of activity $i\ (i=1,2,...,n)$.
$\sigma(t_i)$ - The standard deviation of the duration of activity $i\ (i=1,2,...,n)$.
$\mu(c_i)$ -The expected cost of activity $i\ (i=1,2,...,n)$.
$\sigma(c_i)$ - The standard deviation of the cost of activity $i\ (i=1,2,...,n)$.
t_i^k - The duration of activity $i\ (i=1,2,...,n)$ in simulation run $k\ (k=1,2,...,K)$.
c_i^k - The cost of activity $i\ (i=1,2,...,n)$ in simulation run $k\ (k=1,2,...,K)$.

2.2 RANKING INDEX FOR DURATION OF AN ACTIVITY

In this sub-section the ranking indexes for the duration of an activity are presented. For a more detailed discussion on the ranking indices presented below, refer to Elmaghraby (2000), Demeulemeester and Herroelen (2002).

2.2.1 RANK POSITIONAL WEIGHT (RPW)

Hadad and Keren (2013) suggested to use the Rank Positional Weight (RPW) index that developed by Helgeson and Birnie (1961) for ranking index for duration of activity. The RPW of an activity is the sum of the duration of all activities following the activity in the precedence network, including the duration of the activity itself. The RPW is calculated by:

$$RPW = \frac{1}{K}\left(RPW^1 + RPW^2 + ... + RPW^K\right) \quad (1)$$

where

RPW^k -The RPW index of simulation run $k\ (k = 1,2,...,K)$ is computed by the equation $RPW^k = A \times t^k$.

In this equation, A is the $(n \times n)$ fixed precedence matrix with elements $a_{i,j} = \begin{cases} 1 & \text{if } i = j \text{ or } i \prec j \\ 0 & \text{otherwise} \end{cases}$

2.2.2 SIGNIFICANCE INDEX (SI)

The Significance Index (SI) was developed by Williams (1992). In order to better reflect the relative importance between project activities, the sensitivity index of activity i has been formulated as follows:

$$SI_i = \frac{1}{K}\sum_{k=1}^{K}\left(\frac{t_i^k}{t_i^k + TF_i^k}\right)\left(\frac{T_{\max}}{\bar{T}}\right) \quad (2a)$$

The SI is usually estimated by simulation methods (Vanhoucke, 2010), and is calculated by:

$$SI_i = \frac{1}{K}\sum_{k=1}^{K}\left(\frac{t_i^k}{t_i^k + TF_i^k}\right)\left(\frac{T^k}{\bar{T}}\right) \quad (2b)$$

where

t_i^k - duration of activity $i\ (i = 1,2,...,n)$ in simulation run $k\ (k = 1,2,...,K)$.

TF_i^k - total float of an activity $i\ (i = 1,2,...,n)$ in simulation run $k\ (k = 1,2,...,K)$. (Refer to Demeulemeester and Herroelen (2002) for a definition of total float).

T - total project duration (a random variable).

T^k - total project duration in simulation run $k\ (k = 1,2,...,K)$.

$\bar{T}$ - average project duration over K simulations.

2.2.3 COEFFICIENT OF VARIATION (CV) FOR ACTIVITY DURATION

The coefficient of variation (CV) is often used as a risk measure for time and cost (Levy and Sarnat, 1995). Yeo (1991) claimed that the CV can be used as a reasonable measure of cost variation and as a complement to the sensitivity measures. Khorramshahgol (1988); Khorramshahgol and Steiner (1988); Khorramshahgol and Vassilis (1988) used the CV for project evaluation and selection. The coefficient of variation for the duration of activity i is computed by:

$$CV(t_i) = \frac{\hat{\sigma}(t_i)}{\bar{t_i}} = \frac{\left(\frac{1}{K-1}\sum_{k=1}^{K}\left(t_i^k - \bar{t_i}\right)^2\right)^{\frac{1}{2}}}{\bar{t_i}} \quad (3)$$

2.2.4 ACTIVITY CRITICALITY INDEX (ACI)

A common practice in project risk management is to focus mitigation efforts on the critical activities of the deterministic early-start schedule (Goldratt, 1997). The Activity Criticality Index (ACI) was developed by Van Slyke (1963) and later by Martin (1965). The ACI index of activity i is computed by:

$$ACI_i = \frac{1}{K}\sum_{k=1}^{K}\delta_i^k, \quad \delta_i^k = \begin{cases} 1 & \text{if } i \text{ is critical in simulation run } k \\ 0 & \text{otherwise} \end{cases} \quad (4)$$

For more details about the activity criticality index see Creemers et al. (2010, 2011).

2.2.5 CRUCIALITY INDEX (CRI)

The Cruciality Index (CRI) was developed by Williams (1992) and Elmaghraby (2000). This index defined as the absolute value of the correlation between the activity duration and the total project duration. The CRI of activity i is computed by:

$$CRI_i = \left|\text{corr}\left(t_i^k, T^k\right)\right| \quad (5a)$$

Cho and Yum (1997) suggested calculating the cruciality index according to Spearman's rank correlation. This measure is computed as following:

$$CRI_i = \left|1 - \frac{6}{K(K^2-1)}\sum_{k=1}^{K}\left(\text{Rank}(t_i^k) - \text{Rank}(T^k)\right)^2\right| \quad (5b)$$

2.2.6 SCHEDULE SENSITIVITY INDEX (SSI).

Cho and Yum (1997) proposed to measure the impact of the variability in activity durations on the variability of the project completion time. Their uncertainty importance measure (UIM) is evaluated as flowing:

$$UMI_i = \frac{Var(t_i)}{Var(T)} \quad (6a)$$

The PMI Body of Knowledge (2008) and Vanhoucke (2010) defined a ranking index- SSI that combines the ACI and the variance of t_i (duration of activity i) and T (total project duration). The Schedule Sensitivity Index (*SSI*) is computed as following:

$$SSI_i = ACI_i \sqrt{\frac{Var(t_i)}{Var(T)}} \quad (6b)$$

2.2.7 CRITICAL DELAY CONTRIBUTION (CDC)

The Critical Delay Contribution (CDC) was developed by Creemers et al. (2014). The CDC redistributes the project delay over the combinations of activities and risks that cause the delay. The term $CDC_{i,e}^{(E)}$ represents the proportion of the project delay that originates from the impact of a risk $e : e \in E$ on an activity i and is computed as following:

$$CDC_{i,e}^{(E)} = \frac{1}{K}\frac{\sum_{k=1}^{K} m_{i,e,k} \times \delta_{i,k}^{(E)}\left(T_k^{(E)} - T\right)}{\sum_{i\in N}\sum_{e\in E}\sum_{k=1}^{K} m_{i,e,k} \times \delta_{i,k}^{(E)}} \quad (7)$$

where $m_{i,e,k}$ is the random variable of the risk impact of a risk e on the duration of an activity j in simulation k. $\delta_{i,k}^{(E)}$ equals 1 if *j* is critical in simulation k and 0 otherwise.

2.3 RANKING INDEX FOR COST

In this sub-section the ranking indexes for the cost of an activity are presented. For more details see Hadad and Keren (2013).

2.3.1 EXPENDITURE RATE (ER)

The Expenditure Rate (ER) was used by Hadad and Keren (2013) as a ranking index for project activities. The expenditure rate of activity i, ER_i, is calculated by:

$$ER_i = \frac{1}{K}\sum_{k=1}^{K}\frac{c_i^k}{t_i^k} \quad (8)$$

Where

c_i^k is the cost of activity i in simulation run k.

2.3.2 COEFFICIENT OF VARIATION (CV) FOR ACTIVITY COST

The coefficient of variation for the cost of activity i is computed by:

$$CV(c_i) = \frac{\hat{\sigma}(c_i)}{\overline{c}_i} = \frac{\left(\frac{1}{K-1} \sum_{k=1}^{K} \left(c_i^k - \overline{c}_i \right)^2 \right)^{\frac{1}{2}}}{\overline{c}_i} \quad (9)$$

3. A PROCEDURE FOR RANKING PROJECT ACTIVITIES

In order to rank project activities according to their importance the following procedure is proposed.

Step 1: Plan the project and collect data: Build the CPM network and set milestones. Determine duration and budget for each activity. Estimate the excepted values and the variances for each activity.

Step 2: Determine the managerial objectives (meeting the due date and/or sharing of the managerial care and control) and select the appropriate ranking indexes that would support these objectives.

Step 3: Simulate the project and obtain the needed values for calculation of the selected ranking indexes (durations, costs, variances, criticality, etc.). Calculate the values of the indexes for each activity.

Step 4: If only one ranking index is selected – all the activity should be ranked according to the value of this index (step 5). If several ranking indexes are selected then a multi-criteria ranking method must be selected (e.g., AHP, DEA). The weights of the indexes must be determined and the weighted score of each project activity is calculated.

Step 5: Rank the uncompleted activities of the project in descending order according to their scores. One rank is for supporting the objective of meeting the due date and the second rank is for sharing of the managerial care and control.

This procedure must be performed at each milestone for the uncompleted activities.

4. CONCLUSIONS

This paper reviews ranking indexes of project activities for project management tasks. The ranking indexes can be used for focusing the attention of the project manager on the important activities and to spread correctly his/her managerial efforts and control among the activities. The ranking of the project activities is useful for two distinguished goals: 1) Prioritizing activities in execution and in resources allocation in order to meet the due date. 2) Setting priority in order to share the managerial care and control among the activities. The paper proposes to use multi-criteria ranking methods in order to rank the activities in a case where several ranking index are selected. Note that the decision makers must select the proper indexes for the activities ranking. The selection of the appropriate ranking indexes is very important task because different indexes yield different rank. Moreover, one can find after the indexes selection that some of the indexes are highly correlated with other indexes. In such case one must decide which indexes would be removed.

The proposed method solves the difficulty of determining the relative weights for each ranking index that is used for the ranking by using mathematical methodology (DEA). The proposed method is useful for a project with many activities or for a program that includes several projects which are executed in parallel. In these cases the proposed method allows the project manager to share his or her managerial efforts and care among the activities.

Abstract: *This paper presents the basic concepts for defining the project success and it-s measurement. Based on the literature review, the research was conducted to investigate: 1) the level of development of project management in project-based organizations in Serbia, 2) the level at which the organizations define project success factors and key performance indicators and 3) whether they are used for assessing the project success. The main conclusion is that the success factors of the project, taking into account the organizational and external environment factors are defined in something more than 1/3 of respondent's organizations. The almost same situation is present when we consider performance indicators, and their usage in evaluating the project success, considering organizations in Serbia.*

Keywords*: Project, success, analysis, CSF, KPI.*

1. INTRODUCTION

Project managers today are faced with many challenges of project management specially with the need for fast decision making in selection of an appropriate project and how to make the best use of existing knowledge and information from previous projects in order to avoid waste of resources and achieve better results for further projects.

One of the most common ways of gathering information about the project is the analysis of achieved project results, or in other words, achieved project success. However, the biggest challenge in measuring and analyzing the project success is the transfer of something that is defined as a success or success factor at the operational level, through measurable indicators that will allow the evaluation of the project during and after it's implementation. The starting point of this statement is the organization observation through its four perspectives (according to BSC concept every organization has four perspectives: financial perspective, customer perspective, the perspective of learning and development and internal processes) where only the usage of the strategic map enables the concretion of measures for analysis and evaluation of organizational performances. Similarly, it can be concluded that defined success factors must be transferred to the operational level and become measurable in order to analyze the success of the project .

Below are presented the Critical Success Factors - CSF and Key Performance Indicators - KPI as concepts for project success analysis, along with empirical research that examines the usage of CSF and KPI in project success assessment.

2. PROJECT SUCCESS ANALYSIS TROUGH ITS DEFINITION AND MEASUREMENT

Retrospective of understanding/perception of project success can be shown through three stages. The first stage is a theoretical interpretation of the project success (Pinto and Slevin, 1988a; Baker et al., 1988 cited in Prabhakar (2008); Shenhar et al., 2001; Abdullah and Ramly, 2006; Olsson et al., 2010). The second stage consists of empirical research on the factors that contributes to the project success, resulting in list(s) of critical success factors. The idea of CSF was created with the paper published in Harvard Business Review in 1961. on the topic Management Information Crisis, but the first article which defines the term CSF was published in 1979. According to Rockart (cited in (Fortune & White, 2006)) CSFs are: limited number of areas in which results, if they are satisfactory, will ensure successful competitive performance for the organization. Khandelwal and Ferguson (1999) believe that the definition of success factors present the preconditions for measuring the development of the organization. By applying this approach the scope of project management has been expanded.

Belassi & Tukel (1996) in their work give an overview list of CSFs developed during 70th and 80th in XX century. Researches that led to the formation of the list of CSFs conducted from 90th of the last century are presented in (Freeman and Beale, 1992; Cooke-Davis 2002; Judgev and Muller, 2005; Shenhar et al., 2005; Kerzner, 2011; Diallo and Thuillier, 2012), however, the general conclusion is that there are CSFs which are typical for most projects and that usually were replicaed in these studies, but there is no single list of CSFs,

which can be applied to all projects. CSFs have a role in the business processes controle and according Van Veen-Dirks and Wijn (2002) „controle process begins with the CSF identification". The authors link the concepts of Balanced Scorecard and CSF and claim that the Balanced Scorecard can be used as a diagnostic control system, however CSF allow managers to define the areas that leads to success. The outcome of this process of CSFs identification should be used as a starting point for the Balanced Scorecard. The advantage of using CSFs is that the measurement system can be more associated with the environment.

The third phase streams to development of concepts and models for representing the project success as presented through the perspective of stakeholders (Anbari et al, 2008), life-cycle stages (Yu et al., 2005) and value-centered approach (Freeman and Beale, 1992; Yu et al., 2005).

One of the key challenges of managing project-oriented organizations is how to measure project success in a manner that will contribute to the success of the entire organization? The organizations, whose management models were multiple awarded, have based their management systems on the model of corporate performance management (Paladino, 2011). However the key to success is not in simple definition of performance measures but in defining key performance measures that will serve as a guide for behavior in the organization. The key performance measures are the base for obtaining key performance indicators (KPI), which due to its role in decision-making can have a big impact on the efficiency of organizational management.

There are a several researches conducted in this field by Eckerson (2006), Kerzner (2001), Franceschini et al. (2007), Hubbard (2007) and others who worked on definition of characteristics and categories of KPIs, interdependence of KPI, and the possibility of an integrated performance measurement.

According to Eckerson (2006) KPIs are measures that show how well the organization or individual is performing the operational, tactical and strategic actions that are critical to current and future success of the organization. The first step in selection of the right KPIs is to define the general and specific characteristics that KPIs should satisfy. It can be concluded that conversion of measures in KPI can be performed by reexamine whether the measures meet KPIs criteria (predictable, measurable, actionable, relevant, and automated). If all criteria are met, the measure is KPIs. Notice that the rating of met criteria provides key answers in creating the list of the most important KPIs. Also what can be helpful are the following questions: what is the decision KPI is supposed to support; what really is being measured with KPI; why does this thing matter to the decision being asked; what is known about it now; what is the value to measuring it further (Hubbard, 2007).

Having this facts in mind the aim of this paper was to investigate whether a project-oriented organization in Serbia define CSFs for their projects, whether and how they measure the success of their projects. The main research questiones were:

1. How is the project management process regulated in the organization?
2. Whether and how the organizational processes and procedures an external environment influence the project success?
3. Wherether CSFs are defined on project?
4. In what way the project success is measured and evaluated?
    a) What are the most frequent ways to evaluate the performance of projects?
    b) Do the organizationes define the projects KPIs?
    c) Are the KPIs used in the analysis of the project success?

3. EMPIRICAL RESEARCH

3.1. Research method and sample description

The authors had composed a questionnaire in order to examine does the project-oriented organizations define project success and how, and how they, measure project success (if the answer on the previous question was positive). The questions were based on literature overview and previous studies in this field. Afterwards, the authors conducted structured interviews with project managers in different industries, after which the questions were modified in order to generate the most precise answers.

Out of 400 distributed questionnaires to project managers in different industries (i.e. construction sector, IT sector, energy sector, public sector, education, NGO, agro-industry) 107 or 26,75% participants have completed the survey, 4 questionnaires have been rendered as inadequate on the grounds of being

incomplete. Therefore, only 103 questionnaires have been taken into consideration. The following chapter presents the results of the research processed in SPSS 17.0.

3.2. Findings

54% of respondents were project managers or coordinators of several projects, while the remaining respondents were project team members. As much as 45% percent of them participated in over 15 projects, 93.2% of respondents have university degree. Besides the abovementioned demographic data, the research also encompassed questions relating to the definition and measuring of project success.

The next part of the survey relates to the project management process and on the examination of whether and to what extent CSFs are defined on the project. Within the segments relating to the definition of CSFs following questions were asked:

- Whether the organizational processes and procedures have the influence on project success?
- Whether the organization has documented procedures for the project management?
- Wherether factors from an external environment have the influence on the project?
- Do you define CSFs for your project, considering the organization and factors in the external environment ?
- Who is responsible for defining the CSF project?

According to the survey 96.1% of respondents said that the internal documentation (organizational processes and procedures) have the influence on project success. Respondents ware offered scale of 1 to 5 to assess the impact of the individual procedures and processes in organizations that mainly affect the project success (table 1) showed that the biggest impact on project success has an existing technology (the mean is 3.83), even the variance is the lowest one compared to the rest of organizational procedures and processes. The next one is a business policy (mean is 3.81), than a development strategy (mean 3.71), recent projects (mean 3.69) and a human resource policy (mean 3.61).

Table 1. Organizational procedures and processes procedures impact assessment on the project success

		Org. procedure and processes	Development strategy	Business policy	Human resource policy	Technology	Recent projects
N	Valid	103	103	103	103	103	103
	Missing	0	0	0	0	0	0
Mean			3.74	3.81	3.61	3.83	3.69
Median			4.00	4.00	4.00	4.00	4.00
Std. Deviation			1.038	.919	1.022	.879	1.039
Variance			1.078	.844	1.044	.773	1.079

71.8% of respondents said their organizations have the procedures for project management, while 5.8% did not know the answer on this question. But when they were offered the scale of 1 to 5 to assess the degree of the regulation of individual sub-processes of project management process, the average score was ranged between 3 and 4 (on scale from 1 to 5). It is interesting that higher scores have the process of project planning, project monitoring and reporting on progress and completion of the project, while the processes of project initiation and selection were assessed with the lower grades (average grades ranging from 3 to 3.5). When asked whether factors from the external environment have influence on their project, 97.1% of the respondents answered in the affirmative.

On the question of whether the CSF are defined on their projects, considering the organizational and factors from the external environment, only 36% of respondents said yes, 2.9% said that the critical success factors is not defined, while 61.2% did not know the answer to this question.

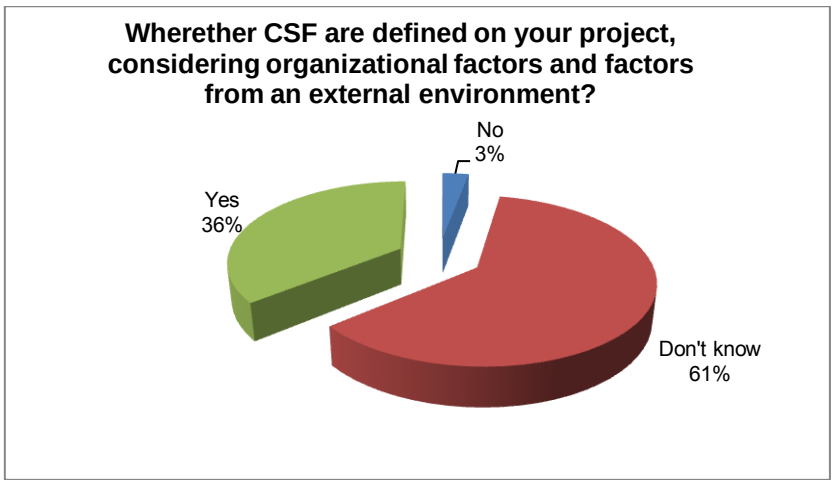

Figure 1. Definition of CSF

Respondents who have previously answered the question in the affirmative said that CSF are determined by top management (40.5%), project manager at 29.7% situation, while the CSF is defined by team members in 13.5% situations.

The next group of questions relates to measuring the project success:

- Is there a defined procedure of project performance evaluation at the project level?
- Do you establish performance measures for the evaluation of the project performances?
- What performance measures are used in the evaluation of the project?
- Do you define a set of KPI for your project?
- Who is responsible for determining the KPI?

In most cases (54.4%) there is no defined procedure of project performance evaluation at the project level, but it is done at the organizational level, while 42.7% of respondents reported that, in their organizations, there is a defined procedure of performance evaluation at the project level. Based on these results it can be concluded that the performance evaluation of the project carried out in 97.1% of cases.

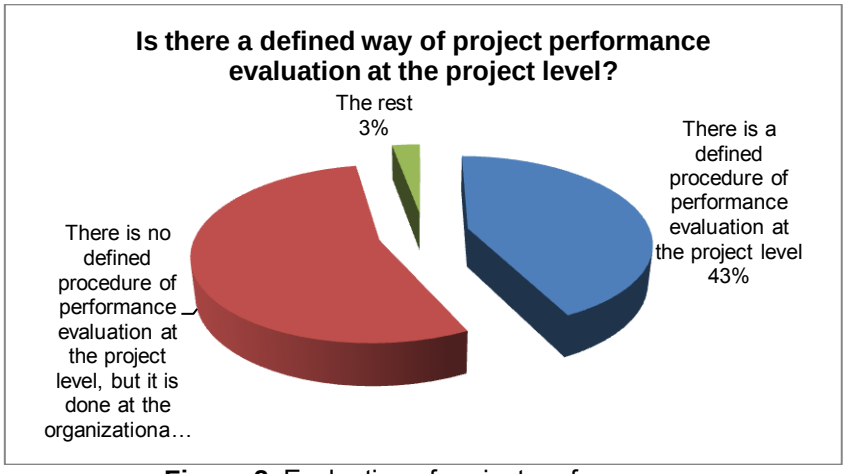

Figure 2. Evaluation of project performance

Slightly more than half of the respondents answered that they determines the performance measures for the evaluation process while 35% of respondents said they do not.

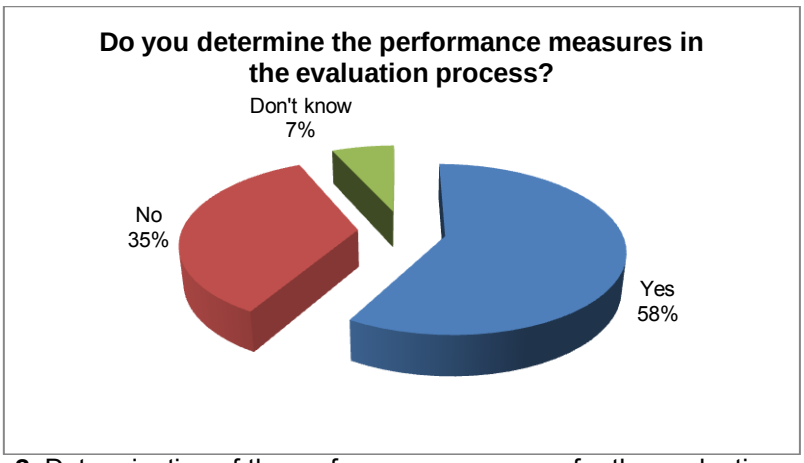

Figure 3. Determination of the performance measures for the evaluation process

The most commonly used measures to evaluate the project performance are: actual cost, the actual time, the technical characteristics of the product of the project, the level of quality etc.). In a much lesser extent (only 16%) used financial measures such as NPV, ROI, payback period etc., while measures related to the process of project management as well as process efficiency and labour productivity are used in only 1% of cases. About 14% of respondents written its own response, and the most of them said that they use a combination of measures related to the project and financial measures.

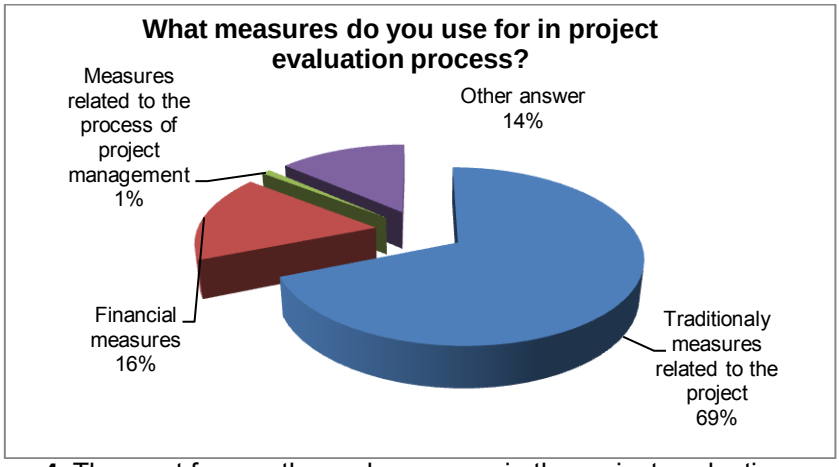

Figure 4. The most frequently used measures in the project evaluation process

34% of respondents determines KPI, only 7% of respondents did not define KPI for the project, while 59% of respondents did not answer to this question.

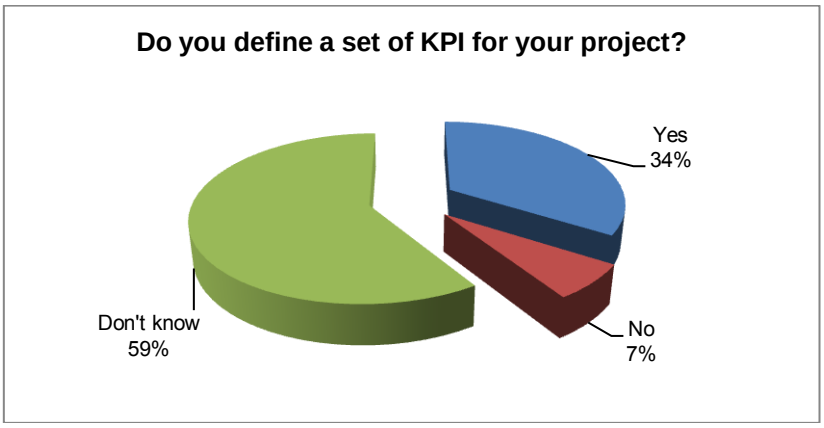

Figure 5. KPI definition

Unlike those responsible for determining the CSFs, the responsible person(s) project KPIs definition in 40% of situations are project team members, in about 34% of the situation the responsible person is project manager, while the participation of top management is in much smaller percentage (14%). Based on a

comparison of the obtained answers to these two questions, it can be concluded that the determination of KPIs more operational and technical issue and is usually in the area of competence of project managers and team members, while the determination of CSFs is more an issue that is considered in terms of the whole organization, by management.

Of those who responded that they define KPIs, 63% are using KPIs to assess the success of the project.

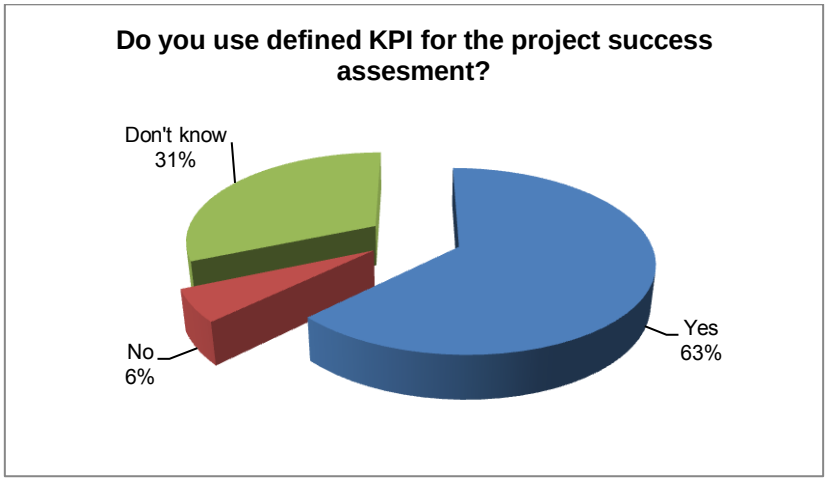

Figure 6. The usage of KPI in project success assessment

4. CONCLUSION

More than 70% of project oriented organizations have project management procedure defined, but the sub-processes that are well regulated are project planning, project monitoring and reporting on progress and completion of the project. The processes of initiation, selection and initiation of the project assessed the lower grades. The organization are aware that factors from external environment can affect the success of their projects, as well as organizational processess and procedures but very small percentage defined project success trough success factor considering those influences. The main conclusion of this paper is that the success factors of the project, taking into account the organizational and external environment factors are defined in something more than 1/3 of organizations. The almost same situation is present when we consider performance indicators. Their usage in evaluating the project success is at a very low level when it comes to organizations in Serbia. The research results show that the definition of CSF is in responsibility of organization management in the most of cases, like this is a more strategic issue. That is very much in line with the literature that link Balanced Scorecard and CSF (Van Veen-Dirks and Wijn, 2002) according to witch Balanced Scorecard can be used as a diagnostic control system and CSF allow managers to define the areas that leads to success (CSF identification should be used as a starting point for the Balanced Scorecard). On the other hand KPIs determination is, regarding presented results here, more operational issue, under the responsability of project team and project manager.

RISK MANAGEMENT METHODS: HOW TO DEAL WITH RISKS IN A PROJECT

Danijela Toljaga-Nikolić[1], Marija Todorović[2], Dragan Bjelica[3]
[1]Faculty of organizational sciences, University of Belgrade, toljagad@fon.bg.ac.rs

[3]Faculty of organizational sciences, University of Belgrade, bjelicad@fon.bg.ac.rs

Abstract: *Projects have complex nature in many fields. That is why during the project implementation many unpredicted situations could be encountered. The answer to the question what can help to deal with them before they occur is that by implementing methods of risk management the project team will have greater control over the overall management of the project. Software project involves many uncertainties, that if not controlled, project will be exposed to risks during the development phases as well as throughout the project life cycle. Every method of risk management has its specific area of application and can be used in order to cut down the risk element of a project to a minimum. Because of the need for cost saving in software development projects, it is important to manage risks during the early project development phases. Then risks can easily be maintained at an acceptable cost level.This paper will emphasize the features, similarities and differences between methods that can be used as tools to minimize risk in software projects: BOEHM method, RISKIT method and GSRM - Goal-driven Software Development Risk Management Model. Methods are different by their nature, but risk management process within the methods provide a structure to ensure visibility into risks and at the end to achieve project success.*

Keywords: *risk, project, risk management method*

1. INTRODUCTION

Risk in a project environment cannot be totally eliminated, but can be shaped and controlled by risk management. The main goal of a risk management process is to minimize the influence of some incidents that have not been planned on the project by identifying and addressing possible risks before negative consequences occur. Risk management process needs to be continuous and with high priority. This is important to the project success because it allows all team members to identify the top risks. Projects have complex nature in many fields, for example in the construction related field or in the software related field. That is why lots of unpredicted problems could be encountered during the project implementation, which results in exceeding budgets, fact that projects fall behind on deadlines, etc.

What can help managers to deal with problems before they occur? The answer is that by implementing methods of risk management, the project team will have greater control over the overall management of the project. Risk assessment, as the first of the two major risk management processes, includes identification, analysis and prioritization of risks. The second one is risk mitigation, which includes developing and monitoring strategies and residual risks. The result of great manager`s effort is a risk management plan that becomes a subset of the project management plan. A project manager needs to manage project risks and control them at the level that is acceptable for the project.

Every method of risk management has a specific area of application and can be used in order to cut down the risk element of a project to a minimum. Also, every method has the framework and is effective within a specific type of project. In different words, the method that could be the most appropriate for one project could be the most ineffective in another project. There are some methods that can be used as tools to minimize risk in software projects. It is important to emphasize the features, similarities and differences among these methods which consider many aspects while assessing and estimating the risks. Methods are different by their nature. It means that they explore different structures in the software development process, use different techniques and are applied over different phases in the development process. The process of risk management provides a structure to ensure visibility into risks and eventually to achieve project success.

Humans are included in developing, managing and using the software. Because of their education, experience, skills, motivation, working atmosphere or other personal reasons, they may commit different kinds of errors. These risk factors which are connected with the humans make it easier for us to understand the great importance that humans have and to realize the relevance of the human role. That is why risk assessment should take into consideration human factors involved in different processes in the software development, and not only to examination of these processes. Since people usually do not work alone, risk management methods need to include observation of the picture of cooperation in the process between different people, people and equipment, people and tasks, etc.

2. LITERATURE REVIEW

Schmidt *et al.* (2001) define risk factors as "a condition in which may be present a serious threat to the complete success of a software development project." Risk management can help project managers to anticipate delays that cause projects not to be delivered on time (Grant *et al.,* 2006). According to Dey *et al.* (2007), although some managers claim that they manage risks in their projects, there is evidence that they do not manage them systematically. Charette (2005) stated that the most common factors why software projects fail so often are: unrealistic goals, inaccurate estimates of necessary resources, badly defined system requirements, poor presentation of the project status and not managed risks.

According to Cervone (2006), project risk management is a necessary and critical task of the project manager and project team, where understanding risk management entails understanding the underlying factors that contribute to project risks. Boehm's (1991) results were quite significant as he identified the list of 10 software risk items and was the pioneer in developing methods for risk management in software industry. Berg (2010) stated that risk management is about making decisions that contribute to the achievement of an organization's objectives by applying them both at the individual activity level and in functional areas. According to Dey *et al.* (2007), managers often address technical risks, instead of dealing with market and financial risks, which are vital for a successful software development. Obviously, there is a need for integrated risk management. Berg (2010) stated that integrated risk management does not focus only on the minimization or mitigation of risks, but also supports activities that foster innovation, so that the greatest returns can be achieved with acceptable results, costs and risks. Ahmed *et al.* (2007) noted that unexpected events occur in projects and may result in either positive or negative outcomes that are a deviation from the project plan.

Dey *et al.* (2007) stated that frameworks suggested by other authors usually present problems from the clients` perspectives. Because of that, there is need for analysing the risk management issues in software development from the developers' perspective, with the involvement of the stakeholders, with the consideration of both qualitative and quantitative risk factors and integrating the risk management process with the software development cycle (project management). Cervone (2006) stated that by managing risks within a project, the project manager and team ensure that the project will be delivered on time and to the satisfaction of the end-user community. Berg (2010) noted that in order to apply risk management effectively, it is vital that a risk management culture be developed. The risk management culture supports the overall vision, mission and objectives of an organization. Cervone (2006) noted that project manager should record the results of risk assessments as well as the mitigation strategies for each of the risks pursued so that he could learn from the past.

3. RISK MANAGEMENT METHODS

3.1 BOEHM method

Barry Boehm was the pioneer in developing methods for risk management in software industry. In 1986. he developed the first risk-driven Spiral model (Boehm, 1986) by using the theory Win–Win model. Then, in 1991. he divided the process of risk management into two main phases: risk assessment and risk control (Boehm, 1991). Furthermore, risk assessment is divided into identification, analysis and prioritization and risk control is divided into planning, reduction and monitoring. The main aim of risk assessment part is to identify the underlying risks and assess the degree of risks and priority of risks. After that estimation, the risk control part has an important role in the whole management process, which includes risk management planning, risk reduction and risk monitoring. In the process of risk estimation and mitigation, it is more convenient to do analysis in the early stages of the software development process in order to encounter and overcome the problems in these early stages.

The Boehm method includes a set of principles and practices called the risk-analysis paradigm. It can be applied to software related projects for managing the risk of developing software. Basic concept in the model is risk exposure, which is defined by:

$$RE = P(UO) * L(U0) \quad (1)$$

where RE is the risk exposure, P(U0) is the probability of an unsatisfactory outcome and L(U0) is the loss to the parties affected if the outcome is unsatisfactory. The valence of the risk event is defined by this.

According to the rating, a project has a relatively low (0.0 to 0.3), medium (0.4 to 0.6) or high (0.7 to 1.0) probability of some risk (Boehm, 1991).

Software projects involve several classes of participants (customer, developer, user and maintainer), each with different, but highly important satisfaction criteria, so the unsatisfactory outcome is multidimensional:

- For customers and developers, budget overruns and schedule slips are unsatisfactory.
- For users, products with the wrong functionality, user-interface shortfalls, performance shortfalls, or reliability shortfalls are unsatisfactory.
- For maintainers, poor-quality software is unsatisfactory (Boehm, 1991).

These components of an unsatisfactory outcome provide a checklist for identifying and assessing risk items. This model uses a decision tree method for identification the software risk items. It could be said that the goal of the risk management is to reduce the risk exposure associated with the software. This method can be used in all phases of software development process. Boehm identifies ten risk items and recommends risk management techniques to address them (Table 1).

Table 1: Boehm's top ten risk items (adapted from Boehm, 1991)

Risk item	Risk-management technique
Personnel shortfalls	Staffing with top talent, job matching, team building, key personnel agreements, cross training.
Unrealistic schedules and budgets	Detailed multisource cost and schedule estimation, design to cost, incremental development, software reuse, requirements scrubbing.
Developing the wrong functions and properties	Organization analysis, mission analysis, operations-concept formulation, user surveys and user participation, prototyping, early users' manuals, off-nominal performance analysis, quality-factor analysis.
Developing the wrong user interface	Prototyping, scenarios, task analysis, user participation.
Gold-plating	Requirements scrubbing, prototyping, cost-benefit analysis, designing to cost.
Continuing stream of requirements changes	High change threshold, information hiding, incremental development (deferring changes to later increments).
Shortfalls in externally furnished components	Benchmarking, inspections, reference checking, compatibility analysis.
Shortfalls in externally performed tasks	Reference checking, preaward audits, award-fee contracts, competitive design or prototyping, team-building.
Real-time performance shortfalls	Simulation, benchmarking, modeling, prototyping, instrumentation, tuning.
Straining computer-science capabilities	Technical analysis, cost-benefit analysis, prototyping, reference checking.

Managers can use the checklist on projects to identify and resolve risk items and the following set of risk-management techniques can be used in avoiding or resolving the source of risk. This is not only a method that covers all phases of software development project, which is its main advantage, but it is also a traditional and relatively simplistic method. On the other hand, its disadvantage lies in the fact that it doesn't handle generic risk implicitly. The Boehm method was the first method of risk management and risk items in the checklist sometimes are insufficient to cover the real situation because of continual changes in an unstable environment.

3.2 Riskit method

Jyrki Kontio, professor at the Helsinki University of Technology, proposed the Riskit method in 1996. The method has its focus on qualitative understanding of risks before their possible quantification. The method

was developed for software development projects and it is mainly applied in large organisations, though the method has some aspects of the business analysis that could be applied to any project in other areas (marketing, technology related business, etc).

Riskit method extends Boehm's approach by maintaining links between risks and stakeholders explicitly (Kontio *et al*, 1998). It is clear that every project has more than one stakeholder and they may have different priorities and levels of expectations. Therefore, risk management should be based on the recognition of their expectations and priorities.

When risk scenarios are defined, each risk can be described by its potential impact on project goals and each stakeholder can use this information to rank risks from their perspective. This allows full traceability between risks and goals (Kontio *et al*, 1998). In RISKIT method, a risk is defined more precisely, as a possibility of loss, the loss itself, or any characteristic, object or action that is associated with that possibility.

The method framework shows that method can be used for any software development project, but it fails to cover small to medium sized organisations. The main advantage of the method is flexibility, which means that it is originally developed for software development projects, but it can be applied to other areas (marketing, business planning, etc). On the other hand, a disadvantage is the fact that the method doesn't bridge the gap between risk estimation and risk metrics, which means that it is very difficult to predict the potential risk reliably.

The method`s main characteristics can be described by the following principles:

- The Riskit method provides precise and unambiguous definitions of risks;
- The Riskit method results in explicit definition of objectives, constraints and other drivers that influence the project;
- The Riskit method is aimed at modelling and documenting risks qualitatively;
- The Riskit method can use both ratio and ordinal scale risk ranking information to prioritize risks reliably;
- The Riskit method uses the concept of utility loss to rank the loss associated with risks;
- Different stakeholder perspectives are explicitly modelled in the Riskit method;
- The Riskit method has an operational definition and training support (Kontio *et al,* 1998).

Summaries of the activities in the Riskit process, as well as the main output of each activity are described in table 2.

Table 2: Overview of outputs and exit criteria of the Riskit process (Kontio *et al*, 1998).

Riskit step	Description	Output
Risk management mandate definition	Define the scope and frequency of risk management. Recognize all relevant stakeholders.	Risk management mandate: why, what, when, who, how, and for whom.
Goal review	Review the stated goals for the project, refine them and define implicit goals and constraints explicitly. Analyze stakeholders' associations with the goals.	Explicit goal definitions.
Risk identification	Identify potential threats to the project using multiple approaches.	A list of "raw" risks.
Risk analysis	Classify and consolidate risks. Complete risk scenarios for main risk events. Estimate risk effects for all risk scenarios.	Completed Riskit analysis graphs for all analyzed risks. Ranked risk scenarios.
Risk control planning	Select the most important risks for risk control planning. Propose risk controlling actions for most important risks. Select the risk controlling actions to be implemented.	Selected risk controlling actions.
Risk control	Implement the risk controlling actions.	Reduced risks.
Risk monitoring	Monitor the risk situation.	Risk status information.

Figure 1. presents flows of information among basic activities within the risk management cycle in a project: defining the scope and focus of risk management, review and definition of goals, risk identification and

monitoring, risk analysis, risk control planning and controlling of risks. Each activity can be performed several times during the project duration and they may be conducted concurrently.

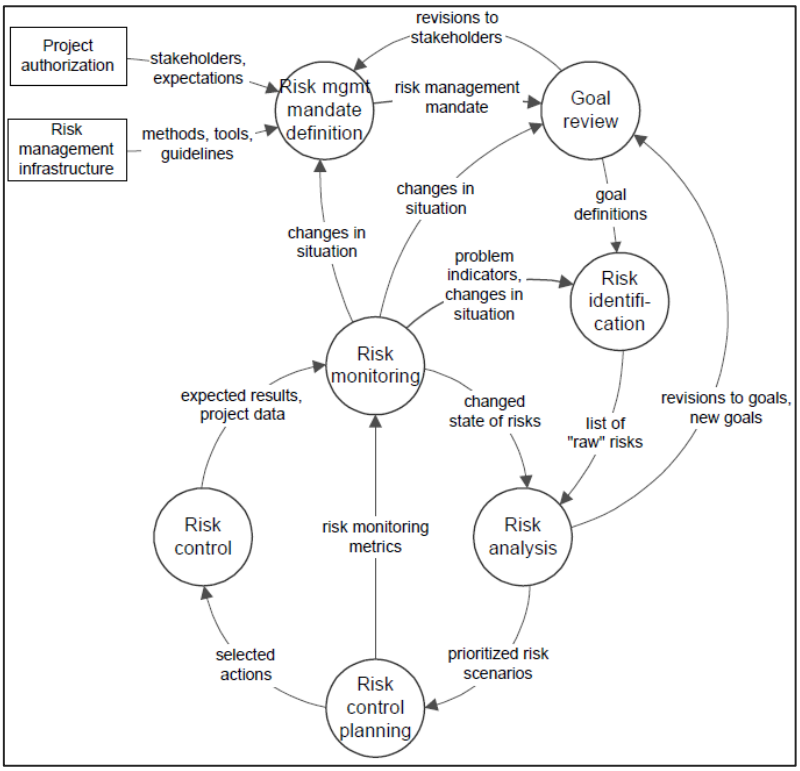

Figure 1: The Riskit risk management cycle (Kontio,1997).

3.3 Goal-driven Software Development Risk Management Model (GSRM)

The model was built with the goal of offering the solution how to integrate risk management activities into the project and it shows which techniques are needed to perform risk management activities. The authors stated that the literature fails to provide comprehensive and detailed guidelines on how to integrate risk management activities into the project at the early stages of development. Also, the practitioners should be acquainted with the impact of risk management practice on software projects (Islam *et al.,* 2014). Therefore, Goal-driven Software Development Risk Management Model was introduced as a goal-driven approach for risk management where risk management activities are integrated into early stages of project development. The model includes techniques identified as necessary to perform the risk management activities. Also, the results produced by the activities are precisely defined.

According to the authors, risk management is considered as an integral part of all organisational processes, including strategic planning and all project and change management processes. They have pointed out that the other risk management methods and frameworks include a number of limitations. Although the Boehms method made theoretical foundation of putting risk management into a single framework, a disadvantage is that this approach requires intensive active involvement of project customers/users, which is difficult to obtain in real on-going project. In spite of the fact that Boehm extended the original method to satisfy the objectives and concerns of the stakeholders, there is still a space for improvement. Also, the Riskit method has some important limitations, according to the authors of GSRM. They have agreed that this method provides a complete conceptual framework for risk management and precise and unambiguous definitions of risks. But, there are no clear sources specified from where the goals originate and how the identified goals are modelled. Also, risks are analysed by creating scenarios, which are always hard to create from factors, and it is difficult to make a comparison between them when a scenario depends upon more than one probabilistic element.

The GSRM adopted the risk management context considering internal and external organisational issues, risk management process and risk criteria from *ISO 31000:2009* standard (Islam *et al.,* 2014). The standard introduces guideline for implementing risk management into organisational processes using process, framework and principals and GSRM follows the guideline to define the risk management context within the

process. The framework of GSRM is an extension of the KAOS goal modelling language with concepts related to risk management (Islam *et al.,* 2014). The KAOS (Knowledge Acquisition in Automated Specification or Keep All Objectives Satisfied) method is a specific goal modelling method.

The framework, which is a layer based modelling framework, is comprised of four layers:

1. *Goal* (focuses on the factors that contribute to completion of the project activities and directly link to the project success),
2. *Obstacle* (identifies the potential software development risk factors and establishes the obstruction link from risk factors to sub-goals and from events to the main goal),
3. *Assessment* (quantifies the risk events as a consequence of single or multiple risk factors, establishes the causal relationship model between risk factors and related risk events);
4. *Treatment* (focuses on the control actions to counter the risks so that goals can be attained, monitors the effectiveness of the implemented control actions and identifies any new risks throughout the development).

Specific activities can be performed under any layer with appropriate tasks, methods and techniques in order to consider these components: project execution, development process, product, human, and internal and external environment. The main aim of this effort is to understand all the layers.

Layer based modelling allows usage of different techniques and methods across the layers which provides that the outcome can be transferred between the layers (Islam & Houmb, 2011).

Figure 2. introduces conceptual view of the model. According to it, goals and obstacles are derived from the development components, stakeholder expectations and project success indicators. And the main output is the goal-risk model.

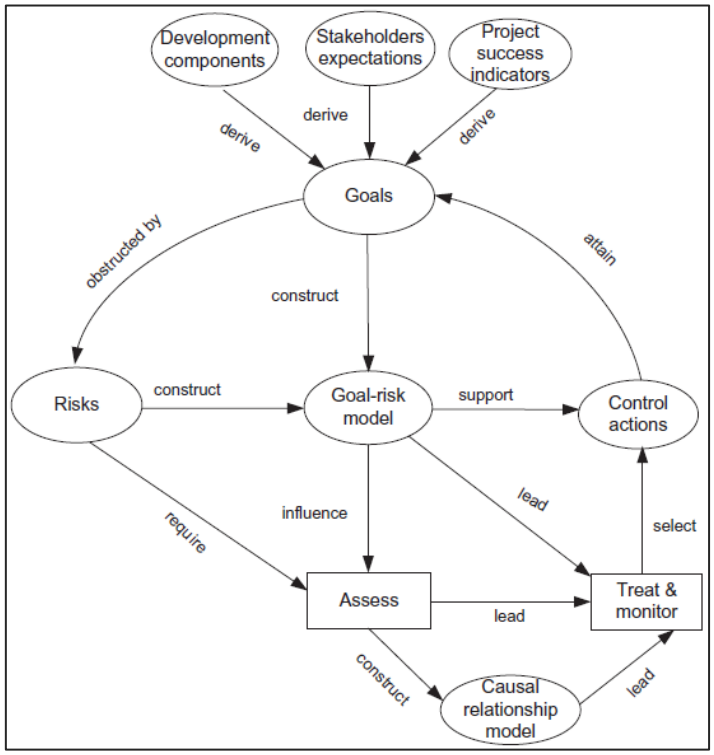

Figure 2: Conceptual view of the model (Islam *et al.,* 2014)

The model includes activities that involve all tasks required for goal-driven risk management:

1. Defining the risk management scope and boundary, schedule and resource allocation and composing a risk management team so the risk management plan could be initialised.
2. Identifying and modelling goals by focusing on the state of the development components and matching them with the project.
3. Identifying and modelling obstacles (as many obstacles as possible so the team is aware of problems from the beginning).
4. Risk assessing by estimating risk level and relevant priority.

5. Risk controlling as early as possible and monitoring the effectiveness of the control action throughout the project.

The requirements engineering phase is an early stage of the project development and includes risk management activities such as formulating goals, capabilities, constraints, system vision and requirements. Since requirements engineering and software risk management process are two different processes, it is important to emphasize that activities of the requirements engineering and risk management process are sequential and techniques used within the activities are similar. The GSRM model provides three techniques to identify and analyze goals and risks: structured interviews with closed questions, brainstorming sessions, analysis of project documents. For example, information gained from the project brainstorming session was verified during the interview session. The integration of risk management into requirements engineering provides early warnings about issues existing in the project (Islam *et al.,* 2014).

The requirement engineer`s role includes activities such as creating and managing the requirement specification by aligning the business needs to the software, establishing the bridge among business analyst, architect, project manager, and customer/user. A risk manager is a person who should have necessary knowledge about managing the project and skills to handle risks in a different project situation. Responsibilities of a risk manager include performing risk assessment and management activities.

4. METHODS REVIEW

Boehm made the theoretical foundation for project risk management with the risk-driven Spiral model, and identified ten risk items with recommendation of appropriate risk management techniques. Later Boehm extended original model in order to satisfy the objectives and concerns of the stakeholders by using the theory Win–Win model. This is a method that covers all phases of software development project, which is its main advantage, and also a traditional and relatively simplistic method. Although the Boehms method made theoretical foundation of putting risk management into a single framework, a disadvantage is that this approach requires intensive involvement of project customers/users, which is difficult to obtain in real on-going project. Managers can use the checklist on a project to identify and resolve risk items and the following set of risk-management techniques can be used in avoiding or resolving the risk source. The Boehm method was the first method of project risk management and risk items in the checklist sometimes are insufficient to cover the real situation because of continual changes in an unstable environment. Also, a disadvantage is the fact that it doesn't handle generic risk implicitly.

The Riskit method extends Boehm's approach by maintaining links between risks and stakeholders explicitly. Risk management should be based on the recognition of stakeholder`s expectations and priorities because they may have different priorities and levels of expectations. Main advantage of the method is flexibility, which means that it is originally developed for software development projects, but can be applied in other areas (marketing, business planning, etc).

The Riskit method framework shows that method can be used for any software development project, but it fails to cover small to medium sized organisations. On the other hand, a disadvantage is the fact that the method doesn't bridge the gap between risk estimation and risk metrics, which means that it is very difficult to predict the potential risk reliably. Although Kontio's Riskit is a goal-driven approach, it is not clear from where goals can originate and the risk analysis is based on scenarios which are difficult to formulate.

And while the Boehm`s method doesn't handle generic risk implicitly, Goal-driven Software Development Risk Management Model supports identification of both project specific and generic risks that need adequate treatment. This model was introduced as a goal-driven approach for risk management where risk management activities are integrated into early stages of project development and relation between project goals and risks that may obstruct these goals is established. That is the best way for selecting the adequate actions to prevent project risks because project goals need to be fulfilled in order to obtain a successful project.

The model was built with the aim of offering the solution how to integrate risk management activities into the project and it shows which techniques are needed to perform risk management activities. The approach requires intensive and active involvement of project customers/users, which is difficult to attain in real on-going project situations. This goal-driven approach is appropriate for project risk management that is well integrated into the early requirements engineering stage.

5. CONCLUSION

Software industry uses knowledge as a resource and many activities are knowledge intensive. There is the need for organizations not only to improve their ability to identify, but also to manage the risks associated with software development projects. Many factors, such as inaccurate estimation of needed resources, badly defined system requirements, unrealistic or unarticulated project goals, risks not managed, etc, need early consideration in the project development stage because of direct or indirect influence on project success.

Different authors proposed different approaches, methods and models for dealing with project risks, with variety of techniques for accomplishing the process of identifying and estimating risks in a project. There is a need for more flexible approaches to risk management which allow taking advantage of new techniques. Risk assessment is often performed once at the project development stage and then never again during the project's lifetime. The truth is that risk assessment should be revisited and risk management plan should be revised whenever something new and important about products and processes is learned.

Among many project risk management approaches, methods and models, the paper considers the Boehm method, the Riskit method and the Goal-driven Software Development Risk Management Model. The Boehm method was the first project risk management method and therefore made the theoretical foundation for project risk management. The Riskit method includes some extensions of Boehm's approach related to stakeholders involvement. Although Riskit is a goal-driven approach, it is not clear from where goals can originate. This is improved with another goal-driven approach that focuses on the factors contributing to completion of project activities and are directly linked to the project success. Because of the lack of literature with comprehensive and detailed guidelines on how to integrate risk management activities into the project at the early stages of development, the GSRM was built. The model includes activities that involve all tasks required for goal-driven risk management.

Abstract: *This paper presents the impact of project management modules on the project information systems implementation and its success. Project management modules, which are taken into consideration, are: Demand management, Portfolio selection and analytics, Resource management, Schedule management, Financial management, Time and task management, Team collaboration, Issues and risk management, Business intelligence and reporting, Portfolio and program management. The research was conducted among 51 project portfolio managers in Serbia. Research results show different perception for Business intelligence and Portfolio selection and analytics modules implementation among project managers in profit, non-profit and public sector.*

Keywords*: Project, success, information system, modules.*

1. INTRODUCTION

Projects usually have a wide variety of objectives and limitations, involving numerous internal and external actors, and are conducted in various activity sectors. Since 1980, many academics and practitioners have agreed that project management software development is one of the most crucial elements of an organization"s success. Modern university curricula in software engineering and project management include broad categories in knowledge-based training from one point of view, and from the other point of view also the acquisition of practical skills or the ability to apply the knowledge to practical situations and problem-solving using initiative, autonomy and creativity. Thus, engineering education in general and software engineering in particular is becoming increasingly complex and requires an integrated approach to practice and non-technical skills, specifically oriented to technical competences.

Therefore, practical implementation includes project planning and control and resource allocation are widely used to create real problems and implementation procedures in the context of project management software. In accordance with the above mentioned, most of the university courses about Software Project Management contain topics about Project Management body of knowledge, planning, scheduling and control and the most widely used software for practical classes (for example Microsoft-Project and Share Point services which are related with web based approach) (Salas-Morera et al., 2013).

In this paper we discuss about software project management module application in context of project success. A positive relationship between project performance and software process standardization is expected based upon management control theory. Managerial control refers to an organization"s attempt to influence employees to behave in accordance with standardized procedures and formal rules. Most documented reports are case studies that experienced a positive relationship between software process improvement and project cost reduction. Nevertheless, some researchers have argued that the management of the project"s scope, schedule, staffing, and other resources is tied to a defined process (Liu et al., 2008).

The mediator role of software flexibility implies that software engineering needs to focus effort on software flexibility as well as standardization. Software flexibility and adaptability to company business needs does impact final project performance. Information systems project managers should not regard software flexibility as an irrelevant issue. The total software quality and stability (e.g., software features and software response time) may indeed increase the overall project cost and require additional time, as argued in some project management textbooks. In this study, however, the result indicated that software flexibility might have a positive, instead of a negative, impact. Different software development guidelines and methodologies exist to enhance software flexibility. Management must choose methodologies and approaches to enforce this quality.

2. PROJECT MANAGEMENT SOFTWARE MODULES

2.1. Demand management

Using the Demand Control Support model as conceptual framework and framework for demand creation, Pintoet al. (2014) analyzed a sample of respondents from four project intensive organizations. Their findings demonstrate that women tend to experience emotional exhaustion to a greater extent than their male counterparts. In construction industry specific attention should be given to how the need to work long hours is justified. Organizations should look to improve managerial and collegial support for construction professionals, but be careful in engaging in socializing and project team-building activities (Bowen et al., 2014). Demand management capabilities this module helps organizations accomplish the following objectives:

- Integrates project proposals, portfolio analysis, and project management
- Captures all work proposals in one place
- Guides the proposals through a multistage governance process
- Helps users make decisions about which proposals to approve
- Tracks progress on project execution until the work is completed

2.2. Portfolio selection and analytics

When project portfolio management offices act as project portfolio managers their activity patterns include handling the challenges of project portfolio management and performing characteristic managerial tasks in project portfolio management. By quantitatively analyzing project portfolio management offices in 278 portfolios, Unger et al. (2012) identify three different activity patterns, which are interpreted as distinctive roles. They highlighted a significant positive correlation of project portfolio management offices" analyzing roles on performance in terms of project portfolio management quality that is a predictor of project portfolio success. Considering different stages of the R&D project portfolio selection process a multi-stage decision framework was proposed by Abbassi et al. (2014).

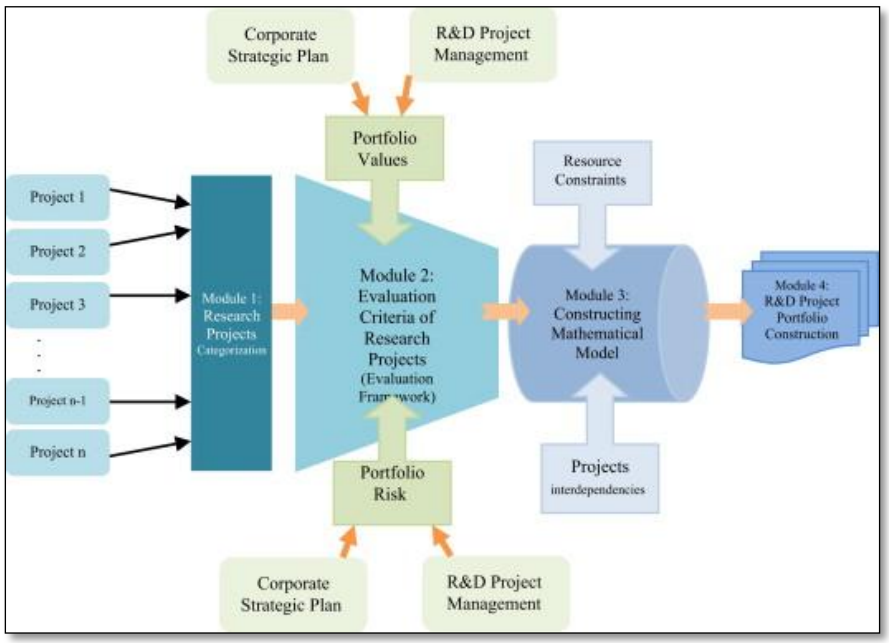

Figure 1: Multistage decision framework for R&D projects (Abbassi et al., 2014)

Adopting structured portfolio selection processes and techniques this module helps organizations accomplish the following:

- Define, communicate, and prioritize business strategy
- Score and assess competing requests from multiple dimensions
- Run what-if analysis optimization scenarios under various budgetary constraints
- Compare and contrast portfolios and gain insight through advanced analysis such as Efficient Frontier modeling

- Assess capacity and adjust project schedules to maximize resource utilization across the planning horizon
- Run and model headcount scenarios

2.3. Resource management

The objective for resource management module is to minimize the project make-span as well as the penalty cost when some projects carry higher priority. Thus, resource center is the crucial part of web based project management software. Since the problem is hard in terms of resource over location, Singh (2014) solve this problem by integrating the project priority with the activity priority, using a hybrid algorithm based on priority rules and analytic hierarchy process. On the other hand, (Obradovic et al., 2014) emphasize technical competences as a key indicator for project success according to IPMA Competence baseline. Adopting best-practice resource management techniques this module helps organizations accomplish the following:

- Consistent definition of resources - resource pool
- Assess resource availability across multiple projects - resource capacity
- Ability to “drill down” to view resource utilization

2.4. Schedule management

Whilst capturing resources can ensure that a tardy but „business-critical“ project is delivered on time, if the organization has no free resource capacity and is also not recruiting more staff, this practice harms the schedule performance of the projects deprived from resources (Yaghootkar and Gil, 2012). Adopting best-practice scheduling methodologies and tools dopting best-practice methodologies this module helps organizations accomplish the following: helps organizations achieve the following:

- Create and update schedules from the desktop or online
- Effectively control and analyze schedules
- Easily communicate schedule information

2.5. Financial management

Halawa et al. (2013) indicates that there are various methods of financial appraisal and evaluations in the investment field. The first one is called “discounting methods”, including net present value and internal rate of return; the second one is called “simple methods”, including payback period and simple rate of return; the third one is called “financial evaluation under uncertainty” and this includes break even analysis and sensitivity analysis. Key challenges that organizations face when trying to improve their financial management processes include the following:

- Standardizing cost and benefit estimates
- Project accounting and change management
- Financial visibility and insights
- Integration with LOB (line of business) systems

2.6. Time and task management

A study by the Standish Group scanned more than 8000 projects and compared their anticipated results with the real outcome. According to this study, only 16% of the projects were able to meet the goals set in terms of time, budget and quality (Hameri and Heikkilä, 2002). Time captures and project progress reporting poses several challenges to organizations, and they need to have the following characteristics:

- Time capture and project progress reporting
- Report working and nonworking time
- Capture projects, operations, and administrative time
- Recurring time periods
- Integrate with LOB systems

2.7. Team collaboration

An increasing number of companies, especially those with knowledge-intensive R&D programs, have turned to virtual project teams in recent years to generate the greatest competitive advantage from limited labor and resources. The empirical results, from a study on a sample of 75 project team members who were making full use of collaborative technologies in their project work context, not only confirmed technology acceptance model, but also demonstrate that the nature of the performed tasks positively influence perceived benefits

and user attitudes towards the use of collaboration technologies in project teams. Users with a high intention to adopt a collaboration technology in their work context, showed increased performance in decision-making or problem solving (Nikas and Argyropoulou, 2014). Effective collaboration techniques within their project portfolio management processes have following characteristics:

- Provide a central location for team collaboration
- Effectively manage a variety of content
- Simplify and enhance team communication

2.8. Issues and risk management

Sanchez et al. (2008) introduce a framework to identify risks and issues during project portfolio risk management process that helps to decrease the uncertainty of achieving the strategic goals of the organization. The final output of the framework is a portfolio risk-opportunity register, which highlights the potential events that could impact the achievement of the goals. Adopting best-practice methodologies this module helps organizations accomplish the following:

- Define a standard way to assess risk for new initiatives
- Standardize project risk collection and management
- Establish proper issue resolution and escalation

2.9. Business intelligence and reporting

Business intelligence module consists of business users and applications accessing data from the data warehouse to perform enterprise reporting, OLAP, querying, and predictive analytics. Most organizations create custom reports based according to the following factors: type of project, level of maturity, number of projects, number of employees, etc. Adopting best-practice methodologies this module helps organizations accomplish the following:

- Standard metrics for measuring performance
- Create Reports and Build Powerful Dashboards
- Create Sophisticated Reports

2.10. Portfolio and program management

Project portfolio selection is the periodic activity involved in selecting a portfolio of projects, that meets an organization"s stated objectives without exceeding available resources or violating other constraints. Some of the issues that have to be addressed in this process are the organization"s objectives and priorities, financial benefits, intangible benefits, availability of resources, and risk level of the project portfolio. Optimal portfolio selection is a major stage in the framework. Adopting best-practice methodologies this module helps organizations accomplish the following:

- Capture, Prioritize, and Select Programs
- Clarifying program and project controls to improve efficiency
- Program Delivery

3. EMPIRICAL RESEARCH

3.1. Research method and sample description

Data collection tool was questionnaire consisted of both independent and dependent variables. Independent variables were personal data of respondents: information about sex, work experience, education and position in organizational hierarchy. Dependent variables were data related to web module in organizations, obtained from the questionnaire consisted of 19 questions that offered answers evaluation from 1 (without influence) to 5 (very high influence). Representative sample consisted of 51 project managers from companies in various sectors – profit (82%), nonprofit (8%) and public sector (10%). Structure of respondent"s position in organizational hierarchy was the following: 33% from executive management level, 16% from operational management level and 51% from middle management level. Also, the sample consists of 60% males, and 40% females.

3.2. RESEARCH RESULTS AND DISCUSSION

Financial Management module is the highest ranked with score of 3.94, and the lowest is Portfolio Selection and Analytics module with score of 3.24. Beside the average value for Portfolio Selection Analytics module, only Business Intelligence module also has the average value below the total average value of all modules.

Portfolio Selection and Analytics and Business Intelligence and Reporting modules have the highest standard deviation (table 1). The key reason is that employees don"t know or don"t understand the usage of these two modules in organizations.

Table 1. Influences of the project management web modules on project management success

Project Management Modules	Average	Standard Deviation	Variance
Project and Resource Center	3.71	0.78	0.61
Time and Schedule Management	3.78	1.01	1.01
Financial Management	3.94	0.76	0.58
Business Intelligence and Reporting	3.29	1.19	1.41
Collaboration	3.78	0.88	0.77
Portfolio Selection and Analytics	3.24	1.19	1.42
Risk Management	3.65	0.87	0.75

Dominant results are indicative for Public sector (table 2). For Public sector highest value is related with time and schedule management, which means that employees in public sector appreciate most the time, but on the other hand conclusion for this module can be related that working time is different according to sector, and with many others criteria (e.g. conditions, job security, advancement, growth, power, affiliation, esteem, decision-making processes, rewarding systems, task-related rules as well as social rules, like punctuality in task completion, agreed time to read and respond to messages, respect of consensus decisions, honesty, truth, preparation for and attendance to meetings, punctuality on meetings, etc).

Also, Business Intelligence and Reporting module in Public Sector has the lowest value, which could be consequentially related with time management and critical success factors (table 3). The implementation of business intelligence and reporting does not always result in expected outcomes. This problem, called paradox of productivity (delays in the observation of an increase of productivity, poor management of business intelligence and reporting, poor qualified workforce, or the difficulty to estimate, by means of an accounting treatment, the result (profit/loss) of an investment in Business Intelligence and Reporting. Raffo, (2005) emphasize „forward-looking" decision support framework that integrates up-to-date metrics data with simulation models of the software development process in order to support the software project management control function, considering the focus on the overall decision framework using outcome based control limits, utility functions and financial performance measures (e.g. return on investment, net present value, break even point and others) which is new.

Table 2. The average value of responses regarding to the Influence of the various web modules on project management success by sectors

Influences of the various web modules on project management success:	Public Sector	Non-profit Sector	Profit Sector
Project and Resource Center	3.2	3.75	3.76
Time and Schedule Management	4.2	3.5	3.76
Financial Management	4	3.25	4
Business Intelligence and Reporting	2.4	4	3.33
Collaboration	3.4	3.75	3.83
Portfolio Selection and Analytics	3.6	3.75	3.14
Risk Management	3.4	3.75	3.67

Table 3. The average value of critical success factors and the average value of influences of the various web modules on project management success

	How often are critical success factors defined in the projects via web platform?	Influences of the various web modules on project management success
Public Sector	4	3.46
Non-profit Sector	4.25	3.68
Profit Sector	4.64	3.64

Project management software packages generally facilitate the integration of project data, the interaction with enterprise systems and the interoperability with business intelligence and reporting systems. Besides optimizing the productivity of the teams, the system allows to make better decisions, to maintain a competitive advantage and to implement an effective project management. This type of software consists of subsystems developed to treat various aspects of project management: procurement, construction, cost control and analysis, planning, quality insurance, etc.

4. CONCLUSION

Successful project management information system implementation in organizations depends on the following criteria: business process definition, maturity level of the company, number of employees, budget, number of projects, number of specific requests, etc. Difference between profit, non-profit organizations and organizations in public sector about project management system implementation could be noted in two modules - Portfolio Selection and Analytics and Business Intelligence and Reporting modules. Future consideration will include agile methodology and its application on software projects. Clients are seen to have matured in their understanding of IT projects, because maturity reveals itself in a greater understanding of the complex issues that confront IT projects and, therefore, a deep skepticism about the ability of IT departments and suppliers alone to deliver value.

Abstract: *This paper analyzes project risk, as risk has been viewed in recent years as a dimension of a project at the same level as the scope, time, and cost. The paper provides a definition of risk index as a model for assessing the project impact of various risk factors. Determination of risk index is presented through the example of construction projects. The results show that political factors are the dominant macro-level risk factors, whereas design factors prevail at the micro level.*

Keywords: *management, project, risk, risk factor, risk index*

1. INTRODUCTION

It has long been thought that a project has three dimensions: cost, time, and scope. However, in recent times, a fourth dimension – risk – has been added (Bobera, 2003). Project risk is an uncertain event or condition which, if it does occur, has either a positive or a negative effect on at least one of the project attributes, such as time, cost, scope, or quality (Project Management Institute [PMI], 2004). Therefore, it is necessary to manage project risk.

In the past decade, there has been a significant increase in the body of published work on project risk management. In her analysis of papers pertaining to project risk, published between 2000 and 2012 in four representative risk management journals, Liisa Lehtiranta (2014) found that 70% of the research deals with construction project risk, 19% with IT and software project risk, and only 11% with risks in other industrial projects and projects in general (645).

This paper: (1) lists the basic project risk causes or factors; (2) analyzes the process of project risk management; (3) defines risk index; (4) describes the method for determining the significance of risk factors and their potential impact; and (5) presents risk index determination using the example of a construction project.

2. PROJECT RISK MANAGEMENT

Project risk management is an organized process of risk identification and measurement, as well as selection, development, and implementation of risk control and monitoring options (Kerzner, 2004). Project risk management contributes to higher probability of a successful project realization – understanding of potential problems and their influence on project realization requires that activities be undertaken which will reduce a potential harmful impact of specific events on the project. This entails certain costs, which is why risk management is considered an investment. Risk management should be invested in, while observing the rule that the costs of risk must not exceed the potential benefits.

2.1. Basic project risk causes

Project management differs from management of any other process. The fact that a project has to solve an unknown problem suggests that project risk is higher than risk in other processes. The majority of risks are directly associated with a project and the activities aimed at its realization. Nevertheless, there are also indirect risks, which are the result of altered business environment of organizations.

Direct project risk causes include the following (Zayed & Chang, 2002, Nouks, 2005, Gohar, Khanzadi, & Farmani, 2012):

- Possibility that the project result will not meet the expectations;
- Refusal of project results by the users;
- Discrepancy between the required and the available resources;
- Increased project costs;
- Prolonged project duration;
- Lack of team members" experience with realization of similar projects;

- Deficiencies in technology for project realization;
- Imprecisely defined tasks;
- Inadequate software support;
- Insufficient project quality;
- Project changes;
- Insufficient safety;
- Inadequate team members‟ knowledge and skills;
- Task complexity;
- Inadequate management support.

Indirect project risk causes associated with business environment include the following (Zayed & Chang, 2002, Noks, 2005, Gohar, Khanzadi, & Farmani, 2012):
- Market changes;
- Market range and competitiveness;
- New investment options;
- Regulatory and legislative limitations;
- Erroneous market assessment;
- Inflation;
- Lack of available funds;
- Public opinion of the company brand.

Causes of task risks are task specific and can be identified and understood if each task is analyzed separately.

2.2. Project risk management processes

Even though there are many ways to structure risk management, project risk management usually involves the following six stages (PMI, 2004): 1) risk management planning, 2) risk identification, 3) qualitative risk analysis, 4) quantitative risk analysis, 5) risk response planning, and 6) risk control and monitoring.

Risk management planning is the process of developing and documenting an organized, comprehensive, and interactive risk management strategy; defining methods for risk identification and analysis; selecting, developing, and implementing risk treatment options; and planning proper resources (Kerzner, 2004). A risk management plan is a document which contains project risk management procedures during the project‟s life cycle and which summarizes the results of risk identification and assessment, response planning, and risk adjustment and control. Risk management plan can also contain risk management methodology, roles and responsibilities for risk-related activities, budget and activity schedule, description and interpretation of risk analysis methods, risk ranking criteria, type of reporting risk management activities, and the manner of monitoring those activities (Bobera, 2003). In addition to the basic plan, the following can also be defined: (1) operation plans – plans for activities conducted in case of a specific and identified risk event; (2) retreat plans – plans devised for risks which heavily impact project goals and which are activated in case a previously planned risk reduction does not produce the expected results; (3) operational reserves – additional means to be used for risk mitigation if there are changes in project scope and quality.

Risk identification implies the establishment and understanding of potential unsatisfactory project results in terms of project nature and goals, scope, time, cost, and quality. It is performed in order to create a list of risk sources and factors, as well as events which can affect goal accomplishment. Such events can disable, reduce, increase, or postpone the realization of defined goals. As the identified events can occur in a variety of ways, it is necessary to devise different scenarios for the events. Most commonly, these are basic scenarios as the most probable risk event scenarios. International standard ISO/IEC 31010 (2009) recommends using the following methods and techniques to identify project risks: brainstorming, survey, interview, checklist, preliminary hazard list, hazard and operability study, „what-if‟ analysis, scenario analysis, cause-and-effect analysis, and probability and impact matrix.

Risk analysis involves the description of identified risks, extraction of the causes, and analysis of how they influence risk (taking into consideration the existing processes, devices, or practice by which a given risk is controlled), assessment of risk occurrence probability and impact, assessment and quantification of risks, creation of priority risk list, proposals of risk response methods, and definition of parameters and metrics for risk monitoring (Savic, Stankovic, 2012). Risk assessment is performed through unified assessments of probability and impact for every risk scenario. Extensive information on the frequency and impact of hazards should be integrated and presented in a relatively simple form for easier understanding and decision making. This could be a unique numerical index, a table, a matrix, a graph, or a risk chart.

Risk analysis can be qualitative, semi-quantitative (qualitative-quantitative), quantitative, and combined. Qualitative and semi-quantitative risk analysis typically includes the following methods and techniques: survey, SWOT analysis, cause-and-effect diagram, expert assessment, the Delphi technique, preliminary hazard analysis, fault tree analysis, failure mode and effects analysis, probability and impact matrix, and multi-criteria analysis. Quantitative risk analysis typically includes the following methods and techniques: probability theory, mathematical statistics, operational research, sensitivity analysis of effectiveness indicators, scenario analysis, fault tree analysis, event tree analysis, Monte Carlo methods, and modelling and simulation methods (ISO 31010, 2009).

In order to properly utilize a risk assessment (for selecting technical and managing actions and for establishing a connection with social and administrative bodies), it is essential to know the degree of indeterminacy of the assessment. Indeterminacy of the assessment depends on the quality of the database, models, and methods of analysis used. Data indeterminacy stems from the fact that an insufficient range of real data is appended with expert assessments or opinions. Such indeterminacies can be mathematically analyzed and quantified. Model indeterminacy is always present due to partial compatibility between the real system and its model. The indeterminacies are difficult to quantify, and they are more precisely determined by sensitivity analysis.

Sensitivity of results towards a model parameter is defined as the change of risk measure with the change of unit parameter. This analysis is performed for all parameters which are assumed or known to have a high degree of indeterminacy. A model parameter with the highest influence on risk also has the highest sensitivity. The effect of indeterminacy can be reduced by means of relative risk assessment. If one and the same methodology is used to assess different alternatives, the resulting risk assessment is subject to the same indeterminacy. Thus, ranking of various alternatives provides a better risk assessment than the absolute assessment.

Use of quantitative risk assessments in practice requires risk classification. The primary problem here is the decision on risk acceptability. The decision on which risk can be considered acceptable often depends on a company"s economic capabilities. Categorization of acceptable risks is a result of expert assessment, in accordance with the framework, content, and goals of the project. In addition to ranking and evaluating risks, risk factors can also be ranked, considering their impact on project risk. Such a list indicates the most important factors of potential risks and, accordingly, the points and paths in which risk reduction measures would be the most effective.

Risk categorization is the foundation of risk response planning. Risk treatment defines activities which expand the possibilities and reduce threats to project goals. The basic risk response planning options are the following: risk avoidance (elimination of uncertainties and high risks); risk reduction (preventive reduction of potential risks); risk retention (voluntary acceptance of risk and keeping it at an acceptable level); and risk transfer (distribution or transfer of risk to other organizations, agencies, or associations).

Risk monitoring is a continual process of monitoring and assessing risk management processes by means of measuring and reporting, as well as through feedback, which initiates re-planning, reassessment, and/or management response ("*Systems Engineering Fundamentals*", 2001)

3. RISK INDEX

Risk index (R) is a model designed to assess the potential impact of various risk factors on a project. It was originally developed by Dias and Ioannou (1995) and modified by Zayed and Chang (2002). The model represents a logical, reliable, and consistent method of risk factor ranking, project evaluation, and establishment of project priorities based on risk index value.

Risk index is a function of two parameters. The first parameter pertains to risk factor or subfactor weight, and the second to the impact of the observed risk factor or subfactor on project goals. Risk index is determined separately at the macro level (management level, where environmental risks are considered) and the micro level (the level of the project itself, where immediate project risks are considered). The total risk index is the product of risk indices for the macro and micro levels of the project.

According to Zayed and Chang (2002) and Zayed, Amer and Pan (2008), risk index at specific levels is determined by equation (1):

$$R_k = \sum_{i=1}^{n} w_i E_i \,, \qquad (1)$$

where:

R_k - risk index at k^{th} level (k=1 at the macro level and k=2 at the micro level),

w_i - weight of the i^{th} risk factor/subfactor determined by the eigenvalue method,

E_i - impact value of the i^{th} risk factor/subfactor,

n - number of risk factors/subfactors.

The total risk index is calculated by equation (2):

$$R = R_1 R_2 . \quad (2)$$

3.1. Weighting

The Analytic Hierarchy Process (AHP) method is used for weighting by the eigenvalue method.

AHP was developed by Thomas L. Saaty in the 1970s. AHP provides a flexible and easily understood way to analyze and parse the decision problem. It is a multi-criteria decision-making methodology that allows subjective and objective factors to be considered in the evaluation process.

AHP method involves the following steps: (1) identification and clear definition of the overall goal (objective); (2) identification of the criteria, sub-criteria, and alternatives which satisfy the overall goal; (3) formation of the hierarchical structure; (4) performance of pairwise comparisons; (5) determination of weights of the decision elements by means of the eigenvalue method; (6) verification of the consistency of results; and (7) determination of the global priority vector.

Goal identification. The goal is to determine weights of risk project factors/subfactors.

Identification of criteria, sub-criteria, and alternatives. Risk factors are identified as criteria (e.g. at the macro level, these include policies, finances, and the market, while at the micro level – technology, resources, organization, project performance, etc.). Risk subfactors are identified as sub-criteria or alternatives (e.g. within policies, these include change in government policy or national legislation, within finances – inflation, interest rate or risk fund changes, or within technology – material risk, equipment risk, change in technology, etc.). If risk index is determined for several projects, the projects then represent alternatives.

Hierarchical structure formation. The Fuzzy AHP method presents a problem in the form of hierarchy: the first level represents the goal; the second level considers relevant criteria; the third level considers relevant sub-criteria; and the last level defines alternatives.

Pairwise comparison. Once the hierarchy has been constructed, the decision-maker determines the relative importance of the elements at each level of the hierarchy. Elements at each level are paired, taking into account their relative contribution to the elements at the first higher hierarchical level, using the 1-9 Saaty"s comparison scale, where 1 means that importance of two criteria is the same, while 9 means that one criterion is extremely more important than the other. For each level, starting from the top of the hierarchy and going down, the pairwise comparisons are reduced in the square matrix form: $A = \left[a_{ij}\right]_{i,j=\overline{1,n}}$, where $a_{ij} = 1$ for $i=j$ and $a_{ij} = 1/a_{ji}$.

Determination of relative weights. The mathematical basis for determining weights based on matrix theory has been proposed by Saaty (1980). The procedure is called an eigenvector approach, which takes advantage of the characteristics of a special type of matrix called a reciprocal matrix. The eigenvector $W = (w_1, w_2, ..., w_n)$ can be generated in different ways. The two most frequently used methods – arithmetic mean method and geometric mean method – follow below.

In the arithmetic mean method, the elements of the eigenvector are calculated as follows:

$$w_i = \frac{1}{n}\sum_{j=1}^{n}\frac{a_{ij}}{\sum_{k=1}^{n} a_{kj}}, \quad i = 1,2,...n . \quad (3)$$

In the geometric mean method, the elements of the eigenvector are calculated as follows:

$$w_i = \frac{\left(\prod_{j=1}^{n} a_{ij}\right)^{\frac{1}{n}}}{\sum_{k=1}^{n}\left(\prod_{j=1}^{n} a_{kj}\right)^{\frac{1}{n}}}, \quad i = 1,2,...,n. \qquad (4)$$

Checking results consistency. Consistency implies that the decision-making procedure involves coherent judgments in specifying the pairwise comparison of the criteria, sub-criteria, or alternatives. Consistency is determined by the consistency ratio, as given in equation (5):

$$CR = \frac{1}{RI}\left(\frac{\lambda_{\max} - n}{n-1}\right), \qquad (5)$$

where RI is a random index (Table 1), n is the number of pairwise comparison elements in matrix A, and $\lambda_{\max}$ is calculated as follows:

$$\lambda_{\max} = \frac{1}{n}\sum_{i=1}^{n}\frac{(AW)_i}{w_i}. \qquad (6)$$

Table 1: Random indices (Saaty, 1980)

n	1	2	3	4	5	6	7	8
RI	0	0	0.52	0.89	1.11	1.25	1.35	1.40

If a consistency ratio is 0.10 or less, it can be considered acceptable; otherwise, the judgments should be improved. This improvement should be made by double-checking the data entry and by omitting bad judgments which have high inconsistency ratios (Saaty, 1980).

Global priority determination. The final stage involves finding a vector of global priority. Since the successive levels of hierarchy are linked together, a global weight vector for the entire hierarchy is determined by multiplying the weight of all vectors of successive levels.

3.2. Impact assessment

The impact of the i^{th} risk factor/subfactor E_i reflects the level of project performance change in relation to that risk factor/subfactor. It is determined through the following two steps: (1) first, the qualitative impact of risk factor/subfactor at project performance level has to be determined by means of the 1-9 scale, shown in Table 2; (2) then, the qualitatively expressed risk impact has to be quantified in a 0-100 point value range, or 0-1 range, as shown in Figure 1.

Table 2: Qualitative performance scale (adapted from Zayed and Chang, 2002)

Qualitative performance scale	Abbreviation	Equivavelt numerical index
Extremaly Undesirable	ExU	1
Substantialy Undesirable	SuU	2
Moderately Undesirable	MoU	3
Slightly Unesirable	SiU	4
Neither Desirable nor Undesirable	Nei	5
Slightly Desirable	SiD	6
Moderately Desirable	MoD	7
Substantialy Desirable	SuD	8
Extremaly Desirable	ExD	9

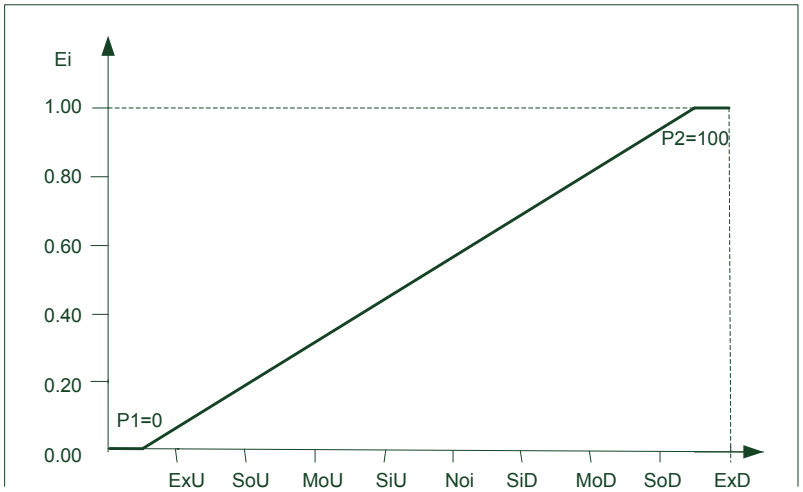

Figure 1: Quantitative performance scale (Zayed and Chang, 2002, p.12)

In Figure 1, there are three areas of risk impact. The first area is the area of acceptable risk impact, which indicates a maximum performance level (P1=0 points, or E=0); the second area is the area of linear growth of risk impact (0<P<100, 0<E<1); and the third area is the area of the highest risk impact and a minimum performance level (P2=100 points, or E=1).

3.3. Ranking

Risk factors/subfactors are ranked based on risk index values for each factor/subfactor. The factor/subfactor with a highest risk index value has the biggest impact on project quality. At the same time, risk index indicates priority actions for project risk reduction.

Based on macro, micro and total risk index values, projects can be categorized as shown in Table 3.

Table 3: Project risk categorization based on risk index

Risk index on the macro and at the micro levels	Total project risk index	Risk categorization
≤ 0.2	≤ 0.04	Low risk
< 0.2 *and* > 0.6	< 0.36 *and* > 0.04	Medium risk
≥ 0.6	≥ 0.36	High risk

The total project risk index is also the basis for ranking different projects. The project with the lowest total risk index is ranked the highest because it has the lowest risk impact on project performance.

4. CASE STUDY: RISK INDEX DETERMINATION FOR A CONSTRUCTION PROJECT

Risks are ever-present in construction project and they affect costs, time, and quality of project realization. They are unavoidable but manageable to the point of acceptable project risk. Zou, Chen and Chan (2010) say that risk management implementation "in construction projects may bring a number of benefits. Therefore it is necessary to have risk management as an integral part of a construction organization"s management practice" (854).

In order to determine the risk index, we conducted five interviews with project managers in organizations dealing with the design and realization of construction projects in Serbia. The aim of the interviews was to identify only the key risk factors/subfactors at the macro and micro levels and their significance and impact on project goals. Task, or activity, risks were not included in the survey, as they are project specific. Based on the results of the interviews, we defined factor/subfactor hierarchies at the macro and micro levels (Figure 2), created pairwise comparison matrices (Tables 4-7), determined the weights and quantified the impact (Tables 8 and 9).

		Inflation	0.068	0.4	0.0272
		CR=0.0375			
Market	0.106	Scope	0.053	0.1	0.0053
		Competitivenes	0.053	0.1	0.0053
		CR=0			
CR=0.0375					
Sub-factors risk index sum					**0.2350**

Table 9: Weights, efects and risk index at the micro level

Factors	Factors weights	Sub-factors	Sub-factors weights	Sub-factors efects	Subfactors risk index
Design	0.633	Errors	0.401	0.6	0,2406
		Modifications	0.165	0.2	0,0330
		Compexity	0.067	0.2	0,0134
		CR=0.0375			
Resources	0.260	Workers	0.068	0.2	0,0136
		Equipment	0.165	0.3	0,0495
		Materials	0,027	0.2	0,0054
		CR=0.0375			
Organization	0.106	Project team	0.059	0.3	0,0177
		Number of projects	0.010	0.1	0,0010
		Use of resources	0.010	0.2	0,0020
		Software tools	0.027	0.2	0,0054
CR=0.0375		CR=0.016			
Sub-factors risk index sum					**0.3816**

The total project risk index, based on equation (2) and Tables 8 and 9, is:

$$R = R_1 R_2 = 0.235 \cdot 0.3816 = 0.0897$$

At both project levels risk is categorized as "medium risk" (R_1=0.2350, R_2=0.3816). Total risk also belongs to the category of "medium risk" (R = 0.03816). The highest risk at the macro level is caused by political and financial factors, such as: the application of regulations (0.0950), investments (0.0492) and changes in regulations (0.0474). At the micro level, the dominant risk results from errors in the project (0.2406); significantly lower risks are caused by equipment (0.0495), modifications of the project (0.0330), etc.

5. CONCLUSION

Risk management is a means of ensuring a project from potential harmful effects of certain events (within and outside of the project) on project realization. Through understanding potential problems, defining the possibilities to be monitored (or ignored) and threats to be responded to (or accepted), developing and controlling responses to potential risk, and creating the need for improvement of the project management plan, risk management contributes to the accomplishment of project goals in the best possible manner.

Risk index is a project risk measure. Its value will be more credible if the problem of project risk is considered at a large number of hierarchy levels (to activities level). This paper considered only two hierarchy levels with factor typical of all construction projects in order to show the procedure of risk index determination.

Nevertheless, every project has its own inherent risks which are to be considered when determining the risk index for a specific project.

THEORY OF COMPLEXITY AND INNOVATION PROJECTS

Zorica Dodevska[1], Marko Mihic[2]
[1]Faculty of Organizational Sciences, zorica.dodevska@gmail.com
[2]Faculty of Organizational Sciences, mihicm@fon.bg.ac.rs

***Abstract**: Complexity, as a new paradigm of scientific thought, finds its place in project management. There is a high projects failure rate, and on account of this, there are many criticisms of traditional project management. The theory of complexity takes into account the context in which a particular project is observed. Innovation projects distinguish from conventional projects primarily, by a greater degree of uncertainty and risk, and they cannot be managed in the same way as conventional projects. The aim of this paper is to consider the complexity of the project and the project environment, searching for relationship with innovation projects, and to give some helpful recommendations for project managers.*

***Keywords**: theory of complexity, project management, criticism, innovation project, uncertainty, risk, project manager*

1. INTRODUCTION

Theory of complexity brings refreshment in traditional project management. Projects have always been guided by the Newtonian paradigm, which implies linearity, determinism and predictability. Despite this, there are many examples of failed projects. Simple rules of cause and effect are not always valid, and a large number of factors affecting the complexity of the project and project environment. Like complex adaptive systems, projects constantly need to adapt to these changeable factors.

Complexity paradigm supports innovation, because there is a strong connection between chaos and creativity. Innovation projects are not structured, their future is uncertain, and traditional tools for managing conventional projects are often not helpful in their case.

In order to provide successful project management, project managers have a lot of to learn from the theory of complexity. The challenge is to manage the chaos of innovation projects, to achieve an agreement within the project team, to predict the future in unpredictable environment, and to manage the risk of innovation projects.

2. INTRODUCTION TO THE THEORY OF COMPLEXITY

Mitchell (2009) writes that “the word *complex* comes from the Latin root *plectere*: to weave, entwine” (p.4). Cooke-Davies, Cicmil, Crawford, & Richardson (2007) concluded that complexity is “generally referring back to the Latin origins of the term (*complexus*, from *complecti*) in which *com* is combined with *plectari* meaning ply or braid” (p.51). It is clear that complexity in the main implies that something is composed of many parts, and there are difficulties in understanding the relationship among them.

Stacey matrix pinpoints the differences among the terms – simple, complicated, complex, chaotic. It contains two dimensions. The horizontal axis represents the degree of certainty, and the vertical axis the level of agreement (figure 1). Certainty means that it is possible to determine the cause and consequence relationship between these two events, but also to predict the future with certainty based on previous experiences. On the other hand, the arrangement means there is a group agreement among certain questions and decisions which are under consideration.

Five fields are observed on this matrix:

- Simple (1) – Close to Agreement, Close to Certainty;
- Complicated (2) – Far from Agreement, Close to Certainty;
- Complicated (3) – Close to Agreement, Far from Certainty;

- Anarchy (4) – Far from Agreement, Far from Certainty;
- **Complex** (5) – zone of complexity, it is located at the transition between zone of stability and zone of anarchy (the so-called "the edge of chaos").

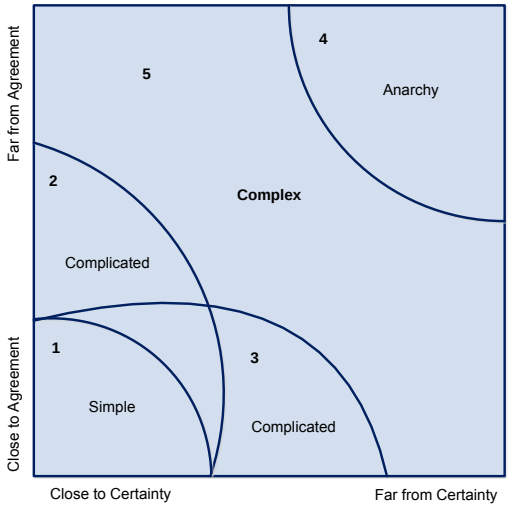

Figure 1: Stacey matrix (Zimmerman, 2001)

Classical science is based on linear systems and determinism, but simple rules of cause and effect are not always valid. Nonlinear systems make a fundamental concept of chaos theory, on which theory of complexity is based. This theory suggests that the universe is full of systems which are constantly adapting to the environment, and hence the term Complex Adaptive Systems (CAS). The rise of CAS as a school of thought took hold in the mid-1980's with the formation of the Santa Fe Institute (Dodder, Dare, 2000).

Adapting to the changes in the environment, CAS develop and evolve with it in time. Constant reorganization in finding ways for adapting to the changeable factors in the environment is present and it happens spontaneously. Systems evolve to the higher order degree through self organization. Keskinen, Aaltonen, Mitleton-Kelly, & Kauffman (2003) have explained that „complex systems are composed of numerous, varied, simultaneously *interacting parts* (or agents)" (p.7). The way in which system parts are mutually connected and the relationships among them are essential for the system's survival. Complex system isn't a mere sum of the parts, but an integrated whole in which very small changes can make huge differences in the results. Meteorologist Edward Lorenz had defined this phenomenon in 1963 as „sensitive dependence on initial conditions", that later, in 1979, called *„butterfly effect"* in one of his paper (Cooke-Davies, Cicmil, Crawford, & Richardson, 2007). Legendary, the flapping of a butterfly's wings in Brazil set off a tornado in Texas. There is high degree of connection among the agents, hence the tendency to fast and surprising behaviour changes. These changes, combined with sensitive dependence on initial conditions contribute to unpredictable behaviour in long-term. Within CAS it is still possible to spot a certain order, and certain patterns of behaviour that lead to the evolution of the system, while all details of the system cannot be fully comprehended.

3. CRITICISMS TO THE TRADITIONAL APPROACH OF PROJECT MANAGEMENT

In addition to constant knowledge improvement on project management and sophisticated development tools and project management techniques, there are still many examples of failed projects or partly unsuccessful projects (based on the following – time, costs, and quality). On account of that, there is criticism toward traditional project management.

"The paradigm of the traditional approach refers to a predictable environment, where the success of the project is attributed to adherence to pre-established standards, and failure is attributed to lack of adherence to the same standards. However, doubts have been raised about the validity of this paradigm and the implicit assumptions for the effective management of projects." (Marquees, 2012)

More attention should be dedicated to context contemplation in which the relative project is being observed. Without the corresponding project environment analysis, or even by ignoring its individuality, easily accessible, verified and "quick" solutions are suggested. However, in practice it often turns out that universal

solutions are not always the best ones, so it is preferable to apply contingency management access because the very definition of the project calls it a unique business venture.

It is often cited in literature that it is necessary to connect interior processes of a project with historical and organizational context since “no project is an island”. Engwall (2003) points out that “in order to understand the inner life of a project in depth, it also needs to be analyzed in relation to: (1) experiences from past activities; (2) politics during the pre-project phases; (3) parallel courses of events happening during project execution; (4) ideas about the post-project future; and (5) institutionalized norms, values and routines of the project’s organizational context” (p.791).

In addition to other complaints, Packendorff (1995) notices it is wrong to treat projects as means for goal attaining, and not premature organization.

4. INNOVATION PROJECTS SPECIFICATION AND RELATION TO THE THEORY OF COMPLEXITY

Complexity paradigm supports innovation. The complexity zone is to be seen on the transgression between the arrangement zone and the chaos zone on a Stacey diagram. “In the zone of complexity the traditional management approaches are not very effective but it is the zone of high creativity, innovation, and breaking with the past to create new modes of operating” (Zimmerman, 2001).

Various types of innovation projects are shown on the figure 2: technology, research, new product development projects and other projects. “Conventional projects tend to have clearly defined goals and targets. On the opposite, innovation projects might not necessarily have this detailisation. Innovation is often elusive and cannot be described before it is actually achieved” (Filippov, Mooi, 2010).

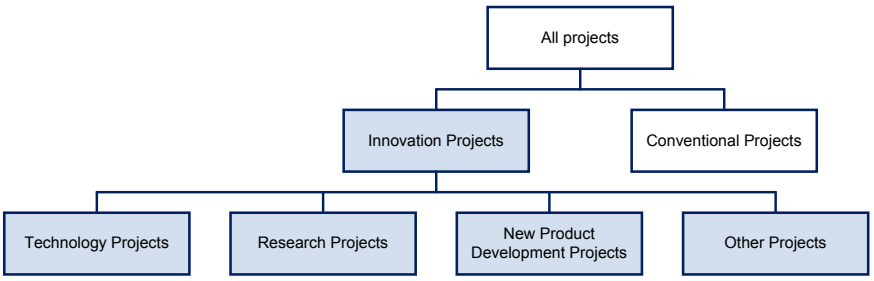

Figure 2: Classification of projects (Filippov, Mooi, 2010)

Innovation projects are distinguished from the conventional projects by its higher degree of uncertainty and risk. They cannot be managed in the same way as conventional projects since it is necessary to include more creativity when compared to standardized methods. In addition, traditional tools for managing conventional projects are often not helpful in managing innovation projects.

Learning is an another important feature of innovation projects. Harkema (2003) concluded that “learning is not focused on the procedural aspect of innovation projects, but on the relational aspect that underlies interacting people” (p.17).

5. PROJECTS MANAGEMENT, INNOVATION PROJECTS MANAGEMENT, AND COMPLEXITY

5.1 Project Complexity

Williams (1999) sees project complexity in two dimensions (figure 3): structural complexity and uncertainty.

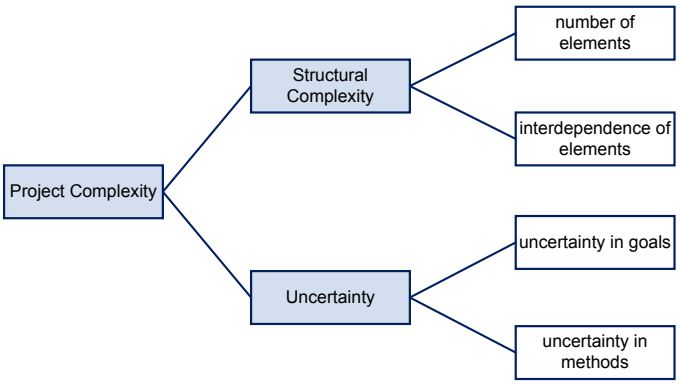

Figure 3: Project complexity (Williams, 1999, p.271)

Projects such as complex adaptive systems are comprised of a great number of elements which have a mutual interaction. Since "complexity can be characterised by two main aspects – quantitative and qualitative" (Geov, 2007, p.1), the quantity complexity aspect in the projects comes from a number of activities and different kinds of activities (for example, preparational activities, operational activities, the ones that happen on paper or in the field, etc.) These activities are mutually intertwined, so it is obvious that there is a great number of connections and dependences which are different as well. For example, in Precedence Diagramming Method (PDM) there are four types of connections: Finish-to-Start (FS), Start-to-Start (SS), Finish-to-Finish (FF), Start-to-Finish (SF). All these relations can have specific lags (such as FS2). Quality complexity aspect is the consequence of quantity aspect when due to many activities and relationships among activities in the project, perception exacerbates and behaviour of the project becomes unpredictable. Apart from the number of activities and number of connections, theirs differences are important for quality aspect of complexity, as well as variability of resources engaged in the project.

When it comes to innovation projects, the biggest problem is weak structuring. There is no previous experience in order to create something new (whether it's a new technology, a new product, or research), and because of that it is hard to know beforehand all tasks that will be undertaken on the project. Frequent changes in the project are usual, as well as the lack of understanding of their consequences.

The *butterfly effect*, known as an important non-linearity factor, is present in the management project systems. Little changes in certain phases of projects can influence the ultimate outcome. Moreover, if we repeat the same thing in a project, we won't get the same results every time. It is sometimes hard to connect cause and consequence since nonlinear behaviour is common for big projects. Apart from the great number of events and high degree of interdependence, what also influences this is organizational structure layers in the project and project relationships with other projects (Remington, Zolin, 2011).

The risk and uncertainty of the project are the highest in its initial phase (figure 4), when it is necessary to define the desired goals of the project. There are additional difficulties in risk management of innovation projects, because project risks come from different sources: management, technology and market (Stosic, Isljamovic, & Mihic, 2013).

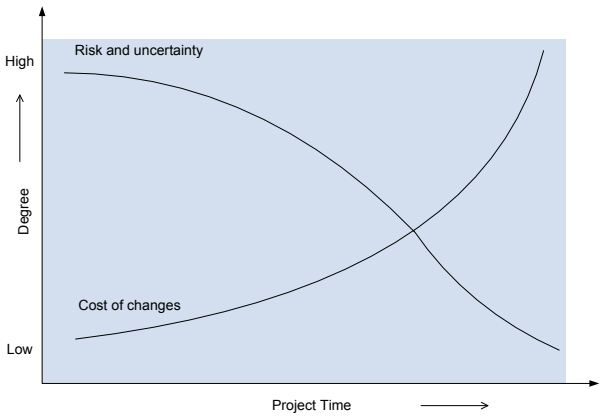

Figure 4: Impact of Variable Based of Project Time (PMBOK, 2013, p.40)

Having in mind that a great number of factors from the environment affect the project complexity and that projects can be long-lasting, it is necessary to examine the adequacy of originally established goals and redefine them. Projects are adjusted to changeable circumstances in the environment like complex adaptive systems. By changing the project goals, methods used for their achievements are changed.

In the same way that CAS behaviour cannot be predicted in a long period of time (similar to weather forecast), it is not possible to predict future occurrences in the projects whereupon its outcome is uncertain.

5.2 Environment project complexity

If project as a structure is being observed, then its closest environment is made by the people participating in its realization. It is important to consider complexity with project team where the source of complexity comes from the human factor in the first place and then from problem complexity problem which is before the team. The life cycle of a project team consists of several phases and certain patterns of behaviour characteristic to it can be seen. Life cycle of a project team consists of several phases and certain behavioural patterns characteristic for each of them can be spotted. There is the highest complexity during the storm phase, when the situation is far from agreement, precisely as it can be seen on the Stacey matrix, that is to say when the agreement among the team members cannot be achieved. Further during the norming phase and functionality phase projects team members agree, overcome conflicts, and move to the „agreement zone“.

All differences between virtual project leadership and leadership in a traditional environment aren't addressed in the PMBOK Guide (Curlee, Gordon, 2011). According to the PMBOOK Guide (2013), part X3.7 Political and Cultural Awareness, „an effective way to manage this cultural diversity is through getting to know the various team members and the use of good communication planning as part of the overall project plan“ (p. 542). But Curlee and Gordon (2011) considered that this „does not offer any practical recommendations about handling the leadership of a culturally diverse or a geographically dispersed team“ (p. 28). There is a chaotic nature of communication in a virtual project, where lines of communications are tangled and less affected by hierarchy (Curlee, Gordon, 2011), so communication plan must be more flexible and more capable for adjusting the changes. One should be particularly cautious in the case of managing the innovation projects by a virtual project team. Some authors think that virtual projects can exacerbate innovation. Chesbrough and Teece (2002) say that „loose partnerships of companies inevitably produce more conflicts of interest than do centrally managed corporations, and those conflicts can hamper the kind of complex, systematic innovation that creates valuable business breakthroughs“ (p.127).

Stakeholders of a project in accordance with standard BS ISO 21500:2012 are shown on picture 5. All of them together are in mutual interaction which increases project environment complexity. That is reflected on the project itself having in mind that it necessary to fulfil the demands and expectations of all stakeholders and oversight by neglecting any of the sides could lead to project failure.

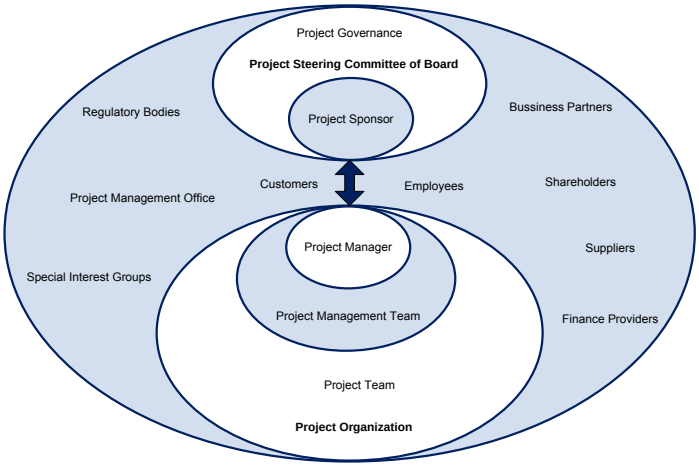

Figure 5: Project stakeholders (BS ISO 21500:2012, p.7)

Even though complexity theory does not advocate the use of any models, just by emphasizing the individuality of each project as well as the impossibility to show complexity by models and ruined picture of reality, there are several attempted models of project management when it comes to complexity.

5.3 Project management models

Depending on **project complexity** and **environment project complexity** which have previously been discussed, Jaafari (2003) suggests the following four project management models:

- Ad hoc model – project complexity and environment project complexity are low, the project management has no system approach, nor the occupation of the project manager can be recognized, decisions are made as you go along, the focus is not on long term achievements;
- Bureaucratic model – project complexity and environment project complexity are low to moderate, the approach is characteristic for projects in the public sector, the focus is not on achieving optimal project results as much as it is on administration respect;
- Normative model – it is distinguished by high project complexity and moderate environment project complexity, the modern model is usually described as the model of the best practice;
- **Creative-reflective model** – there is a high project complexity as well as very high environment project complexity, projects are not structured, the environment is changeable, study and project managers' creativity are necessary.

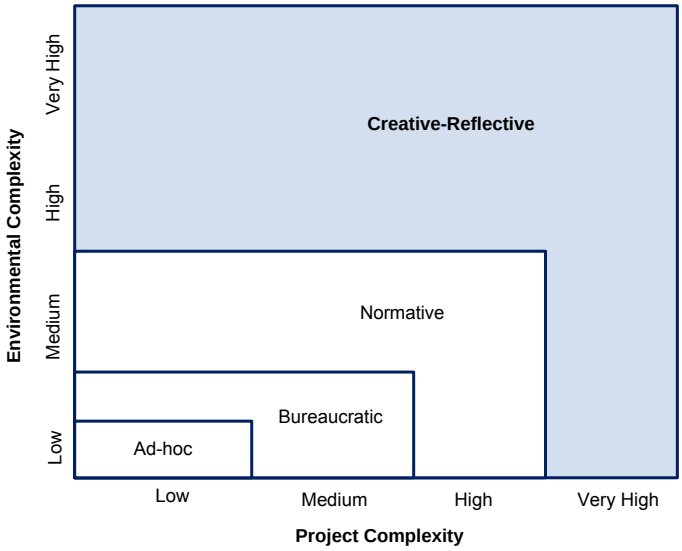

Figure 6: Schematic comparison of four models of project management in terms of complexity (Jaafari, 2003, p.55)

Basically, this classification reflects project management evolution through time in attempt to respond to ascending increase of environment and project complexity (Jaafari, 2003). In this work, the most important is the last crative-reflective model (figure 6) and here is the link with innovation projects.

6. RECOMMENDATIONS FOR PROJECT MANAGERS

The complexity paradigm challenges the conventional understanding that consensus is a good thing. It stresses the importance of expression of different opinions, debate and dialogue in order to promote the creative powers and the presentation of conflicting opinions. Depending on the level of complexity, project managers are advised to use different approaches in decision making process (table 1).

Table 1: Decisions in Multiple Contexts (Ameen, Jacob, 2009, p.14)

Context	Context caracteristics	Approach
Simple	• Repeating patterns and consistent events • Clear cause and effect relationship • Known Knowns	• Sense, categorize, respond • Ensure proper process in place • Best Practices and clear communication

Complicated	• Expert Diagnosis required • Cause and effect relationship not apparent • Known Unknowns	• Sense, Analyze, respond • Create Panels of experts • Listen to conflicting advice
Complex	• Unpredictability and competing ideas • No right answers • Unknown Unknown	• Probe, Sense, Respond • Increase level of interaction and communication • Use methods to generate ideas
Chaotic	• High turbulence • No clear cause and effect relationships • Many decisions to make and no time to think	• Act, Sense, Respond • Look for what works instead of seeking right answers • Provide clear direct communication

In the article 8.1.2.3 (PMBOK, 2013), Ishikawa cause-and-effect diagram is presented as one of the seven tools for quality management. It is used for conceptualization and presentation of relationships among the consequences given (for example, quality characterists' variation) and their potential consequences. It is based on the concept of linear systems, that is to say cause and consequence relationships. Their presentation looks like a fish skeleton (figure 7). Complexity theory pinpoints this tool's flaw. It presupposes one way causality and it doesn't include feedback from effect to causes. As it is shown on this example, classic tools for solving problems can possess flaws when observed form the complexity theory prism. It is possible to use them in certain situations, but it is necessary to develop individual tools for solving problems simultaneously.

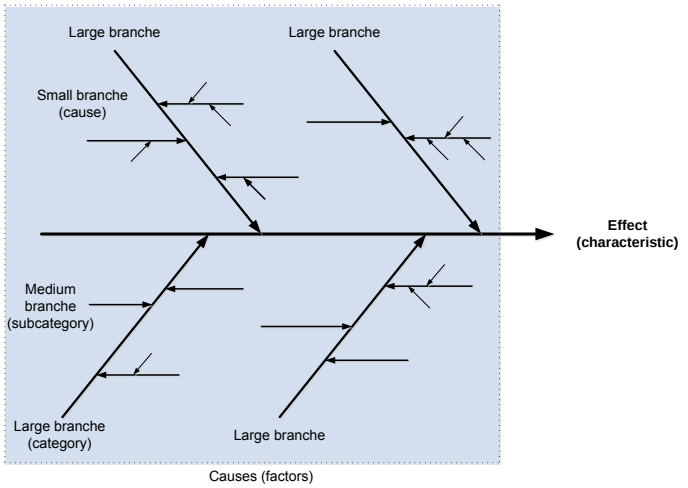

Figure 7: Ishikawa cause-and-effect diagram

In addition to standard tools, there are other tools that project managers can use to help manage the chaos and successfully manage complicated systems. For example, Ojha (2011) suggests *enneagram*, that is originally a tool for personality mapping, but also it can be helpful for project manager to find order in between chaos, by identifying underlying patterns in an organization, because „the map allows project managers to predict certain outcomes, which results in more reliable management systems" (Ojha, 2011).

A great dose of uncertainty in the process of planning the realization of the project, which applies mostly to the innovation projects, when the managers doesn't have previous experience in realization of the relative project. Therefore, the project manager should find an adequate way to treat the present uncertainty in their calculations. PERT method for time planning is suitable to use in these kinds of circumstances. It considers optimistic and pessimistic duration time of an activity in order to get the calculation of the most probable, the most expected duration. Complexity theory advocates inclusion of *fuzzy* numbers during the calculations of a *fuzzy* critical way, so it supports the application of *fuzzy* PERT method with a view to avoiding subjective evaluation of activity duration by the project manager.

In order to provide successful risk management of innovation projects, it is advisable that project managers use combination of the Work Breakdown Structure – WBS and the Risk Breakdown Structure – RBS, called Risk Breakdown Matrix – RBM (figure 8), (Stosic, Isljamovic, & Mihic, 2013). WBS is a structural diagram showing affairs and tasks which need to be performed within a project. RBS identifies project risk, which in

case of innovation project includes management, market and technology on the first level (Stosic, Isljamovic, & Mihic, 2013). RBM is a useful tool for reducing uncertainty in the initial phase of innovation projects.

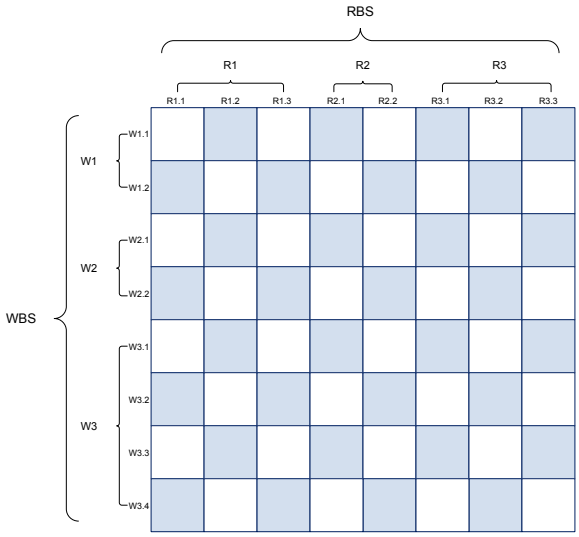

Figure 8: Simple Risk Breakdown Matrix (Stosic, Isljamovic, & Mihic, 2013)

7. CONCLUSION

In comparison to traditional project management, the advantages of incorporating complexity management in project management are significant. Closer consideration of project context is the key to successful project management. Theory of complexity teaches project managers how to deal with complexity, which comes from high project complexity and from very high environment project complexity.

The successful management of innovation projects on “the edge of chaos” is based on an optimal balance between order and chaos. When classic tools of project management are not helpful, it is necessary to develop individual tools. Complexity theory advocates inclusion of *fuzzy* numbers in project planning phase for reducing uncertainty. Risk Breakdown Matrix can be solution for risk management of innovation projects.

Further studies of these topics are related to empirical research that should analyze complexity in the field of project management innovation. Such research would be based on practice in Serbian organizations and have to analyze the key sources of complexity in the innovation projects, which come from weak structuring, great number of poorly known activities, high degree of interdependence among events, uncertain future, high degree of risk, chaotic communication among project team members, cultural and sociological differences in virtual teams, organizational structure layers in the project, project relationships with other projects, stakeholders, technology, market. The aim of this research is to modernize traditional approach of project management, to obtain benefits from the chaos, and improve the PM competencies.

Abstract: *The article aims to discuss the project governance system as a linkage between policies and projects in order to improve success of the public investment projects in developing countries. According to many researches there is increasing number of projects that cannot satisfy the public needs and priorities. Capital projects have also suffered huge costs and time overruns. On the other hand, demand for public capital projects increases because they strive to economic and social development of one society. The key for this paradox situation is establishment of project governance system which should help allocating scarce resources to high-priority public needs. This article gives literature review and points out challenges, critical factors and key features of successful model for project selection and prioritization.*

Keywords*: capital projects, public sector, project governance*

1. INTRODUCTION

There is no doubt that projects are important part of corporate and public life. They are identified as a policy implementation tools whit the aim to contribute to resolving social and economic problems. In order to contribute to human capital improvements, many developing countries invest in infrastructure, education, healthcare and other physical assets. These countries encounter difficulties in developing and implementing public investment programs that meet their needs (Tandberg, 2014). The majority of public projects is very large and complex and requires significant resources in order to be implemented. Furthermore, public projects suffer significant political pressure and they are subjected to public scrutiny. Ad-hoc decisions, huge number of uncertainties and poor methodology encroach upon selection and realization of highly beneficial projects. There are significant inconsistencies and differences in quality between different investment proposals and in many developing countries even the costing of the projects is inadequate. It is widely known that traditional project management performance measures are no longer enough to assess one project as a successful. Nowadays, the key of project success is to create a value - to contribute to strategic goals. Identifying these projects is very difficult especially in public environment which is complex and uncertain and it deals with stakeholder management issues and political pressure. Therefore, it is highly important to select projects which are aligned with public needs and other projects within project portfolio without wasting limited resources.

A result of bad project selection and realization, lack of information, wasting of resources and lack of technical competences are low yields on the public investments. Thus, it is very challenging to ensure making consistent public investment decisions across different sectors and projects. In order to increase yields on the public and private investments there is a need to make an effort to actually invest in the investment process. For developing countries it is vastly important to provide support for carry out development projects. It is clear that investing in the investment process has a high priority and it involves non-politicized selection and prioritization of public projects as well as project monitoring, controlling and ex post evaluation.

This paper discusses some key issues and challenges related to selection and implementation process of investment projects. As we identified nontransparent, politicized and poor project selection methodology as a main cause of wasting public resources on projects with limited social value, we wanted to find out how developed countries managed to establish system for project selection which indeed contributes to country's strategy. We have pointed out above that developing countries need to invest in investment process which will ensure selection and realization of projects which create a value, in other words, developing countries need to invest in investment process which contribute to strategic goals. This linkage between public needs and project objective is project governance. Many industrialized countries have implemented effective project governance system at the top governance level which has resulted selecting the right projects. Project governance was subject to research of many authors and institutions which motivated us to write this article with the objective to present key features of well-functioning public investment process and critical factors for successful implementation of project governance. Finally, this paper should give the basis for further researches which could help build effective process of project selection and prioritization in developing countries.

2. THE VALUE OF PROJECT MANAGEMENT IN THE PUBLIC SECTOR

Dynamic and changeable environment presses organizations to undertake complex and rapid initiatives. However, despite the increasing level of investment being made by organizations in projects, a startling number of initiatives fail to deliver the expected value, never get implemented, or cost substantially more and take substantially longer than planned (Williams & Parr , 2004). For the organizations it is not just important to formulate good strategy, it is equally important to implement it. Here important role has project management. Project and project portfolios are “powerful strategic weapons” (Shenhar, Levy, & Maltz, 2001) and they are considered as critical component for linking strategy to short-term actions (Kaplan & Norton, 2008).

While in the private sector projects have the aim to deliver strategy, in the public sector they are policy implementation tools. In the public sector there is a need for improving performance and ability for successful implementation of change. These take a form of projects which should be aligned with the important priorities in the society and the needs of the users. Projects are designed with the aim of delivering economic, institutional and social development (Shiferaw & Klakegg, 2012). The governments around the world support project management in order to contribute to effective governance through transparency and accountability, efficiency and effective resource usage, improved implementation of policy and change and maintenance of public confidence (Crawford & Helm, 2009).

Many authors claim that important problem in the public sector is the fact that public investment projects are implemented without examining the public needs and priorities. As a result in the public sector there is a situation that the need for projects is increasing but on the other hand the numbers of projects which truly satisfy the public need are decreasing. The phrase used for description of these projects is “white elephant” meaning projects whose cost and subsequent upkeep is much greater to the owner than its value (Williams & Samset, 2010). However, reason for project failure is not lack of efficiency. Projects are not managed badly, what is more management and governance of projects have shown improvements in recent years.

It is emphasized that quality at entry has important role in successful project delivery whereas quality identification, preparation and appraisal have more powerful influence on project performance than key county economic variables, external factors and government consideration (The World Bank, 1996). There exist a need for alignment between organizational strategy and the project concept. Additionally, there is necessity to deal with complexity of project, his impact on other projects in portfolio, and sustainability. Public investment project failure is a consequence of poor project selection methodology as it is not developed from development policies and strategies and in some cases policy/ strategy does not even exist (Shiferaw & Klakegg, 2012). On the one hand, there is no formal and clear system for checking if and how much proposed project contributes to government strategy realization. Furthermore, there is no established system for checking the level of public needs involved in the government objectives. There are a lot of evidence that there is a low efficiency of public investment, which includes delays in design and completion of projects, corrupt procurement practices, cost over-run, incomplete projects, and failure to operate and maintain assets effectively so that the benefits are less than they should be (Rajaram, Minh Le, Biletska, & Brumby, August 2010). Consequently, in the public sector it is difficult to map public needs and priorities, and to analyze the relationship between policies and projects. As a result an argument that fiscal space allocated to public investments should enhance economic prospects is negatively affected. In the public sector, investment projects are facing with cost underestimation and benefit overestimation due to flawed information and methods or systematic skewed estimation which might be politically motivated (Williams & Samset, 2010).

It can be conclude that there has to be established link between project and policy of the country. That is the only way to select and implement projects that meet goals and objectives and expectations of key stakeholders. Traditional approach of project management is no longer enough – the only value which project could give is not only delivering planned output within cost and defined time frame. The main project’s aim is to meet strategic goals. If that is not the case, not only that project will not be implemented, it could also cause the new problems. Therefore, it is important that projects are aligned with strategy. In that way it can contribute to strategy implementation and ensure that benefits are reaped from its realization. This conclusion is confirmed by Williams and Samset (2010), who point out that planner need to have a broad and long term perspective and allow different concepts to be considered in order to succeed in strategic terms. Furthermore, planning should decide on the direction and strategic framework for a project, and anticipate difficulties that might occur, in order to make the right tactical choices.

3. LINKING PROJECTS TO STRATEGY

A result of bad project selection and realization, lack of information, wasting of resources and lack of technical competences is low yields of the public investments. In order to increase yields on the public and private investments there is a need to make an effort to actually invest in the investment process. It is already said above that one of the World Bank's research indicates that quality identification, preparation and appraisal have more powerful influence on project performance than key county economic variables, external factors and government consideration. There is a strong necessity for linking project to country's strategy or sector's strategy in sense of selecting projects which contributes to strategy realization.

Alignment of project and strategy is a role of project governance. Project governance was a subject of many authors and it is identified as a critical successful factor for the delivery of projects (Garland , 2009) and effective project governance is a key feature of successful investments (Weaver , 2007). According to Organization for Economic Co–operation and Development (OECD) public governance refers to formal and informal arrangements that determine how public decisions are made and how public actions are carried out, from the perspective of maintaining a country's constitutional values in the face of changing problems, actors and environment. Turner (2006) points out that project governance provides the structure through which the objectives are set. Main goals of effective government of project management are choosing the right projects in order to ensure that project portfolio is aligned with organizational objectives, delivering chosen projects in that way there is no wasting of project resources, and ensuring that projects are sustainable. On the contrary, poor project governance results in project that does not achieve objectives and does not satisfy public needs and priorities and as a final result does not have positive long term effect (Shiferaw & Klakegg, 2012). In brief, poor project governance leads to project failure while good project governance leads to selection and effective implementation of projects that meet the need of stakeholders.

In order to make possible and effective governance of public investment projects, structure and principles have to be defined through creating governance framework. The governance framework is documented to have vital significance for the planning and management of projects. Klakegg et al. (2012) claims that governance framework is an organized structure established as authoritative within the institution, comprising processes and rules established to ensure project meeting purpose. The governance framework needs to enable projects to be flexible in order to adapt to turbulent environment, ambiguous, fragmented and political reality of project situation. In high performing countries high-quality procedures for planning investment projects have played a vital role (Shiferaw & Klakegg, 2012). Several developed countries have started a development process to strengthen the ability to manage and control major public investment projects. In this paper we will present a short description of Norwegian project governance framework and project governance framework established by of UK's Ministry of Finance as an example of effective project governance. Additionally, these examples will help us to point out "must have features" of every project selection and prioritization process which have to be to incorporate.

The World Bank has identified eight key "must-have" features of a well-functioning public investment system. These features are investment guidance, project development, and preliminary screening; formal project appraisal; independent review of appraisal; project selection and budgeting; project implementation; project adjustment; facility operation; and project evaluation (The World Bank, 1996). Regarding to the identified features of well-functioning public investment system and previously mentioned fact that there is a need to establish formal framework for project selection and implementation, it can be concluded that the starting point for effectual project government system is creating clear development policy and strategy which is in line with public needs and priorities. Projects are initiated from the policy direction of the government formally presented in some strategic plan (Shiferaw & Klakegg, 2012). Policy and strategy are designed by the influence of public needs and priorities and government executives. While government sector is responsible for policy direction, implementation sector is responsible for transferring strategy to actions. It is important that there exist the quality assurance system, with formal criteria in order to ensure the alignment of project and objectives, as a link between the government executives and implementation sector. Strategic guidelines provide selection of investments based upon priorities of the development policy. Therefore, strategic guidelines have to be strongly associated with national and sector strategy. The formal process for project development has to be developed. Every project has to go through the first level screening in order to estimate if project meets the minimum criteria of consistency with the strategic goals of government and if project is cost effective. After first screening test, the projects which meet minimum request are subjected to further economic and financial analysis. There is a require for feasibility analysis that consists of two key components: prefeasibility study which identifies alternative projects and feasibility study which analyses the alternative strategies in depth as well as undertaking social and environmental analysis. The feasibility collects all relevant data from prefeasibility study and outlines all possible outputs and outcomes. It is important that government has formal guidance on the technical aspects of project appraisal appropriate to the technical capacity of ministries and departments. In this condition, project's social and economic value

can be evaluated. However, project's macro, sectorial and project-specific uncertainties should be included into calculations end evaluation process. Consequently, a new investment should only occur when rehabilitating existing assets is not as cost effective as undertaking investment in a new asset (Rajaram, Minh Le, Biletska, & Brumby, August 2010).

Miller and Hobbs have concluded that there is strong correlation between the variety of strategies deployed, strategic depth and project performance (Miller & Hobbs, 2005). Even though, the clear and detailed strategy has to be defined before project selection, preparation and implementation, there exist a necessity for strategic flexibility due to high uncertainty and risk of capital projects. Investment projects are very long and have critical front-end where this front-end phase of projects can last many years. Thus, capital projects have to be developed through time-dependent, non-linear and iterative process. Successful project implementation and alignment with strategy require a strong sponsor, a strong leading coalition and flexible governance structure. If projects are not embedded in institutional framework, every project success will happen by accident. Consequently, without defined methodology for project selection there is practically no chance that projects will deliver strategic values.

4. MODELS FOR SELECTION OF INVESTMENT PROJECT

In the previous section we have emphasized that project success depends on the benefits realized by the venture. In other words, project efficiency – delivering projects by using "iron triangle" (time, cost and scope/ quality), is no longer only relevant measure for judging project performance. Therefore, Zwikael and Smyrk (2012) have proposed the "triple – test" framework which identifies three levels of project success and these are: *project management success*, *project ownership success* and *project investment success*. According to this framework, on the first level efficient project delivery should be judged through evaluation of four criteria: fitness–for–purpose, the time taken, the costs incurred and triggering undesirable, unacceptable or avoidable outcomes. Project effectiveness is measured on the second level where a project success criterion is achievement of the approved business case. In this context, project effectiveness depends upon the ability to adjust to the project environment. That means that every project requires specific outcomes measures that are adapted to organizational context in which the project is taking place. On the final level - third level, determinant of project success is project investment success. Project investment success is estimated through the *Project Investment Evaluation Model (PIE)* (Zwikael & Smyrk, 2011) and it is function of *worth* and *riskiness.*

This model is a ground for developing project governance frameworks. A few industrialized countries have managed to execute project governance systems. On the other hand developing countries are still struggling with low efficiency of public investments (Era Dabla-Norris, 2011). In this paper we will present Norwegian project governance system and UK Gateway review process as examples of governance systems which ensure best practice in planning at the front end. Furthermore, we will emphasize the aspects of project governance that should be upgraded with the aim of establishing process for project selection and evaluation that guarantees the selection of right public investment projects.

The Norwegian project governance system was established in the year 2000 where the aim was to reduce cost overran through introducing control measures in order to ensure realistic budgets and good basis for project execution. Establishing project governance system was a bottom-up process within Ministry of Finance. This system has two key decision points: Quality Assurance 1 (QA1) which refers to making decision to initiate project preplanning, and Quality Assurance 2 (QA2) which refers to making decisions about financing the project. The first quality assurance system (QA1) includes a needs analysis, a strategy document, alternative analysis and overall requirements. The second quality assurance system (QA2) includes cost estimation, contract strategy and an overall project management document. The Sectorial Ministry is responsible for large investment projects and the decision-making process. There is intention to establish system where politic and administration is well divided through interplaying and understanding of both sides.

In the United Kingdom, OGC (*Office of Government Commerce*) project governance framework was also established in the top-down process through implementing the management system. The OGC Gateway™ Process is designed to provide independent guidance to Senior Responsible Owners (SRO), program and project teams and to the departments who commission their work, on how best to ensure that their programs and projects are successful (Office of Government Commerce (OGC), 2007). Projects are examined at key decision points where this process is known as Gateway review process. There are six Gateways:

- Gateway Review 0: Strategic management;
- Gateway Review 1: Business justification;
- Gateway Review 2: Procurement strategy;
- Gateway Review 3: Investment decision;

- Gateway Review 4: Readiness for service;
- Gateway Review 5: Benefits realization.

OGC Gateway Review assesses the project's viability, the potential for project success, the value for money to be achieved, and the proposed approach for achieving delivery of the project's objectives (Office of Government Commerce (OGC), 2007). The OGC Gateway™ Process is a guideline where project could be grouped in four levels by their criticality. The project board for the project with top level of criticality - "mission critical" projects- is the OGC and it has responsibility to inform the Prime Minister's office about the decisions made. Senior people use Gateway process for making decisions about "high criticality" projects. On the next level consisted of "medium-criticality" projects it is important that there exist collaboration of OGC and departments regarding available resources. "Low-criticality" projects – projects on the last level is reviewed within departments.

The Norwegian project governance system is simple, strategy and concept are chosen in early stage and the most important criteria for judging projects are cost and risk. On the other hand, the OGC Gateway™ Process provides complete guideline how to achieve project's goals and objectives, strategic assessment is repeated within the program and projects are focused on creating value for money. Some of these differences are caused by cultural differences and maturity of the frameworks (Klakegg, Williams, Magnussen, & Glasspool, 2008). Regardless of the specified differences, the both project governance frameworks embedded governance principles, such as: transparency, willingness to change, setting common and high professional standards, and external control and nonpolitical review. Their aim is to base project on needs of the users and to implement the quality assurance system where the experts will make decisions closely collaborating with the highest political level. It can be conclude that building accountable and effective public institution requires devising quality assurance system and governance frameworks.

It is clear that the project selection process should establish and incorporate standards for project estimation and selection which have to be assessable. With the aim of ensuring project social and economic value, government has to develop and implement formal and public guidelines for technical aspects of project estimation. For selection of right projects, the nature of strategic guidance, availability of sector strategies and transparency of appraisal are not the only important factors for selecting required projects. As much it is important that there exist the independent review of appraisals conducted (Era Dabla-Norris, 2011).

In this paper we used information from the report of PEMPAL (*Public Expenditure Management Peer Assisted Learning*) countries from the year 2011. According to this report, in developing countries first obstacle for developing effective project governance system is the fact that sectorial strategies do not include enough information so they are not adequate basis for project prioritization. Developing countries are also affected by the lack of formal and precise guidelines for economic analysis. Independent project assessment is one of the issues, too. The reason to claim this is the fact that only four members of PEMPAL countries have external project revision and just in two countries the Ministry of Finance has established standards for project selection and prioritization.

If we compare project selection processes in the developing countries and in the developed countries such as Norway and UK, we can claim that developing countries have to invest in creating and incorporating formal and transparent project selection process. Critical factor for successful implementation of project governance is commitment of government executives. In developing countries the often case is that the government has not implemented project governance system and projects are selected randomly or there is no formal project governance system. For successful implementation of project government system it is important to consider culture norms. That is why it is not possible just to copy entire governance system from developed country. Establishing the formal government framework is important so that stakeholders could ensure successful investment. On the other hand, donors and financial institutions have developed their own methodologies for project support. It could be concluded that county should considered the interest of all stakeholders in designing a project governance systems.

5. CONCLUSION

This paper considers issues affecting how transparent and effective model for project selection and prioritization can be set up, in circumstances where there is a great level of uncertainties, stakeholder management issues and political pressure. The aim was not to build the governance framework, but rather to point out criteria that should be incorporate in system for selecting public projects. This subject inspired many authors in the field of project management to research reasons for capital project shortfalls. We have tried to offer an insight in author's opinions and suggestions. There could be some disagreement, but one is for sure: projects have to be aligned with the top level strategy. Therefore, the first step in developing effective project

selection process is formulating strategy which reflects public's and stakeholder's needs, on both top government and sectorial level. One of the most important rules for successful strategy execution is understanding the management cycle that links strategy and operations. Even though project initiatives in developing countries fail due to lack of information in sectorial strategies, poor project governance is identified as a main cause of project strategic shortfall. In the public sector, project governance has objective to underpin strategy implementation.

We have shown that individual authors and institutional authors, such as the World Bank and International Monetary Fund claim that poor project realization is a consequence of political pressure, corrupt procurement and non-transparent appraisal standards. Capital projects are highly complex and require making judgments about future when there is only scant information. Consequently, they are suitable for political manipulation. Referring to that, quality of identification, preparation and appraisal is crucial for capital projects success. Cost and schedule underestimation and benefits overestimation result in strategic underestimation of projects in the front-end phase due to flawed information and politically motivated processes. It is clear that without good model for project appraisal and selection, every project success is accidental. Countries determined to increase yields on the public and private investments have to invest in investment process which should ensure strong linkage between the projects and strategy.

PROJECT MANAGEMENT ON INTERNET – BLOGGERS AS FOCUS COMMUNITY

Velimir Tasic
University of Warsaw – Faculty of Management
twelimir@hotmail.com

Abstract: *Start with "why" is guide idea of research. Blogging and bloggers are something that each manager connects almost every day. For somebody that is idea of inspiration/curiosity; for others that is idea of motivation. In the research blog posts (articles) are idea of inspiration/curiosity. The research is established with materials from referent project management journals and conferences. Our "why" means that research take a challenge to explore; who is the author of the blog that managers read weekly or with similar frequency? Furthermore, research concludes that bloggers take inspiration from both experience and research literature.*

Keywords*: Project Management, Blogging, Project Manager, Information Technology*

1. INTRODUCTION

When the Project Management Institute (PMI) was founded in 1969, the term Blog (Blogger)—as it relates to the Internet and new technology—was not yet part of the common business vocabulary. Forty years after the founding of the Institute, issues related to blogging on project management topics became popular in the internet, management, business and marketing context.

Nowadays, the Internet is a first communication tool for both life and business. The Project Management (PM) is one of the most popular topics in business part. The research take a challenge to study questions: what are the main issues in terms of project management covered by the most popular Blogs? What are the authors' profiles of Blogs articles on the project management topics? To answer these questions, researches conduct a content analysis of ten blogs articles on the PM that were published in 2013. Bloggers and blogs are just the inspiration for topics and ideas; the topics are presented with research materials from both scientific journals and conferences devoted to the PM field.

Over the last two decades the Internet has been a very important communication channel. Last several years, a list of the most popular blogs on many different topics in the Internet is published. At the beginning of 2014 the ProjectNewsToday.com Blog published the list of the 25 most popular Blogs during the last year. In that study researches analyze last ten topics from ten blogs published at the end of 2013 (a table with detailed description and links is placed in the appendix).

Presented topics are described from the perspective of drawing the points of the research literature in the field of PM which was published in last decade. A definition of the research agenda is explained in the methodology part. The following topics are covered: History of blogging and blogs; Project Management Challenges, Project Manager, Projects and Leadership, Project Management and Information Technology.

The topics are very attractive for researchers. All topics are developing/changing very fast. Each year several new models and good quality books coming on the market. Before discussing the results of the analysis and offering some recommendations, the article firstly presents short history of blogs and the author research method.

2. HISTORY OF BLOGGING AND BLOGS

History of blogging begins in 1990s; blogs are place/virtual space where people share their interest, hobbies, and thoughts online. The main goal of blogging is online self expression. During time blogging became profitable business. In the last decade very profitable sales offers in blogging business have appeared.

Except for individual use, companies also saw the value in blogging. The companies use blogs to present their leadership, social responsibility and an expertise thought. Nowadays blogs are part of company's social media channels usually for external communication.

Many different factors have contributed to growing interest/influence of blogging in the business world. For example, the evolution of search engines in the Internet, made the Internet's content an important tool for measuring the visibility of companies' brands. At the beginning, sharing a new post was much harder, but when other social networks appeared it became much easier. On the one hand social networks support promotion process of the blogs but on the other hand they give chance much bigger amount of communities can express both their interest and thoughts; that means, creating broader competition.

Project managers use the blogs to share experience, promote new book and develop new ideas. All these activities are guided with the objective of improving business environment. The blog as a tool and the blogging as a communication channel help managers to easily show their expertise and present themselves to much broader community.

Many interesting statistics and other information about the blogs and the blogging can be found at: http://socialmediatoday.com/ and http://www.jeffbullas.com/, in the references are a list of several direct links to interesting perspectives. As mentioned in the introduction and deeply presented in the methodology part; the main idea of the research is to explore: what are the main issues covered by the most popular Blogs in terms of the project management? What are the authors' profiles of the Blogs articles on the project management topics?

3. METHODOLOGY AND RESEARCH AGENDA

The research starts with an analysis of the contents of the most popular blogs of 2013. Over the last year, the blog posts (articles) have been published weekly, monthly, quarterly, or with different frequency, in a total of approximately 600 articles. Our first task is to identify, among those 600 articles, those that could be an interesting stream to follow on the PM topics. Furthermore, research will follow the framework/content of last ten topics of each blog from the list of the 25 most popular blogs in 2013. The search resulted in 100 articles, which included many different topics on the project management.

The next task was to conduct coding of the titles. The coding was guided with an idea of indentifying whether each of the 100 articles was actually concerned with the PM. The coding is important due to provide us with topics that later are describe on the basis of the referent research literature. The exact titles and the coding are presented in the appendix (Table 1.).

The summarizing of an article was decided upon reading only its title. When the title was not clear enough, the full article was explored and the final decision was made afterwards. The final database of the content analysis includes 95 articles, as listed in the appendix (Table 1.).

The next idea was to answer our second question: What are the authors' profiles of blog articles on project management topics? The research tested the following ideas. The information was collected on the 15 individuals who authored the 95 articles. Firstly, blog authors were classified according to either academic (university degree, book writers and lecturers) or professional (project managers, consultants, analysts and others) profiles. Secondly, the research explores the involvement of the authors in the general PMI or IPMA activities/certification. To do so, we built the publication profile of the 15 authors by searching for a name of each author and checking the professional web presentation. The links to 90% of authors' profiles is given in the appendix (Table 1.) 05.03.2014 year (Date when links are checked). The research question/concept (the author profile) is explored and presented briefly, due to limits of the conference paper requirements. In the following chapters the answers on the first research question and the topics that bloggers mostly discuss at the end of 2013 are presented.

4. PROJECT MANAGEMENT CHALLENGES

The project management (PM) concept characterizes many challenges. In chapter we focus on: complexity, risk and uncertainty (Lechler, Edington, & Gao, 2012; Jaafari, 2001; Loch, DeMeyer, & Pitch, 2006; Saynisch, 2010; Shore, 2008; Maylor, Vidgen, & Carver, 2008).

How will the world develop in the future? The answer would require a special prize. What is more, the answer for the question which techniques will contribute to the future development of the world is quite obvious – the PM is both current and future business advantage. Therefore, the complexity of projects is constantly increasing (Saynisch, 2010). At the same the world is time rapidly growing and developing. Hence, business complexity follows those trends and classical knowledge loses ability to master —complexity" challenge (Cicmil, Cooke-Davies, Crawford, & Richardson, 2009).

New lights are already with us; both new technologies and social improvements are proposing different ways to overcome or simplify current and future challenges (Saynisch, 2010). The different research subjects from

both the natural and social science (e.g. evolutionary and chaos theory, self organization, synergetic, brain research, social systems theory, theory of complex systems, etc.) gives managers new alternatives to find better solutions (Saynisch, 2010). In the studies (Saynisch, 2010) the world class researches in the modern natural and social scientific theories take the challenge to recommend new models as they define —Beyond Frontiers of Traditional Project Management". Thus, the research target was the applicability of modern theories in the PM context.

The current classical PM knowledge is structured on —mechanical, mono causal, non dynamic (static), linear structure and a discrete view of human nature and societies and their perceptions, knowledge, and actions. It works on the basis of reductionist thinking and on the Cartesian/Newtonian concept of causality (the mechanistic science)" (Saynisch, 2010). Therefore, the classical PM needs both new assumptions and paradigms for future development of society.

A contingency approach could be an alternative for decreasing complexity in the PM practice. Therefore, the idea of contingency approach is opposite of almost Tayloristic model —one-size-fits-all" to management practice. The contingency idea gives freedom to the managers to explore entire situation or a project challenge context (Maylor, Vidgen, & Carver, 2008). Moreover, to understand better and simplify the PM complexity it could be divided according to structural (number of elements and interdependence of elements) and uncertain issues (goals and methods) (Williams, 2002).

In the recent research (Lechler, Edington, & Gao, 2012), there are discovered both risk and uncertainty of the PM concept. The researchers discuss the challenge as dilemma of definition between those two topics (Lechler, Edington, & Gao, 2012). The importance in a context of educating project managers is especially emphasized (Lechler, Edington, & Gao, 2012).

The projects are unique by definition and project uncertainties are imminent, regardless how much information is collected before a project is proposed (Hubbard, 2007; Sydow & Staber, 2002). When the economist debate on the uncertainties; they conclude it is the necessity for the possibility of convenience. Hence, with reference to several studies, the uncertainties are not inevitably defined to pessimistic issues, sometimes interpreted as synonyms for risk (Jaafari, 2001; Loch, DeMeyer, & Pitch, 2006; Lechler, Edington, & Gao, 2012).

The PM methodology endeavor many tools for both predicting and counting the project risk, but in the case of the uncertainties alternatives are very narrow and often just negative opportunities are visible (Lechler, Edington, & Gao, 2012).

5. PROJECT MANAGER

The earliest human societies, as Greeks, Romans and Egyptians used the PM techniques to build both working and living environment. The researches Walker and Dart (2011) take up that issue and present the following examples: the Great Wall in China, the pyramids and magnificent urban structures such as temples, administration palaces etc. Moreover, the researchers create an idea of similarities in style, order, decisions and compare ancient leaders and contemporary managers: focus of the leaders in Roman time was on —get things done"- focus of the contemporary managers is on optimization and efficiency.

First lights on the PM topic came from construction, shipbuilding, aerospace and manufacturing projects as cases of projects - they attract a —scientific" view on operations management influence (Walker & Dart, 2011; Turner, Huemann, & Keegan, 2007). Therefore, those projects could be defined as —engineering" type of projects. Hence, even in contemporary practice of the PM that early start style is recognizable.

Outsourcing is an idea that has very positive influence on developing the PM practice. Moreover, it interesting is that the idea is with us from the Romans projects practice - they used to outsource most of maintenance and construction work to private companies (Walker & Dart, 2011). Furthermore, knowledge management and knowledge sharing alike have some lights in Romans the PM practice (Walker & Dart, 2011). Both the outsourcing and knowledge management models shift very positively the contemporary PM leadership practice.

Nowadays, we are dealing with constantly changing business environment. Changes in culture and technology have revolutionized opportunities for the PM techniques and it is necessary to develop to take up new challenges (Walker & Dart, 2011). The PM environment is different than classical day-to-day operations environment (Turner, Huemann, & Keegan, 2007). Over last 20 years the PM literature have changed attention from technical to people oriented, especially in classical human resource management context (Turner, Huemann, & Keegan, 2007). Moreover, the development of both technology and power/information sharing give an additional shift in the PM practice and science (Walker & Dart, 2011).

6. PROJECTS AND LEADERSHIP

Practice of the PM in the 21st century is facing a challenge of doing business in very dynamic and fast changing environment (Tyssen, Wald, & Spieth, 2013). Implementation of the PM methods is growing almost in any industry (Sydow, Lindkvist, & DeFillippi, 2004; Bakker, 2010). The course change from standard to temporary organizations is one of main discussion streams in the PM literature and the practice (Tyssen, Wald, & Spieth, 2013).

The standard (contemporary) organizations setting assumption is somewhat stable and continuous organizational environments. The temporary organizations require flexibility, cross-disciplinary integration, short-term orientation, limited duration, unique in terms of tasks etc. (Tyssen, Wald, & Spieth, 2013). Therefore, a leadership approach of 21st century needs to change and adapt in order to serve better new business challenges.

Contemporary leadership theories are focused on relationships, interaction and subjective perception (Yukl, 2012; Bluedorn & Jaussi, 2008). Temporary leadership may require a different paradigm as a result of different business environment and perception of the leadership alike, as important factors for project success (Tyssen, Wald, & Spieth, 2013).

The temporary organizations require a different team approach. General team characteristics are similar as in the contemporary organization but the team approach is different. A team is a unit of two or more employers, who are capable and have the same purpose, mission, objectives, and expectations (Lussier & Achua, 2009). The team approach of the temporary organizations requires —carrying out time-limited undertakings and disperse upon completion; paving the way for a joint course of action with the goal of completing a non-routine task; often accompanied by non-routine processes and uncertain working conditions; whereas complexity in terms of roles and participant backgrounds is often caused by a variety of different experts working together" (Tyssen, Wald, & Spieth, 2013). Therefore, the temporary team deals with higher uncertainties and risks in terms of tasks, activities and processes.

Most of the PM literature is based on assumptions from construction/engineering industries. The main ideas are focused on —planning" and —structuring" (Zwikael & Unger-Aviram, 2009). The PM concept in the last several decades slowly has been changing the course of both the practice and the literature to a broader concept. New concepts draw the new models with softer leadership style and it requires further studies (Tyssen, Wald, & Spieth, 2013).

Five main characteristics of the temporary organizations are: *Temporariness; Unique Outcome; Missing/Ambiguous Hierarchies; Heterogeneity of Team Members; and Changing Work Teams* (Tyssen, Wald, & Spieth, 2013). Hence, one of main questions for further research is: how does leadership take place in these new environments?

7. PROJECT MANAGEMENT AND INFORMATION TECHNOLOGY

The histories of development of the Project Management (PM) and Information Technology (IT) show significant relationship and influence on each other. The PM started to shift the market after establishing the PM associations in 1960s. The PM and the IT subjects connect points for many other business and academic areas, as finance, construction, marketing, sociology, culture, politics etc. (Rivard, & Dupré, 2009). Moreover, in January 2006, between 15-20% of members in the PM association (PMI) were coming from IT industry or working in companies that produce software (Rivard, & Dupré, 2009). However, nowadays popularity of the information technology projects (ITP) is decreasing due to low success of implementing and general crisis on the market (Pratt, 2012). Additionally, education of ITP manager is one challenge in the ITP subject (Pratt, 2012). The PM knowledge base needs to adapt both new skills and techniques in order to serve the ITP requirements (Pratt, 2012).

An initial company's reaction or action on the changes at the market is research projects (R&D). As a consequence of the R&D project companies build new services, models and innovative solutions (Brocke & Lippe, 2013). The R&D projects are usually organized as collaborative research projects between academic, public and business partners (Brocke & Lippe, 2013). Moreover, in the study (Rivard, & Dupré, 2009) is presented a content analysis of the Project Management Journal (PMJ) from 1988 to 2005. The outsourcing projects as a subject is not covered and the authors recommend the topic as a gap for future research.

Currently, multi partnership on the R&D projects between above mentioned partners is very common. Reasons for collaboration are different: economical, scientific, innovative and social (Todeva & Knoke, 2005; Etzkowitz, 2003). Therefore, many stakeholders show interest to fund these R&D projects (Brocke & Lippe, 2013).

8. CONCLUSION

The described topics are presented in three thematic parts of the article. Firstly, research start with an historical overview of both terms the project management and the blogs/blogging. Secondly, research describe challenges which each of the topics faces in contemporary business environment. Lastly, research present short answer to the interesting question: What are the author profiles of Blogs articles on the project management topics?

The third part of the article or the above mentioned question opens many different opportunities for exploring. The research uses an alternative and in short presents that the authors of blog articles are both very experienced and business oriented. Furthermore, power of both bloggers and blogging is constantly growing (many examples of powerful influence of blog posts (articles) on different companies‘ campaigns could be easily found on the market). Therefore, research calls researchers to come with more creative ideas and bring new paradigms from emerging blog business.

The research literature is rich with many different topics. Both practice and science are agreed that experience is very important characteristic of the project manager or a project management researcher. Building the profile of the most popular blog authors draw a new picture on type of information that could be read in the blogs in future. The topics covered in the research are the most popular topics covered by bloggers at the end of 2013. As a result of research conceptualization in general terms and research requirements to create a new research in accordance with referent literature; blogger posts are alike the inspiration source for the research.

The reader could ask now at the end: Why does the research focus on topics such as Project Management and Information Technology, Projects and Leadership, Project Manager, Project Management Challenges; it is a result of the bloggers posts which are focused also on the topics at the end of 2013, as presented in the table 1. in the appendix and in the methodology chapter. The research conclusion is guided from the perspective of closing the answers on the main research paradigm. The main research paradigm follows the concept that each topic is presented from the perspective of leading challenges that researchers found in referent PM research literature. Therefore, the summary of each study topic is formed as a chapter of the research and its conclusion is back on the research questions and the summary of beginning idea of the research.

The research has a vision that the article is just the beginning of exploring the challenge. Exploring many other aspects similar to blogs (e.g. websites, news, slideshare, linkedin, etc), researchers found it very inspiring.

9. ACKNOWLEDGEMENTS

Special thanks to Professor Ph.D. Witold Chmielarz (University of Warsaw – Management Faculty) for review, advices and inspiring with excellent ideas.

Furthermore, thanks to Erasmus SIGMA scholarship program for providing great opportunity for studying at University of Warsaw – Management Faculty.

ASPECTS OF PUBLIC RELATIONS AND FINANCIAL MODELS WITHIN NGO'S

Milenko Radonić[1], Ivana Drecun[2], Marko Dogović[3]
[1] Faculty of Organizational Sciences, E-mail: (milenko.radonic@estiem.org)
[2] Faculty of Organizational Sciences, E-mail: (ivana.drecun@estiem.org)
[3] Faculty of Organizational Sciences, E-mail: (marko.dogovic@estiem.org)

Abstract: *This document presents a unique paperwork on the basics of project and program management in NGO's. Purpose of this research is to present main issues of PR and finance in such organizations, with main focus on student organizations. The lack of formal documents with scientific approach considering online public relations and funding in non-profit organizations motivated three authors to use their experience in non-profits. The aim of this paperwork is to combine different sources of theoretical knowledge in basics of program and project management, online PR, and organization activities and funding of non-profit organization, creating inimitable paperwork useful for people working in non-profits.*

Keywords: *program management, project management, public relations, NGO, finance*

1. INTRODUCTION

The modern era of Project Management began in the 1950s but Project Management techniques can be found as far back as the days of the pyramids.

In the 1950s, businesses such as GE and DuPont realized there were benefits to organizing work around projects and communication was needed across various functional departments and units. There were a number of informal techniques and tools in use, but —projects‖ tended to ad hoc. Tools such as Gantt charts (Henry Gantt (1861-1919) were in use but Gantt charts were not enough to ensure proper control and ensure completion of projects on time and on budget.

During this time period, two mathematical project-scheduling models were developed:

- "Critical Path Method" or CPM
- "Program Evaluation and Review Technique" or PERT
- PRINCE 2

These tools and techniques as well as a number of others spread quickly as businesses looked for new ways to manage large and complex activities, evolving into project management, as we know it today (Anheier, 2010).

2. PROJECT MANAGEMENT

Project management is the process and activity of planning, organizing, motivating, and controlling resources to achieve specific goals. A project is a temporary endeavor designed to produce a unique product, service or result with a defined beginning and end (usually time-constrained, and often constrained by funding or deliverables), undertaken to meet unique goals and objectives, typically to bring about beneficial change or added value. The temporary nature of projects stands in contrast with business as usual (or operations), which are repetitive, permanent, or semi-permanent functional activities to produce products or services. In practice, the management of these two systems is often quite different, and as such requires the development of distinct technical skills and management strategies. If some non-profit organization, such as student organization is project oriented, it is doing its purpose through such projects, where each project has the personal goal that is not connected to the other project (Applied Agility, 2010).

3. PROGRAM MANAGEMENT

Program management or program management is the process of managing several related projects, often with the intention of improving an organization's performance. In practice and in its aims it is often closely related to systems engineering and industrial engineering.

The Program Manager has oversight of the purpose and status of all projects in a Program and can use this oversight to support project-level activity to ensure the overall program goals are likely to be met, possibly by providing a decision-making capacity that cannot be achieved at project level or by providing the Project Manager with a program perspective when required, or as a sounding board for ideas and approaches to solving project issues that have program impacts. Typically in a program there is a need to identify and manage cross-project dependencies and often the PMO (Program or Project Management Office) may not have sufficient insight of the risk, issues, requirements, design or solution to be able to usefully manage these. The Program manager may be well placed to provide this insight by actively seeking out such information from the Project Managers although in large and/or complex projects, a specific role may be required. However this insight arises, the Program Manager needs this in order to be comfortable that the overall program goals are achievable.

There are two different views of how programmes differ from projects.

On one view, projects deliver outputs, discrete parcels or "chunks" of change; programs create outcomes. On this view, a project might deliver a new factory, hospital or IT system. By combining these projects with other deliverables and changes, their programs might deliver increased income from a new product, shorter waiting lists at the hospital or reduced operating costs due to improved technology. Most of non-profit organizations (student organizations) that are project oriented are actually program oriented. Some of these organizations are ESTIEM (European Students of Industrial Engineering and Management), BEST (Best European Students of Technology), AIESEC, etc.

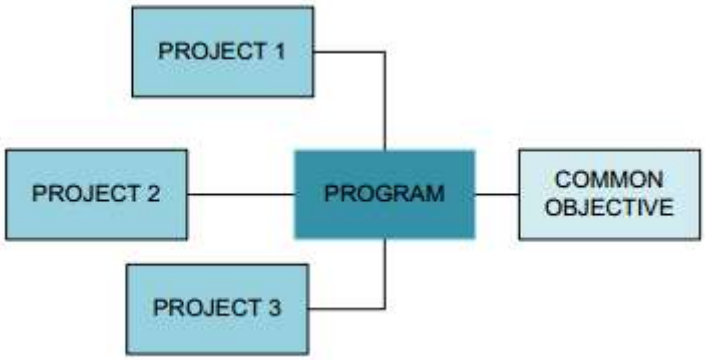

Figure 1. Program management and its connection to projects (Zambruski, 2007)

There are many important things when we talk about managing projects and programs, but there are three factors that are really crucial for the success of the project/program: time, resources and scope and those factors form, so called “Project Triangle” (Zambruski, 2007).

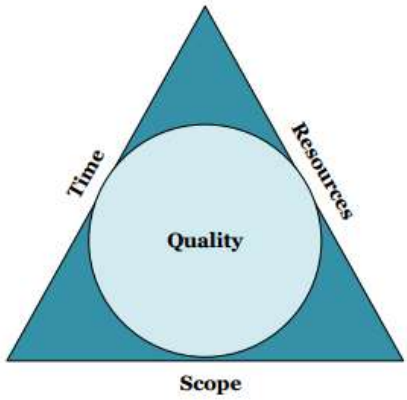

Figure 2. Project triangle (Zambruski, 2007)

Beside project triangle, there are many other things that could help follow the success of the project. Some of those things is a project life cycle.

Project life cycle is —a collection of generally sequential and sometimes overlapping project phases whose name and number are determined by the management and control needs of the organization.

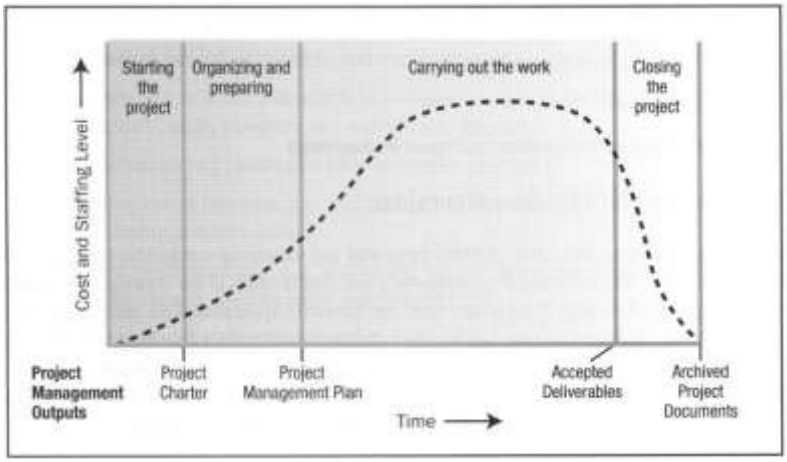

Figure 3. Typical costs and stuffing levels across the project life cycle (Zambruski, 2007)

4. WHAT MAKES A GOOD PROJECT?

There are four yardsticks to measure the quality of a project:

- Is it relevant? Does it really tackle the problem it sets out to address? If the problem, for example, is that the children in the village can't read, is a new school the best answer, or should one look at the parents' attitude to education, the shortage of teachers, the lack of money in the village's budget, the need for labor in the fields, or the government's lack
- of investments in the social sector? Does the project have a credible "entry point"?
- Is it feasible? Is it likely to achieve its objectives? What risks does the project face? What resources – financial and human - does it have? How realistic is it?
- Is it cost-effective? What is the relationship between the cost of implementing the project and its expected benefits? Is there a strategy that would have achieved the same results at lower costs? For example, sending all the children in the village who can't read to an expensive boarding school would probably improve their literacy, but the cost would be immense, and the impact on the community would be very destructive. So building a school might be a more cost-effective strategy.
- Is it sustainable? Can it go on delivering its benefits after the external assistance has come to an end? For example, with there be teachers for the school, money to pay them, parental support, good educational policies from the government – long after the school has been built, and the project has closed down? (Participant's Workbook, 2012)

5. STAKEHOLDER'S ANALYSIS

The "stakeholders" in a project are all the people or organizations who either stand to be affected by the project, or who could "make and break" the project's success. They may be winners or losers, included or excluded from decision making, users of results, or participants in the process. Stakeholders analysis is the mapping of a project's key stakeholders, who they are, what interests they have in the project (positive or negative), and how these interests can affect a project, "make or break" it.

Such a mapping activity will help you identify:

- Which individuals or organizations to include in your "coalition" or network
- What roles they should play, and at what stage
- With whom to build relationships, which relationships to nurture
- Whom to inform and consult about the project

You can use a matrix that would look like the table on the next page.

Table 1. Stakeholder analysis (Participant's Workbook, 2012)

Infuence/Importance	High influence	Low influence
High importance	**Stakeholders who can gain or lose a lot from the project, *and* whose actions can affect the project's ability to meet its objectives** These actors are powerful – you need to develop good relationships	**Stakeholders who stand to gain or lose a lot from the project *but* whose actions cannot affect the project's ability to meet its objectives** These actors lack power – but you need to make sure their interests are fully represented
Low importance	**Stakeholders whose actions can affect the project's ability to meet it's goals, *but* who have little to gain or lose from the project** They may be a source of risk, unpredictable, so keep an eye on them!	**Stakeholders who have little to gain or lose from the project, *and* whose actions have little influence on the project** Just keep them informed.

6. PROJECT STRATEGY

First of all, you need to determine **who is going to benefit** from your project, who will be its beneficiaries. Can you be precise: how many, where are they to be found, what are their social, economic and cultural characteristics? Then ask yourself who will be your partners, not only at the local, but also at the national level. If you have done the stakeholders analysis, the answers should be obvious. Create a network, integrating beneficiaries and partners, that is, make sure they talk to each other. Decide on their roles: how will you communicate with them? What are the lines of authority (this is especially important if you work with other groups who share your objectives, but whom you don't control – they have their own funding and staff)? Who takes decisions? Do you need a steering committee to bring everyone to the table?

Then you need to decide on a **project approach**. There are two types of approach, and they each require a very specific project design. *Direct* support (DS) is one type of intervention, and it means that the project works directly with the beneficiaries (e.g., children, their families, a group such as landmine victims) through the provision of services such as education and training, health care, or construction of shelter. Many projects, however, choose a second type of intervention, called institutional development (ID). Examples are the strengthening of NGOs or government institutions so they can deliver better services to the target group, those children, families or landmine victims. In that case, the NGOs or the government (for example, the national mine action center) are the direct recipients of the project, but the beneficiaries ultimately are the people who get improved services. The advantage of those "ID" projects is that they have a multiplier effect, as eventually more people will be reached. But if the proper institutions are not there to be strengthened, or if they are not interested, direct support may be preferable (Niven, 2008).

7. PROJECT PREPARATION

Before starting a project's preparation, it is important to fully understand the terms which are commonly used in any given project development and implementation. As far as European Union projects are concerned, in here we will use the definition available in Aid Delivery Methods: Project Cycle Management, a manual released by the European Commission in March 2004. The main objective concerning this manual is identification of project intensions. At the beginning of a project's preparation, the project leader should have a clear idea of the problematic situation that needs to be addressed, the improved situation to be reach and the stakeholders who will be directly involved.

Every project can be presented as a sequence of consecutive phases:

1) **The Concept Phase** – During this phase, the complete concept of the project is developed.
2) **The Analysis Phase** – The project's specific objectives, expected results, activities as well as the analysis of the risks which can affect its implementation are defined.
3) **The Planning Phase** – Stakeholders are identified as well as the project's beneficiaries and specific target groups which will be addressed by the project. Furthermore, the resources (financial and human) the project requires should be identified in addition to clear coordination and management arrangements as well as monitoring and evaluation systems.

4) **The Implementation Phase** – The project becomes operational and activities are executed.
5) **The Evaluation Phase** – The implementation of the project's activities is monitored through indicators that have been developed during the planning phase. It is continuous process which might lead to adjustments before a final evaluation, at the termination phase.
6) **The Termination Phase** – The initial assumptions are compared with the project's actual outcomes in order to evaluate the project results and impact and draw recommendations for future actions.

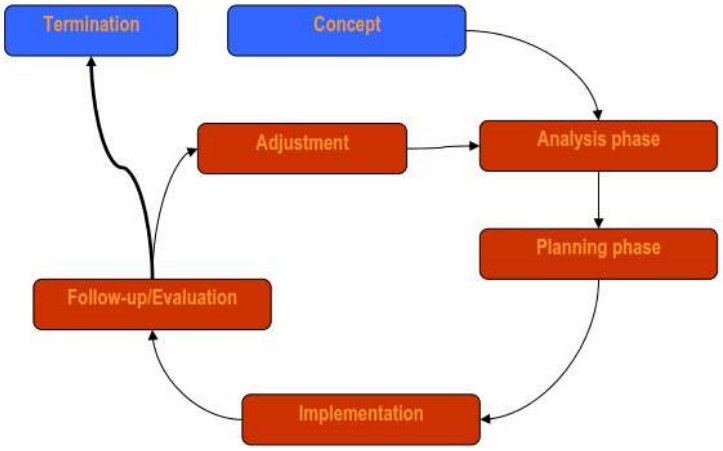

Figure 4. Preparation process in NGO's projects (Participant's Workbook, 2012)

8. MODERN NEEDS OF THE NGO

With the technology development and new business models, NGO's have found a new ways of doing their activities successfully and more efficiently. Viral marketing, but also online public relations have become a standard for this type of organizations, and not to mention companies. Online PR is taking a bigger part of the whole PR by giving better and faster results of promoting the organizations. For example, ESTIEM LG Belgrade (student's organization) has become one of the most recognizable and most active local groups, thanks to the online PR, which has made this organization more attractive to every stakeholder, including companies, institutions such as universities, government, students, etc. Why is this important?

Almost every student organization depends on some institution, because they are non-profitable. That's the reason why NGO's has to have a good PR strategy, focusing on modern aspects of promoting the organization that will bring the organization to the main sponsors, that will provide a donation to the organization. Those sponsors could get in return different types of promotion, getting active in some activities, etc. But there are some sponsors, such as some public institutions that give a funds without reaching for something in return.

9. MODERN ASPECTS OF PUBLIC RELATIONS IN NGO'S

Public relations are the practice of managing the spread of information between an individual or an organization and the public. The term "Public Relations" is often misunderstood especially because people tend to associate it exclusively to media relations. Public relations have started out as media relations, but in the recent years, they have become much more. And, with the introduction of many Internet services, it has also become clear that public relations deserve to be named "communications".

When making a difference between Offline and Online public relations (PR), it is very important to clear out the difference between the terms „Offline" and „Online". Offline addresses the traditionalll way of communicating with target audiences - using traditional, well-established communication channels like printed material (newspapers, magazines), television and radio, press conferences and special events. With the introduction of mainstream Internet usage, there has been a shift of focus for all communication activities, and with the growing popularity of social media, the Internet has taken a primary channel for communicating different messages.

Today, Online Public Relations represent a way of creating identity, and building and increasing the image and reputation of specific subjects through selected Internet channels: social media and networks.

Non-profit organizations have similar goals in promotion and PR just like profit organizations. Creating visibility, building loyalty and trust through positive image and reputation, and creating a stable system of interactions with target audiences with a fail-safe key in crisis situations. Online PR, through a strategic use of social media capacities, helps the members of the non-profit sector to be on the same level (or on a higher one) comparing to entities with profit. By active listening, and conversation encouragement, an active online presence is built, that after some time clearly leads to the accomplishment of PR (and promotion) goals.

Social media defines online media, like text, photos, and messages or video that is social in nature. In other words, media that starts conversations, encourages people to pass it on to others, and finds ways to travel on its own. Social media as a tool cannot be used as a whole. It has to be strategically analysed, and then the right mix of social media tools is to be selected. Creating the social media mix starts with understanding two groups of tools it offers: blogging platforms and social networks.

A shorthand term that means „Web log“ is an online, chronological collection of personal commentary and links. Easy to create and use from anywhere with an Internet connection, blogs are a form of Interne publishing that has become an established communications tool. Bloggers (blog authors) review products, services, public images, they write about organizations and individuals, and address the popular problems and trends. Non-profit organizations often have a similar mission and vision with specific bloggers, and that is a niche that should be recognized and tapped into.

A branch of public relations named „Community management“ is a new trend using the potential of the digital business world. Social networks are a subset of social media, Internet communities allowing interactions between users through a specifically, and in many cases functionally oriented, interface. They allow users to have personal profiles, get in touch with friends, colleagues, acquaintances and business contacts, and share relevant textual and multimedia content with them. On the other side, organizations and specific individuals use different social networks for creating a loyal fan base, conversations, feedback systems, and fail-safe tool in crisis. Top 10 most used social networks in 2014 are respectively Facebook, Twitter, LinkedIn, Pinterest, Google Plus+, Tumblr, Instagram, VK and Flickr.

Using the potential of social networks is done through constant activity on organization’s profile pages. Starting, developing, and sustaining the conversation with different members of the target audience enables the creation of a dynamic feedback system, loyalty building, and image and reputation development. Besides reaching the traditional public relations goals, Online PR for non-profit organizations works in the fundraising sphere, events promotion sphere, and as active contributing factors to advocacy and recruiting and engaging volunteers.

Enormous success of online public relations, created a huge amount of interactions on social networks. In the manner of good PR practice, interaction on social networks should be continuous, on-time and useful for our audience. Therefore, that kind of demand created a new job position in PR sectors called community manager. The purpose of community manager is to monitor, participate and engage on social networks of his company. This position does not have non-working days, according to successful implementation of constant interaction. Also, one of the most important parts of community management is careful monitoring of social networks, not only those on which one organization presents itself, but every network that has potential customer or audience.

Although everything above is particularly important for a community manager to do, without engagement, none of those activities will have visible improvement of communication. The engagement is the activity that creates a community around the organization, a wide group of people committed to an organization. And it’s about building communities which really means building relationships. The engagement is an activity that requires the most time spent on this position, but the only one that gives positive result on communication organization towards its audience.

For non-profits, good community manager is essential part of online public relation. Due to exponential growth of internet users, and lack of finance, internet with the social networks gives sustainable solution for communication between organization and people in both ways. To attract people to hear them, community manager usually post interesting news, encourage interaction with comments and mutually sharing. Community manager is the person, who has to present his company to people as their friend, with all its virtues.

As every process in management, evaluation presents an important segment in detecting the strength of simpact on public relation. Evaluation of online PR effects is much easier due to huge amount of online tools

for tracking and monitoring. A number of good keyword research tools are available without charge. Leading free tools include Google Keyword Tools and SEO Book keyword tool.

Online public relations have a traditional purpose when talking about non-profit organizations. The goals of public relations concerning identity, image and reputation are achieved through regular communication with all of the target audiences .What differs the Online public relations of non-profit organizations from the profit ones, is the unique nature of the community management. Combined with the interactive approach to dynamic social networks maintenance, it creates a good environment for fundraising and advocacy activities, approaches, and systems for volunteer management. (Đorđević and Ignjatović, 2012)

10. FINANCING OF NGO'S

NGO funding can vary by source, terms, and the type of organization funded. There are several different kinds of foundations and individual donors who provide NGO financing. Some give donations while others reward funds via a grant application process.

Two overarching types of NGO financing are restricted and unrestricted funds. Restricted funds must be earmarked for a specific purpose as dictated by the donor. The only typical requirement for unrestricted funds is that they be used to help the NGO accomplish its mission.

Restricted funds are often specific to a type of project or other need that is outlined during the grant application process. Typically the overall required focus is dictated by the donor, while the NGO can determine the specifics that apply to its particular needs. There may also be restrictions as to how or when the money will be spent once it is awarded.

Unrestricted funds can be an important part of NGO financing as they may be used to fill whichever need is most urgent. Often they will be used to cover non-specific operational and other ongoing costs that are usually difficult to fund with grant money. Common sources of unrestricted funds include donations from the general public, money earned by the NGO selling products or offering services, and institutional funding.

Self-financing is one of the options that a nonprofit organization has to develop a more diverse income stream. It can also help to support programs and cover expenses that donors and grant makers do not want to fund (Zarinpoush, 2006).

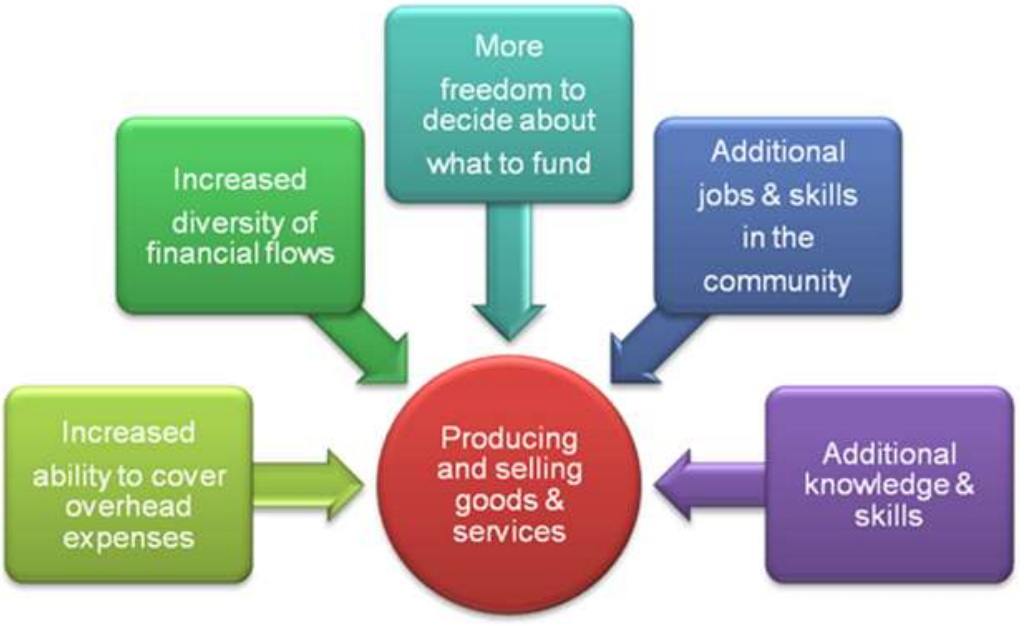

Figure 5. Benefits resulting from self-financing (The Sustainable NGO, 2014)

The universities encourage student organizations to raise funds and sell their projects to the local companies, enabling them to contribute to the University's rich environment.

Self-financing require preparatory work, necessary before the organization can decide whether selling projects and services for a profit is an option that has chances to succeed.

The preparatory work involves market research and analysis of core competence. The preparation requires special knowledge and skills from those that will conduct these activities.

Figure 6. Preparatory work that NGOs will have to perform (The Sustainable NGO, 2014)

In the time of economic crisis, government grants budgets are reduced, as well as municipalities. Funding from universities and faculties do not have to be reduced compared to the previous years, but certainly the financial situation of the organization may be affected, if the faculty budgets are reduced as consequence of lover government dotation to the university.

Therefore, it is necessary to find companies and individuals willing to invest in student organizations and their projects, which benefit both NGO, by receiving more funds, and companies, by recruiting new interns or employees and through marketing and promotion in the public and especially at the university level among students and professors (Rouson, 2010).

11. CONCLUSION

It is predictable that, within the next decade, the Internet will exist as a seamless fabric of classic networks and networked objects. Content and services will be all around us, always available, paying the way to new applications, enabling new ways of working; new ways of interacting; new ways of entertainment; new ways of living. In such perspective, the conventional concept of the Internet as an infrastructure network reaching out to end-users' terminals will fade, leaving space to a notion of interconnected "smart" objects, forming pervasive computing environments. The Internet infrastructure will not disappear. On the contrary, it will retain its vital role as global backbone for worldwide information sharing and diffusion, interconnecting physical objects with computing/communication capabilities across a wide range of services and technologies.

All of that affected on the activities of the NGO's that are mostly project or program oriented, which means that they have various types of projects focused on one or more target groups. Those organizations must have a strong connection, but also a balance between public relations and finance. Only with the good balance of those two departments, organizations will manage to get bigger and attractive to its stakeholders. Beside everything, this paperwork has focused on financial and PR activities, but every NGO should have other departments such as human resources, corporate relations and others in order to have a strong organization.

QUALITY MANAGEMENT

SERVICE QUALITY IMPROVEMENT: THE BUSINESS PROCESS MANAGEMENT APPROACH

Abstract: This paper is primarily focused on investigation of issues related to application of business process management (BPM) approach in the service organizations. Almost every management model, including the one related to business processes, has been originally created for the manufacturing industry. In order to successfully implement these models in the service industry it is important to understand how services are different from manufacturing activities. Proper comprehension is possible only once the identification of services, their classification and characteristis are addressed. The central piece of the paper examines implementation stages of the BPM and analyses the possible challanges that service organizations can face based on the expirience of a business unit of a UK service organization. Examples of BPM practice in service organizations are rare in the literature and mostly based on short analyses of case studies. For that reason, the value of this work lies in the combined study of theoretical background and practical challanges related to basic issues that service organizations have to consider when they are establishing a system for improvement of business processes.

Keywords*: quality management system, service, business process management*

1. INTRODUCTION

In the recent decades, attention of experts in the particular fields of management has been increasingly shifting from manufacturing to service sector. Starting from 1970s the issue of implementation of management models that were crafted for the so called “hard” industries in service companies has been addressed ever more. Consequently, today it is possible to detect, both in academic literature and business practice, development and evolution of numerous process management and quality improvement models that are specifically designed for requirements of the service industry.

An important feature of the service industry is that, thanks to its resources and expertise, it provides its users with considerably better capabilities to satisfy their needs than they could do on their own. Some of these needs (i.e. long-distance communication) can only be satisfied by large enterprises that possess necessary technology and knowledge (for the mentioned need those could be postal services, mobile phone operators or internet providers). Particular service industries owe their entire existence to own superiority (speed, price, high quality, convenience) over the independent realization of tasks. On the other hand, a significant number of services is devoted to satisfying certain psychological and physiological needs, such are needs for entertainment, sport, culture, religion etc.

Service sector has expanded greatly in the last few decades. In the USA, for example, around 23 million people were employed in the service industry in 1945, while there were 18,5 million people working in manufacturing. In 1997, there were already 100 million people working in services and only 25 million in manufacturing. That means that roughly 80% of employees outside of agriculture were actually working in the service sector. (Fitzsimmons and Fitzsimmons, 2001)

In Serbia, the ratio is also changing in favour of the service industry, though still considerably below the American level. This paper analyses how some of the key concepts of business process management can be utilized for quality improvement of service activities.

2. SERVICE PROPERTIES

2.1. Basic distinctions between manufacturing and provision of services

One of the main conceptual issues with implementation of process approach is process classification. For the purpose of this paper it is significant to consider distinction between **product** and **service** types of processes (Melan, 1992).

There is a considerable number of differences between manufacturing and provision of services. Boone and Kurtz (1998) have defined the following important criteria for making the distinction:

- **Users' needs** – it is much more difficult to identify and measure them in case of provision of services than it is with the production of goods.
- **Tangibility/Intangibility** – in contrast to goods, that are tangible, services are intangible even when they are visible to the user. Quality of goods can be measured using specifications, while quality of service is often determined by subjective measures of a user (i.e. past experiences – good or bad). User can possess goods, while he may only remember the service. Goods can be returned or replaced, while only ramification for poorly provided service can be apology or some sort of compensation.
- **Schedule of production and consumption** – services are "created" and consumed simultaneously, while production of goods must precede the consumption. Furthermore, many services have to be provided when it is convenient for the user. Service can't be stored, inventoried or inspected, like it is the case with goods, before it comes in contact with the user. Because of that, it is important to devote more effort to training and "building-in" quality into service processes.
- **Presence/absence of a user** – users are frequently present, even involved in the process of service provision, while production of goods is mostly performed far away from them. Users of fast-food restaurants are good example of that. They order food, take it to their table, consume it and afterwards take care of waste, dishes and cutlery. A more sophisticated example of user participation can be found in education (previous knowledge and students' effort are contributing in many ways to the output of the education's "production system") and health care (output of the "production system" is affected by the capability of a patient to recognize and communicate symptoms to a doctor, as well as his ability to act in line with the given instructions).
- **Labour or capital intensive** – services usually demand exercise of work, while production requires investment of capital as well.
- **Output durability** – tangible outputs of manufacturing are lasting, while only memory and consequences remain after a provision of service. That means that results of services perish considerably faster.
- **Consistency of quality** – services are frequently more inconsistent in quality than manufactured goods. Considering that service quality depends mostly on the person that is providing it, the competence, physical and psychological wellbeing can be decisive factors.

According to the same source, service market is affected by the following factors:

- changes in regulations,
- privatization,
- lowering standards of professional associations,
- technological innovations, including computerization and telecommunication developments,
- establishment of profit centres for services in manufacturing companies,
- financial pressure on social and non-profit organizations to discover new sources of income,
- globalization of service industries,
- expansion of leasing and renting business,
- emergence of a new group of entrepreneurial and innovative managers,
- development of quality initiatives, especially in the service industry.

2.2. Definitions, classifications and characteristics of services

There are many definitions of services. The following ones can be highlighted as frequently quoted in the literature:

"Services are intangible tasks that satisfy the needs of consumer and business users." (Boone and Kurtz, 1998)

"Service is an act that takes place in direct contact between the customer and representative of the company that is providing the service." (Zeithaml and Bitner, 1990)

"Service is an act or an action that provides benefits to a customer, by realizing changes that are convenient for the service recipient." (Zeithaml and Bitner, 1990)

"Service industries" include:

- transportation (railway, air transportation, bus lines, metro, truck transportation, pipelines),
- activities of public enterprises (phone connections, delivery of all sorts of energy, water supply and sanitation),
- trading (food, cloths, cars, department stores),
- financial services (banks, insurance, investments),

- mediation business (real estate business, visa application, marriage proposals),
- hospitality industry (restaurants, hotels, motels),
- news media,
- marketing services (advertising),
- health care (hospitals, ambulances, retirement homes, childcares, medical labs, health tourism),
- education and training services,
- personal services (amusements, laundry and cleaning, beauty salons, barber shops),
- professional services (lawyers, consultants, private medical and dental practice),
- renting (apartments, rent-a-car),
- product, machine, building maintenance (car repairs, painting),
- state-controlled public services (defence, health care, education, social care, municipal services),
- non-profit organizations (Red cross, religious institutions, army).

Purposefulness of services is determined by their characteristics that user (client) recognizes as useful. Evans and Lindsay (2005) distinguish several important dimensions of services:

- **time** - how long user has to wait for a service and how much time does the provision of service take,
- **timeliness** - will a service be provided at the arranged time,
- **completeness** - i.e. are all pieces that were ordered delivered,
- **courtesy** - it relates to the attitude and behaviour of the personnel that is providing a service,
- **consistency** - is service provided every time and to every customer in the same way (robots can almost always replicate actions in the same manner, but people can't)
- **accessibility and convenience** - is there an easy access to services,
- **accuracy** - was the service provided in the right way,
- **responsiveness** - how fast can personnel react to unexpected problems,
- **numerical accuracy** - i.e. how accurate is the transfer of assets in the bank,
- **cleanliness** - i.e. how clean are hotel rooms.

According to the same source, additional characteristics of services that can sometimes be crucial are of:

- **psychological nature** - i.e. appreciation of regular customers, beauty of the environment (landscape, interior of a restaurant), comfort,
- **technological nature** - i.e. transmission without interference (related to phone, TV and radio transmissions),
- **ethical nature** - i.e. truthfulness of information from commercials, no discrimination of customers (respecting religious, national and sex differences, providing equal treatment to people with a disability etc.),
- **legal nature** - assuring that all obligations are fulfilled (i.e. travelling tours should be done on time and include visits to all locations that were previously promised).

Differences between manufacturing and service organizations have led to creation of specific management. Many service organizations, such as airline companies, banks and hotels, have excellent quality assurance systems (Filipović & Đurić, 2009). Most of them are based on the business experience from the manufacturing industry and, therefore, is more product- than service-oriented. For example, quality assurance systems of hotels are frequently limited to technical standards, such are the ones related to furnishing and maintaining rooms. It is much harder to establish standards for intangible characteristics of quality. Often, they are set in arbitrary manner and later tested in practice. Having in mind that work and behaviour of workers, as well as the speed of service provision, are key determinants of users' perception of quality, it is clear that two most important components of quality systems in the service industry are employees and informational technologies. Certainly, this doesn't mean that these factors aren't important in the manufacturing industry, but simply that they are vital for service industry just like production technologies are in the manufacturing.

3. BUSINESS PROCESS MANAGEMENT IN SERVICES

3.1. Stages of BPM implementation

BPM is becoming popular in companies as a holistic management tool for achieving and sustaining corporate success. However, applying BPM in whole organization is not a simple task. The very implementation is usually divided into five main phases (Rosemann, 2008).

First, **it is necessary to create awareness of the BPM methodology and potential benefits of its implementation**. In many instances, insufficient understanding of the BPM concept can be identified as an obvious cause of unsuccessful implementation of BPM. This can be explained by already present high level

of organizational activity, previous commitment to some other methodology of organizational engineering or, commonly, to lacking of initiatives for change or improvement. Sometimes, it occurs that even proponents of this concept lack in knowledge about methods, assets and issues related with the BPM. Overall, lacking of awareness can be assigned to insufficient training in most of the cases. Once the training is properly organized, it represents the best instrument for creating, enhancing and sustaining the awareness of the concept and its importance.

Second, **previously mentioned awareness and comprehension of BPM must be transformed into a real desire for actual adoption of the concept**. This is a critical phase and it demands presence of drivers (i.e. introduction of a new, large system or merging of organizations) and a leader – at least one person with strong commitment to the concept. These can be found in various organizational departments and hierarchical levels of the company. Initiative can emerge from IT department, HR department, business improvement teams or internal stakeholders, such are line and executive managers. One of the biggest obstacles is the fact that BPM doesn't have its typical "home" inside of an organization.

Next, **if the initiative for adoption of the concept was accepted, individual projects for quality improvements have to be set up, executed and monitored within the BPM**. It is recommendable to ensure early that visible results are achieved, especially those that can be used for promotion and development of the concept within the organization. This is usually the phase in which organizations develop organizational capabilities for implementation of BPM and faith that it will yield expected results (Tregear, 2005). Individuals are, at first, fascinated with BPM. They explore the potential career opportunities related to development of concept and later, mostly unofficially, take ownership over it.

Fourth, **if individual projects were successful, organization will seek for the opportunities for further expansion of BPM.** Individual BPM projects will be combined into centralized BPM program that will be in charge of the whole organization. At this stage, the overall BPM methodology has to be fully designed. Methods, techniques and tools have to be specified, established, documented and maintained, accompanied always by appropriate communication. One of the most significant issues at this point is development of BPM strategy that should contain the specification of activities planned for the following 3 to 5 years.

At the end, in the final stage of the change, typical scenario includes establishment of centralized group for BPM. This group needs to have precisely defined internal roles related to the company wide BPM implementation. In this way, BPM-related values will be created and will affect the overall system of values.

3.2. Example of usage of BPM for quality improvement in service industry

Some basic principles of BPM will be analyzed on the example of a large enterprise that is in the business of servicing of capital equipment. This company has over 4000 employees in 50 different locations all over the United Kingdom and more than 24000 across Europe, Asia and Africa. The study was conducted on one of the six business units that is in charge of delivery and service within the particular region. (Lee & Dale, 1998)

Company started its BPM journey by adopting the following definition: "BPM is about measuring core processes, analyzing what works and what doesn't, and improving them". Simply put, the concept was related to "waste elimination and adding value".

By analyzing the internal documentation of this service organization, it is possible to notice that there are three crucial factors affecting the success of BPM implementation:

- Process discipline - imply accurate and consistent application of business processes in the whole organization and constant monitoring of performances;
- Process improvement – improving business processes that includes:
    - ensuring that processes are designed from the customer's perspective,
    - using benchmarking,
    - practicing continuous improvement activities,
    - practicing improvement though breakthroughs, and
    - insisting on quality of information;
- Cross-process integration - user-oriented process management and integration of improvement initiatives in a way that will make them visible to users.

BPM is a helpful instrument for improving processes that are crucial for achieving company's objectives. This organization possesses a set of standard processes in its business architecture and they are supported by BPM principles that are complied with rules of pervasiveness, ownership, documentation, measurement and inspection. (Zairi, 1997)

This organization is assuring compliance with these rules in the following way:

- **Pervasiveness** - understanding BPM principles throughout the whole organization,
- **Ownership** - every process must have appointed owner who will review process performances and be responsible for its continuous improvement,
- **Documentation** - each process has to be modelled from the beginning to the end and have standards for documentation defined in a way that will correspond to the needs of all process users; this includes in-process control measures, documentation and information usage procedures, management controls, as well as a description of process realization,
- **Measurement** -indicators that are used for process measuring are classified into cost, quality and time parameters. All key processes are monitored by usage of indicators related to flow and outcome of the process. Measurements are performed in the critical stages of the process in order to ensure that user requirements are met, mistakes avoided, variations reduced, time of the cycle improved and productivity boosted,
- **Inspection** - process owners have to monitor performances, identify gaps through regular reviews and close them. This principle is related to the need for reduction of variations as well.

BPM approach in the organization includes also understanding of connections among different functions and initiatives. They are another source for the improvement that can be achieved using:

- investments in technology,
- factual approach to decision making,
- simplification, and
- innovation.

Processes in this organization share characteristics with ones that Mitchell (1991) described in his work:

- „they have customers (internal or external), they have defined outcomes and there are users for those outcomes“,
- „they can cross organizational boundaries“ .

The study of BPM practice in this business unit has shown that there is an active effort for maintaining process discipline. The most of the key processes are documented, measured, controlled and owned. However, there is a difference in the level to which a discipline is present. Out of five principles of BPM, measurement is applied in the most vigorous way. It is easy to spot that there are too many measures in the business unit, which is obstructing managers to apply them effectively. Principles of pervasiveness and documentation are not applied, even though they are necessary for application of measurement and control - before simplification and improvement of the process, it has to be understood and documented.

All of the key processes tend to be owned but with variations in the level of documentation. For that reason, some processes are fully documented, some partially and some are not at all. Service engineers that work in self-managing work groups (“SMWG”) are the most advanced in the level of application of BPM principles. Every group has managed to successfully establish ownership over the key processes for which they were responsible, document them and have them inspected bi-monthly by line-managers. Processes are measured during the monthly service reviews and their key measures are presented on quarterly tracking chart as part of a visible management system. Despite this, there are great variations in application of the concept between different self-managing work groups. This leads to conclusion that individual and team motivation are important factors that can influence the effectiveness of implementation.

When asked about the reasons for problems related with the inconsistent application of principles, some of process owners complained that there wasn’t enough time for realization of “demanding” process or that they couldn’t deal with the process simplification because of the overload which is created during the process realization. It is clear that the organization needs better cross-process integration and more effort in improvement activities.

Matrix organization form that is in between functional and process orientation is present both on the organizational level and on the level of the business unit. For complete adoption of process approach it is necessary to secure strong leadership and change of organizational culture. Another challenge is the presence of isolated departmental teams that work according to own procedures and have job attitude that makes understanding and communication in the organization even more difficult.

This and other studies dedicated to BPM implementation in service organizations are missing an adequate process description which would provide better insight on the practical implications of the concept application in the specific circumstances.

4. CONCLUSIONS

There is a significant number of differences between manufacturing and provision of services that has created a need for adjustment of existing and development of new BPM approaches specifically for service activities. Effective creation and adoption of these methodologies depends on proper understanding of essential differences between products and services and resulting consequences.

Some of the most important criteria for distinction are users' needs, tangibility, schedule of production and consumption, presence/absence of a user, labour/capital investments, output durability and consistency of quality. It is also important to have in mind that service market is affected by specific circumstances that are frequently different from the ones related to goods. Even the very category of the services is today covering considerably broader field of activities than it was the case before.

Adoption of BPM throughout the organization usually implies five particular stages. Firstly, the awareness of the BPM methodology and its potential benefits has to be created. Secondly, consciousness and understanding of BPM have to be transformed into a desire for application of the concept. Thirdly, if initiative for change is accepted, individual quality improvement projects within the BPM have to be established, executed and monitored. It is preferable to strive for results that can be achieved fast and be useful for the promotion and expansion of the concept in the organization. After that, if individual projects are successful, organization will explore how to use BPM idea further and, finally, create a centralized BPM program that is in control of all projects and is responsible for bringing the maximum value to the organization. In the final phase, organization creates centralized BPM group that works on incorporating BPM-related values to the overall culture of organization.

These general stages of BPM implementation are, however, influenced to a great extent by the particular nature of services. Analysis of the business unit of an international UK service organization has shown that there are certain critical factors, principles and rules in the BPM approach that should be considered in the BPM implementation.

This organization that is working on delivery and service for its customers has defined the BPM concept as "elimination of waste and value adding activity". The implementation experience of this company has shown that there are three crucial factors for successful adoption of BPM: process discipline, process improvement and cross-process integration. The organization utilizes a set of standard processes that are supported by BPM principles, which are in compliance with the rules of pervasiveness, ownership, documentation, measuring and inspection. Processes in this organization are set in a way that every process has its customers (internal or external), precisely defined outcomes and freedom to exceed organizational boundaries if it is needed for effective functioning.

One of the conclusions that emerged during the implementation of the concept is that process has to be understood and documented before it is simplified and improved. Establishment of ownership over the key processes, their documentation and bi-monthly inspections are some examples of good practice. Processes should be measured during the regular service reviews and their key measures monitored using the visual tools of quality management.

By analyzing the studies on BPM implementation in the service industry, it can be noted that critical factor of success is always the improvement program that is based on clear categorization of processes.

Abstract: *The popularity of documented quality management systems in accordance with ISO 9001 standard is evident in many countries. Implementation and certification to ISO management system standards should be observed in relation to economic performance of the company. The aim of this paper is to explore correlation between business performance of Serbian enterprises in the restructuring process and ISO 9001 certification. Main hypothesis of paper has been proved, as existence of statistically significant difference in business income per employee between enterprises with and without ISO 9001 certificate.*

Keywords: *Restructuring, business efficiency, business performance, standardization, ISO 9001*

1. INTRODUCTION

The implementation of management systems, in accordance to requirements of international standards, reflects a socially responsible company and positively affects both image and reputation of the company. According to ISO/IEC (2004) and CEN (European Committee for Standardization, 2013), standard is: 'a document, established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context'. The development of international standards is based on the results related to science, technology and experience. The ISO 9001 is a generic standard and, as such, it can be implemented in all organizations regardless of their size, activities or organization method. The ISO 9001 standard defines quality management system requirements, but fails to define the method an organization should or could use to meet such requirements. Sukhija (2009) indicates that ISO 9001 standard enables companies to create their own quality management systems.

Basic idea followed by the authors of ISO 9001 standard is that, in order to successfully manage an organization, it is to be managed and run systematically and transparently. Eight principles of the Quality Management System standards (QMSs) ISO 9001 are the following: customer focus, leadership, involvement of people, a process approach, a system approach to management, continual improvement, a factual approach to decision making and mutually beneficial supplier relationships (ISO, 2005). Based on ISO 9001 (ISO, 2009):

- *customer focus* typically leads to ensuring a balanced approach between satisfying customers and other interested parties
- *leadership* typically leads to: considering the needs of all interested parties; creating and sustaining shared values; fairness and ethical role models at all levels of the organization; establishing trust and eliminating fear, providing people with required resources; training and freedom to act with responsibility and accountability; inspiring, encouraging and recognizing people's contributions.
- *involvement of people* typically leads to people freely sharing knowledge and experience and openly discussing problems and issues.
- *a process approach* typically leads to evaluating risks, consequences and impacts of activities on customers, suppliers and other interested parties.
- *continual improvement* typically leads to providing people with training in the methods and tools of continual improvement.
- *a factual approach to decision making* typically leads to ensuring that data and information are sufficiently accurate and reliable.

ISO 9000 series standards present useful guide for (Thorpe & Sumner, 2004): clarification on what quality management includes, system approach and process approach in the organization management, development of policy and objectives of quality, defining the top management role within the quality management system, defining the importance and types of documentation used in the quality management

process, relations with other management systems and basis for relations between the quality management system and the excellence module.

Contemporary certification is a procedure in which the 'third party', certification body (registrar), issues a document (certificate) confirming that a product, process or management system meets the necessary requirements (Hesser, Feilzer & De Vries, 2007). The quality management system certification proves that the organization is provided with the whole, consistent and (sufficiently) well documented quality management system. Certified quality management system does not necessary means that the organization provides high quality products or services. The certification is voluntary and is under no power by the International Organization for Standardization ISO. The organization may decide to implement the quality management system according to the requirements of ISO 9001 standard, but not to adhere to certification of its own quality management system.

2. OVERVIEW OF LITERATURE ON FORMALIZATION OF AN ORGANIZATION

Even though the formal process of adopting ISO standards is widely accepted and well-known method of formalization of an organization, it is not the only one. According to Mintzberg, there are three ways to increase formalization within an organization (Mintzberg, 1979): **Formalization by job**, where the specifications refer to work performed by an employee at the specific work position, which results in more precise ***job descriptions***; **Formalization by work flow**, where the specifications refer to the work activity process, which results in more precise description of ***standard work procedures***; and **Formalization by general rules**, where the specifications refer to general instructions and regulations not specially aimed at job descriptions or standard work procedures, which results in ***general regulations***, such as dress codes at work or rules of using the internal forms. Standards used to achieve the above mentioned practically may be but don't have to be in written form. Right example may be an organization with specific ethical behavior standard – even though the standard is not written, everyone is aware of it, it is always being communicated and applied in practice in the same way, and therefore behavior related to ethical issues within an organization is formalized (Burton, 2011). Jones (2000) specifies six principles that may help us recognize highly formalized organizations: Duties, responsibilities and deciding authorities are clearly defined; Rules, standard work procedures, job descriptions and norms are used for the control of behavior and relations between roles within an organization – logic of suitability dominates in the organization; Formalized organizations are based on a principle of legitimate rational authority; Organizational positions are filled based on technical competencies of workers, and not based on social status, friendships or inheritance; Positions within an organization are organized hierarchically so the inferior position is controlled and supervised by the superior one; Administrative decisions and rules are created in written form.

3. RESEARCH HYPOTHESIS AND METHODS

Subject of analysis presented hereafter refers to restructuring enterprises in Serbia, and the aim of the analysis was determination of correlation between holding a certificate of conformity with ISO 9001 standard and business results achieved by such enterprises. Taking that into consideration, we can present the base hypothesis of this paper **H1**: There is statistically significant difference in business quality measured in income per employ between a group of restructuring enterprises holding ISO 9001 standard certificate and a group of enterprises with no ISO 9001 certificate.

For collecting data on restructuring enterprises in Serbia we used the data issued by the Privatization Agency and the Business Registers Agency. Using the documentation analysis method, we have selected relevant data for our analysis. Based on the collected data, there are currently 178 enterprises in restructuring process in the Republic of Serbia.

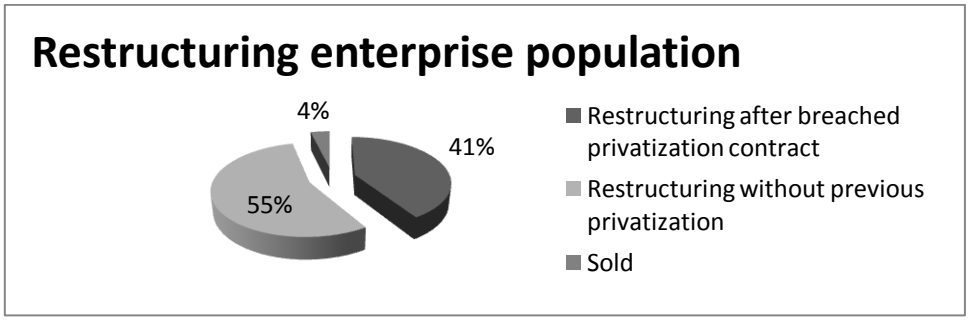

Figure 1: Restructuring enterprises according to 2013 data

Total of 76 enterprises have entered the restructuring process following the termination of privatization contract, whereas the rest of enterprises have never been privatized. Only 7 of the restructuring enterprises have been sold, 3 of which are in business today, whereas 4 have gone bankrupt.

4. RESULTS

Collected data have firstly been analyzed by descriptive statistics method, following the exclusion of enterprises outliers from the population, with annual profit per employee exceeding RSD 30 million, and annual loss per employee exceeding RSD 30 million. Based on the assumption that, due to size of the sample following the exclusion of outliers (N = 168), the observed parameter is normally distributed, such collected data are later analyzed by parametric methods.

Data presented in figure 2 indicates the number of restructuring enterprises in Serbia meeting ecological requirements under law, as well as whether an enterprise holds certificate of quality management system in accordance with ISO 9001. It is clear that the highest number of enterprises meets the ecological requirements, whereas a few enterprises hold ISO 9001 certificate. Considering the fact that certain number of enterprises failed to meet ecological requirements, it can adversely affect them in terms of attracting investors.

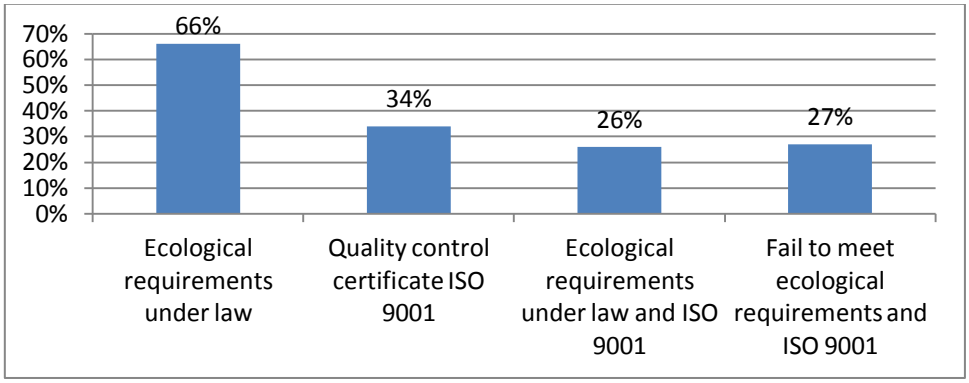

Figure 2: Having a certificate and meeting ecological requirements

Table 1 indicates descriptive statistics of the observed enterprise population. As indicated, intermediate values as well as standard deviations of income per employee are always higher in the previous three years in restructuring enterprises holding ISO 9001 certificate.

Table 1: Descriptive statistics

Indicator / Holding ISO 9001 certificate		N	Intermediate Value	Standard Deviation	Standard Deviation – Intermediate Value
2010 income per employee (in RSD 000)	No	109	1004.35	1862.33	178.38
	Yes	57	1953.58	3489.94	462.25
2011 income per employee (in RSD 000)	No	109	1041.38	1510.78	144.71
	Yes	57	1720.68	2836.13	375.65
2012 income per employee (in RSD 000)	No	108	1141.22	1543.60	148.53
	Yes	57	1721.44	2040.04	270.21
Income per employee (in RSD 000) 2010-2012	No	108	3205.52	4597.48	442.39
	Yes	57	5395.71	7748.97	1026.37

Table 2 provides parametric statistics analysis of intermediate values for income per employee in the past three years, as well as three-year period in total. F statistics value in the first column regarding the income per employee in 2010 indicates that the observed parameter has no equal variance in the two observed groups of enterprises, and in the relevant column the t statistics value of -1.92 with significance of .059 indicates that we may not claim statistically significant differences ($p<0.05$), but we can do that with $p<0.1$, which practically means that there are 10 or less percent of probability that our results were produced as a consequence of coincidence. The following two columns providing monthly income per employee in 2011 and 2012, as well as the fourth column providing collective indicator for three relevant years, all have the F statistics value referring to equal variances in parameter values in enterprise groups with and without ISO 9001 certificate, whereas values and significance of t-statistics indicate statistically significant difference in

parameters ($p<0.05$) in all of the three observed cases. Thus, it could be concluded that the hypothesis **H1** stated at the very beginning of the paper has been proved.

Table 2: t-test of intermediate values of income per employee

Levene's Test of Variances			T-Test for Equality of Intermediate Values						
	F	Sig.	t	Degrees of Freedom	Sig.(2-side)	Difference in Intermediate Values	Difference in standard deviations	95% of Confidence Interval	
								Bottom	Top
2010 income per employee - Assumed difference in variances	8.74	.00	-1.92	73.08	.059	-949.23	495.48	-1936.70	38.23
2011 income per employee- Assumed equality of variances	1.69	.195	-2.02	164	.045	-679.30	336.96	-1344.64	-13.95
2011 income per employee - Assumed equality of variances	.596	.441	-2.05	163	.042	-580.23	283.28	-1139.59	-20.85
Income per employee2010-2012 Assumed equality of variances	2.338	.128	-2.28	163	.024	-2190.19	961.68	-4089.15	-291.23

5. DISCUSSION AND CONCLUSIONS

Holding a certificate of conformity with ISO 9001 standard is not legally binding but does present certain advantage. When exporting or entering foreign market, domestic enterprises often feel the need to implement this standard and have ISO 9001 certificate. On the other hand, as previously indicated (Mijatović, Čudanov & Jaško 2012), standardization and formalization in organizations is not necessarily limited by certification motives according to the international standard requirements. In order to find solution for matching problems organizations might consider other ways of standardization - ad-hoc de-facto standardization (de Vries, 1999; Hesser, Feilzer & De Vries, 2007; de Vries, 2010) can be one of the possibilities. The obtained results indicate that business of the enterprises holding formal certificate ISO 9001 as measured in income per employee is better compared to the group of enterprises with no ISO 9001 certificate. The results are statistically significant ($p<0.05$), except for the 2010 records with $p<0.1$. Conclusion that may be reached is that better regulated organizations, having progressed with the restructuring process and obtaining higher income per employee tend to enter the quality management system certification process according to the ISO 9001 requirements. Considering the fact that according to the ISO 9001 requirements quality management system fosters engaging all of the employees within an organization, it may result in higher value generated by the employees. On the other hand, information and methods used in this paper fail to provide the possibility for the noticed relationship between the formal ISO 9001 certification and income per employee in a restructuring enterprise to be interpreted as causality in any direction. In the following researches special attention is to be paid to other factors indicating a relationship between a restructuring enterprise business performances and certification according to the standard ISO 9001.

Abstract: *In addition to quality, enterprises give more and more attention to aspects such as environment, occupational health and safety, food safety and other management systems. Addressing all the relevant stakeholders' concerns, many enterprises have implemented integrated management system (IMS) in order to overcome the problems resulting from multiple management systems, to create competitive advantages and to achieve sustainable development.*

This paper aims to examine and compare both benefits and problems that are expected from implementation of an integrated management system (IMS) for enterprises. The benefits and problems were generated through analysis of experiences in the implementation of integrated management system pointed out in literature by different authors in this field. Additionally, benefits and problems that were practically proved are singled out from those that are stated as author's opinion or expectation. This examination and comparison can give a valuable insight into overall effectiveness of integrated management system implementation.

Keywords*: integrated management system, benefits, difficulties*

1. INTRODUCTION

Globalization and increased focus on sustainable development bring in new stakeholders and their needs that enterprises need to satisfy (Abrahamsson et al., 2010). In order to satisfy stakeholders' needs and thus create competitive advantages and achieve sustainable development, many organizations have implemented quality (ISO 9001), environmental (ISO 14001) and occupational health and safety (OHSAS 18001) management systems, which has become a widespread practice around the world in recent years (Esquer-Peralta et al., 2008; Jørgensen et al., 2006; Rocha et al., 2007). To meet these requirements, each management system demands a lot of documentation, written procedures, checking, control forms and other paperwork (Karapetrovic & Jonker, 2003). In practice, it has been proved that it is difficult to handle separate management systems, where the major problems for organizations to operate multiple management systems are complexity of internal management, lowering of management efficiency, incurring cultural incompatibility, causing employee hostility, and increasing management costs (Zeng et al., 2007). Undoubtedly, at the operational level, organizations strongly desire to integrate these systems, due to not only these difficulties encountered in managing different management systems separately, but also because of the important advantages gained from the integration. Hence, there is a trend towards implementing an integrated management system (IMS) (Jørgensen, 2008; Salomone, 2008). Integration normally leads to a strong and comprehensive management system (Karapetrovic & Jonker, 2003). Different management systems which have similar implementation procedures should be integrated to improve performance (Wilkinson & Dale, 1999). As it is stated by Zutshi & Sohal (2005), the imperative is to integrate management systems to one system in order to achieve full realization of the potential benefits of each individual system. Many empirical studies have documented the benefits and problems achieved by companies that implemented an integrated management system. The general impression from studies carried out is that there are more benefits than downsides and problems when management systems are integrated (Karapetrovic, 2002).

2. MANAGEMENT SYSTEMS INTEGRATION

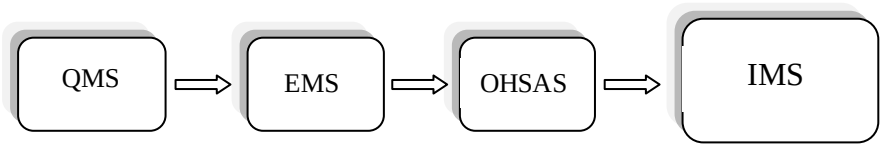
According to Karapetrovic (2003), an integrated management system is conceptually seen as a set of interrelated processes that share the same resources (personnel, information, materials, infrastructure and finance), to achieve goals aimed at meeting numerous of stakeholders' needs. Therefore, anything that could affect operating results and stakeholder satisfaction has to be within the system. Hence, the IMS should integrate all the current formalized systems that focus on quality, environment, occupational health and safety, food safety etc.

Implementation of IMS can be carried out through two approaches of integration (Zivkovic et al., 2010):

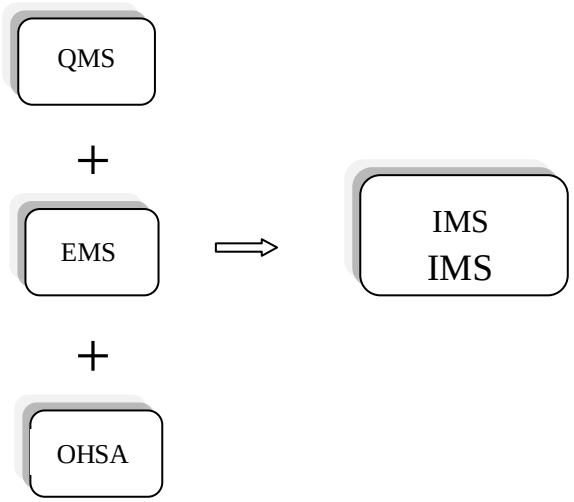
- Integration of requirements of different standards,
- Integration of management systems.

Integration of requirements of different standards is conducted through the consideration of similar or compatible requirements of different standards and integration of one part of documentation in the IMS. This approach involves consideration of the common requirements of the standards as the basis for design and implementation. It is possible, within this approach, to distinguish three approaches:

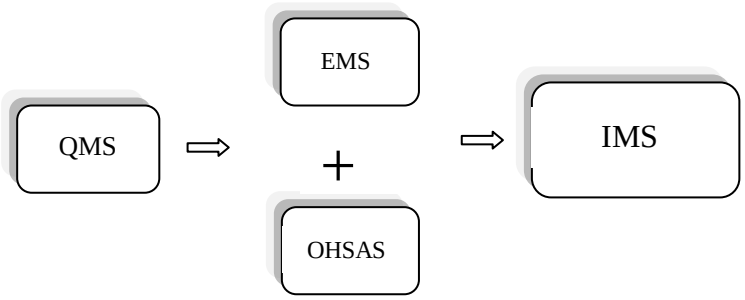
Sequential approach - involves successive application of different management systems - management system is established first, then other management systems are establish, one by one:



A parallel approach - refers to the simultaneous application of two or more management systems:



A combined approach - a combination of the previous two approaches - two or more management systems are upgraded to the already implemented management system:



Integration of management systems is carried out through the identification of requirements of various stakeholders and then through analysis of products and processes of designing and integrating these systems into the existing management system. The basis of this approach is stakeholders' requirements, system approach and the existing management system of the company.

If the company decides to integrate management systems, it is necessary to decide to what extent, that is, to choose the level of integration, which depends on the complexity of the existing management system and reasons for the integration. There is no unique level of integration model that could be applied, but many authors have defined different levels of integration. It is shown in Figure 1, where the level 0 means that there is no integration, and level 3 means the full integration.

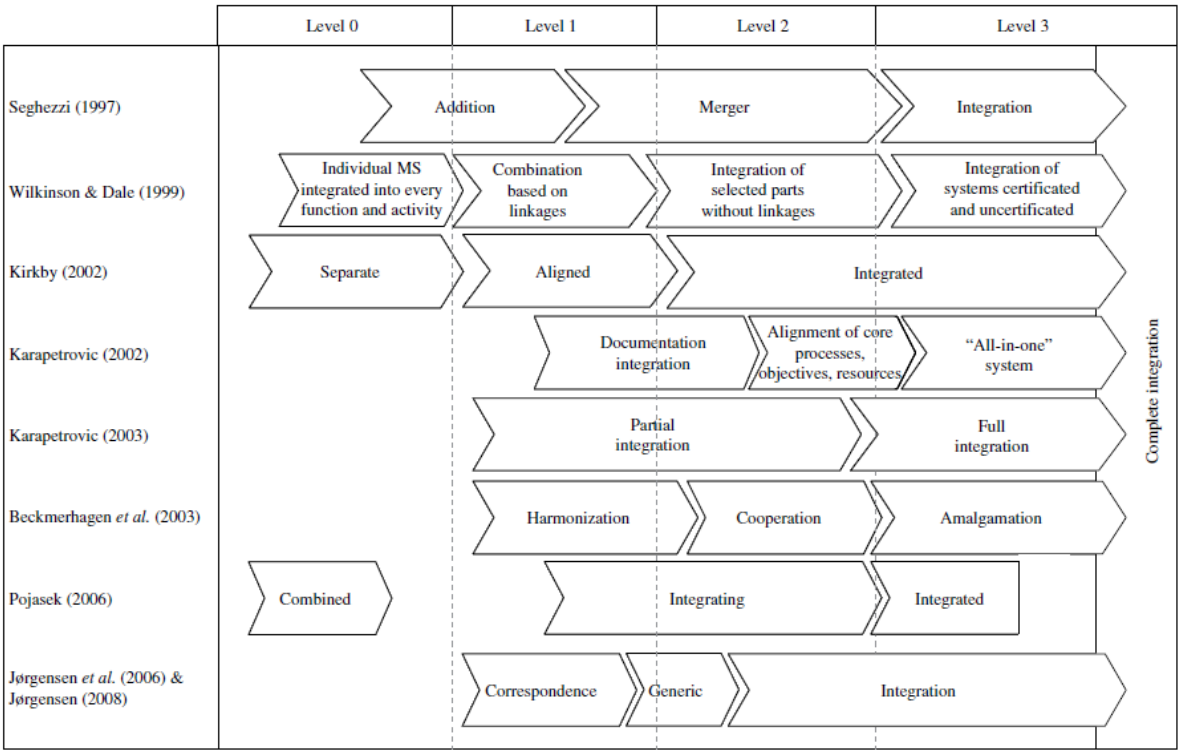


Figure 1: Levels of integration according to different authors (Bernardo et al., 2009)

Generally, there are the following three levels of integration (Zivkovic, 2012):

- The highest level - Implementation of the requirements of management systems into the existing management system of organizational system. Recognizes the existence of management systems as a basis for full integration.
- Intermediate level - Implementation of requirements of standards and designing the relevant management system of organizational system that does not recognize the existence of the management system and leads toward two parallel management systems.
- The lowest level - A variation of the previous levels of integration that is deepened in the case of the further implementation of requirements of other standards. Involves the implementation of the requirements of the relevant standard and design of observed management system, with or without its integration with existing, pre-designed management system. Does not recognize the existence of basic management system and usually leads to several parallel management systems.

Organizations decide to integrate management systems because of a number of reasons. The list of advantages and difficulties of IMS implementation is given below.

3. BENEFITS AND DIFFICULTIES IN MANAGEMENT SYSTEMS INTEGRATION

The purpose of this paper is to make an overview of benefits and difficulties in integration of management systems. We have drawn this overview from the existing literature on the subject. Table 1 shows the benefits of IMS as perceived by different authors, while difficulties in integration are presented in Table 2.

All the benefits, drown out the existing literature, could be classified into six groups: improvement of processes effectiveness and efficiency, improvement of human resources management, improvement of relations with stakeholders, improvement of the company's reputation, competitive advantage and market share increase, more comprehensive compliance with laws. It is obvious from the table that the first group of benefits (improvement of processes effectiveness and efficiency) is the most cited.

Table 1: Benefits of IMS implementation

Benefits		Supporting literature
Improvement of processes effectiveness and efficiency	Lower operating costs	Brecka (1994), Terziovski et al. (2003), Casadesus and Karapetrovic (2005), Karapetrovic et al. (2010), Moljevic et al. (2013), Suditu (2007)
	Decreased management cost	Zeng et al. (2011), Olaru et al. (2014), Moljevic et al. (2013)
	Reduced wastage	Brecka (1994), Terziovski et al. (2003), Casadesus and Karapetrovic (2005), Karapetrovic et al. (2010), Moljevic et al. (2013)
	Decreased paperwork	Zeng et al. (2011), Olaru et al. (2014), Moljevic et al. (2013)
	Time saving	Olaru et al. (2014)
	Improved efficiency and productivity	Brecka (1994), Terziovski et al. (2003), Casadesus and Karapetrovic (2005), Karapetrovic et al. (2010), Asif et al. (2010), Olaru et al. (2014)
	Decreased complexity of internal management	Zeng et al. (2011), Olaru et al. (2014), Moljevic et al. (2013)
	Simplified certification process	Zeng et al. (2011), Olaru et al. (2014), Moljevic et al. (2013)
	Facilitates continuous improvement	Zeng et al. (2011), Olaru et al. (2014), Moljevic et al. (2013)
	Clearer responsibilities and relationships	Olaru et al. (2014)
Improvement of relations with stakeholders		Moljevic et al. (2013), Suditu (2007), Asif et al. (2013)
Improvement of human resources management	Increase in employee motivation, awareness and qualifications	Moljevic et al. (2013), Suditu (2007)
Improvement of the company's reputation	Improvement of company's image	Moljevic et al. (2013), Suditu (2007), Asif et al. (2013)
	Creation of a better company image among employees	Moljevic et al. (2013), Suditu (2007), Asif et al. (2013)
Competitive advantage and market share increase	Competitive advantage	Moljevic et al. (2013), Suditu (2007), Asif et al. (2013)
	Improvement of market place	Moljevic et al. (2013), Suditu (2007), Asif et al. (2013)
	Gained new customers/higher satisfaction of existing ones	Moljevic et al. (2013), Suditu (2007), Asif et al. (2013)
More comprehensive compliance with laws	Better evidence of legal compliance	Moljevic et al. (2013), Suditu (2007), Asif et al. (2013)

Problems that may arise in the integration process can be related to two phases: problems that arise during IMS designing, and problems that arise during IMS implementation, where both the phases carry similar number of problems.

Table 2: Difficulties in IMS implementation (adopted from Asif et al., 2009)

Difficulties		Supporting literature
Problems in IMS designing	Unavailability of formal standard for integration of management systems	Labodova (2004)
	Unavailability of common denominator (common characteristics)	Karapetrovic (2002)
	Different scope of individual systems	Wilkinson and Dale (2001), Zeng et al. (2007)
	Different structure of individual systems	Karapetrovic (2002), Seghezzi (2000)
	Lack of understanding of the relevant individual management system	Karapetrovic (2002), Bernardo et al. (2008)
	Risk of not assigning the right level of importance to each function (such as quality, environment, and health and safety)	Salomone (2008)
	Misunderstanding of integration concepts	Salomone (2008), Wilkinson and Dale (2001)
Problems in IMS implementation	Employees' resistance during integration (due to loss of individual functions)	Karapetrovic (2002), Matias and Coelho (2002), Zutshi and Sohal (2005)
	Inadequate audit methodologies	Karapetrovic (2002)
	Reduced flexibility	Crowe (1992)
	Insufficient financial resources	Zutshi and Sohal (2005)
	Lack of information and knowledge of how to integrate systems	Salomone (2008), Zeng et al. (2007), Zutshi and Sohal (2005)
	Cultural aspects (requires cultural transformation)	Jorgensen et al. (2005), Wilkinson and Dale (1999), Zeng et al. (2007)
	Lack of human resources	Asif et al. (2009), Simon et al. (2012)

4. CONCLUSION

The analysis shows that organizations which implemented IMS gain significant operational, financial and marketing benefits. IMS integrates all business components in order to reduce documentation, to reduce costs, to increase profitability, to eliminate problems of responsibilities and relationships, to direct focus on business goals, to improve internal and external communication, to facilitate the process of training and to increase competitiveness.

Although ISM implementation can bring in many advantages, it is very important for companies to be aware of the possible problems that can occur within the process of integration. Thus, the analysis also points out the difficulties which organizations should take into consideration before processing standard integration. These difficulties are related to the risk of creating parallel system separately, excessive documentation, different scope of individual systems, insufficient financial resources, etc.

Highlighting benefits and problems in IMS implementation can give a basis for improvement of integration process of management systems, such as quality management systems, environmental management systems, occupational health and safety management systems (ISO 9001, ISO 14001, OHSAS 18001) and etc.

CONCEPTS OF STANDARDS AND STANDARDISATION IN PUBLIC ADMINISTRATION JOURNALS

Jelena Ruso[1], Mladen Đurić[2]
[1]Faculty of organisational sciences, jelena.ruso@fon.rs
[2]Faculty of organisational sciences, djuric.mladen@fon.rs

Abstract: We examined the ways how ISO and other standards were used in papers published in four leading journals of public administration and analyzed perceptions of these standards by scholars. Results of our study show that they rarely use the concept of management system standards in researches published in journals of public administration, which particularly stands for ISO standards (ISO 9000, ISO 14000, ISO 26000, ISO 27000 and other ISO standards families). Specific standards were mentioned in very few articles, generally without greater importance assigned. One of the possible reasons for this is that the practitioners have been less introduced with standards or they simply do not understand the role and benefits of ISO and other management system standards in public administration. This paper also presents examples of the most commonly used terms, related to standards in journals of public administration.

Keywords: *standards, management system, standardization, public administration, journals*

1. INTRODUCTION

Public administration is "often regarded as including also some responsibility for determining the policies and programs of governments. Specifically, it is the planning, organizing, directing, coordinating, and controlling of government operations."[1] M. Holcer (2011) defined public administration as information and implementation of public policy. There are four values that are fundamental to understanding the administrative systems: political responsiveness, organizational efficiency and effectiveness, individual rights, and social equity. (Murray, 2006) Public administration is the management of affairs of the government at all levels-national, state and local. (Basu, 2004)

Since public administration is the only study that studies government in all its aspects (and not just from disciplinary defined angles), it is fundamentally an umbrella discipline. Public administration's object of study, government, is also of interest to scholars in other social sciences, to political officeholders, to career civil servants, to corporate executives, and to citizens.".(Raadschelders, 2011)

The ISO standards (ISO 9000, ISO 14000, ISO 26000, ISO 27000 etc.) are widely implemented in public institutions in all countries but results show that scholars have less believed in standards or they simply do not understand the role of standards as "de facto" or "de jure" standards. It could be a new hypothesis for researches. We also analyzed other "de facto" standards (Standardization carried out by parties other than Formal Standardization Organizations (Hesser W., 2007)) but the results were not much different. "The aim of ISO is to promote the development of uniform standardization so as to achieve a situation in which goods and services can be exchanged freely on an international level" (Hesser W., et. al, 2007).

The aim of this paper is to analyse of presence of term of standard and provide key insight in scholar's perception of standards. Paper is organised in three main parts: research methodology including data collection and data analysis. An analysis was performed to understand the perception of standards by scholars.

2. CLASSIFICATION OF STANDARDS

De Vries (1999) cited, in Hesser W. (2008), classified standards as: basic standards; requiring standards; and measurement standards. Basic standards provide general descriptions and requiring standards define requirements for an entity or relations between entities. Measurement standards provide methods to be used in checking whether the criteria given in requiring standards are met. In this category, requiring standards

[1] http://www.britannica.com/EBchecked/topic/482290/public-administration prezeto 17.08.2012

include: compatibility standards; quality standards; and interference standards. Compatibility standards are used for fitting interrelated entities to one another to enable them to function together; quality standards define the requirements for entity properties to have minimum levels of quality; and interference standards set requirements regarding the influence of an entity on other entities such as safety, health and environmental requirements.
The ISO standards (ISO 9000, ISO 14000, ISO 26000, ISO 27000 etc.) are widely implemented in public institutions in all countries but results show that scolars have less believed in standards or they simply do not understand the role of standards as “de facto” or “de jure” standards. It could be a new hypothesis for researches. Authors also analyzed other “de facto” standards (Standardization carried out by parties other than Formal Standardization Organizations (Hesser W. 2007)) but the results were not much different. “The aim of ISO is to promote the development of uniform standardization so as to achieve a situation in which goods and services can be exchanged freely on an international level” (Hesser W. et. al, 2007).

3. RESEARCH METODOLOGY

3.1 Data Colection

Subjects of work were the electronic articles of public administration and the Internet browser was a main tool for researching. The data were collected from the Internet using KOBSON browser, and relevant papers were published between 2000 and 2013. Key search words were: standard, stadndardization and ISO. All 67 papers used in analysis are from the four leading journals of public administration which have impact factor greater than 0.9. including:

1. “Public adminstration” (IF=1,026)
2. “Public administration review” (IF= 0,9)
3. “Journal of Public Administration Research and Theory/J PART” (IF=1,951)
4. “Regulation and Governance” (IF=1,625)[2].

3.2 Data analysis

The articles are divided into three categories (Figure 1):

Category (I) The frequency of occurrence of word “standard”,
Category (II) Citing specific standards (refer to ISO or other standards) and
Category (III) The article is concerned with the certain standard

The idea was that the papers be classified into three categories depending on whether the word "standard" was only mentioned as part of the text without reference to a specific standard (n-number of words greater than 3). Second, if the article cited certan standard in any context (e.g. ISO). Third, if the whole paper examines the standard in any form. The articles published between 2000 and 2014 were taken into consideration.

4. RESULTS

It has been found that the practitioners didn’t explore and use standards, particularly ISO management system standards. The results are shown as the percentages in Figure 1, and Table 1 including descriptions of individual papers.

Table 1: Number of papaers used in analysis

Journal name	**Number of papers used in analysis [1]**	**[%]**
Public administration	33	49%
Public administration review	19	28%
Journal of Public Administration Research and Theory	10	15%
Regulation & Governance	5	7%
Total	**67**	**100%**

The results showed that researchers generally little studied standards in the journals of public administration. Because of that, it cannot be single out as the significant trend of occurrence of the term "standard" in the

[2] It should be noted that the authors of this study were analyzing only the articles that had been given access to over KOBSON portal. (www.kobson.nb.rs)

text. Therefore, we decided to comment on the individual papers, and to make some conclusions about scholar's perception of standard. The survey showed that most of the articles (61%) belonged to category (I), where the "standard" was mentioned in various contexts, including:

1. National/International standards (Rothstein, 2004) (Schrank, 2013);
2. Principles of standards (Brereton and Temple, 2002);
3. Service standard (Boyne, 2003);
4. Service standard initiative (Torres, 2005);
5. Standards of operation (Vigoda, 2000);
6. Quality standards/standards of quality (Schiavo, 2000), (Torres, 2005) (Verdun, 2012);
7. Set of standards (Karsten et. al, 2010);
8. Quality management standard (Macadam and Walker, 2003);
9. Standardized assessment tools;
10. Standard performance indicators;
11. Organizational standards;
12. Developing standard;
13. Certification standards (Doelle et. al, 2012);
14. Public standards (Allmendinger, 2003);
15. Standard operating procedures (William L. Waugh Jr., Gregory Streib, 2006);
16. Risk management standards (Rothstein, 2004) etc.

*Example of "service standard":"…perhaps because comprehensive data on local service standards have become available only in recent years" and "…inspectors' views about ability to improve were shaped by authorities *existing* service standards, as reflected in the core service performance scores." (Andrews et. al, 2005)

**Example of "standard of operation":" The environment of PA had started to change and called for establishing new standards of operation in the public services of western societies" (Vigoda, 2000)

***Example of "organizational standard": "Organizational standards or guidelines, although commonly applied in public sector organizations…" (Dahl, et. al 2006)

****Example of "developing standard": "Helen Gunter's criticism on our proposal for developing standards for the publication of school performance indicators…". (Karsten, Visscher, 2010)

*****Example of "certification standard": "Like other forest certification standards and hard law forest practice regulations, it allowed for on-the-ground flexibility with respect to how these outcomes were to be achieved". (Doelle et. al, 2012)

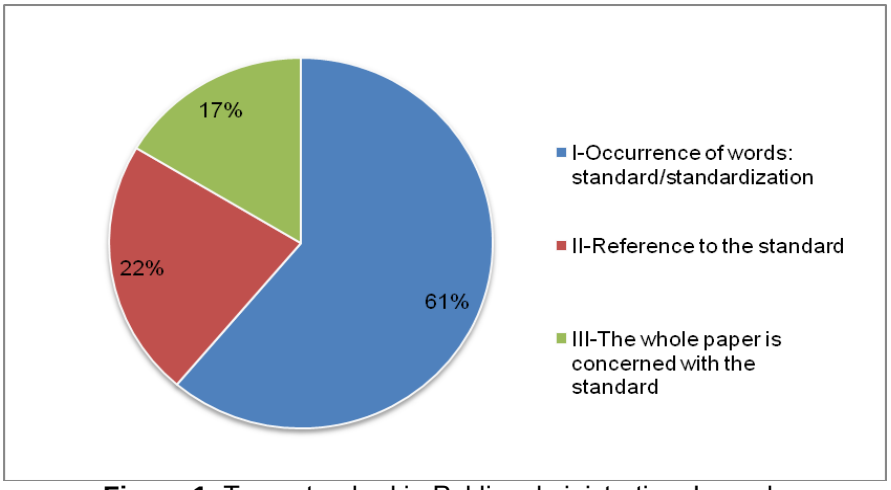

Figure 1: Term standard in Public administration Journals

This finding suggests that the individual practitioners have understood the concepts of standard and there were technical terms used in connection with standardization but it did not refer to any specific standard. It has showed that use of the term “standard” is popularized and these findings lead to the following conclusion: 1. Scholars are not familiar with the specific standards, 2. Scholars do not believe that certain system management standards (or other standards) are relevant. 3. Scholars perceive definition of "standard", in different ways. In the Table 2, it is shown that the scholar’s perception of standard is the highest in “Public administration” journal.

In the „Public administration“ journal, which dealt with the quality standards in public administration, was not included standard ISO 9001. The article showed „cultural differences in the usage of the concepts of servise quality standards between the UK experience and the Italian“ (Schiavo, 2000). In the whole paper, authors didn't mention any specific standard of management systems, especially, keeping in mind that in the same period of time it was the first edition of ISO 9001:2000.The same situation was in the article by L. Torres, 2005. There wasn’t any sign of ISO 9001 too.

The papers that mentioned a specific standard (II-Citing specific standards) have represented 22% of total, only 15 papers of total 67 analyzed. The most common were ISO (International Organization for Standardization) standards (Gunter, 2010), (Torres et. al, 2011) mainly ISO 9000 (Mcadam, Walker, 2003), (King et. al, 2004), (Milakovich, 2006), ISO 14000 (Doelle et. al, 2012), (Bovaird, Russell, 2007) and ISO 31000 (Ferreira Da Cruz, Marques, 2012) as far as the of management systems. This fact demonstrated that the knowledge of specific standards was used in the right context, but only as secondary/incidental information. (Milakovich, 2006) Also, it was mentioned that standards such as „The Food standards“ (Tomlinslon, 2010), (Schofield and Shaoul, 2000), (Rothstein, 2004), „Common Language Standard - CLS“-compatibility standards, (de facto standard) (Dahl, Hansen, 2006), standards of the National Committee for Quality Assurance (PCMH standards) (Klein et. al, 2013) and „de jure“ standards such as „NFPA 1600 - the international standard for emergency management programs“ and EMPA standards (Waugh Jr. and.Streib, 2006)

The last but not the least category is Category III-The article is concerned with the certain standard, where the authors dealt with standards in articles (17%). The one example was in paper by Korego et al., 2010, talking about how non-compliance with OSHA standards changes as an establishment undergoes repeated inspections and what the implications are for regulatory enforcement. It is about interference standards. It was one of the few papers in four analyzed papers which dealt with issues of non-compliance with the requirements of the U.S. standard, including inspection checks, as far as occupational injuries. Nor in this paper it didn’t mention occupational health and safety management system standard (OHSAS 18001).

Another example (Skov, 2006) was the article, which dealt with compatibility standards as a softer program and its speed of application, ie. standard diffusion through a certain period of time. This paper considered the speed of acceptance of this standard, depending on many factors, but it didn’t emphasize any certain standard, for example ISO 27001 (Information security management) which is necessary to support this standard due to successful diffusion. It is about compatibility standards. The same example is the article by Potoski, 2001, which studied competition for industrial development, creates a “race to the bottom” in which states relax their environmental standards to avoid losing businesses to states with more “business-friendly” regulations. The article presented the reasons why the states exceed the USEPA standard but it was interesting that nowhere was mentioned ISO 14000 standards (Environmental management). It is about interference standards

In another article (Karsten, 2010), the policy context of this development, in the education sector, is analyzed in conjunction with the problems associated with the public reporting of school performance indicators. This is followed by a discussion of the need for an accepted set of publication standards. The aim of this article is to initiate a debate about whether international consensus can be reached on the content of such a set of standards, and whether a particular set of standards is applicable in and relevant to other countries. This is the case where generic set of de facto standards is a model with the defined rules for writing “report cards” in primary schools. Likewise, there weren’t used any of management system standards (For example: ISO 9000, ISO 14000, ISO 26000, ISO 27001).

Also, there was one part of the article (Waught and Streib, 2006) where was mentioned NFPA 1600 standard (The international standard for emergency management programs). Autors said: „Standards have made it difficult for public officials to ignore the need to invest in programs to address hazards and these standards have also made it easier to hold public officials accountable when they do not address known risks and prepare for disasters reasonably“. It is much more difficult to claim ignorance of risks when the standards identify potential hazards and provide assessment procedures. Standard ISO 31000 was exempted in this paper.

Klein et al, 2013, in the article talked about PCMH standards by The National Committee for Quality Assurance. “As a private organization, it maintains a unique governance role because it develops its own standards and accreditation guidelines for many government (and private) health care initiatives: medical homes, accountable care organizations, disease management, and even health plan evaluations, among other offerings. Practices can also apply to other organizations such as the Joint Commission and the Accreditation Commission for Health Care, which have also crafted recognition standards for medical homes”. This was an example of “de facto” standards and only one part of article wrote about it without explicitly citing of system management standards.

Hence, all the examles above indicate that standards so far have studied rarely by practitioners and scholars, especially management system standards. Perhaps they thought that these standards were outdated or not interesting for a science or they haven’t seen the potential importance and role of standards in public services.

5. CONCLUSION

Conclusions were identified from citations in these articles and in review articles. Standards were obviously understood as set of norms, guidelines, and rules by the authors (Category III) (Noordegraaf et. al, 2014), (Alvarez and Hall, 2008). The articles of the third category (III) didn’t relate to the ISO standards and 22% of papers only mention some of the ISO standards (Category III and Category II). Also, they didn’t write about terms “de facto” or “de jure” standards, differences between them or any examples. The reason for this could be that they thought that these standards were outdated, uninteresting for a science or they don't see the importance of role of standards in public services. The overall conclusion is that researchers in journal of public administration didn’t address standard as a specific problem. This paper has researched and showed date but not the reasons why it was the case.

It should be noted that there are the limitations in this research such as the number of analyzed journals, lack of access to all articles over the internet, unspecified areas of public administration and the journals with impact factor (IF). It would be suggested direction for future research. More broadly, questions remain about the extent to which the conclusions presented here apply to other public areas such as: education, health care, police service and judiciary. The answers to such questions will help scholars and policy-makers to understand how the quality and standards are perceived and used in public administration. There is the possibility of conducting research among researchers about what they think about the standards and application of standards in their field and then compare those results with the present.

CRITICAL ANALYSIS OF THE ISO METHODOLOGY FOR ASSESSING THE ECONOMIC EFFECTS OF STANDARDS

Ana Trajković[1], Ivana Mijatović[2]
[1]University of Belgrade, Faculty of Organizational Sciencies, anat@fon.bg.ac.rs
[2]University of Belgrade, Faculty of Organizational Sciencies, ivanamt@fon.bg.ac.rs

Abstract: *The impact of standards on modern business is evident. However, it is not easy to provide objective evidence of their effect on economic performances of company. This paper provides some aspects of critical analysis of the ISO Methodology 2.0 for assessing primarily the economic benefits of standards. This ISO Methodology and many case studies, in which ISO approach to assessment of economical benefits of standard is explained, are publicly available on the official ISO website. The main intentions of the authors of this methodology and case studies are to justify the use of standards in company through the achievement of certain economic benefits within it. However, the dynamics of business activities and many influential internal as well as external factors that affects business performance cause that determination and measuring of single and specific influence of standard implementation to specific business performance are complex and need more sophisticated approaches.*

Keywords*: Standards, ISO Methodology, Economic Benefits*

1. INTRODUCTION

Standardization has been crucial for the development of the industrial society. The rapid progression of the globalized and increasing complex knowledge economy not only demands new standards, but it also challenging the form of standardization (Blind 2004). Understanding of different aspects, concepts, complexity and technological, economic and social implications of standards and standardization is complex task. The job of standardization is a hard job (*Kondo, 2000*). The majority of studies on standards and standardization are based on experiences and practice of developed countries and technology advanced companies. Many authors have dealt with problems of economic benefits of standards and the economic benefit of standards seems to be widely acknowledged within scientific authors (see more in David (1987), Tassey (2000) and Blind (2004)). David (1987), Tassey (2000) and Blind (2004), even, proposed a categorization of standards based on the economic problem they solve. Later some writers have extended the number of categories of standards to this (Tassey 2000, Blind, 2004):

- Compatibility and interface standards
- Minimum quality and safety standards
- Variety-reducing standards
- Information and measurement standards.

Leaving aside the perspective of the individual actors and taking a comprehensive macroeconomic view, it is evident that standards help to reduce costs of transactions between the different actors and therefore the emergence and organization of markets. This perspective is taken from the so-called institutional economists (Blind 2004). More comprehensive researches on the economic effects of formal standards began in year 2000 within German national standardization body (DIN) and other (ISO, 2010). ISO has worked with over 20 of its members, national standards bodies in different countries, to develop case studies to assess and quantify the benefits companies can obtain from the use of standards (ISO 2010). Many organizations from the private and public sector use standards and participate in standards development. A few of them see standardization as directly linked to their core business strategy. Some approach standardization in a highly organized way and have a clear perception of the impact of standards on their activities and performance (ISO, 2014). Others may use standards from a narrower perspective, for specific processes or activities. Most of them realize that standards bring benefits to their organization, although the level of awareness and the perception of such benefits vary considerably (ISO, 2014).

2. ISO METHODOLOGY CONCEPT

The ISO Methodology has been designed to support analysis of a company, or a specific organizational entity in order to assess the economic benefits of standards. (Gerundino, Hilb, 2010)

2.1 ISO Methodology Objectives

The methodology has the following three objectives (ISO, 2010):

- to provide a set of methods that measure the impact of standards on organizational value creation with an emphasis on business organizations;
- to provide decision-makers with clear and manageable criteria to assess the value associated with using standards; and
- to provide guidance on developing studies to assess the benefits of standards within a particular industry sector. ("Standards" in the ISO Methodology are not limited to standards developed and published by ISO, but comprise all consensus-based standards issued by any standards-developing organization. Companies often call these "external" standards to distinguish them from internal company standards. "External" standards include International Standards developed by ISO and the International Electrotechnical Commission (IEC), regional and national standards, standards developed by sector-based standards development organizations, as well as consortia standards if the consortia are open to participation by interested parties in addition to consortia members (ISO 2010).

2.2 ISO Methodology Process

Generally, the assessment of the effects of standards proceeds in accordance with the steps below:

- Understand the value chain of the industry and the company.
- Identify the impacts of standards.
- Analyze the value drivers and determine operational indicators.
- Assess and calculate results.

The first step is to determine the value chain of the industry, and to position the organization to be assessed in the context of this value chain. (Gerundino, Hilb, 2010) A value chain comprises a sequence of activities to generate a certain output, a product or a service. (ISO, 2010) Standards used by the organization are considered in relation to the organization business processes and its specific activities.

The methodology first identify in which activities standards are used and how these activities, supported by the use of standards, contribute to the creation of value for the company (ISO, 2010). The next step is to create standards impact map aims to determine the impact resulting from the implementation of standards on each of the main business functions and associated activities.
Operational indicators associated with the activities impacted by standards then need to be identified to allow quantification (EBIT accounts for the gross profit for a company (revenue minus costs) at a given point in time), Fig 1.

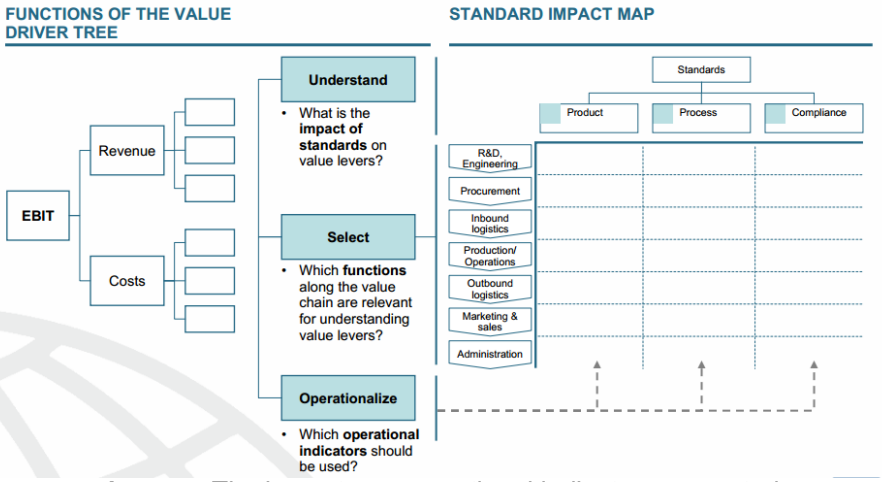

Figure 1: The impacts on operational indicators converted in EBIT impacts (ISO, 2011)

This is done by translating the impact into financial metrics. It can be directly measurable (for example, cost savings for the procurement of materials and components), or determined on the basis of existing company data (for example, the reduction of manpower needed to complete the design of products is converted into estimated cost savings on the basis of the average cost of personnel). (Gerundino, Hilb, 2010)

2.3 Some Methods for Measuring the Impacts of Standards

Basic approach to measuring the impacts of standards in this Methodology is given through some comparison:

- Before-after comparison.
- Comparing concurrent conditions – Projects.
- What-if comparison.

The second type of comparison is situation when standards may be used in some projects, and not for others. The simplest case is a "before-after" comparison when an organization may have changed from situation (1) - when it did not use standards to a situation (2) when it uses relevant standards. The final "What-if "- assumption, which is based on estimating how certain activities/processes would be performed without standards (situation 1) and comparing such a condition with the existing situation, in which standards are applied (situation 2) (ISO 2010). This methodology provides basics for:

- The assessment of economic benefits of standards for an industry sectors (given in Annex A of the Methodology).
- The extension of the methodology to assess non-economic benefits of standards (covered in Annex B).
- An overview of the individual tools (given at Annex C).
- A definition of the individual business functions (is given in Annex D Terms and definitions).

2.4 Company Case Study Findings - Application of the Methodology according to ISO

ISO Methodology has been tested in over 20 countries across the world in 30 company covering areas such as the agri-food business, the chemical industry, construction and construction materials, electrical appliances, electrical power transmission, food retail and food logistics, heating, ventilation and air conditioning, industrial automation equipment, information and telecommunication, pipes and piping systems, ship building, and water supply. Since October 2010 a case studies about the economic benefits of standards were undertaken in South East Asia (Indonesia, Singapore, Thailand and Vietnam), Southern Africa (Botswana and South Africa), South America (Brazil, Colombia and Peru), Europe (Germany and other). The set of case studies are published in couple of books edited by ISO.

Table 1: Comparative analysis of two case studies in organizations Festo Brasil and Danper

Criteria	Festo Brasil	Danper
Economic benefits generated by standards	BRL 4.5 million (USD 2.7 million) annually, which amounts to 1.9 % of sales revenues.	USD 648 158 annually which amounts to 0.73 % of sales revenue.
Key qualitative benefits	Standards are considered an essential component of good engineering and manufacturing practices, with a potential that has not yet been fully exploited	Standards helped instil a culture of continuous improvement in the company
What were the major benefits of using standards?	Using standards allowed Festo Brasil to : • Implement an efficient procurement process resulting in significant work savings • Save around 30 % in its purchase operations by buying standardized supplies • Optimize the design times of its engineers and shorten time to market • Improve communication between different technical departments in the company • Implement a company-wide continual improvement process that streamlined manufacturing and brought significant savings	Using standards (and certifications) allowed Danper to : • Continually improve its skills and implement an efficient and reliable production chain • Manage a highly efficient cold chain and delivery service for fresh produce, ensuring product quality requirements in overseas markets are met • Demonstrate to overseas customers its ability to produce and deliver safe, high-quality products and qualify as a supplier for them • Export close to 100 % of its produce and penetrate new markets by meeting the requirements and building the confidence of key international retailers

These case studies were made in close cooperation among ISO member bodies, academic institutions, companies and staff of the ISO Central Secretariat, acting as advisors to the project team. Just as illustration of comparative potential of those case studies we provide comparative analysis of two case studies of Festo Brasil and Danper. Festo Brasil is one of the group's largest companies and manufactures a wide variety of products for the Brazilian market and for export to other Festo subsidiaries and to the parent company. Danper is one of the largest agro-exporter companies in Peru.

Also, there are some interesting findings in undertaken case studies such as that the results show an incidence of the impact from standards ranging from 0.15 % to about 3 % of turn-over – depending on the company and the business function analyzed. To give a better appreciation of the scale of the standards impact, the above estimate has been projected to the total industry revenues for 2008. As a result, the total contributing impact would be between USD 38 billion and 55 billion. (Gerundino, Hilb, 2010)

Table 2: Example of Activities in the production function and standards used (Source: Juhayna, Egypt)

Business function	Activities	Standards	Description
Manufacturing	Raw material reception	ISO 22000:2005 ISO 17025:2005	• Food safety management systems • General requirements for the competence of testing and calibration laboratories
	Materials preparation : sugar syrup and other production ingredients	GMP standards ISO 22000:2005	• General requirements for the competence of testing and calibration laboratories • Good manufacturing practice • Food safety management systems
	Mixing process	GMP standards ISO 22000:2005	• General requirements for the competence of testing and calibration laboratories • Good manufacturing practice • Food safety management systems
	UHT treatment (pasteurization)	GMP standards ISO 22000:2005	• General requirements for the competence of testing and calibration laboratories • Good manufacturing practice • Food safety management systems
	Filling and packing	GMP standards ISO 22000:2005	• Good manufacturing practice • Food safety management systems
	Palletizing	GMP standards ISO 22000:2005	• Good manufacturing practice • Food safety management systems
	Storing until dispatch to distribution centre	ISO 22000:2005	• Food safety management systems

3. CRITICAL ANALYSIS OF ISO METHODOLOGY

3.1 Advantages of ISO Methodology

The first survey that DIN (2000) was conducted within different organizations and countries was using different methodologies of assessment and had different goals. But due to different methodologies and goals the results obtained were not sufficiently comparable (ISO 2010), Having this in mind, ISO Methodology provided to standard user common methodology to asses economic benefits of standards in order to give basic possibility to intercompany comparison in area of economic benefits of standards.

Because of the way through empirical attempt to quantify certain indicators this Methodology is trying to economically justify the application of standards which is very important for any organization. ISO managed to implement its complete Methodology within 30 organizations around the world for four years. With this step ISO and its Methodology succeeded in provoking many organizations to analyze and gain insight which standards they were using within their company and for which processes and activities. The fundamental point in the ISO Methodology is to consider the company perspective: its environment, objectives, business processes and activities (ISO, 2010). It is an accomplishment to conduct so many case studies and thereby including huge number of participants help to raise awareness of the importance of standards.

The ISO Methodology also offers a toolbox to support the assessment process, the capturing of information and data, and the calculation of the impact of standards (Gerundino, Hilb, 2010). Consistent with the above, case studies provide evidence that a focus on standards can be the core of an upgrading strategy through which companies aim at entering higher value-added segments of the value chain in their respective industries (ISO, 2010).

3.2 Disadvantages of ISO Methodology

It is difficult and risky to apply a specific methodology to different types of companies or various forms of organization and functioning because of their different nature, needs and goals. It is important to leave some

latitude in describing the process of the company. “The benefits associated with participating in standards development are only addressed at a qualitative level” (ISO, 2010).

As explained in section 1.3 of ISO Methodology it is important to underline that the impacts from internal company standards (even if they are not related to external standards) can also be assessed using the same approach and the same set of tools provided by the ISO Methodology (ISO, 2010). This is a delicate assumption because it is necessary to clearly distinguish what are internal standards within an organization. A frequent replacement of the thesis is that the documentation resulting from fulfilment of the requirements of external standards are so called as an internal standard of organization.

Internal company standards are excluded from the assessment except if they are related to or based on external standards. In such cases, the interplay between internal and external standards needs to be carefully analyzed, because the influence and impact of external standards can be substantial, even if the effect is achieved through internal standards. (ISO, 2010) In external standards it is always given what you need to fulfil but almost never how. Bearing this in mind, each organization can in its own way to achieve fulfilment of requirement of the standard. Therefore it is very difficult in such circumstances to make a comparative analysis of the impact of the internal or/and external standard of two or more organizations.

The approach and the tools provided by the ISO Methodology can be applied to both voluntary standards and technical regulations (ISO, 2010). We think this is overambitious due to the nature of the regulations that they are always mandatory and that they differ from one state to another. It is naive to believe that the offered method in ISO methodology can extract the effects of standardization of other effects in some organizations. This requires significant research in the context of effects separation in some organization because they are most often seen at the end of process and it is not simple to get to the cause of such an effect. And, also certainly not enough to monitor just one economic indicator, in this case, EBIT, but these complex analyzes require identification of some additional important economic indicators and their consideration.

4. CONCLUSION

The ISO methodology for assessing primarily the economic benefits of standards describes the key stages of the assessment process and provides references to some of the tools which should be applied at certain stages of the assessment. It presents the key elements and concepts of the methodology, including practical advice on the organization of projects, on steps in the assessment process, and on methods to calculate the benefits of standards. The set of case studies (published and edited by ISO) were made in close cooperation among ISO member bodies, academic institutions, companies and staff of the ISO Central Secretariat.

The ISO Methodology succeeded to provide to standard user common methodology to asses economic benefits of standards and provide basic tool for intercompany comparison in area of economic benefits of standards. ISO methodology can motivate many companies to analyze economic benefits of usage of standards and gain insight into standards usage (what standards and for which processes and activities). However, the main problem within this methodology might be related with extraction of the effects of standards usage from other influential factors on company economic performances. The methodology need to address this issue more clearly. Certainly it is not enough to monitor just one economic indicator, like EBIT, complex analyzes require identification of some additional important economic indicators and their consideration.

Abstract: *This paper presents an overview of current knowledge regarding the practice of corporate social responsibility in small and medium-sized enterprises. The paper first gives an overview of the definition of social responsibility, based on the literature review. It also shows the specific features and motives for corporate social responsibility in small and medium-sized enterprises. As a standardized basis on which SMEs can build their socially responsible practices, the international standard ISO 26000 is summarized. It also shows the process of implementation of SR in SMEs. At the end of the paper, an overview of the main advantages and disadvantages of the concept of CSR in SMEs application was given through SWOT analysis, and the conclusion shows how CSR and the recommendations of ISO 26000 contribute to business sustainability of SME.*

Keywords: Social responsibility, SMEs, Sustainability, Corporate Social Responsibility, Standard ISO 26000,

1. INTRODUCTION

There is an increased number of those who advocate that companies can not be exclusively focused on obtaining the highest possible profits for the owners. It is clear that companies must take appropriate responsibility. Social responsibility is one of the pillars of operational excellence of organizations. It contributes to economic growth and development on healthy basis, both in developed and in developing countries. If properly practiced, the principles of social responsibility given in the standard ISO 26000 can be a key tool in the struggle for environmental and fair business activities, contributing to a better society.

While social responsibility has traditionally been the domain of the corporate sector, recognition of the growing importance of the small and medium-sized enterprise (SME) sector has led to an emphasis on their social and environmental impact of SMEs (Nejati & Amran, 2009). Supporting SMEs is a cornerstone of the EU"s drive for growth and jobs. Since 99% of all EU companies are small and medium-sized enterprises (SMEs), accounting for 67% of jobs, it is clear that what is good for small businesses is good for Europe"s economy (EPC, 2012). They are a major source of entrepreneurial skills and innovations, and they contribute to economic and social cohesion. In its publication "Opportunity and Responsibility - How to help more small businesses to integrate social and environmental issues into what they do", the European Commission mentioned: "*SMEs have always been very close to what we call today "CSR". Through their typically local anchoring, they are well placed to make a strong contribution to socio-economic development at a local level and act as responsible members of a community. But it is possible to help and encourage SMEs to go further down the road of CSR*."

Increased global competition means that corporations need to find innovative ways to engage stakeholders and other interested parties. One of the factors contributing to the ambiguity of CSR is the lack of consensus as to what the concept really means (Sweeney, 2007). As levels of sophistication among stakeholders and other interested parties continue to rise, businesses will come under increasing pressure to find ways of participating in sustainable development (Planken, Nickerson & Sahu, 2013). One area in which a corporation"s sustainability stance can be communicated to stakeholders and other interested parties is in the construction of a social responsibility strategy (Planken et al., 2013).

2. THE CONCEPT OF CSR

The African Policy Institute research (API, 2011) indicates that the history of social responsibility is as old as the history of the business. Taking care of business that contributes to society and has a positive impact on both the people and the environment existed in societies at a much lower level of development than today. The best sources of examples from the ancient history on this topic can be found in the books whose primary

topics are the history of law and legal rules, which give us an insight into how the ancient people resolved their legal and economic issues. Some of these examples date back to 5000 years ago, such as the laws that regulate the protection of forests. In this sense, we should not forget the ruler of ancient Mesopotamia, Hammurabi and his Code of Hammurabi, which dates from 1700 BC, as an essential example of regulation of various forms of business relationships, such as norms which prescribed the death penalty for builders, farmers or supervisors whose negligence caused an accident or death of other people (Asongu, 2007).

The concept of CSR evolved from two parallel developments (Nejati & Amran, 2009). The first comprises the efforts of policy-makers and organizations to spread the idea of socially responsible behaviour at every level, by means of numerous initiatives, formal definitions and so on (Tencati, Perrini & Pogutz, 2004). The second path consists of academic contributions, evolved from an initial, vague awareness of the relationship between companies and social-environmental contexts into an explicit identification of rules of conduct and management tools (Nejati & Amran, 2009).

To begin with, it is necessary to look at the definition of corporate social responsibility (CSR) that can be found in the academic literature. CSR concept was initially proposed in the literature of the early 1950s (Carroll, 1999). In 1980, Jones (1980) states that corporate social responsibility means that the company has a liability in respect of all stakeholders in the society, not only to their stakeholders, and that this responsibility applies not only to what is required by law or contract. In the 1990s, practitioners began using CSR as an essential part of their business language and practice (Carroll, 1999). Modern jurisprudence is presented by Marsden (2001) stating that corporate social responsibility is the basic behavior of the company and the takeover of responsibility for the overall impact on the society in which it operates. According to Holme & Watts (2000) CSR is "the continuing commitment by business to behave ethically and contribute to economic development while improving the quality of life of the workforce and their families as well as of the local community and society at large." Authors McWilliams & Siegel (2001) define corporate social responsibility as well as activities that have a positive impact on society, which are above the interests of the company and legal requirements. Scholars have demonstrated that it is important that companies spend the resources allocated to CSR in ways that yield optimum benefits to society as well as to their stakeholders such as customers, employees, investors, supply chain associates, strategic alliances, communities, as well as governments (Poolthong & Mandhachitara, 2009). The definition that is much cited in the literature is the definition formulated by Pinney (2001), which defines corporate social responsibility as a set of management techniques that enable the company to minimize the negative and maximize the positive impact of its operations on society. Author Dahlsrud (2008) studied the definition of CSR and concluded that all the definitions include some of the following dimensions: 1) the social dimension, 2) the size of the environment, 3) the economic dimension, 4) measuring stakeholder and 5) measuring volunteerism.

"*Corporate social responsibility is the obligation of the firm to use its resources in ways to benefit society, through committed participation as a member of society, taking into account the society at large, and improving the welfare of society at large independently of direct gains for the company*" (van der Wiele, Kok, McKenna & Brown, 2001). As authors Pérez & del Bosque (2014) mentioned "*CSR refers to the company activities demonstrating the inclusion of social and environmental concerns in business operations, and in interactions with stakeholders, also according to the ambition levels of corporate sustainability*". Social responsibility, according to the authors Djuric, Vujosevic & Kovacevic (2012) could be described through the process of identifying stakeholders, identifying current and potential problems associated with them and creating appropriate strategies and processes to solve these problems. The most representative definition of corporate social responsibility given by ISO (ISO 26000, 2010) reads as follows: "*the responsibility of an organization for the effects of its decisions and activities on society and the environment, through transparent and ethical behaviour, such that it contributes to sustainable development that includes the health and welfare of the society; takes into account the expectations of its stakeholders; is in accordance with applicable law and international norms of behaviour; and which is integrated throughout the entire organization and applied in all of its relations*".

3. SPECIFIC CHARACTERISTICS OF THE CSR IN SME-S

No SME company is completely isolated from its surroundings and it usually represents an important part of its local community and the environment within which it operates. The ability of a business to succeed on a long-term basis depends on the relationships it has with its owners, investors, employees, customers, suppliers, the local community and other involved parties, who are collectively referred to as interested parties. All stakeholders should be encouraged to see the opportunities that can arise from engaging SMEs on social and environmental issues. In order to effectively implement ISO 26000 recommendations, SMEs have to understand and appreciate value of their involvement with their interested parties. This is because corporate social responsibility is not just about the advocating of the company's values and principles but also about understanding expectations of those who have an impact on the company and who are being impacted by the company. A large proportion of SMEs have always done things that could today be called "social responsibility", even if they do not know or use the term themselves. CSR in SMEs is less formal and more intuitive than in larger enterprises, but that does not make it less valuable, according to the European

Commission. SMEs are means of combating poverty in developing countries, Serbia being one of them. If the recommendations of ISO 26000 are perceived by SMEs as protectionist, inappropriate to the culture or excessively bureaucratic, the ultimate effect will be negative. On the other hand, we must not allow the SMEs to become a training ground for excessive pollution or exploitation of labour. The right understanding of the ISO 26000 recommendations points to the fact that the support in the development of SMEs is within the domain of the responsibility of large companies and that the improvements in the field of social and environmental protection go hand in hand with quality and management improvement, according to Filipovic (2008).

Governments and other public authorities in Europe are putting increasing pressure on SMEs in order to make them realize that respect for ethical codes of conduct and ISO 26000 is not only a concern of multinational corporations (Luetkenhorst, 2004). Besides, the concept of family businesses, often present in SMEs, carries elements of ethics, philanthropy, patriarchy, ethnicity and community, which provides an additional color of social responsibility. These elements are part of the essence of the social responsibility of SMEs, and therefore, aspects that need to be considered and included in all social responsibility programs aimed at SMEs, especially those in developing countries, according to Filipovic (2008). To remain competitive, companies need to be able to adapt to new demands from the market and the society in which they operate (Nejati & Amran, 2009). The flexible and personal nature of many small and medium-sized enterprises often allows them to respond quickly to these changes, because they can spot and take advantage of market opportunities more easily than many larger companies (Nejati & Amran, 2009).

Surveys and research in the field demonstrate that many SMEs tend to handle CSR activities unsystematically and on a personal ad hoc basis (Murillo & Lozano, 2006). The CSR concept is generic in nature and is applicable to organizations regardless of type and size (Nejati & Amran, 2009). The roots of CSR in SMEs seem to lie neither in purely utilitarian motives nor in ethical and altruistic decisions (Nejati & Amran, 2009). A key difference between large and small firms is that in small firms, ownership and management are not separated to the extent that they are in large multinational firms (Spence & Rutherfoord, 2001). Thus, control remains in the hands of one of the owners, potentially enabling him or her to make personal choices about the allocation of resources (Spence, 1999). Thus, in SMEs, the acceptance of CSR is largely a factor of the personal attitudes of the owner/manager (Perez-Sanchez, 2003). SMEs by their nature may experience specific barriers to CSR (Sweeney, 2007). It has been argued that SMEs are constrained by time and financial resources (Vives, 2006). A focus on the short term can mean long-term investment projects in CSR are not of immediate concern (Carlisle & Faulkner, 2004). On the other hand, it has been argued that being smaller and flatter, SMEs may be better placed than large firms to take advantage of the changing needs of society (Sarbutts, 2003; Perez-Sanchez, 2003). In one study conducted by Sweeney (2007), it was concluded that "*The volume and diversity of CSR activities was positively correlated with size. While large firms believe SMEs experience barriers such as perception and resource limitations such as financial, human and time constraints, in reality the only barrier noted by SMEs was financial constraints*". Concerning the motivations of SMEs to engage in CSR, Revell & Blackburn (2007) found that "*SMEs are only motivated to take environmental actions as a result of external pressure. Here one can think of adverse publicity, legislation and damage to the company's image leading to a reduction in a firm's competitive advantage*". Another external pressure motivating SMEs to engage in CSR is supply chain pressure from large companies (Revell & Blackburn, 2007). When companies see these external pressures as the main driver to engage in CSR their motivations fall into the integrative category of Garriga and Melé (2004), because these companies feel they depend on society for their existence, otherwise they would not see external demands as pressure. Enderle (2004) found that SMEs engage in CSR because they want to be good citizens, based on the moral obligation to contribute to the well-being of society, and not to increase profits.

According to the survey conducted by Hellenic Network for CSR, corporate social responsibility in SMEs has several components:

- **Environment** - The activities of all enterprises, independently of their size, may affect the natural environment. Implementation of comprehensive systems managing and controlling the influence each productive procedure has upon the environment may not be a simple task for a small medium enterprise.
- **Human resources** - Human resources is the most precious asset of the enterprise. Among other things, human resource is the company"s main representative to all interested parties (customers, partners, local communities etc.). A constant and socially responsible management of human resources ensures not only the company"s profile as a preferred employer but also the employees" creative involvement towards achievement of business goals.
- **Marketplace** - The most crucial factor of each enterprise"s economic effectiveness is the marketplace and the business environment into which it operates.
- **Society** - Being a "responsible citizen", the company participates definitively in local progress and development. The conscious participation of businesses in the society may also be expressed through CSR activities.

4. THE ESSENTIAL CHARACTERISTICS OF THE ISO 26000 STANDARD

Standard ISO 26000:2010 provides guidance to all types of organizations, regardless of their size or location, whether they are public or private, operating at any stage of development. The standard represents an incentive to organizations to make a difference in relation to the formal compliance with the laws, recognizing that acting in accordance with the regulations is the basic obligation and an essential part of their social responsibility.

ISO 26000:2010 integrates seven social responsibility core subjects and within each of them addresses other, broader relevant issues:

- **Organizational governance** - the system by which an organization makes and implements decisions in pursuit of its objectives. At the same time it represents the most crucial core issue that organizations should consider when applying ISO 26000;
- **Human rights** - organizations should ensure that their activities uphold the internationally recognized human rights. They should ensure that they are not complicit in human rights abuses; that staff are aware of the recommendations in the field of general culture and human rights, as well as the recommendations of the ISO 26000;
- **Labour practices** - includes all forms of policy and practice in relation to work on behalf of the organization, including wage labour. It goes beyond the scope of an organization and its relationship with employees. Include recruitment and promotion of staff, transfer of employees, training and skills development, health, safety, practices that affect working conditions, trade union activities, and the like;
- **Environment -** Organisations should ensure that their activities comply with internationally recognized principles and obligations concerning the protection of the environment. They should support a cautious approach towards environmental issues; popularize greater environmental responsibility; encourage the development and expansion of technologies that favour the environment; accept the polluter-pays principles, and so on;
- **Fair operating practices** - Organizations should ensure that their activities are in accordance with internationally recognized principles of fair dealing. For example, they should promote the application of these principals with business partners; and to consider the willingness of others to accept these principles as an important factor in deciding on partnerships;
- **Consumer issues** – They involve basic user rights: the right to fair marketing practices, protection of healthy, safe and sustainable energy, dispute resolution, the right to compensation, data protection and privacy, the right of association and the like;
- **Community involvement and development** - contribute to the strengthening of civil society based on the contention that an organization represents "a community stakeholder". A socially responsible attitude towards community organizations can contribute to its technological development, promotion and preservation of culture and the arts, developing educational programs, strengthening institutions, creating and promoting environmental protection, reducing poverty, unemployment and the like.

5. CSR IMPLEMENTATION IN SME-S - MAJOR STEPPING STONES

According to the Polášek (2010), the prescribed basic steps to be followed in the implementation of CSR in SMEs are as follows:

- **Management commitment to social responsibility** - should make efforts to ensure the management's thorough understanding of the benefits of applying the CSR principles. For larger SMEs, personal management commitment, based on an ethical approach to business, can contribute to the effectiveness of the implementation of CSR and the formation of a special team of social responsibility. It should include experts in the fields of human resource management, communication, marketing, process management, finance, manufacturing, health and safety and sales. For smaller SMEs, it is the owners, management and employees that should provide the function of such a team.
- **Identifying key stakeholders** - In today's business practices, companies are faced with the increasingly diverse range of demands and interests of its stakeholders and interested parties. They include employees, suppliers, customers, owners, narrower and wider community in which SMEs operate, a state with its institutions, groups that advocate for issues of society and the environment, future generations, etc. The identification of stakeholders and their involvement is essential for social responsibility.
- **Analysis of the current situation** - before defining the basic values and principles of corporate social responsibility, SMEs should conduct an internal and external analysis of the current situation. As part of the internal analysis, SMEs need to analyze the current situation when it comes to their involvement in the area of corporate social responsibility (legislation, current activities, tools and methods for communication, policies and documents, etc). In the external analysis, SMEs should focus attention on the identification of external factors that can affect their business (globalization, new regulations, technological advancement, etc), analysis of the activities that use competition in the area of social responsibility, the comparison of their performances, of SMEs with the best socially responsible practices (benchmarking).

- **Defining Fundamental Values and Principles** - it is essential that SMEs identify values that on which their CSR policy should be based. These values are used as the criteria for defining the proposed instruments and activities in the field of corporate social responsibility. In order to successfully direct its activities, SMEs need to identify the core values relevant for all the stakeholders.
- **Setting Key Objectives and Corporate Social Responsibility Approach** - Based on the defined values and principles, SMEs need to determine the direction in which they want to develop their CSR activities. In order to ensure effective implementation of the commitments, the SMEs must set measurable goals and identify measures for the realized performance.
- **Preparation of the Action Plan** - Considering all that has been done so far, a matrix of proposed actions related to social responsibility should be created. Most often this is done by summing up the current and by planning new activities, processes, products and impacts in terms of SMEs social responsibility, in regard to economic, social and environmental aspect. The implementation of the CSR „obligations" involves the pursuit of daily activities, processes, decision making process and so on, by which SMEs implement all their commitments deriving from the adoption of the CSR strategy.
- **Implementation Phase** - During the implementation of CSR, MSP monitors the action plan, including it in their daily activities. SMEs need to perform analysis at appropriate intervals to determine the progress in relation to their goals related to social responsibility and to identify the necessary changes to processes. When deciding which activities will be monitored, SMEs should focus on activities related to the most important and influential stakeholders.
- **Monitoring of Corporate Social Responsibility** - Performance review is used to determine the progress with the implementation of CSR principles, to identify areas in need of change and the activities that require improvement. In addition to reviewing current activities, SMEs should take into account the changes in conditions or expectations, legal and regulatory framework affecting the social responsibility and the opportunities for improvement. One of the most commonly used methods is the monitoring of the measurement with respect to the indicators.
- **Communicating and Reporting** - There are many types of communication related to social responsibility: meetings with stakeholders, the communication between management and employees in order to increase general awareness of social responsibility, communication with suppliers on the requirements for procurement, communication with the public about the emergency situations. Different methods that could be used for communication and they incorporate meetings, public events, forums, reports, newsletters, magazines, posters, advertisements, letters, voice mail, live performances, video, web sites, podcasts, instructions for use and product labels.
- **Preparation and Implementation of Improvement Measures** - Based on the periodic review of activities in the area of social responsibility and recommendations by stakeholders, SMEs should consider ways in which they can improve their performance. The review results should be used to help them achieve continuous improvement of social responsibility. These improvements can include changes to the general and specific objectives of social responsibility, expanding the scope of activities and programs in the area of social responsibility, obtaining additional resources for socially responsible activities or complete revision of the CSR strategies of SMEs.

6. ADVANTAGES AND DISADVANTAGES OF CSR IMPLEMENTATION IN SME-S

Social responsibility entails new demands that the SMEs in developing countries are expected to meet. Accepting the social and eco standards are increasingly becoming a precondition of cooperation with large companies. These are taking the form of individual codes or more widely adopted standards. Market movements can cause a situation where the social and eco- responsibility extends from SMEs that are in direct partnership with multinational companies to those which are indirectly related. This scenario occurs through local competition, strengthening of the mechanisms for the implementation of local laws, targeted investments, or through a change in user behavior. A certain number of multinational companies are very actively involved in the creation of partnerships, through enabling SMEs from developing countries access to otherwise inaccessible markets for them, funds, programs, education and training, infrastructure. Lack of access to technology, eco eligible materials, credit, information and trainings represent an insurmountable obstacle to the promotion of SMEs in terms of social responsibility and especially eco eligibility and liability, according to Filipovic (2008).

Table 1: The main characteristics of the relationship between social responsibility and SMEs (Filipovic, 2008)

DANGERS	CHANCES
'Back door' protectionism Loads as a result of needs for reconciliation and monitoring SR Paradox: Is it possible for MSPD not to benefit from the SR?	Business benefits: better compliance with user needs, cost reduction, increased productivity, innovation The positive implications of the SR to SMEs Additional benefits of SR, continuous improvement and development of local communities
OBSTACLES	**DRIVERS**
Lack of technology, expertise, training and investment necessary for improvements. A small number of initiatives aimed at SMEs. Lack of understanding of the SMEs characteristics Initiatives within the supply chain very rarely go in depth, ie. they retain on the first level Pressing of the necessity for improvement of technology, management and marketing Price competitiveness and limited pressure	Pressure by the transnational companies whose supplier chain they belong to, the requirements for certification and compliance with the Code Changing markets, the need for adjustment of production to the changing preferences of the user, the internationalization of standards Local pressures by regulation, public opinion, civil society Strategic business benefits

Improving SMEs social responsibility may prove to be a very successful business move, according to Filipovic (2008).

By applying the concept of social responsibility SMEs achieve:

- better cognition of user requirements,
- greater customer / employee / business partner loyalty
- better relate to user - supplier chain ,
- improve relations between employees and managers,
- increased ability to recruit and retain competent staff ,
- readily coping and risk management, increased capacity for learning and innovation,
- improve productivity and increase the capacity for learning, creativity and innovation ,
- increase mutual trust between companies,
- savings achieved through measures such as eco-efficiency ,
- enhance its image and reputation, improved company reputation
- opportunity to create partnerships with multinational companies ,
- increase productivity and profitability,
- greater competitiveness.

However, the aforementioned benefits will not be important for all SMEs. In the case of SMEs in the developing countries priorities are undoubtedly in the domain of mastering new production, management and marketing technologies, among which the quality management occupies an important place, according to Filipovic (2008).

7. CONCLUSIONS

ISO 26000 is intended to assist organizations in contributing to sustainable development. The intention is to encourage them to do much more than merely observing the law, given that the compliance with the law is the basic responsibility of each organization and a key part of its social responsibility. Its goal is to promote a common understanding of social responsibility, as well as to complement, but not to replace other instruments and initiatives related to social responsibility.

CSR is not a short-cut to business success, but an investment that can pay off in the longer term. It can bring advantages, for example in terms of staff retention and recruitment, staff development and motivation, customer loyalty and reduced expenditure on energy. In the knowledge economy it can increasingly be a source of innovation and it can facilitate access to and sharing of information. By managing CSR in a more strategic and conscious manner, enterprises can better reap these advantages. CSR is about continuous improvement and should be seen as part of the modern model of business excellence (according to European Commission). The personal and ethical values of SME owners, managers and employees are a strong motivation for an enterprise to pay more attention to social and environmental issues.

Small and medium-sized enterprises (hereinafter SMEs) are becoming an increasingly important part of national economies around the world. As for Europe, as early as 2001, the European Commission emphasized the need for the SMEs to fully participate in public debate on social responsibility, and to better promote their good SR practices. In the period 2004 - 2007 the number of SMEs in the total number of companies in the Republic of Serbia reached 99.7%, while the number of employees and revenues

participated with 60.6% and 67.2%, which in itself emphasizes the need for this campaign being included in the SR. Although they do not have the capacity and ability of large companies in terms of being able to make large donations, grants or engage in infrastructural projects or large projects related to the environment, SMEs are generally better integrated into local communities than large entities. Often SMEs in local communities conduct a series of socially responsible activities that are not adequately recognized as such. These activities, which are conducted periodically, in most cases point to the ethical principles of the owner rather than the idea that they could bring benefits and advantages to the owners of the business. All in all, the main obstacles to the inclusion of SMEs in CSR are the lack of awareness and lack of funds.

Keeping in mind the upcoming process of integration into the European Union, on the one hand, there is a growing opportunity for companies in Serbia to improve their approach and the presence in the single market of the European Union, but on the other hand, it is there that they are faced with the expectations of consumers, supervisors and investors regarding the implementation of CSR practices. In addition, the companies in Serbia that intend to cooperate with large foreign companies need to introduce the CSR practices because they are often in accordance their policies and a prerequisite for business cooperation (according to Strategy for development and promotion of Social Responsibility in the Republic of Serbia for the period 2010-2015).

ACKNOWLEDGEMENT

This paper is part of a project supported by the Ministry of Education, Science and Technological Development of Republic of Serbia, under the heading III 43008 and entitled "Development of methods, sensors and systems for monitoring the of water, air and soil quality".

THE ECONOMIC SUSTAINABILITY OF STANDARDS – CAN ISO METHODOLOGY HELP?

Stevan Gojkovic[1],
[1] Faculty of Organizational Sciences gojkovics@live.com

Abstract: *In publication by ISO, Economic benefits of standard-ISO methodology 2.0, is explained how one organization can measure the economic benefits that introduced standard brings with it. Methodology consists of four basic steps that defines what the company needs to do to make the results relevant and accurate. Using various tools and techniques that this methodology suggests, one can easily distinguish economic improvement that is caused by standard and economic improvement caused by other factors. But in practice it is more difficult than in theory. It is very hard, nearly impossible to measure economic impacts of standard. There are many issues that should be clear such as cost of assessment, determine of operational indicators and validity of results.*

Keywords: Standards, Sustainability, Economic Sustainability, Economic benefit of Standardization

1. INTRODUCTION

1.1. Importance of Standards in Business

There are many definitions of standards as term of “standards” is used in the world in almost all spheres of life. According to CEN, standard is “a document that sets out requirements for a specific item, material, component, system or service, or describes in detail a particular method or procedure. Standards facilitate international trade by ensuring compatibility and interoperability of components, products and services. They bring benefits to businesses and consumers in terms of reducing costs, enhancing performance and improving safety” (CEN-CENELEC,2014).

According to ISO “a standard is a document that provides requirements, specifications, guidelines or characteristics that can be used consistently to ensure that materials, products, processes and services are fit for their purpose” (ISO,2014). This is one of the many definitions of IEC gives two little rougher definition of standards but also the definition of a standard observer from two aspects, in terms of formal standard bodies and industry. Standard is an agreement developed by several parties with the intent that all parties comply, and also standard is a product or service with a significant market share (IEC,2007). In terms of formal standard bodies a standard is “a document established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context” (ISO/IEC, 2004b, p.8). From the aspect of industry “A standard can be of any form or type. A standard is also one of the agents used to bring about market change” (IEC, 2007)

Standards are produced for many different products and services, and may be created for company, national, regional or global application. They may be used on a voluntary basis, or made mandatory by company policy, national or international regulation, or by law (ETSI,2014).

In Europe there are three different categories of standard (ETSI,2014):

- international standard – a standard adopted by an international standardization organization
- European standard – a standard adopted by a European standardization body
- national standard – a standard adopted by a national standardization body and made available to the public

Standards are by nature associated with the sustainability of the business system and the environment in which it operates, simply because the standards are trying to meet the criteria of sustainability arises. The environmental stewardship and social responsibility values of sustainability are reflected in the missions of

the participating organizations. In addition, many of the systems have developed environmental vision statements that articulate an organizational commitment to sustainability (Boone, Jayaraman, Ganeshan, 2012)

1.2. Relationship between standardization and sustainability

A mission is also public affirmation about how the organization defines itself. Public promotion of an organization's sustainability must be carefully managed. On the one hand, sustainability may help to bolster the organization's brand and reputation. Research has indicated that intangible assets such as reputation may provide a more enduring competitive advantage than other business assets and support long-term success. Signaling the strategic value of sustainability conveys a powerful message to communities and customers (Boone, Jayaraman, Ganeshan, 2012). Authors Darcy Hitchcock and Marsha Willard (2006) in their book "The business guide to sustainability practical strategies and tools for organizations" on sustainability told :" Unless you want to be buffered by each change you need framework for making sense what is happening in world, so that you can foresee changes and take actions before they happen. Sustainability is that kind of framework. It doesn't encompass everything you'll need to track to be successful and it's not a crystal ball. However sustainability helps you to see relationships between issues and more accurately forecast what may you occur in the future. It examines our world as a whole system revealing threats and opportunities. It forces you to see relationship between social, economic and environmental trends."

Hitchcock and Willard (2006) recognize the following Benefits of pursuing sustainability:

- Reduce energy, waste and cost
- Differentiate yourself
- Sidestep future regulations
- Create innovative product or process
- Open new markets
- Attract and retain best employees
- Improve your image with shareholders and public
- Reduce legal risk and insurance costs
- Provide a higher quality of life

After these advantages pursuing sustainability it is unavoidable mentioning definition of economic sustainability. The widely accepted definition of economic sustainability is maintenance of capital, or keeping capital intact. Thus Hicks's definition of income–the amount one can consume during a period and still be as well off at the end of the period–can define economic sustainability, as it devolves on consuming value-added (interest), rather than capital (Goodland, 2002). "Economic sustainability is the word used to pinpoint numerous strategies that make it conceivable to use accessible resources to their best advantage. The idea is to uphold the use of those resources in a way that is both skillful and responsible, and likely to deliver long-term benefits"(Ask.com, 2014). Every society can be described as comprising four dimensions, the economic, social, environmental and institutional. "Each of them is a complex, dynamic, self-organizing and evolving entity in its own right, making the coupled system one of tremendous complexity. For this system to be sustainable, each of the four subsystems has to maintain its capability to survive and evolve while the interlink ages of the subsystems must enable a permanent co-evolution. In the macro-economic debate, few other economic sustainability criteria are mentioned, like innovativeness, competitiveness or public debt, while criteria like inflation or trade imbalances are politically prominent, but hardly ever located in a sustainability context with its broader perspective and the need to balance different interests. Again, other, partly more traditional criteria like aggregate demand, consumption levels and savings rates play a minor role in the current debate. So whereas there are ideas to be found in the economics literature regarding the environmental, social and sometimes also the institutional sustainability of the economic system, there is hardly any information available on the economic sustainability of the economy (and thus not on the overall sustainability of the economy, which comprises all four components). Even less so, criteria of economic sustainability have been developed for the other dimensions. This is all the more surprising, as the economic sustainability of social security systems or environmental protection legislation is a prominent issue of the policy debate." (Spangenberg J., 2005)

Close connection between standardization and sustainability is recognized in numbered benefits of standardization. It can be seen that some benefits of pursuing sustainability and sustainable development, are also some of the benefits of standardization by ISO. International Standards bring technological, economic and societal benefits. They help to harmonize technical specifications of products and services

making industry more efficient and breaking down barriers to international trade. Conformity to International Standards helps reassure consumers that products are safe, efficient and good for the environment. ISO recognize standardization benefits for business, society and government. For business main benefits is ensuring that business operations are as efficient as possible, increase productivity and help companies access new markets. (ISO,2014)

According to ISO (2014) benefits include :

- Cost savings - International Standards help optimize operations and therefore improve the bottom line
- Enhanced customer satisfaction - International Standards help improve quality, enhance customer satisfaction and increase sales
- Access to new markets - International Standards help prevent trade barriers and open up global markets
- Increased market share - International Standards help increase productivity and competitive advantage
- Environmental benefits - International Standards help reduce negative impacts on the environment

Majority of stated benefits can be linked with the economic improvement of one organization in direct or indirect way.

2. ISO METHODOLOGY FOR MEASURING ECONOMIC BENEFITS OF STANDARDS

"ISO has developed a simple, step-by-step methodology and a robust set of tools to measure the economic benefits of standards. The methodology can be applied to all companies and industry sectors in order to identify the contribution that standards make to their performance." This is introduction line in the book published by International organization for standardization "Economic benefits of standard-ISO methodology 2.0",which can be used to measure economic impact of standards involved in organization.
In a few steps using certain methodology suggested in this publication organization can easily measure improvement expressed in money. The primary scope of the ISO Methodology is assessing the economic benefits of standards (i.e. the contribution of standards to the creation of economic value) for a company.

ISO methodology is explained in Figure 1 with all necessary steps.

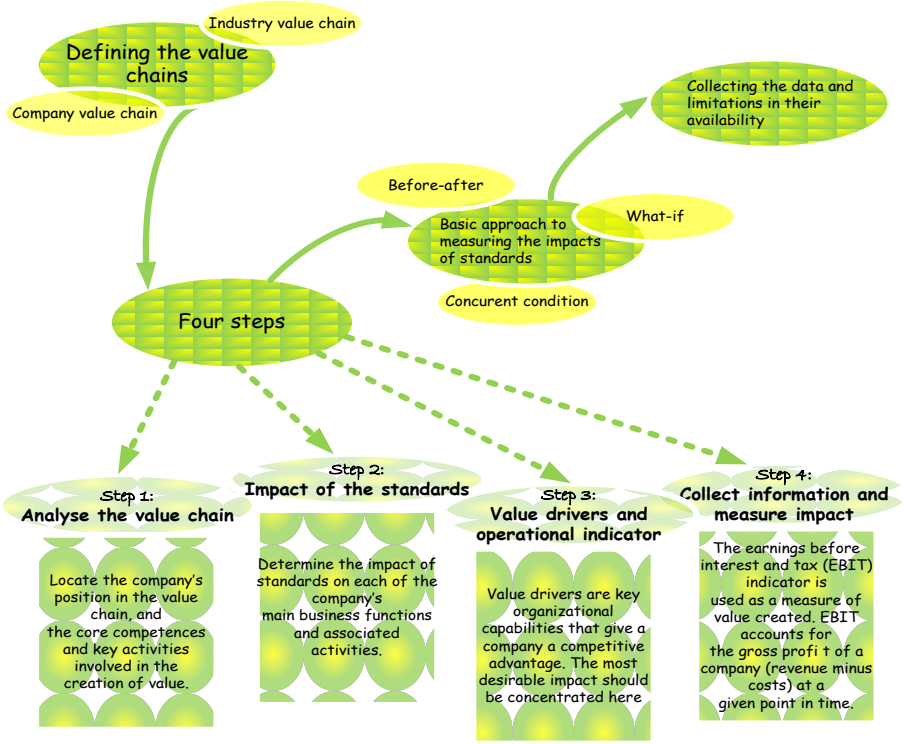

Figure 1: ISO methodology (Modified in accordance to Economic benefits of standard-ISO methodology 2.0)

There are two types of value chain explained in methodology, company value chain and industry value chain. A company value chain represents the chain of activities conducted inside a company. Those chains represent internal processes of every company and it explains their relationships.(ISO Methodology,2013)

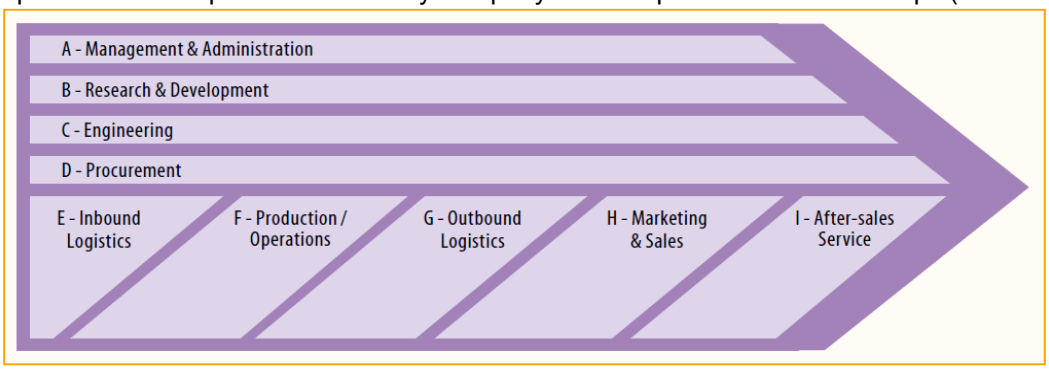

Figure 2: The value chain of manufacturing company (ISO Methodology,2013)

On the other hand value chain model can be extended to a whole industry sector, in which case the various stages of production and services and the network of suppliers and customers are included in the perspective. This is referred to as the " industry value chain " (ISO Methodology,2013)

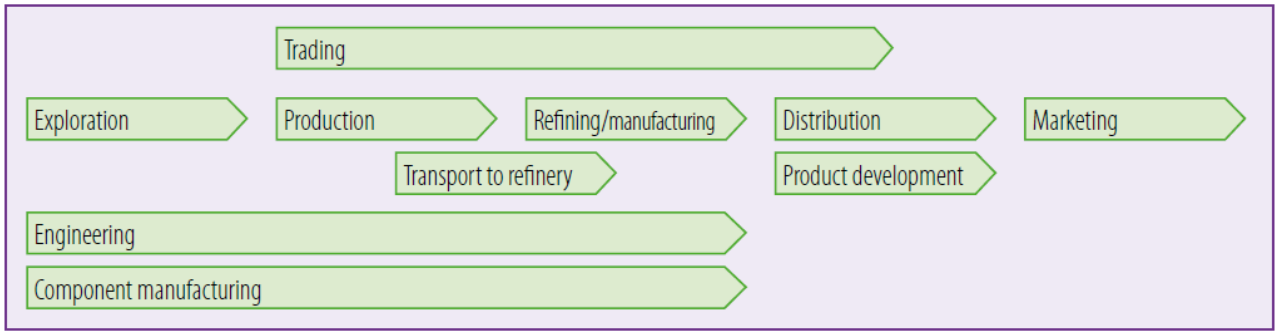

Figure 3: Oil and gas engineering industry value chain and scope (according to ISO methodology,2013)

After those steps company should have all required information needed for measuring benefits of standards. There are some techniques that organization can use for analyzing impact of standard before and after their introduction in certain company. It can be used before-after comparison, comparison of concurrent condition and what if analysis. Technique that ISO methodology recommends is before-after comparison because of information that are clearly stated after assessment. (ISO Methodology,2013)

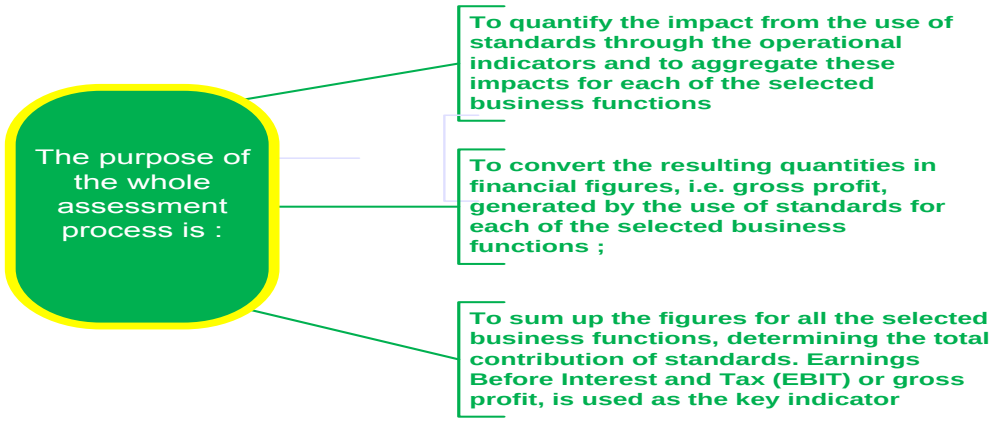

Figure 4: Purpose of assessment (Modified according to ISO Methodology,2013)

Organization after the measurement and data collection use the main indicator. The main indicator in ISO methodology is EBIT."EBIT is an indicator of a company's profitability, calculated as revenue minus expenses, excluding tax and interest. EBIT is also referred to as "operating earnings", "operating profit" and "operating income".

Income Statement for the Year Ending December 31, 2009	
Sales Revenue	$1,000,000
Salaries	(100,000)
Rent & Utilities	(100,000)
Depreciation	(50,000)
Operating Profit (EBIT)	**$ 750,000**
Interest Expense	(50,000)
Earnings Before Taxes (EBT)	**$ 700,000**
Taxes	(100,000)
Net Income	**$ 600,000**

Figure 5: Example of EBIT calculation (Investopedia, 2014)

EBIT = Operating Revenue – Operating Expenses (OPEX) + Non-operating Income

Also known as Profit Before Interest & Taxes (PBIT), EBIT equals Net Income with interest and taxes added back to it.

In other words, EBIT is all profits before taking into account interest payments and income taxes. An important factor contributing to the widespread use of EBIT is the way in which it nulls the effects of the different capital structures and tax rates used by different companies. By excluding both taxes and interest expenses, the figure hones in on the company's ability to profit and thus makes for easier cross-company comparisons." (Investopedia US, A Division of IAC,2014)

3. DOES ISO METHODOLOGY WORK?

According to ISO methodology with steps explained in this publication organization can easily measure impact of every standard introduced in system. It is also explained how organization should measure and distinguish every impact that is not caused by standard implementation and advised to be very careful in order to calculate impacts properly. (ISO Methodology,2013)

In order to implement such a methodology proposed by the ISO, the organization must meet certain requirements. One of the conditions is that the organization must be certified by a recognized standard for at least three years (ISO Methodology,2013). If organization wants to examine the impact of standards in the last three years, it needs to analyze the data at least for past three years for the sake of accuracy and relevance of the results. The question that arises is whether small and medium enterprises keep records of all operational indicators that are needed to calculate progress in accordance with ISO publication. Information system should provide information that will be easy to monitor the effect of standard. Most companies their information systems about operational indicators that has influence on economic aspect of standard, established after the introduction of relevant standards so that information from previous periods are generally useless or does not exist. Such an approach, which is present in most of the companies that have a need for an assessment of the economic effects of standards, hampers the analysis proposed by the ISO.

Determine the operational indicators is another problem that arises in ISO methodology. Operational indicators referred in this publication should not be taken for granted simply because the impact on a particular part of the organizational unit can not be measured only through the standard and its impact on the process. It also depends of all others factors that have influence on certain process. In company operational indicators point to improvement or deterioration which occur due to the influence of various factors on the process. Some operational indicators such as employee morale, which in some cases significantly affects productivity, is immeasurable. It is impossible to determine that implementation of certain standard is credited for raised staff morale .It's just another reason why you can not accurately gauge the impact of standards on entire organization. If one can not accurately determine the impact on individual organizational levels, each error is multiplied by switching to the next hierarchical level in the organization.

While introducing generic type of standard in organization it is very difficult to determine what direct impact of standard is and what is a impact of some others factor involved. Other factor includes political, economic, social and technical changes in business environment. For example, a productivity increase is achieved for certain activities after the introduction of standards. This improvement is determined by changes in the work practices that have been driven by the new standards – but also by organizational changes and the use of newly introduced technology. Also improvement of organization can be caused by various market developments that could lead to weakened competition, and thus increase organization market share.

4. CONCLUSION

According to ISO methodology with steps explained in this publication organization can easily measure impact of every standard introduced in system. It is also explained how organization should measure and distinguish every impact that is not caused by standard implementation and advised to be very careful in order to calculate impacts properly. However, in business practice it is not always easy to define performance measures, obtain data related to performance indicators and make reliable conclusion about economic effects of standards. There are many issues that should be clear:

- ISO methodology is retrospective in meaning that for adequate implementation of this methodology need at least three years of standard' implementation for first conclusion about economic effects
- Operational indicators referred in this publication should not be taken for granted simply because effects of standard can not be isolated from other influential factors as well as changes in business environment.
- Some operational indicators are immeasurable
- ISO methodology is not taking into account dynamics of performance measures and influence of others factors on particular performance measures during the measuring period (e.g. three years).

Abstract:*This article discusses the topic of ISO 20000 standard implementation, which is very important for an organization in order to achieve continuous improvement and growth. ISO 20000 standard is a subject of numerous studies which highlight the its importance as well as its main purpose. This paper presents briefly the development and structure of ISO 20000 standard and summarizes its implementation in Serbian companies.*

Keywords*:ISO 20000 standard, IT service, ISO 20000 standard implementation*

1. INTRODUCTION

In today's business organizations are constantly trying to be better and better by improving their products and their way of work, which made a huge space for new companies to enter the market. In this manner, small changes can make a big difference. The same goes with usage of ISO/IEC 20000. There is a thesis that organizations that are using standards do a better business.This paper discusses the development and structure of ISO 20000 standard in order to stress the importance of having well defined goals and implementation of standards as a step towards stable growth. Afterwards, the successful implementation of ISO 20000 standard in Serbia has been presented by giving the description and basic information about certified companies.

Development of ISO/IEC 20000 is shown in second paragraph, explaining its roots and extensions afterwards. It also shows division of standard into 13 IT processes. The third paragraph shows the structure of the standard divided into 8 areas. The nextparagraph suggests implementation steps. First of them is to answer several questions of high importance. Besides, there is a growing trend of companies being certified, also presented in the benefits that organizations can gain by attainingthe certificate. Fifth paragraph presents current state of usage of ISO/IEC 20000 in companies in Serbia with examples of their certificates. The last paragraph is conclusion of information given and thoughts about certification and use of standard.

2. DEVELOPMENT OF ISO 20000

ISO/IEC 20000 is the first International Standard for IT Service Management processes. It was developed in 2005 by ISO JTC 1/SC 7 Technical Committee. It was based on BS15000 standard (published in 2000) which was retreated later. ISO/IEC 20000 helps organizations to effectively manage services to meet business and customer requirements.

In June 2011 comes the first update to ISO/IEC 20000, called ISO/IEC 20000-1:2011. (Part 1: Service management system requirements) It describes systems for managing services (SMS – Service Management System). It includes all requirements company should fulfil in terms of planning, establishment, application, implementation, monitoring, review, maintenance and improvement of Service Management System. This standard contains 256 requests, divided in 6 groups, which relate to design, change, delivery and service improvement. Also, it can be divided into 13 IT processes (from four key service management processes)(source: http://www.standards.org):

1. Service Delivery Processes – includes Service Level Management, Availability Management, Capacity Management
2. Relationship Processes – involves interfaces between the service provider and customers and suppliers
3. Resolution Processes – focuses on incidents being resolved or prevented
4. Control Processes – involves managing changes, assets and configurations

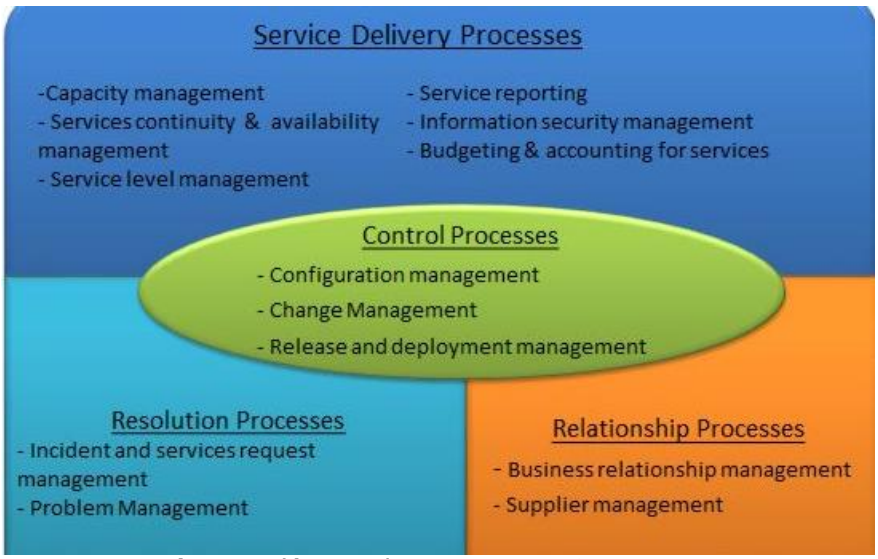

Figure 1: Key service management processes

In 2012, a new version was introduced – ISO/IEC 20000-2:2012 (Part 2: Guidance on the application of service management systems) Includes instructions for application of SMS based on the requirements in ISO/IEC 20000-1. It includes examples and suggestions for system usage. ISO/IEC 20000-2:2012 gives organizations an opportunity to interpret and apply ISO/IEC 20000-1:2011 more accurately and to use it more effectively.

ISO/IEC TR 20000-3:2009 (Part 3: Guidance on scope definition and applicability of ISO/IEC 20000-1) Provides guidance on scope definition and applicability of ISO/IEC 20000-1. It can help organizations that are considering implementing a Service Management System into their business.

ISO/IEC TR 20000-4:2010 (Part 4: Process reference model) Facilitates the development of a process assessment model according to ISO/IEC 15504 process assessment principles. Model described by this standard is a logical representation of the process' elements within the service management that can be performed at a basic level. It describes all the processes on the abstract level, including the SMS processes described in ISO/IEC 20000-1, as a primary purpose and output elements.

ISO/IEC TR 20000-5:2010 (Part 5: Exemplar implementation plan for ISO/IEC 20000-1) Is an example of implementation plan providing guidance to service providers on how to implement a SMS to fulfil requirements of ISO/20000-1 or those intending to use ISO/20000 as a business goal. ISO/IEC TR 20000-5:2010 is only for guidance. The service provider has the option of choosing their own implementation sequence to implement a service management system.

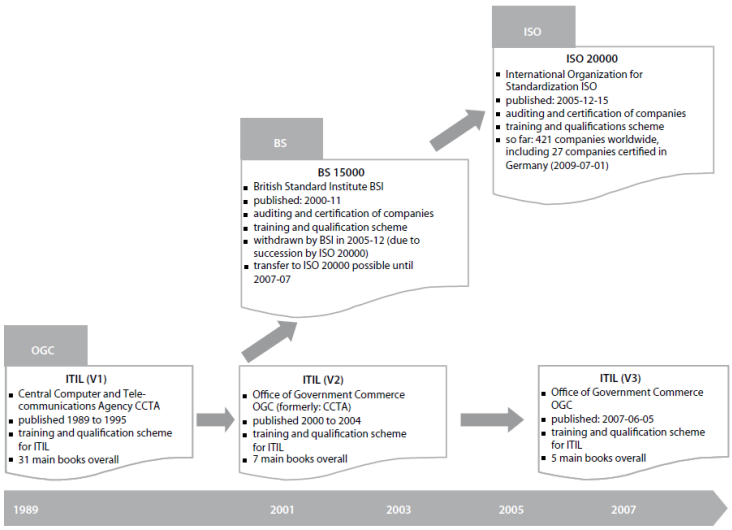

Figure 2 shows the origin and development of ISO 20000.

Figure 2: Origin and development of ISO 2000

3. THE STRUCTURE OF ISO 20000 STANDARD

ISO 20000 standardis codified into two documents:

1. ISO 20000–1 (2005)
2. ISO 20000–2 (2005).

The first document is known as “mandatory criteria” (Buchsein et al., 2007; Greb et al., 2006) because it represents the formal specification of the standard, where all the requirements that one organization needs to comply with in order to attain certificate are precisely described. In other words, this document provides an absolute set of standards that a company must meet for successfull accreditation.The second document represents an addition to the first one, in which all of the requirements are classified and the recommendations for successfull implementation are provided.for verification of conformity with the standard (MacFarlane and Dugmore, 2006). This means that here a company can consider wider optional set of best practise approaches and decide which of them to include in order to obtain better assessment.

The superordinate management processes are supposed to secure a strategic alignment of IT services, in particular an alignment to the objectives of (internal and external) customers as well as economic and quality objectives.

The structure of ISO/IEC 20000 can be divided in several areas (source: http://www.barclayrae.com):

1. Requirements for a management system –this area describes that the management of a company must deploy all suitable processes and policieson aregularly basis in order to be able to manage IT services in line with the business needs.
2. Planning and implementing service management – this area describes that the organization must plan and manage all service activity. Within ISO/IEC 20000 this implies the use of Deming’s famous PDCA (Plan, Do, Check, Act) approach.
3. Planning and implementing new or changed services – this area describes that the organization should plan any new or changed activities are carefully in terms of decreasing their impact on business and maximising the expected service quality benefits as soon as possible.
4. Service Delivery processes
    a. Service Level management – this section describes that a company must have defined, agreed level of services in order to be able to record and manage it.
    b. Service Reporting – this section describes the importance of producing agreed, timely, reliable and accurate reports in order to realise informed decision making and effective communication.
    c. Service continuity and availability management – this section describes that a company should be able to meet agreed obligations to customersin all circumstances.
    d. Budgeting and accounting for IT services – this section describes that a company should budget and account for the cost of service provision.
    e. Capacity management – this section describes that a company must have at all times, sufficient capacity to meet the current and future agreed demands of the business.
    f. Information security management – this section describes the importance of managing information security effectively within all service activities.
5. Relationship Processes
    a. Business relationship management – this section describes the importance of establishing and maintaining a good relationship between the service provider and the customer.
    b. Supplier management – this section describes the importance of managingthird party suppliers to ensure the provision of quality services.
6. Resolution Processes
    a. Incident management – this section describes that a company should have the ability to restore agreed service to the business or to respond to service requestsas soon as possible.
    b. Problem management – this section describes the importance of proactive identification and analysis of the cause of service incidents, as well as the importance of managing problems to closure in order to minimise disruption to the business.
7. Control Processes
    a. Configuration management – this section describes that a company should maintain accurate configuration information, but alsodefine and control the components of the service and infrastructure.
    b. Change management – this section describes that all changes should be assessed, approved, implemented and reviewed in a controlled manner.
8. Release Process
    a. Release management – this section describes that a company should deliver, distribute and track one or more changes in a release into the live environment.

Figure 3 shows the structure of ISO 20000 standard, described above.

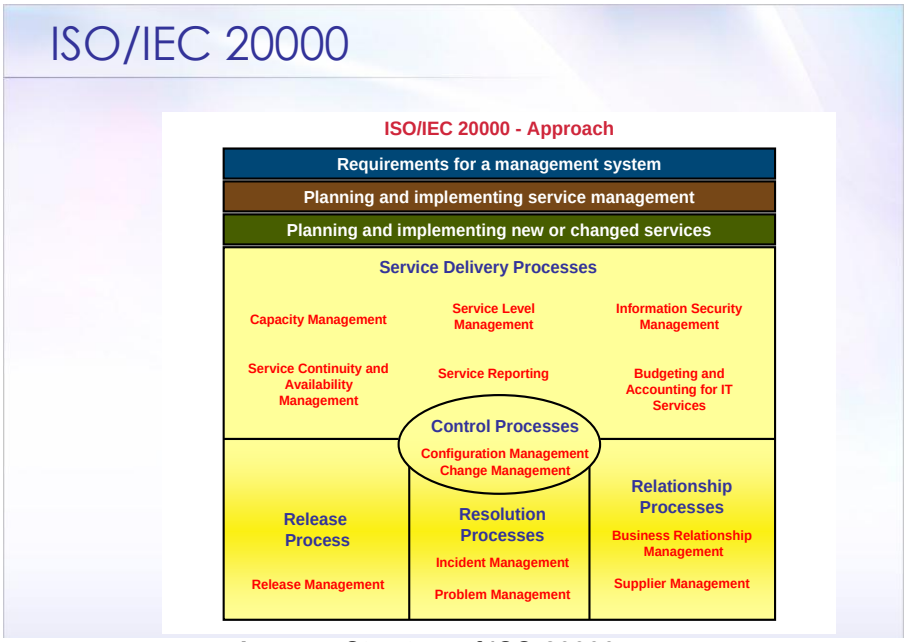

Figure 3: Structure of ISO 20000

4. IMPLEMENTATION EXPERIENCES

When considering the implementation of ISO/IEC 20000 standard, a company should seriously answer the following key questions:

- Is this right for us? – are we eligible, is this a mandatory business need, will we get clear benefits
- Where do we stand currently against the standards? – how actually are we ready for implementation and what are the current problems that need to be solved
- What benefits do we expect from ISO/IEC 20000? – what are the industry standing, cost and quality benefitsof ISO 20000 standardimplementation
- What work is involved? – how much planning, costs, time and resources are required to achieve ISO/IEC 20000 accreditation

The implementation of ISO 20000 has different internal and external effects on organization as a whole (Disterer, 2009). From an internal perspective, before organization becomes ISO 20000 certified, the anchoring of continuous improvement processes for IT services within the organization intensifies while pursuing the certificate. The employees that are involved in continuous improvement become more motivated and when the goal is reached it represents an impulse and reinforcement by highlighting the achievement of the certificate. For the senior management certification can serve as a relatively clear-cut objective of a complex transformation process. The success of implementation can be easily observed by means of the attained certificate and the position and reputation of organization on the market that improves and becomes more trustworthy and recognized by certain level of service quality. Since the certificate represents a proof of conformity with implemented standards, it is clear that it can serve the company as a marketing tool. This is closely related to an external perspective of standard implementation impacts on organization. Emphasizing that an independent body has certificated the company by using well defined procedures, customers are provided with evidence that all the conditions and requirementsof ISO 20000 standard are met. This is extremely important when customers tend to choose IT providers based on their compliance with the standard.
Figure 4 shows the number of ISO 20000 certified companies in Europe, Asia and the rest of the world (RoW) (Disterer, 2009).

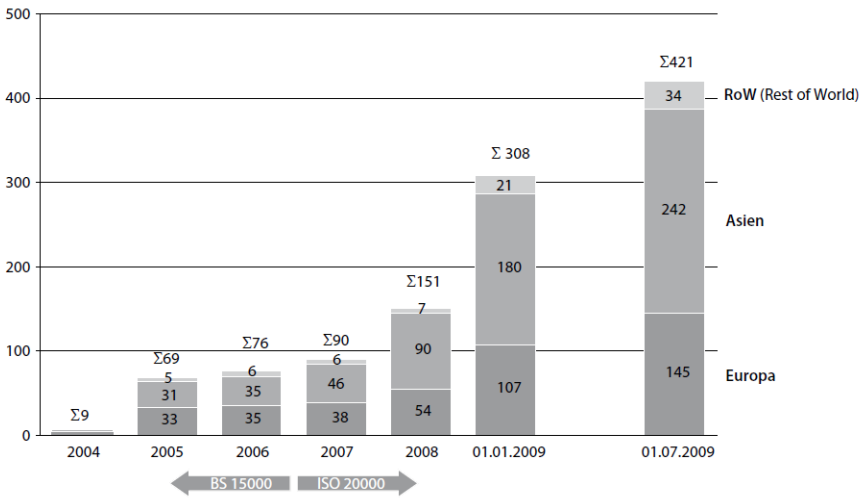

Figure4: Certified companies

Benefits

Usage of ISO/IEC 20000 benefits organization in many ways. It reduces costs, risk and time spent to introduce products/services to the market. All of this contributes to company's competitiveness. It changes way of doing services from technology driven to business driven, which makes service provides more responsive. IT becomes pro-active rather than re-active, and it brings KPI measurement criteria. Company using ISO/IEC 20000 shows service reliability and consistency, and it is more preferable to be chosen over one without this standard. "Certification audits are continual and should be treated as a mechanism for educating and raising awareness of employees. Certification can also reduce the amount of supplier audits thereby reducing costs. Finally, the use of qualified and independent auditors can be used as a benchmark" (Menken, 2009).

5.IMPLEMENTATION OF ISO 20000 IN COMPANIES IN SERBIA

ASW Engineering

Company ASW Engineering was founded in 1990 and now it operates on large IT service market in Serbia, Slovenia and Bosnia and Herzegovina (source: http://www.asw.eu). The services, that company ASW Engineering offers, include implementation, customer support and consulting. Company's most important products are shown in figure 5.

Figure 5: ASW Engineering products

Having the goal to broaden the range of solutions, company growth and expansion in region and in EU, ASW company started with serious planning and decision making regarding the regarding standardization of processes in quality management system and the quality of its products. Before making a final decision the following reason for standards implementation were identified:

- the trend of growing needs for services in IT sector
- the key income sources are services

Because of these reason it has been decided to implement first ISO 9001 (QMS) in 2005 and then ISO 20000 (SMS) in 2013. The implementation of ISO/IEC 20000 in ASW lasted over 3 months and over 50 persons participated.

Basic processes improved and implemented while attaining ISO/IEC 20000-1 include:

- Service provision processes
  - capacity management
  - managing the level of services
  - reporting about provided services
  - managing the continuity and accessibility of services
  - budgeting and accounting for services
  - managing the security of information
- Connection processes
  - managing business relationships
  - managing the suppliers
- Problem solving processes (diagnosing the source of problems and decreasing the number of incidents):
  - managing the incidents and needs for services
  - managing problems
- Control processes (controlling the change, managing new versions):
  - managing configuration
  - managing changes
  - managing versions

The changes and improvements in capacity management were made in recording the knowledge of employees, increasing the independency of individuals, creating the catalogue of products and services, company's responsiveness to short deadlines. When it comes to managing the continuity and accessibility of service handling of irregular situations in providing services become more efficient and the business continuity plan was created.Managing the level of services and reporting about provided services was improved by enriching and specifying the content of service, speeding up answering to customer needs, performing calculation on used time, creating a team for customer support, providing the customers withasw:officius–toolfor customer support and asw:portal.

The expected and achieved benefits from implementing ISO/IEC 20000-1 can be summarized with the following:

- increasing the client's satisfaction by increasing the level of IT services
- optimal resource usage
- continuous service provision
- participating in projects that require ISO/IEC 20000 standardimplementation
- better position on IT market
- integration with existing system ISO/IEC 9001, which leads to Integrated management system

Figure 6 shows ASW Engineering's ISO/IEC 20000-1certificate.

IT Service Management System

Certificate of Approval

Ovim se potvrđuje da je IT Sistem Menadžmenta Uslugom:

ASW-Inženjering doo

Takovska 45A, Beograd
Srbija

ocenjen i da ispunjava zahteve:

ISO/IEC 20000-1:2011

Sertifikat je važeći za sledeći delokrug rada:

Sistem upravljanja uslugama koji podržava pružanje IT usluga, konsultacija, korisničke podrške, razvoj i implementacija softvera u okviru tehničkih i organizacionih granica ASW-Inženjering doo

Datum izdavanja sertifikata: 06. novembar 2013.
Sertifikat važi do: 05. novembar 2016.
DAS sertifikacija od: 06. novembar 2013.
Broj sertifikata: SO1-1333-006-DC-IT

Overava:

DAS CERTIFICATION LTD

Ovaj sertifikat je u vlasništvu DAS Certification Ltd. i predmet je redovnih nadzornih provera
Re-sertifikaciona provera do 21. oktobra 2016.

DAS Certification Ltd., Company Number: 3384526, 1 Wellington, Clare, Horndean, Hampshire PO8 0UR UK

Other ISO 20000 certified companies in Serbia

The PREMIUM Software doo company has attained ISO/IEC 20000 certificate on 11 Nov 2013 (source:http://www.isoiec20000certification.com). The company has been certified under the APM group ISO/IEC 20000certification scheme. This certificate guarantees IT Service Management that includes the provision of enterprise and internet applications services to all external clients within the technical and organizational boundaries of PREMIUM Software doo, Serbia.

Societe Generale deSurveillance, Swiss has provided the PARALLEL d.o.o. company with ISO/IEC 20000 on 07 Oct 2013 (source: http://parallel.rs/). PARALLEL d.o.o. company is engaged in consulting and implementation of IT solutions, technical support and administration, Oracle training and licencing Oracle softwwares.

On 12 Dec 2012 the Xpro companyhas attained ISO/IEC 20000 certificate concerning the areas of sales, implementation and managed print services provision, creation and integration of document management system, application development, processing and providing services in the area of variable and transactional printing and mail packaging (source: http://www.xpro.rs). Xpro company is the Xerox corporation exclusive distributer, which means that the organization and the quality of sales and servicing are in compliance with the standards of Xerox corporation. Figure 7 shows their ISO/IEC 20000 certificate.

LL-C (Certification)

Ovim putem verifikuje se da je sistem upravljanja IT uslugama u

Xpro d.o.o.
Pavljanina Baja 53a
11000 Beograd
Srbija

ocenjen i utvrdjeno je da je u skladu sa standardom
ISO/IEC 20000-1:2011

Primenjuje se na:

Sistem upravljanja uslužnim delatnostima u oblasti savetovanja, prodaje, integracije i implementacije poslovnih rešenja u oblastima: Upravljanje procesima štampe (MPS), Upravljanje poslovnom dokumentacijom (DMS) I Upravljanje razvojem aplikacija, procesiranjem i pružanjem usluga varijabilne štampe i pakovanja pošiljki.

Sertifikat je izdat pod brojem **3810053** za period registracije od 12 Decembar 2012 do 12 Decembar 2015 godine

Figure 7: Xpro's ISO/IEC 20000 certificate.

6. CONCLUSION

There is a growing trend in using standards, especially ISO/IEC 20000. Today, we are all witnesses to market globalization. That is why companies from Europe and other continents started introducing standard to their business. Every organization, considering whether to implement ISO/IEC 20000 standard or not, should review all the benefits that can be gained from attaining the certificate as well as the costs of implementation and assessment. In Serbia, not many companies have attained ISO/IEC 20000 certificate, but those who have, prove its good practice. The question regarding the lack of ISO 20000 standard implementation in Serbian companies remains opened. Reasons for such behaviour may lie in the low awareness of the importance of obtaining standard certificate and therefore standardizing all key processes of one company and taking a stable place on the market by providing customers with products of high guaranteed quality. Exploring these reasons will be our focus in future work.

STRATEGIC MANAGEMENT

STRATEGIC SHIFTS IN STRATEGIC RESEARCH – SHORT REVIEW OF ORGANIZATIONAL AND PROGRAM CHANGES

Nebojsa Nikolic
Strategic Research Institute, Ministry of Defense, nidzan@ptt.rs

Abstract: *This paper presents program orientations and reorientations of the Strategic Research Institute. We envelop a number of representative research projects for each of few main phases of development and transformation of the mentioned organization. At the moment, Strategic Research Institute tends to be a member of academic comunity of organizations accredited according to the actual standards for scientific research in Serbia. It is good time to look in past, think about that and realize what could be possible ways for future program orientation, projects selection, organizational development and organizational allocation inside an bigger organization as it is Ministry of Defence.*

Keywords*: Defence, Military, Strategic Research, Projects, Accreditation, Science*

1. INTRODUCTION

Strategic Research Institute (SRI) is an organization in the Defence Policy Sector of the Ministry of Defence (MoD) of Republic of Serbia. Its mission is to make research in different scientific areas such as next: national security, defence strategy, various military issues related to the organization, management, doctrine, resources, different aspects of human resources management, military history, etc. SRI is an integral part of the Ministry of Defence and functioning according to the rules of the Ministry, serving and supporting the MoD needs and preferences with particular sense for specific needs of the Serbian Army. At the same time, the Institute tends to operate according to the high standards of scientific work declared and defined at the level of state law of Republic of Serbia. Also, SRI always has strong and dynamic cooperation with the Military academy in Belgrade, as well as with a number of civilian faculties and institutes.

At the moment, SRI has about two dozens of researchers, organized in three sections: security analyses and integration section, defence studies section, and military history section. Span of past few years was a period of intensive actions to obtain researcher's formal competencies. The goal has been to achieve at least needed formal condition of minimal number of qualified researchers, that is: 7 research fellows and 5 junior research fellows. At this moment, SRI reached the goal obtaining 8 research fellows, two professors and 5 junior research fellows for few different sub-disciplines of social sciences and humanities, which imply that the Institute is ready to apply for accreditation at Ministry of education and science.

Life-cycle and development of Strategic Research Institute could be presented through few phases:

- First phase was from 1977 to 1984. A strategic research organization at that time has the name: "Center for Strategic Studies", and was organizationally allocated in General Staff of Yugoslav People's Army. At that time, Center has been much more dedicated to operational need of GS, than to pure academic work. A little of those works have been available, particularly for public usage, nor it has been strongly in line with pure academic standards. However, even existence of the Center is a proof of intention and will to establish a research organization for strategic studies near to the top of military hierarchy.
- Second phase was from 1984 to 1990. On the basis of one ministerial order from June, 1984, current Center for Strategic Studies changed its name to: "Institute for Strategic Research". Organizational allocation of the center was also changed, and it became a part of a structure of the military education system (Center of Higher Military Schools). Internal organization consisted of next entities: Section for researching the National Defence and Societal Self-Protection (that was a kind of national security strategy in that time); Section for researching armed combat; and Section for researching military policies and strategies.
- Third phase roughly starts around 1990 and ended in 2006. During this phase, the Center for strategic research renamed its title and became the "Institute for Military Art" (September 1992, on the basis of an order of the Chief of General Staff). In this period the Institute consists of next subdivisions: Section for military strategy; Section for operations art; Section for tactics; Section for combat information systems. This phase is complex and it consists of two sub-periods: 1990-2000, and 2000-2006.
- Fourth phase started in 2006 and continue up to now (2014). This is actual phase, and the name of the strategic research organization is: "Strategic Research Institute". The SRI became part of Defence Policy Sector of MoD. Also, it changed its program orientation as well as a structure. Part of human and

material resources of disbanded Military History Institute, has entered the Strategic Research Institute and became its integral part.

2. RESEARCH TOPICS IN PERIOD 1984-1990.

In the period 1984-1990, the organization exit General Staff and became part of wider military education establishment (Center of Higher Military Schools), and got the new name: “Institute for Strategic Research”. Program orientation was towards research of main concept of national defence in that time; investigating armed combat operations, and studying defence policies and strategies including those of foreign countries.

Research projects are in the line with national defence strategy and military doctrines in that time (the Concept of overall national defence and social self-protection). It was a time of cold war and sharp divide at the international level on two military-political blocks (NATO and Warsaw pact). At the level of military doctrine, it is a time when armed conflict’s research was under dominant perception of large scale conflict.
Also, it is a time of strong influence of ideology, and promotionally oriented research that should confirmed actual state of the art rather than to expose actual concept to the research critics and objective evaluation.

Research topics were next:
- Concept of National Defence and Societal Self-Protection (Concept of NDSSP, 1983-1990.)
- Strategy of National Defence and Societal Self-Protection (Strategy of NDSSP, 1984-1987.)
- Improvement of Counter Airborne Combat System in the system of NDSSP (1984-1986.)
- Counter Electronic Combat in the System of NDSSP (1983-1986.)
- Initial Period of War (1986-1988.)
- Combat Operations Modeling at Operational and Tactical Level (1986-1987.)
- Possible Attritions of Personnel and Equipment in General National Defencive Warfare (GNDW, 1986-1987.)
- Methods of Staff works on Estimation of Personnel Attritions and Filling Losses in Combat (1987.)
- Tito’s Military Works (1986-1991.)
- Education System in Armed Forces of Socialistic Federal Republic of Yugoslavia (SFRY, 1987-1990.)
- Use of Armed Forces in Emergency Situation (1989-1990.)
- Scientific Basement of Control and Evaluation of Combat Readiness of Armed Forces of SFRY (1989-1991.)

Research projects in this phase were complex with big project teams and were well funded. And, as a result there had been produced 142 research studies and monographs. However, much of those project’s results were not approved for public use, and were dedicated for internal usage. At the end of story, a destiny of many classified project’s results finished as other classified papers. It is fair to say that academic environment and standards in that time were very different from today. There wasn’t Internet, no Bologna process, nor transparency in dealing with defence and military issues as it is today, not only for a particular state. It was a time of the Cold war, large armies, a dominance of quantitative aspects of military forces in research, etc.

3. RESEARCH TOPICS IN SUB-PERIOD 1990-2000

Main events which define this period are dissolution of a former state (Socialistic Federal Republic of Yugoslavia, 1991), and boiling after war period and social change around 2000 year. Program orientation was dedicated to: investigating of strategic problems of armed conflict, doctrinal and strategic documents, security and defence strategies of foreign countries, realizing different studies for top managers in national defence, and realizing scientific projects in the field of military arts.

In the period up to 2000 year, there were realized next projects:
- Scientific Development of Military Arts (1990-1996.)
- History of Military Arts (1995-1998.)
- International and Internal Factors of Dissolution of Yugoslavia and its Armed Forces (1992.)
- System of Military Education in the Yugoslav Army (1996-1997.)
- Strategic Consequences of the NATO Engagement in the Balkans (1996.)
- Prevlaka (1998.)
- Military Strategy and Scientific-Technical Factor (1998.)
- Contemporary Aspects of Crises in Kosovo and Metohija (1998.)
- Fighting Commando-Terrorist Forces, Experiences and Forecasts (1999.)

- Combat Actions of Yugoslav Army in opposing NATO Aggression on Federal Republic of Yugoslavia - Lessons Learned (1999-2000.)
- Low Intensity Conflict – Unarmed Aggression on Yugoslavia and the Means of Opposing it - Expert's Talks (2000.)
- Basic Characteristics of a Future War in This Region (1999.)
- Serbian Military Memorial (1999-2000.)

There were more than 20 publications in this period, and that shows one of big change in approach to the research and treatment of the research results. Comparing the publication opus of two successive phases it is evidently that things were radically changed. Looking at the titles of research projects it is viewable research directions change, abandoning some traditional fields and perceiving new security challenges.

4. RESEARCH TOPICS IN SUB-PERIOD 2000-2006

In 2000 year, the Institute of Military Art had got formal document from his founder (the Government) for its establishing as a research organization in the MoD. The mission of Institute of Military Art was defined according to next: to make research in next disciplines: warfare art and military science in the field of strategy, operational art and tactics. Additional task were to investigate: armed combat; military doctrines; military management, command and control; as well as to make military-strategically estimations, to develop research resources, to cooperate with other institutions, etc.

In practice, the mission of the Institute of Military Arts in this sub-phase was realized dominantly through research in next disciplines: security analyses, issues on security integrations at international level, gender issues, investigating military public opinion on different topics, and making insight into new security challenges. In the period from 2000 up to 2006 year, there were realized next projects:

- The Role of Special Forces in Combat Operations (2000-2001.)
- The Partnership for Peace and Federal Republic of Yugoslavia – Expert's Talks (2000-2001.)
- Constituents of Military Strategy of Federal Republic of Yugoslavia – Symposia on a Military Science (2000-2001.)
- Civilian Control of Armed Forces – Expert's Talks (2001.)
- International Association and Organizations as Centers of Power in International Relations and Their Influence on Security of Federal Republic of Yugoslavia (2001.)
- Professionalization of Yugoslav Army – Expert's Talks (2001.)
- Security Challenges in South-East Europe – Ways Out of Crises – Expert's Talks (2002.)
- Serbia and Montenegro – Security Challenges, Risks and Threats, State-of-the-Arts and Trends – Expert's Talks (2003.)
- Military Experts Analyses of Armed Conflicts in SFRY and FRY in period 1991-1999 (2002.)
- Conflict Genesis in Kosovo and Metohija (2004.)
- Theoretical Basis for Determining the Effectiveness of Military Organizational Systems (2002-2005.)
- Scope and Models of Engaging Women in Modern Armed Forces (2003-2005.)

5. RESEARCH TOPICS AFTER THE LAST SHIFT (2006 UP TO 2014)

Main event that distinguishes this period was organizational, personnel and program transformation of the Institute of Military Arts, into the Strategic Research Institute (SRI), which is defined as a research institution of the MoD working in the fields of security, defense, and military history. The Strategic Research Institute was founded on October 1, 2006, merging resources of the Military Arts Institute and the Military-history Institut. The Institute consists of next entities: Section for strategic assessments and security integration, section for defense studies, section for military history and group for general administration.

Organizationally, SRI is allocated inside structure of the Defence Policy Sector of MoD. Basic tasks of the Strategic Research Institute are: analyzing international relations processes and factors that affect serbia's security and international status; researching the experience of regional and world conflicts important for serbian security; providing analysis, assessments and recommendations to help serbia react when its security is threatened; researching how serbia could be included and engaged in international security organizations; researching the field of defense system management; researching civil-military relations in democratic and transitional countries, with an emphasis on conversion and the reform of civil-military relations in serbia; researching psychological aspects in the military; researching public opinion within the MoD, and Serbian Armed Forces (SAF) on relevant issues; researching military history; preparing and conducting scientific and expert meetings in the fields of security, defense and military history; participating in

the Military Academy's educational process and the SAF training process; and publishing books, magazines and other scientifically useful documentation.

In the period from 2006 to 2014 year, there were next projects:

- Attitudes of High School Youth About Schooling at Military Academy (2006-2008.)
- Defence System of Republic of Serbia in Opposing Contemporary Terrorism (2007.)
- Model of Evaluating of Moral of Serbian Army in Contemporary Conditions (2007.)
- Value System of Serbian Army – Recommendation or Barrier for Security Integrations (2008-2009.)
- Opinion of Serbian Military Public on Military Reform and Security Integrations (2008-2009.)
- Military Profession in Serbia – State-of-the-Art and Perspectives (2009.)
- Democratization of Security Sector in Serbia (2009.)
- Defence from Threats in Cyber Space (2009-2011.)
- Opinion of Population in Ministry of Defence on Current State of Affairs of the Military Organization (2011-2012.)
- Security and Defence Aspects of Association of Republic of Serbia to the European Union (2011-2013.)
- History of Serbian and Yugoslav army in 19. And 20. Century (2006-2014.)

The last project, entitled "History of Serbian and Yugoslav army in XIX and XX century", is a complex multiyear project of special kind: it deals with military history through the lens and with the methods and standards of history as specific scientific discipline (humanities).

Some of publications in the current phase of strategic research are next:

- Woman in Defence: From Past to Present
- Women in the Armed Forces
- Education of Female Cadets at Military Academy
- Women in the Security Sector: A Regional Perspective
- In Step with Time – Ministry of Defence and Serbian Armed Forces on the Path of Gender Equality Objectification
- Defence from Cyberspace Threats
- Information Handbook on Defence System of the Republic of Serbia
- Proceedings: Security and Defence Aspects of the Republic of Serbia's Accession to the European Union
- Proceedings:Serbia in Contemporary Geostrategic Surroundings
- Military Profession in Serbia: Review and Perspectives
- Proceedings: Civil Emergencies
- Emergencies: How to Manage Them?
- High School Graduates' Opinion on Military Profession
- The Role of Humanitarian Organizations in Providing for Civilians during Emergencies
- The Automobile in the Serbian Armed Forces 1908-1918
- War after the War: The Kingdom of Serbs, Croats and Slovenians Armed Forces in Kosovo and Metohija and Macedonia 1918-1920
- Balkan Pact 1953-54
- Europeanization of Serbian Armed Forces from 1878 to 1903
- Serbian Military Luminaries

6. CONCLUSION

Current Strategic Research Institute and all its predecessors have dynamic life-cycle due to internal organizational changes inside Ministry of Defence, but also due to changes of a wide set of different conditions coming from military, security, political, international and technological field. Thematic orientation of scientific research depends heavily on the MoD stakeholder preferences, but also on the initiative of the management of the Institute.

Besides organizational and program transformations, subject of change were also a size of organization (number of employees), education and professional background of the staff, and least but not last a gender (sex). The general trends about staff characteristics are towards preferring younger rather than more experienced staff; civilian rather than military educational background; sexual distribution share has also dynamic character in favour of women.

Growing openness in overall work is one of strong characteristics of current phase. This stands for threefold aspect: first, openness for all kinds of international cooperation; second, openness towards all domestic organizations and institutions; and third, adjustment towards academic standards valid for science institutes and scientific work in the state. The last aspect is seen as one of the main challenges for the future, that will obtain arise of quality level of research rather then expanding quantity.

Abstract: *This paper suggests that in the development phase and during pacification of the crisis, security management is experiencing significant functional and institutional changes. There are several organizational and functional properties of the security management in case of crisis situations which will illustratively be presented by perceiving experiences in achieving the organization's objectives of security management in crisis situations, the content and features of functioning of the security management in crisis situations.*

Key words: *security management, crisis situations, characteristics of functioning of the security management in crisis situations.*

1. INTRODUCTION

To understand the security management, an important aspect present the doctrinal documents dealing with the areas important to engage the Army in specific situations . These specific situations, conditionally come under crisis situations and are defined by a specific mission of the Army of Serbia . In order to present these issues it is necessary to consider the importance of entities and parts of the security management , security environment of the Republic of Serbia and the specific conditions of crisis situations in which crisis management can be an essential element of resolving the situation in the Republic of Serbia.

2. IMPORTANCE OF ENTITIES AND PARTS OF THE SECURITY MANAGEMENT

Subjects of crisis management are the carriers whose activities generate the totality of relationships in resolving certain crisis . They are also the actors of this crisis and subjective factors on the scale at which the crisis is concerned. Their key feature is the effect of the crisis within a certain scale. However, it should be emphasized that the subjects of security management within the framework of resolving certain crisis are part of a broader environment which influence resolution of the specific crisis. It is important to emphasize that they present specific carriers of subjectivity in resolving certain crisis and are carriers of specific activities or events characteristic to a particular crisis and which has impact on particular organization.

From the standpoint of complete understanding of this issue, one fact should be noticed which is based on the essence of complete factors' analysis that led to the problem or crisis, which means it is needed to carry out an analysis of all the aspects of the organization. These are the elements which are essential and which have an impact on the entire management that resolves the problems directly associated with the crisis.

In order to examine the role and importance of the subjects and parts of the security management, it is essential to evaluate the adequate perspective of a particular organization in the future. This means that each specific organization needs to look far enough into the future to have enough time to prepare itself. This is especially true for military organization, which is primarily conditioned by an generally unstable environment. For these reasons, it is necessary to think and plan for the long-term effects of what would happen. The essence of this stems from the need to adapt to the changes in the environment and, therefore, impose the need for an adequate adaptation to such changes.

Context of the importance of entities and parts of the security management and the difficulties encountered in resolving the crisis may be qualitatively similar to other elements with which the organizational system meets in its work. It is primarily the similarity with resolution or conduct of specific projects, so that the holders of the security management have several common characteristics primarily expressed through:
- Unusual activities that are rarely repeated,
- Demand for skills and experiences of people of different functions,
- Limited duration and
- After the crisis, the immediate actors return to their regular duties.

These elements suggest that the holders of the security management or crisis teams should be organized and access the problems in the manner the work project teams do. This means that they need to gather experience, areas and skills needed to master the situation. However , there are some differences , primarily expressed in the lack of time to plan their activities. The teams gathered for the sake of specific hazards (e.g., fires, floods, etc.) have plans for emergency situations. Still, they also lack some knowledge of what to do, since the crisis often occurs unpredictably.

Bearing in mind that project management has four stages: defining and organizing , planning, implementation management and closure of the project, in this sense the holders of the security management can successfully adapt these steps to their needs.

2.1. Defining and organizing

At this stage are clearly defined the project objectives and organized the right people and resources. Thus, the following questions are asked:" What exactly is the problem?"," What we need to do to resolve it?"," Who should be included to help us?" and" What resources will we need to resolve an issue and bring the situation back to normal?".
The first assumption of successful action of the security management subjects is defining the crisis, gathering the right people and resources, which is also the basis for the start of action.

2.2. Planning

The main task of the manager is to ensure the successful carrying out of activities for which it is responsible. This requires a lot of thinking about future events and undertaking steps in advance to provide a normal operation. All these activities are called by one word: *planning*.
Planning begins by setting clear targets and takes place in the past in four consecutive steps: (*Luecke, R. 2005*).
- Determination of specific tasks that need to be implemented,
- Determination of the fittest individuals or groups for the execution of each task,
- Estimation of the time required to execute a specific task and
- Concretization of holders for each task.

If you approach the realization of the tasks in this manner, inevitably follows the dismantling of these tasks into sub-tasks. What is more typical in terms of the role of the management security holders is determining the holders responsible for a specific task, as it provides high-quality execution of the task.

2.3. Management implementation

The phase management implementation includes all the usual tasks of effective management as well as careful monitoring and control. These two together provide compliance to the plan, standards and budgets. In particular should be borne in mind the coordination of activities of the engaged stakeholders or teams in the implementation process.

2.4. Closing the project

A common feature of the project and the crisis is their end. The project is finished the moment its objectives are met. Security management has the final stage, and one of the main tasks of this phase is to review the development and the experience and to draw conclusions: What was good? What was done wrong? Whether and how to change the approach if and when a similar situation hits the organizational system? Drawing conclusions is an area that is assessed in detail and which is implemented in the contingency plans.

The most important thing is to declare the end of the crisis, to indicate the most important events and ensure that the immediate holders of resolving the crisis participate in subsequent analysis in order to implement these experiences in contingency plans.

2.5. Response to crisis and dangers

The crisis and sudden event can often involve a natural human reaction, surprises, denials, angers and fear. How one organization controls emotions will determine how the organization will deal with crisis or sudden event. Fight or flight risk syndrome can be overcome by internal faith. Without inner faith, the procedure is sentenced to panic and collapse. When the crisis reaches a climax, the emphasis should be on understanding, explaining and reorientation of events.

In this regard, the quality of good managers should have the following properties: perception, intuition, knowledge in one or more areas, the ability to take on additional responsibilities, the ability to think clearly, determination and composure under pressure. Of course, the question is raised whether all managers have such capabilities and whether they can carry out activities required in the process of resolving the crisis? All managers must be familiar with the work they do - aspect " work knowledge "; should have the skill and ability.

3. RESOLVING CRISIS SITUATIONS

From the aspect of understanding resolving crisis situations in the domain of defense system, it is important to emphasis that within the context of the aforementioned issue, there are acquired and generally accepted principles in the most developed countries in the world and they are mainly definad into war doctrine. In order to successfully overcome crisis situations and its actions in each stage, the elements of crisis situations are shown in Fig. 1.

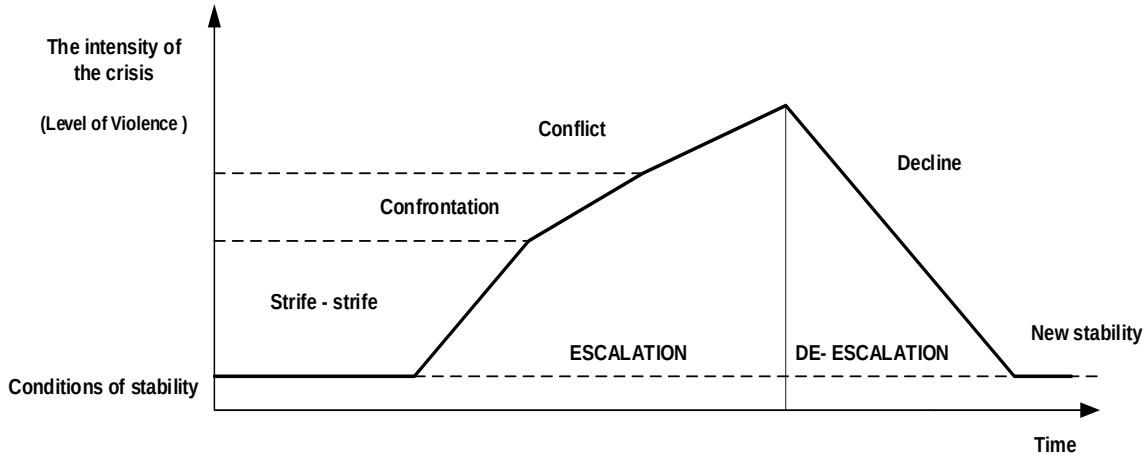

Figure 1: The general form of a crisis situation
(Karović, S. 2014.)

It can be observed in the figure that at certain stages of the crisis there are indicated elements which in the pre-crisis stage stem and are connected in a continuum; which then leads to its culmination and the highest point, regardless of whether it is a crisis in the system or a crisis caused by the act of nature. However , it is important to distinguish the effects of the particular situation where there is not an elaborate system that would fully meet all the necessary criteria. Yet, there is a general attitude that leads to that, depending on the type of crisis, quite certain resources would be engaged. To define the specific model of action is not possible, because in this case are activated the already prepared plans for a specific situation. This means that the plan is the basis fn the action model in a specific situation. (*Karović, S. 2014*).

According to the standpoints of the modern armies, primarily NATO, the approach or model for resolving crisis situations has elements shown in Figure 1. It is characterized by existence of two phases which are divided by the culmination point, i.e., the phase of escalation and de-escalation of the crisis.

In the escalation phase, there are two phases of crisis' development processas – the escalation phase, followed in certain points by the de-escalation phase. This transition occurs in any form of defining the crisis process. What characterizes the escalation phase and is apparent in the diagram as the "stability condition", is presented in the form of a crisis where there is no violence or threats to priority objectives. There is a lack of potential tensions between the conflicting parties.

The diagram unit can be moved upwards to the "disagreement - strife" showing that a threat to priority objectives is identified. It is characterized by the growth of warning of the impending crisis.

The curve can progress to a "confrontation" point, indicating that the actions of violence growth are retrieved from one or the other side of the crisis, showing that there is a crisis and, of course, the curve can present crisis growing up to the point where it escalates into conflict.

De-escalation phase is characterized by such kind of the crisis effect intensity which will eventually decrease showing its flow on the diagram. The curve shows decline passing through a phase of decline of the conflicting parties. It may include a recognition that the threat to priority objectives is in decline. This does not mean that

the crisis is over,nor that it is brought into the state *favorably*, but it only shows that the worst is over as a form of crisis. The curve decreases to a relatively low intensity showing "new stability" on the diagram which may be a crisis of intensity higher or lower than the original, shows the new "status quo" acceptable to all parties involved in the crisis. (Karović, S. 2014).

In such conditions of resolving the crisis, the position of the crisis management is oriented towards enforcement of activities substantially shown in Table 3.

Table 1: Main activities of the security management (Karović, S. 2014).

SECURITY MANAGEMENT ACTIVITIES' CONTENT	***CRISIS FORMS***					
	ESCALATION				***DE-ESCALATION***	
	Stability	***Rift***	***Confrontation***	***Conflict***	***Decline***	***Stability***
Situation monitoring	*X*	*X*	*X*	*X*	*X*	*X*
Crisis detecting support	*X*	*X*				
Crisis content		*X*	*X*	*X*	*X*	
Permitted engagement				*X*	*X*	*X*
Building stability					*X*	*X*

Situation monitoring as an activity that is conducted in resolving the crisis is characterized by properties expressed in the assessment of the operating environment, principally on collection and information analysis. It is important for one simple reason, which has its stronghold in the process of engagement the forces and the risk assessment which is born by operation performance. Information and their analysis will provide the operational planning process for the engagement of forces to be done completely and a decision to be brought which should ensure the success of the implementation of such operation. This segment is distinctive because it is done at the all crisis stages and is directly related to intelligence assessments of the battlefield, which reflects the operational planning process,

Crisis detecting support is directly related to the segment when the crisis is identified. The information in the function of supplementing previous solutions or supplementing decision with new information that will enable successful implementation of the operation.

In the crisis escalation stage are manifested certain action forms and manifestations of such a condition. Most often they are expressed in the form of discord, confrontation and conflict. In such situations the crisis management activities are focused on the development and implementation of concrete actions which lead to prevention of the crisis escalation. Actions may be substantially different and are primarily determined by the type of operation being conducted.

As particularly important should be noted that in the escalation phase when there is a conflict, it is possible to engage the power of the army. Simply, there is no reason for postponement of the force application or operation implementation that leads to dismissal of such a situation. The use of force remains at the stage of de-escalation as well, especially in the decline segment which should lead to stability condition.
The last significant activity on the dismissal of the crisis relates to building stability and is applied in the stage of de-escalation as a natural consequence of continuously conducted prior contents. Particularly are significant the development and implementation of new forms of post-crisis stability.

In order to understand the essence of crisis management, it should be emphasized that the effects of crisis management usually occur where the potential crisis is detected and where the treatment is done before the crisis emerged. In this case, the lines of communication are clean and the plan prepared in advance will prove to be effective. The management and organizations without the crisis management system will in this case inevitably have to deal with an unexpected crisis, i.e., will expect the unexpected as a specificity from such condition. *(Karović, S. 2014.).*

According to the doctrine of the Army of Serbia, the Army of Serbia plans, prepares and performs operations in peacetime, in emergency and state of war. In relation to the forces that are engaged, these operations may be: Army operations; air force and airborne defense operations; operations of the territorial forces, special forces' operations and operations of joint forces; according to the form of combat operations – they can be attack and defense. The basic division of the military operations according to the manner of their applications is: combat and non-combat operations. Special type of operations are the multinational operations, in which can participate parts of the Army of Serbia, in accordance to the law.

As part of the campaign, according to importance, one operation is planned, prepared and executed as the main operation of the campaign, while the others are ancillary operations. *(Доктрина Војске Србије, 2010.).*

It is important to emphasize from the perspective of the security management that the Army can perform non-combat operations independently or as part of combat operations performed in peace, in a state of emergency and a state of war. Non-combat operations are: an information operation; operation of civil- military cooperation and support operation to civil authorities in combating unarmed security threats.

For the needs and understanding of functioning of the security management in the defense system, support operations to civil authorities in combating unarmed security threats are carried out in the event of natural disasters, industrial accidents and epidemics. The goal of executing operations is to support civil authorities and citizens to protect and rescue people's lives, material assets and the environment. For a success in the execution of operations are needed: direct cooperation and coordination with state authorities that govern all the forces in the affected area and a use of a fully trained and equipped units of the Army of Serbia. (Доктрина Војске Србије, 2010.).

3.1. Principles of resolving crisis situations

If it is understood that settling crisis situations involves planning and undertaking appropriate measures that can be subsumed under principles, then they are generally reflected through: prevention (taking measures to prevent the outbreak of crises), retention of crisis situations in existing borders and preventing their spread and settling of crisis situations.

The aim of resolving the crisis situations is providing adequate and balanced response to the occurrence of any hot spots. The jurisdiction of the Assembly of Serbia is involvement of the Army in dismissal of crisis situations. In the context of commanding with the Army, the responsibilities are defined and in case of crisis remain unchanged.

Hierarchical line for resolving crisis situations remains unchanged and goes in the direction of: Assembly - Department of Defence - Army General Headquarters - Command of the forms - Unit commanders, or compositions. These principles of command apply to all situations when the Army is used in the process of resolving the crisis situation, especially in the context of the defined mission. Based on the decision of the Assembly and on the basis of government policy, the Ministry of Defence is responsible for the realization of all varieties of military engagement in the process of resolving a crisis situation.

3.2. Command and control in crisis situations

System of successful command and control, from the highest to the lowest level, should provide a unique deployment of all forces toward a common goal and their most efficient use. Commanders must ensure the maximum possible freedom of action, within the given political and military guidelines for the execution of the tasks.
The command and control system should be simple and maximally unique, and the decisions brought must be precise and unambiguous. Each commander must be given the command responsibilities in accordance to the level of its responsibilities. This system will have its own particular specificity for different types of operations , but is primarily based on the adopted procedures. (Karović, S. 2014.).

Means of mass media should be engaged so to ensure continuous reporting on the progress of operations and the engagement of the Army. Their work has to take place within the official (government) information campaign according to specific crisis situation. The statements and briefings from top political and military figures have special significance in informing the public about the development of the overall political and military situation in the crisis area and during the course of the military operations.

Their activity has to take place within the official (government) information campaign towards specific crisis situation. The statements and briefings from top political and military figures have special significance in the public information about the development of the overall political and military situation in the crisis area and during the course of military operations.

During the operation a coordinated and continuous monitoring should be ensured of its results for timely identifying potential failures and shortcomings and prompt undertaking measures for their elimination.

After the operation, it is a must to make an overall analysis of its success (or failure) to use the experience gained to possible change of certain doctrinal solutions, the size and structure of the Army and its operational capabilities in order to provide better and more effective response to future challenges in mediating crisis situations.

4. CONCLUSION

Understanding the security management in the process of resolving the crisis can be understood through certain stages that characterize the process. The process, basically, is the dynamic that involves certain stages and they make the unity of continuous action towards resolving the crisis.

It follows from the properties of the crisis manifested in the fact that the crisis is largely left to the subject of time and the possibility to act, it requires action in order to survive. In this sense, the crisis is any entity that perceives a part of its state, which is reflected in the decline of its mechanisms of regulation, as a threat to its own existence.

In order to restore these mechanisms of regulation, security management just tends to find objects that will act to restore the function of an entity that was in a given moment found under "suffering" because there is no object which acts on it. Therefore it is essential to the functioning of the security management, for the mass media to receive special significance which makes the security management specific in the process of resolving a crisis situation.

Abstract: *This article presents the simulation in iThink software in personnel costs optimization. The model is based on the correction of number of personnel in defence based on desired defence cost structure, as well as the estimated defence budget. This method considerate consequences at the height of personnel costs and cost structure of the defence, before correction of number of employees are implemented in practice. iThink, as a simulation software can be used to simulate all processes in the defence organization in order to the determine the optimal development strategy. On the other hand, the use of the program iThink requires expert knowledge of organizational processes and iThink software, ability to represent organization model using different mathematical and logical functions, and creativity, in order to obtain the required results.*

Keywords: *Strategic management, Defence, Human resources management, Simulations, iThink software*

1. INTRODUCTION

Some of Defence strategic management aim is to determine defence development goals and objectives according to environment assessment; determine strategies to achieve the goals and objectives; assessments of resources needed for the strategies implementation, as well as deploy and direct resources thru defence organization. For properly deployed and directed defence's resources in order to provide development, all the costs that defence generates need to be considered.

The total cost of the defence organization is usually classified according to usage purpose in personnel costs, operational costs and investment. Practice shows trend of continuous increase in personnel costs at the expense of operational cost and investment, so that personnel costs are the largest share of the total cost structure. There is the need to control personnel costs in the defence, and to ensure a smooth development and implementation of Long-term goals.

The value of personnel costs are influenced by many parameters. Parameters that affect the amount of personnel costs varied, and most often these are the remuneration of employees, the amount of benefits and the number of employees in the defence. Control of the height of personnel costs can be achieved by impact on some of these parameters, and thus the overall defence cost structure.

One of the parameters that are most commonly affects the control of personnel costs is the number of the employees. The question is, what is the impact of the budget and the desired cost structure to the number of employees in the defence. One way to examine this impact is by using simulation. Simulations, as a form of modal experiments, allow observation of the interconnections of the experimental factors, in this case the defence budget and desired cost structure and the experimental object, or number of employees in the defence organization. In this way, simulations can examine a variety of strategies to reduce personnel costs by influencing the number of the employees, as well as the effects of the strategy implementation before the implementation. Simulations provides to strategic management timely risk assessment for strategies implementation and provide accurate data on the number of employees that need to be corrected in order to achieve the desired cost structure.

One of the tools for the defence models development and experimentation with strategy implementation is software iThink. With this software the processes within the defence organization can be simulated, as well as the movement of resources within it, making it suitable for simulation and experimentation of the defence organization costs. In this way, required number of the employees in the defence may be a timely projected, in order to achieve the desired cost structure.

2. PERSONNEL COSTS IN DEFENCE

System of wages is a part of the remuneration of employees includes all the material rewards that an employer gives to employees in exchange for the work. Management see wages as the biggest expense (cost of personnel in companies ranging up to 50% of total costs), as well as the main instrument to influence the behavior of employees and improving organizational results (Bogicevic, 2006).

The wages system includes two types of wage earnings: direct and indirect. Direct forms of wage earnings include elements that employees receive in cash. The direct forms of earnings are: basic salary, salary increases in order to maintain purchasing power and wages depend on the performance. The base salary is the most important element of earnings that an employee receives based on the work they perform, regardless of what is his effect on the workplace. Salary increases in order to maintain the purchasing power of wages is an element that ensures the maintenance of the purchasing power of the basic pay in the long run, through a permanent salary increase based on the index of retail price increase, in most case it is CPI index or other indicator for which particular organization decides. Salaries based on the performance are the element of wage that takes into account the contribution of the individual in achieving organizational results, the result of the organizational unit or team in which the employee works and include various forms of short-term and long-term incentives.

Indirect forms of wages include conveniences and benefits. Conveniences are an element of profit that aims to provide safety to employees and their families. Conveniences include two types of applications, including: program to protect employees through health insurance, pension, social security, disability insurance, life insurance etc; and paid absence program that includes military service, vacation, sick absence, etc. Benefits are indirect earnings that is related to status and status symbols and includes a variety of forms such as free meals or meals at lower prices, use of a company car, free entertainment, the use of mobile phones and more.

In the any organizations disparity in the high of employee's wages has been present. Wages of some employee depends on which personnel category it belongs in the established personnel structure frame. For example, in some organizations personnel structure frame is divided into categories: Clerk, lower executive, middle manager, senior managers and the like. etc. Personnel costs of specific personnel category *k* depend on the number of employees who fall into that personnel structure frame (N_k), the average height of the direct forms of wage (Dw_k) and the average height of the indirect wage (Iw_k), and it is calculated according to the formulae 1,

$$P_k = N_k \times (Dw_k + Iw_k), k = \{1,2, \dots, n\} \quad (1)$$

In present formula, *n* is total number of personnel category in established personnel structure frame in some organization.

Height of personnel costs in the defence is even more pronounced, ranging from 50% to 80% of the total budget of defence. That is because of the specific involvement of human resources, which affects the level of benefits, free food of some categories of personnel, the cost of training staff, as well as clothing prices and footwear (uniforms, protective clothing and footwear, and civil suits for people who follows procurement of civil suits). Typical Europe country in the biggest share of personnel costs in total defence costs are: Romania with 80%, Portugal 78.5%, Albania 77.1%, Belgium 75.4%, Italy 74.8% and Slovenia 74.6%. By the smallest share of personnel costs in total costs of the defence in Europe country are Estonia with 32.3%, UK 35.7%, Norway 43.4% and Luxembourg 44.3%,. The average share of personnel costs in total costs of defence for European countries is around 60% (Military balance, 2012).

In defence, personnel structure frame is usually divided into the following categories: officers, non-commissioned officer, civilian personnel, professional soldiers and cadets (Military Compensation Congressional budget office, November 2012). Due to the involvement of different tasks and level of education, the average cost of certain categories of personnel in the defence depend on the average cost of training staff (*T*), average clothing and footwear purchase price (*C*), average food price (*F*), average participation in multinational operation price (*M*), average extras and fees price (*G*) and average cost of business travel in the country and abroad (*S*) (Steven, 2005). In this case, the formulae 1 is expanded with the above mentioned costs and will have a shape as shown in formulae 2,

$$P_k = N_k \times (Dw_k + Iw_k + T_k + C_k + F_k + M_k + G_k + S_k), k = \{1,2, \dots, n\} \quad (2)$$

Total personnel costs (*P*) is the sum of personnel costs of all personnel categories in the defence organization, on the basis of formulae 3,

$$P = \sum_{k=1}^{n} P_k, k = \{1,2, \dots, n\} \quad (3)$$

To manage personnel costs, we can affect on one or more of the elements that make up this cost (Bogicevic, 2006). Because personnel costs in defence are in dominant height compared to the other costs, for strategic

management control of this cost are of great importance. According to formulae 2, manage personal cost can be done on two ways:

- Control of the number of employees;
- Control of average wages value.

Control of the number of employees is a common method of controlling personnel cost, while maintaining the same average level of wages (Carl, 2007). By keeping the average wages maintaining the status of employees is achieved, which greatly affects the prevention of personnel leaving and positively influence employee behavior and organizational results. Disadvantages of the number of employees control is reflected in the legal regulations in many countries, in the impact of the reduction of capability of the company for the execution of mission and tasks, increasing the degree of combustion of staff, as well as the amount of the required financial resources for the payment of retirement benefits to employees who terminate employment. All of the above deficiencies can result in the reduction of profits to a profitable organization, or loss of role, due to the impossibility of conducting tasks for non-profitable organization, so in control of the number of employees should be approached carefully.

3. APPLICATION OF ITHINK SOFTWARE IN OPTIMIZATION OF PERSONNEL COSTS

Personnel costs in defence have a tendency of continuous growth and influence the changes in cost structure so the operational costs and investments are getting lower. On achieving defence long-term goals most affect have investment and operational costs, so optimization of the cost structure is one of activity that provides defence development. One of the possible ways to optimize the cost structure is the use of simulation, in order to comprehend the long-term effects of using certain strategies.

The basic preconditions for the application of simulation are: the existence of the model (the experimental situation), the ability to set the experimental factors, the ability to repeat the experiment, the possibility of permanent control of results, providing personnel for data collection and development of appropriate tools for data logging. With development of personnel computers usage of simulation are gaining in importance in the social sciences. The processes can be simulated in real time, fast or slow, depending on the intentions of researchers, research subjects and capabilities of simulators and computer. Also, simulations can be carried out reconstruction of certain events from the past, to simulate the phenomenon of present or may have prognostic character. The difference is primarily in the number, nature and organization of data, which may relate to past, present or future (Sakan, 2006).

According to iThink official web page, iThink is software for modeling and simulation of business processes. As such, it is useful to create models that simulate the original business processes and procedures, shows the consequences of new procedures and policies, and in particular to show the unwanted outputs from the process and the development of options for the control of undesirable outputs. The importance of iThink for Strategic planning is reflected in the way that it indicates the output from the system that can be critical, and therefore cause material loss or decrease of reputation of the organization. iThink provides a wide view on a particular issue, operation and the entire organization by enabling dynamic modeling and simulation, which can examine or modify the parameters of all the key points and processes in the system. In this way, iThink prevents decisions that can have harmful consequences. In this connection, iThink, besides tools for modeling and simulation, also support tool for decision makers (Systems Thinking for Business, 2014).

One possible application of iThink software is for the personnel costs optimization, taking into consideration the achieving of the desired cost structure of the defence organization and defence budget constraints. As an example, model of the cost structure and the personnel number of defence organization are created.

In created model experimental factors are:
- The defence budget -*B*;
- Cost structure-*Cs* (in defence organization it is usually divided into personnel costs - *P*, operational cost- *O* and investment- *I*);
- Personnel cost escalation- *E* (increase the salaries of employees in order to maintain purchasing power, and increase the the cost of of other forms of indirect wages, such as food and clothing);
- The average individual wages per personnel structure frame - *W*.

The experimental object is a total number of personnel in the defence organization - *N*.

With experimental situations processes related to personnel costs are isolated from the impact of other costs of defence, such as the operational costs and investments.

A simplified model of optimization of personnel costs using the software iThink is shown in Figure 1.

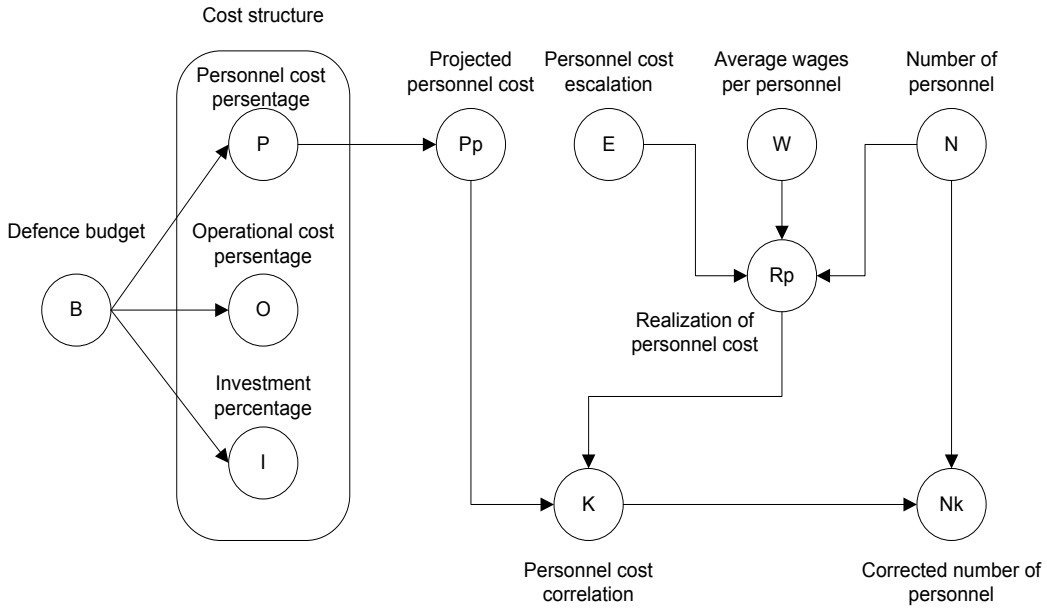

Figure 1: Simplified model of optimization of personnel costs using the software iThink

Part of the operational model in iThink is shown in Figure 2. Using the available tools for graphical data input in interface layer, the defence budget are entered the model. Entering the budget is done for each subsequent year of the simulation period starting from the initial year. Thereafter, an entry of the desired cost structure is made.

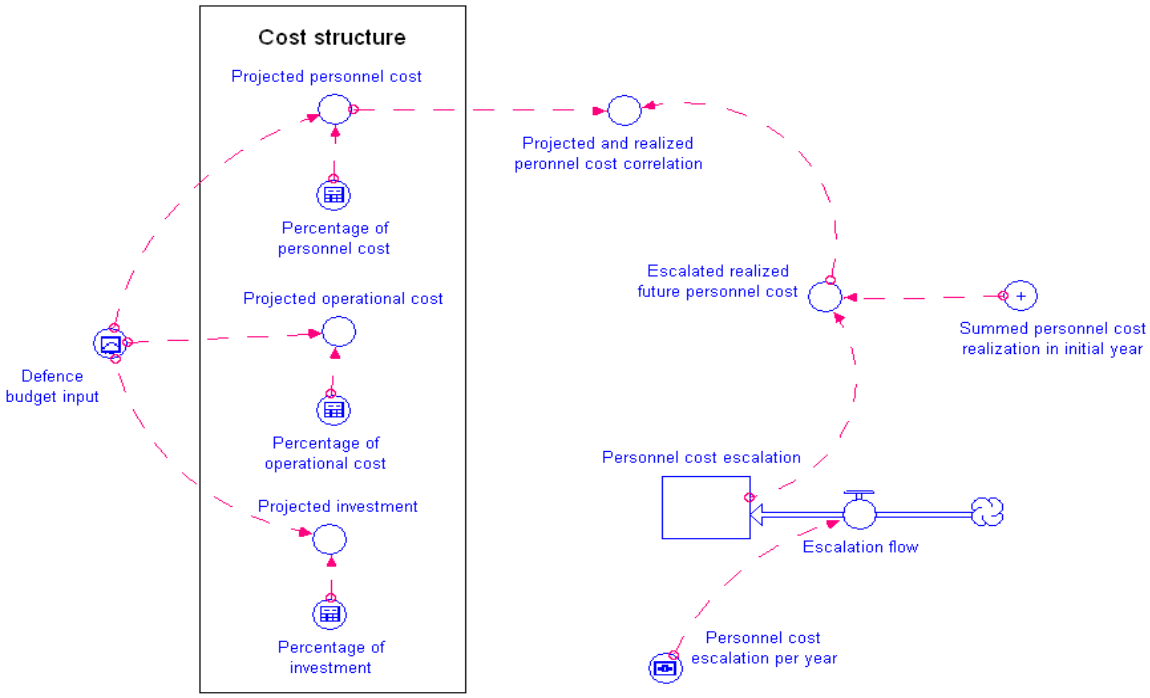

Figure 2: Part of the operational model of personnel cost optimization using iThink software

Personal costs are isolated with experimental environment, so the amount of personnel costs to be achieved, or projected personnel costs (*Pp*) are calculated according to formulae 4,

$$Pp = \frac{B \times P}{100} \qquad (4)$$

On the other hand, the number of personnel of defence organization and the average earnings per personnel structure frame, affects the level of personnel costs realization. In addition, the height of personnel costs realization in the future are also affected with escalation of personnel costs in order to maintain purchasing power, which is annually. Personnel cost realization (*Rp*) are calculated according to formulae 5,

$$Pr = N \times W + \frac{N \times W \times E}{100} \quad (5)$$

Often the personnel costs realization differ from the projected amount of personnel costs. One of the tasks of defence strategic management is to harmonize personnel costs realization and the projected amount of personnel costs in order to provide sufficient funds for operating costs and investments. Also, strategic management must reconciled cost realization with allocated budget in the long term period. The goal is to achieve a statement from the formulae 6,

$$\frac{B \times P}{100} = Ne \times W + \frac{Nk \times W \times E}{100} \quad (6)$$

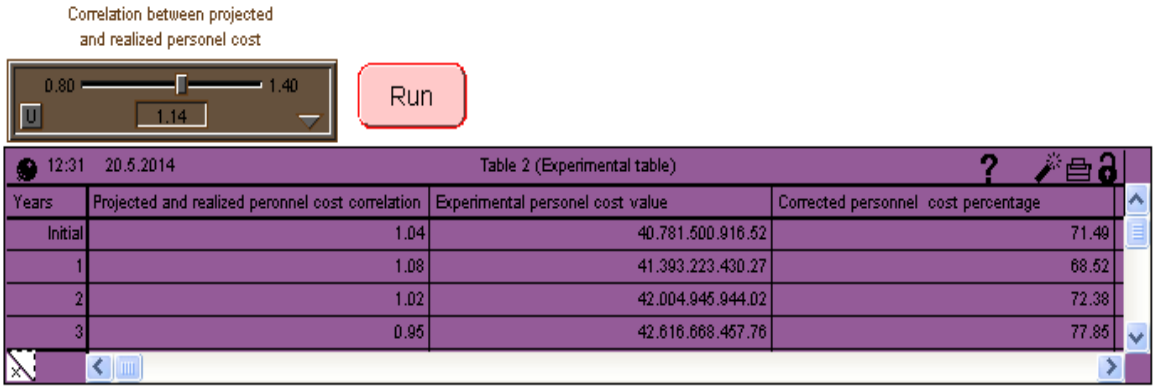
In presented formulae *Ne* is corrected number of personnel, so that projected and realized personnel costs are equal. Based on the above, the corrected number of personnel in defence organization is calculated according to the formulae 7,

$$Ne = \frac{B \times P}{W \times (100 + E)} \quad (7)$$

Ratio between realized and projected personnel costs (*K*) is equal to formulae 8,

$$\frac{Pp}{Pr} = \frac{1}{N} \times \frac{B \times P}{W \times (100 + E)} = K \quad (8)$$

By changing the ratio (*K*) between projected and realized personnel cost in the simulation, as a result new and corrected value of personnel costs and cost structure was obtained, as shown in Figure 3. In this way, synchronization of designed and realized personnel costs are achieved.



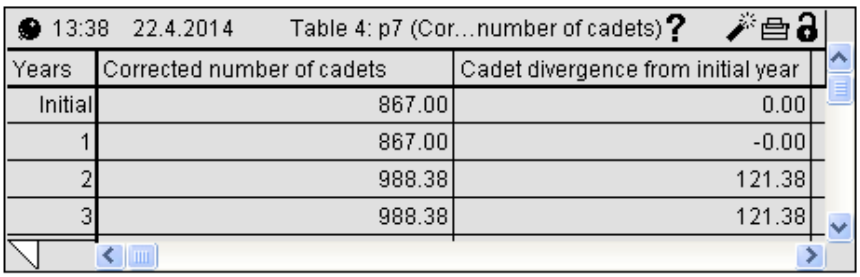
Years	Projected and realized peronnel cost correlation	Experimental personel cost value	Corrected personnel cost percentage
Initial	1.04	40.781.500.916,52	71.49
1	1.08	41.393.223.430,27	68.52
2	1.02	42.004.945.944,02	72.38
3	0.95	42.616.668.457,76	77.85

Figure 3: Correction of the amount of personnel costs and cost structure by changing ratio between designed and realized of personnel costs

Based on the above, the corrected number of personnel (*Ne*), which is adapted to the projected cost structure, is calculated based on the formulae 9,

$$Ne = K \times N \quad (9)$$

Practically correction of number of the personnel in the defence are executed by changing the value of K in the model, which represents the ratio between designed and realized of personnel costs. The results of simulation can be observed in Table in interface layer, as shown in Figure 4.



Years	Corrected number of cadets	Cadet divergence from initial year
Initial	867.00	0.00
1	867.00	-0.00
2	988.38	121.38
3	988.38	121.38

Figure 4: Table in interface layer that show corrected number of personnel

In this way we get a new number of personnel in defence in the categories of personnel and years, as well as the difference between corrected number of personnel and number of personnel in initial year.

4. CONCLUSION

The simulations can be successfully used in defence strategic management to investigate various options of managing the defence organization, before a particular strategy is implemented. In this way it allows the selection of optimal management options and preventing of uncertainty in strategies implementation. The development of computers and various software allows usage of simulations in strategic management and it is becoming more common.

One of the tools for creating process models and defence organizational elements, as well as execution of experiment is the iThink software. This software allows creation of a model in a very simple way by using the available tools, and then changing the value of the experimental factors and environment, which allows objectiv analysis of all the consequences of the specific strategies implementation.

One of the areas of defence strategic management is to manage cost structure of the defence, taking into consideration that the share of personnel costs in total costs are dominant, relative to other costs. Therefore is particular significance for defence strategic management to establish control on personnel costs. Because the height of the personal the cost depends on the number of employees in the defence and the average value of individual wages, controls of total the amount of personnel costs can be establish by impact on one of those parameters.

By using iThink software the model of the cost structure of the defence organization are created. The model allows the correction of the personal costs in defence, by influencing the number of the personnel in the organization. Number of personnel, as an experimental object, directly depends on value of experimental factors, in this case, the difence's budget, the projected cost structure, the average wage per person and escalation of personnel costs. In this way, model enables optimization of personnel costs in order to conform defence budget and the desired cost structure.

This model, with the extension, can be used to optimize operating costs and investments, which includes the entire cost structure of an defence organization. In this way it allows the selection of optimal defence development options and presentation of these options and the consequences of their implementation to the decision makers.

Abstract: *The paper presents evaluation results on capacity development in strategic planning in Central Institutions of Government of Republic of Serbia. A wide range of actions has been undertaken over the period 2005-2012 in order to build and develop sufficient capacity in Central Government to strengthen planning, monitoring and policy coordination process for effective support needed for addressing complex policy challenges. As a result, the policy-making and co-ordination system in Serbia now posses some elements required for an effective public management and public administration system. Evaluation showed that* capacities for strategic planning on individual and enabling environment level are fairly developed, but it still have to be developed on organizational level. In depth evaluation has been conducted using survey *and structured interviews with state authorities' representatives. The research showed that the highest level of capacity development was achieved in the process of strategic plan development, but the problem are planning function institutalization and capacity development support.*

Keywords*: strategic management, strategic planning, capacity development, strategy implementation, public administration system development*

1. INTRODUCTION

The Government of Republic of Serbia faces many complex policy challenges as the country pursues European integration and in the same time struggling with economic crisis. The Government needs a public management and public administration with sufficient capacity to provide effective support and strengthening central institutions and government processes (Obradović, Mihić and Mitrović 2011).

A wide range of actions has been undertaken over the period 2005-2012 in order to build and develop sufficient capacity in Central Government to strengthen planning, monitoring and policy coordination process for effective support needed for addressing complex policy challenges. The process started in 2005 when the Government of Serbia decided to launch an important project to improve the efficiency and the effectiveness of the central public administration in the field of planning, budgeting, monitoring and reporting. In the first phase 2005-2006 it was a pilot project entitled: *Joint Project - Towards the More Effective Implementation of Reforms: Improving Planning, Budgeting, Monitoring and Reporting*, that was extended to the majority of line ministries and other central key agencies for the period 2007-2008. Starting with June 2007 the project was redesigned and renamed: *GOP –Towards the more effective planning and implementation of reforms.* During 2009-2010 the project: *Support to strengthening of policy coordination in the Government of Serbia* endured already started work on reform of various elements of policy system. This was continued with the project *Reforming Policy of Coordination of the Government of Serbia* planned for period 2011 - June 2012. During this period mentioned projects were designed to support the Government of Serbia to implement the reforms more effectively by developing capacity and tools that (Obradović, Mihić and Mitrović 2011):

- Strengthen planning capacity within Ministries through the development of a comprehensive action plan per Ministry, bringing together all reforms and strategies within the sector into one framework to be used as a basis for implementation and monitoring of progress;
- Improve the efficiency of the overall reform process by consolidating and bringing together activities and networks across the Government / sector ministries that are initiated and managed by Serbian European Integration Office (SEIO), Poverty Reduction Strategy Implementation Focal Point (PRS IFP), Ministry of Finance (MFIN), DACU, the General Secretariat (GS) of the Government and during the last year the Office of the National Investment Plan; and
- Provide conditions and develop tools and systems for future strengthening of the central coordination role of the Government.

As a result, the policy-making and co-ordination system in Serbia now has some of the elements required for an effective public management and public administration system. These include (Obradović, Mihić and Mitrović 2011):

- The legal framework was revised in (2005/6), including a revised Law on Government, Rules of Procedure, Regulation on the General Secretariat of the Government, and Regulation on the Cabinet of the Prime Minister.
- There are legally established committees of ministers to discuss items prior to their reaching the government session, which is supported by the General Secretariat of the Government.
- The Rules of Procedure establish the concept of the government"s collective responsibility, requiring that in all public communications members of the government should support its decisions regardless of their own views or of how they voted in the government sessions.
- The Rules of Procedures establish basic requirements for policy preparation in ministries, including appropriate procedures for inter-ministerial consultations, public debate, certification of harmonisation with the *acqui*, assessment of alternative approaches, assessment of financial consequences, and a full regulatory impact assessment (RIA).
- There are provisions for the preparation of an Annual Work Plan for the Government, for the regular monitoring of the implementation of the Annual Work Plan and for an Annual Report to Parliament on the implementation of this Plan.
- A Budget System Law is finalized to institutionalize a more policy-driven budget process and the middle term planning methodology as a key element of policy and budget planning. All ministries are now involved in this process.
- New department is established in General Secretariat for planning, monitoring and coordination of policies, with skilled staff to perform this process. IT system that supported new processes.
- Improved Annual Government Work Plan process linked to strategic planning model.

To evaluate the results it is necessary to consider methodological recommendations of relevant bodies. UNDP (2009) defines capacity development as the process through which individuals, organizations and societies obtain, strengthen and maintain the capabilities to set and achieve their own development objectives over time. OECD defines it as the process by which individuals, groups and organizations, institutions and countries develop, enhance and organize their systems, resources and knowledge; all reflected in their abilities, individually and collectively, to perform functions, solve problems and achieves objectives (UNDP 2009). World Bank on the other hand gives own definition: “Capacity development is a locally driven process of learning by leaders, coalitions and other agents of change that brings about changes in sociopolitical, policy-related, and organizational factors to enhance local ownership for and the effectiveness and efficiency of efforts to achieve a development goal” (Otoo, Agapitova and Behrens 2009).

In contest of capacity development in Serbian Central Government it was long-term process that lasted for seven years, through which individuals, organizations and society (the process included all line ministries and related organizations, Secretary General, other funding organizations all leaders and almost all staff of this organizations), strengthen and organize their systems, resources and knowledge, in area of strategic planning should enabled better planning, coordination and control of policies and politics, which should enabled effective and efficient implementations of reforms that on the end will contribute to sustainable development.

Literature suggests capacity development on following three levels individual, organizational and enabling environment (OECD 2006) (Bloger 2000) (UNDP 2008):

- **The enabling environment** is the term used to describe the broader system within which individuals and organizations function and one that facilitates or hampers their existence and performance. This level of capacity is not easy to grasp tangibly, but it is central to the understanding of capacity issues. They determine the „rules of the game“ for interaction between and among organizations. Capacities at the level of the enabling environment include policies, legislation, power relations and social norms, all of which govern the mandates, priorities, modes of operation and civic engagement across different parts of society (UNDP 2008). In the case of Serbian Government there was vast of policies, legislations and strategies that support reforms of Central Government. The first is commitment of Serbian Government to strategic priorities that are mainly defined by two pillars the European Integration process (EIp) and of the Poverty Reduction Strategy (PRS). The Government"s strategy for public administration reform (PAR) was adopted in November 2004 and with this strategy is implemented five key lows - Law on Government, Law on Public Administration, Law on Civil Servants, Law on Administrative Procedures and Law on Pay with the Decree on Grading. Beside mentioned lows there is the Budget System Law and revised legal framework included Rules of Procedure, Regulation on the General Secretariat of the Government, and Regulation on the Cabinet of the Prime Minister. Power of determination to pursue policy of European Integration and all strategies, laws and procedures that are adopted because of it, brought to society the new social

norms. So the capacity development in Central Government has enabling environment. (Obradović, Mihić and Mitrović 2011)

- **The organizational level** of capacity comprises the internal policies, arrangements, procedures and frameworks that allow an organization to operate and deliver on its mandate, and that enable the coming together of individual capacities to work together and achieve goals. If these exist, well resourced and well-aligned, the capability of an organization to perform will be greater than that of the sum of its parts (UNDP 2008). The organizational level is maybe the poorest point of capacity development and building in this case, except the part that concerns General Secretariat that have developed internal procedures and frameworks that facilitate capacity development and building on organization level. This level of capacity development is slowest on ministry and related organizational level because it demands commitment of ministries and their deputies, which are political appointed. They are still not under pressure of performance measurement so they are not forced to be managers beside their political role. This need for managerial behavior is one of basic doctrines of New Public Management. This trend in the Serbia is very slowly progressing. Since 2011 with support and dedication of Central Institutions and laws the most of line ministries and related organization had working groups with deputy ministries headed or deputy directors of related organizations. Even if there is in the most cases bottom up approach to developing middle term plans the monitoring and requested accountability for planned results would made ministry and his deputies to be more seriously included and as matter of fact to mange planning process. (Obradović, Mihić and Mitrović 2011)
- **The individual level** capacity refers to the skills, experience and knowledge that are invested in people. Each person is endowed with a mix of capacities that allows them to perform, whether at home, at work or in society at large. Some of these are acquired through formal training and education, others through learning by doing and experience (UNDP 2008). At this level the Human Resource Department within Secretariat General doing great work. There are regularly trainings for all interested parties. So all the members of working groups in ministries and related organizations could pass the trainings and beside that every working group have a mentor that help to enquire needed education through learning by doing. (Obradović, Mihić and Mitrović 2011)

Considering that the poorest results of capacity development are achieved on the organizational level we decided to further investigate the issues. The following chapters present methodology, results and discussion of the research.

2. METHODOLOGY

Data collection consisted of survey and structured interviews with state authorities‟ representatives. Questionnaire was specifically structured to enable the assessment of the strategic planning process step-by-step by evaluation of processes, methodologies and methods and techniques used for strategic / medium-term planning processes and evaluation of the results of the process. The first segment consisted of questions were spread over 4 sections:

1. Institutionalization of the planning function
2. Establishing the strategic foundations, conducting strategic diagnosis and developing strategic plan
3. Management of strategic plan implementation
4. Capacity development support

The second segment consisted of three questions with 10 statements that need to be ranked by importance from 1 (the most important) to 10 (the least important), namely:

1. Goals of strategic planning process capacity development
2. Results of strategic planning process
3. Challenges of strategic planning process

Sample consisted of 32 respondents; most of them (26 (81.25%) out of 32) were from organisations with more than 100 employees. Further, 12 (37.5%) respondents were working as Advisors, 15.63% (5) as Senior Adviser, 12.5% (4) as independent advisers, 9.38% (3) as civil servant, one respondent as junior counsellor and the rest of the respondents 21.88% (7) were working as project team members. The average work experience of the respondents was 14.2 years. It was interesting to note that respondents employed in the ministries have much longer experience of respondents employed in related organizations, or organizations that have fewer than 20 employees.

All respondents, except one who has recently become a member of the working group, have already participated in processes of medium-term planning. Further, 11 (34.38%) out of 32 respondents was the contact person in front of working group who correspondent with General Secretariat. Average length of membership in the working group was 2.7 years. Respondents have following positions in working groups:

- Manger/Deputy (6.25%)
- Secretary (6.25%)
- Member/Deputy (87.5%)

The research results and discussion are presented in following section.

3. RESEARCH RESULTS

An analysis of the data collected from survey and interviews for first segment of questions showed that in most cases their organizations have developed up to some level capacities for strategic planning process, but that there is still work that have to be done in order to develop sufficient capacities. The questionnaire employed a rating scale, with „5" for highest level of development. The researcher set a level of 4 and below. Any score below 4 signals the need for improvement.

Table 1 – Level of capacity development

	Segments	Ratings
1	Institutionalization of the planning function	3.87
2	Establishing the strategic foundations, conducting strategic diagnosis and developing strategic plan	4.26
3	Management of strategic plan implementation	3.60
4	Capacity development support	4.18

Results showed that fairly developed segments of strategic planning capacities are establishing the strategic foundations, conducting strategic diagnosis and developing strategic plan and capacity development support. Then follows level of institutionalization of planning function and the lowest rated is managing strategic plan implementation, both segments should be under of serious consideration.

Analysis of every segment independently showed where improvement is most needed. As institutionalization of planning function matters, the poorest results are achieved because top executives failed to take formal responsibility for the organization"s strategic planning and they insufficiently actively participate in planning process. Also one of the problems that could be alarming is that responsibilities for medium-term planning activities are not in certian number of organisations formaly included in job descriptions. More detailed results are shown in Table 2.

Table 2 – The level of institutionalization of the planning function

	The level of institutionalization of the planning function	Ratings
1	Top executives take formal responsibility for the organization"s strategic planning.	3.89
2	Strategic planning is a top priority activity that is performed on a regular basis.	3.75
3	Ministry/Department provide resources (managers' time, staff support, etc.) for strategic planning implementation.	3.53
4	Ministry/Department consistently follow a defined set of procedures in its strategic planning process.	4.44
5	Ministry/Department consistently follow a budget calendar.	4.57
6	Managers actively participate in planning process.	3.44
7	Responsibilities for medium-term planning activities are included in job descriptions	3.45

Evaluation of segment *establishing the strategic foundations, conducting strategic diagnosis and developing strategic plan* as we already mentioned is fairly developed. Every element of this section is highly rated with average rat above 4, except that there is still in some of organizations lack of methodological support for project/program prioritization. The best results are achieved in a field of participatory approach in definition of goals. More detailed results are illustrated in Table 3.

Further, the results of evaluation of section management of strategic plan implementation are shown in Table 4. Notice that the only developed element is that strategic decisions are based upon the strategic plan. Every other element here needs special effort in order to be improved. The most underdeveloped segment is that individuals responsible for strategic planning and implementation are not rewarded for successful performance. This could be related to the fact that activities on strategic planning in certain number of organizations are not yet included in job descriptions.

Table 3 – The level of development of activities of establishing the strategic foundations, conducting strategic diagnosis and developing strategic plan

	Establishing the strategic foundations, conducting strategic diagnosis and developing strategic plan	Ratings
1	Vision/mission statement been distributed to all the Ministry/Department's staff.	4.11
2	All the Ministry/Department staff, particularly management and higher-level staff understand this vision/mission statement.	4.36
3	Goals are defined in participatory manner and all the Ministry/Department staff understands them.	4.47
4	Situation analysis (which includes one or more of the following analysis: analysis of the strategic framework, SWOT, PESTLE, stakeholder analysis, problem analysis) is a regular activity in the strategic planning process.	4.38
5	The results of the situational analysis are used for plan development (objectives, programs, projects, budgets), re-examination and revision of goals or initiating new initiatives.	4.37
6	There is a methodology for prioritization and selection of programs / projects.	3.91
7	The planning of programs/projects always includes consideration of cross-sector cooperation.	4.26
8	Projected costs of programs/projects are included in the budget of organization.	4.21

Table 4 – The level of development of capacities for management of strategic plan implementation

	Management of strategic plan implementation	Ratingss
1	Strategic decisions (implementation action plans) are based upon the strategic plan.	4.14
2	Lead responsibility for action plan implementation is clearly assign to one person.	3.56
3	Sufficient resources are allocated for implementation of projects/programs.	3.11
4	Ministry/Department review monitoring data regularly, and revise strategic decisions as appropriate.	3.88
5	Ministry/Department has at its disposal all the information necessary for quantitative and qualitative monitoring of the implementation of the plan.	4.00
6	Individuals responsible for strategic planning and implementation are rewarded for successful performance.	2.71
7	Stakeholders are regularly informed on results of medium-term planning process.	3.87
8	Top management uses a medium-term plan, and requires regular monitoring and reporting on the implementation of the same.	3.45
9	Ministry/Department has a tracking system that allows measurement of the actual results achieved against planned targets.	3.69

The last section of this segment is related to evaluation of support of General secretariat to capacity development of strategic management process. The results are shown in Table 5. Respondents rated the mentor support as highest and Human Resources Management Service (HRMS) with poorest rates, sending a message that need to have more proactive approach in the process of capacity development.

Table 5 – Evaluation of capacity development support

	Capacity development support	Ratings
1	The training system for strategic/medium-term planning is well designed and meets the requirements.	4.22
2	There is a need for additional training for strategic/medium term planning at all levels of management.	4.20
3	Human Resources Management Service (HRMS) is adequately involved in the development of capacity.	3.79
4	Mentor support is adequate for the working group in the process of implementing strategic/medium term plan.	4.42
5	Support of the General Secretariat is adequate and meets the needs of the working group in the process of implementing strategic/medium term plan.	4.25

Respondents‟ highest ranked answers on question what are the most important goals of introducing strategic/medium-term management were:

- Meeting the requirements of the EU accession process
- A results-oriented public sector
- Increase transparency of state administration

Respondents‟ highest ranked answers on question what are the most important results of the introduction of strategic/medium-term planning were:

- Formed working groups
- Developed capacities for strategic planning
- Introduction of the Budget Law, Fiscal Strategy and other relevant documents

Respondents‟ highest ranked answers on question what were the biggest challenges in the process of the introduction of strategic/medium-term planning were:

- Lack of commitment of managers
- Unclear roles of people involved in the planning process
- Opposite instructions and the requirements of the Ministry of Finance and the General Secretariat

The answers showed that respondents have developed understanding of why the capacity development process for strategic planning is important. Also the segment showed what is considered to be the biggest challenges in this process suggesting where further actions are needed.

4. CONCLUSIONS

The first part of the paper is consisted of background review of capacity development process for strategic planning in Central Institutions of Government of Republic of Serbia. A wide range of actions has been undertaken over the period 2005-2012 in order to build and develop sufficient capacity in Central Government to strengthen planning, monitoring and policy coordination process for effective support needed for addressing complex policy challenges. As a result, the policy-making and co-ordination system in Serbia now posses some elements required for an effective public management and public administration system.

Capacity development in Serbian Central Government was long-term process that lasted for seven years, through which individuals, organizations and society (the process included all line ministries and related organizations, Secretary General, other funding organizations all leaders and almost all staff of this organizations), strengthen and organize their systems, resources and knowledge, in area of strategic planning should enabled better planning, coordination and control of policies and politics, which should enabled effective and efficient implementations of reforms that on the end will contribute to sustainable development. Evaluation showed that capacities for strategic planning on individual and enabling environment level are fairly developed, but it still have to be developed on organizational level.

In depth evaluation has been conducted using survey and structured interviews with state authorities‟ representatives. Evaluation was consisted of assessment of institutionalization of the planning function, development of strategic plan, management of strategic plan implementation and capacity development support; and evaluation of goals, results and challenges of strategic planning process capacity development. The research showed that the highest level of capacity development was achieved in the process of strategic plan development, but the problem are segments of planning function institutalization and capacity development support. For further development of capacities the following actions have to be made:

- Top executives have to take more active role and formal responsibility.
- Responsibilities for medium-term planning activities have to be formaly included in job descriptions.
- Methodology for project/program prioritization has to be developed.
- Human Resources Management Service (HRMS) need to take more proactive approach in the process of capacity development.

Finally, results that this paper provides are significant in the way that they could contribute to further development of capacity development on organisational level.

ACKNOWLEDGEMENTS

This paper is a result of Strategic Project founded by Ministry of Education and Science of republic Serbia: Exploring modern trends of strategic management of the application of specialized management disciplines in the function of the competitiveness of Serbian economy, No 179081.

[2]University of Agricultural Sciences and Veterinary Medicine Bucharest, 59 Marasti, District 1, 11464, Bucharest, Romania, camelia_slave@yahoo.com

Abstract: *Danube, the second longest river in Europe through a tortuous path in the Black Forest to the Black Sea. River arises through union sources: Breg, Brigach, Donau Quelle and joins the sea by three branches: Chilia, Sulina and St. George forming the Danube Delta. As space crosses so large and diverse to establish the International Commission for the Protection of the Danube River which aims to ensure the sustainable use and equitable access to water resources along the river basin, the Commission's work jumpers Danube River Protection Convention which is an important instrument for cooperation and transboundary water management in the Danube basin. Romania was in 2007 president of the International Commission for the Protection of the Danube River. Romania is interested to protect the water of the river, given the length that it crosses the country and the fact that the arms of the Danube flows into the Black Sea forms one of the most rare and beautiful wetlands, named Danube Delta. It is appreciated that the Danube Delta Biosphere Reserve has become as compared to other deltas of Europe and the Earth has retained a high biodiversity, that a multitude of species from a variety of systematic units. In the European continent, Delta retained natural habitat. This area has special significance both ornithological aspect and morphological and climatic factors have described it as a very important reserve. Nature reserves in the area of 41500 ha were delineated in three different biotypes of the delta and was placed in the international studies program "Man and Biosphere" attached to UNESCO to recognize the importance of Romanian scientific nature reserves and the richness and variety of flora and fauna elements.*

Keywords*: biosphere, convention, delta, flora, river.*

1. INTRODUCTION

Nature recommences same things again, every year, day, hour, so it creates a kind of infinity and eternity – Blaise Pascal Danube from its source at the river mouths- Danube Delta.

The Danube River is the second largest in Europe after Volga and it is formed by the confluence of the rivers Briegach and Brege that arise from the Black Forest. The Danube has a length of 2 840 km; an area of its basin is about 817 000 km2; the incoming flow into the Delta is of 6350m3/s and is divided in the three branches: Chilia 58%, Sulina 19%, Sf. Gheorghe 23%. The Danube Delta is shared by Romania and Ukraine and has a total area of 4178 km2, of which 82% (3446 km2) in Romania and 18% (732 km2) in Ukraine.

Because of its route, the Danube can be called the river of ten countries (Germany, Austria, Slovakia, Hungary, Croatia, Serbia, Romania, Bulgaria, Republic of Moldova, and Ukraine) and also the river of four capitals (Vienna, Bratislava, Budapest, Belgrade).

2. MATERIALS AND METHODS

2.1. The International Legal Regime of Danube

Water is an indispensable element of the existence of life on the planet, a renewable, vulnerable and limited natural resource, a raw material for productive activities, an energy source and a transport pathway, a key factor in maintaining the ecological balance for the existence of life and the realization of all human activities (Dutu, 2010). “This scarce resource essential for life should be considered a natural treasure that is part of the common heritage of the mankind”.

2.2. The international regulations on the protection of the Danube

The international regulations on the protection of the Danube appeared relatively late in comparison with those for other continental waters. For a long time the international legal regime of the Danube referred exclusively to the freedom of navigation, to the economic and technical use of waters and to the fishing (Marinescu, 2003).

Since it crosses a vast space it was set up the International Commission for the Protection of the Danube River. The Commission aims to ensure sustainable use and equitable access to water resources along the river basin. The Commission's activity has the Convention of the Danube River Protection as a starting point, which is an important instrument for cooperation and trans-boundary water management in the Danube basin.

An important moment in the history of Danube´s protection efforts is the signing of the Declaration of Cooperation between the Countries of the Danube in the Management and Protection of the Waters of the River against Pollution on 13 December 1985 in the Conference of Bucharest (Dutu, 2010).

After 1990, the riparian concern regarding cooperation in order to protect the river from pollution, both bilaterally and multilaterally grew. The situation materialized with the signing of several conventions and agreements, among which the Convention on Cooperation for the Protection and Sustainable Use of the Danube River - signed in Sofia, at June 29, 1994.

2.3. Current International Legal Framework

The international legal framework for protection against pollution of the Danube border currently has three categories of international norms: rules and principles on trans-boundary pollution, specific regulations targeting watercourses and international lakes, and regulation governed by coastal states within bilateral and regional cooperation.

2.3.1. Principles on trans-boundary pollution

Most of these principles are rooted in customary international law. The Stockholm Declaration on the Human Environment in 1972 established the fundamental rule which provides that the states must proceed in such a way that activities within their jurisdiction do not damage the environment of other states. This rule was taken up and proclaimed subsequently in the texts adopted at the 1992 Rio de Janeiro Convention on Environment and Development (Cobzaru, 2013).

Other principles and rules were set out in the Espoo Convention -1991- on environmental impact assessment in a trans-boundary context. The same category of principles on trans-boundary pollution includes rules concerning the responsibility of polluters, the duty to inform immediately the states likely to be affected by any event which may cause adverse effects on their environment, the rule of equal application of the national law, regardless of the place producing the environmental damage.

2.3.2. Specific regulations regarding watercourses and international lakes

The development of this category of regulations occurred through two framework agreements: the Helsinki Convention -1992- on the protection and use of trans-boundary watercourses and international lakes and the Convention on the right of use of waterways for purposes other than navigation -New York, 1997.

The concept of trans-boundary waters and of trans-boundary impacts was explained and regulated according to the terms of The Helsinki Convention which is the international regulatory framework on the subject. The injurious effect of the trans-boundary impact can "take many forms: attacks on human health, flora, fauna, soil, air, landscape and historical monuments, buildings; the interaction among these factors may also means a breach of cultural heritage and of socio-economic conditions resulting from alterations of those factors."

The Helsinki Convention has created a general legal framework that was an incentive for the elaboration of agreements between riparian of international watercourses to prevent and reduce trans-boundary pollution.
The New York Convention aims "to enable to use, highlight, devote, manage and protect international watercourses and promote optimal and sustainable use for the benefit of current and future generations".
The general principles of the previously mentioned conventions are equitable and reasonable use, the obligation to not cause significant damage, paying special attention to meet the essential needs in conflict resolution etc.

The Sofia Convention -1994- on the sustainable protection and conservation of the River was signed by the ten Danube countries and the European Community, and it has a sub-regional integrative character.
The fundamental objectives of cooperation between the Danube countries, the basic principles of the river protection, and so on were thus established. (Dutu, 2010)

A series of bilateral documents aimed preventing and combating the pollution of the river was agreed between riparian states. Such documents are: in 1991 the Convention between Romania and Republic of Moldova, in 1991- the Convention between Romania and Bulgaria in 1993 the Agreement between Germany and Romania, in 1993 the Convention between Romania and Slovakia, in 1998 the Convention between Romania and Yugoslavia on operation and maintenance of hydropower and navigation systems "Iron Gates I" and "Iron Gates II".

Community environmental law is constantly growing. The member states of the European Community have already assimilated the Community rules into law while the candidate states are in the process of harmonizing and assimilating those; the adoption of EU legal regulations (represented by about 20 directives on water) is an important milestone, especially for determining the water quality objectives and the regulation of water discharges.

The International Day of the Danube is celebrated every year on the 29th of June, as initially proposed by the Danube countries and under the auspices of the International Commission for the Protection of the Danube River (ICPDR in Vienna). This day marks the signing of the Convention on Cooperation for the Protection and Sustainable Use of the Danube River, an event that took place in Sofia (Bulgaria), on June 29, 1994.
Danube Day celebrations take place in all Danube states to mark their mutual desire to join forces in support of protecting this unique river in Europe.

The International Commission for the Protection of the Danube River launched "Danube Box", an educational project in the domain of the water protection. This project is designed as a tool (kit) to be use by teachers and students in the education process at the level of elementary school.

"The Book of the Blue Danube" has a special role to inform and educate children on values and traditions belonging to the Danube area and increase their awareness regarding the need to protect and preserve the aquatic ecosystem of the river basin.

The Danube creates a delta with three great branches at its mouth to the Black Sea. The first branch is Chilia. With a length of 120 km it is the most vigorous as it accounts for 58% of the Danube's flow. Chilia, with its many biffs and islets, has the greatest depth of the three channels, 39m.

Sulina, the second branch, is mainly used for navigation because there was done extensive work to deepen and to correct the meanders. The channel length decreased from 93 km to 64 km because of these works which took place between 1862 and 1902.

The third branch, Sfântul Gheorghe, is the oldest and it carries 24% of the volume of water and river deposits (alluvia). The branch has undergone significant transformations, namely the cutting of six meanders, which brought its length down to 70km.

Remarkably, the Danube Delta has become a biosphere reservation. It has retained a high biodiversity (a multitude of species from a variety of systematic units) in comparison with other deltas in Europe and even on Earth. The Danube Delta has become a Biosphere Reservation due to the fact that compared to other deltas on Europe or on the Earth; it has retained a rich biodiversity, ie a multitude of species from a variety of systematic units. Given the importance of this unique space, since 1991 the Romanian government started a comprehensive program to inventory the flora and fauna of the Danube Delta Biosphere Reservation. The purpose of this ample effort is to gain a better understanding of an important component of the natural heritage in a biosphere reservation and identifying species that require protective measures and / or conservation.

As a result, this huge puzzle represented by the Danube and its delta is a habitat for a wide variety of plant and animal communities estimated at 30 types of ecosystems and 7405 animal and vegetal species.

Given the unique nature of the Danube Delta, the concerns about environmental protection, rational use of resources and preservation of its ecological balance have increased.

Regarding the delta, technical and scientific research revealed two relationships that are fundamental from an ecological point of view. These relationships affect an area far beyond their geographical boundaries, namely:
a.- the key position for the ecology of fish fauna in Danube Floodplain and the Black Sea coastal zone;
b.- the key position in the life of migratory avifauna in Europe, taking into account that delta is situated at the crossing of the main bird migration routes.

3. CONCLUSION

The Danube Basin contains various riparian countries and a total population of about 250 million inhabitants, which generates pressure on the river environment. Generally, Coastal States have not sufficiently developed economies and they do not give due consideration to environmental issues; from the point of view of the industry, agriculture and technology, the most developed is the upper basin, followed by the middle basin and the lower basin.

The Cooperation of the Danubian states is influenced by reporting to the process of European integration in the context that a part of riparian countries are members of the European Union (Germany, Austria, Czech Republic, Hungary, Romania, Bulgaria).

The Conservation of the natural conditions and historical and cultural monuments aligns with the basic concerns of our state: "It is necessary to take rigorous measures to control the industrial hazards, to prevent water and air pollution, to protect the forests, rivers, mountains and lakes considered monuments of nature. Within the European committee, the Danube Delta maintains its natural biotope and thus it has an exceptional significance taking into account the ornithological rapport and the morphological and climatic factors that have made from it an important reserve with many rare vegetal and animal species. These features have made the delta to be considered absolutely unique compared to any first rank touristic area in our country.

The Danube Delta integrates:
- Resources of reed (cane) for cellulose and paper manufacturing industries;
- Areas for hunting and fishing;
- Recreation places for tourists;
- Areas of scientific interest.

In 2000, due to the favorable conservation status of the ecological systems and species in the Danube Delta, the Council of Europe awarded the European Diploma for this reserve, diploma renewed in 2005. Home to a wide variety of plant and animal species as well as associations and communities particularly interesting and valuable, the Danube Delta remains one of the best preserved deltas in Europe, being declared Natura 2000 site both as Special Area of Conservation and Avifaunistic Special Protection Area.

The objectives that we have set through the establishment of the Danube Delta Biosphere Reservation are based on the principle of sustainable development whose primary goal is re-naturalization of the delta by removing the disastrous effects of the past. Parallel efforts were made to preserve the entire Delta ecosystem's potential fauna and flora, to be able to offer to people loving the nature not only eco-tourism, but also the opportunity to enjoy - now and in the future - the benefits of nature.

The fragility and the active dynamic of the deltaic system aroused for a long time the interest of scientists. At the same time, all actions that must carry ARBDD require a scientific foundation for a rational, environmental management, ensuring both biodiversity conservation and sustainable development. The Danube Delta is the chosen place by nature and people, where all actors involved are trying to understand and learn how to use natural resources and, at the same time, preserve them for the future.

The Romanian wetlands were defined as stretches of swamps, marshes, natural or artificial, permanent or temporary waters, where the water is stagnant or flowing, fresh or salted, including the marine water bodies whose depth at low tide does not exceed six meters. The above mentioned areas are areas where the saturation with water is the main determinant of the soil nature, and of the types of plant and animal communities living in the soil or on the soil surface.

The Convention on Wetlands signed in Ramsar, Iran, in 1971, established February 2nd as World Wetlands Day; the document was ratified by Romania through Law 5/1991. This year, the World Wetlands Day is celebrated under the slogan “Without wetlands there is no water" and is the occasion to draw attention to the

fact that the sustainable use and conservation of the wetlands must be part of any solution to reduce the global drinking water crisis.

MULTIPLE CRITERIA APPROACH TO SELECTING SITES FOR PORTS OF NAUTICAL TOURISM

Mirjana Kovačić[1], Alen Jugović[2] Ana Perić Hadţi ć[3]
[1]University of Rijeka, Croatia, Faculty of Maritime Studies, E-mail – mirjana051@gmail.hr
[2] Faculty of Maritime Studies, E-mail – ajugovic@pfri.hr
[3] Faculty of Maritime Studies E-mail – ana@pfri.hr

***Abstract**: In this scientific paper the authors explore the issue of selecting a site for a nautical tourism port using the methodology of multi-criteria analysis (MCA). Given the huge importance of tourism, in particular, nautical tourism in most maritime countries, including the Republic of Croatia and its coastal counties, any help in resolving that issue would be of immense significance. In Croatia, the existing distribution of nautical tourism ports (NTPs), their capacities and the quality of their services are not fully suited to the spatial features. Often these ports fail to blend with their environment and provide no effective protection to natural assets. The distribution of capacities does not match actual spatial potential, while the quality and level of facilities and services varies greatly and is generally inadequate. Hence, the aim of this paper is to identify criteria for the location and development of NTPs in coastal areas. The paper applies the multi-criteria approach to selecting a site for NTPs in Split-Dalmatia County (SDC). Potential micro locations (35) in that region have been studied and criteria and sub-criteria for selecting sites for NTPs, identified.*

***Keywords**: criteria, multiple criteria analysis, site analysis, nautical tourism port, Croatia.*

1. INTRODUCTION

Site selection is a strategic problem addressed in many studies and by many authors whose scientific work have provided a better understanding of the importance of using the right methodology. Different issues are often united in a methodological approach involving the use of multiple criteria analysis (MCA). The reason for this is the fact that using MCA at the scientific level helps to expand the number of NTP sites and sites for accommodating vessels on land, thus resolving the problem of lack of space and the growing demand for berths by boaters.
This paper focuses on identifying the current state of nautical tourism in Croatia, specifically in Split-Dalmatia County (SDC), comparing it with Mediterranean trends, and analysing its spatial and environmental factors. Upon analysing existing and proposed NTP sites in SDC, the advantages and carrying capacities of marine areas are evaluated and criteria for selecting sites on the mainland and on islands are established.
Through research and analyses, the authors seek to accomplish the purpose of this paper which is to define spatial possibilities and constraints, and to propose criteria to ensure the selection of a location for NTPs. With regard to the research problem, the general and special goals set call for the application of MCA in selecting the criteria critical to determining the location for NTPs.

2. THEORETICAL DETERMINANTS AND NAUTICAL TOURISM DEVELOPMENT IN CROATIA

One of the most promising forms of tourism in Croatia, nautical tourism is a complex tourism and maritime concept and its pervasive connection with the sea and navigation makes it all the more difficult to define (Luck, 2007). Namely, the maritime component does not define nautical tourism in its entirety, although superficial analysis may make this seem so (Luković, 2007). Given the fact that both *tourism* and *nautical tourism* are derived concepts representing a set of activities adherent to them but which can change and be added to over time, the authors conclude that nautical tourism is a multidisciplinary phenomenon.
The Tourism Activities Act (Official Gazette 8/96, 19/96, 76/98) defines nautical tourism as "*the navigation and sojourn of tourists/boaters in vessels and in NTPs, for the purpose of recreation and entertainment*".
In the Croatian Adriatic, nautical tourism received powerful incentives and a strong identity in the mid-1980s through the construction of the ACI Marina system, which quickly became the leading nautical organization in the Mediterranean. However, due to various reasons, this role as a leader was lost during the two decades following Croatia's independence. During that period, France, Greece, Turkey, Italy, and other Mediterranean countries invested heavily in marina construction. Today the nautical tourism capacities of Italy are five-fold greater than those of Croatia. An analysis of the current state of nautical tourism in Croatia indicates that the assets of Croatia's Adriatic coast and islands have still not been valorised to any sufficient

extent (Bošković et al, 2006). An analysis of statistical and other available data and the Development Strategy of Nautical Tourism in Croatia (2008) suggest that less than half of all vessels and yachts sailing the Croatian Adriatic in the summer season use berths in commercial marinas, while the majority of vessels and yachts are freely anchored in natural coves or moored in transient local harbours. The main reason for this is the shortage of marina capacities in the summer period, in particular, on the islands. Less than half of nautical tourism traffic (excluding small vessels that do not use marinas) in Croatia is encompassed in the organized accommodation of vessels, an activity which has an environmental protection function as well as an economic function. SDC is no exception; it accounts for a mere 13% of all available berths in Croatia. Considering that the existing offering of berths at sea and on land is lacking, many authors are of the opinion that it is necessary to plan sites for the organized accommodation of vessels.

Table 1: NTPs in Croatia and SDC, 2006 - 2012

Year	NTPs, total		Share of SDC in %	Indices	
	Croatia	SDC		Croatia	SDC
2006	95	11	11.6%	-	-
2007	94	11	11.7%	99	100
2008	97	11	11.3%	103.2	100
2009	98	13	13.3%	101	118.2
2010	98	13	13.3%	100	100
2011	98	13	13.3%	100	100
2012	98	13	13.3%	100	100

Source: the authors after CBS

Table 1 shows the number of NTPs in Croatia and SDC. The table demonstrates a continued growth in the number of NTPs in Croatia over the years, the greatest increase being in 2008. SDC also displays an upward trend, with the greatest boost being in 2009.

Table 2: Number of berths in Croatia and SDC, 2006-2012

Year	NTPs, total		Share of SDC in %	Indices	
	Croatia	SDC		Croatia	SDC
2006	15 973	1 591	9.9%	-	-
2007	15 834	1 581	9.9%	99.1	98.4
2008	16 403	1 576	9.6%	103.6	103.6
2009	16 848	1 789	10.6%	102.7	101.1
2010	16 913	1 792	10.6%	100.4	101.1
2011	17 059	1 913	11.2%	100.9	106.8
2012	17 454	2 238	12.8%	102.3	117

Source: the authors after CBS

Table 2 shows the number of berths in NTPs in Croatia and in SDC per year. Both Croatia and SDC display an obvious upward trend, with SDC accounting for about one-tenth of all berths in Croatia.
An analysis of the current state of NTPs in Croatia compared with the Mediterranean countries (Kovačić et al, 2012), together with an analysis of the existing state of infrastructure for accommodation of vessels in SDC, reveals there are:

- Sites which are established in existing plans
- Sites already being used for the purpose of nautical tourism although there is no organized accommodation of vessels at such sites and
- Sites which need to be included in new spatial plans.

Previous practice indicates that without the approval of the local community, the business policies of investors and the location of new NTPs come up against resistance as early as the initial phase of site preparation.
SDC spatial plans have identified sites for the construction of new NTPs, spurred by the growing demand for berths, the distinctiveness of the destination and the vicinity of outbound tourism regions. NTP capacities foreseen in plans are in accordance with the county's spatial potential and the interest of boaters. A large

number of NTPs in SDC are used only during the summer season. The existing ports and harbour that do not have NTP status are exploited extensively and their marine areas are mostly occupied by small vessels, with no economic effect for the local community.
A survey conducted in SDC local government units points to poor communication (interaction) between towns/municipalities and NTPs, primarily as a result of imposed coexistence in a constrained area of two separate entities whose interests and goals apparently seem to differ:

- A port of nautical tourism – a marina, in particular – is a business entity focused on business efficiency, productivity, market competitiveness and development.
- A town/place/municipality, as a community of residents, is focused on promoting the well-being and quality of life of its citizens, and accordingly aspires to the environmental and visual assets and the expectations of people (residents).

From these diverging visions, conflicts may emerge bringing the physical and functional use of space into question (Kovačić et al, 2013). Hence, it is essential to involve the local government in the preparation phase of spatial planning, not only to gather opinions but also to communicate the socio-economic effects that the organized accommodation of vessels could bring (Favro et al, 2005).
The Development Strategy of Nautical Tourism (2008) is a fundamental document of the future development of nautical tourism in Croatia. It foresees the construction of NTPs as follows:

- Marinas in the vicinity of airports
- Marinas and moorings within urban centres
- The organization of transit berths at tourist moorings in traditional island ports
- The organization of a system of anchorages
- The construction of marinas for mega yachts.

3. BASIC FEATURES AND METHODOLOGY OF MCA

If conducted correctly (Nikolić and Borović, 2006), MCA requires the cooperation of all interested parties and the practical involvement in the decision process of all stakeholders to whom a problem applies, which, on the other hand, facilitates the realization of obtained priorities and eliminates any doubts concerning subjective decision making (Favro and Kovačić, 2010). The importance of building NTPs and using natural resources in contemporary conditions is particularly emphasized, as well as the number of parties interested in reaching a suitable solution (Jugović et al, 2011). The transparency of available data used in making analyses is highly important because it makes it possible to check whether parameters have been correctly evaluated. From a methodological perspective, MCA represents a systems approach, and in terms of methodology, it is the most effective and functional approach to problem resolution (Kovačić, 2010).
A systems approach to the problem of selecting sites for NTPs in SDC points to an unstructured problem which at strategic and tactical levels of decision making required a complex analysis of the goals set in this research. Problem structuredness or refinedness is the most important characteristic with regard to the decision-support methods and procedures available for a concrete problem (Brans and Vincke, 1985).
Before MCA methodology can be applied, it is necessary to establish whether the problem is characterized by alternative solutions. This was established for the problem of selecting sites for NTPs in SDC. It is also essential to ascertain whether all relevant criteria have been taken into consideration and have been properly evaluated, in particular parameters which are the product of expert judgements. Previous experience in evaluating the use value of space has justified the convenience of using MCA because it makes it possible to understand and then evaluate all aspects of a problem across a variety of criteria.
A number of methods can be applied in resolving a problem, such as linear programming (Barković, 2002), AHP (Saaty, 1990), ELECTREE (Čupić et al, 1991), PROMETHEE (Brans et al, 1986, 2005), GAIA (Mareschal, 1988) and other methods. The experiences of authors in this field differ (Brans et al, 1984, 1986, Martić, 1992, Nikolić et al, 1996). In accordance with this paper's research problem, the PROMETHEE and GAIA methods have been applied.
PROMETHEE is an MCA method that makes it possible to express differences in the soundness of a particular site or part of the coastal zone. A mathematical procedure helps to objectivize the suitability of the selection of an NTP site.
The use of the GAIA software provides numerical results and charts that help decision-makers to understand the problem more clearly and gain better insight into the relations between criteria and activities.

4. METHODOLOGY FOR ASSESSING THE IMPORTANCE OF CRITERIA

Based on the research conducted and the results obtained from analysing the facts, the authors have identified the crucial criteria and ranked them in accordance to their importance. The weighting coefficient has been calculated for each criterion, and its preference level.

Any multiple criteria problem contains a number of different and, usually, conflicting criteria that can be of differing importance to decision makers. Most methods of multiple criteria decision-making (MCDM), require information on the relative importance of each criterion (Roubens, 1990). A number of methods can be applied in assessing the level of importance of criteria, each of which relies completely upon human judgement. The techniques in this category may pertain to individuals or to groups of people. Measuring opinions consists of a series of methods used to obtain information from an individual or to gather information from a certain number of people, mostly experts in a field relating to the given problem. The advantage of group opinion over individual opinion is that it provides a broader spectrum of information and brings expertise and experience to the analysis. However, there are certain problems related to the use of expert groups. An important aspect of assessing criteria importance is the fact that the involvement of a number of people will generally result in a varied ranking based on an individual judgement. So, methods are required that serve to synthesize these differing assessments. Relative criteria importance can be expressed in terms of priority or weight. Priority relates to cases in which criteria are listed in order of importance. In this, until a higher level (more important) criterion is taken under consideration, the next (less important) criterion may not be considered. On the other hand, weighting is used to numerically express (usually in percentages) the importance of a criterion or to distinguish between the relative importances of several criteria within the same priority. For the purpose of this research, group weighting methods have been used. These are: (Nikolić et al., 1996).

• **Ranking** – It is assumed that n criteria Aj (j = 1, 2, ..., n) need to be assessed and that l experts Ek (k = 1, 2, ..., l) are involved in this task. Each referee (expert) is required to rank all criteria according to their importance, by assigning the number $n-1$ to the most important criterion, the number $n-2$ to the second most important criterion and so on, down to the least important criterion that is assigned the number 0. This is a fairly simple method and requires little time to obtain the judgements of experts. Because only a set of whole numbers is obtained from each referee, there is no need for weighting the assessments of each individual referee. Instead, only the rankings of all experts are weighted.

• **Rating** – Each referee is presented with the criteria and asked to give a numerical rating to each criterion. Ratings are usually made on a given scale of, for example, 0 – 10 or 0 – 100. Each criterion is weighted separately as the sum of elements in a given line in the table. If these weights need to be normalised, this is done by dividing each criteria with the sum of all weights, which is equal to the number of referees.

5. APPLYING MCA IN SELECTING NTP SITES IN SDC

This chapter analyses SDC spatial and environmental factors and presents criteria and sub-criteria for selecting NTP sites.

5.1. ANALYSIS OF SDC SPATIAL AND ENVIRONMENTAL FACTORS

According to data of the Croatian Bureau of Statistics (2013), SDC is the largest Croatian county in terms of space. SDC has a total area of 14,045 km^2 of which, land accounts for 4,572 km^2 and 67.5% is sea (9,473 km²), (RiĐanović, 2002). The county is located in the central part of southern Croatia in the historical district of Dalmatia. It stretches from Vrlika in the north to the islands Vis and Palagruţa in the south, and from Marina in the west to Vrgorac and Gradac in the east. Its population numbers 455,242 people, of which 67% live in the coastal area; 7%, on the islands; and 26%, in the hinterland. SDC comprises 368 settlements organized in 16 towns and 39 municipalities.

Being the most populated and developed part of Dalmatia, the coastal zone of SDC has always played an important role in terms of traffic in this part of the Adriatic. This is where the traffic corridors running parallel to the coastline intersect with traffic corridors running vertical to the coast from the hinterland (neighbouring Bosnia and Herzegovina), and continue in the direction of the islands and across the Adriatic.

The island area comprises 74 islands and 57 rocks and reefs. The islands are poorly populated. Although economically more developed than the hinterland, the islands have experienced steady emigration due to a variety of circumstances. Four islands stand out in terms of size and population density: Šolta, Brač, Hvar and Vis. Six more islands are also populated: Veli Drvenik, Mali Drvenik, Sv. Klement, Šćedro, Biševo and Sv. Andrija. The islands have a pronounced Mediterranean climate and gentle relief.

Table 3: Spatial features of large SDC islands

Island	Area km^2	Length of coast (km)	Indentedness coefficient
Šolta	58.98	73.1	2.69
Brač	394.57	175.1	2.49
Hvar	299.66	254.2	4.14
Vis	90.26	76.6	2.88

Source: by the authors according to CBS data for 2012

SDC is within the zone of the Adriatic type of Mediterranean climate, the primary features of which are dry, hot summers and mild, humid winters (Filipčić, 1996). Mean annual temperatures drop from the islands towards the coastal zone and hinterland, while the amount of annual precipitation increases. The island area has a warm climate with abundant sunshine, temperatures that rarely drop below zero and little precipitation, unlike the climate of the hinterland where temperatures during the autumn and winter often fall below zero and there is much more precipitation.

5.2. ANALYSIS OF MCA INPUT PARAMETERS – CRITERIA AND SUB - CRITERIA

In resolving the problem of selecting NTP sites in SDC, factors relevant to site selection were previously analysed. The analysed factors were grouped according to their importance and parameters were identified that can be recognized as criteria for site selection. The importance of each criterion based on rating is defined by its weight or priority. Priority represents the importance of an individual criterion in a group of factors. These criteria, together with others identified during analysis, make up the information basis that enables decision makers to choose one solution from a number of proposed solutions. This is important with regard to management structure and the management level of the decision-makers.
Considering that an array of factors impacts the quality and suitability of a coastal area for NTP development, target analysis was used to separate those factors (criteria and sub-criteria) that have the greatest influence on the quality of specific sites and parts of the coastal zone. Elimination criteria were also needed to exclude those areas whose natural features would be substantially threatened by NTP construction.

Table 4: Criteria and sub-criteria for selecting an NTP site in SDC (with assigned weights and established min/max)

Criterion/sub-criteria		***weight***	***min/max***
Institutional and political	**A**	**10**	
Spatial plans of micro locations	**A1**	**8**	**max**
Regional tax and surtax system	**A2**	**2**	**max**
Natural and accommodation	**B**	**25**	
Geo-morphological features (relief of the coastal area, etc.)	**B1**	**5**	**max**
Hydrographic features of the site	**B2**	**7**	**max**
Oceanographic features of the micro location	**B3**	**6**	**max**
Micro climate features	**B4**	**7**	**max**
Environmental	**C**	**25**	
Ecological value and vulnerability of micro location to human activity	**C1**	**8**	**min**
Environmental impact assessment	**C2**	**8**	**min**
Amount of investment in environmental protection (5%-30%)	**C3**	**9**	**max**
Technical and technological	**D**	**15**	
Carrying capacity of micro location – size of vessels (yachts); assumed installed fleet	**D1**	**4**	**max**

Level of development of transport and other infrastructure, distance from airport, distance from Port of Split	**D2**	**3**	**max**
Distance from town cores	**D3**	**3**	**min**
Safety and sailing conditions at the micro location	**D4**	**5**	**max**
Economic	**E**	**15**	
Nautical services offering in the region (potential scope of market activity)	**E1**	**2**	**min**
Offering of providers in surrounding area	**E2**	**3**	**max**
Concession fee	**E3**	**3**	**min**
Investment amount	**E4**	**5**	**max**
Available personnel (professional ability)	**E5**	**2**	**max**
Socio-cultural	**F**	**10**	
Direct and indirect benefits	**F1**	**4**	**max**
Level of urban development and distinctiveness of micro location	**F2**	**3**	**max**
Improvement in quality of life of local community	**F3**	**3**	**max**

Source: the authors

For some (or all) criteria, corresponding qualitative ratings may be given which are translated into quantitative values using a linear scale of 0 – 10 and the ratings *poor*, *average* and *good*. Criteria have two characteristics:

- They can be of the maximization or minimization type.
- Most often they do not have the same importance and it is customary to assign weight coefficients. The sum of sub-criteria weights equals the global (total) weight of a criterion.

In the rating procedure, criteria weights were normalized by the total possible sum (100), which greatly facilitated further analysis.

The greatest weights were given to the Natural and Accommodation criterion and sub-criteria, and the Environmental criterion and sub-criteria. The importance of the Institutional and Political criterion and Socio-cultural criterion is relatively small. The Technical and Technological criterion and Economic criterion are of slightly less importance, which is understandable considering that the economic criterion is not necessarily crucial in selecting suitable sites and is dependent upon technological solutions. Distance from the town core, road and other infrastructure is not a crucial factor considering that research is focused on sites on islands which already have to deal with the problem of distance and accessibility. When sub-criteria are analysed, it is evident that some sub-criteria have greater weights than others. For example, all three sub-criteria of the Environmental criterion have distinctly greater weights. Interestingly, sub-criteria A1- Spatial plan of micro location – has greater importance than most of the sub-criteria of the Technical and Technological criterion and the Economic criterion. This is because sub-criterion A1 could be a constraining factor in cases where a spatial plan has not been adopted or does not foresee a possible NTP site in a given micro location. Such cases require preliminary research to be carried out and the presentation at the local level of all benefits and advantages that an NTP built at a specific micro location could bring. Special attention should be called to the importance of safety and sailing conditions in selecting a site, as experts have rated this sub-criterion as important in ensuring the safety of boaters and their vessels. Considering the widespread trend in the Mediterranean and worldwide towards vessels exceeding ten metres in length, sea depth plays an important role in selecting sites for NTPs.

6. RESULTS ANALYSIS AND PROPOSED MEASURES FOR FURTHER RESEARCH

The ratings are the results of research based on available data and cartographic presentation of the Croatian Hydrographic Institute of Split for each individual location. Taking into consideration the collected data and the importance of factors for selecting sites for NTPs, the ratings for each group of criteria can be explained.

The Natural and Accommodation criterion is especially important and its sub-criteria were analysed for each individual location, where, for example, the depth of the marina area was established and assigned a certain value. All three sub-criteria were maximized. Criterion C – environmental factors – was rated on a 1-10 scale using five sub-criteria. While the importance and influence of some of these sub-criteria was maximized, in

others (C1 and C2) it was minimized. Criterion D – technical and technological factors – consists of four basic sub-criteria rated on a 1-10 scale. Because of their importance, the value of these sub-criteria was mostly maximized. Sub-criteria D2 and D3 referring to the distance of an NTP to the Port of Split and the airport, and to the distance from the town core, respectively, were expressed in separate ratings based on the geographical position of each site. The distances from each site were calculated and a value in points assigned. Criterion E – economic factors – was broken down into five sub-criteria rated on a 1-10 scale, with the exception of sub-criterion E4 which was expressed in actual monetary value. It should be noted that an estimation of the costs of building NTPs in the selected sites is not possible without a comprehensive cost analysis of individual sites. Such an analysis involves the meteorological and hydrographic features of areas. The need to build a breakwater or set up a floating pontoon or sea-wall is determined based on the specific features of each site, considerably impacting construction cost. The availability of infrastructure and the condition of the shore (stone waterfront or a rocky shore full of shoal) also have a great impact on the NTP construction costs. The estimation involved the cost of building NTPs (with 50, 100, 150 or 200 berths). A preliminary cost estimation, which assumes the basic preconditions to building NTPs, was done for the sites included in MCA. This estimation represents the minimal investment required for constructing an NTP and while it may give a site a certain advantage in this phase of research, it is still not the deciding criterion or sub-criterion. The value of the overall investment increases depending on the facilities and services planned and the technological capacity of the nautical port. Criterion F – socio-cultural factors – consists of three sub-criteria, the importance of which has been maximized. The distinctiveness of a micro location contributes towards its selection and may bring direct and indirect benefits to residents. The rated criteria and sub-criteria and their maximization or minimization enable the presentation of the MCA procedure carried out.
The objective of research was to identify the criteria and sub-criteria required for selecting sites for NTPs in the SDC region. Research results point to six groups of criteria and 21 sub-criteria. Obtained by using the MCA method, these results may be used in the decision process to select sites for NTPs in SCD, which will be the subject of further research by the authors.

7. CONCLUSION

Great progress has been made in the Croatian Adriatic in the past 15 years through the development and construction of accommodation facilities for vessels, justifying the market orientation towards nautical tourism. The nautical tourism market is experiencing an upward trend in the Mediterranean and worldwide.
The paper examines the opportunities of developing NTPs in SDC from the viewpoint of proper spatial use and protection. The research conducted has accomplished the goals set out. Stress is placed on the correct selection of methodologies using the group weighting method and MCA, which can be applied in the decision process of selecting the optimum location and facilities for NTPs. The research results point groups of criteria and sub-criteria. In accordance with research problem, authors recomended the PROMETHEE and GAIA MCA methods and Visual PROMETHEE as very usefull software. Based on these insights, further progress can be made in research pertaining to the valuation and management of the marine domain and NTPs.
The criteria have been correctly chosen and are appropriate for the selection of NTP sites in SDC. Research results provide decision-makers with a scientific foundation on which to base further NTP development and site planning.

ALTERNATIVE – RSE ENERGETIC RESOURCES IN SLOVENIA AND SERBIA AND ITS POSSIBILITIES OF EXPLOATATION IN PRACTICE

Davorin Ţnidarič
FOV Kranj-Slovenija
davorinznidaric@gmail.com

Abstract: *Energy represent important source on the whole parameters of life. For human and other living organisms-give us an imortant souce for growth, progress, industry for resources, and production, nature for its survive. In this time and place, so many states, reduce its own consumption and with energy dependence and on the other hand with searching alternative sources, which will replace gas, oil, coal. Because of market demands, reducing fosil fuels, economic circumstances and in connection with political dependence and not at the end growth of environment senses. Countries have different nature possibilities depends of geografical, geological and generally economical situation. Many resources are have been disregarded, because of different reasons and energetic lobies. Today in time of many crisis with those alternative resources, countries can improve better and reliable use of energents. In this paper we will represent comparative possibilities two states Slovenia and Serbia, as future members of EU and compare with European. We will try to represent greath potention of exploatation sources in the case of development and economical potential two countries*.

Keywords*: energetic dependence, fosil fuels, alternative sources, European union, ecological minds*

1. ENERGY AND RENEWABLE SOURCES OF ENERGY (RSE)

The word energy derives from Greek words *ergon* which means work, power and vitality, and from the word *energeia* which means activity. Because of this the concept of energy is connected with the ability of a body to perform a work (Rant, 2008).

Renewable sources of energy (RSE) are sources which can restore and replace utilized resources as are wood-biomass, wind, hydro energy, sun energy.

Various states use different strategies to fulfil everyday needs of energy. These strategies depend on energy needs, trends in future, own resources etc. Slovenia for a certain period of time balances between criteria and demands resulted from the membership in European Unity, its own resources and dependence from foreign resources which presents about 50% of total energy need. Because of facts which have been already mentioned it is urgent to chose the adequate energetic scenario as soon as possible.

- **Fossil-nuclear scenario** with supposes energy increase for 30-40%. These scenario incorporates considerable increase of capacity of thermal power plants (TPP) using coal or gas; extension of operation of Nuclear power plant in KRŠKO (NEK – Nuklearna Elektrarna Krško) and construction of the second block Nuclear power plant Krško, construction of gas terminal in Koper, or construction of wind power plants and hydroelectric power plants.

- **Bad sustainable scenario** which assumes stabilization of electric energy use, continuation of operation for existing thermal power plants with the change of fuel (transition from coal to gas), eventual extension of operation for nuclear power plant in Krško, construction of hydroelectric plants along the entire Slovenian section of the Sava river, and smaller wind power plants and considerable number of photovoltaic power plants.

- **Significantly decentralized sustainable scenario** which assumes continual decrease in the use of electric energy and increased number of thermal plants for district heating– power plants (co-generation of thermal and electric energy) which will use gas and biomass as a fuel, closing of nuclear power plant in Krško until 2030, more hydroelectric power plants along the entire Sava river, increased number of small hydroelectric plants as well as use of geothermal energy and photovoltaics (Plut, 2010).

According to the available information and the facts that a new block in Thermal power plant Šoštanj (TEŠ 6) is in construction and there can be also observed strong tendencies to build additional block in nuclear power plant Krško it seems that the centralized and intensive fossil-nuclear scenario is the most probable (Plut, 2010).

In the long term energy balance for Slovenia until 2030 it is expected that 580 GWh of electric energy will be provided from dispersed renewable energy sources and 1.555 GWh from intensive centralized sources. The main contribution to the increase in the production of electric energy is expected from small hydroelectric power plants, wind power plants and from the use of biogas and wooden biomass.

1.1 Renewable Energy Sources in energetic balance of Slovenia until 2030

According to demands of EU which suppose continuous growth of production and use of energy from renewable sources in Slovenia it is expected that until 2030 the production of electric energy will increase on the following segments:

- Small hydroelectric power plants 72 MW (construction of new plants and extension of existing plants)
- Biogas power plants 41 MW (landfill gas, gas from agriculture and waste water treatment plants)
- Wind power plants 150 MW
- Photovoltaic plants 100 MW
- Wooden biomass plants 35 MW
- Big hydroelectric power plants 350 MW (finalization of plants in the lower Slovenian part of the Sava river 154 MW, construction of plants in the middle part of Sava 189 MW and reconstruction/finalization of plants in the upper part of Sava 12,5 MW).

In the period until 2030 it is expected that the total use of energy from renewable sources from existing 32,3 PJ will increase on 53,8 PJ (increase of 67%) (SURS, 2014)[1].

EU demands obligate Slovenia to increase production and use of energy from renewable sources. Nevertheless, there can be observed the influence of certain lobbies which try to limit the use of energy from renewable sources. This presents a step back in the process of green energy production. This is particularly evident in legislative regulations which limit or hinder the construction of small hydroelectric power plants, wind power plants and photovoltaic plants. The most evident regress in promotion of green energy presents the construction of the sixth block in the Thermal power plant in Šoštanj (TEŠ 6).

2. RENEWABLE SOURCES OF ENERGY AND EU

Today become more and more evident two facts: the exhaustion of stocks of fossil fuels and consequential tendencies to reduce energetic dependency as well as increased care for environmental protection and reduced degree of pollution. Therefore, many states turn from conventional energy sources as are coal, oil and gas to alternative sources of energy. They try to satisfy their energy needs with their own resources and thus increase energetic independence. Which energy alternative sources of energy are used depends on natural – geographical specialities of a particular country, by example Iceland exploits geothermal energy, Spain sun energy, countries with rich water resources exploit hydro energy etc.
States, members of EU as well as states which plan to join EU like Serbia have to reach in the period until 2020 certain goals in coordination to the Climatic-energetic package of measures accepted by EU on January 23rd 2008. Renewable sources of energy relate to three fields: electric energy, heating and traffic.

1 Original - SURS Statistični urad Republike Sovenije – english-Statistical office of the Republic of Slovenia

The concrete way on which particular states will reach these goals depend on their own natural and energetic-economic resources. Particular goals, emphasized in EU documents, are:

- At least 10% energy used in traffic should derive from bio-fuels
- Reduction of annual carbon dioxide emissions for 600-900 millions of tons for the entire EU
- Reduction of fossil fuel use for 200-300 millions of tons for the entire EU
- Reduction of dependence from fossil fuel import and thus increased stability of energy supply in EU
- Increased initiatives for the development of high technological industry offering new economic opportunities and creating new working places.

From Figure 1 it can be seen that particular countries have already reached the planned goals (20% of energy from renewable sources, by example Sweden, Finland, Denmark and Austria. On the other hand, countries classified at the frontend of ranking as are Malta and Cyprus will hardly reache the goals. Slovenia with 19,6% of renewable energy used in 2013 approached very close to the fulfilment of planned goals.

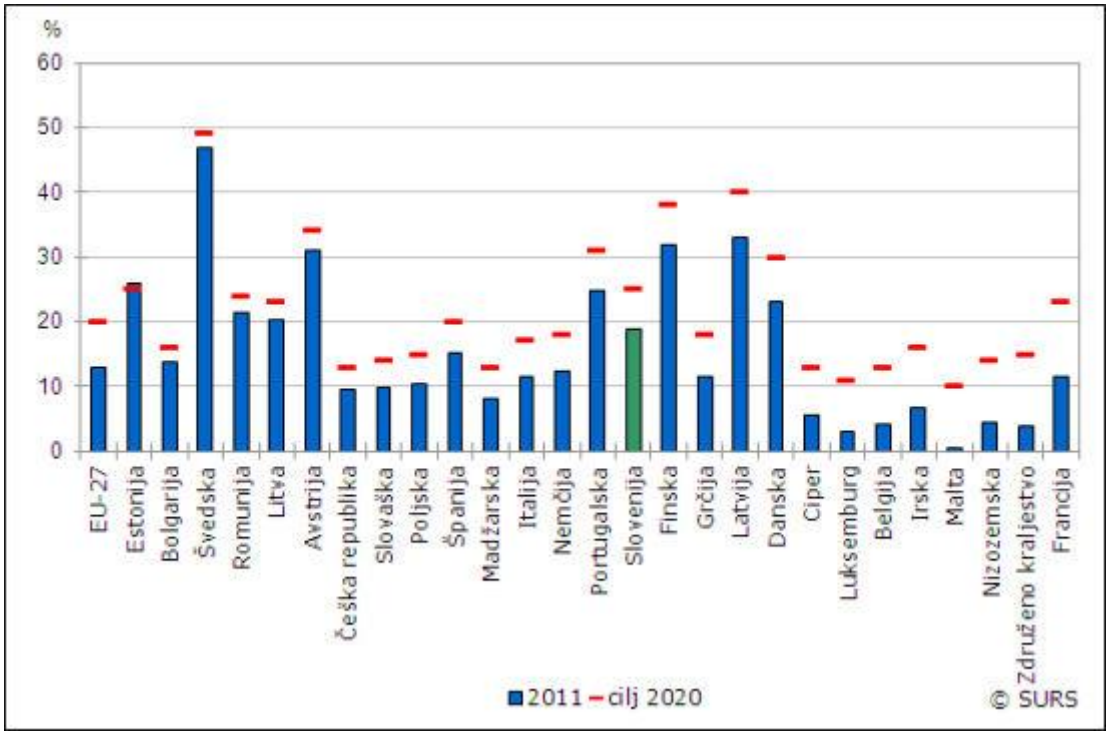

Figure 1: Share of energy from renewable sources in the total energy balance for EU countries (SURS, 2014).

3. SLOVENIA AND RENEWABLE SOURCES OF ENERGY

Slovenia as meber of EU is obligated to reach the following goals in the period until 2020:

- 25% share of crenewable sources in the final energy use
- 20% increase in energy efficiency
- 20% reduction of greenhouse gases emissions
- 10% share of biofuels use in traffic.

Biomass Slovenia has on disposal various potentials to meet the obligations and planned goals. Wooden biomass is one of the most important natural resources in Slovenia. 62,8% of the Slovenian territory is covered by forests. This ranks Slovenia in the third position in Europe, following Finland (73,9%) and Sweden (66,9%) (Bončina, 2013). The entire area of forests in Slovenia is 1.264.000 hectares. The annual increase of wooden biomass is 7.900.000 m^3 or 6,64 m^3 per hectare (Ministrstvo za kmetijstvo in okolje-

Ministry of Agriculture and the Environment and Zavod za gozdove Slovenije- Slovenian Forest Service). Biomass use is reasonable in the case of better utilization of wood and improved systems for combustion in larger as well as in smaller local heating systems.

Hydro-energy On the second place after wooden biomass in Slovenia are water resources. Potentials exist on bigger as well as in smaller rivers which derive in Slovenia, by example the degree of exploitation in Sava is only 34%, in Soča 18,5% meanwhile the greatest unexploited potential exist on Mura and Idrijca (now only 0,3% degree of exploitation). On the other hand, Drava is its Slovenian part (entrance from Austria by Dravograd and exit in Croatia by Ormoţ) already exploited at the degree of 97,8%. Hydro-energy presents the second most important source of renewable energy. The estimated energetic potential of Slovenian rivers is 19.400 GWh/year meanwhile technical potential is about one half of this (9.100 GWh). Economic viability is estimated between 7.000 and 8.500 GWh/year. In the case of construction of hydro electric power plants in the middle and lower part of Sava river the installed power will increase up to 274 MW. This would be reached in the case of construction of hydro electric power plants Blanca at Sevnica, Krško, Breţi ce and Mokrice.

Solar energy and potential of sun energy present additional potential of green energy. Periods of solar irradiation in various parts of Slovenia differ considerably due to the relief specificities. They range from 2.000-2.500 hours/year to 1.650-1.850 hours/year average in the continental part of Slovenia (Ogrin, 2002). The important differences exist among various parts of the year by example in winter valleys are often covered by fog meanwhile in mountain regions is the sunny weather. Sunny regions in the world often reach the average 2.500 kWh/m^2 meanwhile in Slovenia this is only 1. 500 kWh/m^2 (Medved and Novak, 2000, Medved and Arkar, 2009).

Geothermal energy presents very important potential which in Slovenia for certain period of time is already exploited in the North-eastern part of the state. Geothermal sources which were found in the North-eastern Slovenia exhibit considerable possibilities and can be exploited for the operation of 15 to 30 power plants with average capacities of 7-15 MW. In the near future it would be possible to produce 100-200 GWh of electric energy per year in the case of appropriate partnership between state and investors.

4. RENEWABLE SOURCES OF ENERGY IN SERBIA

Serbia as a future member of EU in the field of renewable sources of energy has to follow EU directives and goals obligatory for EU member states. However, Serbia will reach these goals (by example Slovenia has goal until 2020 to use 25% of energy from renewable sources) in a longer period of time. The most important problems in Serbia are low energetic efficiency, outdated technological systems in energetics, lack of investments and various lobbies in energetics.

In Serbia in 2006 only 6% of total energy use derived from renewable sources. The majority of renewable energy is produced in big hydroelectric power plants and a very small part derives from use of geothermal energy or biomass – only 39.272 PJ of 609.096. The most important energy source in Serbia in the year 2006 was coal (55%) followed by oik (26%) and gas (13%). The major part of renewable energy as has been already mentioned in Serbia is produced in big hydroelectric power plants with capacities more than 10 MW and annual production of 10,3 TWh – 25.200 TJ..

4.1 Potentials of Serbia for production of energy from renewable resources

Total technical potential is over 160 PJ per year. The greatest part of this – 62% (100,4 PJ) presents potential of biomass, almost 17% presents solar energy with 26,7 PJ, 10% (16,7 PJ) energy from small hydroelectric power plants, and 5% geothermal energy (8,3 PJ) as well as wind energy (7,9 PJ). According to the official projections the share of renewable energy in the total energy production will remain unchanged until 2015.

Hydroelectric power plants In Serbia exist 900 locations on small rivers with possibilities for construction of power plants. 90% of these power plants would have capacity less than 1 MW. However, there exist also considerable possibilities to reconstruct big hydroelectric power plants as are Đerdap and Bajina Bašta. Small hydroelectric power plants with capacities between 216 kW and 8 MW are planned in Sopočani, Bela

Palanka, Rečica, Rainara, Javor, Sokolovac and Bovan. The total capacity will be 0,5 millions of toe[2] or 5.815 GWh.

Wind energy is another potential form of renewable energy. However, exploitation of wind energy is reasonable only in seven areas in which average wind velocity is about 6-7 m/s. Moreover, only one location – on the Miţo r mountain – can be classified as good. Potential of wind energy is 0,2 millions of toe or 2326 GWh. Other potential locations are Eastern part of Serbia-Stara Planina, Ozren, Rtanj, Vlasina, Zlatibor, Kopaonik, Divčibare and in Panonian plain Vršac and Bela Crkva.

Biomass There exist considerable possibilities for biomass use in Serbia. However, modern advanced combustion systems should be applied. To estimated potential of 314.000 GWh or 2,7 millions of toe potential of 314.000 GWh or 2,7 millions of toe presents more than half of total renewablewable energy resources (except big hydroelectric power plants). Remnants from wooden industry and forestry present about 1 million of toe. The total area of forest in Serbia presents 27,3% of the total Serbian territory: Vojvodina 6,8%, central Serbia 32,8% and Kosovo and Metohija 39,4%. Energetic potential of livestock is about 42.000 toe, in agricultural, vineyard and fruit sector is estimated to approximately 1,7 millions of toe.

Geothermal energy: Geothermal energy in Serbia exhibits great potential which is today exploited in a very low degree. About 100 locations with thermal wells have potential of about 2.300 GWh/year. The regions with the most pronounced geothermal potentials are in Vojvodina, the highest temperature of spring water is Vranjska banja, Jošanička banja and in Sijerinska banja.

Solar energy: The estimated potential of solar energy in Serbia is 0,6 millions of toe or 6.978 GWh and thus presents presents the third most importanr potential of renewable energy. The sun radiation intensity in Serbia is about 40% higher than European average. Nevertheles, the exploitation of solar energy in Serbia is still much less intensive than in many other European countries. Average annual level of solar irradiation in Germany is 1.000 kWh/m^2 meanwhile in Serbia is 1.400 kWh/m^{2}The areas in Serbia which are particularly interesting for exploitation of solar energy are the sorroundings of Leskovac, Pirot, Vranje and Prešovo, but also in 50% of other parts of the state the exploitation of solar energy is reasonable (Despotović, 2009).

5. CONCLUSION

Slovenia and Serbia have considerable potential for production of energy from renewable sources. However, the adequate vision of future energetic policy is necessary. The support of the state and orientation to green energy production is also very important. Slovenia has great potential in wooden biomass and geothermal energy as well as in construction of small hydroelectric power plants. In Serbia there is potential in construction of big and small hydroelectric power plants. However, the realization of these possibilities for green energy production in practice depends on many factors. These factors include economic power of the state, interests, environmental awareness of the citizens etc. Today, unfortunately, to often happens that political-economic lobbies limit expansion of production and use of energy from renewable resources – as shows in Slovenia by example the case of TEŠ 6 (the sixth block of thermoelectric power plant in Šoštanj). Also in the case of exploitation of renewable sources of energy it is very important to take care for protection of environment and wildlife. When locating various objects into the environment there must be paid considerable attention to all possible effects on the nature. In Slovenia exist great possibilities for the so called dispersed regional production of renewable energy which will enable safe supply with energy on the entire territory of the state. There should be emphasized that also in the case of production of energy from renewable sources certain negative impacts on the environment can not be avoided. However, in the case of production of energy from renewable sources these negative impacts on the environment are smaller than in the case of fossil fuels or nuclear energy.

When regarding the production of energy from renewable sources Serbia is in the beginning of a journey. There exist considerable potentials for the production of energy from renewable sources in the state.

2 1 toe is 1 ton of oil equivalent, or 11,360 kWh.

Particularly should be emphasized the potential of hydroelectric power production – big power plants as well as construction of many smaller power plants. There is necessary to restore existing power plants as well as investments in new objects. Besides hydro electric power in Serbia interesting potential exhibits also geothermal energy. The fact that Serbia is still in the beginning has also some advantages as experiences of some other countries can be used and examples of good practice can be followed.

Both, Slovenia and Serbia, must take care of lowering energy consumption. The introduction of systems with more rational energy use is necessary as well as change consumer habits of citizens. The zero degree of energy consumption growth should be reached as soon as possible as well as reduction of personal environmental footprint until 2020.

Trends to exploit alternative and domestic sources of enegy become more and more actual because of recognition that stocks of fossil fuels are limited. The exploitation of domestic energy sources is interesting also because of economic effects as well as because of political independency of imported energy. Appropriate procedures exist, they should only be implemented in practice – however, this depends on economic power of the society. When regarding protection of the nature and sustainable development energy deriving from renewable sources presents undoubtedly the energy of future. energije, su svakako energenti budučnosti.

THE MODEL OF AN ORGANISATION OF THE EFFECTIVE PUBLIC COMMUNICATION IN HAZARDOUS WASTE MANAGEMENT

Suzana Ţilič Fišer[1], Jure Fišer[2]
[1]Faculty of electrical engineering and computer science, University in Maribor, suzana.zilicfiser@um.si
[2]Gorenje Surovina d.o.o, jure.fiser@surovina.com

Abstract: *The presenting paper maps the problem of communication in hazardous and industrial waste management. It discusses the model of successful waste management with the support of communication strategy. The case of remediation of acid tar dump explains the necessity to accommodate the rising democratic expectation of public participation in deliberations over the incineration waste policy. Accordingly the transparency and the communication of the process with the dissemination of results is an important element in the successful model of hazardous waste management. The technical elements of the process are discussed with the explanation of successful communication model. The waste management in the case of acid tar remediation in Slovenia stresses the need for investment at the level of public participation and public communication.*

Keywords*: communication, public communication, waste management, model of communication, public, communication tool*

1. INTRODUCTION

Environmental activities that are part of any industrial projects need the strategy of communication as part of public interest. The public communication about the waste management, particularly hazardous waste, has often been excluded from policy processes.

People's responses to different risks are determined by psychological factors and technical information would rarely have a very strong impact to people's reaction. Awareness and understanding of public concerns must be the basis of an effective risk management strategy. (Frewer, 2004)

In oil refinement process, based on the treatment with sulphuric acid, a bituminous residue, called acid tar, is formed. With such a treatment, linear paraffin molecules (desired fraction) are divided from undesired additions (aromatics, iso-paraffines, heterocyclic compounds). Acid tar is a mixture of liquid, paste-like and solid hydrocarbons, containing free and bound sulphuric acid (Nanut, 2010). The remediation of acid tar dump in Slovenia can be analyzed as hazardous waste management. This was the basis for our investigation about public communication in this sphere of action (Ţilič-Fišer, Dvoršak 2010). As a case study we analyzed the remediation of the area, called Pesniski Dvor that is situated in North East part of Slovenia, close to the border of Austria. The project was coordinated by company Gorenje Surovina which is a leading company in the field of waste management in Slovenia. The technical elements of hazardous waste management were included in the process in production but are not key elements for the aim of this paper. Our focus was to present the importance and the potential of the public communication in the field of waste management. For the aim of public communication we produced the documentary film that was discussed as important communication tool in the hazardous waste management.

In Maribor the re-refining of the used motor oils with the process of treatment with concentrated sulfuric acid was done. Refinery disposed the acid tar, which is the residue after the treatment with sulfuric acid since 1967 in landfill in Pesniski dvor. Acid tar is a thick, viscous substance with an acidic smell; it can contain 10-50% sulfuric acid and a noticeable amount of oil and resin and is highly corrosive toward metals. Acid tars are amenable to oxidation and solidification in air; therefore, their properties could substantialy vary during storage (Kolmakov, 2007).

The landfill was built in accordance to the applicable regulations and permits of the competent administrative authorities in 1966, an operating permit was issued in 1967. The refinery disposed the acid tar until the year 1983. Since then, the old abandoned landfill is a burden, which represented a significant risk for the environment and required the intervention for the remediation. Historically, acid tars have been disposed with or without prior treatment in worked out quarries, clay or gravel pits, or landfills, normally referred to as acid

tar lagoons. This dumping is not environmentally sustainable because of the potential risk posed by the components of acid tars to human and ecological receptors (Leonard, 2010). Once acid is generated, it may contaminate receiving water, lowering the pH and increasing the concentration of dissolved elements (particularly metals) of environmental concern. If unchecked, acid drainage can result in acute and chronic impacts on aquatic ecosystems, as well as community health risks. The paper maps the communication importance in the hazardous waste management and presents the business model that can be applied into area in the broader region.

2. RESEARCH OBJECTIVES

The first research objective was to analyze the results of the technology solution for the acid tar remediation in Pesniski Dvor during the whole process. The remediation of the dumping site of the acid tar at Pesniski Dvor includes the preparation works, excavation of the acid tar and contaminated soil, process of the solidification and energy recovery of the solidificate, recycling of the contaminated soil into construction materials, dismantling of the technological equipment and removal of the objects and revitalization of the dumping site.

The second research objective was to analyze the public participation and integrating environmental monitoring results in effective public communication. Public participated in the complete process of the remediation of the disposal site of acid tar in Pesniski Dvor from the obtaining of the construction and environmental permit until the end of project activities and revitalization of the disposal site. The project activities and objectives were transparent and all the monitoring results were published.

The third research objective was to examine the appropriate communication tool for presentation of acid tar remediation to broad audience and to design the model of communication that can be implemented in the hazardous waste management in Balkan area. Public concerns influence consumer behaviours, citizens' support of environment pressure groups, and political preferences of voters during elections. Therefore, the effective risk communication and successful communication to broader public should be the priority in hazardous waste management.

The model of acid tar remediation in Pesniski dvor explained the importance of dissemination of results in the way that could be easily perceived by the broader public. Moreover, the research and the explanation of the remediation with the audio-visual product resulted in the positive attitude toward the waste management.

3. METHODS TO DESIGN THE MODEL OF WASTE MANAGEMENT: CASE STUDY OF PESNISKI DVOR

3.1. Method of technological solution for the remediation of acid tar in Pesniski Dvor

The main criteria for selecting the technological solution for acid tar remediation were the sustainability of the technology. Due to these criteria different technological solutions were examined. The technology was approved by the investor and the Ministry of Environment in Slovenia. The chosen technology had the minimal environmental impact during the construction of the equipment for the solidification on site, operating and dismantling of the equipment.

The technology for solidification of the acid tar had the capacity of the 10t/h and was installed in the immediate vicinity of the dumping site. The excavated acid tar was delivered to the receiver-mixer, where waste wood, stones and bulky waste were sorted out non-reactive additives (saw dust, coal dust...) were added to the acid tar and the consistence of the mixture was adjusted. The pre-mixture went through the metal separator into the lamella mixer where reactive additives were added and neutralized the acid substances in the mixture. To achieve the best results of the neutralization it was necessary to have the suitable mixing and exact time. The type of added reactive additive depends on the analyses of the acid tar, availability, price and distance from the local sources of supply. The mass flow diagram is shown in Figure 1.

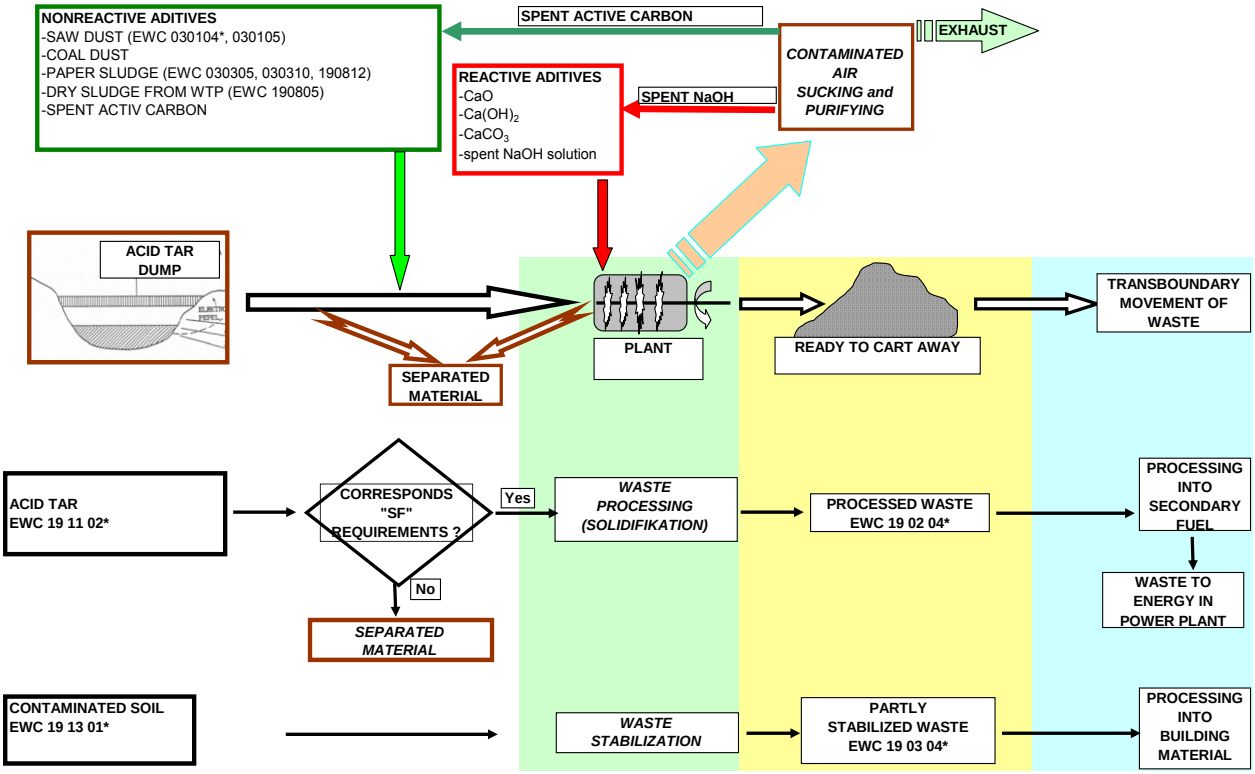

Figure 1. Mass flow diagram (Lipovšek, 2007)

A number of serious and highly publicized pollution incidents associated with incorrect waste management practices, led to public concern about lack of controls, inadequate legislation, environmental and human health impact (Giusti, 2009). Monitoring is essential to assess changes in the environment, to provide early warning of potential problems, to assess efficacy of remedies, and to assess possible future adverse effects on humans and the environment (Burger, 2008). Due this reason a detailed monitoring plan was prepared, that include all environmental parameters.

3.2. Organization of communication model for acid tar remediation

The information about technical risks alone does not form the basis for coherent management policy that is also acceptable by consumers. Researchers as Slovic (Slovic, 2000) has consistently demonstrated that factors such as whether a risk is perceived to be involuntary, potentially catastrophic, or uncontrolled are more important determinants of public response that technical risk information alone. Risk communication and waste management must also take into account of societal concerns and values. Risk perception also has a direct impact on how citizens respond to risk management activities. It is public concerns and attitudes that have direct consequences for human health, food safety and security, economic expansion and international regulation (Frewer, 2004, Petts 1992). The issue of public participation and the engagement of the broad public at different level of process is the priority in the hazardous waste management. Some authors (Gusti, 2009) stressed the need for public participation in waste management at the local and regional level.

Moreover, the level of social responsibility of waste industry is becoming the priority issue in democratic modern world. In modern democracy citizens should be educated and included in political process. The criteria for democratic political process (Dahl, 1998) are effectiveness of participation, voting equality, control over the agenda, equal opportunity and most important enlightened understanding. To realize all the steps of democratic political process, education and awareness of citizens has to be considered. The awareness about the environmental issues is high on the agenda of modern global and national political processes.

Best practices in risk communication encompass developing ways to communicate these to broader public. Institutions and organizations must consider how to develop and maintain public confidence in risk

management practices. Trust and confidence is particularly important under circumstances where people feel that they have very little personal control over their personal exposure to potential hazards. This was the case with public perception of the case of Pesniski dvor where local community opposed to any waste management industry in the area. Accordingly, the principle of N.I.M.B.Y (not in my backyard) is widely accommodated in the perception of citizens when issue of waste management is discussed. In the local communities in Slovenia the rebellion towards any waste management practice came from citizens, particularly after the early 90s when political system with new national state developed. The political democratic development of new government supported any public debate regarding the economic, political and environmental issues.

It is important to communicate the uncertainty about the risk with the explicit and understandable way that is focused on the information needs of target audiences. There is little evidence that elite groups in the scientific and policy community have underestimated the ability of non-experts to understand uncertainty (Frewer et al, 2002.)

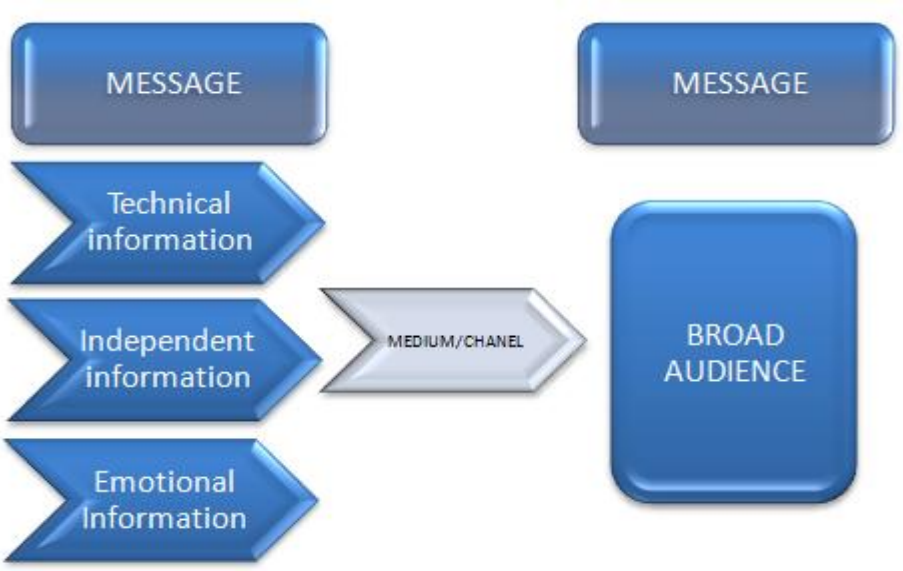

Figure 2. Model of communication in documentary case of acid tar

The non-experts need the communication in the way to establish trustworthiness and certainty about the waste management. For the successful communication of this matter the appropriate tool of communication should be chosen. For the case of Pesniski Dvor the audiovisual documentary (Zavrl, Zilic, 2008) was chosen as a tool of communication. The documentary film covered all the stages of remediation. Research behind the documentary film included interviews with experts from different companies, experts from independent and governmental institutions, local inhabitants and opinion makers from the region.

The audiovisual product, which based on the presented model of communication, could describe the best practices in the way that are successfully perceived from broader public (Figure 2).

The situation of the audiovisual viewer is paradoxical. There is a sense in which person is living in two places, and sometimes two times, at once – in the world in which he is physically situated and the world that documentary presents to him (Scannell, 1991). The media with the sound and the picture could bring the waste management closer to the individual.

The best practices in waste management described in journals are well perceived by experts; however the broader public could get closer to the issues with the (media) product that better appeals to the emotions. The medium for communication that has strong effect is television/screen where picture and sound bring the “reality” to the audience.

3.3. Results of the waste management process

The final result of the acid tar remediation in Pesniski Door was excavation and recovery of all acid tar, contaminated soil, the removal of complete facility used for the processing of acid tar and re-cultivation of the area.

The results of the environmental impact assessment before the remediation showed very high risk of the pollution of the soil and ground water near the dumping site. The acid tar remediation was successfully finished due to the effective technological solution that limited any possible negative impact on the environment.

Communication is a two way process and organizations need to learn how to internalize public views and societal values into the process of hazardous waste management. Woolgar (1996) has discussed the ways in which science and social world are often viewed as independent of each other, one result being the discounting of social factors. This separation (Frewer, 2004) produced the decline in public confidence in risk management practices that became the focus of regulatory concern in the 1980s and 1990s. In the paper we wanted to express the importance of public enlightenment regarding risk issues. Moreover, according to Hilgartner (1990) it could often resolve some problems of technology acceptance in waste management businesses.

The documentary about the hazardous waste management in the case of acid tar remediation tried to explain the process of waste management that leads to revitalization of local area. The sound, picture and interviews with independent experts and non-experts combined the successful way of persuasion in the documentary film. The successful waste management method was accompanied with the suitable communication tool as it was shown in the case of acid tar remediation in Pesniski Dvor. The goal of documentary was the development of the effective message for the broad public.

4. CONCLUSION

The conclusions and recommendations of this paper arise from an examination of the waste management, environmental impact and impact of public concerns about waste management in Slovenia. The model of waste management in Pesniski dvor explains the good practice of hazardous waste management. The model of acid tar management in Pesniški dvor brings the sustainable development of the nature. The reference communication model of waste management could be applied into the countries of Balkan region; however the special circumstances of the local area should be taken into account. The elements of the model that comprise of modern technological process, transparency with monitoring and film documentary as a main communication tool are important elements in the suggested model of waste management.

The suggested model of acid tar remediation is successful business model that company Gorenje-Surovina tries to apply into the area of Balkan region. The waste management in the case of acid tar remediation stresses the need for investment at the level of public participation and public communication. The issue of waste management should be discussed to engage participaton of broad audience.

The results of the acid tar remediation in Pesniski Dvor was complete remediation and revitalization of the old disposal site which previously presented high environmental risk for the nature and humans. During the process of remediation 18.200t of acid tar, 14.600t of contaminated soil and 600 m^3 of the waste water from the disposal site was neutralized and recovered. The quality of the nature in Pesniski Dvor increased and the old dumping site is well integrated with the surrounding forest and meadows. The model of communication with suitable communication tool for broader audience was important part of the project. Therefore it can be apply to other projects in the field of waste management where public participation and public awareness is extremely important.

ENVIRONMENTAL SUSTAINABILITY SCREENING OF SMALL-SCALE URBAN WATER SUPPLY SYSTEMS

Bojan Kovačević[1], Ivana Marković-Kovačević[2]
[1]United Nations Development Programme, bojan.kovacevic@undp.org
[2]Megatrend University Belgrade, imarkovic@fpe.edu.rs

Abstract: *Practitioners and researchers are in need to develop practical tools to quickly measure environmental sustainability of an urban infrastructure system through its life cycle. This paper proposes a framework for an environmental sustainability screening of urban infrastructure systems, which is based on interactions between infrastructure and surrounding environmental systems. One way of quantifying these interaction effects is through use of environmental sustainability indicators selected on basis of simplified life cycle assessment (LCA). A small set of selected indicators was applied in a case study of the urban water supply system of Bratunac, Bosnia and Herzegovina.*

Keywords*: life cycle assessment, environmental sustainability, indicators, water supply systems*

1. INTRODUCTION

Urban water supply systems in developing countries experience difficulties in meeting challenges of increasing population and lack of funding for intensive capital infrastructure solutions. Much of municipal water supply infrastructure which was built during the 1960s and 1970s is now outdated and deteriorated. Municipal authorities are faced with not only with the existing infrastructure reconstruction but also with the demand for its development. Also, national and international development agencies and financing institutions face problems when appraising the commercial viability and sustainability of infrastructure project proposals. Water systems which can satisfy the changing demands placed on them now and in the future without system degradation can be called “sustainable” (ASCE, 1998, p. iv).

Over the last few decades, numerous attempts have been made to describe and measure various aspects of sustainability, with emphasis often being put on the environmental aspects. One approach included environmental sustainability indicators (ESI). Several organizations used frameworks based upon Pressure-State-Response model proposed for use at country, regional or municipal levels by the OECD (OECD, 2001). Pressure indicators measure environmental pressures from human activities influencing the environment through emissions and exploitation of natural resources. State relates to the state of the environment, such as the quality and quantities of natural resources while response measures the extent to which society is responding to environmental changes and concerns. In 1997, another approach, life cycle assessment (LCA), was designed for evaluation and possible reduction of environmental impact of the entire life cycle of products, processes, projects and services (ISO 14040:1997). It is standardized method that includes life cycle impact assessment (LCIA) phase where potential impacts are aggregated and quantified (ISO 14042:2000). Four components of LCA include goal and scope definitions, inventory analysis, impact assessment and improvement analysis (results interpretation). Several LCA studies on urban water systems estimated environmental loads from urban water systems although mainly addressing specific wastewater systems (Lundin et al., 2000, Godin et al., 2011, Feijoo, 2013) while fewer studies on water supply have been published (Lundie et al., 2004).

Although LCA is a rather complex and time-consuming analysis, it can provide a systemic foundation for selection of relevant indicators of environmental performance, including measurement techniques at company level (ISO 14040:1997). In this paper we propose a selection of ESI as a less complicated method through an iterative technique based upon simplified LCA methodology.

2. FRAMEWORK FOR A SCREENING LCA OF URBAN WATER SUPPLY SYSTEMS

Acknowledging that the life cycle perspective is important for environmental sustainability, the challenge is to adapt the LCA methodology and simplify its use. With a simplified or screening LCA it would not be possible to retrieve detailed results of the environmental performance of a product or a system and comparative statements according to ISO 14044 cannot be based upon it. This type of study yields an estimate of environmental performance (EeBGuide Project, 2012). A suggested framework for using the simplified LCA method for urban water supply system is described in Figure 1.

The screening LCA commences with specifying the goal and scope of the iterative process, as presented in Figure 1. The goal here is to conduct an initial overview of the environmental sustainability of the urban water supply system in order to support investment decision-making at the level of a water utility and beyond. Attempts to define general sustainability criteria for urban infrastructure systems have been presented in several studies e. g. Sahely et al (2004) but here we limit to the quick screening of environmental sustainability of an urban water supply system which include major environmental impacts along life cycle.

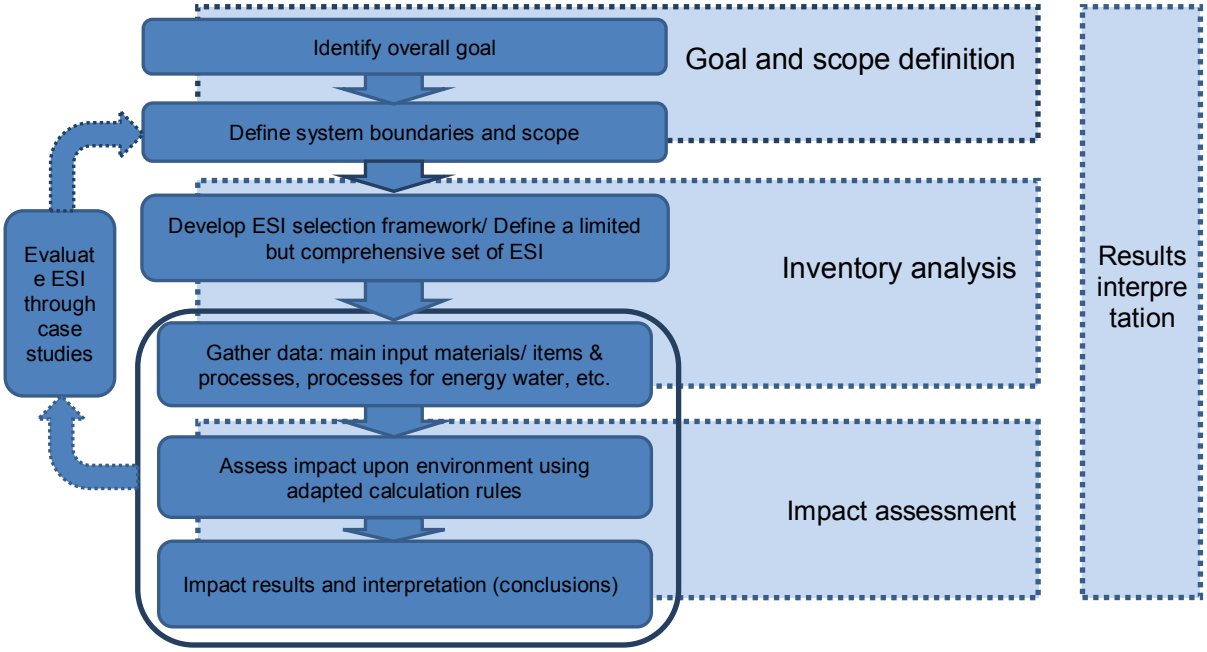

Figure 1 – Framework for environmental sustainability screening of an urban water supply system based on the Life Cycle Impact Assessment phases (square dotted), *source ISO 14040/14044*

The next step is definition of system boundaries, which encompasses time, spatial and life-cycle boundaries. In the planning and design of an urban water supply system a time perspective of several decades is usually considered. Spatial boundaries of a water supply system are limited to include one or several municipalities or watershed area. The life cycle boundaries define the unit processes which are to be included in subject system and for a water supply system life cycle starts with extraction of water from groundwater or surface water source including water treatment. In this case, the lifecycle ends with distribution of potable water to consumers: households and industry. Of course, different choices could be made for system boundaries to include wastewater treatment, disposal of sewage sludge to landfill or agricultural land and surrounding technical and agricultural system.

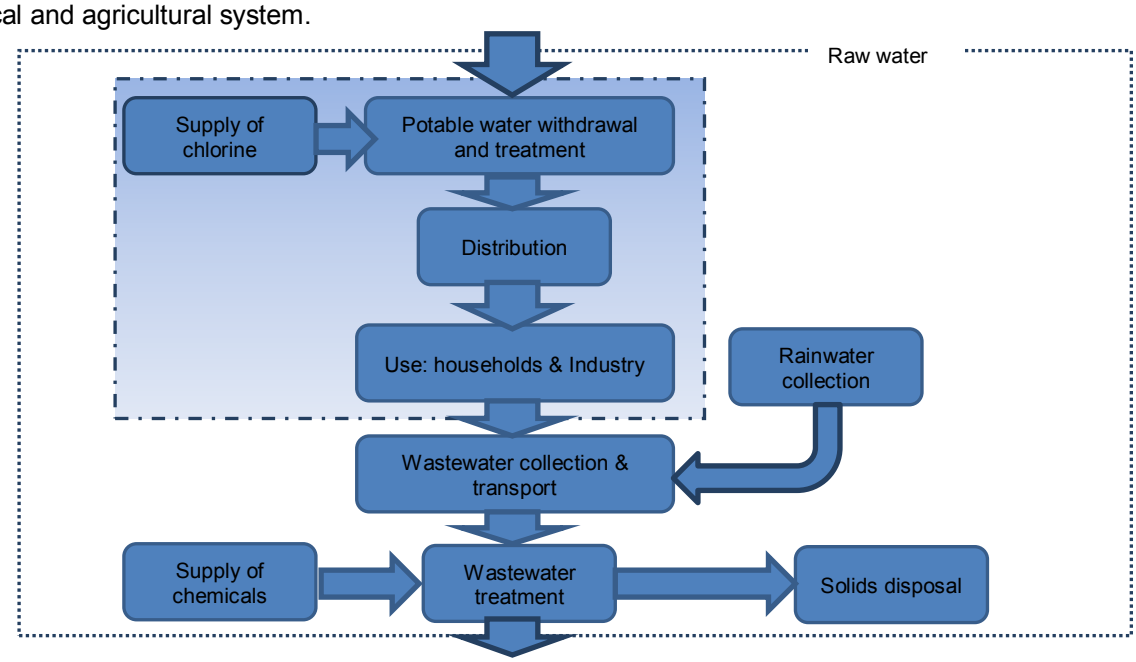

Figure 2 – System boundaries used in this paper (dash-doted rectangle)

The following step is developing framework for selection of ESI, which is a kind of a structure from which relevant indicators are selected through identifying most important issues for the stated purpose, such as the water quality, water resources and energy use. General frameworks used for sustainable development indicators have adopted a conceptual driving force-state-response approach widely used for environmental indicator development, such as the Pressure-State-Response (PSR) model developed by OECD (2001). This has led to selection of 10 key environmental indicators extracted from the OECD Core Set of environmental indicators (approx. 40 indicators), which covers the issues of climate change, ozone depletion, air and freshwater quality, waste generation, freshwater, forest and energy resources and biodiversity. Examples of indicators related to water quality and resources are presented in Table 1.

Table 1 – OECD indicators related to water quality and resources and their place in PSR framework (source OECD Environmental Indicators, 2001, pp 41-51)

Set of indicators	Selected Indicators	Place in framework
Water quality	Quality of surface waters (oxygen and nitrate content)	S
	Sewerage treatment and network connection rates	R
	Public expenditure on waste water treatment	R
Water resources	Intensity of use of water resources	P
	Water supply prices	R

Similar frameworks have evolved from PSR approach to one focusing on four primary dimensions of sustainability - social, economic, environmental and institutional. Within these categories, indicators were then classified in accordance to their driving force, state and response characteristics (UNCSD, 2001). LCA framework includes all major impacts/ benefits on environment occurring throughout the life-cycle, and relates them to functional units or performance characteristics, such as per person, day, etc. Functional units set the scale for comparison of two or more systems including improvement to one system (EEA, 1997)

Following framework development, appropriate ESIs can be selected from the previous LCA case studies, literature reviews and indicators already used within an organization. It is important that a limited but comprehensive set of ESIs is selected so that the most important aspects are addressed. The indicators should allow for comparisons through use of aforementioned functional units. In this paper we have chosen a list of 20 indicators for urban water systems categorized in terms of four environmental and technical systems: freshwater resources, potable water, waste water and development, proposed by Lundin (1999, p. 37). Each system was represented by certain dimensions broken down into indicators. Then, 6 of 20 initially proposed environment sustainability indicators have been short-listed in order to quickly appraise environmental sustainability of Bratunac water supply system (Table 2). Of course, hereunder proposed set of indicators does not include all aspects of environmental sustainability of an urban water supply system.

Table 2 - ESIs used in this paper (adapted from Lundin, 1999, p. 37)

Suggested indicator	Data availability	Type	Suggested reference value
Freshwater withdrawal	Available	Pressure	<100% of raw water quantity
Water consumption	Available	Driving force	Above WHO standard (20 l/capita/day)
Potable water quality	Available	State	% of tap tests within WHO or national regulation
Energy use for water supply	Available	Efficiency	As efficient as possible
Chemical use	Available	Efficiency	As efficient as possible
Leakage/ water losses, %	Moderately available	Efficiency	Low

After selection of ESIs, data were collected for the period available, and the impact upon the environment was assessed using different weighting methods. Data gathering and data quality is important for LCA as well as for EPI. Lundin and Morrison (2002, p. 149) conceptually described various levels of environmental sustainability for urban water systems as shown in Table 2.

Table 3 – Environmental sustainability levels of urban water supply infrastructure (adapted from Lundin, Morrison, 2002, p. 149)

Level	Infrastructure characteristics
A	Environmental and health objectives are met. Efficient use of resources.
B	Environmental protection standards are fulfilled and exceeded but focus is still on compliance with standards and end-of-pipe solutions. Potable water is regularly monitored.
C	Minimum environmental and health protection standards are fulfilled.
D	Basic standards ensuring human and environmental health and adequate water supply are not met. There is uncertainty in water supply on daily basis. Minimum environmental monitoring

3. EXAMPLE OF A SCREENING LCA: BRATUNAC URBAN WATER SUPPLY SYSTEM

The use of environmental sustainability indicators in infrastructure decision making is not applied widely in Bosnia and Herzegovina and surrounding countries. Main challenge here is collection and compilation of data at the urban water supply system level. A walkthrough energy audit of Bratunac urban water supply system is used as an example where data were compiled and synthesized from utility and municipal officials and from measurements taken in the field (Kovacevic et al. 2013).
The area of the municipality of Bratunac is supplied with potable water through an urban water supply system and several rural water supply systems. “Bjelovac” water source, located in the vicinity of the Drina River supplies the urban area with drinking water after chlorination treatment at the Bjelovac water intake plant. Urban water supply system covers the city area and most of the suburbs with a total population of 11,000 or 2,945 households, which is approx. 51% of the entire municipal population. The rest of population is supplied through rural water supplies which are not under jurisdiction of the “RAD” Bratunac Public Utility Company. Water supply system operates without major restrictions with maintained water quality regardless of annual rainy or draught periods. Apart from chlorination, water is used without any additional treatment.

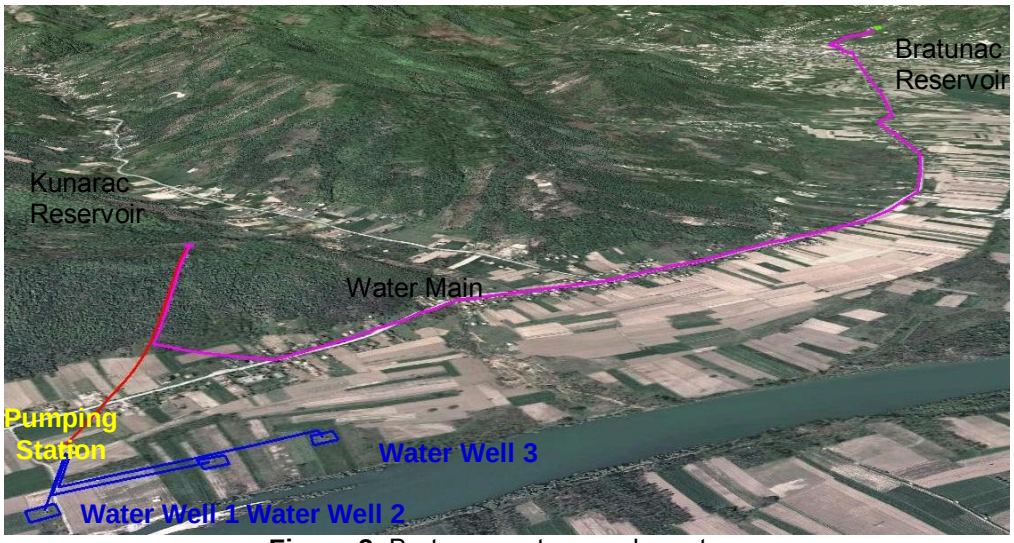

Figure 3: Bratunac water supply system

There are three freshwater wells of 3 meters in diameter and average depth of 10 meters, and of total capacity of 65 l/s. The wells are located in the protected area with strictly enforced sanitary rules. Withdrawn water is pumped through the 800 meters long thrust pipeline into the retaining reservoir of 100 m³, adjacent to the pumping station from which the water is pumped up to the Kunarac Reservoir of 120 m³ and further gravitationally transmitted into the Bratunac storage reservoir of 1.350 m³ through water main of 200, 300 and 350 (mm) in diameters and total length of 9,560 meters. Total length of distribution mains is around 30,500 m, made of pipelines of 50 through 350 (mm) diameters.

Major deficiencies of the existing water supply system are: inadequate quantities of extracted raw water at the water source, especially in the summer period, lack of adequate reservoir storage, undeveloped distribution network with under-dimensioned pipeline sections which causes unequal pressure distribution as well as high water losses of 55-60%. Urban water supply network is outdated and dilapidated as it was mostly built in 1962 through 1964. Detailed design for rehabilitation and reconstruction of Bratunac water supply distribution network was funded by United Nations Development Programme (UNDP) in 2011 while

the funds for reconstruction were secured through European Investment Bank (EIB) in 2012. The works are foreseen to commence in 2014.

3.1 Purpose of the screening LCA and system boundary definition

The aim of this screening LCA was to assess environmental performance of the Bratunac urban water supply over the last few years for which most of data were available. In accordance with the proposed framework, the water system was divided into two technical sub-systems following the life cycle of urban water management: (1) withdrawal and treatment of raw water and (2) distribution and consumption of potable water. For both sub-systems ESI were adopted in terms of environmental performance and pressure on the environment (Table 2).

3.2 Environmental Sustainability Indicators (ESIs)

3.2.1 Freshwater withdrawal

The freshwater withdrawal indicator is calculated by dividing the annual freshwater withdrawal by the annual available amount. It shows whether or not withdrawal is at an acceptable level or future shortages are expected. The withdrawal indicator also relates to population and population growth, the future demands for agriculture and industry and water losses in the system.

Total raw water withdrawal in 2011 was 1,903,673 m^3 with average withdrawal 61.20 l/s. Average daily quantities of withdrawn water were 5.400 m^3 a day. In accordance with the Long-term programme for drinking water supply of the population and industry in Bosnia and Herzegovina (Water management institute of BiH, 1988), Bratunac water supply system should completely rely on Bjelovac water source, with forecasted yield of 300 l/s, which satisfies the needs for water until the end of the programme period by 2020 and beyond. The reference value for this indicator is that the withdrawal should be less than 100% of the raw water quantity. Collected data show that the withdrawal volume has been around one fifth of total available water resources which is at the satisfactory level.

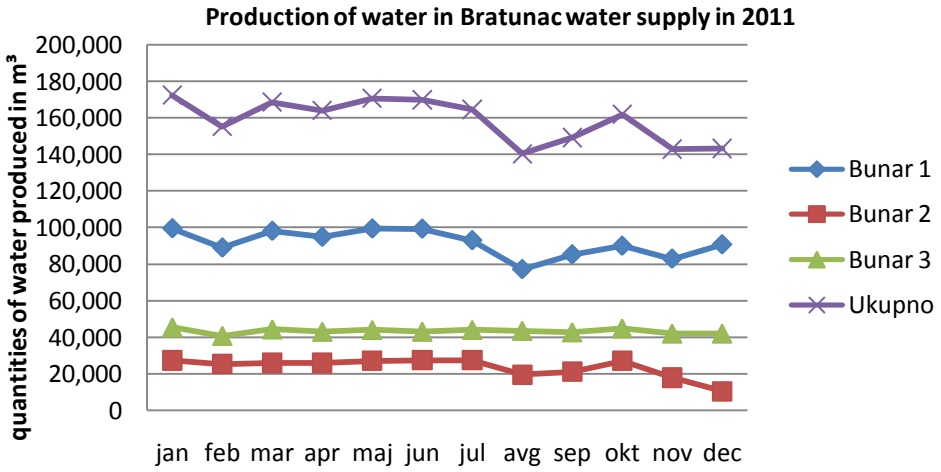

Figure 4 – Monthly production of water in 2011 in m^3 (Kovacevic et al. 2013)

3.2.2 Water consumption

With population increase and economic development increased quantities of water will have to be supplied for domestic and industrial purposes. Since the consumption of potable water affects use of energy and resources, it is directly linked to the environmental sustainability of the water system. Suggested water use indicator is *l/capita/day*, which is compared to target.

Consumption was calculated by dividing inflow values at the Bjelovac reservoir by Bratunac population estimate, which was adjusted in accordance with the projected population increase (1.30%). Water consumption (including industrial use) has increased from approximately 166 l/capita/day (2005) to 175 l/capita/day (2013) and is forecasted to 200 l/capita/day for the next two decades (Table 1), which significantly exceeds a minimum for basic level of service given by WHO (2003, p. 25). This is slightly above the European average as urban water use has decreased in the 1990s in many European countries as a result of measures to reduce demand and because of economic restructuring. The largest amount of household water used is found in Spain with 265 l/capita/day (Figure 5.11), followed by Norway (224 l/ capita/day), Netherlands (218 l/capita/day and France (164 l/capita/day). Lithuania, Estonia and Belgium with

85, 100 and 115 l/ capita/day, respectively, have the lowest household water use in those European countries with available information.

Table 4 – Calculation of needed quantities of water for Bratunac water supply system (Kovacevic at al. 2013)

Description of consumption	Unit of measure	Projected population increase				
		2005	**2013**	**2015**	**2025**	**2035**
Number of residents connected to system		**11,436**	**12,199**	**13,013**	**14,807**	**16,848**
Average specific residential consumption	l/capita/day	166	175	180	190	200
Access to urban water supply system	%	100.00	100.00	100.00	100.00	100
Average household consumption	l/s	21.97	24.71	27.11	32.56	39.00
Average industrial consumption - 20 % of household consumption	l/s	4.39	4.94	5.42	6.51	7.80
Total average consumption: households + industry	**l/s**	**26.37**	**29.65**	**32.53**	**39.07**	**46.80**
Total daily average consumption: households + industry	**m^3/day**	**2,278**	**2,562**	**2,811**	**3,376**	**4,044**
Total monthly average consumption: households + industry	**m^3/month**	**69,291**	**77,921**	**85,494**	**102,686**	**122,993**
Total annual average consumption: households + industry	**m^3/year**	**831,489**	**935,047**	**1,025,924**	**1,232,227**	**1,475,916**
Seasonal household consumption unevenness coefficient		1.50	1.50	1.50	1.50	1.50
Maximum daily household consumption	l/s	32.96	37.06	40.66	48.84	58.50
Seasonal industry consumption unevenness coefficient		1.25	1.25	1.25	1.25	1.25
Maximum daily industry consumption	l/s	5.49	6.18	6.78	8.14	9.75
Total maximum daily consumption: households + industry	**l/s**	**38.45**	**43.24**	**47.44**	**56.98**	**68.25**
Total average water losses in the system	%	57.84	40.00	35.00	30.00	25.00
Total average needs for water in the Bratunac water supply system	**l/s**	**62.54**	**49.42**	**50.05**	**55.82**	**62.40**
Total maximum needs for water in Bratunac water supply system including losses	**l/s**	**91.20**	**72.07**	**72.99**	**81.40**	**91.00**

3.2.3 Energy use

Data relevant for use of energy were gathered from water utility officials and measurements of electrical parameters were taken, such as currents, voltages, powers (active, reactive and total power) and actual energy use. Also current, voltage and power waveforms were measured at the engines running the thrust pumps in the Bratunac water supply system. Engines and pumps were scanned using a thermal camera. Energy consumption analysis was based on monthly electrical energy use bills taking into account energy tariff group of the consumer as well as changes in energy prices during the observed period.

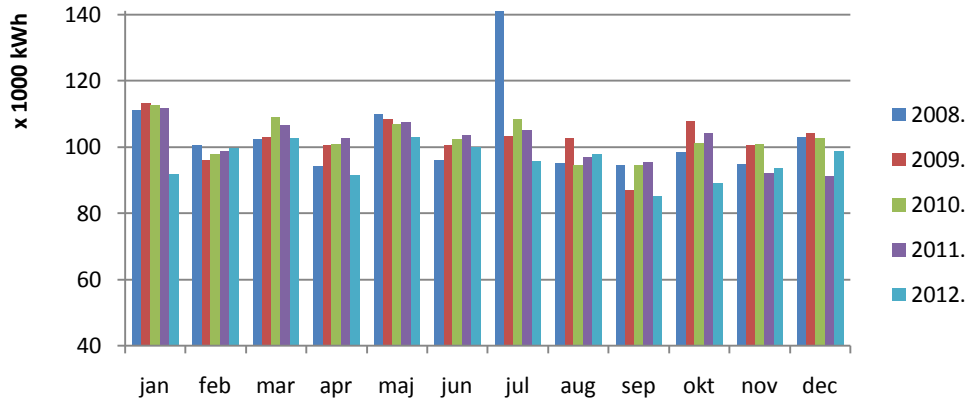

Figure 5 – Monthly electrical energy use in kWh for period from 2008 to 2012

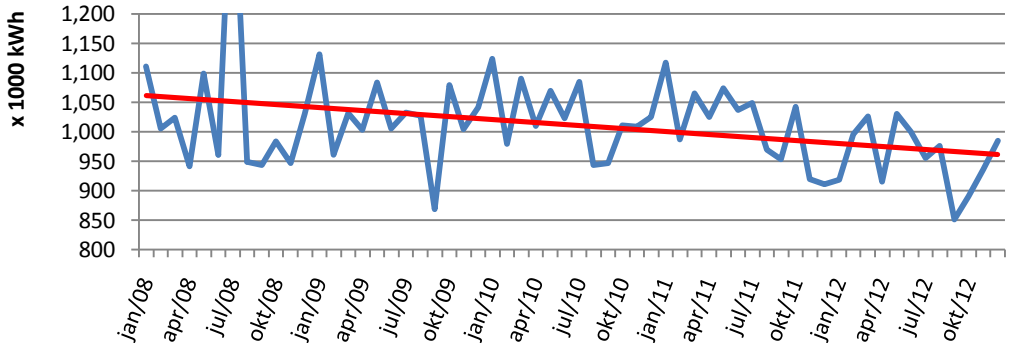

Figure 6 - Electrical energy use in kWh for period from 2008 to 2012

Electrical energy use was quite equally spread throughout the year and there was no typical division between summer and winter months. However, a general notion of decrease in energy use can be observed, especially since January 2011. This trend seems to have been influenced by the changed regime in power supply system i.e. third thrust pump was occasionally shut down during the night hours. Energy Use Assessment Tool developed by the US Environmental Energy Agency (EPA) for assessment of energy use in small to medium water supply systems was utilized in the analysis of electrical energy use, produced water and costs in order to determine the areas with the highest potential for savings. The highest energy consumers were the thrust (circulating) pumps with 85% of total consumption then the water well pumps with 11% while the remaining 4% of energy relates to other consumers (lighting, heating, etc.).

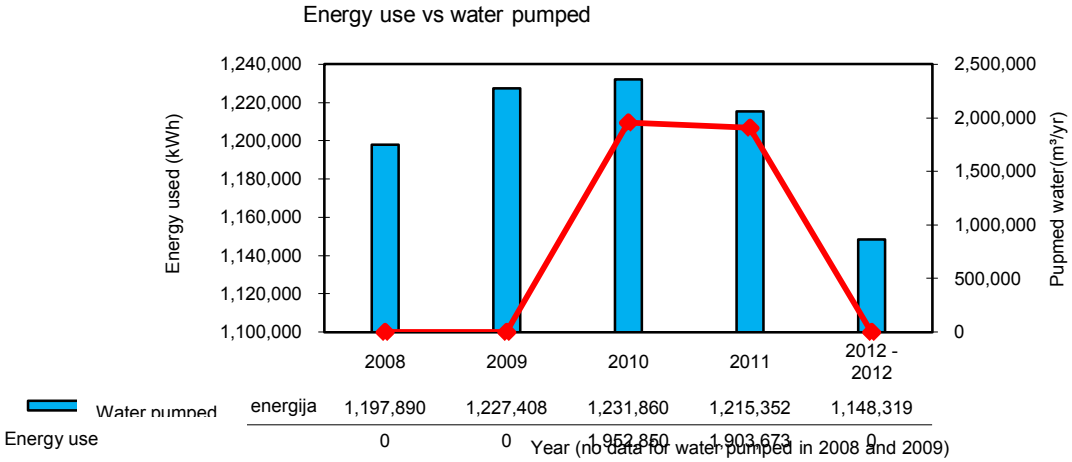

Figure 7 – Energy use vs. water pumped (source Kovacevic et al. 2013)

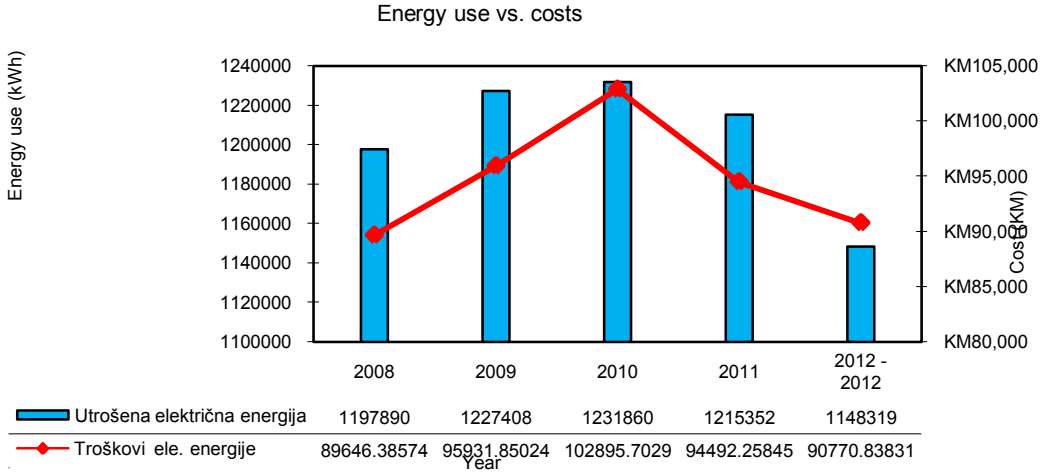

Figure 8 – Energy use vs. costs (source Kovacevic at al. 2013)

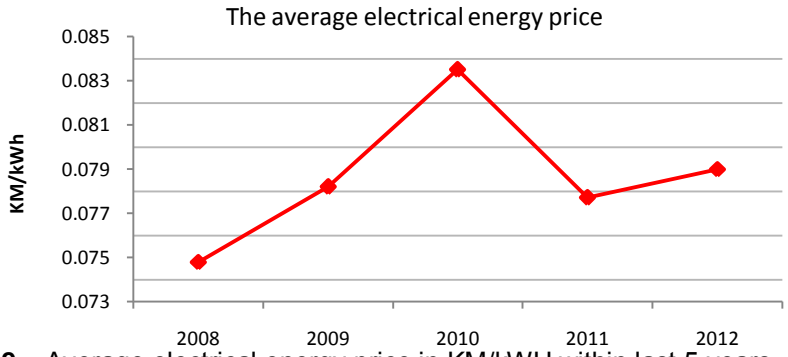

Figure 9 – Average electrical energy price in KM/kWH within last 5 years

Water distribution is therefore the most energy intensive process in the urban water supply system. In 2010, average electrical energy use to operate pumps was 0.63 kWh/m^3. This average is above the average value in the engineering literature, which is around 0.48 kWh/m^3 although this value is illustrative since it does not incorporate critical elements such as the distance the water is transported, which vary greatly from site to site (World Business Council for Sustainable Development, Water, Energy and Climate Change, 2009). During 2010, 1.952 Mm^3 was pumped directly from Bjelovac pumping station into the transmission system.

Higher or lower electrical use costs (Figure 8) appear to be directly related with the average annual electrical energy price expressed in KM/kWh (Figure 9).

3.2.4 Potable water quality

The quality of potable water is highly important as it directly impacts human health. It should be within tolerable limits of bacteria and chemicals. Bulk potable water is sampled at the water intake facility but because it may deteriorate before reaching consumers due to corrosion or contaminations caused by leakages, water is also sampled at the tap at 2 independent locations within the system twice a month.
Bratunac water utility performs regular water quality tests through the Public health institute of Republika Srpska and the test results satisfy in over 95% cases. The results of recent physical-chemical analysis from February 2014 showed that the level of nitrate are below the hygienically regulated maximum of 50 mg NO_3/l and that the concentrations of residual chlorine seem to be below regulated maximum of 0.5 Cl_2 mg/l.
Generally, potable water quality in Bratunac is considered to be good. The recently conducted microbiological analysis from February 2014 showed that there were no either coliform of other bacteria in water system.

3.2.5 Chemicals use

This indicator is affected by raw water quality and the degree of protection of freshwater resources. Since the raw water withdrawn from Bjelovac water wells is of high quality, only chlorine is utilized in the water treatment for Bratunac water supply. The dosage of chlorine has been relatively stable during the observed period (0.3 mg/l Cl_2). Efficiency improvements introduced gas chlorinators which apply dosage in accordance with the withdrawn water quantities. The current chemicals use for water quality in Bratunac water supply system can be considered efficient.

3.2.6 Leakage/ water losses

Large volumes of water are lost due to leakage in pipes which leads to increased pumping costs, loss of water (and revenue), loss of pressure and increased risks of contamination by bacteria and corrosion products (e.g., copper, iron and zinc). Data on water production is obtained through a water flow meter installed at the water intake facility next to the water pumps on thrust pipelines. The meter displays cumulative flow values recorded on daily basis. Also, at the exit of Bratunac reservoir there is a flow meter which registers data on quantities of water flowing into the distribution system. Accuracies of both meters having been checked through ultrasound flow meters, it was concluded that the flow values were identical; however, the installed meters need to be calibrated. Water use, namely quantities of water delivered to consumers, is registered through water meters and where there is no water meters installed water use is calculated as flat rate service. Water meters are read quarterly.

Table 5 – Water losses in the distribution system (source Kovacevic et al. 2013)

Time of year		Water production			Water losses in the system					
					Distribution network			Household installation		
Month	No. of days	m^3/month	m^3/day	l/s	m^3/mth.	l/s	%	m^3/mth.	l/s	%
January	31	157,140	5,069	58.67	59,366	22.16	37.77	26,255	9.80	16.71
February	28	148,150	5,291	61.24	58,898	24.35	39.76	23,715	9.80	16.01
March	31	172,090	5,551	64.25	74,316	27.72	43.14	26,255	9.80	15.26
April	30	175,100	5,837	67.55	80,167	30.93	45.79	25,408	9.80	14.51
May	31	171,420	5,530	64.00	73,646	27.50	42.97	26,255	9.80	15.32
June	30	170,210	5,674	65.67	75,271	27.68	42.15	25,414	9.80	14.93
Total	**181**	994,110			421,664			153,303		
Average:			**5,492**	**63.57**		**26.96**	**42.42**		**9.80**	**15.42**

Month		Total losses		
	No.of days	m^3/mth.	l/s	%
January	31	85,621	31.97	54.49
February	28	82,613	34.15	55.76
March	31	100,571	37.55	58.44
April	30	105,575	40.73	60.29
May	31	99,901	37.30	58.28
June	30	100,685	38.84	59.15
Total	**181**	574,967		
Average			**36.77**	**57.84**

Data from Table 4 shows that water losses in Bratunac water supply system are in range 55 - 60 % i.e. water losses exceed water loss levels from European urban water networks level (Figure 9) thus increasing costs and decreasing revenues of the water utility and negatively impacting raw water resources.

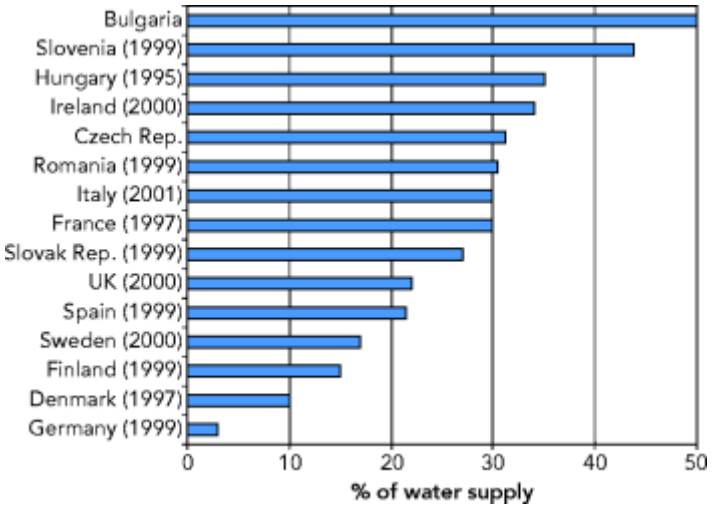

Figure 9 – Losses from urban water network in Europe (source EAA, factsheet, 2003)

Such high losses negatively impact upon the water balance within the Bratunac water supply system as shown in Table 6. This indicates that there is no point in pumping additional quantities of water into the system until the leakage is reduced down to acceptable level.

Table 6– Water balance within Bratunac water supply system (source Kovacevic et al. 2013)

Water supply system	Max. Daily needs for water (l/s)				Water intake withdrawal In Bjelovac (l/s)				Needed quantities of water (l/s)			
	2005	2013	2020	2035	2005	2013	2020	2035	2005	2013	2020	2035
Bratunac	91.20	72.07	82.18	91.00	63.57	63.57	63.57	63.57	-7.63	-8.50	-18.61	-27.43

4. CONCLUSION

In this paper an LCA based, iterative procedure for selecting ESIs for environmental sustainability screening of urban water supply systems has been proposed and exemplified by a screening LCA on Bratunac water supply. The concept of environmental sustainability has been defined by a small set of quantifiable and measurable indicators that enabled quick overview of environmental sustainability of the water supply system over time. Most indicators were easy to apply as data were readily available. All indicators were found to be useful for the subject water supply system and were recommended for future studies.

By taking a look at the chosen set of environmental indicators (Table 1) and the levels of environmental sustainability in Table 2, Bratunac urban water supply system falls within the level C of environmental sustainability, characterized as a reactive decision-making system which meets minimum environmental protection standards and health objectives and which relies on consumer complaints. This means that the system is not moving towards sustainability and there is much room for improvements in terms of water and energy efficiency, primarily in the management of water losses.

Abstract: *In this paper, the main research subject is sustainable waste management, and consequently utility workers' perception on public behaviour in regards to habits they perform in waste disposal. Due to the increasing amount and harmfulness of waste to the environment, it is considered to be one of the most important problems of the modern world. Waste is generated at all levels, national and local, in households, manufacturing facilities, public administration, retail stores, educational institutions, tourism organizations and enterprises, medical institutions, military institutions, etc. Disposal of municipal and industrial waste without any impact to the environment is one of the major issues facing modern society. More than 150 waste collecting workers covering the territory of 10 Belgrade municipalities participated in the survey. In order to evaluate the results of the survey, statistical software package SPSS 20 was used. And discussion on results is presented in the conclusion of the paper.*

Keywords: communal waste, municipal workers, job satisfaction, cost effectiveness, waste management, environment.

1. INTRODUCTION

Waste management is the implementation of measures prescribed for the treatment of waste within the collection, transport, storage, treatment and disposal of waste, including supervision of such activities and maintenance of waste management facilities.

Waste is generated at all levels, national and local, in households, manufacturing facilities, public administration, retail stores, educational institutions, tourism organizations and enterprises, medical institutions, military institutions, etc. Waste generation depends on the level of industrial development, living standards, lifestyles, social environment, energy and other parameters within every community. The amount of waste can vary significantly between countries, but also within the parts of the same country.

The basic classification of waste is the following:

According to the place of origin:

- Municipal waste - household waste, as well as other waste which, based on its nature or composition, is similar to waste from households.
- Commercial waste - waste generated by businesses, institutions and other organizations that are wholly or partially engaged in trade, services, office affairs, sport, recreation or entertainment, except for household and industrial waste.
- Industrial waste - waste from any industry, except for the tailings and associated minerals from mines and quarries.

According to characteristics that affect human health and the environment, waste can be (UNESCO – UNEP., 1993; UN., 1992):

- Non-hazardous waste - waste which, because of its quantity, concentration or physical, chemical and biological nature, as opposed to hazardous waste, does not threaten human health or the environment and does not have the characteristics of hazardous waste.
- Inert waste - waste that is not subject to any physical, chemical or biological changes; Insoluble, does not burn or in other ways physically or chemically react, is not biodegradable or adversely affect other matter which it comes into contact with in a way that could lead to pollution of the environment or endanger human health; does not possess any of the characteristics of hazardous waste (acute or chronic toxicity, infectivity, is carcinogenic, radioactive, flammable, explosive); the content of pollutants in its water extract may not exceed the statutory level.

• Hazardous waste - waste which by its origin, composition or concentration of hazardous substances can cause harm to the environment and human health, and has at least one of the hazardous characteristics (explosive, flammable, tendency to oxidation, organic peroxide, acute toxicity, infectivity, tendency to rust in contact with air, releases flammable gases in contact with air or water, releases toxic substances, contains toxic substances with delayed chronic action and eco toxic properties), including the packaging in which hazardous waste is or was packed.

Municipal waste is divided into (Marković Luković Lj., 2010):

• organic (biological or biodegradable waste - food scraps, yard waste, grass, leaves, cut off branches, trees, and paper packaging contaminated with food, paper towels, and dust from combustion of wood);
• paper and cardboard (newspapers, books, magazines, commercial printing, office paper, wrapping paper, cleaning paper, corrugated paper);
• plastics (packaging materials, boxes, bottles, plastic bags, foil and other plastic products);
• glass (bottles, jars, containers for beverages, flat glass);
• metal (tin cans, aluminium, iron and other metals);
• textiles and leather;
• other (dirt, ashes, street sweepings, dust, unidentified materials).

Waste material is usually found in solid state, but can also take the form of liquid and the form of sludge. Collection, transport and treatment of the latter require special equipment.

Table 1: Quantity and composition of municipal waste by countries, (EC., 2002).

Waste characteristics		Countries	
		Developed	Developing
quantity per resident	kg/day	0.8-2.2	0.3-1.0
	t/year	0.3-0.8	0.1-0.4
Density	kg/m3	100-200	200-500
Humidity	% mass	20-40	40-80
calorific value	MJ/kg	8-12	3-10
composition:			
• paper, cardboard	% mass	20-40	10-30
• glass, ceramics		4-10	1-10
• metals		3-13	1-5
• plastic		4-10	1-8
• leather, rubber		1-5	1-5
• wood		1-5	1-5
• textiles		2-5	1-10
• bio-waste		20-50	40-85
• hazardous waste		0.5-3	0.5-1
• other inert waste		1-20	1-40

2. ENVIRONMENTAL INFLUENCE OF COMMUNAL WASTE

The impact of solid waste on the environment has multiple negative effects, and the primary reason for such impact in the Republic of Serbia is insufficient coverage of municipal services, which is causing illegal dumping, landfills, major disorders and low public awareness of the environmental issues.

Therefore, illegal dumping sites that are spreading uncontrollably on the municipal territories are created. Main landfills in villages and small urban areas are usually overloaded and without proper cattle burial grounds, all of which are potential source of infectious diseases affecting population and the environment.

Waste affects all categories of the environment: air, land and water. During the breakdown of organic matter, under aerobic and anaerobic conditions, gases are usually released from the waste into the environment: methane, which is explosive, and carbon dioxide. When decomposing, animal carcasses and food remains of animal origin release ammonia, hydrogen sulphide, aromatic acids and other substances that make the air extremely unpleasant to breathe and at higher concentration can be toxic or cause shortness of breath, impaired blood flow, fatigue and sleepiness.

Landfills that are poorly maintained and rarely treated with clay are prone to spontaneous combustion. Gases formed by rotting or by burning of landfills are released into the atmosphere and pollute the environment. Besides gas, the air is polluted with dust and odours. Thus, air pollution and harmful substances accumulated in the atmosphere can adversely affect human health. In places where organic matter decomposes regularly, flies, insects and various birds, rats and other rodents gather. Flies and rodents can become carriers and spread infectious substances (SEPA, 2013).

The key principle of waste management is the principle of sustainable development and it is based on six sub-principles. Sustainable waste management implies more efficient use of resources, waste minimization and handling of waste in such a way that it contributes to the objectives of sustainable development. Sustainable development is a coordinated system of technical-technological, economic and social activities in the overall development in which the principles of cost-effectiveness and the reasonableness of the use of natural and man-made values are met in order to preserve and enhance the quality of the environment for present and future generations (Dţ ozef & Ţarden, 2006; Đukanović.,1996; Milutinović., 2005; Đukić., 2008)

Waste management is based on the following principles:

- The principle of proximity and regional approach to waste management,
- The precautionary principle,
- The "polluter pays" principle,
- Principle of the hierarchy of waste management,
- Principle of the optimal option for the environment,
- The principle of accountability.

2. COMMUNAL WASTE MANAGEMENT IN THE REPUBLIC OF SERBIA

Disposal of municipal and industrial waste without any impact to the environment is one of the major issues facing modern society. Some villages and local communities, due to limited resources, are unable to independently provide all the services that should be a concern of municipal waste management and other projects that are of public importance. One of the strategies usually developed by the municipalities in order to increase the efficiency of service delivery is regionalization.

Also, the strategy discusses a need for institutional strengthening, development of legislation, education and public awareness. The National Strategy is the basic document that provides the conditions for the rational and sustainable waste management at the national level. In the next phase, the strategy should be supported by several implementation plans for the collection, transport, treatment and disposal of controlled waste.

In the Republic of Serbia there is a need for strengthening of the institutions, development of legislation, education and public awareness ("Sl. glasnik RS", br. 36/2009 i 88/2010). Furthermore, there is a need to determine economic and financial mechanisms necessary to maintain and improve waste management, and to ensure the system for domestic and foreign investment in the long-term sustainable activities.

The implementation of the basic principles of waste management set out in the strategic framework is essential (EEA., 2003), i.e. solving the problem of waste at the source, the principle of prevention, separate collection of separate materials, the principle of neutralization of hazardous waste, solving regional waste disposal and remediation of landfills, implementation of the basic principles of the EU in the field of waste and prevention of further danger to the environment and future generations.

The stated goals express strategic choices and main priorities of the Republic of Serbia for the next few years. A long-term strategy for the country in the field of environmental protection is to improve quality of life by providing desired environmental conditions and nature conservation based on sustainable environmental management.

Data on municipal waste of the Republic of Serbia is shown in Table 2 (NWMS, 2010)

Table 2: Data on municipal waste of the Republic of Serbia for the year 2012.

Waste quantities and composition			
1.	Total yearly quantities of collected waste	1... Measured 2... Estimated	Quantity t/year.
	Municipal waste, except bulky waste		583.738
	Municipal bulky waste		2.471
	Waste from businesses and institutions (except industrial)		No available data
	Industrial waste		143
	Waste from public areas		No available data
2.	Quantities of specific waste materials	t/year	%
	Paper	341	<1,00
	Glass	0	
	Plastic	159	<1,00
	Rubber	184	<1,00
	Metal (iron)	112	<1,00
	Metal (aluminium, etc.)	466	<1,00
	Organic waste (food, grass, etc.)	0	
	Construction waste	142.959	19,60
	Textile	0	
	Other	454	<1,00
	Total:	144.675	100%

Municipal waste is household waste, as well as other waste which, because of its nature or composition, is similar to waste from households. It is estimated that around 60 percent of municipal waste in the Republic of Serbia gets collected. The collection is organized mainly in urban areas, while rural areas are much less covered by the services of the municipal waste collection services. The largest number of local governments has the mechanisation and vehicles for waste collection, however, there is a lack of proper equipment.

Table 3: Data on generated municipal waste in 2012 in the Republic of Serbia (SORS., 2012)

Municipality	Number of residents	Mass of generated waste	Mass of waste per resident daily	Mass of waste per resident yearly
		(t/week)	(kg/resident/day)	(kg/resident/year)
InĆja	49 258	363	1,05	383
Sombor	56 734	269	0,67	246
Novi Kneţ evac	9 648	40	0,59	214
Šabac	123 155	463	0,59	209
Topola	25 292	51	0,29	105
Kragujevac	185 000	897	0,70	252
Bor	55 817	125	0,32	116
Niš	239 596	1 230	0,73	266
Novi Sad	314 192	2 560	1,16	424
Beograd	1 392 691	10 382	1,08	394

The social aspects of the national waste management strategy refer to:

- Use of materials, the generation and disposal of waste and other needs and requirements for waste management;
- Public participation in waste management through a variety of activities;
- Social conditions of workers employed in waste management.

Waste generation in the population is primarily a consequence of their consumption and thus their socio-economic characteristics. At the same time, the generation of waste is largely related to the attitude of people towards waste: their use of materials and waste handling, their interest for the reduction and minimization of waste, the extent to which they separate the waste and the level of unauthorized waste disposal. Their attitude affects not only the characteristics of the waste, but also the effective demand for waste collection services, and their interest and willingness to pay for waste collection. Their relationship can positively influence the development of public awareness campaigns and educational measures for avoiding the negative impacts of inadequate waste collection on human health and the environment and the value of

the effective disposal. Such campaigns should also inform people about their responsibilities as waste producers and their rights in relation to waste management services.

3. SURVEY OF WASTE COLLECTORS IN PUBLIC UTILITY COMPANY ON WASTE COLLECTION IN THE REPUBLIC OF SERBIA

The sample of this research is formed out of permanently employed municipal workers which work on waste collection in Belgrade, Serbia. According to the current data, the company has around 620 full-time employees working on waste collection. The sample used in this research consists of approximately 25 percent of full-time employees. More precisely, 150 waste collecting workers covering the territory of 10 Belgrade municipalities participated in the survey. Municipalities taken into account by the survey are Novi Beograd, Zemun, Zvezdara, Savski Venac, Rakovica, Stari grad, Vraćar, Voţdovac, Ćukarica and Palilula. The age range of the survey participants was 18 – 58. Out of 150 participants, 7,33 percent haven't graduated from elementary school, 63,33 percent have graduated from elementary school, while 27,33 percent have graduated from high school.

More than 78 percent participants states that citizens are extremely negligent when disposing their waste, while only 11.33 percent stated that citizens dispose their waste in a satisfactory manner.

Almost 90 percent of participants state that their job is so crucial for regular City functioning, that they believe that in only five days without proper waste disposal services, serious health and environmental threats would arise.

More than half of the participants involved in the survey state that the biggest problem that leads to the inappropriate waste disposal by citizens is the general lack of environmental and health awareness and the lack of awareness of the effects waste have towards environment and general public.

In the survey, some cases are noted where workers found weapons, hand grenades, dead animals, bricks, car parts and all other sorts of waste which certainly does not have its place in a container - a shot, stones, ashes etc. Improper sorting of waste can lead to various diseases among the workers, and most of them at least once in a lifetime encounter with a health care problem related to their profession.

More than 96 percent of participants believe that inappropriate waste disposal should be penalised in one way or another. On the question of what they think would be sufficient penalisation of inappropriate waste disposal, participants stated in 64 percent of cases that financial fine should be imposed, while 18 percent believe that community service (street cleaning, waste collection) would do better and 5.33 percent states that such behaviour in some cases should be treated as a criminal act as it can be health threatening to the entire public.

In order to evaluate the results of the survey, we used statistical software package SPSS 20. The relationship between two categorical variables was explored by chi-square test. Correlation, between two scale variables was done by parametric Pearson correlation, while correlation between two nominal variables was evaluated with non-parametric Spearman's rho correlation. A p value is used to indicate if the differences between two particular groups that were in this research are statistically significant (where $p<0.05$ is considered statistically significant at 95 percent confidence level). In order to calculate effect size we used Cohen's interpretation of Pearson correlation.

- When participants were asked whether they would participate voluntarily in educating the citizens through educational projects, seminars, public demonstrations by explaining their experience and elaborating on their attitudes in order for overall waste disposal improvement, statistically significant difference was noted in comparison of groups of waste collectors who have suffered certain health problems because of their profession and the ones that have not. The results are given in the following table ($p<0,01$).

We can note that 93.88 percent of the workers that experienced health problems would be willing to participate in educational process of the broader public on the proper waste disposal, while only 66.33 percent of those who haven't experienced health problems due to lack of public awareness would do the same. We see that both groups agree that further education and increasing awareness of the citizens would ease up the job that they do, but those that even had health problems significantly more have such belief. According to Cohen (1988), the influence of these differences is medium to large r=302 ($0.3<r<0.5$ medium to large effect size).

Table 4: Correlation of health experienced and willingness to participate in educating broader public

Experienced health problems and willingness to participate in education of the public					
Willingness to participate in education of the public					Total
			Yes	No	
Experienced health problems	Yes	Count	46	3	49
		Expected Count	37.0	12.0	49.0
	No	Count	65	33	98
		Expected Count	74.0	24.0	98.0
Total		Count	111	36	147
		Expected Count	111.0	36.0	147.0

4. CONCLUSION

Due to the increasing amount and harmfulness of waste to the environment, it is considered to be one of the most important problems of the modern world. The public shows willingness to participate in solving this problem only when threatened by it or when this is in their immediate interest. We must remember that each of us every day produce waste which means that every individual is responsible for the creation and disposal of waste. Today, the idea prevailed entirely, that the waste should not be destroyed, but it should be used. Waste is not garbage, but good natural resource with a small percentage of garbage that has no practical value.

Without greater involvement of the government, the economy and all the inhabitants of the country waste management plans cannot be achieved. The opening of new landfills to suit environment and sanitation is not the ultimate solution. The solution is to reduce huge quantities of waste production, technological advances in processing of waste and the development of civic environmental awareness, changing old habits and adopting new ones. This study has achieved its goal, to prove that we need to act now in order to preserve the environment for the future and future generations that have to be educated from an early age on how to properly manage waste.

Abstract**:** *The Sustainable Society Index describes social progress along three dimensions: human, environmental and economic. Being a composite indicator, its aim is to be a comprehensive and quantitative measure of sustainability and a quality of life of a nation. The objective of this paper is to offer a new approach to a framework for objective evaluation of the SSI. To this end we have improved the SSI by implementing a statistical I-distance method that synthesizes several indicators into one quantitative indicator. The applied I-distance method offers the possibility to obtain an optimal set of variables for future revisions of the Sustainable Society Index. In addition, the differences in ranks between countries have been discussed. We hope that our results may initiate further studies concerning the framework of the Sustainable Society Index.*

Keywords*: Sustainable Society Index, I-distance, Ranking of countries, Sustainable development, Country's welfare*

1. INTRODUCTION

Since the 1992 United Nations Conference on Environment and Development in Rio de Janeiro, the limitations of Gross Domestic Product (GDP) as a measure of *sustainable development* have been frequently elaborated (Davidson, 2000; Pissourios, 2013; Cameron et al., 2013). Therefore, many different frameworks for evaluating socio-economic development and welfare of countries have been introduced (Cracolici et al., 2010), with majority of them concerned with economic indicators (UNDP, 2008). As a counterpart of economic growth philosophy, the concept of sustainable progress was introduced in 1980's. It was defined by the Brundtland report as *"development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs"* (WCED, 1987; Petrovic et al., 2011). Social and ecological factors as well as economic ones must be taken into account for defining *sustainable development* (IUCN, UNEP and WWF, 1980). Over the past decades there has been considerable interest in analyzing the relationship between economic growth and environmental impact (Wang et al., 2013).

During the World Summit on Sustainable Development in 2002 (UN, 2002) sustainability was formalized on three pillars – social, environmental and economic. Economic sustainability, as economists see it, is focused on various kinds of ~~c~~apital" (man-made, natural, human, social) that should be sustained (World Bank, 2006). *Sustainable development* is fundamentally perceived as the use of renewable natural resources in a manner that does not eliminate or degrade them or otherwise diminish their usefulness for future generations. Furthermore, it requires a sufficiently slow-rate of depletion of non-renewable energy resources to ensure the high probability of an orderly social transition to renewable ones. A specific definition of a social dimension of *sustainable development* is a less clear-cut (Martin, 2001). Understandably, the diversity of economic, social and cultural conditions in individual countries makes development of a uniform definition of social sustainability very difficult. Black defined social sustainability as *"the extent to which social values, social identities, social relationships and social institutions can continue into the future" (Black, 2004)*. It is precisely the social ~~p~~illar" of sustainable development that is probably the most important and critical for long-term survival of human civilizations as shown in Jared Diamond's insightful study of the past (and contemporary) societies (Diamond, 2005). Last of the ~~t~~hree pillars" concept, the environment, has not been closely scrutinized as the previous two pillars. According to Goodland, environmental sustainability *"seeks to improve human welfare by protecting the sources of raw materials used for human needs and ensuring that the sinks for human wastes are not exceeded, in order to prevent harm to humans" (Goodland, 1995)*. He also identifies environmental sustainability as a set of constraints on the four major activities regulating the scales of the human economic subsystem: *"the*

.

use of renewable and nonrenewable resources on the source side, and pollution and waste assimilation on the sink side".

Given the above mentioned it can be concluded that the problem of sustainability is multi-dimensional. Besides being formalized on three pillars, sustainability is more than a mere aggregation of the indicators because it encompasses their interlinkages (Singh et al., 2012). Also, the indicator should be able to serve as a benchmarking instrument, to show trends in time and set targets. Accordingly, there is a need for indicators that could cover the linkages between the environmental and the other two dimensions of sustainability (Moldan et al., 2004). To this end composite indicators have been used to measure sustainability.

According to *KEI (2005), "Indicators and composite indicators are increasingly recognized as a useful tool for policy making and public communication in conveying information on countries' performance in fields such as environment, economy, society, or technological development"*. According to *Meadows (1998) "Indicators arise from values (we measure what we care about), and they create values (we care about what we measure)"*. Another definition states that a composite index is a combination of multiple sources of information measured in or off a system in order to provide a summary of the system that itself is not directly measurable (Dobbie & Dail, 2013).

There is a strong political desire for the comprehensive assessment of changes in economic, environmental, and social (including institutional) conditions: an issue that cannot be clearly measured and difficult to improve (Böhringer and Jochem, 2006). The construction of a composite index is a dynamic process, which may be roughly simplified in three steps. In the first theoretical step, experts are often involved to select the most representative underlying variables (Yuan et al., 2003; Esty et al., 2005). The second step (operational step) involves data collection and handling. Once the variables are normalized, the resulting variables could be aggregated into an overall index by an aggregating method. Then, in the final step, the collected data are aggregated leading to a composite index.

Many of the sustainability composite indicators fail to meet fundamental scientific requirements. There are three central issues to be addressed. Firstly, in selecting input variables one should be conscious that the themes determine a thematic aggregation method, and the units determine a technical aggregation method. Secondly, as there are no general rules for normalization of these variables and their weighting these procedures should be treated in a transparent way, with a great reserve, and be subject to comprehensive sensitivity analysis. Thirdly, commensurability of input variables should be assured (Ebert and Welsch, 2004).

Bearing this in mind our paper will try to address several topics. Firstly, we will point out the significance of socio-economic composite indicators and how they are constructed. Secondly, we will review the *Sustainable Society Index* which has been developed since 2006 with the aim to be a comprehensive and quantitate method to measure and monitor the health of coupled human-environmental systems at national level worldwide.

In search of an adequate set of indicators to measure the level of sustainability of a country, the main existing indexes have been examined. However, the conclusion appears to be that none of them seem to fit the needs completely. The main shortcomings are a limited definition of sustainability, a lack of transparency, and absence of regular updates. For this reason, a new index — the *Sustainable Society Index (SSI)* — was developed in 2006. It aims at describing social progress along all the three pillars – human (social), economic and environmental. Since then the SSI has been refined methodologically in order to arrive at an index that is both conceptually and statistically sound (Saisana, Philipapas, 2012). Sustainable Society Foundations was released for the fourth time in 2012, having undergone a revision by the Joint Research Centre. The latest update concerns the used aggregation method which has been changed from arithmetic to geometric mean. The SSI integrates the most important aspects of sustainability and the quality of life of a nation in a simple and transparent way. Consisted of 21 indicators, grouped into 8 categories, three Wellbeing dimensions, it is based upon the definition of the Brundtland Commission, measuring and summarizing the complex concepts underlying a sustainable society.

The paper is organized as follows: Section 2 focuses on the methodology used to perform the analysis. Section 3 features the comparative analysis of the latest SSI rankings based on the revised methodology (Saisana and Philipapas, 2012) and the *I-distance* method applied on the 2012 database. The final section of the paper underlines conclusions of the paper.

.

2. METHODOLOGY

Subjectivity in creating composite indicators may affect the measurements to a great extent. In order to overcome this problem the *I-distance* method can be used. It was originally defined by Ivanovic (Ivanovic, 1977) who devised this method to rank countries according to the level of development based on several indicators, where the main issue was how to use all of them in order to calculate a single synthetic indicator which will afterwards represent the rank.

The *I-distance* measurement is based on calculating the mutual distances between the entities being processed, whereupon they are compared to one another so as to create a rank (Seke et al., 2013). It is necessary to fix one entity as a reference in the observed set using the *I-distance* methodology. The ranking of entities in the set is based on the calculated distance from the referent entity (Jovanovic at al., 2012).

For a selected set of variables $X^T = (X_1, X_2, ...X_k)$ chosen to characterize the entities, the I-distance between the two entities $e_r = (x_{1r}, x_{2r}, ...x_{kr})$ and $e_s = (x_{1s}, x_{2s}, ...x_{ks})$ is defined as

$$D(r,s) = \sum_{i=1}^{k} \frac{|d_i(r,s)|}{\sigma_i} \prod_{j=1}^{i-1} (1 - r_{ji.12...j-1}) \qquad (1)$$

where $d_i(r,s)$ is the distance between the values of variable X_i for e_r and e_s e.g. the discriminate effect.

$$d_i(r,s) = x_{ir} - x_{is} \quad i \in \{1,...k\} \qquad (2)$$

σ_i the standard deviation of X_i, and $r_{ji.12...j-1}$ is a partial coefficient of the correlation between X_i and X_j, $(j < i)$ (Radojicic et al., 2012).

To overcome the problem of negative coefficient of partial correlation, which can occur when it is not possible to achieve the same direction of variables, it is a suitable to use the square I-distance (Jeremic et al., 2013). It is given as:

$$D^2(r,s) = \sum_{i=1}^{k} \frac{d_i^2(r,s)}{\sigma_i^2} \prod_{j=1}^{i-1} (1 - r_{ji.12...j-1}^2) \qquad (3)$$

3. RESULTS OF THE ANALYSIS

Within the aim of the paper to provide an appropriate framework for evaluating countries' sustainability, we applied the *I-distance* method on 151 countries and compared it to the official SSI rankings. The input data was obtained from the official 2012 SSI database. Table 1 contains 21 variables that enter the SSI framework, which are divided into eight categories and three wellbeing dimensions. This framework aims at picturing the global landscape of societies in regard to their sustainability level.

Table 1: Human, Environmental and Economic indicators for countries' wellbeing

Wellbeing dimensions	Categories	Indicators
Human Wellbeing	Basic Needs	Sufficient Food
		Sufficient Drink
		Safe Sanitation
	Health	Healthy Life

.

		Clean Air
		Clean Water
	Personal & Social Development	Education
		Gender Equality
		Income Distribution
		Good Governance
Environmental Wellbeing	Nature & Environment	Air Quality
		Biodiversity
	Natural Resources	Renewable Water Resources
		Consumption
	Climate & Energy	Renewable Energy
		Greenhouse Gases
Economic Wellbeing	Transition	Organic Farming
		Genuine Savings
	Economy	Gross Domestic Product
		Employment
		Public Debt

The above variables have been chosen in an iterative process during the framework revision carried out by Joint Research Centre and the SSI team in order to achieve a conceptual and statistical coherence and arrive at SSI components that are relatively balanced (Saisana, Philipapas, 2012). We have applied the proposed *I-distance* method on the first ten officially ranked countries in 2012. Table 2 shows the results of the I-distance method, square I-distance value, I-distance ranks and official SSI ranks. According to the I-distance method Norway and Sweden top the list.

Table 2 : The results of the I-distance method, square I-distance value, I-distance ranks and official SSI ranks for year 2012

Country	I^2 - distance	I^2 - rank	SSI - rank
Norway	110.90	1	5
Sweden	107.95	2	2
Switzerland	107.02	3	1
Finland	103.77	4	8
Austria	100.04	5	3
New Zealand	94.50	6	11
Denmark	91.47	7	34
Luxembourg	91.04	8	27
Iceland	90.53	9	92
Netherlands	89.90	10	44

Table 2 shows that Sweden and Switzerland remained in the top three countries regardless the method applied. Countries among the top 10 by the official SSI ranking that are not in the same rank after applying the I-distance method are: Latvia (4), Costa Rica (6), Slovenia (7), Slovak Republic (9), Sri Lanka (10). They are replaced by New Zealand (6), Denmark (7), Luxembourg (8), Iceland (9) and the Netherlands (10). Several countries have significantly improved their ranking, with Iceland and the Netherlands leading the way.

Before we continue with the comparison of rankings and reasons for the differences in them, we should analyze a correlation between the official SSI ranking, the ranking obtained by applying arithmetic mean on the 2012 database, and the I-distance ranking. We carried out the Spearman's correlation test on these rankings to determinate whether there is a correlation and whether it is positive or negative.

As expected, the correlation between the 2012 SSI official and 2012 SSI arithmetic ranks is very strong ($r=0.835$, $p<0.01$). What makes the difference between them is the fact that the arithmetic mean approach does not penalize more uneven performance of countries, whilst the geometric does. Geometric mean is far better in representing the improvements of indicators, while the arithmetic

.

mean compensates a good performance in one indicator by a poor performance in another indicator (Saisana and Philippas, 2012). The correlation important for this paper is the correlation between the 2012 SSI official and I-distance ranks, which is strong (r=0.666, p<0.01).

The SSI official methodology takes into account all three Wellbeing dimensions equally, while same do not apply to the *I-distance* method. Implicitly, SSI official methodology provides equal weight to all three wellbeing dimensions which could easily be challenged. The countries to top the list in official ranks have had a similar level of all three Wellbeing dimensions, while other countries performed well in the Economic, but at the expense of the Environmental Wellbeing. This inverted shaped relationship is named Kuznets curve (Kuznets, 1955), which is seen in most developing nations who still have economic growth corresponding to a degradation of environmental wellbeing.

We already pointed out that the *I-distance* approach proposed here, besides providing the ranking list of countries, can also explore in-depth significance of each observed indicator and its contribution to the final rank. By applying our method, we are able to point out crucial indicators of countries' sustainability and determine their significance. Thus, the dataset was further examined and correlation coefficients of each indicator with the I-distance value were determined. The crucial indicators which correlate highly (r>0.6) with the I-distance values are given in Table 3.

Table 3: The correlation between I^2-distance and input indicators

Indicators	r
Good Governance	0.851
Gross Domestic Product	0.760
Healthy Life	0.738
Gender Equality	0.734
Education	0.718
Organic Farming	0.692
Clean Water	0.667
Clean Air	0.615
Sufficient to Drink	0.606

The correlation coefficients between the *I-distance* and initial indicators demonstrate which indicators are important in analyzing a country's socio-economic and environmental development (Milenkovic et al., 2014). (Un)surprisingly the most important indicator for measuring countries' welfare is Good Governance with r=0.851 (p<0.01), followed by GDP r=0.760 (p<0.01) and Healthy Life r=0.738 (p<0.01). Countries that improved their ranks have significantly better scores in these indicators. The fact that more than 50% of top 10 countries are from northern Europe can be explained by the Scandinavian welfare model that has been in practice in these countries since the beginning of their development in 1960's and 1970's. At the core of this welfare model stands the principle of universalism and broad public participation in various areas of economic and social life, which is intended to promote an equality of the highest standards rather than an equality of minimum needs (Magnussen et al., 2009). Since in the Scandinavian model the state has a crucial role as a supplier of social service, it follows that the model leaves relatively high support for low-wage groups (Torben, 2004). Nordic health care systems are intrinsically related to the development of the welfare state, building on the same principles of universalism and equity. Central features have traditionally been an egalitarian ideology, promoting equal access to health services, low levels of cost sharing and high levels of tax-based financing to realize this ideology, public ownership of hospitals and decentralized responsibility for managing the services (Magnussen, Vrangbaek et al., 2009).

Luxembourg entered the top 10 nations in the list according to the I-distance method. These results are in compliance with previous studies which emphasized Luxembourg's welfare and economic openness as the goals other countries should try to achieve (Koster 2013). In particular, its GDP per capita is the highest in the EU and numerous researchers emphasize its importance as a driving force of socioeconomic development while still taking into account renewable energy and sustainable development aspects wherein Luxembourg excels (Djuran et al., 2013).

New Zealand, a country that moved up for 83 places, ranks above the OECD average in terms of health spending, with 10.3% of GDP spent on health in 2011. One of the key reasons New Zealand changed its rank so dramatically is not Healthy Life, but Good Governance indicator. Namely, its score on this indicator is 8.52 compared to the country which holds the same rank in the official SSI ranks with the score 6.22 (Costa Rica). Policy makers are increasingly attuned to social equity and welfare. Welfare reforms, besides education and training of youth at risk, have a goal to improve

.

education, health, employment and social outcomes for large groups of Maori and other Pacific indigenous people in order to reduce social disparities (OECD Economic Survey, 2013).

The Netherlands found its place in the top 10 thanks to its high GDP (9.58) and Healthy Life (8.89) score. In 2006, the country's government introduced a structural health care reform. The reform can be seen as the realization of a long-standing political struggle to unite the health insurance fund and the voluntary private health insurance scheme. This reform gave results and health spending as a share of GDP in Netherlands was 11.9% in 2011 (OECD Health Data, 2013). The European Commission predicts a growth rate of 1 per cent in 2014, which is a recovery from rate of -0.8 per cent in 2013 (European Commission, 2013). Although it had a negative growth rate in the previous year, the Netherlands was ranked 17th on the World list based on the GDP in millions of US Dollars (UN, 2012).

4. CONSLUSION

Since the Rio Earth Summit environmental and sustainable development indicators have proliferated. All that with the purpose of providing decision-makers with tools for assessing sustainability from global to local integrated nature–society systems in short- and long-term perspectives in order to assist them to determine which actions should or should not be taken in an attempt to make society sustainable (Kates et al.,2001). While composite indicators are usually used to present sustainability, they still have drawbacks such as subjectivity, due to the assumptions in estimating the measurement error in data, mechanism for including or excluding indicators in the index, transformation and/or trimming of indicators, normalization scheme, choice of imputation algorithm, choice of weights and choice of aggregation system (Pissourios, 2013). Although there are international efforts on measuring sustainability, only few of them have an integral approach which takes into account environmental, economic and social aspects (Singh et al., 2012). Amongst many, the *Sustainable Society Index* stands out as a simple instrument, based on a solid definition, which is used for assessing a country's present sustainability, as well as its distance to full sustainability (Van de Kerk, Manuel, 2007)

This paper covers an assessment of the *Sustainable Society Index* by applying the *I-distance* method to it. This methodology can easily integrate economic, social and environmental variables with different measurement units into one composite indicator (Isljamovic et al., 2014) which represents the rank. As the SSI synthesizes 21 social, economic and environmental indicators in eight categories, then to three wellbeing dimensions and finally to one single number, we suggest that I-distance method be applied not only to all indicators, but also to these categories in order to get a deeper insight of rankings of countries within a category. Not only does this approach enable *ranking of countries*, but it also allows for a better exploration of the differences between them. The results obtained by applying I-distance method to the official SSI 2012 database clearly demonstrate that Scandinavian and certain Western European countries lead the rank list due to their high level of living standard.

The difference in ranks between the SSI official and I-distance rankings can be explained by the fact that the SSI official rewards a balanced score in all three Wellbeing dimensions, in contrast to the I-distance method which rewards the countries with the higher score in the indicators which have greater significance. The reason the SSI official uses this kind of methodology is that *"the sustainability of the whole depends on mutual assistance and reciprocity among the parts"* (Moldan et al., 2011).

Indicators of sustainable development should be selected, revisited and refined based on the appropriate communities of interest (Singh et al., 2012). As the I-distance approach can identify crucial indicators for the ranking process, which means it can be used to reduce the number of indicators used to calculate a certain indicator (Milenkovic et al., 2014). This feature can be used to further reduce the number of indicators of the SSI, which was already done in 2012 when the index was revised by JRC (Saisana and Philippas, 2012).

We hope that our research will contribute to further improvements of the SSI, all with the purpose of creating a complete *"equilibrium between social, economic and environmental goals which is needed to reach a true index of sustainable development"* (Bravo, 2014).

THE RESEARCH ON THE DEVELOPMENT OF ENVIRONMENTALLY RESPONSIBLE LOGISTICS IN SERBIA

Igor Jovanović[1], Luka Jakovljević[2], Milica Pavićević[3]
[1]Faculty of Organizational Sciences, igor.jovanovic.bl@gmail.com
[2]Faculty of Organizational Sciences, jakovljevicluka.8@gmail.com
[3]Faculty of Organizational Sciences, milicampavicevic@yahoo.com

Abstract: *This paper presents the research on how environmentally responsible logistics will develop in Serbia, in the period of the following 10 years. According to the ways of application of environmentally responsible logistics, a Delphi research was conducted, in order to have a clear picture of occurrence of different, strategically important events. The result of the research shows that the most important aspects of environmentally responsible logistics and supply chain management are supposed to occur by the end of 2018, which will allow the application to progress at a regional level, as well.*

Keywords*: environment, logistics, Serbia, research, development, Delphi*

1. INTRODUCTION

The matter of environmentally responsible logistics is a very complex one, including numerous factors, which affect the creation of such, “green” supply chains. Scientifically, this field has been worked on, especially at the end of the 1990s (Rodrigue, Slack and Comtois, 2001), but the knowledge still remains parted, and the field still remains in the process of development. However, the topic has been connected to the matter of sustainable development, and as such, it has become more up-to-date.

Logistics has been proved to be environmentally the least responsible and the most damaging function of everyday business (Jovanović et al., 2013). Therefore, its development towards sustainability was a logical way of progress (Rodrigue, Slack and Comtois, 2001). The main factors that decide whether a supply chain can be called “green”, or environmentally responsible, are the “green” paradoxes of logistics, intermodal transportation systems with all of their components, the development of information and communication technologies in sustaining an overall interconnection and the development of eco-innovations, laws, regulations and standards on an international level (Jovanović et al., 2013).

Since the topic is still new and underdeveloped, the most certain way of forecasting for its crucial events in Serbia was the Delphi method, where the experts were taken from within the educational system, rather than the economy. All of the experts are the representatives of the University of Belgrade and the Faculty of Organizational Sciences in Belgrade.

2. TECHNICAL DETAILS AND THE EXPERT PANEL

The years taken for the framework of the research were all in range from 2014, as the base year, to 2023, as the final year. The research has been conducted from February to April 2014, which included the preparation of the questionnaire, selection of the expert panel, sending the questionnaire, gathering and analysis of the answers, returning the answers and the questionnaire to the experts for the second round and final analysis of all the answers gathered.

The expert panel consisted of professors and teaching assistants of the Faculty of Organizational Sciences, so that different perspectives of the problem would be met. They were selected accordingly to their scientific development and fields of teaching and scientific work, regarding logistics, technological development, innovations, environmental management and other related topics. The final list of the expert panel, arranged according to their titles and Serbian alphabet, is PhD Lečić-Cvetković Danica, PhD Levi Jakšić Maja, PhD Marinković Sanja, PhD Mijatović Ivana, PhD Stošić Biljana, MSc Jovanović Milica, MSc Milutinović Radul, MSc Petković Jasna, MSc Rakićević Jovana and MSc Rakićević Zoran.

With the opening of the research, the maximum potential number of rounds was three, where the first round would contain 3 answers (o, m and p), and all the others only 1 (x). However, with a high level of consolidance for most of the questions after round 2 and close similarity of respective answers from both rounds, it was decided that the research ends after round 2 (Somerville, 2007).

3. THE QUESTIONNAIRE

The questions sent to the expert panel were followed by additional information. This was sent due to the fact that environmentally responsible logistics is still not very developed in the world, and the scientific contribution is what can best be relied on. There were 10 questions, examining the time of occurrence of 10 different factors, which affect the settlement of an environmentally friendly supply chain (Rodrigue, Slack and Comtois, 2001). The questions, along with their respective additional information, are in the following text.

1. When do you think the topic of environmental responsibility within logistics and supply chain management will become a syllabus part of subjects, related to the matter, in technical faculties in Serbia?

Additional information 1: Even when it comes to worldwide renowned Universities, there is not much data about mandatory subjects, which study this matter in particular (Rodrigue, Slack and Comtois, 2001). However, many papers concerning it, in the past few decades, show us that there is progress in this area. Furthermore, lately there has been interest for this topic, which can be infered from the SPIN'13 conference in Belgrade and other, similar symposia.

2. When do you think a hub-and-spoke network will be developed in Serbia, in the transportation of goods and people?

Additional information 2: A hub-and-spoke network considers merging a number of small terminals to one, much bigger and more complex, especially an airport or a haven. This structure has a negative impact on the environment, focusing a large number of people and quantities of goods to one point, thus increasing the level of pollution (Rodrigue, Slack and Comtois, 2001). Furthermore, according to population listings from 2011. almost ¼ of overall population of Serbia lives in Belgrade.

3. When do you expect the companies in Serbia will start developing their own “green” programs within supply chains?

Additional information 3: DHL Serbia has already started implementing the GoGreen program, but on a worldwide basis, DHL has been actively implementing other CSR programs. The GoGreen program was started five years ago in the world. Within this program, DHL sends CO_2 emission reports to their clients, according to which it forms eco-optimization of fuel spending for their own vehicles. Furthermore, they offer “become carbon-neutral” services. For more information, you can open the following link http://www.dhl.rs/sr/about_us/green_solutions/gogreen_products_services.html.

4. When do you believe the laws, which regulate certain rights and obligations related to “green” logistics operations, will be implemented in Serbia?

Additional information 4: In Serbia, there are already certain environmental laws, such as the Law on environmental protection, but there are still no laws that regulate the development of intermodal transportation, limitations of E-commerce etc. in the Parliament’s agenda.

5. When do you expect that E-commerce will start exponentially growing in Serbia?

Additional information 5: Although E-commerce has started to develop in Serbia during 2011 and 2012, many believe that it will never live in its real form. E-commerce has a negative impact on the environment, since it means increasing the number of shipments and thus using additional fuel (Jovanović et al., 2013).

6. When do you believe the companies in Serbia could start implementing intermodal supply chains?

Additional information 6: Intermodal transportation means using more than one type of transportation for the shipment of the same goods, in such a manner that the overall effect is not only related to the increase of efectiveness, but also environmental responsibility (Rodrigue, Slack and Comtois, 2001). For example, transporting one shipment by truck to the closest railway station, after which it will be transported further by train to the city of its final destination, and then by truck again to the warehouse is much more environmentally responsible than transporting the same shipment by truck entirely (Jovanović et al., 2013). Some of worldwide renowned companies, such as DHL and COSCO already use their own intermodal supply chains (LiSiyi and WeiYi, 2011).

7. When do you suppose the first company in Serbia will be able to manage its own intermodal supply chain?

Additional information 7: Bear in mind that this is how COSCO and DHL function globally (LiSiyi and WeiYi, 2011). By opening the following link http://www.coscologam.com/page/view/intermodal you can see how the intermodal supply chain of COSCO, which is based on a number of different services, works.

8. When do you expect that the first international and other standards for the development of ICT in the transportation sector (especially intermodal) will be acknowledged?

Additional information 8: The Strategy of development of rail, road, water, air and intermodal transportation in the Republic of Serbia for the period from 2008 to 2015 already exists. More information on it can be accessed to by clicking the following link http://www.putevi-srbije.rs/strategijapdf/Strategijatransport_lat.pdf. Global coordination is one of the key points in the development of intermodal transportation, which could lead to harmonizaton and seamlessness in organizing such a transportation model. Even when it comes to a global level, there are still only ideas about solving this problem (Jovanović et al., 2013).

9. When do you believe that there will be competition in the railway sector in Serbia?

Additional information 9: Intermodal transportation cannot be adequately developed as long as the railway sector is downsized to monopoly (Rodrigue, Slack and Comtois, 2001). This way, the consumers of railway transportation are "condemned" to not only one price, but also the applying quality and reliability (Jovanović et al., 2013). In 2013, the government in Serbia was discussing opening the railway market.

10. In which year do you believe the companies in Serbia will start working on eco-innovations, especially within transportation systems?

Additional information 10: The question relates primarily to local Serbian companies, which do not have a central counterpart, from which they could take over the ideas. On the other hand, when it comes to the eco-innovations of big worldwide companies, DHL has developed its own programs of waste decrease, especially in the manner of paper and packaging, water consumption and increase in biodiversity. For more information, you can access the following link http://www.dpdhl.com/en/responsibility/environmental-protection/improving_efficiency/other_environmental_impacts.html.

4. RESEARCH RESULTS – ROUND I

Once again, as mentioned before, the Delphi research was conducted in two rounds. The results will be shown and elaborated on, in order for the whole concept to be understood. After the results of the second round have been shown, the results of both rounds will be analysed in comparison to one another, in order to best present the conclusions of the research. The results of the first round will be presented in Table 1, the results of the second round in Table 2, and the comparative results will be presented in Table 3.

Table 1: Research results in round I

Question/ Indicator	Expected time of occurrence	Year of occurrence	Dispersion	Standard Deviation
1	3.1	2017	1.3085	1.1439
2	3.9667	2017	1.1348	1.0653
3	2.3333	2016	0.9832	0.9916
4	2.2667	2016	0.9638	0.9817
5	2.85	2016	1.0723	1.0355
6	3	2017	1.3081	1.1437
7	2.7833	2016	0.996	0.998
8	3.6333	2017	1.2991	1.1398
9	4.3667	2018	1.1542	1.0743
10	4.15	2018	2.0179	1.4205

As we can infer from the table, all of the events are supposed to occur in a range starting in 2016 and ending in 2018. What can further be inferred is that the level of dispersion is relatively low, meaning the experts have a high level of consolidation in their own opinions, especially since the answers were 3 values – o (optimistic), m (expected) and p (pessimistic). On the other hand, many questions still do not fulfil the condition of consensus, which is dispersion having a value lower than 1 (Hsu and Sandford, 2007).
Analysing the answers one by one, we can say that "green" logistics should become a part of teaching syllabus in technical universities in Serbia in early 2017. However, the value of dispersion is about 1.3, so this question will have to undergo a second round, in order to reach a more accurate answer.

With a similar level of agreement as for the first question, we can say that a hub-and-spoke structure will be created in Serbia at the end of 2017. With hub-and-spoke network being an environmentally damaging structure, the authorities should take care of this problem in the early stages, as soon as possible (Jovanović et al., 2013). However, a second round will have to prove the accuracy of this answer.

When it comes to environmental responsibility in logistics, within the corporate sector in Serbia, it is expected to occur at the beginning of the second quarter of 2016. Furthermore, the level of consensus is reached for this question, so it can be treated as the final answer. However, since the value of dispersion is close to 1, the question will be repeated in round II.

The law is expected to change, in a more environmentally responsible manner for logistics, at the beginning of the second quarter of 2016. Again, the consensus, with the dispersion value close to 1, has been reached, and therefore another round will be conducted for this question as well, in order to verify the result.

The exponential growth of E-commerce is predicted for the end of 2016. The level of dispersion is 1.07, which means the answer could be tolerable. However, it will undergo a second round, as well, since the result needs to be verified when the experts can only use one answer.

When it comes to companies in Serbia using intermodal transportation systems, we can say that this is expected to occur at the beginning of 2017. However, the dispersion level is not as low for this answer as it is for the ones prior to it, and thus round II will verify it.

In contrast, there is a high level of agreement, a consensus on the matter of the first company in Serbia using an intermodal supply chain for its own operations, and this event is predicted for the end of 2016. However, round II will provide a sharper image of this matter.

The time of implementing standards of ICT within the transportation sector in Serbia is expected in the second half of 2017. The dispersion level is 1.29, which means that a more accurate answer is expected in round II.

The level of agreement on the matter of appearance of competition in the railway sector in Serbia is not very high. The value of dispersion is close to 1, but it can still not be taken as consensus. The proximity of the answer from round II will show a more precise picture. For now, it is predicted for the second quarter of 2018.

Finally, companies are predicted to start working on eco-innovations, in terms of transportation systems, with the beginning of 2018. However, this answer has the highest dispersion of all 10 answers, and since the value is higher than 2, the second round will have to show a more accurate result. Again, the proximity of the answer from round II followed by a lower level of dispersion will have the same effect.

Generally speaking, the level of dispersion was not very high for most questions, especially since all the questions were supposed to be answered with 3 answers, thus creating internal dispersion. It is expected that the dispersion level will decrease in round II and that the answers will present a sharper image (Hsu and Sandford, 2007).

5. RESEARCH RESULTS – ROUND II

In the following text, Table 2 presents the answers from round II.

Table 2: Research results in round II

Question/ Indicator	Expected time of occurrence	Year of occurrence	Dispersion	Standard Deviation
1	3.1	2017	0.69	0.8307
2	3.7	2017	0.61	0.781
3	2.5	2016	0.65	0.8062
4	2.3	2016	0.61	0.781
5	2.9	2016	0.49	0.7
6	2.9	2016	0.69	0.8307
7	2.6	2016	1.04	1.0198
8	3.5	2017	0.65	0.8062
9	4.3	2018	1.21	1.1
10	4	2018	1.6	1.2649

As noticeable, the figures from Table 1 were sharpened, meaning they have fewer digits after the comma. This is conditioned by using only one answer, instead of an optimistic, the most expected and a pessimistic one. This has decreased the dispersion level of each answer, and thus the overall dispersion, per question. What we can also notice is the fact that almost all questions have reached a level of consensus, indisputably. Another conclusion is that the answers have almost not been changed.

In order to better present both rounds of the research, a new table, showing answers from both rounds, and the final year of occurrence of each event will be presented and elaborated on. As of now, what can be mentioned is that round III has not been undertaken, since respective answers from rounds I and II are have not been changed significantly, and the levels of dispersion, in almost all cases, have been reduced relevantly. As of questions 9 and 10, for which a consensus has not been reached in either round, and explanation of why round III has not been undertaken will follow.

6. COMPARATIVE RESEARCH RESULTS FROM ROUNDS I AND II

In the first round, consensus has been reached for only 3 out of 10 questions, while in round II consensus was reached for 7 out of 10 questions. Furthermore, the figures in round II are more precise than the ones in round I and the answers have been either slightly changed, or completely unchanged. The comparative results, comparing the expected times and dispersions for each respective question in the two rounds and the final year of occurrence of each event, follow.

Table 3: Comparative research results from rounds I and II

Question/ Indicator	Expected time I	Dispersion I	Expected time II	Dispersion II	Year of occurrence
1	3.1	1.3085	3.1	0.69	2017
2	3.9667	1.1348	3.7	0.61	2017
3	2.3333	0.9832	2.5	0.65	2016
4	2.2667	0.9638	2.3	0.61	2016
5	2.85	1.0723	2.9	0.49	2016
6	3	1.3081	2.9	0.69	2016
7	2.7833	0.996	2.6	1.04	2016
8	3.6333	1.2991	3.5	0.65	2017
9	4.3667	1.1542	4.3	1.21	2018
10	4.15	2.0179	4	1.6	2018

Once again, we can claim that environmental responsibility as an aspect of logistics and supply chain management will become a part of subjects in technical faculties in Serbia at the beginning of 2017. However, despite the fact that the answer is the same in both rounds, consensus has been reached in round II. In case that the answers were different, the one from round II would have been taken as final.

There was a slight change in the hub-and-spoke structure occurrence answer. Namely, round I suggested the structure would occur at the very end of 2017, while round II infers it will occur some time earlier, at the end of the third quarter of 2017. With dispersion of 0.61 from round II being lower that 1.13 from round I, the end of the third quarter of 2017 will be taken as the final answer, rather than the very end of 2017.

Eco-awareness programs in Serbian companies were almost certain to start being worked on at the beginning of the second quarter of 2016. However, with a higher level of precision, the experts have decided that this will rather occur a few months later, at the beginning of the second half of 2016.

The consensus for question 4 from round I has also been corrected, or, better said, sharpened. The laws that define certain rights and obligations when it comes to logistics operations are expected to be implemented in the second quarter of 2016. The answers from both rounds are very approximate, but a higher agreement level has been reached in round II.

The exponential growth of E-commerce was expected for the end of 2016, and the second round has confirmed this expectation, with a lower level of dispersion. With this answer, we can be very certain of the prediction.

The first implementation of an intermodal supply chain in Serbia was predicted for the beginning of 2017 by the answers in round I. Round II, however, suggests that the event will occur at the very end of 2016. However, since the difference between the answers is only slight and the dispersion level in the second

round is lower, and in the consensus zone, we will say that an intermodal transportation system will be operational in Serbia at the very end of 2016.

When it comes to the question of a company having an intermodal transportation system, used for its own operations, something interesting occurred during the research. Namely, the dispersion level shifted from the level of consensus (0.996) in round I to a level outside of consensus (1.04) in round II. However, since the dispersion difference is only slight, and the answers are approximate to one another, we can use them to set a time framework for the occurrence of this event. Furthermore, since there was a consensus in round I, we will take that answer as final and say that the first company in Serbia will have its own intermodal transportation system in the final quarter of 2016.

International standards in the field of ICT are expected to be implemented at the beginning of the second half of 2017. Since the answers from rounds I and II are not in a dissonance from one another (3.63 and 3.5 respectively, and the dispersion in the second round is in the level of consensus, we will take the middle of 2017 as the final answer.

When it comes to the matter of the occurrence of competition in the railway sector in Serbia, there has not been a consensus in either of the rounds. In fact, the dispersion from round II is slightly higher than the one from the first round. On the other hand, both dispersion levels are only tolerably close to the value of consensus, and the answers are almost the same. Therefore, we can say that if the third round was undertaken, the answer would be close to the ones from the first two rounds. Also, the dispersion level would most probably be close to the two values. In conclusion, the third round will not be started for this question, and the answer from round I will be taken as final, since the dispersion was slightly lower in the first round. This means that competition in the railway sector in Serbia is expected to emerge in the second quarter of 2018.

Finally, the question of eco-innovations as a driver of development of “green” logistics is the last one, again, never reaching a consensus. The answer from round I indicates that this event should occur at the beginning of 2018, but with a high level of dispersion (2.02). The answer from round II, again, shows that the event will occur at the beginning of 2018, only with a lower level of dispersion (1.6). Neither of the two answers is within the tolerance, or the consensus zone. However, with the two answers indicating the same period of time and the dispersion level decreasing significantly in the second round, we will assume that if the third round was to be undertaken, the experts would have given the same answer, potentially only with a lower level of dispersion, or even within the level of consensus. Therefore, the third round will not be started at all, and the beginning of 2018 will be announced as the expected time when the companies in Serbia will start working on eco-innovations in order to support the creation of intermodal supply chains and “green” logistics.

7. CONCLUSION

In this research paper, we have inspected the times when certain events, crucial for the development of environmentally responsible logistics, are supposed to occur, by using the Delphi method and sending the questions to the teaching staff of the Faculty of Organizational Sciences in Belgrade, who have shown interest in the topic prior to the research, through their contribution to scientific work.

The factors included in the research, concerning environmentally responsible, or “green” logistics were scientific approach, “green” paradoxes of logistics operations, standardization and the legal system in Serbia, eco-innovations, intermodal transportation with all of its components and factors and eco-innovations. These factors were differentiated into 10 questions, sent together with additional information, to keep the experts on the right track, which has resulted in answers having a high level of consensus even in the first round of the Delphi research.

Finally, the answers show us that all of the examined factors will occur in less than 5 years from now, or, precisely, from 2016 to 2018. In fact, most of the examined factors, even 5 out of 10, are supposed to occur in 2016, according to the predictions. What can be expected in Serbia in 2016 is the implementation of environmental responsibility programs in the corporate sector, implementation of the laws, regulating some of the “green” logistics problems, exponential growth of E-commerce and the establishment of intermodal supply chains, within and among companies.

Furthermore, in 2017, we can expect the problem of “green” logistics to become a part of subjects taught in the technical faculties in Serbia, the occurrence of a hub-and-spoke structure and the implementation of international standards in this field.

Finally, in 2018, the railway sector in Serbia should become more competitive and partially privatized, in order to increase the quality of service. Furthermore, the companies in Serbia are expected to start working on eco-innovations, especially in the transportation and supply chain sector, in 2018, as well.

Since environmentally responsible logistics is still only given in a theoretical framework, rather than a practical innovation matter, there needs to be put more effort in its scientific development, prior to its use in practice. The matter still has a complex character. Therefore many more researches need to be undertaken before logistics operations would become completely "green", minimizing the environmental damage to the lowest possible level. This scientific contribution should be followed and continued, in theory and practice, so that one day logistics will turn from "environmentally the least responsible field of business" to a completely "green" operation.

ECO-INNOVATIONS AS A SOURCE OF COMPETITIVE ADVANTAGE IN ENTERPRISES

Maria Urbaniec
Cracow University of Economics, maria.urbaniec@uek.krakow.pl

Abstract: *The paper aims at assessing the impact of eco-innovations on the competitiveness of enterprises, and especially at answering the question which advantages resulting from ecological innovations businesses find decisive for their competitiveness. A review of mainstream literature on eco-innovation as well as on competitive advantages will be conducted followed by document-based research. The paper focuses on various and complex dependencies between the competitiveness of businesses and their eco-innovative activities. Resorting to numerous empirical studies, one may observe that an increase in the significance of ecological innovations in the process of building corporate competitiveness becomes noticeable. Enterprises undertake innovative actions in the field of sustainable growth, and especially ones related to environmental aspects, in this way increasing their market credibility and attractiveness. These results have important implications for business strategy decisions. Therefore, this paper contributes to existing literature on corporate sustainable development by achieving competitive advantages resulting from eco-innovative activities of enterprises. The presented benefits of competitive advantage resulting from eco-innovation activities of businesses may be used among others for a further study of the dependencies between the implementation of eco-innovations and increase in the competitiveness of businesses, as well as for the appropriate adjustment of business strategies to the changing conditions of the environment.*

Keywords: *eco-innovation, competitiveness, competitive advantage, sources of competitiveness, indicators, enterprises*

1. INTRODUCTION

Competition is a phenomenon present in many fields of everyday life: social, political, economic, cultural, etc. It is the foundation for the operation and development of market economy. Competition between enterprises is a special area of current interest of many economists, as businesses are generally considered the main source of real economy, and it is on their behaviours that the condition, directions, and pace of development of national economies and the standard of life of populations depends to a major extent. Thanks to the presence of competition, ever higher quality goods are delivered, and companies are forced to innovate and run reasonable pricing policies (Teece, 2010, p. 186). The capacity of an individual business for competition depends not only on how it achieves its basic economic goals (e.g. profits, profitability, and liquidity), but also on whether it considers a variety of political, legal, economic, and social influences as well as the impact of interest groups that represent them. Due to the growing environmental-oriented requirements on behalf of various stakeholders, whose number includes staff and investors, in their operation an increasing number of enterprises account also for questions related to environmental protection. These changes have made business perceive environmental protection as an important competitive factor, while executive boards and shareholders consider it a strategic managerial duty. Beyond doubt, the changes that take place in business macro- and micro-environment, the growing requirements expressed by customers, and increasingly strong restrictions concerning environmental protection enforce new methods of managing production and environment, which contributes to a more effective management of environmental resources (Bata, 2011, pp. 265-267). Positioning of businesses thanks to a more effective environmental protection and/or ecological products and services may bring a range of competitive advantages, including acquisition of new markets, cost reduction, legal safety, image enhancement, and efficient organisation (Shrivastava, 1995; Dangelico & Pontrandolfo, 2013).

A significant role in achieving a competitive advantage in businesses is ever more often played by the eco-innovative activities they undertake (OECD, 2009, p. 11). As any innovations, the ones in the area of ecology should first of all provide an added value for the clients, be more competitive, and contribute to the creation of profit for the innovators. Their main characteristic feature is their environmental aspect. The goal behind eco-innovation is reduction of the negative impacts on the environment, establishment of new markets opportunities, products, services and/or processes focused on environmental matters, and improvement of environmental impact (OECD, 2009, p. 11). Generally, ecological innovations are integrated with new environmentally-friendly products and services that aim at the improvement of the natural environment by saving energy and other resources, and reducing pollutants and waste (Urbaniec & Gerstlberger, 2011).

These grounds allow a claim that eco-innovations, being an answer to both environmental and socio-economic challenges, play a significant role in building the competitiveness of enterprises. The paper aims at assessing the impact of eco-innovations on the competitive advantages of enterprises, and especially at answering the question which advantages resulting from ecological innovations businesses find decisive for their competitiveness. Thus, the study focuses on various and complex dependencies between the competitiveness of businesses and their eco-innovative activities. To achieve this, the paper first presents the significant circumstances of enterprise competitiveness, and the multi-aspect character of ecological innovations.

2. THE ESSENCE AND SIGNIFICANCE OF ENTERPRISE COMPETITIVENESS

In general, the competitiveness is a feature that distinguishes entities operating within the field economy from the point of view of the results obtained, and the capacity for achieving them in future (Atkinson, 2013, p. 5). As views on the subject diverge, literature proposes an array of definitions of the notion, usually in reference to macroeconomics systems. Approaching the notion of competitiveness at enterprise level, the OECD defines competitiveness as ~~-a~~bility of companies, industries, regions, nations, and supranational regions to generate, while being and remaining exposed to international competition, relatively high factor income and factor employment levels on a sustainable basis" (Hatzichronoglou, 1996, p. 20). This definition fully illustrates a view on competitiveness of businesses that depends mainly on the skills and ways of using the internal potential. The greater the competitiveness of an enterprise, the easier it can operate on the market. Moreover, a high degree of competitiveness is perceived in a better light by the potential investors and/or shareholders. That is why improving the competitiveness is of profound significance for businesses and influences their external perception and position in the market.

In the traditional economic approach, a competitive business is one whose economic activity leads to long-term increase of market value. The following are most frequently taken into account while assessing the changes in the competitiveness of businesses: analysis of changes in sales revenue, changes of financial results, changes of the level of investment outlay, changes of market share, etc. (Bressler, 2012). These parameters make it possible to assess the vector of competitiveness changes, while an increase in sales revenue is not always tantamount to an increase in goodwill (as the costs necessary to achieve the increase matter), nor does always a surge in investment outlay lead to a rise of goodwill (as investments may be failed, and companies have been known to overinvest, thus negatively affecting their liquidity).

Although many authors in economic sciences examine various aspects and circumstances of competitiveness, there is no consensus on the question of the definition (Atkinson, 2013, p. 2; Feurer & Chaharbagh, 1994, p. 49). Due to the complexity of the problem in literature, the definition proposed by Feurer and Chaharbagh (1994) seems most adequate. The authors claim that the competitiveness of an enterprise is a multi-dimensional trait, unique for the given enterprise, that results both from its internal properties and the skill of coping with external circumstances (Feurer & Chaharbagh, 1994, p. 58; Pulaj & Kume, 2014, p. 48-49). Moreover, it must be mentioned that the works of M.E. Porter – who claimed that competitiveness must primarily be perceived in the capacity to be innovative, to increase continuously the level of innovation and to the acquisition of an appropriate level of effectiveness in its result (Porter, 2008) – had a significant impact on the studies of competitiveness in economy. According to Porter, the foundation of the competitiveness is productivity – the efficiency in consumption of resources – and in the final appraisal, it is what decides about the competitiveness of businesses.

Thus, a competitive edge can be construed as a higher rank of a business in the sector, achievement of better results, and the skill of doing something better than the competitors. The factors that determine competitiveness of businesses known from literature cover a multitude of various approaches and classifications (Gupta, Guha & Krishnaswami, 2013), that can be synthetically divided into those directly dependent on the enterprises (internal, the potential of the enterprise) and those that are independent of them (external, resulting from the environment), (Birkinshaw, Hood & Young, 2005, pp. 228-233). The following can be counted among the basic sources of the competitiveness (Piercy, Kaleka & Katsikeas, 1998):

- technological sources (R & D, innovativeness)
- production-related sources (e.g. effect of the scale of production)
- distribution-related sources (developed distribution network, advanced logistics)
- marketing sources (efficiently implemented marketing activities)
- place in the market (trademark, patents, reputation),
- the unique quality of the company and its products (high level of differentiation)
- quality of management (managerial talents, closely knit organisation)

- know-how and information (the skill of aggregating and processing)
- time management (speed of reaction to changes in the environment).

The factors presented above depend to a great extent on the businesses themselves. Nevertheless, the competitiveness may also be influenced by circumstances that are independent of businesses, whose number includes, for example, the international economic climate, technological progress, fluctuations in supply and demand structure, and changes of principles of cooperation and competition in the market (Jeanjean, 2011). Moreover, an important role is played by the impact of the national policy on the creation and/or disappearance of the competitive edge by the development of a legal and institutional environment, and macroeconomic, structural and social policy, which is related to the participation of the given country in the sharing of the benefits stemming from international trade.

As far as current challenges, going beyond the economic conditions, are concerned, from business perspective, competitive advantage can be said to be increasingly often assessed on the grounds of a business's capacity for long-term sustainable development, where the scope of analysis goes beyond commercial issues, and covers not only an increase in the market share and profitability, but also environmental and social goals (Miron, Petcu & Sobolevschi. 2011). This means that the matrix of enterprise goals should also include the elements of environmental friendliness, e.g. cuts in the consumption of natural resources and pollution of the environment resulting from the production and managing by-products/waste. Thus, in the context of activities in support of the environment, the innovative activity, being the subject of the following chapter, plays a significant role in achieving a competitiveness.

3. MULTI-ASPECT DIMENSION OF ECO-INNOVATION

Much like in the case of innovation, literature and economic practice know many definitions of eco-innovation, which differ in their scope and degree of detail. Generally, they concern innovation that brings benefit to the environment. Ecological innovations were for the first time a subject of research already in the late 1970s. Strebel defined the so-called „economic innovations in environmental protection" as innovations that are related to the conscious implementation of environmental-oriented activities, and also to the environmentally friendly products and production processes to decrease or prevent environmental pollution, and thus achieved cost reduction (Strebel, 1979, p. 5). A more extensive definition of ecological innovations was formulated in the latter half of the 1990s and covers „all measures of relevant actors (firms, politicians, unions, associations, churches, private households) which; develop new ideas, behavior, products and processes, apply or introduce them and which contribute to a reduction of environmental burdens or to ecologically specified sustainability targets" (Rennings, 2000, p. 322).

According to the OECD, ecological innovations cover all the innovations that have a favourable impact on the environment, independent of whether the effect itself is the main purpose of the innovation or not (OECD, 2008, p. 8). Thus, eco-innovations are defined as „the creation of new or significantly improved, products (goods and services), processes, marketing methods, organisational structures and institutional arrangements which – with or without intent – lead to environmental improvements compared to relevant alternatives" (OECD, 2008, p. 19). Moreover, they are not limited only to innovations in products, processes, and marketing methods, but also include innovations in social and institutional structures. This definition is promoted mostly as part of the Environmental Technology Action Plan (ETAP), in whose view every investment made by a given organisation is bound to a choice (intended or not) between more and less environmentally friendly technologies. Therefore, an eco-innovation does not need to be a global novelty nor be a result of purposeful activity or strategy of an enterprise (Kemp & Pearson, 2007, p. 7). With the definition presented above in mind, one can claim that any innovation that contributes to environmental benefits as compared to significant alternative possibilities is an eco-innovation (e.g. environmental technologies, organisational innovations, product and service innovations, and green systemic innovations), (Kemp & Pearson, 2007, pp. 10–11).

In line with the OECD Innovation Strategy, eco-innovations are a significant element supporting the environmental-oriented, i.e. „green", economy. A key element of the OECD Innovation Strategy, in the Green Growth Strategy, is accounting for the instruments that introduce price-related incentives, encouragement for businesses promoting greater involvement in „green activity", and the financing of basic scientific research (OECD, 2010). At the level of the European Union, eco-innovations are perceived as innovations supporting the comprehensive objectives of the Lisbon Strategy supporting competitiveness and economic growth. Moreover, they play a specific role in the Europa 2020 document of the European Commission, defining the strategy of smart and sustainable economic growth. The document covers three mutually intertwined priorities (European Commission, 2010 a, p. 5):

- smart growth: developing an economy based on knowledge and innovation

- sustainable growth: promoting a more resource-efficient, greener and more competitive economy
- inclusive growth: fostering a high-employment economy delivering social and territorial cohesion.

With respect to the growing role of eco-innovations, especially in the context of Europa 2020 strategy, Eco-innovation Observatory (EIO) was developed at the level of the European Union in 2010 as a framework for analysing eco-innovation across the European Union. The EIO Methodological Report (EIO 2010) defined eco-innovation as ~~t~~the introduction of any new or significantly improved product (good or service), process, organisational change or marketing solution that reduces the use of natural resources (including materials, energy, water, and land) and decreases the release of harmful substances across the life-cycle" (European Commission, 2010 b, p. 7.). The Eco-innovation Scoreboard (Eco-IS), a system of indicators that provided the first tool for assessment of eco-innovation, was developed as part of the project (European Commission, 2011, pp. 21–22). At the preliminary level, the results of EIO works were presented in the Eco-innovation Scoreboard 2010 through 13 indicators, a number that was expanded to 16 in the following years. The Eco-innovation Scoreboard is an index based on indicators in five areas (European Commission, 2013, p. 18): eco-innovation inputs, eco-innovation activities, eco-innovation outputs, environmental outcomes, and socio-economic outcomes (see Figure 1).

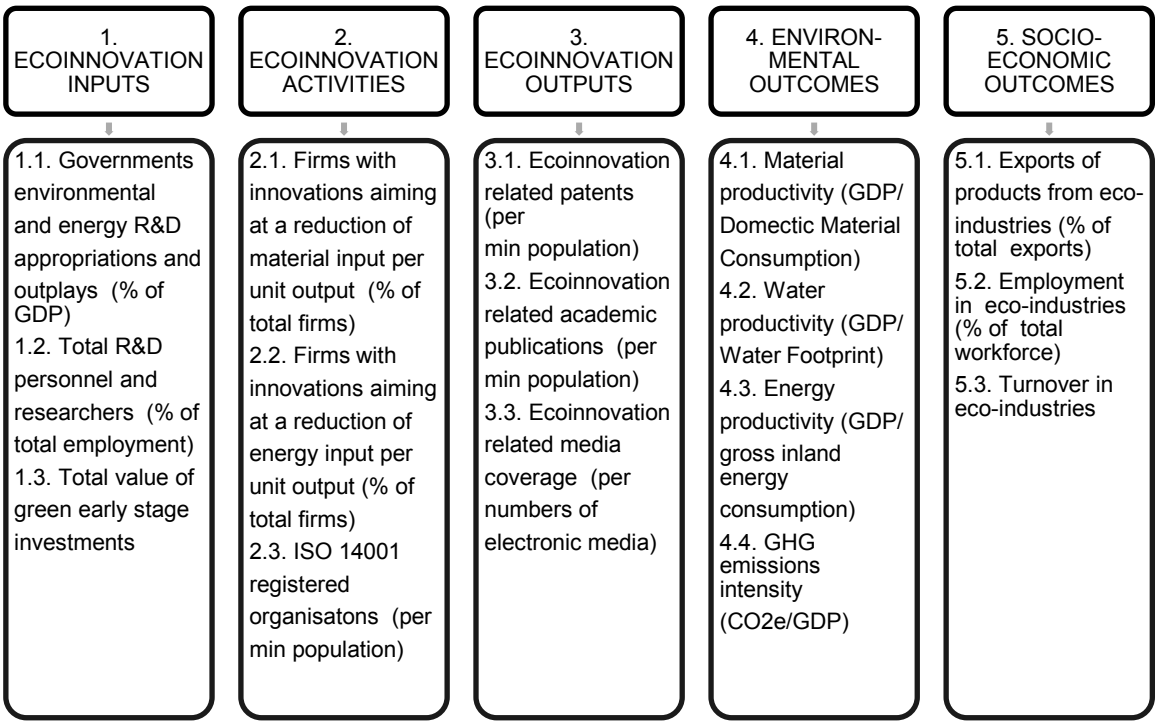

Figure 1: Structure and indicators of the Eco-innovation Scoreboard

It needs emphasising that only the first three groups of indicators concern eco-innovation directly, as the remaining two show the impact of introduced eco-innovations. Therefore, the Eco-IS score is calculated on the grounds of the previously mentioned 16 constituents indicators for all the EU states in reference to EU average, which allows the identification of strengths and weaknesses in ecological innovations in individual EU states.

Moreover, it should be noted that national statistical offices (institutes) and/or appropriate ministries in EU states are involved in statistical research in innovation in line with the international programme of statistical studies in innovation (Commission Regulation (EC) No 1450/2004 of 13th August 2004 implementing Decision No 1608/2003/EC of the European Parliament and of the Council concerning the production and development of Community statistics on innovation), (European Commission, 2004). The studies are conducted according to methodological guidelines used in OECD countries and the EU, presented in a series of OECD manuals known as the Frascati Family Manuals (OECD, 2002).

Recapitulating, one must notice that despite the numerous and varied definitions present in literature, eco-innovation may be defined for the needs of this paper as innovations that lead to the improvement of the quality of natural environment and have been implemented to increase the environmental efficiency of an

enterprise. This is justified by the fact that an ever greater number of businesses implement eco-innovative projects that contribute to the development of their brand among clients and to the improvement of the company's image. These and other advantages are decisive for the competitive superiority of eco-innovative businesses, and are the subject of the following chapter.

4. COMPETITIVE ADVANTAGES RESULTING FROM ECO-INNOVATIVE ACTIVITIES

Should we assume that ecological innovations are related to a complex pattern of determinants, the political, market, and social environment provides a particular system that is the grounds for defining the factors that have a bearing on ecological innovations. What must additionally be mentioned here are enterprise-specific factors. Due to a large number of relevant studies, attention in this chapter is turned to the significant factors that influence the competitiveness of businesses, as specified in – mostly English – literature.

The main constituents of competitiveness that belong to the so-called systemic (i.e. enterprise independent) determinants include environmental rules. In this context, the so-called Porter's hypothesis requires special attention. In its light, restrictive rules concerning environmental protection may increase efficiency and encourage introduction of innovations that help to improve the competitiveness of businesses. To quote: „The new paradigm has brought environmental improvement and competitiveness together. It is important to use resources productively, whether those resources are natural and physical or human and capital. Environmental progress demands that companies innovate to raise resource productivity – and that is precisely what the new challenges of global competition demand" (Porter & van der Linde, 1995, p. 133). This hypothesis suggests that restrictive regulations on environmental protection help to identify and introduce ever more environmentally-friendly technologies, and improve the condition of the environment. The results of innovation make production processes and the products themselves more effective. The savings that can be achieved in this way are sufficient to compensate for the costs both related directly to observing the new rules and to introducing the innovations. Porter and van der Linde emphasise that appropriately designed legal regulations in this area may have a bearing on the direction of innovations among others through (Porter & van der Linde, 1995, p. 128):

- signalling of the current lack of efficiency in resource use and possibility of technological improvements to businesses
- raising the awareness of businesses and undertaking of remedial actions wherever legal regulations are aimed at providing information
- decreasing the uncertainty of net returns on investment
- motivation to implement innovation and achieve progress
- ensuring a level playing field, which is necessary in the context of limited compensations.

Besides the legal regulations concerning environmental protection, literature knows many other factors that also influence the shaping of corporate competitiveness. It is commonly assumed that innovations are a source of competitive advantage at the level of the enterprise. Zollo and Winter pointed out that innovations of varied value may lead to a lasting competitive edge (Zollo & Winter, 2002, pp. 339–351), while homogeneous innovations are developed rapidly and account only for a temporary competitiveness for innovators (Grave, 2009). To create a varied value, one needs to adjust the resources and potential of business, so as to make it difficult to copy or transfer. Similarly, the competitors' slow pace of reaction may provide innovators with a competitive advantage. On the other hand, building a competitiveness requires quick diffusion, which means that innovations should be quickly embraced by the clients. According to Shrivastava, the competitiveness may be developed along the supply chain, i.e. the use of raw materials, processes of production, and final effects of the production. At the input (e.g. raw materials) stage, the competitive edge may result from cost-effective use of materials and energy, which is reflected in cost reduction (Shrivastava, 1995, pp. 183–200; Bata, 2011, p. 267). Cost reduction as well as generation of savings are a significant stimulus for the development of ecological innovation. At the stage of production process of, application of environmentally friendly technologies contributes among others to environmentally-friendly and cleaner production by improving production efficiency and minimisation of waste and other pollutants. In turn, competitive advantage at the final stage of the process of production may result from better design of products and business models.

Moreover, Porter and van der Linde point to the improvement of revenue resulting from the advantage of being the first mover in the market (Porter & van der Linde, 1995, p. 127). The authors explained that environmental aspects may be perceived as potential competitive advantages. Especially companies leading in new markets may expect benefits from the title of being the first movers and improvement of the corporate image, which lets them charge higher prices for ecological products. For that reason, ecological innovations

may be used as a tool for a differentiating strategy, which helps to increase the market share (Peattie, 2001, pp. 187–199; Pulaj & Kume, 2014, p. 51), and therefore to obtain a competitive advantage.
Empirical studies provide grounds for the conclusion that obtaining a competitive advantage through ecological innovation is measured through various indicators. Depending on the context of the studies conducted, various types of indicators can be identified: ones that are enterprise-dependent (internal, e.g. costs) and ones that are not (external, e.g. market share).
The aggregated list of constituents of competitive advantage in businesses was presented by Wagner, who listed four basic types of benefits. They were operationalised with respect to the following (Wagner, 2009, pp. 296–297):

- market factors: regarding sales, new potential in the market, and market share
- image: related to the corporate image, and product and/or service brands that aim at differentiating the enterprise and its products from those offered by competition/competitors
- risk-related factors: related to financing options and terms of insurance
- efficiency-related factors: with impact on profitability, cost efficiency, and other financial indicators.

Therefore, it can be assumed that the four types of benefits stemming from the competitive advantage may lead to better results obtained by the enterprises in a longer term. Falling back on the presented classification of constituents of competitive advantage from the title of carrying out eco-innovative activities, other classifications of factors that influence the competitive advantage of businesses are also possible.

5. CONCLUSIONS

The competitiveness of an enterprise is a basic goal defining the strategy of its development. With the consumers increasingly aware of the need to protect the natural environment, businesses must be capable of meeting the requirements of the market. It is already generally known that businesses capable of offering their clients products that fulfil the aforementioned requirements become more competitive in the given market. The motivation motivating companies to undertake eco-innovative activities is an increasing sense of intensifying international environmental protection regulations, greater levels of ecological awareness among consumers, and expectation of earlier benefits which will let eco-innovators favour setting higher prices for their products (Valentine, 2010, pp. 284–298).

Ecological innovations play an important role not only in the process of minimising the negative impact of the company‘s operation on the environment but also contribute to increasing competitiveness. Resorting to numerous empirical studies, one may observe that an increase in the significance of ecological innovations in the process of building corporate competitiveness becomes noticeable. Enterprises undertake innovative actions in the field of sustainable growth, and especially ones related to environmental aspects, in this way increasing their market credibility and attractiveness. The presented benefits of competitive advantage resulting from eco-innovation activities of businesses may be used among others for a further study of the dependencies between the introduction of ecological innovations and increase in the competitiveness of businesses, and to the appropriate adjustment of business strategies to the changing conditions of the environment.

In summary, one may maintain that ecological innovations can be perceived as an instrument of a differentiating strategy serving the improvement of the competitive position of the enterprise. Enterprises perceive an array of environmental-oriented solutions as a significant stimulus to improve the competitiveness, because only thanks to those they are capable of standing up to the challenges of building the future, and react successfully to the dynamic developments in the market, scientific progress, ecological requirements, and social changes. For that reason, embarking on innovative solutions in such a manner that development of new products and/or methods of productions accounts not only for economic but also ecological and social goals is what remains the main challenge for businesses.

Abstract: *Article discusses the possibilities of more frequent use of constructed wetlands for waste water treatment in Slovenia and Serbia. Situation about the use of drinking water and production of waste waters both in Slovenia and Serbia is briefly presented. Principles of functioning of constructed wetlands are briefly shown as well as their structure and types. At the end is also given information about cost for a typical individual constructed wetland object.*

Keywords*: Constructed wetlands, Waste water treatment, Environmental protection, Rural areas, Touristic destinations, Drinking water*

1. INTRODUCTION

Constructed wetlands present a very convenient mode for treatment of waste waters in areas with dispersed settlement. Therefore they are particularly applicable in rural regions as well as in areas with high density of touristic objects and are very efficient in treatment of sewage and agricultural waste waters. In the case of individual houses, groups of houses, villages, hotels, touristic camps, farms or similar objects where collection of waste waters and connection to central waste water treatment plant is not possible . In such occasions constructed wetlands are much more convenient and environment friendly solution as are septic tanks.
Constructed wetlands enable efficient secondary and tertiary part of waste water treatment. This is efficient way to prevent pollution of water and to protect underground waters and resources of drinking water.

2. SOURCES OF DRINKING WATER AND GENERAL DATA ABOUT MUNICIPAL WASTE WATERS IN SLOVENIA AND SERBIA

As has been already mentioned constructed wetlands present ideal solution for solving problems of waste water treatment in areas of dispersed settlement where the use centralized systems for treatment of waste waters is not able due to geographic or economic reasons. This is particularly important today as the use of drinking water is in continual increase. In Slovenia the use of drinking water according to the data from 2012 was 84,8 millions m^3/year which presents about 50% of the total quantity of water pumped in Slovenia. The total production of municipal waste waters was 200,9 millions m^3/year which presents 32,6% increase in comparison to the previous year (SORS, 2012). As much as 84,9 millions m^3 of waste waters (42,2%) remained untreated. According to the accessible data from 2005 the total quantity of municipal waste water was more than 360 millions m^3/year and less than 10% (5,6%) of these quantity was adequately treated. In Serbia only about 75% households in cities and 9% households in rural areas is connected to centralized sewage systems (Veljković, 2005).

Constructed wetland plants for waste water treatment seem very convenient for rural areas both in Slovenia and in Serbia, as in these regions waste waters are released in the environment and present potential danger for ground water pollution. Constructed wetlands present adequate solution also for villages which already have not adequate waste water treatment systems. This is important because of protection of drinking water resources as purified water from constructed wetlands can be used in agriculture. In such way can be reduced consumption of water from primary resources. Constructed wetlands can also help to meet legislative requirements which determine obligatory treatment of waste waters from individual houses until 2018. This can be also interesting solution for owners of individual houses as taxes for waste waters treatment in the case of constructed wetland use can be reduced as much as for 85%.

At this moment Slovenia in comparison to Serbia has on disposal enough qualitative sources of drinking water. Nevertheless, the fact the quality of drinking water is decreasing and that quantity of waste waters grows continually can be a matter of serious concern. According to the data for 2012 in Slovenia the average water use is 114 liters/day per person (41 m^3 /year per person) which is still much less than average use per

person in Serbia 350 liters/day (400 liters/day in cities, 200 liters/day in rural regions). The quality of drinking water in Serbia seems at least very questionable - according to the data from 2007 results of drinking water analysis for various samples indicate on certain chemical pollution. In many samples have been obtained also positive results according to the microbiological test (possible bacterial pollution) (Trofej, 2014). The results of the survey of local and public water sources in Serbia are still more alarming as they show very bad quality for all of the 1.092 samples. In Slovenia except some individual houses the great majority of villages use water from public sources what is in Serbia not the case. However, the quality of drinking water must always be the matter of permanent concern.

Constructed wetlands are as mentioned particularly applicable on rural regions as they can solve the problem of waste water treatment as well as reduce the use of drinking water. In Serbia according to the data of Serbian statistical institute only 46% of households is connected to the centralized waste water treatment system. Thus many households have to search their own solution for the treatment of waste waters and this is also in Slovenia considerable problem as unsuitable treatment of waste water jeopardizes ground water.

3. PROJECTION AND DIMENSIONING OF CONSTRUCTED WETLANDS

In the course of projection and dimensioning of constructed wetland population equivalent (PU) is used as a unit. PU presents the degree of average water pollution caused by a person per day. It is expressed as BOD_5 (Biological oxygen demand – mg of oxygen used for oxidation of biologically degradable pollutants present in 1 liter of waste water, included are only those pollutants which are biochemically decomposed in the period of 5 days). 1 PU unit is equal to 60 g BOD_5 per person per day (Roš, 2001).

However, this pollution is not unique for all countries. By example, in Slovenia PU is according to the use of drinking water between 110 and 150 litres per day meanwhile in United States as much as 400 litres/day. In Serbia this quantity is 350 litres/day (Trofej, 2014). The quantity of used drinking water in particular country can be also indicator of environmental awareness of citizens.

The treatment of 1 PU requires the surface of 2-2,5 m^2 which depends also on meteorological conditions. Constructed wetlands operate during the entire year independently of weather conditions. As the majority of water treatment process is driven by micro-organisms and not by plants constructed wetlands are effective also during winter period. However, in winter different species of micro-organisms are present in the system. The purifying efficiency of wetland is in winter 15-20% lower because of vegetation break. This fact must be respected in the process of dimensioning of constructed wetland.

In Figure 1 is schematically shown constructed wetland for waste water treatment from individual house.

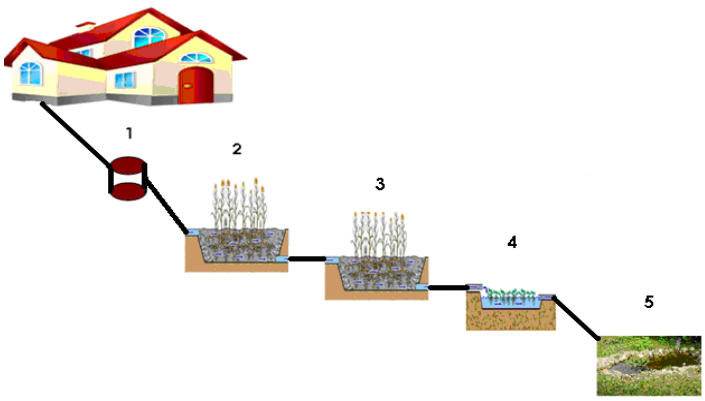

Figure 1: Principle of operation of waste water treatment by constructed wetland for individual house (1 – existing septic tank, 2-filtration bed-secondary pollution, 3-treatment bed, 4-polishing bed, 5-purified water – outflow (pool or environment).

4. MECHANISM OF WASTE WATER TREATMENT IN CONSTRUCTED WETLANDS

Mechanisms of waste water treatment are mutually connected and include:

- Sedimentation of suspended insoluble particles
- Filtration and chemical precipitation
- Chemical transformation
- Adsorption or ion exchange in surface of plants, substrate, sediments and waste plants

- Decomposition and transformation of pollutants and nutrients due to micro-organism or plant activities
- Natural decay of pathogens
- Biological reactions: photosynthesis, respiration, fermentation, nitrification, denitrification and microbiological removal of phosphorus.

Municipal waste waters need at the beginning mechanical purification. Septic tanks, Imhoff tanks, rough horizontal rock filters and anaerobic lagoon are used into this purpose. The basic composition of constructed wetland includes impermeable layer (foil) on which are positioned layers of sand and gravel (substrate). This presents adequate environment for plants. Various species of plants which like moist condition can be used as are common reed (phragmites communis), sedge (carex), water hyacinth (eichhornia crassipes), bulrush (typha latifolia) etc.

Important parameter for functioning of wetland is the time of waste water flow through gravel, substrate and roots of plants as there are located bacteria which take the main role in water treatment process. When the time is adequate the plants can use nitrogen and phosphorus for their growth and development. Therefore, in the case of too intensive growth the number of plants per area unit should be reduced by harvesting.

Lagoons are water treatment plants where processes of purification take place on natural way. They are constituted from various parts. In the first part sedimentation of rough particles takes place. The second lagoon is also called facultative anaerobic lagoon and there oxidation of organic substances by oxygen takes place. Oxygen enters in the water from air by diffusion or is provided by photosynthesis from algae. Bacteria and algae function in symbiosis as bacteria utilize oxygen and transform it into carbon dioxide meanwhile algae vice versa transform carbon dioxide into oxygen. According to the oxygen quantity contained lagoons can be divided into anaerobic and facultative anaerobic lagoons (Limnos, 2010).

Constructed wetlands for waste water treatment imitate self-purification ability of natural systems. They operate without any mechanical and electric equipment. Therefore, their construction, operation and maintenance are rather unsophisticated and cheap. The constructed wetland system consists of sequential pools which are isolated by foil and filled with substrate. Because of avoiding undesired gaseous emissions and dissemination of insects the subsurface flow of water is often used. The purification of water to the degree determined by adequate standards is reached due to natural physical and chemical processes and by function of microorganisms and wetland plants. The majority of purification process – 80% is performed by microorganisms and the additional 20% by plants. Those species of plants which like wet environment are mainly used as are common reed (phragmites communis), sedge (carex) water hyacinth (eichhornia crassipes), bulrush (typha latifolia) etc. Poisonous substances are partly decomposed during purification process or they are absorbed by plants. A certain part of noxious substances remain in the substrate from where they are periodically removed. Sludge resulted from the mechanical treatment of water is composted. Constructed wetland presents an appropriate environment for many animal species. In the case of additional pollution the constructed wetland can be simply upgraded.

4.1 Substrates used in constructed wetlands

Various kinds of sand are usually used as a substrate in constructed wetlands (according to the dimensions of particles, as is shown in Table 1):

Table 1: Composition of substrate used in constructed wetlands

Substrate type	Dimensions of particles (mm)	Porosity (%)	Hydraulic conductivity ($m^3/m^2/d$)
Sand (fine particles)	2	32	1
Sand (large particles)	8	35	5
Gravel (small particles)	16	38	7,5
Gravel (medium particles)	32	40	10
Gravel (large particles)	128	45	100

4.2 Preparation of municipal waste water for treatment in constructed wetland

Municipal waste waters require mechanical treatment before purification in constructed wetland. This can be performed by septic tank, Immhof tank, coarse horizontal gravel filter or anaerobic lagoon. Usually wetland contains foil at the bottom where substrate (gravel or sand) is located. This presents adequate environment for wetland plants.

The important parameter for operation of constructed wetland is the time of flow of water through medium – substrate and roots of plants as there are located bacteria which perform the majority of water purification process. When the flow of water is slow plants can use nitrogen and phosphorus for their growth and development. In the case of intensive plant growth they should be diluted, most often by harvesting.

4.3 Implementation of project in practice

In the course of projection of constructed wetland it is necessary to obtain the adequate information about:

- Number of citizens living in households connected to the wetland
- Quantity of used water
- Classification of users (households, agriculture, livestock, craft activities).

Constructed wetland can be used in different ways

- as individual objects in the case of dispersed settlement,
- in clusters for villages
- or some combination of both ways can be used.

In Figure 2 example of the project for a small village is shown. In the case shown in Figure 2 adequate infrastructure – the main (central) pipe – already exists but it is not yet used in practice. As can be seen from Figure 2 certain households can be directly connected to the main pipe meanwhile in the case of other households due to their distant location or other geographical conditions connection to the central system is not possible or reasonable. In these cases individual systems can be used. It should be emphasized that in the case of increase of inhabitants in the area and consequent increased degree of water pollution waste water treatment systems can be simply upgraded. This upgrading is possible due to modular type of construction. Upgrading can be performed in a very short period of time.

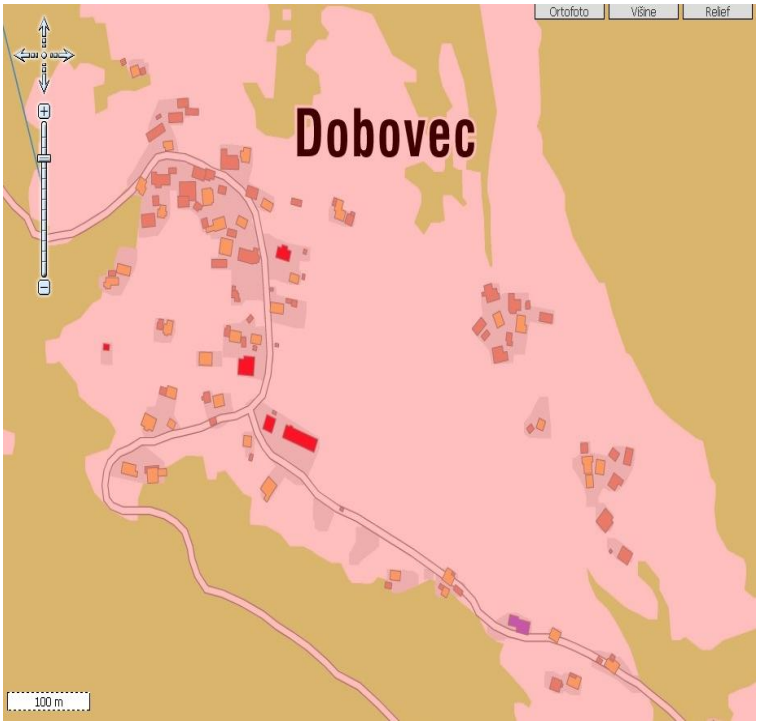

Figure 2: The example of connections to the constructed wetland for waste water treatment (village Dobovec in central Slovenia)

4.4 Types of constructed wetlands

Constructed wetlands can be basically classified in two groups:

- wetlands with surface flow of water (**f**ree **w**ater **s**urface, FWS)
- wetlands with subsurface flow of water (**s**ub**s**urface **f**low, SSF)

In the case of FWS water flows in the level of the ground or a bit lower, meanwhile in the case of SSF underground flow of water is used. SSF enable more efficient purification of organic pollutants and nitrogen

and at the same time prevent the contact of people with the polluted water as well as dissemination of insects. On the other hand, SSF are less convenient from the economic view point as the construction of wetlands with the underground flow of water is more expensive. Besides this, it is also more difficult to control the process of water purification.

FWS are more often used for central systems as they are usually located outside villages where surface flow of water is less annoying meanwhile SSF are more appropriate for individual systems in the case of dislocated households where connection to central systems is not possible.

a) b)

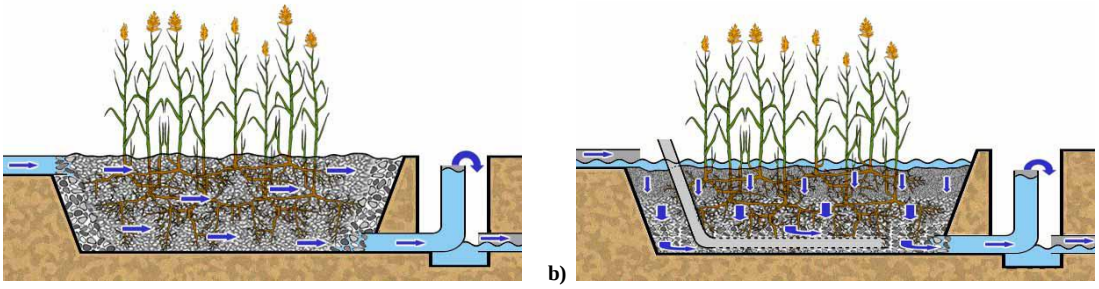

Figure 3: Constructed wetland with surface flow of water – FWS (a) and constructed wetland with underground flow of water – SSF (b) (Limnos, 2010).

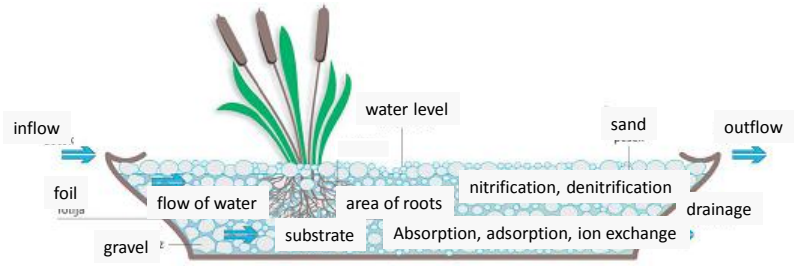

Figure 4: Cross-sectional drawing of constructed wetland (Vrhovšek & Vovk Korže, 2009)

According to the available data (April 2014) in Slovenia 130 constructed wetlands exist and the majority of them operate as individual objects.

4.5 Cost of construction

Cost of constructed wetland operating as an individual object with the capacity of 4 population units (PU): The investment costs for a typical constructed wetland for individual house is between 2.500 and 3.500 Euros (RČN, 2007).The difference in cost can be generated because of possible additional construction works which are sometimes necessary for connection between septic tank and constructed wetland. The average price for PU is 550 Euros. This price includes project outsourcing, material (substrates, plants) and monitoring. Monitoring is usually performed in the beginning of operation and later in three to nine-months periods for surveying of water purification efficiency. The price mentioned above does not include the cost of tank as existing septic tank can be used in the case that it is waterproof. When construction works are not

outsourced the costs of construction can be lowered. However, adequate control of works is necessary – (quality of used materials, fluidity of wetland). The costs of investment are refunded to the investor in a certain period of time due to 90% lowering of taxation for water pollution.

5 CONCLUSION

Constructed wetlands present ideal solution for waste water treatment in areas where central waste water treatment systems do not exist – as are areas with dispersed settlement or dislocated objects. The appropriate treatment of waste water is particularly important for the objects which are located in the vicinity of water protection areas.

Constructed wetlands because of their capacity for purification of water efficiently contribute to environmental protection. They can be easily incorporated in the environment and do not present a disturbing factor neither to the people neither to the animals. The use of constructed wetlands efficient helps to reduce consumption of drinking water, waste waters can be efficiently purified and re-used.

GREEN INNOVATION AS THE TRIGGER OF ENVIRONMENTAL RESPONSIBILITY

Luka Jakovljević[1], Igor Jovanović[2], Stefan Lazin[3]
[1]Faculty of Organizational Sciences, E-mail: jakovljevicluka.8@gmail.com
[2]Faculty of Organizational Sciences, E-mail: igor.jovanovic.bl@gmail.com
[3]Faculty of Organizational Sciences, E-mail: djlazin@gmail.com

Abstract: *This paper's purpose is to present how the green innovation process triggers environmental responsibility within the corporate sector in the world. Environmental responsibility is one of the key factors of sustainable development, which tends to preserve the environment and its resources for future generations, rather than exploiting them carelessly. Green innovations and environmental responsibility are accompanied by a phenomenon called corporate social responsibility, which improves the business model of companies, helping them face market needs, accordingly satisfying the conditions of sustainability. This process also affects the creation of green economy, as a global phenomenon. Furthermore, we shall present an example of how companies actually fulfill these tasks and keep the market leadership.*

Keywords*: green, innovation, corporate social responsibility, eco-innovation, green economy*

1. INTRODUCTION

The aim of our research is to show how green innovations affect the environment and how they can be a trigger of corporate social responsibility (CSR) within companies. Green innovations can be characterized as innovations in technology and business, which are environmentally friendly and suitable for sustainable development. They are essential in modern business and they ensure a better competitive position in the market.

There are numerous definitions for the notion "eco-innovation". One of the first, provided by Fussler and James (1996) defines eco-innovations as "new products and processes which provide customer and business value, but significantly decrease environmental impacts" (Schiederig, Tietze, Herstatt, 2011).

In a similar manner Kemp and Pearson define eco-innovation as "the production, assimilation or exploitation of a product, production process, service or management or business method that is novel to the organization (developing or adopting it) and which results, throughout its life cycle, in reduction of environmental risk, pollution and other negative impacts of resources use (including energy use) compared to relevant alternatives" (Schiederig, Tietze, Herstatt, 2011).

The Europe INNOVA panel concludes that "eco-innovation means the creation of novel and competitively priced goods, processes, systems, services, and procedures that can satisfy human needs and bring quality of life to all people with a life-cycle-wide minimal use of natural resources (material including energy carriers, and surface area) per unit output, and a minimal release of toxic substances" (Schiederig, Tietze, Herstatt, 2011).

Eco-innovation in companies leads to reduced costs, improved capacity to capture new growth opportunities and enhances their reputation among customers. (Schiederig, Tietze, Herstatt, 2011). In recent years, eco-industries have emerged as an important segment of the European economy. This sector has an estimated turnover of around €227 billion, corresponding to 2.2% of the European Union's GDP, and employs 3.4 million people directly. Eco-innovation is therefore a powerful instrument, combining reduced negative impact on the environment with a positive impact on the economy and society (EC Europa, 2014). This means that eco-innovations are not only beneficial for the environment, but also help businesses to improve their processes and the economies to move to a new, more sustainable level, thus improving the overall quality of life and preserving natural resources for the future generations, as well.

It is thus understood that to eco-innovate is to go beyond the adoption of environmental technologies. In developed countries this is characterized by the transition from investments in pollution control technologies to addressing cleaner production processes, recycling systems, and products (Kemp, 2008).

2. SUSTAINABLE DEVELOPMENT

Sustainable development is in short: environmental, economic and social well-being for today and tomorrow. It has been defined in many ways, but the most frequently quoted definition is from Our Common Future (*p.43*), also known as the Brundtland Report (WCED, 1987):

"Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs. It contains within it two key concepts:

- the concept of needs, in particular the essential needs of the world's poor, to which overriding priority should be given; and
- the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs."

All definitions of sustainable development require that we see the world as a system - a system that connects space; and a system that connects time (IISD, 2014).

It is about improving the standard of living by protecting human health, conserving the environment, using resources efficiently and advancing long-term economic competitiveness. It requires the integration of environmental, economic and social priorities into policies and programs and requires action at all levels - citizens, industry, and governments (EC, 2014).

3. BENEFITS OF CORPORATE SOCIAL RESPONSIBILITY

The idea of corporate social responsibility would have drawn a round of blank looks just a few years ago. But things are changing. Whether sparked by headline-grabbing protests against globalization and compounded by the attacks on America on September 11, we are waking up and wanting to know more about the major influence on our world. It's no longer just the radicals who are questioning the impact that business has on society (Financial Times, 2002).

CSR helps any business to be more competitive by supporting its efficiency; risk control is improved; stronger relationships with communities and an enhanced license to operate; better relations with investors and better access to funds; improved relations among employees; and improved reputation and branding.

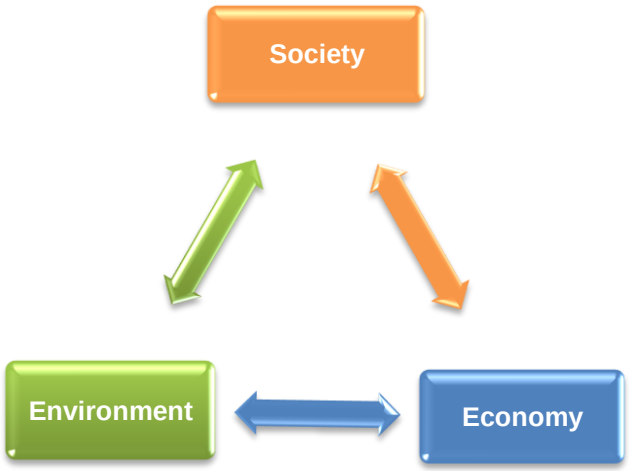

Figure 1: The interconnection of corporate social responsibility factors

Because of the uncertainty surrounding the nature of CSR activity, it is difficult to define CSR and to be certain about any such activity. It is therefore imperative to be able to identify such activity and we take the view that there are three basic principles which together comprise all CSR activity. These are: sustainability, accountability and transparency (Crowther and Aras, 2008).

4. ECO-INNOVATIONS AS A FACTOR OF GREEN ECONOMY

The European Environmental Agency (EEA) defines green economy as the increase in prosperity, with the preservation and sustainability of natural systems that surround us (O'Brien et al., 2012). In order to sustain natural systems, material resource spending needs to be reduced to a point where sustainable supply is met.

When compared with the current economy state, green economy has certain benefits. These benefits are mostly environmental, but also keep the operations at a functional and efficient level. A study, comparing the current and green economy in the European Union, follows (O'Brien et al., 2012).

Table 1: The comparison of current global economy and green economy in the EU

Aspect	Current global economy	Green global economy
Environment	One and a half planet is required to regenerate viable resources and absorb the CO_2 emissions at the global rate of resource exploitation.	Excavations and emissions are set within the planetary borders. For the European Union this requires the decrease in the level of overall exploitation of primary materials, land, water and energy.
Society	870 million people are chronically underweight, according to the data from 2012. 1.29 billion people live in extreme poverty (The World Bank, 2012). People in the industrialized countries spend up to 20 times more materials than the people in the least developed countries.	The available global resources should be distributed more adequately, on the global level. For the EU, this considers a significant decrease of overall resource consumption per capita.
Economy	The economic prosperity is mutually connected to the exploitation of resources.	The economic prosperity is detached from the primary resource consumption. For the EU, this considers the transformation of economy, in such a manner that helps increase the growth of the efficient consumption of resources, recycling, reuse and new business models.

The report of Eco-innovation Observatory (EIO) tells us in what way the eco-innovations will take part in the transition towards the green economy. Achieving efficiency alone will not be enough. The green economy will also have to find an alternative for the lack of moderation, which characterizes industrialized economies. Eco-innovations will most certainly play the key role in motivating and including all economy drivers to move towards the changes. This means that the green economy is only a framework for changes, and eco-innovations are the main instrument of igniting those (O'Brien et al., 2012).

Eco-innovation Observatory further identifies certain possibilities in cost decrease by implementing eco-innovations. A case study analysis in Germany has shown that a company can save around €200,000 per year simply by attaining material efficiency in the production sector. On average, these investments pay off after 13 months. However, when it comes to investing in eco-innovations, there is a gap in the quantity of investments and their results. In order to achieve better results with eco-innovations, some systematical changes need to be pushed, considering opening new markets, in parallel with upgrading the existing business models, so that they would be able to accept the current and the future global challenges (O'Brien et al., 2012).

Furthermore, while EIO is developing the new eco-innovation policy throughout the European Union, many companies see this as a new and growing field, but not many have felt the need for the systematic approach in public support of eco-innovations. The eco-innovations are still not considered to be a part of the strategy of social and economic transformation. As of now, the focus was on the research of the environment and employing technology with a financial support, without any further need to adapt the overall conditions of the economy to eco-innovations (O'Brien et al., 2012).

Many authors claim that the next "innovation wave" will actually be "the green wave", and that the concentration of innovative forces will be on the achievement of sustainability. The following decade will be the potential test for green economy, when it comes to using the synergy of social-economic and environmental goals. On the other hand, it is obvious that many innovations worked on as we speak actually have the completely opposite goal from sustainability, and not all radical innovations will be developing in this direction.

There are innovations and discoveries, such as new types of unconventional fuels, which are only realized for their economic advantages, not the goal of sustainability. With the increase in efficiency of drilling techniques, especially horizontally, the relative gas costs in North America have been reduced significantly in the past few years. In the USA, heating methods have turned from coal to gas consumption. In fact, more and more chemical production systems, fertilizer and plastic companies have started running on gas. According to reports, the benefits for the US economy due to this kind of material consumption were over $100 billion worth, in 2010 solely. This example shows that economic benefits are sometimes chosen rather

than the social or environmental ones, and that there are different strategies, which can affect how companies run their business (O'Brien et al., 2012).

The strategy of the European Union, "EU 2020", promotes structural changes, with the focus on sustainability. In order to achieve these goals, the transition towards sustainable consumption of natural resources has to be in strong coordination with business practice and perceptions in the following five dimensions:

- Dynamics in the relative structure of production input costs
- Anticipated innovation trends
- Organizational criteria and principles
- Cooperation models
- Business models.

Dynamics in the relative structure of production input costs can lead to more efficient resource consumption and thus presents the most attractive choice for profitable innovations and investments, especially in the conditions of instability of material costs and expected price increase. In practice, this considers the decrease in material costs, through the eco-innovation process, reuse and recycling, and changes in material usage. Anticipated innovation trends expect the entrepreneurial advantages to be at a high level. Organizational criteria and principles consider a practice that shows how special management methods and structures are able to use the power of new eco-innovations for maximum efficiency and profit. Organizations that tend to expand the usage of eco-innovations help overcome the problems of coordination, which follow such changes. Cooperation models expect businesses and public organizations to be equally engaged in search for new partners for forming networks and coalitions among sectors and organizational value chains. The business models are supposed to help the organizations redefine their exported value and find new ways for delivering their services to the customers (O'Brien et al., 2012).

What directly affects a country's inability to ignite the development of eco-innovations is either the lack of funds (the economic factor), or the lack of will and strategy to deal with global problems (the social and environmental factors). In fact, some policies, such as unsustainable subventions, can directly affect the environmental impact. Furthermore, on a global level, the differences in solving this problem can be significant. Namely, while the US and Japan can directly work on solving these problems, the EU must coordinate between 27 different countries, thus including their needs and possibilities to worry about economic, social and environmental factors. There are many obstacles that have a direct influence on the strategy of a company. The lack of dedication to eco-innovations from the highest levels of management can be caused by different factors (O'Brien et al., 2012):

- Uncertainties about the future input prices (especially materials, but also other resources, such as carbon, or water)
- The lack of information from other departments concerning the profitability of production-integrated environmental technology, energy and materials, efficiency of changes and other innovation processes
- The lack of managerial capacities and capital, in order to start exploring the obstacles of eco-innovations
- The lack of orientation, concerning the long-term trends and key challenges.

5. ECO-INNOVATIONS FROM THE APPLE COMPANY

In recent years, many international companies have become concerned with the amount of carbon dioxide they produce in their business processes. Therefore, they have calculated the footprint of carbon dioxide generated in their facilities in order to innovate their processes so that the footprint is reduced to a minimum. In contrast, during their process of innovation, Apple has not only departed from the footprint of carbon dioxide in their facilities, or in production, but has considered the entire business process and their products' life cycles (Apple, 2014).

Figure 2: Total carbon footprint created by Apple, in percentage

Apple has, therefore, engaged in a comprehensive life cycle analysis of their own operations, in order to determine where the emissions of greenhouse gases come from. What can be seen as a part of a business process in that matter are manufacturing, transportation, usage and recycling of products, in addition to monitoring the amount of the gases that arise within their business facilities.

If we consider the impact of all Apple operations on the environment, it can be concluded that most of the carbon dioxide footprint by as much as 61% comes from manufacturing, 5% from transportation, 30% from product usage, 2% from recycling and 2% from commercial buildings. Because of this way of observing the big picture of its ecological processes, this company can be categorized as environmentally very responsible.

The Apple Company is trying to reduce its negative environmental impact and to improve the environmental performance of its products. Therefore, in the production of these products, it uses fewer materials, ships the products in smaller packages, and designs them to be energy efficient and recyclable. What Apple saw as the potential benefits and process innovation is that with the faster growth than the market and the industry in general, products should be created as much more environmentally friendly, with the least negative consequences for the environment.

Although the profit of the company has increased in the past decade, emissions per dollar of revenue in 2008 have declined by 21.5%. In addition to this fact, Apple is the only company in the industry, of which the entire product line meets, and also exceeds the strict energy limit, set by the ENERGY STAR specification.

Creating smaller, thinner and more energy-efficient products does not only reduce carbon dioxide footprint, but it also means that products can be transported in smaller packages. The way Apple ensures high quality of these smaller product is by employing teams of experts from the fields of design and engineering, developing packages that are thinner and lighter, which, on the other hand, provide very good protection. Efficient packaging design reduces material consumption and waste, and has an impact on the reduction of emissions that occur during transportation (Apple, 2014).

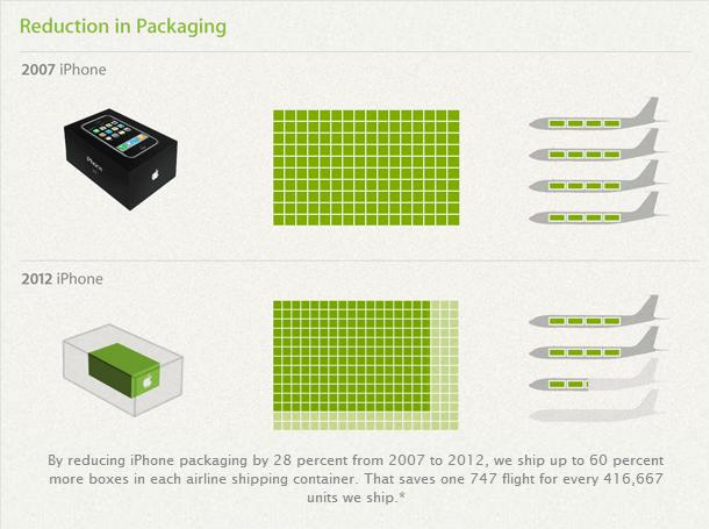

Figure 3: The decrease in iPhone packaging from 2007 to 2012

In the period from 2007 to 2012, iPhone packaging has been reduced by 28%, enabling the delivery of up to 60% more boxes in each container by air transportation systems. This implies the fact that for every 416,667 transported units of this product, a full Boeing 747 is "saved". Furthermore, this causes lower carbon dioxide footprint, which means that in this way, the Apple Company has a double impact on the reduction of emissions, producing additional environmental contribution.

The Apple Company does not only monitor its own CO_2 emissions in order to minimize them, but by using the life cycle approach, it measures the footprint produced by its consumers, while using its products. Looking at this branch of industry, it is not recorded that any other company goes as far in measuring the carbon dioxide footprint. Apple has managed to reduce the emissions produced by its users, by designing hardware and operating system on its own, in such a manner that they work together to save energy and thus reduce the CO_2 emissions (Apple, 2014).

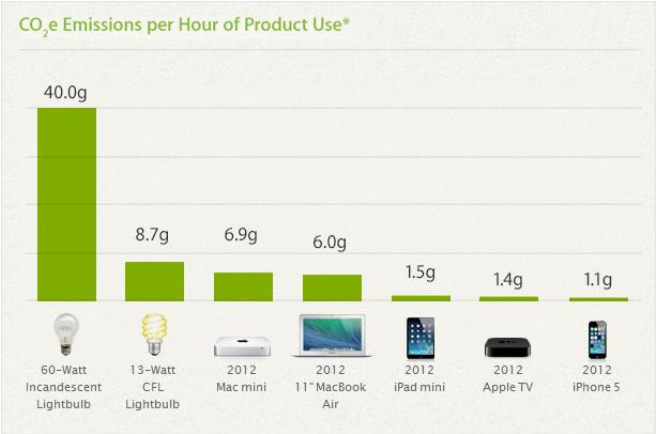

Figure 4: CO_2 emissions of Apple's products, compared to emissions of light bulbs

Since 2008, Apple has managed to reduce the average fuel consumption of its products by 40%, demonstrating the fact that one of its goals is to create the most energy efficient devices. As a result of this procedure, it was found that the carbon dioxide emissions, resulting from the use of Apple's products have declined by 43% since 2008. Furthermore, not only do all of Apple's products generate less CO_2 emissions than a regular 60-Watt or the frugal 13-Watt light bulb during their life cycle, but iPhone 5, from 2012, produces almost 40 times less carbon dioxide than a regular light bulb.

The Apple Company controls its own regulatory programs of collecting e-waste around the world, where all the waste is processed and recycled in the region where it is collected. This means that no waste is transported to other parts of the world for either disposal or recycling, which affects not creating new carbon dioxide emissions.

In addition to this, the company provides its own very strict procedures for recycling its products, which are based on health and safety laws. Furthermore, the company itself does not allow prison labor at any stage of the recycling process of its products. Another method that Apple prohibits is discarding hazardous electronic materials to landfills or incinerators, and currently operates with 153 partners worldwide, whose objects are tested and evaluated on an annual basis, considering the health and safety of workers, material tracking, social responsibility and ecological needs and requirements.

Other ways in which Apple has improved their business processes are recycling programs and responsible disposal, which are bound to the cities and university settlements in 95% of the countries in which the company sells its products, which has shifted more than 151.504 tons of equipment from landfills, since 1994. As of the countries that do not have disposal and recycling centers, Apple organizes the collection, transportation and environmentally responsible disposal and recycling of electronic products that are at the end of their life cycle.

A goal of the Apple Company in 2010 was to achieve the level of recycling of 70% of the worldwide level. To calculate this, they have used the product, the expected life of usage of which is seven years. The total weight that Apple had recycled each year was compared to the total weight of the product that the company had sold seven years earlier. Therefore, in 2010, it was necessary to recycle 70% of the weight sold in the 2003. The goal of 2010 has not only met, but also exceeded. The figure that the Apple Company has reached is far beyond their nearest competitors, Dell and HP, whose figures did not exceed even 20%. Once they have set and continued to maintain this level in the coming years, their expectations were that this trend would continue at least until the end of 2015 (Apple, 2014).

While most companies focus on reducing CO_2 emissions in their facilities, Apple believes that turning the lights off and recycling office waste do not have an impact on the environment that is strong enough. As previously disclosed, Apple has discovered that business objects generate only 2% of the total carbon dioxide emissions, and have therefore turned the focus to environmental responsibility in other activities of the business process and supply chain.

Although it focuses primarily on innovations and improvements in product design, Apple has not neglected the business objects, but has taken the necessary steps to ensure that their emissions around the world have been reduced to a minimum. One way to achieve this is with, so-called, clean energy. The term actually refers to renewable energy, which Apple uses in its facilities and data centers.

The company has constructed new objects and upgraded old ones, in order to be able to fully utilize this kind of energy. This is achieved by building solar panels and fuel cells, along the existing object. Furthermore, in order to achieve the balance among its energy needs, Apple tends to sign many long-term contracts with energy suppliers, at least to the maximum extent that is permitted by the law. In this way, the company has managed to convert 75% of its total energy needs of their office objects and data centers into renewable energy.

When it comes to data centers, all in the ownership of the Apple Company are powered by 100% renewable energy. Using solar panels and renewable energy sources has led to the fact that in 2012, total emissions have been reduced by as much as 93 million kilograms of carbon dioxide.

We found that the Apple Company is not only very innovative, in terms of products and processes, but also socially responsible. Another aspect that shows the social and environmental responsibility of the company is the transportation system of its employees.

In the fiscal 2012, more than 13,000 employees have participated in the "Commute Alternatives" program, which has increased the number of participants by 30% in several years. In this way, the employees were going to work by taking transit options that reduce traffic congestion and carbon dioxide, using only one vehicle for this entire process, instead of one or more transit lines per person.

In this way, 1,600 employees have used free transportation to work by taking buses or shuttles that run on biodiesel fuel and 50,000 arrivals to and departures from work by bicycles, which the company has provided for its employees to use, were recorded. The overall effect of the program in 2012 was the prevention of the occurrence of more than 102,500 kilograms of carbon dioxide emissions, by using the electronic charging stations for these vehicles (Apple, 2014).

6. CONCLUSION

As mentioned previously, eco-innovations present the new “wave” of innovations, which tends to not only increase the efficiency and effectiveness of the business process, but also to fulfill the goal of sustainability, carefully consuming natural resources and keeping the planet viable enough for future generations. As such, the eco-innovations do not only trigger environmental responsibility, but also pose a critical factor for maintaining sustainability, corporate social responsibility (CSR), green economy and other global development tendencies.

Sustainable development, as a matter affected by eco-innovations, concerns technological development in such a way that not only natural resources, but also health and well-being of people are saved. Furthermore, long-term competitiveness is achieved by the development of technology, especially when it is viable and, even better said, sustainable.

Corporate social responsibility is a clouded expression, not being able to precisely describe its activities. Be that as it may, as long as an activity of a company concerns three factors – economic, social and environmental – it is considered a CSR activity. This helps the company achieve some of its main goals, such as efficiency and effectiveness, improved risk management, better relationships with stakeholders and many more. Corporate social responsibility (CSR) is, as sustainable development and green economy, enhanced by the effect of eco-innovations.

Finally, green economy is a global tendency of preserving the planet and sustaining natural materials and creating a “playing field” for global sustainable development. Eco-innovations are its key running factor, since they are what triggers the economy to change in a sustainable manner. The green economy is based on three main factors, as CSR, economic, social and environmental. Generally speaking, having a green economy tomorrow means lower consumption of natural resources and their better distribution today.

Furthermore, we have shown how the Apple Company works on its green innovations and improves its processes, giving a good example to the rest of the corporate sector, thus creating conditions for global sustainable development. Thinking outside the box, as one of its main parameters, has led the company to decrease its own carbon footprint, not only by decreasing it in its facilities, but also by decreasing it throughout the life cycle of its products. Therefore today, Apple is one of the most environmentally responsible companies in the world.

In conclusion, the eco-innovations run the process of creating a sustainable economy and development, thus increasing the level of environmental responsibility, within a company and globally, as well.

Abstract: *Production and use of renewable energy sources has become an imperative for development around the world, including Serbia. The aim of this paper is to study the possibilities of production and use of renewable energy sources, especially bioethanol, as well as their place in the strategic objectives in the energy sector in Serbia. For this purpose, we will firstly frame the policies related to the production of renewable energy, and afterwards display the results of the cost-effectiveness of bioethanol production from the most important domestic biomass-based feedstock - corn. Our assumption is that, despite the existence of sufficient quantities of raw materials required for the production, knowledge, and the potential consumers of bioethanol in Serbia, its wider use will not be possible without the application of a systematic approach, especially without the development of adequate infrastructure in the production and use of energy resources.*

Keywords*: renewable energy, bioethanol, sustainable development, Serbia*

1. INTRODUCTION

Energy crisis and environmental pollution are two vital challenges the world is currently facing. Energy is a component of major significance for all sectors of modern economy and plays an essential role in improving the quality of life. The way energy is produced, supplied and consumed strongly affects the local and global environment and is, therefore, a key issue in sustainable development (Mojović et al., 2013). At the current rate of consumption, crude oil reserves, natural gas and liquid fuels are expected to last for between 60 and 120 years (British Petroleum Statistical Review, 2011).

Approximately 80% of world energy supplies rely on rapidly exhausting non-renewable fuel sources (e.g. coal, oil, natural gas) which are used to produce fuels, electricity, chemicals and other goods. Emission of greenhouse gases (GHGs) represents an additional challenge with fossil fuel consumption. Growing global energy needs and release of environmental pollutants from fossil fuels have finally directed the attention towards clean liquid fuel as a suitable alternative source of energy. Even though bioenergy from renewable resources currently already represents an alternative to fossil fuels, in order to meet the increasing need for renewable energy, new and abundant raw materials need to be considered. The alternative renewable energy sources, not only cut the dependence on oil trade and reduce the doubts caused by the fluctuations in oil prices, but also secure reductions in environmental pollution due to their high oxygen content (Huang et al., 2008; Boer et al., 2000).

In this context, the availability of renewable energy in its two main forms, wood and agro energy can offer cleaner energy services to meet basic energy requirements. Biofuels can be obtained from agricultural crops, crop residues and processing wastes from agroindustries, forests, etc. (Mekala et al., 2014). Interest in various agricultural crops such as cereals (maize, wheat, triticale, barley, rye, sugar cane, sweet sorghum, millet etc.) and some tubers (sugar beet, potato, Jerusalem artichoke, cassava, sweet potato etc.), as renewable and biodegradable feedstock for biofuel production are growing (Semenčenko V. et al., 2013). All petroleum-based fuels can be replaced by renewable fuels produced from biomass such as: bioethanol, biodisesel, biohydrogen etc. (Mojović et al., 2013).

Existing biofuel policies have been very costly; they produce slight reductions in fossil fuel use and increase, rather than decrease, in GHG emissions (Wuebbles and Jain, 2001). However, recent fluctuations and rise in international fossil fuel prices make biomass increasingly competitive as energy feedstock. Current renewable energy research around the globe should direct us toward reduced production costs, higher energy conversion efficiency and greater cost-effectiveness of biofuels (Mekala et al., 2014).

By implementation of the Kyoto Protocol, Serbia sends to international community and the EU a clear signal of readiness to implement the concept of sustainable development and monitor of global socio-economic trends, which will improve the investment climate and increase the confidence of potential foreign investors (Mojović et al., 2013).

2. DIFFERENT FORMS OF RENEWABLE ENERGY

There are many forms of renewable energy**.** Most of these renewable energies depend in one way or another on sunlight. Wind and hydroelectric power are the direct result of differential heating of the Earth's surface which leads to air moving about (wind) and precipitation forming as the air is lifted. Solar energy is the direct conversion of sunlight using panels or collectors.
Biomass energy is stored sunlight contained in plants. Organic matter holding bioenergy sources in side is known as biomass. We can utilize this biomass in many different ways, through something as simple as burning wood for heat, or as complex as growing genetically modified microbes to produce cellulosic ethanol (Adler et al., 2009). Since nearly entire bioenergy can be traced back to energy from sunlight, bioenergy has the key advantage of being a renewable energy source.
Other renewable energies that do not depend on sunlight are geothermal energy, which is a result of radioactive decay in the crust combined with the original heat of accreting the Earth, and tidal energy, which is a conversion of gravitational energy.

3. RENEWABLE ENERGY PRODUCTION IN EU

Heat and electricity production from biomass increased over the past 10–15 years by 2% and 9% per year, respectively, in the European Union between 1990 and 2000, and biofuel production increased about eight-fold in the same period. Today, the EU is the third producer of fuel-bioethanol in the world after the United States and Brazil; however its production is much lower than the first two (by a factor of about 10). Bioethanol production in EU was 4.97 billion liters in 2012, which is an 11% increase over 2011 (Mojović et al., 2013, Renewable Energy Magazine, 2013). However, although the amount of biofuels produced in the EU is growing; the quantities in general remain insufficient and low in comparison to the total volume of mineral-based transport fuel sold.
One of the significant regulations which impact the EU biofuels market is the European Directive 2009/28/EC on the promotion of renewable energy which aims at achieving a 20% share of energy from renewable sources by year 2020 in the EU's final consumption of energy and a 10% share of energy from renewable sources in each member state's transport energy consumption. In order to achieve that effect, EU members follow the Directive implementation with various political, fiscal and technical measures and incentives. Each EU Member State should adopt a National Renewable Energy Action Plan, setting out its national targets for the share of energy from renewable sources consumed in transport, electricity, heating and cooling in 2020 (European Biofuels Platform Technology, Gitiaux et al., 2012). More renewable energy will enable the EU to cut greenhouse emissions and make it less dependent on imported energy. Boosting the renewable energy industry will encourage technological innovation and employment in Europe.
On 27th of March 2013, the European Commission published its first Renewable Energy Progress Report under the framework of the 2009 Renewable Energy Directive. Since the adoption of this directive and the introduction of legally binding renewable energy targets, most Member States experienced significant growth in renewable energy consumption. Figures for the year 2010 indicate that the EU, as a whole, is on its trajectory towards the 2020 targets with a renewable energy share of 12.7%. Moreover, in 2010 the majority of Member States already reached their 2011/2012 interim targets set in the Directive. However, as the trajectory grows steeper towards the end, more efforts will still be needed from the Member States in order to reach the 2020 targets.
With regard to the EU biofuels and bioliquids sustainability criteria, Member States' implementation of the biofuels scheme is considered too slow.
In accordance with the reporting requirements set out in the 2009 Directive on Renewable Energy, every two years the European Commission publishes a Renewable Energy Progress Report. The report assesses Member States' progress in the promotion and use of renewable energy along the trajectory towards the 2020 renewable energy targets. The report also describes the overall renewable energy policy developments in each Member State and their compliance with the measures outlined in the Directive and the National Renewable Energy Action Plans. Moreover, in accordance with the Directive, it reports on the sustainability of biofuels and bioliquids consumed in the EU and the impacts of this consumption (European Comission, 2013).

4. BIOETHANOL

Bioethanol accounts for the majority of biofuel use worldwide (Margeot et al., 2009, Semenčenko et al., 2011). It is a liquid biofuel which can be produced from several different biomass feedstocks and conversion technologies. Nearly all bioethanol is produced by fermentation of corn glucose in the United States, or sugar cane sucrose in Brazil, but any country with a significant agronomy-based economy can use current technology for bioethanol fermentation (Balat and Balat, 2008). This biofuel is produced by fermentation of simple sugars present in biomass or the sugars obtained by prior chemical or enzymatic treatment of the

biomass. The bioethanol fermentation is performed by microorganisms, traditionally by yeasts (*Saccharomyces strains*) (Mojović et al., 2013).
Bioethanol has the potential to be a sustainable fuel, as well as a fuel oxygenate that can replace gasoline, in transport sector which is considered one of the largest energy consumers as well as environmental pollutant (Kim and Dale, 2004). According to the International Energy Agency statistics (2008), the transport sector accounts for about 60% of the world's total oil consumption. It is responsible for about one fifth of CO_2 emission on a global scale (Joint Research Centre, EU Commission, 2007).
The production of bioethanol has been increasing over the years, and has reached the level of 85 billion litres in 2013. According to the Global Renewable Fuels Alliance (GRFA), this level of the bioethanol production was predicted to reduce GHG emissions by 100 million tonnes in 2013 (Renewable Fuels Association - RFA, 2013). An increase in bioethanol production up to more than 125 billion litres until 2020 has been predicted assuming the production support by governmental policies and exemptions (Demirbas, 2013). The fact that the existing fossil fuel infrastructure, eventually with minor modification, can be used for bioethanol distribution and utilization puts this biofuel in front of other energy alternatives (IEA, 2008).
The economic and temporal constraints that crop feedstocks pose are the main downfalls in terms of the commercial viability of bioethanol production (Harun et al., 2014).Even though bioethanol production for decades mainly depended on energy crops containing starch and sugar (corn, sugar cane etc.), new technologies for converting lignocellulosic biomass into bioethanol are under development today.5 As an alternative to crop feedstocks, significant research efforts have been put into utilizing algal biomass as a feedstock for bioethanol production.
With the exception of sugar cane, corn provides the highest bioethanol yields compared to any other traditional feedstocks being used (US Grains Council, 2012). Alternative fuel - bioethanol is mostly produced from starchy parts of the maize grain leaving significant amounts of valuable by-products such as distillers' dried grains with solubles (DDGS), which can be used as a substitute for traditional feedstuff. Maize grain consists of approximately 70% of starch, which makes it a very suitable feedstock for the bioethanol production (Radosavljević et al. 2008). Renewability of maize and growing environmental pollution by oil products represent two principal reasons for maize becoming one of the major raw materials for the energy production (Radosavljević et al. 2009).
The rapid increase in biofuels production from traditional feedstocks during the last few decades has brought dramatic changes to food and agricultural systems especially in countries that are the biggest bioethanol producers (e.g. United States and Brazil).
Studies have found that, in general, with increased ethanol expansion, the prices of both the agricultural feedstock commodities and their competing crops increase with implications for land allocations, food prices, and the environment.(Elobeid and Hart, 2007, Elobeid et al., 2007).
Recent increases in biofuel production, particularly the dry grind corn-to-ethanol process, creates a sizable stockpile of its co-product in the form of dried distillers' grain with solubles (DDGS), which is made by blending distillers' wet grains (DWG) and syrup and drying the mix (Liu et al., 2012). A gallon (3.78 L) of bioethanol produced from corn kernels generates about 7.4 pounds (3.36 kg) DDGS (Pimentel 2003). During the production of bioethanol, starch is removed from the grain and converted to alcohol and carbon dioxide. As a result of starch removal, the concentration of the remaining nutrients in the grain increases approximately three-fold. The DDGS contains higher percentages of protein, fibre and lipid contents than those in corn (Liu et al., 2012).
Application of DDGS in livestock and poultry diets in concentrations greater than traditional could positively affect the economic viability of this biofuel production, but also stabilize the current imbalance in the food and animal feed market. However, DDGS feedstuff should not be treated as a perfect substitute for corn, because the complexity of ration formulation determined at the farm or feedlot level is driven by energy and protein and other nutrient requirements, as well as their relative costs in the ration (Semenčenko et al., 2013 a).

5. RENEWABLE ENERGY PRODUCTION IN SERBIA

Serbia and other Balkan countries interested in joining the EU, has accepted the obligation to follow EU policies and programs, including those that oblige them to introduce the production and use of fuels from renewable energy sources. Among renewable energy sources in Serbia, the most important are biofuels, especially bioethanol. Apart from natural resources, research and development within the National Innovation System of the Republic of Serbia are of great importance (Semenčenko D. et al., 2009). Starting from the first National Innovation Systems, energy has played an important role in stimulating the economic development. National innovation systems of today must, as well, demonstrate a significant level of innovation in research and application of new renewable energy sources (Semenčenko D., 2009). Better coordination between institutions and academic and private sector is a very important step in order to realize cost-effective bioethanol production in Serbia (Mojović et al., 2013). By implementation of the Kyoto Protocol, Serbia sends to the international community and the EU a clear signal of readiness to implement the concept

of sustainable development and monitor of global socio-economic trends, which will improve the investment climate and increase the confidence of potential foreign investors.
With the ratification of the Agreement established by the Energy Community (Coordinating European Council - CEC, 2006), Serbia has, among other things, accepted the obligation to implement the Directive 2001/77/EC on the promotion of electricity produced from renewable energy sources and Directive 2003/30/EC on the promotion of the use biofuels and other fuels from renewable energy sources in the transport sector, to ensure the emergence of a certain quantity of biofuels on the market - 5.75 % of the total fuel used in traffic by the end of 2010. This directive is in accordance with the Kyoto protocol signed in 1997, with the aim to reduce emissions of gases that contribute to the greenhouse effect, which Serbia is a signatory. However, in 2009 European Commission has adopted a new Directive 2009/28/EC, which was established to promote the use of energy from renewable sources. This directive changes and consequently abolishes Directives 2001/77/EC and 2003/30/EC, by establishing a common framework for the promotion of energy from renewable sources. It sets obligatory national targets for the overall share of energy from renewable sources in gross final energy consumption, and for the share of renewable sources in transport: at least 20 % share of energy from renewable sources in gross final energy consumption in the Community and a 10% share of energy from renewable sources in energy consumption for transportation of each member country by the year 2020. In addition, sustainability criteria for biofuels and bioliquids have been established. Serbia has adopted the Directive and it is embedded in the Biomass Action Plan which was adopted in 2010.

6. BIOETHANOL PRODUCTION IN SERBIA

Today in Serbia, the bioethanol production is being conducted in seven plants, with total production capacity of 23,225 t per year. Raw materials predominantly used in these plants are molasses and cereals. In these plants, 96% vol. bioethanol is produced, and it is subsequently being used mainly for alcoholic beverages and medical and pharmaceutical purposes (Mojović et al., 2013). Bioethanol production in Serbia from fermented substrates amounted 8.69 million liters in 2011, which is only 30% of annual production capacity in Serbia. This indicates that the capacity utilization of bioethanol plants is rather small. The highest bioethanol production of 19.17 million liters was achieved in 2007 (Statistical Office of the Republic of Serbia, Biomass Action Plan for the Republic of Serbia 2010-2012). It is important to point out that despite current low level of industrial production of bioethanol, Serbia has main prerequisites to develop and improve this production since it possess a large feedstock potential, tradition and also educated human potential.
In Serbia, conventional energy crops such as starch-based raw materials are the most suitable and available agricultural raw material which can be used for industrial bioethanol production. However, a growing demand for the corn and wheat on global market are currently increasing their price and make these feedstocks less appropriate. For these reasons, possibilities of using cheaper substrates such as damaged crops and for example, triticale are being investigated (Pejin et al., 2009, 2012).
By applying the methodology used by the International Energy Agency – IEA, estimation of the amount of bioethanol that could be produced in Serbia in the future (from 2015 to 2030) was performed (Mojović et al OECD/IEA, 2010). The agency in its regional and global estimates of energy potentials used data recommended by FAO that assume global annual crop growth of about 1.3% and about the same global growth of agricultural biomass (waste). For Serbia, this analysis assumed slightly lower amount of crop growth of 0.9%. The estimation of first generation bioethanol production in Serbia based on available feedstocks taking advantage of surpluses of crops and use of marginal land showed there is a great potential for bioethanol production in Serbia of $1,188,030 \cdot 10^3$ lifters, i.e. 937,356 tons in 2015. Similar analysis has been performed to estimate the country potential for the production of second generation of bioethanol. The analysis was performed for two possible scenarios, the first for the possible utilization of 10% of the lignocellulosic biomass for the production of bioethanol and the second for the utilization of 25% of the biomass for the production of bioethanol. Results calculated for year 2015 were $258,385 \cdot 10^3$ lge (liter of gasoline equivalent), i.e. $645,962 \cdot 10^3$ lge, for these two scenarios, respectively.
Recently conducted studies revealed that Serbia will need to build new bioethanol plants in order to produce enough bioethanol for use as a fuel and thus follow the aims of the European Directive 2009/28/EC. Based on the given replacement of 20% of gasoline by bioethanol by year 2020 according to European directive 2009/28/EC, it has been reported (Dodić et al., 2009) that it will be needed to produce 233,000 t of bioethanol until 2026. If it is assumed that the needs of the ethanol industry and pharmacy stay the same (52,000 t), total demand for bioethanol would be 285,000 tons, which is 12 times the installed capacity in Serbia.
There is a great interest in the world today in the development, selection and cultivation of maize hybrids that can produce higher bioethanol yields. In that manner, maize hybrids with higher content of fermentable sugars are being developed. In the USA, two great companies "Pioneer" and "Monsanto" make efforts to identify and develop new corn hybrids, examine the impact of the environment on their growth, and the impact of corn varieties on the composition of useful by-products. Both companies have commercial corn varieties specifically cultivated for use in bioethanol production with obtained ethanol yield up to 4% higher than with conventional varieties (for the annual production of bioethanol of 150 million liters it means annual

profit increase of 1-2 million US dollars). Further research in the world should result in modification of properties of starch and other complex carbohydrates by methods of genetic engineering (Mojović et al., 2013).
Furthermore, significant efforts have been made at the Maize Research Institute, Zemun Polje, Serbia, in order to determine the suitability of local maize hybrids for bioethanol production. The calculation of average potential costs of bioethanol production from corn grain in Serbia performed on some of these hybrids is shown in Table 1.

Table 1: Average potential costs of bioethanol production from corn grain in Serbia calculated for 2012 prices, for most widely used local maize hybrids (Source: Semenčenko V, 2013)

Cost component	Average price, € l^{-1}
Feedstock costs	0.132
By-product credits	
DDGS	0.042
Carbon dioxide	0.001
Net feedstock costs	0.089
Cash operating expenses	
Electricity	0.011
Fuels	0.041
Waste management	0.001
Water	0.0007
Enzymes	0.008
Yeast	0.001
Chemicals	0.007
Denaturant	0.01
Maintenance	0.012
Labor	0.011
Administrative costs	0.008
Others	0.0009
Total	0.1116
Total cash & net feedstock costs	0.2006
Ethanol yield per hectare, l	3888.67
Ethanol production costs per hectare, €	778.69
Net income per liter, €	0.3094
Net income per hectare, €	1204.53

From the data presented in Table 1 it can be concluded that the average net income per liter of bioethanol produced from maize grain 0.3094 €, and the net income per hectare of 1204.53 €. The table shows the fact that the price of bioethanol fermentation by-product – dried distillers' grains with solubles (DDGS) amounts 0.042 € l^{-1} ethanol, which means that based on the total revenue from the sale of one liter of this fuel represents about 14%.

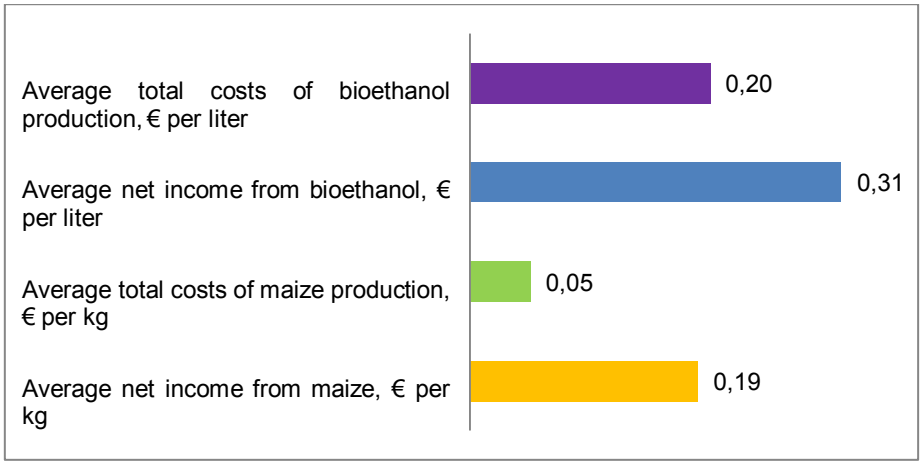

Figure 1: Average net income and costs of maize and bioethanol production in Serbia, calculated for prices from 2012 for most widely used local maize hybrids (Source: Semenčenko V, 2013)

From Figure 1 it can be concluded that by selling one liter of bioethanol higher profit can be achieved than by selling one kilo of maize grain. However, profitability per hectare of commercial maize grain sold is higher. This can be explained by the fact that for the production of one liter of ethanol was requires, on the average, 2.5 kg of maize grain.
In real terms it cannot be expected that all maize grain, intended primarily for human and animal nutrition will be used for the production of biofuels. The obtained results indicate that the production of a certain quantity of bioethanol from corn grain could be cost-effective, and it is necessary to design the production process in a way to find appropriate measures between the food industry and the alternative fuels production. Taking into account the fact that Serbia is a signatory of the Kyoto Protocol (1997), which refers to the reduction of greenhouse gas emissions and that the Biomass Action Plan (2010) established sustainability criteria for biofuels and bioliquids, the start of production of at least and the minimum amount of bioethanol would be a significant step towards achieving these goals (Semenčenko V, 2013).

7. CONCLUSION

Bioethanol production in Serbia is now at a very low level, even lower than the production scale at the very end of the twentieth century, and it is not sufficient enough to fulfil the country's ethanol needs for beverages, medical and pharmaceutical purposes. This is the main reason why in Serbia, there is still not an organized production and utilization of bioethanol or other biofuels for gasoline and diesel substitution. Recently conducted studies revealed that Serbia will need to build new bioethanol plants in order to produce enough bioethanol for use as a fuel and thus follow the aims of the European Directive 2009/28/EC. The obtained results, furthermore, indicate that the production of a certain quantity of bioethanol from corn grain could be cost-effective, and it is necessary to design the production process in a way to find appropriate measures between the food industry and the alternative fuels production. The revenues from corn bioethanol co-product – DDGS sold for animal feed could reach 14% of total income. In Serbia, it is necessary to introduce new strategies for the bioethanol production - large capacity plants that apart from bioethanol also include the production of animal feed and carbon dioxide; or introduce a network of small plants for the production of bioethanol within the petroleum industry.

[2] University of Coimbra, Faculty of Science and Technology, nikola.sahovic@gmail.com

Abstract: This work is focused on a specific segment of devices that facilitate a smart use of energy and relations with consumers. Throughout this document a Cost-Benefit analysis will be showcased. The aim of this work is to combine and explain key information about the technology being implemented; Cost-Benefit analysis for consumers, benefit from the smart meter implementation in households and four utility prototypes that influence the overall business case for smart meters.

Keywords: smart meter, advanced metering infrastructure, energy efficiency, consumer, energy management

1. INTRODUCTION

Energy and its sustainable use has become the top priority for both developing and developed countries. With the upcoming growth of both population and energy consumption, being able to be more efficient and effective with the allocation of this resource is a challenge that the world and its leaders are embracing. In spite of efforts, the impacts of an unbalanced use of natural resources have led the world to a critical situation where the environment and society are under an unhealthy and dangerous burden. The development of technologies and the engagement of energy users towards a more conscious use of the energy they consume is critical, as well as, the development of the market to allow these innovative solutions to be both reliable and affordable, to ensure that their potential is achieved and their expected benefits delivered.

2. THE CONCEPT OF SMART METER

The concept of smart meter can be defined in general terms as (Obenchain, Thurber, Quenn, et al. 2011) electronic measurements devices, installed by the utilities at the consumer facilities to allow communication of the consumption of energy (gas, electricity, water). These devices have been used by utilities to deliver accurate billing information, for a part of their customers. At first the devices were mainly used by industrial consumers given the higher consumption and the need of specific consumption data, to allow the right and best quality service to be delivered, and also to provide specific and detailed billing data. The evolution of the market and consumer needs facilitated a decreased price of the technology, and increased need of information by all consumers, leading to the migration of these systems from the industrial sector to all customer classes. From the consumer side smart meters can be defined as (SEDC, 2012), communication and control systems, which have the ability to directly empower the consumers to understand, control, produce and earn from energy. Through this definition the consumer becomes an equal partner in the energy value chain.

A broad view of smart metering, published by the European Commission (EC, 2010) states that an intelligent metering system or “smart meter” consists of an electronic device used to measure the consumption of energy, delivering more information than a conventional meter, and that can transmit data through a communication network. In this perspective, the key feature of a smart meter is the possibility of bidirectional communication between the consumer and the supplier/operator; the system should also promote the dissemination of services that improve energy efficiency within the home. On a market perspective, shifting from old and static meters to smart active devices is a matter of increased importance for competition in energy markets.

A considerable array of definitions for what smart meter and smart metering is, are available in the literature and in industry reports. From the definitions stated above (Obenchain, et al. 2011; SEDC, 2012; EC, 2010) it is possible to build a comparison table to highlight different focus of different authors (*table 1*).

Table 1 Smart meter definition comparison (Obenchain, et al. 2011; SEDC, 2012; Martin, 2011)

Smart meter definition comparison			
Author	Obenchain *et al*, 2011	SEDC, 2012	Martin, 2011
Key concept	Electronic devices, providing billing information to allow better management by the companies and utilities.	Electronic devices, that allows consumers to manage and benefit from a better control of their energy expenditure.	Intelligent meters, that provide more and better information, allowing energy efficiency to be improved, while increasing competitiveness of the energy market.
Focus on	Utility benefits from smart meters, and management of resources	Consumer benefits from smart meter, as well as, utilities.	Consumer, utilities and the market benefit from the roll-out of smart meter technologies.

The general structure of the smart meter (*figure 1*) consists on a hardware combination of the meter and the platforms needed to gather the information, and the necessary software and communication layer that transmits and processes data, and enables the system to communicate consumption data for accurate billing, controlling and monitoring purposes.

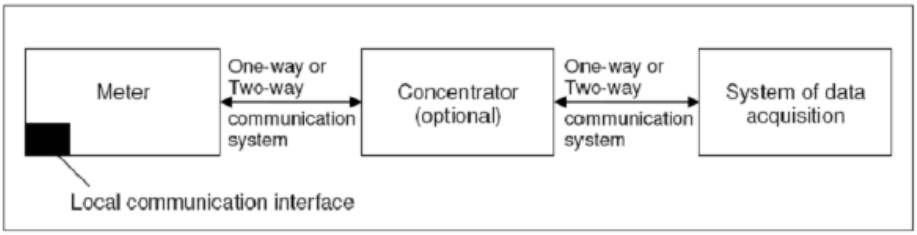

Figure 1 The general structure of a smart meter (source: Martin, 2011)

The general system architecture as demonstrated in *figure 1* represents the possibility of "one-way" or "two-way" communications between the different layers of the structure.
The evolution of the systems technology from "one-way" communications to "two-way" communications is linked with the shifting from the Advanced Meter Reading (AMR) systems (one-way communication) to the Advanced Metering Infrastructure (AMI) (two-way communication). The main differences between these two systems, AMI and AMR, are (Obenchain, et al. 2011):

AMI: Consists on the combination of the electronic meters with two way communication technology, for information, monitoring and controlling energy use;

AMR: Utilized one-way communications to collect meter data only.

The evolution of the communication system and its impacts on the smart meters capabilities are represented on the diagram below (*figure 2*), including the evolution of functionalities and the stakeholder benefits as a result of these evolutions.

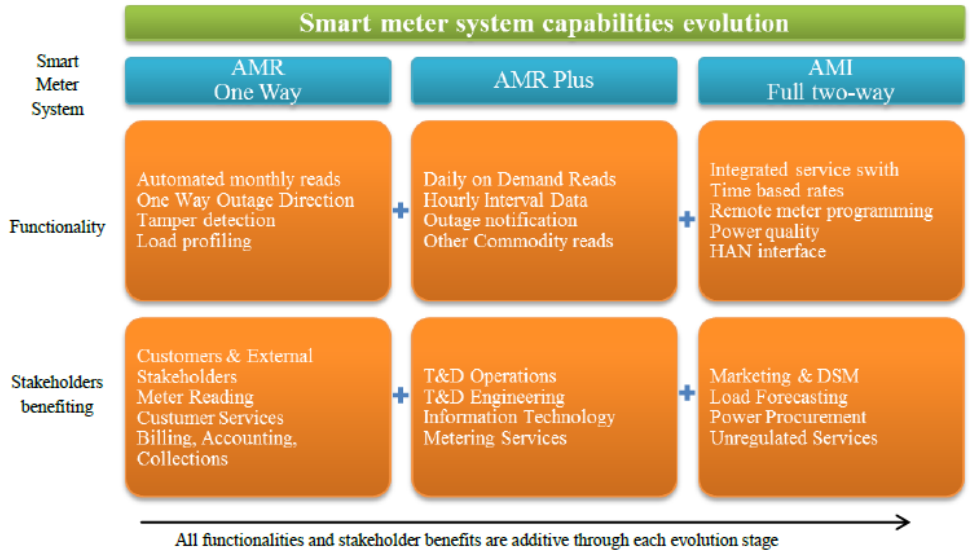

Figure 2 Smart meter system capabilities evolution (adapted from: Obenchain, et al. 2011).

Smart meters represent the new generation of meters, with the ability to replace existing electro-mechanical meters while offering a range of benefits for both the individual consumer and the energy system in general.

3. SMART METER AND CONSUMERS

Imagine a typical modern day Southern European family of four, husband and wife and a couple of grown up college kids living together. They go about their daily lives to work and university sharing their two cars and when necessary visiting the gas station to refill. In this world the system is such that they don't actually pay for gas at the gas station but simply fill the tank as necessary and receive a bill every month or two, once they have already forgotten who and with which car visited the gas station and how many times they have poured how much fuel into their vehicles. Let's also assume that their cars don't have a speedometer or a gas gauge, therefore they have absolutely no feedback in order to manage their fuel expenses. This is how we spend electricity and account for its usage in the world of today.

The widespread installation and utilization of AMI, and Smart Meters as its essential part, by homes and businesses will transform the way we purchase, spend, account for and manage our electricity consumption and needs. In preparations for widespread distribution of smart meters utility companies in Europe, North America, Australia and parts of Asia have during the past decade carried out numerous feedback and pricing pilot trails with their customers to assess the potential impact of smart meters and other AMI components on improving energy savings, increased energy efficiency, changes to customer behavior, their potential monetary savings in bills and reduction of greenhouse gas emissions. This section will provide an overview of cost benefit analysis of smart meter application, followed by a summary of selected feedback pilots carried out and their results[1].

3.1. Cost-Benefit analysis for the customer

Despite the rapid growth in the home energy management, and the significant energy management opportunity that is possible with the combination of smart meters and smart home energy management devices, concerns whether the costs outweigh the benefits of smart meters are a persistent concern among all stakeholders in the smart meter roll-out initiatives.

Smart meters provide an opportunity for two-way digital communications between the utility and the customer and establish a platform for customer energy management and demand response via both information feedback and rate programs. They are a tool for improving utility operational functions such as outage detection and management, remote meter reading, and remote customer (dis)connections. Furthermore, smart meters allow smart charging of plug-in electric vehicles as well as integration of distributed generation resources (Ehrhardt-Martinez, Donnelly, & Laitner, 2010).

Benefits from smart meters can be driven by changes in consumers' expected consumption behavior. Two potential sources of change in average consumption behavior may arise (DECC, 2010):

- a reduction in overall energy consumption/demand as a result of better information on costs and use of energy which drives behavioral change, and
- a shift of energy demand from peak times to off-peak times.

Smart meters provide benefits for utilities, customers and society as a whole (Faruqui, Mitarotonda, Wood, et al. 2011):

Operational – Allow the utility to deliver more reliable service, remote connection, better outage detection and recovery to its customer base at lower overall cost.

Customer – Arise from engagement in energy management driven by information and/or price signals, which leads to electricity usage reduction or load shifting and the opportunity to lower bills and mitigate cost increases.

Societal - Arise from demand response and direct load control, enabling reduction of peak purchases, thereby applying downward pressure on energy prices in spot markets, offsetting the need for new generation and transmission and distribution capacity, and potentially lowering carbon emission.

[1] (Ehrhardt-Martinez, et al. 2010; DECC, 2010; Faruqui, et al. 2011; Griffiths, 2012; Johnson, 2010; EComm, 2011)

A very elaborate cost benefit analysis of smart meters was carried out by The Edison Foundation, Institute for Electric Efficiency in their 2011 publication, *"The Costs and Benefits of Smart Meters for Residential Customers"* (Faruqui, et al. 2011).

Firstly the analysis defines profiles for four utility prototypes that influence the overall business case for smart meters, including the electricity generation mix, the renewable energy portfolio, the regulatory environment, emphasis on efficiency and conservation, and other factors.

- Pioneer: A utility that previously invested in automated metering with very high energy prices and that purchases power from a variety of generation sources;
- Committed: A utility with relatively high energy prices, primarily natural gas-fired generation, and a mandate to aggressively pursue renewable generation;
- Exploratory: A utility with relatively low-cost generation available, high population density, and highest demand in winter months;
- Cautious: A utility with low population density, high annual demand growth, and coal, nuclear, and natural gas dominant in its generation portfolio.

To continue, the authors define consumer adoption patterns and assume they will align with their energy worldviews. We developed energy management participation plans to correspond with four dominant customer segments, described below.

- Basic: For consumers who do not wish to engage at all;
- Comfort: For those with large load homes with air conditioning, pool pumps, smart appliances, minimal interest in energy engagement, and limited concern about their bills;
- Saver: For those primarily motivated by the opportunity to save money on their bills or mitigate potential bill increases;
- Green: For those motivated by environmental concerns and willing to be more engaged.

Out of the four consumer types, the authors of the study assume that each can have five different engagement pathways in terms of their usage patterns of smart meters:

- Passive: Unengaged households that benefit indirectly from operational improvements due to smart meters and incrementally if they coincidentally defer usage on demand response event days;
- Active: Engaged households that make conscious and manual adjustments to their electricity use based on energy information and price signals from peak rate plans (either no risk peak-time rebate (PTR) or heat wave critical peak pricing (CPP)) obtained via a web portal, a display, or other communications methods (e.g., email, text, or phone);
- Set and forget: Engaged households that use automation to adjust their electricity use via technologies such as programmable communicating thermostats (PCT) or home energy management systems (HEMS) based on energy information and price signals from peak rate plans (either no risk PTR or heat wave CPP);
- Utility automation: Households that allow the utility or a third party to directly control their central air conditioning via a signal sent to their smart thermostat or to a switch on their air conditioner. Customers retain the ability to override;
- Energy partners: Highly interested and engaged households that have electric vehicles and home energy management systems to automatically control electricity usage. The time of use rate applies to the entire household on a daily basis, not just on event days.

The model assumes that customers will choose an engagement path in line with their preferences in terms of price and in accordance with the appliances they use at home but also their sustainability sensibilities and willingness to take action.

Costs and benefits, as presented in *table 2 below,* are calculated based on investments in technology and the benefits arising as of their utilization.

Table 2 Costs and benefits (adapted from Faruqui, et al. 2011)

Costs and Benefits		
Costs	**Operational Benefits**	**Customer Benefits**
AMI	Avoided metering	Avoided generation and capacity
Enabling technology	Avoided outage	Avoided transmission and distribution
	Remote connection and disconnection of service	Avoided energy
		Avoided GHG emissions
		Avoided Gasoline

Even with conservative assumptions regarding consumer engagement in technology, programs, and rate plans, the results of the analysis show positive net benefits are possible for all four utility types. The model assumes a service territory of one million households. According to the study findings, the total costs of investing in AMI and associated technologies for home energy management varies across the four utility prototypes based on the utility and customer characteristics from a low of $198 million for the Pioneer utility to a high of $272 million for the Committed utility. The benefits also vary across the four utility prototypes based on both utility and customer characteristics.

- The operational savings vary from a low of $77 million for the Pioneer utility (who has already deployed AMR) to a high of $208 million for the Cautious utility;
- The consumer-driven savings vary from a low of $100 million for the Cautious utility to a high of $150 million for the Pioneer utility;
- The net benefits vary from a low of $21 million for the *Committed* utility to a high of $64 million for the Exploratory utility.

Although the net benefits are positive for each utility in this analysis, signifying that investments in smart meters make economic sense, customer-driven benefits could be much greater with more investment in and focus on customer education and engagement.

Furthermore if we consider an analogy to recycling, which took some time to get a substantial amount of people on board with the effort, we can assume that customers will migrate from passive engagement in energy management to much more active strategies. A potential area for further study is how to accelerate this process so that a broad array of customers are ready, willing, and able to engage in energy management soon after smart meters are deployed. Given the high satisfaction ratings of feedback pilot participants where education is a key component, the combination of program choice based on personal preferences (with comprehensive consumer education) could yield financial and societal benefits.

4. CONCLUSION

Smart metering is a way to reduce energy consumption, which is otherwise projected to keep growing across the Europe over the next two decades. Smart meters have the proven ability to enable significant changes to the current scenario regarding energy consumption (Johnson, 2007). Their purpose is to improve efficiency, not just at the household level, but utility-wide. For energy providers, smart meters promise to slash uncertainties in electricity consumption data and billing, eliminate the cost of manual meter readings and alert utilities to problems and outages more quickly and effectively.

The development of smart metering and the evolution on has the potential to change the energy industry and the interactions between consumers and distributors of electricity. Providing more and better quality information, these devices set the basis for realistic demand side programs and initiatives, focused on reducing unnecessary consumption, and shifting flexible load outside of peak hours. Reducing the peaks on demand will be possible through dynamic pricing, feedback and strong consumer engagement.

Smart energy systems deployment will positively impact safety and the overall service quality achieved, whilst providing distributors and network operator with essential information to enable demand side initiatives and programs to be implemented with success. Realizing the potential benefits linked to smart meter systems and their dissemination will depend on the success of consumer engagement initiatives and how the available information is organized and used to create more value for the energy market, for the society and for the environment.

Abstract: *This study is based on a survey of possible ways and adopted methods and techniques for achieving adequate model of sustainable development in Republic of Serbia. For that reason, sustainable development is seen first at the global level, giving an example of good practice of European Union. Then, it provides an overview of state strategies and legal framework for sustainable development of the Republic of Serbia. The aim of this study is the assessment of the state of sustainable development of the Republic of Serbia.*

Keywords*: Sustainable Development, Strategy, Indicators of Sustainable Development, Goals, European Integration, Climate Changes, Global Pollution*

1. INTRODUCTION: ABOUT SUSTAINABLE DEVELEOPMENT

The rapid technological advancements and industrialization have resulted in an increased level of negligence and insensitive behavior, leading to the destruction of environmental balance (Cetin & Nisanci, 2010). Human civilization has never been closer to ecological collapse: one third of humanity lives in poverty, and another 2 billion people are projected to join the human race over the next 40 years (Worldwatch Institute, 2012). The implication of this ecological situation is obvious: to be sustainable, human beings must live within nature's carrying capacity; and they must measure where they are now and how far they can go. In 1992, governments at the Rio Earth Summit made a historic commitment to sustainable development - an economic system that promotes the health of both people and ecosystems. Otherwise, “sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (WCED, 1987). In addition, it is important to notice that since sustainability is a multidimensional concept, economic, social and environmental aspects must be considered and integrated, too (e.g. WCED, 1987; Piątek, 2007; Sanchez, 2008; Pawlowski, 2009; Pawlowski, 2010; Tuziak, 2010).

2. EU SUSTAINABLE DEVELOPMENT STRATEGY

Sustainable Development Strategy has its origins back in Agenda 21, which is a key document for achieving Sustainable Development. Agenda 21 was adopted at the Earth Summit in Rio de Janeiro in 1992. Agenda 21 called all countries to develop a strategy for Sustainable Development, with the involvement of all stakeholders (Eurostat, 1998).

As originally stated in Chapter 40 of Agenda 21, the role and importance of statistical indicators for monitoring progress towards Sustainable Development have been identified as key items for the management strategy of the European Union.

Sustainable Development Strategy of the European Union, launched by the European Council in Gothenburg in 2001, and renewed in June 2006 contains goals for continuous improving the quality for present and future generations. Eurostat, the statistical office of the European Union, every two years publishes the monitoring report that supports the European Commission's report on the progress of implementation strategies. Objectively, the report provides a statistical picture of progress on the EU set of Sustainable Development Indicators. Through indicators, the quantitative rules are consistently applied; as well as the time direction, through certain symbols. In order to provide approximate assessment whether Europe is moving in the right direction, given the goals and objectives set out in the Strategy.

Sustainable Development Strategy is based on four distinct pillars: economic, environmental, social and international, which should mutually reinforce one another. Economic, social and environmental effects of all policies should be examined in a coordinated manner and should be taken into consideration when these policies are drafted and adopted. The EU also needs to assume international obligations in terms of Sustainable Development, and its various aspects, including peace, security and freedom, should promote outside the EU (Eurostat, 1998).

The strategy is based on the following guiding principles: the promotion and protection of fundamental rights; solidarity within and between generations; guarantee of an open society, the participation of citizens, businesses and the involvement of social partners; policy coherence and policy management integration; use of the best available knowledge, the precautionary principle and the "polluter pays" principle.

3. EUROPEAN UNION'S GOALS OF SUISTAINABLE DEVELOPMENT STRATEGY

The first, long-term goal of the strategy is limitation of the climate change and its effects to perform the obligations under the Kyoto Protocol, and taking the action to prevent the increase of global medium temperature above 2 degrees Celsius, above the level that was before the industrial era. The EU should pressure major industrialized countries to meet their obligations under the Kyoto Protocol and it should seek to provide an appropriate international framework for the period "after the Kyoto". It must implement measures and adaptations and testing ways of expanding greenhouse gas emissions; trading system to other sectors and other greenhouse gases (The Renewed EU Sustainable Development Strategy, 2006).

Limiting the negative traffic effects and reduction of regional disparities, is another long-term goal, for which is necessary to break the link between economic growth and development of transport So that the development of transport could be more environmentally friendly and suitable for health. Among other measures, the strategy envisages charging infrastructure, promotion of road transport and vehicles that produce less pollution and use less energy.

To promote more sustainable modes of production and consumption, the relationship between economic growth and environmental degradation should be terminated and also the attention should be on the tolerance of the ecosystems. With this goal, the EU, among others, should also promote Green Public Procurement; it should define the goals of environmental protection and social performance of products in collaboration with stakeholders; it should expand the distribution of eco-innovation and environmental technologies and produce relevant information on the labeling of products and services.

Also, the EU goals include the greater responsibility in natural resources management. Therefore, over-exploitation of resources should be avoided; the efficiency of use of natural resources should be improved; the value of services provided by the ecosystem should be recognized and further loss of biodiversity should be ceased.

In particular, the EU must make an effort in the fields of agriculture, fisheries, forestry; it should define and implement the priority actions for the protection of biodiversity.

Another Strategy goal is limiting the major threat to the public health. Food safety and quality must be ensured through the food chain. Threat to public health and the environment from chemicals should be removed by 2020 year, and research of the connection between health and pollutants must be developed.
In order to fight against the social exclusion and poverty and to mitigate the effects of the aging society, the EU needs to support the so-called "active ageing", which implies the inclusion of older people in different kinds of activities, whether it is voluntarily or not. Also, the effort should be made for assuring the sustainability of the pension system and social protection; integration of legal migrants and improvement of family situations (especially when it comes to children), and to promote the equality of sexes.

4. NATIONAL SUSTAINABLE DEVELOPMENT STRATEGY OF THE REPUBLIC OF SERBIA

National Sustainable Development Strategy of the Republic of Serbia defines Sustainable Development as long-term, continuous, comprehensive and synergetic process that affects all aspects of life (economic, social, environmental and institutional) on all levels (National Strategy for Sustainable Development of Serbia, 2008).

The goal is to achieve balance between three key factors, i.e. three Sustainable Development pillars: Sustainable Economic Development, Economy and Technology; Sustainable Development of Society based

on social equality and Environmental Protection with the rational use of natural resources. At the same time, the Strategy aims to bring together these three pillars as one whole, which will be supported by suitable institutions.

Strategy settlements are in line with European integration: EU Sustainable Development Strategy (adopted in 2001, and restored 2006) and the Lisbon Strategy (adopted by the Council of Europe in March 2000). The strategy is aligned with the Millennium Development Goals (UN) and the Millennium Development Goals in the Republic of Serbia, the Government of the Republic of Serbia adopted in 2006. The strategy is based on the reform goals identified in the strategic documents adopted by the Government. The strategy is fully in line with the principles and goals set out in the National Strategy of Serbia for Serbia and Montenegro's approaching to the European Union (adopted by the Government in June 2005) and Poverty Reduction Strategy (adopted by the Government in 2003), as well as strategies to regulate the economic development and environmental protection programs of the Republic of Serbia. It should also be noted that the Strategy is aligned with the entire set of strategies in almost all areas of economy, development, education, energy, in order to facilitate its application in various segments.

Indicators are very important for the successful evaluation of measures and activities for implementation of the Strategy. The choice of indicators reflects the connection with key instruments. In order to be internationally comparable, the selected indicators are aligned with new revised UN List of Sustainable Development Indicators, which also includes the indicators for the Millennium Development Goals. The indicators compliance is primarily reflected at the highest level, while some regional differences are recognized in the Indicators of the second, and especially of the third level. All indicators are gender-supported and they cover all aspects of Sustainable Development: economic, social and environmental (environmental indicators). Classification of indicators of Sustainable Development in Serbia is shown in the following tables (Milanovic, 2010).

Table 1: Poverty

I Level	II Level	III Level
1. Poverty	2. Lack of Income	3. Percentage of population below the national poverty line.
		4. Ratio of the average earnings of women and men.
	5. Inequality	6. GINI Coefficient
		7. HDI - Human Development Index
		8. Index of regional disparities in human development
	9. Help for the Poor	10. Population covered by State Help and Support programs
	11. Living Conditions	12. Percentage of constructed social housings regarding the total number of constructed dwellings

Table 2: Managing

I Level	II Level	III Level
1. Managing	2. Corruption	3. CPI - Corruption Perception Index
		4. Level of Citizen's General Trust
	5. Crime	6. Number of recorded violent crimes per 100,000 population
	7.Efficiency of the State Administration	8. Degree of computer automation in the state administration

Table 3: Public Health

I Level	II Level	III Level
1. Health	2. Mortality	3. Mortality rate of children under 5 years
		4. Life expectancy in good health
		5. Years of living with a disability / incapacity
	6. Provision of Health Care	7. Percentage of population with access to primary health care
		8. Percentage of women using some of the type of contraception.
	9. Health Status and Risks	10. Prevalence of smoking among children from 13 to 15 years
		11. Prevalence of smoking among adults aged 20 years
		12. Number of suicides

Table 4: Education

I Level	II Level	III Level
1. Education	2. Second Level Education	3. Percentage of population with a university degree
	4. Literacy	5. Adult literacy rate
	6. Level of population education	7. Rate of enrollment in primary and secondary education

Table 5: Population - Demographic Indicators

I Level	II Level	III Level
1.Population	2. Population	3. Percentage of population with a university degree
		4. Fertility rate
		5. Dependency ratio of elderly population
		6. Indicators of internal migration
	7. Tourism	8. Density in major tourist regions and destinations

Table 6: Economic Indicators

I Level	II Level	III Level
1. Economics development	2. Macroeconomic performance	3. GDP *per capita*
		4. Percentage share of investment in GDP
		5. Internal and External debt
		6. Trends in the retail price index
	7. Employment	8. Unemployment
		9. Employment rate
		10. Employment rate for women
		11. Unemployment rate for young people under 28 years
		12. Unemployment by region
	13. Information and Communication Technology	14. Number of active Internet users per 1000 population
		15. Number of Mobile phone subscribers per 100 inhabitants
	16. Research and Development	17. Expenditures for Research and Development as a percentage of GDP

Table 7: Global Economic Partnership

I Level	II Level	III Level
1. Global Partnership	2. Trade	3. Trade Deficit
	4. External Funding	5. ODA as a percentage of GDP

Table 8: Production and Consumption

I Level	II Level	III Level
1. Production and	2. Balancing Current Production and Consumption	3. Ratio of Current Production and Consumption
	4. Energy Use	5. Energy Consumption *per capita*
		6. Energy Intensity (energy per unit of GDP)

Consumption		7. Share of Renewable energy in total energy consumption
	8. Waste generation and management	9. Generation of waste
		10. Generation of hazardous waste
		11. Amount of waste that is subjected to the treatment
	12. Transport	13. Energy Intensity of Transport

Table 9: Natural Disaster

I Level	II Level	III Level
1. Natural Disaster	2. Sensitivity to Natural Disaster	3. Number of victims of Natural and Technological disasters
		4. Percentage of population living in natural risky areas

Table 10: Climate Change

I Level	II Level	III Level
1. Atmosphere	2. Climate Change	3. Emission of CO2 *per capita*
		4. Emission of Greenhouse gases
	5. Ozone Layer	6. Consumption of substances damageable for Ozone Layer
	7. Air Quality	8. Ambient concentration of pollutant urban areas

Table 11: Natural Resources

I Level	II Level	III Level
1. Natural resources	2. Land Use and Status	3. Change of the land use
		4. Land Degradation
	5. Desertification	6. Land degraded by drought
	7. Agriculture	8. Share of permanent crops in the structure of arable land
		9. Use of mineral fertilizers
		10. Use of pesticides
	11. Forest	12. Share of forest land total land
	13. Fishing	14. Annual catch five most common species of fish
	15. Water Amount	16. Annual amount exhausted quantity of grounded water and surface water, as part of an absolute and total of renewable water
		17. Water consumption by sectors
	18. Water Quality	19. Presence of fecal bacteria in drinking water
		20. Biochemical Oxygen demand in streams
		21. Percentage of waste water being treated
	22. Ecosystems	23. Share of protected areas regarding the total area of land
		24. Areas under the selected key ecosystems
		25. Index endangered species
	26. Types	27. Change in status of threatened species
		28. Share of endangered species in the total number of species.

5. CONCLUSION

Advanced climate changes, global population growth, changing market disinclination lifestyle, a global growth industry, and almost the lack of natural resources (water, food, oil) are just some of many problems that exist or will occur in the near future due to non-compliance with the laws of nature and its process (Strategy for Sustainable Development of Serbia, 2008). With that, human society is increasingly moving away from the environment, which provides the basis for life and survival.

In order to enable future generations to live in prosperity we have to turn to Sustainable Development. Sustainable Development is a multidimensional phenomenon that integrates several aspects of every individual's life (economic, social, and environmental), with emphasis on their mutual influence. Sustainable Development Indicators are qualitative indicators that evaluate the situation and change those aspects.

The introduction of the concepts of Sustainable Development over the past two decades became a turning point in our societies. Current policy should not mainly focus on their short-term impact, but they have to look for the long term one, and be more in tune with each other. Considering the complexity of the concept of Sustainable Development: taking into consideration of what counts for the benefit of both present and future generations; well-appointed official statistics that lead to impartiality and diversity available to provide expert statistical tools for both generations; and especially, statistical indicators necessary for adequate assessment and implementation of current policies are some of the basic and the key matters that need to be directed so that the concept of Sustainable Development could give positive effects, both today and tomorrow.

Since the concept of Sustainable Development has become increasingly present in our country, through the National Strategy for Sustainable Development, its indicators were first identified and currently are developing measurement models for those indicators that are not in the statistical system of the Republic of Serbia. The analysis of sustainability indicators, both the EU and the Republic of Serbia, will enable not only understanding the differences, but also the steps and actions necessary to take, in order to overcome those dissimilarities and according to the Republic of Serbia's strategy of joining the European Union. Comparing the indicators the Republic of Serbia and the European Union, it could be said that they are substantially oriented in the same topics and the same structure. However, it is noticeable that the EU, being much larger entity than the Republic of Serbia and whose institutions and laws are more developed, has certain indicators globally oriented, which in Serbia, a developing country, are not possible and measurable.

In Serbia, the indicators of sustainability are positioned on a lower level (in comparison to the level of the EU) because the awareness of Sustainable Development is not very high, and therefore it is necessary to begin from collecting the less complex indicators data, which doesn't require a certain institutional level and the ability to access data and financial resources, since in Serbia it is still not possible obtain. This is precisely the path that Serbia should take and it lies in strengthening the economic stability of the country, increasing the awareness of Sustainable Development, the adoption of laws that enable the framework for progress and application of indicators and general activities towards sustainability in the future time (National Strategy for Sustainable Development of Serbia, 2008). Indicators of sustainability can be useful for different types of communities and in different ways. Above all, they may indicate negative trends of certain aspects of human life, in order to preventively access to these areas before they should turn into a problem, in the future time.

For those communities that already have certain economic, social and environmental problems, indicators can show the way to a better progress. At the global level, indicators can initiate a joint discussion of people with different attitudes and coming from different surroundings, and during that process it can help to create a common vision towards Sustainable Development.

RESEARCH ON THE SUBJECT OF STUDENTS AWARENESS AND KNOWLEDGE ABOUT GREEN IT

Jelena Novaković[1]
[1] Faculty of Organizational Sciences jekanovakovic@gmail.com

Abstract: *The aim of this work is to show whether and to what extent the young generation is familiar with the concept of Green IT based on the survey which has been conducted. Furthermore, the goal is to inform primarily the students, and then the others as well, on how ICT can reduce the harmful impact on the environment and contribute sustainable development through various forms of informing. The introductory part shows how the use of ICT, and all its equipment individually, creates a detrimental impact on our environment. In addition, the concept of Green IT is outlined in more detail as well as the reasons why it needs to be implemented. As this approach shows its advantages, the following concepts are introduced: cloud computing, grid computing, virtualization technologies, utility computing, client server and peer-to-peer networking. A research has been conducted, where data has been collected by means of a survey, on whether and to what extent the students are familiar with the concept of Green IT. The research encompasses 82 freshman students from the Vocational College of Technology in Arandjelovac who attended the lectures from 'The Essentials of Information and Communication Technologies'. Young generations are overwhelmingly uninformed and don't possess awareness of this issue, the consequential emissions of harmful gases and harmful effects of ICT in general.*

Keywords: *Green IT, cloud computing, sustainable development, environmental, ICT*

1. INTRODUCTION

Thomas Friedman, in his well-known book —Hot, Flat, and Crowded" came to the following conclusion: —The convergence of global warming, global flattening, and global crowding is driving those five big problems – energy supply and demand, petro dictatorship, climate change, energy poverty, and biodiversity loss – well past their tipping points into new realms we've never seen before." Considering just how widespread ICT is and the fact that people can't imagine day to day life without it, it shouldn't come as a surprise to learn that it contributes a great deal to those five problems. People, in general, are not very aware of these problems and what they can mean, not only to us, but also to future generations. It is for their benefit that we should think about environmental sustainability, that is, about —development that meets the needs and aspirations of the present without compromising the ability of future generations to meet their own needs" (Development., 1987).

2. DETRIMENTAL EFFECT OF ICT USE ON OUR ENVIRONMENT

Today we rely on the Internet to find whatever we need, for example, library catalogs and databases, digital libraries, institutional repositories, e-books, e-journals, and so on. Access to this information is provided by an IR system. Such an extensive use of IR systems, which uses ICT (Information and Communication Technologies) at every stage of its creation and management, has an adverse effect on environment. Whenever ICT equipment is created or destroyed, it creates harmful gases, called GHG (greenhouse gases, a term used to measure environmental impact of a product or service). In running the ICT we use energy, and that also generates a substantial amount of GHG. In other words, as we are, in our daily life, becoming more and more reliant on IR systems for accessing and using digital information in a variety of forms, we are creating more environmental damages because of the increased use of ICT and energy. Because of that, it can be argued that we need to find a way to develop IR systems and services that are environmentally sustainable. As environmental sustainability has become a major area of concern for various national and international bodies, many different measures are being proposed for reducing the impact of industries and businesses on environment. One of those measures is the appropriate use of ICT which can reduce the overall GHG emissions of businesses.

The environmental impact of ICT can be significantly reduced by employing Green IT and cloud computing (Chowdhury., 2012). It has become a competition between computer hardware and software manufacturing firms to use environmentally sustainable energy efficient technologies in their products and services. Also, many companies and organizations are trying to make their businesses environment friendly, sustainable and cost effective by implementing green sustainable technologies (Lamb., 2009). Environmental sustainability is becoming imperative in data centers. Data centers are used by business facilities which contain ICT infrastructure platform (ICTP), cooling and power delivery equipments, servers and storage devices to store and process digital data and information (Lefurgy et al., 2007). Financial services, media, high-tech, universities, government institutions, and many others use and operate them to aid business processes, information management and communication functions (Daim., 2009). Data centers form the base of a large number of different services offered via the Internet including e-commerce, Web-hosting, social networking, and a variety of more general services such as software as a service (SAAS), platform as a service (PAAS), Internet as a service (IAAS), grid and cloud computing (Loper & Parr, 2007).

Many world known organizations like Green Grid, Energy Star, Green Data Center Alliance and many others are trying to develop green IT frameworks which are meant to reduce the emission of green house gases through maximum usage of already installed resources and devices in data center industry (Uddin & Rahman, 2012). However, not only do individual users but also systems and services that make extensive use of ICT have to change so that the target of reducing the GHG emissions of the overall business, industry and government could be met. The increasing use of ICT in its current form is not environmentally sustainable, as is proved by the research. The same research estimates that ICT‘s own sector footprint currently stands at 2% of global emissions and it will almost double by 2020 (Chowdhury G., 2012). In the same report it is suggested that appropriate use of the Green IT is a solution and that it can reduce ‗annual manmade global emissions by 15% by 2020 and deliver energy efficiency savings to global businesses of over EUR 500 billion‘‘ (Group., 2008) (Chowdhury G., 2012). ‗Gartner emphasizes that ICT industry is responsible for about 2% of global CO2 emissions which is almost equivalent to the aviation industry. An EPA report to U.S congress in 2007 emphasizes that current energy consumption in data centers is leading to an annual increase in the emission of CO2 (green house gases) from 42.8 million metric tons (MMTCO2) in 2007 to 67.9 MMTCO2 in 2011‘‘ (Uddin & Rahman., 2012).

From the mid-2000s onward, the amount of energy that is used by the applications available on the Internet has become a concern because of the rise of greenhouse gas (GHG) emissions; due to those concerns power-saving architectures and protocols have been seriously considered (Gupta & Singh., 2003). Since 2009, ICTs take amazing 4% of the world wide electricity consumption, and this number is expected to double within the next few years (Leisching & Pickavet., 2009). Zhang et al. have submitted a complete review on energy-efficiency plans in different parts of the telecommunication networks (Zhang at el., 2010). Energy-management is for the most part established on turning off, or putting in low power (sleep) mode, the components that are not in use such as line cards, network interfaces, router, and switch ports. There are also plans and projects for energy-efficient ICTs which require special power-saving hardware and architectures (Mouftah & Kantarci., 2012).

In the report from 2009 it is said that IT equipment contributes to global GHG emissions in the following percents: PCs and monitors contribute 40%, servers and their cooling equipment 23%, fixed line telecommunication equipments 15%, mobile telecommunications equipment 9%, local area and office network devices 7%, and printers 6% (Leisching & Pickavet., 2009). Keeping these numbers in mind, we can conclude that significant amount of energy could be saved in PCs and monitors by moving the IT services to distant servers. In this area, cloud computing could reasonably provide a solution for the green IT purposes. However, there is a negative side to the migration of services to distant servers in remote data centers. It will have two main impacts on global energy consumption and in direct correlation to the GHG emissions: (i) there will be an increase in the usage of data center servers, and (ii) moving the resources over the Internet will overload the Internet backbone traffic which will lead to an increase in power consumption of routing and switching equipments. Therefore, as Baliga et al. have stated,” energy-efficiency in cloud computing needs to maintain a balance between processing, storage, and transport energy” (Mouftah & Kantarci., 2013). As well, the Berkeley study concludes that laptops and desktop comprise approximately half of the Internet‘s total power consumption (Chowdhury G., 2012).

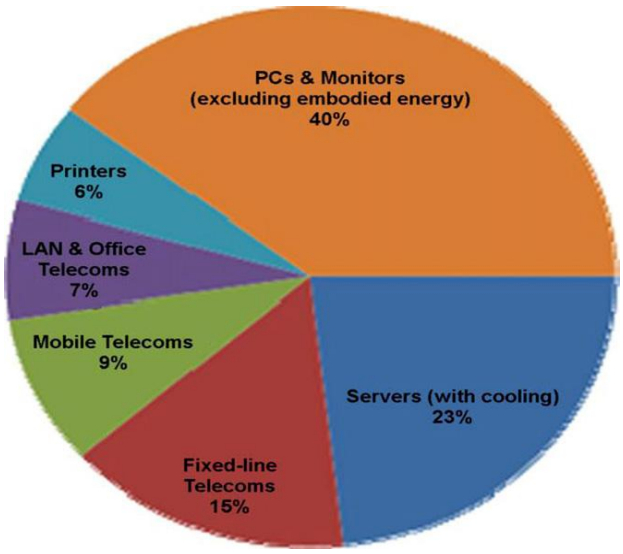

Figure 1: Estimated ICT CO2 emissions

In this picture we can see CO2 emissions for each ICT category. Based on this we can conclude that carbon emissions and energy consumption will only grow from year to year. The SMART 2020 study shows us that CO2 emissions from ICT are increasing at a rate of 6% per year and with such a growth rate they could represent 12% of worldwide emissions by 2020 (Kumar & Mieritz., 2007). It is becoming clear to the people all over the world that the humanity will have to pay dearly for the irresponsible behavior of the enterprises that have done the great damage to the environment. As we have already stated, information and communication systems account for 2–2.5% of the global carbon emissions, but it must be understood that if indirect energy use was to be included, then the number would rise to 14% of the total global carbon emissions (ITU-T, 2007). The problem becomes even greater if we take into consideration the e-waste made by massive usage of the IT equipment. About 500 million PCs were discarded between 1994 and 2003. That many PCs contain approximately 2872,000 t of plastics, 718,000 t of lead, 1363 t of cadmium and 287 t of mercury. The environmental problems that are connected to the IT are without doubt one of the most pressing concerns not only for the IT society, but for the general public as well. To date, the largest number of the environmental regulations and measures of control are being focused on the IT equipment manufactures. Every day environmental problems are more closely connected to the unsustainable trends in consummation than to the human population and technology. In particular, for the IT system, system‘s overall environmental impact largely depends on the system owner‘s decision concerning design. As Kohler and Erdmann concluded (Köhler & Erdmann, 2004), there are three levels of environmental impact: the environmental impact which is a result of the hardware‘s full lifecycle, the shifting of other connected non-IT processes, and the change in people‘s daily life and economy. A good system design results in lower environmental risks and impacts and improves corporate social responsibility (Zhang et al., 2011).

3. WHAT GREEN IT REPRESENTS AND WHY IT SHOULD BE IMPLEMENTED

Green IT refers to the initiatives and programs that directly or indirectly address environmental sustainability (Jenkin et al., 2011). Its objective is to lessen the overall environmental impact of ICT by applying various measures some of which are taking environment-friendly approaches to the production and use of ICT equipment and facilities and optimizing the use of those equipments and network infrastructure so that the energy consumption at every stage would be reduced (Chowdhury G., 2012). If we observe only the direct environmental impact of IT system, then we could define Green IT as ‗the study and practice of designing, manufacturing, using, and disposing of computers, servers, and associated subsystems— such as monitors, printers, storage devices, and networking and communications systems—efficiently and effectively with minimal or no impact on the environment.‘‘ (Murugesan., 2008)

Green IT or Green Computing helps us create more environment friendly and cost effective use of power and production technology. Green IT is a term that covers many different concepts like virtualization, cloud computing outsourcing, recycling, procurement and power management, etc. The main goal of Green IT is to achieve higher energy efficiency in the use of IT devices and to increase the utilization of already installed devices in data centers. On the other hand, organizations need to deliver new IT Services in short time while keeping in mind high reliability, performance and availability requirements as important issues in supporting

the business processes. IT must have a clearly defined Green IT strategy or framework which is in tune with business strategy and goals in order to realize and achieve both of these objectives at the same time. IT needs to translate IT Strategy to IT operational processes efficiently and clearly in order to assure effective business IT alignment in the most secure way (Uddin & Rahman., 2012).

4. TECHNOLOGIES WHICH ENABLE THE IMPLEMENTATION OF GREEN IT

Recent years, maybe even decades, have been marked by astonishing advances in information technology (IT). Their sole purpose is to achieve high performance data processing, data storage, and high speed wired/wireless communications on the Internet. Distributed systems, each aiming at a specific target, have become possible solutions, because of the limitations of local resources and power-efficiency concerns. For example," IBM's *autonomic computing* aims at building self-configuring, self-healing, self-optimizing, and self-protecting distributed computer systems for complex and unpredictable computing environments". As another example, *grid computing* comprises a" group of computers located at physically distant locations and sharing computing and storage resources to accomplish a specific task on an on-demand basis". There are also client–server and peer-to-peer networking. Client-server networking is a ~~-d~~istributed system consisting of a high performance server and lower performance clients", while peer-to-peer networking defines a" distributed system consisting of peers that share hardware resources such as storage, processing power, and network link capacity". Similar to the distributed computing services, *utility computing* is another business model that ~~-d~~elivers the computing resources among several computers based on an on-demand basis and bills the computing facilities such as in electricity and Internet billing" (Mouftah & Kantarci.,2013). The idea of distributed systems has in the end evolved to the *cloud computing* concept which offers almost infinite computing resources on-demand as well as the dynamic provisioning, release, and billing of computing facilities. On top of that, the expenses of service providers who use cloud computing are reduced (Armbrust, et al., 2009). As a matter of fact, as stated by Zhang et al., cloud computing is just a new business model that merges several distributed system concepts. (Zhang et al., 2010) According to the definition of the National Institute of Standards Technology (NIST), which is the one most often referred to in literature, cloud computing denotes ~~-a~~ shared pool of resources available to the users, which can dynamically be provisioned and released without interacting with the service provider" (Mouftah & Kantarci., 2013).

Grid computing comes closest to the cloud computing because it offers a distributed, powerful and cheap computing platform over the Internet. The difference is that cloud computing offers a homogeneous pool of resources to the users while the ones that grid computing offers are more heterogeneous. Also, cloud computing may be better than grid computing because of its high reliability assurance from the service providers (Kondo et al., 2009). For instance," Amazon-EC2 assures 99.995% reliability, which leads to 27 min or less downtime per year" (Mouftah & Kantarci., 2013).

IT infrastructure is growing almost daily, so we can consider cloud computing as a natural extension of virtualization technologies. These technologies enable scalable management of virtual machines over a number of physically connected systems. That is why cloud computing which is based on virtualization can offer practical and applicable approach to green IT/clouds. These are the clouds which emphasize the construction and development of scalable, energy efficient network software applications (NetApp) through improved utilization of the primary resources. The key precondition for upgraded security services as an integrated component of the infrastructure management strategy is emphasized by boosting the sharing of hardware and data in a multi tenant cloud architecture/environment and through this the former is achieved. Not only is the virtualization technology at the forefront in the sphere of industry but it's also grown into paramount technology in building a green IT infrastructure.

Since modern computing is prone to lead to high energy consumption it creates technical issues as well as environmental challenges. Due to the growth of the sizes of IT infrastructure, it has become an imperative to come up with efficient green IT solutions in order to minimize its effect on our environment. Cloud computing provides a natural extension of virtualization which enables scalable management of virtual machines dwelling on distributed hosts, thus permitting maximal usage of the concealed resources and supplanting the traditional ‗one server, one application'' model with a multi-tenant architecture/model of cloud services (Li, et al., 2011). The carbon footprint of ICT can be reduced in different ways, as is shown by Green IT/IS research. Some of those ways are the following: (1) by developing more sophisticated software and business systems that can help in the reduction of GHG emissions of businesses, (2) by developing new and improved technologies for manufacturing ICT equipments and infrastructure, and (3) by sharing computing

and ICT infrastructure and thereby optimizing the use of computing and network resources and also reducing energy consumption of ICT (Chowdhury G., 2012).

5. DISCUSSION AND RESULTS

With regard to the cognitions which have been reached on the basis of former research, and bearing in mind people's feeble awareness on the topic of environmental conservation and the facts which imply this, a research on Green IT has been conducted. In conformity with the already mentioned, this research also starts from the presumption that the majority of the respondents aren't acquainted with the term. On the basis of the results of the survey which has been conducted on the Vocational College of Technology in Arandjelovac, and where 82 freshmen students of vocational studies who attended the lectures on The Essentials of Information and Communications Technology', in autumn semester of the school year 2013/14 were surveyed, the following conclusions have been reached:

- Out of 31 surveyed students on the study program Information Technology, out of which 23 are members of the male and 8 of the female sex, 30 (96,7742 %) have never heard of the concept of Green IT, while only 1 (3,2258%) student is familiar with this term.

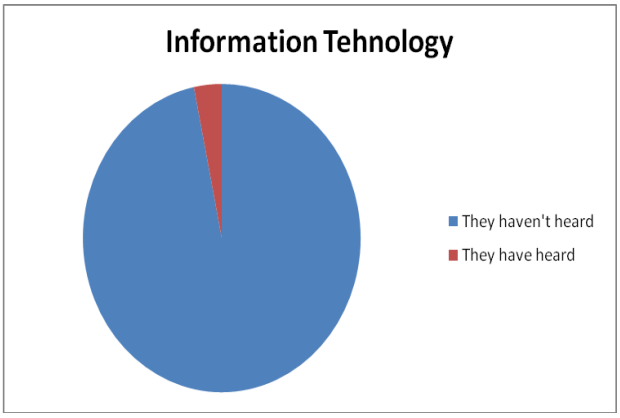

Figure 2: Percentage of students' familiarity with the concept of Green IT

- Out of 23 surveyed students on the study program Management in Tourism and Hospitality Industry, out of which 7 are members of the male and 16 of the female sex, 20 (86,9565%) have never heard of the concept of Green IT, while only 3 (13,0435 %) students are familiar with this term.

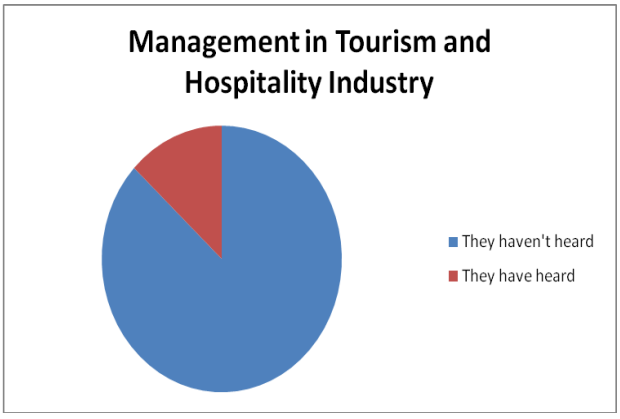

Figure 3: Percentage of students' familiarity with concept of Green IT

- Out of 6 surveyed students on the study program Technology and Engineering, out of which 3 are members of the male and 3 of the female sex, no one has heard of this term.

- Out of the 22 surveyed students on the study program Environment Conservation, out of which 8 members are of the male and 14 of the female sex, 20 (90,9091%) have never heard of the concept of Green IT, while only 2 (9,0909%) are familiar with this term.

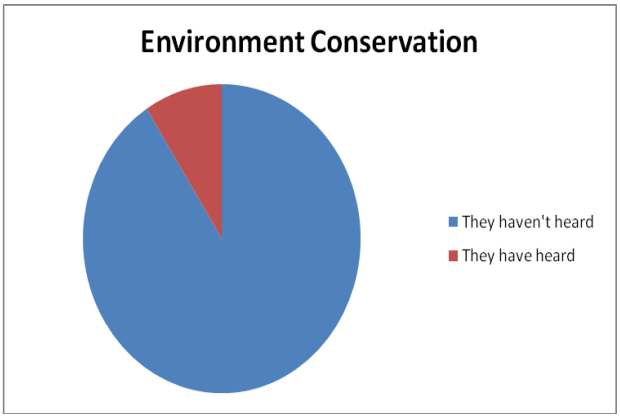

Figure 4: Percentage of students' familiarity with the concept of Green IT

6. CONCLUSION

Given its rapid development and progress, ICT has become part of our everyday life and is an integral part of many activities. Although ICT is very useful, emission of harmful gasses threatens to contaminate the environment. Green IT produces minimal greenhouse gas emission and can contribute significantly to the achievement of sustainable development, and play a key role in the aforementioned. The goal of Green IT is to directly or indirectly reduce the impact of ICT on the environment, that is, the ecological and economic costs by adopting a series of measures. Therefore, it is especially important that people are familiar with this concept. According to the results of this study we can notice that younger generation, which to a large extent uses ICT for various purposes, has a poor understanding of these relevant concepts. Consequently, it is necessary to inform and create awareness that through the use of ICT they should think and adhere to the measures that have been proposed in order to protect the environment and reach sustainable development.

CLIMATE CHANGE TREATMENT IN NATIONAL SECURITY DOCUMENTS

Nebojsa Nikolic
Strategic Research Institute, Ministry of Defense, nidzan@ptt.rs

Abstract: *Climate change is a threat multiplier. It is hard even to list all concrete security threats generated from climate changes. Perception of this factor as a threat is relatively new. Natural disasters are one of logically expected implications of climate change. One of the missions of the defense forces in many countries is dedicated to supporting the civil authorities and population in a case of natural or man-made disasters. While traditional missions of defense forces are well presented in strategic documents and well evaluated towards implementation, the question arise how much defense forces are prepared, equipped and trained for conducting a mission of supporting society in a case of disasters. We started with investigating a placement of this mission in a strategic documents related to national security and defense. In dealing with climate change security implications, lessons learned from the similar cases in the past could be of help.*

Keywords*: Climate change, Disasters, Security, Military, Strategy*

1. INTRODUCTION

People around the globe become more and more aware of possible impacts of climate change on their life. There are many aspects of considering climate change impact on our civilization. Marshall (2012); and Pain (2013), offer some interesting analyses of a climate change possible impact on some common everyday issues. Alexander (2013), considered an real disaster event which occurred few years ago (Iceland volcano eruption in 2010), and noted some impressive facts about consequences on everyday life and particularly on air traffic.

Climate change issue arises, during last few decades, as a security threat worth of consideration and mentioning in a national security documents. It also earns growing attention. Tanner and others (2009), registered changes in priorities among security threats, and found that higher priority has been given to the climate change. In a long-term perspective for security, some nations see climate change as one of the most important factors, like in Finnish Prime Minister's Office Publications (2012).

In order to recognize climate change as a threat in a comprehensive way, there is a room for research in different scientific fields. First, what are causes and effects of climate change? Climate change may be a consequence of some natural phenomena, as well as the consequence of the mankind activities (global warming). Climate change made by the nature may be a consequence of orbital changes of the planet, Sun activities, a change of Earth's magnetic field, meteor impact, or gigantic volcano eruption, to mention some of the well known causes. Climate change affects almost all fields of human life and society, and negative aspects of that influence make that we perceive climate change as a threat.

Climate change is a threat multiplier in many aspects. Climate change may be a cause for generating problems in many other fields: agriculture, transportation, health, energy, technology, economy, social issues, migrations, and consequently, politics and security domain. Climate change may appear gradually (as it is considered for global warming), or in a short time with enormous changes. Climate has complex and global dynamics, and scientific climate models are still far from enough reliable tools for good, comprehensive and long-range forecasting.

Human civilization experienced various kinds of natural disasters. In last decade we had a series of severe mega-storms with devastating effects in the USA, volcano eruption in Iceland that heavily blocked air transportation in Europe (Budd and others, 2011), tsunami in Indian Ocean, earthquake with tsunami in Japan, wildfires in Australia, Mediterranean countries but in Russia as well, heavy earthquakes in Haiti and in Asia, long drought in Africa, devastating floods, and so on. One should not separate such disastrous events from climate change perceived narrowly just as global temperature grow. Common sense may suppose that body's volume enlarges proportionally with grow of temperature. In the case of our planet, that means that Earth's tectonic plates will make some motion which could be a trigger for earthquakes, tsunamis, volcano eruptions, etc.

2. DEFENSE FORCES MISSIONS AND CLIMATE CHANGE

In any nation state, defense forces are considered as highly organized, structured, robust, respective, trained and equipped social entity that are very appropriate for meeting different types of security challenges including natural or man-made disasters. In general, it is a kind of a last resort capacity of one society for dealing with various large-scale security challenges.

The purpose of the defense forces (tasks, duties, responsibilities) is usually given in strategic documents related to the national security and defense. Number and type of declared missions varies depending on country. However, there are three general types of missions for the military that could be found in strategic documents of different countries:

- Defend the country, nation and national interests (traditional tasks of armed forces).
- Contribute to the global peace (by participating in peace missions abroad).
- Support the civil authorities in a case of natural or man-made disasters.

The first mission is the most traditional task and every military organization is very familiar with that. Personnel strength, size of organizational structures, quality of equipment, military training and strategic and doctrinal documents, are mainly determined and oriented towards preparation for use of military forces for the purposes of the first mission: defending the country.

The second mission becomes very actually during the last few decades: many troop-contributing countries, many missions, many different places, increased mission duration, etc. Peace supporting is relatively new mission (comparing with the first mission) for the military. It is a lot different from the first mission. It demands new capabilities from military organization and particularly from the military man and woman as individuals. Fortunately, peace missions are in their essence of international character. Wide portfolio of specific training and operating procedures has been developed during decades in many countries. International military cooperation developed and sustained during the peace missions, evolve progressively on many other activities before (training, and preparation) and after mission (lessons learned, training improvement, etc).

For the first and the second mission, it could be said that modern military organizations are well prepared, trained, equipped and more or less familiar with. However, it couldn't be said for the third mission. The military organizations usually are not exclusively dedicated to the preparation of capabilities for natural or man-made disasters. However, the third mission is in a very close relation with negative consequences of climate change.

While traditional missions of defense forces are well presented in strategic documents and well evaluated towards implementation, the question arise how much defense forces are prepared, equipped and trained for conducting a mission of supporting society in a case of disasters (third mission). We start with investigating a placement of this mission ("third mission" in a further text) in a strategic documents related to national security and defense for a number of countries.

De France and Witney (2013), gave comparative qualitative analyses of security strategic documents for a European Union countries. This analysis generate ranking list of national security documents against criteria of comprehensiveness and currency. We used theirs results to pay more attention on those strategic documents that are estimated as very good, in order to recognize successful approaches and use them as a model in a future work.

In national strategic documents of various countries, the mission of defense forces related to challenges caused by (but not exclusively) climate change, appears in next forms:

- Support to civil authorities in countering security threats (Serbia).
- Defend the Homeland and Provide Support to Civil Authorities; and Conduct Humanitarian, Disaster Relief, and Other Operations (USA).
- Supporting civil emergency organizations in times of crises (UK).
- Protect nation and territory from major crises resulting from natural, health, technological, industrial or accidental risks (France).
- Supporting civilian bodies (Czech Republic).
- Contribute to countering natural and industrial disasters, mitigating their consequences, managing humanitarian crises and, if necessary, and participating in the support of civilian authorities (Hungary).

- Contribution to the National Security in Peacetime includes: protection and support to the population in case of natural disasters, industrial accidents and ecological crises; providing humanitarian relief; support to migration control; search and rescue activities; support when necessary to other government organizations and local authorities to prevent and overcome the consequences of natural disasters, industrial accidents, ecological crises and epidemics (Bulgaria).
- Assistance in the case of natural catastrophes and disasters of exceptional magnitude (Austria).
- Support other authorities on the basis of their requests for executive assistance, or in accordance with jointly implemented contingency plans (Finland).
- Assisting the civil authorities in response to major emergencies, natural disasters and in the maintenance of essential services (Ireland).

3. CLIMATE, WEATHER AND MILITRAY OPERATIONS

One of direct implications of climate change is change of weather conditions. Temperature, rain, snow, wind, in all theirs aspects and combinations, are factors that have tremendous impact on living and working conditions and all other activities of human society including international and internal conflicts and warfare. Weather conditions may have direct and indirect influence on national security and on engagement of national army. Potential influences of severe weather conditions on planning and conducting military operations could be numerous. To mention some of the most famous events from historical evidence where weather conditions made crucial impact:

- Debacle of the Spanish Armada at the end of 16.century. Spanish Navy, during expeditionary operations against Kingdom of England in 1588, had been faced with very strong North Atlantic storm that destroyed the Spanish fleet. It was introduction in the historical change of the strategic balance on the Atlantic between Spain and England.
- Influence of severe Russian winter on military operation in French-Russian war in 1812, and again on military operations during the World War II, particularly in 1941 and 1942.
- Weather conditions influenced a delay of the D-Day in operations Overlord in World War II (Allied invasion of Normandy, France). Landing operation was planned to start on the beginning of June, 1944, but it was threatened by strong wind, high seas and clouds. Initially planned D-Day was shifted to June 6, 1944. Weather forecast by military meteorologists suggested that day as it was expected to be slightly gentle weather and sea conditions. Otherwise, whole operation would have been delayed for at least one month.

Climate change makes impact on all sides in potential conflict, but also it changes the “theatre of operation”. Climate change may generate much worst weather conditions then mankind ever experienced in its history. That may place new challenges to the military organizations and on planning and executing of military operations. Some consequences of climate change could be indirect reasons for triggering situations for any of those three missions. In cases of first and second mission, climate change may:

- Induce tremendous increase of the need for some vital resources (energy, water, food, etc).
- Dramatically reduce availability of the currently available natural resources.
- Open new problems (new transportation routes across the Arctic Ocean; border issues on sea; under-sea resources exploitation; etc).
- Large-scale migration.

4. ALL MISSIONS SIMULTANEOUSLY – ONE HISTORICAL EXAMPLE

Looking back in history, it could be found some good examples of use of military forces for support civil population in some dramatic natural disasters. There are many examples where national armed forces are used to help civil population and authorities in fighting with floods, earthquakes, wildfires, high snowdrifts, etc. It is clear that respective logistical resources and well organized and disciplined military units are of great help in emergency situations caused by natural disasters.

However, natural disasters may arise in any time. They may appear in a peacetime, but also during some war. So, the military forces may be affected to perform two or even all three pointed missions at the same time. This may seem as logical exercise of scholar strategists, but it actually happened in not so far past. During the World War II, in March 1944, there was volcano eruption (Vesuvius, Naples region) in south Italy, just in period of famous Monte Casino battle.

Telling the story in a modern vocabulary, US and UK military forces performed the first mission (defending the country and national interests), which was somehow extended towards the second mission (wide international coalition that included: democratic states, common interest partners and resistance movements, conducted peace enforcement operations outside of national borders). Suddenly, in the middle of military operations, volcano eruption generated the need for performing the third mission. Comprehensive description of that situation with very good conclusions and recommendations was presented by Chester and others (2007). Frontline between Allied and German forces was few hundred kilometers on the north from Vesuvius, and final battle of Monte Casino started on 15 March 1944. Southern part of Italy, including Vesuvius region, was under Allied forces administration. The volcano eruption started in the middle of afternoon on 18 March 1944, and became a threat for around 600,000 people who leaved at that time in the Vesuvius area.

The responses of the USA and UK military forces were timely and comprehensive to that natural disaster. They took over complete responsibility for volcano emergency response: started with situational awareness; used military meteorology capacities to predict wind direction and intensity (because of volcano ash); call for cooperation local population and some local scientists for volcano behavior; engaged military engineering equipment (bulldozers, trucks) for sustaining transportation routes functional; helped in rescue and evacuation on hot spots; and prepare contingency plan for large-scale evacuation of civil population mostly by sea, for the case of worst-case scenario.

5. CONCLUSION

Long-term vision of the national and international security, incorporate the climate change issues and theirs complex implications as one of the most important factors. At the moment, climate change security consequences (mainly in the form of natural disasters) are recognized in many strategic documents related to national security and defense. Defense forces are seen normatively as a supporter of civilian authorities in coping with disasters, and not as a chief executive body.

Order of magnitude of needed resources, skills, information, etc, for comprehensive respond to possible disasters caused directly or indirectly by climate change, could be so huge that no single organization could cope with it, at least not so effectively and efficiently as it could be in coordination and cooperation with other organizations of the national states, but also with others at the international level. In that sense and in this context, future research could be related towards investigating concepts known in the field as: The whole of government approach; International military cooperation; Smart defence; Civil-military cooperation; etc.

TECHNOLOGY AND INNOVATION MANAGEMENT

SUSTAINABLE TECHNOLOGY MANAGEMENT AND DEVELOPMENT - STATE, UNIVERSITY AND INDUSTRY PERFORMANCE MODEL

Maja Levi Jakšić[1], Milica Jovanović[2] Jasna Petković[3]

[3]University of Belgrade, Faculty of Organizational Sciences petkovic.jasna@fon.bg.ac.rs

Abstract: *In this paper a general model is created for measuring the performance of Technology and Innovation Management (TIM) related to the crucial dimensions/elements of the Triple Helix (TH) model. More precisely, the Triple Helix Model (high education – government - industry) is analysed in relation to its fulfilling the three main functions of TIM: planning, organizing and control (POC). The general model – TMD-TH (Technology Management and Development – Triple Helix) represents the framework for further more specific research into the relations of the observed dimensions. The general model is further divided into sub-models: TMD-G, TMD-U and TMD-I, where G stands for government, U stands for university and I denotes industry. The sub-models are to be investigated in more detail and the research results will be presented in separate papers. In the general model, the performance of each TH dimension is to be monitored by a set of indicators classified into categories according to the specific management function (POC) of TIM. The general model enables better systematisation of the indicators of TIM with links established with the main roles of the actors in the TH model. When applied in concrete situations in practice, at the level of national economy, the results obtained represent a base for developing policies and strategy that will be oriented at introducing change in the domains of highest priority in the aim of achieving more efficient and effective results in sustainable development.*

Keywords*: Triple-Helix (TH) concept, Sustainability, Technology and Innovation management (TIM), General model, Performance Indicators*

1. INTRODUCTION

In the dynamic global environment, with continuous and exponential technological growth and development, the relevance of the research conducted in managing technology, innovation and change is of high priority. The ultimate goal of achieving global competitiveness of firms and economies means that one of the crucial competitive factors today, technology and innovation, is to be managed by closely measuring, monitoring, controlling its performance. Why is managing technology so important? As stated in (White & Bruton, 2007), the necessity for technology management lies in: (a) the rapid pace of technological changes which require multidisciplinary approaches; (b) the rapid pace of technological development which shortened product life cycles; (c) the need to cut time for product development and create more flexible organizations; (d) the necessity to maximize competitiveness effectively by using new technologies; (e) the importance of changing management tools caused by rapid technology changes. Technology and innovation is placed at the centre of the policies and strategy developed for firms, industries, national economies, regions, sectors, etc. In this paper we develop the general model of sustainable technology and innovation management based on the assertion that it is the management of technology and innovation, not just the new technologies themselves, that represents the true competitive force leading to sustainable development.

Effective TIM is dependent on the capacities to measure and monitor performance which is not an easy task having in mind the interrelatedness of the activities, the time dimension and delays inherent to research and development inputs and effects, synergies, etc. Up to now, in both practice and theory, mostly used indicators of technology and innovation management (TIM) were related to research and development (R&D) activities, intensity of technology changes and degree of implementing innovations. The overview of literature in the field of TIM, as evidence of theoretical and empirical studies, shows that it is necessary to develop a complete, comprehensive approach. In this paper, an original attempt is made to classify and systematize TIM indicators according to basic management functions - planning, organizing and control (POC) linked to the performance of Triple Helix (TH) actors. The role of TIM as key factor in accomplishing sustainable development is clearly pointed out in theory and justified in practice, as sustainable new technologies and innovation lie at the core of economic, social and technological progress. The capacities and competencies in managing technologies are becoming at least as important, if not, even more significant than the capacities of the technologies, *per se*. TIM performance is measured and tracked by indicators at different levels: national economy, economy sectors, and companies. In this way, priorities are set for future actions in

order to improve management areas that are not developed enough, and to achieve the overall goals of efficiency and effectiveness of technology management at all levels.

The perspective of sustainable development requires an overall approach, encompassing indicators classified by using the Triple Helix concept (Etzkowitz & Leydesdorff, 1995). The TH comprises the hybridization of three dimensions/elements university, industry and government in order to generate new institutional and social formats for the production, transfer and application of knowledge (The Triple Helix Concept, 2013).

The basic hypothesis and assumptions elaborated in this paper are the following:

General hypothesis:

1. Technology management and entrepreneurship is as important as development of technology, *per se,* for sustainable development, and

Special hypothesis and assumptions:

1. TH model is a basic model for sustainability and TIM indicators are established according to the dimensions/elements of TH,
2. TIM functions, elaborated by POC, classified according to TH dimensions/elements, enable the establishing of the comprehensive, general model,
3. The general model with feedback relations is applicable for effective strategic management in the state, university and industry domains,
4. Application of the model with systematized indicators in practice is a valuable tool for more effective strategic analysis, establishing policies and strategy and their implementation, with specific tasks for TH-state, university and industry related to different functions of TIM.

In this paper, the authors have created a new general cross-functional model for measuring sustainable technology management and development, TMD-TH, based on two concepts: (1) TH concept with three dimensions: university, industry and government; (2) management concept based on three management functions – planning, organizing and control.

2. THE PRODUCTIVITY PARADOX AND THE TRIPLE HELIX CONCEPT

Building knowledge-based economy and society in the traditional sense is not sufficient enough for substantial economic and social progress and development. Theoretically and in practice it has been discovered that, despite the undoubtedly central role of investments in new knowledge in economic growth, there is still a neglected, missing link to economic growth, employment opportunities and international competitiveness. (Levi Jakšić et al., 2011a)

The productivity paradox detected in the 1950s discovered a new phenomenon: the investments in physical capital were increasing, but the productivity indicators decreasing (Bailey, M. N., Chakrabarti, A. K., 1988, pp.5). The fact that intangible components have been neglected showed that a new perspective and paradigm was necessary. The Japanese management approaches that emphasize the «soft» elements had proved effective and were pouring into Europe (especially Sweden, Germany) in the 1960s and by the mid-1970s in the United States emerged the shift of focus towards intangible assets. Knowledge, creativity, ideas and knowledge based capabilities and skills were found to have been neglected whereas resulting in productivity slowdown while the physical capital investments were still growing. This result pointed out to intangible technology components and knowledge as inevitable in economic growth models (Levi Jakšic, 2011).

The scholars were quick to point to the common denominator for success: a shift away from the factor of physical capital towards knowledge capital, which generally consists of: science, technology, creativity, ideas. (Acs, Z.J., Audretsch, D. B., Strom, R. J, 2009., p. 7) Different forms of knowledge capital alone were obviously not sufficient in creating competitive strength and firm growth. Technology as the integrative concept emerged, consisting of physical/tangible and intangible elements. This opened a new perspective in understanding the forces of competitiveness in the detailed analysis of the factors relevant to technological progress and growth.

The productivity paradox of the sixties has evolved as the Swedish paradox in the last decades of the past century – «as measured by the most common benchmarks of knowledge investments, such as R&D, university research, patents, human capital, education, creativity and culture, Sweden has ranked consistently among world leaders. However, following more than a decade a stagnant growth and rising unemployment, concerned policymakers in Sweden started to worry about what they termed as «the Swedish paradox».(Acs, Z.J., Audretsch, D. B., Strom, R. J, 2009., p. 7) Detecting of the persistent stagnant

economic growth despite high levels of knowledge investments...for the European context, had been termed the European Paradox. (Acs, Z.J., Audretsch, D. B., Strom, R. J, 2009., p. 7)

The new approaches show a clear turnaround focusing on soft elements not only in the form of intangible assets but involving also management principles and practices, entrepreneurship, leadership and emergence of technological rather than technical dimensions at the focus of competitiveness (Levi Jakšić, 2011).

Evidence from the case of Serbia clearly points to the very explicit roles of entrepreneurship that are missing in a country where resources are invested in scientific research but not effectuated in the economy and society. The indicators show that although intensive research in Serbia, when it comes to practical results and commercialization, the R&D phases of innovation lack entrepreneurship. In more detail it is shown that there is very low correspondence between fundamental and applied research. The links between the phases of Research, Development, Commercialization are in need of entrepreneurial cohesion. The entrepreneurship roles are viewed as necessary links to be introduced as follows: Research-Entrepreneurship-Development-Entrepreneurship-Commercialization (Levi Jakšić, 2011).

In the document presented in 2010 by the Ministry of science and technological development of the Republic of Serbia, «Strategy of Scientific and Technological Development of the Republic of Serbia», it is cited that one of the most serious problems of science in Serbia is the fact that a small amount of funds, from mainly one source invested in scientific research are distributed over more than 1 000 projects that were financed by the Ministry in 2009: 501 project of fundamental research for which 50.2% of the budget is allocated and 471 technology development and 129 innovation projects for which 39.2% of the Ministry funds are invested. According to their main definition and goal, the projects of technological development as result are expected to generate applied technological solutions, patents, pilot plants, new sort innovations, technological advancements and results with direct applicability. In the past period, 2003-2007, in the technological development field, over 3400 technical solutions have been realized. But, in spite of the high number of technical solutions, the number of patent applications from research and development institutions in the period of 2003-2009 has been extremely low, only 54. With these results Serbia has the lowest position in Europe.

Serbia is facing the same difficulties as detected for the situation in Europe. ,,The Europe 2020 strategy clearly signalled the importance of industrial competitiveness for growth and jobs as well as for Europe's ability to address grand societal challenges in the coming years. Mastering and deploying Key Enabling Technologies (KETs) in the European Union is central to strengthening Europe's capacity for industrial innovation and the development of new products and services needed to deliver smart, sustainable and inclusive European growth"(HLG on KET Final Report, 2011).

The High-level expert group (HLG) has identified the major difficulties Europe has in translating its ideas into marketable products – in crossing the internationally recognized "valley of death". This situation, namely the gap between basic knowledge generation and the subsequent commercialization of this knowledge in marketable products, has been commonly identified across the KETs and is known in broad terms as the "valley of death" issue. Its effects can include not only relocation of manufacturing and R&D, but also the disruption of entire value chains with their ultimate consequences on the sustainability of various strategic sectors in Europe. The "valley of death" is due to many factors including the absence of smart regulation, the unavailability of pre-commercial R&D support, insufficient access to large scale finance, and lack of political support and pro-active KET. To cross this valley, it recommends a strategy comprising three pillars: a pillar focused on technological research, a product demonstration pillar focused on product development, and a production pillar focused on world-class, advanced manufacturing.

Crossing the "valley of death" in the key enabling technologies in Europe requires the delivery of solutions to the three successive stages implicit in this crossing. The first stage, called "Technological research" consists of taking best advantage of European scientific excellence in transforming the ideas arising from fundamental research into technologies competitive at world level. The second stage, called "Product demonstration" allows the use and exploitation of these KETs to make innovative and performing European process and product prototypes competitive at world level. The third stage, called "Competitive manufacturing" should allow, starting from product prototypes duly validated during the demonstration phase to create and maintain in Europe attractive economic environments in EU regions based on strong eco-systems and globally competitive industries (HLG on KET Final Report, 2011).

Whilst European R&D is generally strong in new KET technologies, the HLG has observed that the transition from ideas arising from basic research to competitive KETs production is the weakest link in European KET

enabled value chains. This is demonstrable evidence of the impact to-date of the absence of a major focus on enabling innovation in the EU and an over-emphasis on basic research both within EU research programs and in some Member States. By focusing on these key stages of the innovation chain, the HLG proposals can trigger a virtuous cycle, from knowledge generation to market flow with feedback from the market to knowledge generation support, thereby strengthening economic development in Europe.

Innovation and opportunity at the base of entrepreneurship is viewed in the perspective of the critical role of institutions in the promotion of innovation defined by national innovation systems, and universities that are cited as critical institutional actors in national innovation systems (Mitra, 2011). The Triple Helix concept is used as the general framework emphasizing the network of institutions in the innovation and entrepreneurship system to be viewed and taken into account in relation to the new roles and responsibilities universities take in the modern world. (Levi Jakšić et al., 2012b) The Triple Helix model does not consider manufacturing as the driving force of economic development in the post-industrial stage. It assumes that the creation and dissemination of socially organized knowledge are playing the key role in creating competitive advantage of an economy. In this sense, institutions that generate knowledge increasingly play a role in the networks of relations among the key actors: University, Industry, and Government. In distinction to the knowledge-based system, which can be considered as an outcome of interaction among different social coordination mechanisms (markets, knowledge production, governance at interfaces), the Triple Helix model gives a heuristic for studying these complex dynamics in relation to developments in the institutional networks among the carriers (Leydesdorff & Meyer, 2006) and those components should generate new institutional and social formats for the production, transfer and application of knowledge. Also, the distinction between these entities and their activities are increasingly overlapping. In areas of intersection, the actors can partially substitute for one another (Ivanova & Leydesdorff, 2012).

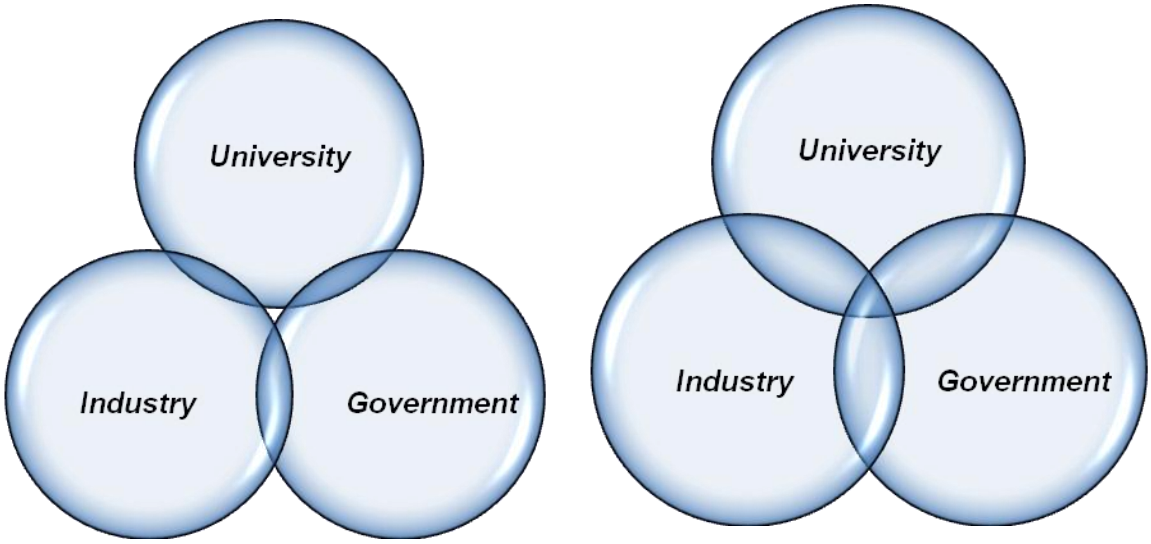

Figure 1: A Triple Helix configuration with negative and positive overlap among the three subsystems (Leydesdorff, 2012b)

The relationship between TH's elements is shown in Figure 1 as alternating between bilateral and trilateral coordination mechanisms or-in institutional terms-spheres. The systems remain in transition because each of the partner institutes also develops its own mission. Because of that, a trade-off can be generated between integration and differentiation, and new systems in terms of possible synergies can be explored and potentially shaped (Leydesdorff, 2012b). TH does not use only economic forces (*Industry*), regulations given by *Government* or research inventions performed by *Universities:* it can combine these categories and focus on examining the dynamics two or even all three components.

TH models can be elaborated in various directions. Networks of university-industry-government relations can be considered as arrangements which can be made the subject of social network analysis. This model can also be used for policy advice about network development, for example in the case of transfer of knowledge and the incubation of new industry. The new role of universities in knowledge-based configurations is the most explored topic among the three TH components, and it can be explored in terms of different sectors, regions, countries etc. (Godin & Gingras, 2000; Shinn, 2002). In some previous research studies (Levi Jakšić et al., 2012a), the thesis was confirmed that there is a constant need to research the universities' role in society, especially the one in practice and compatibility of the practical knowledge with current study programs at different educational levels.

In the TH system, universities have the leading role and this concept assumes that the knowledge universities produce is useful enough to be widely shared and applied, which should lead to national development. Industry operates in the Triple Helix as the place of production, government has the task to create contractual relations that will guarantee stable interactions and exchange, and in the end, the university is the source of new knowledge and technology, the generative principle of knowledge-based economies (The Triple Helix Concept - Theoretical Framework, 2011). The boundary between institutional spheres is blurred, because universities assume entrepreneurial roles by focusing on the production of useful knowledge and its exchange across a wider network of key players in socio-economic system. Also, industry should not only use practical appliance of knowledge, but also producing knowledge with a purpose of creating a wealth. And, finally, government has the task to facilitate interactions of industry and universities by creating policy frameworks for successful functioning of this cooperation. In developing countries, the challenge is to operationalise the TH system in order to provide sustainable basis for wealth creation and poverty reduction (Saad & Zawdie, 2011). Because of that, it is necessary to have some measures and indicators which will show the performance of a country within each TH area. In this paper, we develop a general model that examines all three components of the TH concept, and further research focuses on each component separately.

3. CROSS-FUNCTIONAL TIM MODEL

Technology and Innovation management implies: planning, organizing, leading, directing, organizing, coordinating and controlling all technology activities (operations) with the ultimate goal of providing continuous success (profitability, market share, environmental protection etc.). It includes all technological activities, strategic ones, related to management of technology development, through management of innovation, technology transfer, R&D activities and operational ones including managing a specific technology system, processes and operations as the form of implemented technology. (Levi Jakšić et al., 2011b) TIM, as specific set of competencies in the competency based competitiveness approach, is recognized as the critical success factor for firms, sectors, economies and regions. The integral TIM concept is focused at managing technology as external force and internal factor of the firm meaning that both the innovative and technological infrastructure and the technology and innovative capacities of the firm are taken into account. Managing technological diversification is a significant dimension of the new paradigm leading to operations competitiveness of the firm closely related to its innovative capabilities. (Levi Jakšić et al., 2012a)

In the previous section, it was postulated that the original TH model considers three entities represented in Figure 1. However, in some previous research (Levi Jakšić et al., 2012b), the authors concluded that for the relevant analysis of universities' impact in the economy, society and economic development it is necessary to introduce an extended Triple Helix model with an additional, fourth component - knowledge and science development (**Figure 2**). Its necessity derives from the interrelation between the dynamic category of science and knowledge development results and industry/economy/society sustainable needs with the government special roles in creating policies and funding research and development as well as educational and entrepreneurial activities in the economy and society. This new component influences the development of study programs which have the task to quickly respond to the latest environmental requirements by introducing the latest scientific results and findings in the study programs. In this paper, we examine measuring performance of TIM indicators based on the original TH model, but further research should include the science component, as well, because of its influence and a special role it plays in each of the traditional components of the TH model.

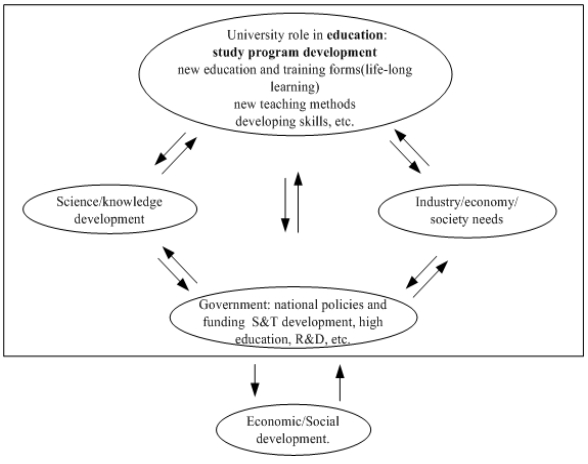

Figure 2: Study program development, Triple Helix and economic development. (Levi Jakšić et al., 2012)

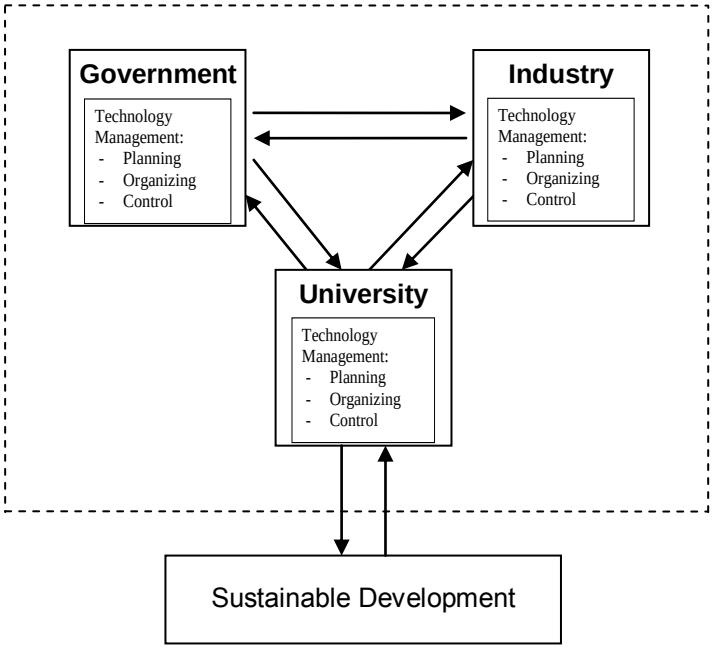
Figure 3 shows the basic cross-functional TIM model, developed from the perspective of the Triple Helix (TH) concept and basic technology management functions. Firstly we have three separate TH entities: Government, Industry and University. Within each of the dimension we measure how successful the entity is in managing technology by evaluating its performance in each management function: planning, organizing and control. In this way, it is possible to view the current state, set the priorities within each category and to determine tasks that have to be performed in order to enhance sustainability based on prioritized actions in



certain areas. All these dimensions determine sustainable development, and by using the established model the relevant feedback is possible for effective decision making.

Figure 3: General cross-functional model

At a closer look at the model (**Figure 4**), we can examine in more detail the performance of technology management. Within each TH dimension, performance indicators are divided by basic management functions: planning, organizing and control. Planning activities and indicators are considered as inputs. These indicators measure infrastructure, investments and all other assets that are necessary to execute the main tasks and to achieve the results of the entity. Organizing performance is observed as a process that is transforming inputs (results of planning activities) into outputs..

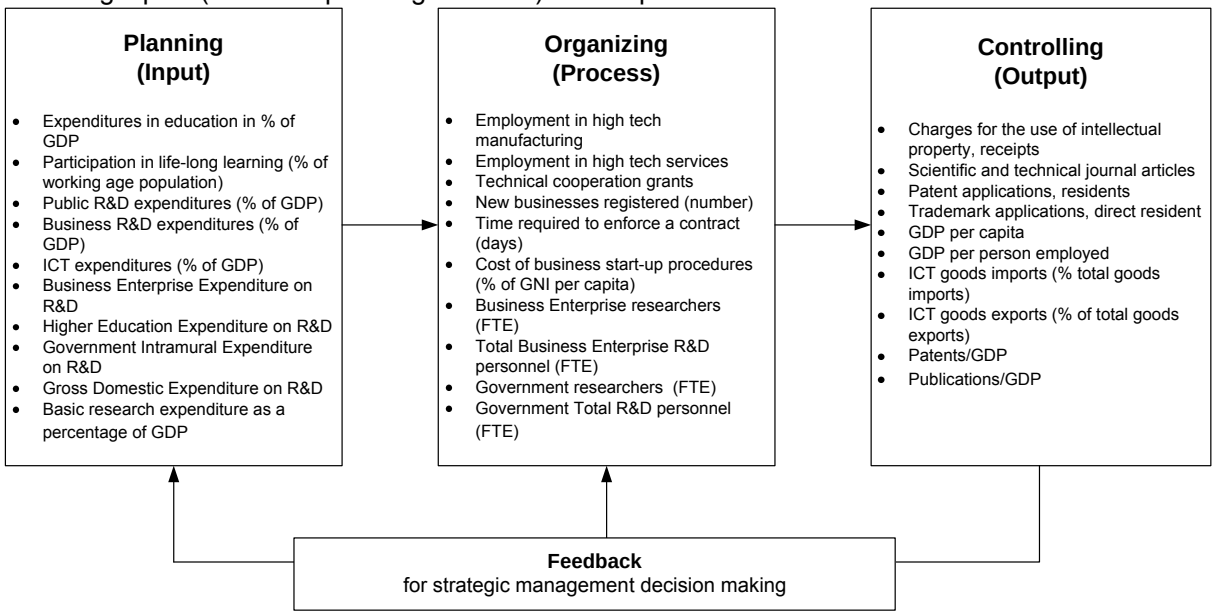


Figure 4: Technology Management Model[1]

[1] Indicators taken from (World Bank Indicators, 2014;EIS Indicators, 2009; Eurostat Indicators, 2014; OECD Indicators, 2014)

And, at the end, control is considered as the result of inputs (planning) and transformation in process of organizing. The control indicators are related to measuring the results of investing and managing (i.e. no. of patents, published papers etc.). These results are providing the feedback which is crucial for further decision making process related to achieving more in the level of sustainability. It should be noted that it is very difficult to separate indicators by these two dimensions (TH and TIM functions), and some overlapping and, the so-called "grey zones" are inevitable (as shown in **Figure 1**), especially in control activities, which are outcomes, the results that cannot be easily assigned to a category. In this case indicators would be repeated and classified in more than one category.

The model is decomposed for each TH component, and each component consists of its own indicators of TIM performance as shown in **Figure 5**.

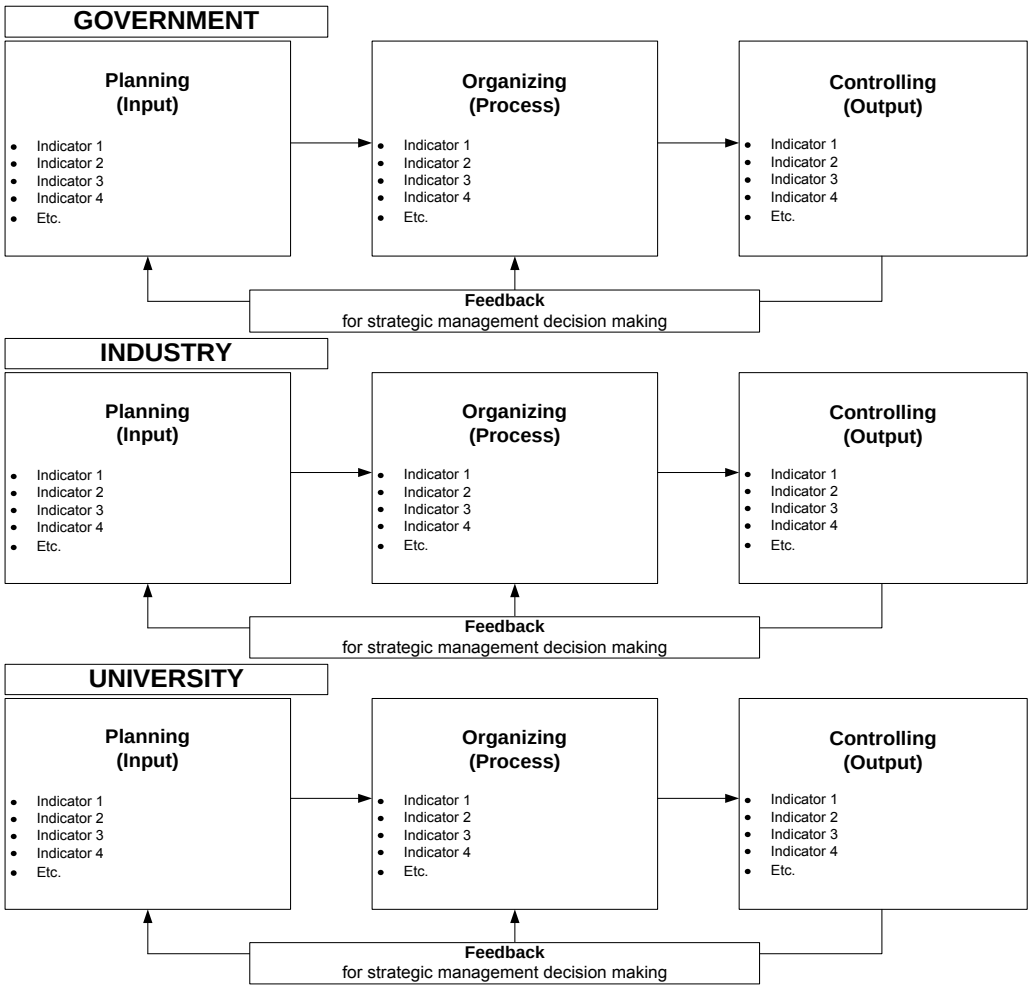

Figure 5: Developed sub-models of TIM model for each TH component

This model not only presents and classifies indicators, but it also highlights the connections that exist between these groups of indicators. At the end, the general model presents a framework for measuring performance of TH entities in TIM at the level of a national economy. It should be noted that the set of indicators may not be the same for each country, because of the specificity of each environment, but the majority will be applicable in most cases. In the general model presented in Fig. 5, the indicators are not specified and it should be noted that they need to be separated by TH components. Every component is to be examined separately and indicators for each management function should be defined. The indicators are developed according to the following criteria: easy measurable, accurate and the relevant data available. The model presented in Figure 4 consists of indicators measured by Eurostat, European Innovation Scoreboard (EIS) World Bank, OECD and similar organizations which provide relevant data and further research, considering identifying indicators for each TH component, and each management functions, would necessarily rely on these sources.

4. CONCLUSION

In the highly competitive global environment, with interminable and accelerating technological growth and development the necessity for technology management is not questionable (White & Bruton, 2007) Technology provides competitive advantage and is the crucial dimension in government, firm, industry, regional, and other, strategies. Levi Jakšić et al. 2011 state that, theoretically and in practice, it has been discovered that there is a missing component in acquiring economic growth with new employment opportunities and technological development. The missing link is the management of innovation and technology and technological entrepreneurship. It is crucial to enable scientific and technological developments oriented at creating new value in the economy and society. Efforts at achieving the efficient transition of science into new technologies and new technology into new value are the main task of effective TIM. In this effort, all the players within the TH model are significant as the TH notes the network of actors in the innovation and entrepreneurship system to be viewed and taken into account. The TH concept underlines the role of university in new, modern, knowledge-based economy. It also inspects the relations among the three components of a knowledge-based economy: (1) the knowledge-producing sector (University), (2) the market (Industry), and (3) Governments (Cooke & Leydesdorff, 2006).

In this paper we develop a general cross-functional model for measuring TIM performance of a national economy, from a TH perspective, creating separate sub-models for each TH component. This general model with the relevant indicators represents a base for measuring and monitoring how successful a national economy is in managing technology. All the basic management functions in TIM are evaluated (POC) enabling specific tracking of their performance coupled with the analysis of the contribution of each TH dimension in the specific performance of TIM. The complete analysis performed after the model is applied in concrete, real world situation, is the necessary tool for setting priorities and achieving better results in fulfilling the relevant goals of sustainable development: economic, social, environmental. In this paper, a list of the indicators is proposed based on the material provided by the World Bank and OECD, but the list is not closed and still needs to be extended and classified for each component of the TH model. It is planned that the general model as well as the sub-models be tested in a concrete situation, starting from the concrete results for Serbia and further to compare the situation with the countries in the region, as well as with the developed countries. This would enable a complete picture to be established with the cause and effect relationships more clear and leading to more precise and targeted policies and strategy with effective and sustainable TIM achieving sustainable development.

Abstract: *This paper analyses the role of the state/government as one element of the Triple Helix model, and its role in Technology and Innovation Management (TIM). In order to observe the results of the measures and actions taken by the government, specifically related to the management of technology and innovation, a model was created based on selected quantitative indicators and indices. The model is developed for measuring and monitoring the performance in TIM, where we: first, classified the indicators according to the three basic management functions – planning organizing and control, observed as input, process and output, respectively; and second, show the relations that exist between these three categories of indicators. Planning indicators are observed as the investments in technological and innovative activities; Organizing indicators include the infrastructure, public administration efficiency and cooperation support, while control indicators refer to the national economy R&D and technology transfer effects and entrepreneurship outcomes. The model is tested based on the indicators for the Republic of Serbia. It is shown that the model is applicable in real world situations as, a useful tool to: 1) analyse the dynamics and changes that occur, 2) notice the interactions between functions of TIM, and 3) use the feedback as support in strategic TIM decision making of a national economy.*

Keywords*: Triple Helix, Technology and Innovation Management, State/Government, Performance, Serbia.*

1. INTRODUCTION

Contemporary management literature and practice recognize technology and innovation management (TIM) as critical success factor for firms, sectors, economies and regions. There is high evidence of steep rise in the development of the scientific field of technology management (Cunningham, 2011) corresponding to the practical needs of managing technology as the fundamental source of competitive advantage of firms and economies (Eskandari et al., 2007). Technological innovations in areas such as materials, electronics, aerospace, computers, telecommunications and biotechnology have influenced the rising dominant forces in the world economy. Yet, there are serious concerns about "our effectiveness in generating and exploiting technology" (Mallick & Chaudhury, 2000). The integral technology management concept is focused on managing technology as external force and internal factor of the firm, meaning that both the innovative and technological infrastructure and the technology and innovative capacities of the firm are taken into account (Levi Jaksic et al., 2012). The main institutions and actors in technology and innovation management process (at macro and micro level) can be identified as university, industry and government - the same elements that are recognized in the Triple Helix concept.

The concept of the Triple Helix (TH) was proposed by Etzkowitz and Leydesdorff in 1990s and today it is still developing through theoretical and empirical research. "The Triple Helix thesis is that the potential for innovation and economic development in a Knowledge Society lies in a more prominent role for the university and in the hybridization of elements from university, industry and government to generate new institutional and social formats for the production, transfer and application of knowledge" (Ranga & Etzkowitz, 2013). University-industry-government relations develop in terms of institutional arrangements that recombine three functions of the socio-economic system: (1) wealth generation and retention, (2) novelty production, and (3) control at the interfaces of these sub-dynamics (Leydesdorff, 2006). Overlap among governments, enterprises and universities, is the core of an innovation system. Interaction among these three players is important determinant of knowledge production and dissemination. During this process, active interaction among these three players promotes the rising spiral of innovation (Rao et al., 2012).

In recent decades, federal, state and local governments have created a variety of mechanisms to encourage knowledge-based economic development (Etzkowitz, 2002). The structure of national R&D system can be examined through the use of a Triple Helix framework that studies the relations among academia, business, and government (Etzkowitz, 2008). Development of a knowledge base is dependent on the condition that knowledge production be socially organized. The interfaces between institutions and functions can be

expected to resonate into co-evolutions in some configurations more than in others (Leydesdorff, 2006). This confirms the relevance of studying country specific university-industry-government configurations (see for example Rao, 2012; Park & Leydesdorff, 2010). Also, each element of Triple Helix could be examined, putting in the context of technology and innovation management and country competitive position.

In this paper, we analyse one aspect of the Triple Helix model – the government sector, and develop a model for measuring and monitoring government performance in technology and innovation management (TIM). We classify TIM performance indicators (of the government sector) into three basic management functions: planning, organizing and control (POC). Since we observe these management functions as input, process and output (respectively), and present indicators for their measurement, we are able to: (1) analyse if there is a correlation between these three functions of TIM and (2) see which function is "ahead" of the others and which one "lags behind", which enables us to determine the weaknesses of government sector performance in TIM. The model is tested and applied in a real world situation, with indicators taken for Serbia.

This paper is organized as follows: Section 2 explains the government role in the Triple Helix model, and observes ways of measuring government performance; in Section 3, a model for measuring and monitoring government performance in TIM is presented; in Section 4 the model is applied in the real situation of Serbia, and Section 5 concludes the paper.

2. GOVERNMENT IN THE TRIPLE HELIX MODEL

The neo (institutional) perspective distinguishes three main configurations in the positioning of Triple Helix (TH) elements. (Ranga & Etzkowitz, 2013) In **statists' configuration**, government plays the leading role, driving academia and industry, but also limiting their capacity to initiate and develop innovative transformations. These examples could be found in Russia, China, Some Latin American and Eastern European countries. **Laissez-faire configuration** us characterized by a limited government intervention in the economy (US, some Western Europe countries), with industry as the driving force and university with limited role in innovation, acting mainly as a provider. Government in laissez-faire configuration is also limited, acting as a regulator of social and economic mechanisms. The Knowledge Society is characterized by **balanced configuration** where universities and other knowledge institutions act in partnership with industry and government and even take the lead in joint initiatives (Etzkowitz & Leydesdorff, 2000). There has been a shift from the model of the state encompassing industry and academia. Development strategies, whether based primarily on the industrial sector as in the US or the governmental sector as in Latin America, are being supplemented, if not replaced, by knowledge-based economic development strategies, drawing upon resources from the three spheres of Triple Helix (Etzkowitz, 2002).

2.1. Measuring government performance

Building knowledge based economy and society in the traditional sense and as defined by traditional indicators is not sufficient enough for substantial economic and social progress and development. Theoretically and in practice it has been discovered that, despite the undoubtedly central role of investments in new knowledge in economic growth, there is still a neglected, missing link to economic growth, employment opportunities and international competitiveness (Levi Jaksic et al., 2011).

Traditional performance measurement systems have concentrated on development of indicators largely relating to economy (inputs) and efficiency (costs) due to the limited ability to measure effectiveness or outcomes in government organizations (Kloot and Martin, 2000). Although government is not, neither the supply, nor in most cases, the demand side of new knowledge and new technologies, it can promote effective enterprise-university interaction in order to facilitate university technology transfer by institutional arrangements, policy making and so on (Rao et al, 2012).

According to Rao et al. (2012) there are two aspects of government R&D investments: one is government R&D funding which indirectly promotes university patent technology transfer activities by supporting teaching and research activities; the other is specialized government R&D programs (foundation) which directly support university patent technology transfer activities. Thus, based on triple helix theory, government R&D investments, including government R&D funding and government R&D programs, can influence university patent technology transfer activities (Rao et al., 2012). It was shown (Chang-Yang, 2011) that it is difficult to evaluate the aggregate effect of public R&D support. The author found out that there are different effects of public R&D support on firm R&D, depending on various firm- or industry-specific characteristics. Four potential channels are identified: the technological-competence-enhancing effect, the demand-creating effect, the R&D-cost-reducing effect and the (project) overlap (or duplication) effect.

The study (Caerteling et al. 2013) showed that government championship is an important positive factor for the performance of technology development projects. Government championing has more impact than

government financial/technical assistance on both project performance and benefits to customers. Implications for practice were identified as: from a policy perspective, government should extend its technology policies by taking on the role as a champion, while companies should invest in building professional relations with champions in government. Despite the general growth of government R&D funding, R&D is potentially an area of government spending that is perhaps the most vulnerable to a budgetary cut in economic downturns. There are cross-national differences in government R&D funding in times of economic hardship (Kim, 2013). Strategic performance management demands an approach that is oriented at financial measures, but also at community concern and long-term development. The framework that presents strategic and balanced local government performance management is presented in Table 1 (Kloot and Martin, 2000).

Table 1: Choice in Local Government Performance Management (Kloot & Martin, 2000, p. 248)

Traditional Approach	vs.	Performance-oriented Approach
Top-down State Government and council-imposed, control-oriented performance management.	vs.	Strategic, collaborative, development of a performance management system involving all stakeholders.
Imposition of universal, industry-wide measures with less validity for specific council.	vs.	In-house development of valid, council specific measures to be used for organizational improvement and benchmarking with like councils.
Periodic reporting for the purpose of meeting control requirements of senior management, councillors and State Government.	vs.	Real-time up-to-date performance information for all stakeholders to monitor progress, demonstrate accountability and manage outcomes.
Piecemeal, myopic approach with a focus on the measurement process.	vs.	Integrated performance management system across the organization focused on value-for-money service delivery and organizational improvement.
Focus on financial measures only.	vs.	Focus on financial and non-financial measures: a results and determinants approach.

Investments in science and technology (S&T) are not the privilege of developed countries. According to Kim (2013) there is much to discover and learn from the experiences of non-OECD countries; in the recent years R&D funding in the developing world, especially countries such as Brazil, Russia, India and China, have been soaring, defying the predictions based on their economic and social levels of development. Political leaders in these countries promote S&T heavily as a springboard to move their nation forward in the increasingly knowledge-intensive economy of the 21st century.

3. A MODEL FOR MEASURING AND MONITORING GOVERNMENT PERFORMANCE IN TECHNOLOGY AND INNOVATION MANAGMENT

There are multiple indicators focused on measuring outputs at the level of industry, academia and government, independent of each other and much less systematic approaches in monitoring influences of outputs of industry, university and government to outcomes (effectiveness) (Singer & Peterka, 2012). In this paper we analyse one aspect of the Triple Helix, the government performance in TIM, and develop a model for its measurement and monitoring. The created model, in which government TIM performance indicators are classified into three crucial management functions – POC, is presented in Figure 1. We observe these three management functions also as three categories of indicators as: input, process and output, respectively.

As planning (input) indicators of government performance in TIM, we identified nine indicators, which refer to the *Investments* in technological and innovative activities of a country. These indicators are: R&D expenditures (% of GDP), Gross Domestic Expenditure on R&D - GERD (% of GDP), Government Intramural Expenditure on R&D - GOVERD (% of GDP), ICT expenditures (% of GDP), Basic research expenditure (% of GDP), Applied research expenditure (% of GDP), Experimental development expenditure (% of GDP), Government expenditure for new ventures/subsidies for new ventures (% of GDP) and Total investments in equipment (% of GDP).

Organizing (process) indicators of government performance in TIM refer to: *Infrastructure*, *Public administration efficiency* and *Cooperation support*. We identified eighteen organizing indicators: (1) nine infrastructure indicators (Government total R&D personnel (FTE), R&D organizations – government sector (number), Internet users (per 100 people), Fixed-telephone subscriptions (per 100 people), Mobile-cellular subscriptions (per 100 people), Personal computers (per 100 people), Electric power consumption (kWh per capita), Science and engineering graduates (% 20-29 population) and Population with 3rd level education); (2) eight public administration efficiency indicators (Time required to enforce a contract (days), Procedures to enforce a contract (number), Time required to register property (days), Procedures to register property (number), Cost of business start-up procedures (% of GNI per capita), Time required to start a business (days), Start-up procedures to register a business (number) and Time to prepare and pay taxes (hours); and (3) one Cooperation support indicator (Technical cooperation grants (BoP, current US$)).

We also identified twelve control (output) indicators of government performance in TIM and classified them into three main groups: *R&D results*, *Technology transfer results* and *Entrepreneurship results*. R&D results indicators refer to the patent activity of a country (Patent applications - resident, EPO patent applications (per million population) and USPTO patent grants (per million population)) and publishing activity (Number of scientific and technical journal articles). Technology transfer results include following indicators: Charges for the use of intellectual property, payments (BoP, current US$), Charges for the use of intellectual property, receipts (BoP, current US$), ICT goods imports (% total goods imports), ICT goods exports (% of total goods exports) and ICT service exports (% of total service exports). Entrepreneurship results are measured through the following three indicators: Number of new ventures (SMEs) with government support, New business density (new registrations per 1,000 people ages 15-64) and New businesses registered (number).

The model consists of thirty-nine indicators of government performance in TIM, classified into three main categories: planning (input), organizing (process) and control (output). The idea of the model is not only to present and classify indicators, but also to highlight the connections that exist between these categories of indicators. Planning indicators are seen as an input in technological and innovative activities of a county, measured through different indicators of investments in R&D and an indicator of government support for new ventures. The idea is to see if these investments are correlated with the Control (output) indicators, which refer to the patent and publishing activity of a country, results of technology transfer and entrepreneurship outcome. As the middle part of this model, which enables transformation of the observed inputs into outputs, we see the organizing (process) indicators which refer to technological and innovative infrastructure, public administration efficiency and cooperation support. The fourth element of the model is the feedback (from control to organizing and control to planning) which helps in making strategic management decisions in the area of TIM at the level of national economy.

Therefore, it is evident that this model presents a framework for measuring government performance in TIM that can be tested in any country. When applying this model, it is possible to include only the indicators that rest upon available data at a country level, so the next step was to make a choice of only those indicators from this list that were available and accessible (through large internet databases such as World bank, OECD, UNDP, UNdata and through the country's Statistical Office) for Serbia.

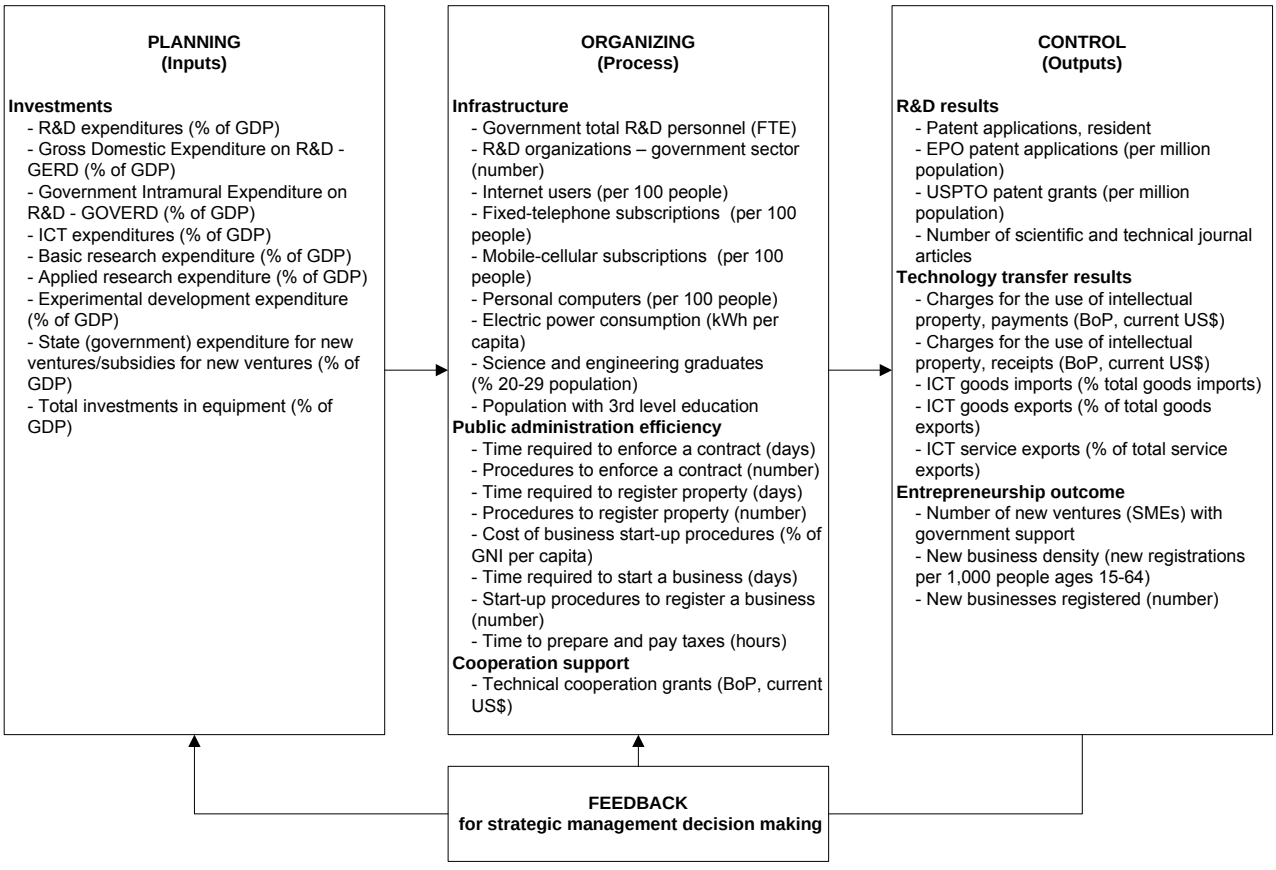

Figure 1: Model for measuring and monitoring government performance in TIM

4. APPLICATION OF THE MODEL WITH INDICATORS FOR SERBIA, RESULTS AND DISCUSSION

In this section we present an application of the created model in the case of Serbia. Thirty-one out of thirty-nine identified government performance indicators in TIM are measured at the country level. Data were collected from different sources: World Bank (2014), UNDP (2014), UNdata (2014), Statistical Office of the Republic of Serbia (2014) and European Commission – ERAWATCH country report – Serbia (2014). Lack of the available data for Serbia is the reason why eight indicators are excluded from this analysis.

In Table 2 we present the analysis of the government performance in TIM for the Republic of Serbia during the period 2008-2011. Column 2 presents the measured indicators of government performance in TIM. Column 3 presents the data source for indicators in Column 2. Columns 4-7 refer to the values of indicators for each year the observed period of time. Columns 8-10 present the indices of change (*IC*) over years, calculated as follows:

$$IC_{\frac{c}{p}} = \frac{Value_c - Value_p}{Value_p} \quad (1)$$

where *c* presents the current year and *p* the previous one. But, this equitation has to be applied with caution, because sometimes increase in value of an indicator over a two-year period has a negative influence on TIM (and vice versa – negative value has a positive influence), so we have to use the opposite value of IC in order to get valuable total result. For example, if we observe Table 2, $IC_{2011/10}$ for the indicator *Time required to register property (days)* is negative because value of this indicator decreased from 91 in 2010 to 11 in 2011 ((11-91/91) = - 0.87912), which is actually a positive phenomenon, so we have to use the opposite value for this IC. This is why this $IC_{2011/10}$ has a positive value of 0.87912. ICs with "opposite" values are marked with a sign * in the table.

Table 2: Indicators of government performance in TIM for the Republic of Serbia, period 2008-2011

						TOTAL CHANGE	**0.2073**	**-0.0209**	**-0.0042**

Based on the calculated ICs for the observed indicators, we calculated ICs for input, process and output. These ICs represent the average values of ICs of the indicators included in each of these three groups. Then, the IC of total change over a two-year period is obtained as the average value of the ICs for input, process and output. In our research, we analyze the following changes: 2009/08, 2010/09 and 2011/10.

2009/08: Planning (input) indicators, which refer to the investments in technological and innovative activities, oscillate during the observed period of time. $IC_{2009/08}$ equals 0.7687 which indicates that great efforts are made at the country level, as far as investing is concerned. The reason why this happened is that, comparing with 2008, in 2009 R&D expenditures increased almost 3 times (reaching almost 1% of GDP – which is the highest value of the observed period). Basic research expenditure, applied research expenditure and experimental development expenditure also increased more than two times. This shows that a good basis for great results is formed, as far as we observe the input indicators. But, it is interesting to see what actually happens at the output side of the model represented by the Control indicators. Before that, if we observe the Organizing (process) indicators, $IC_{2009/08}$ equals -0.1761. Infrastructure is slightly improved ($IC_{2009/08 =}$ 0.0203) and Public administration efficiency also ($IC_{2009/08}$ = 0.10803), but Cooperation support decreased dramatically, resulting in $IC_{2009/08}$ = -0.65658, which caused Organizing change to be negative. But, it is

encouraging to note that for Control (output) indicators, $IC_{2009/08}$ has a positive value of 0.0293. However, this is not a very good result if we observe the IC for the input indicators. Nevertheless, we know that, regarding technological and innovative activities, input cannot be immediately translated into output, so we expect this positive change to be seen in the following years. Total $IC_{2009/08}$ equals 0.2073, which is a good total result that indicates positive movements in government performance in TIM in Serbia.

2010/09: Input indicators' $IC_{2010/09}$ equals -0.0487 which is a bad result, compared to the previous one ($IC_{2009/08}$ = 0.7687). Investments stayed almost at the same level in 2010 as in 2009, excluding R&D expenditures, GERD, Applied research expenditure and Total investments in equipment, which decreased over these 2 years. Organizing (process) indicators improved - $IC_{2010/09}$ = 0.0578. This is a slight improvement that occurred because of the positive changes in all three groups that it includes (Infrastructure: $IC_{2010/09}$ = 0.0152; Public administration efficiency: $IC_{2010/09}$ = 0.00844; Cooperation support: $IC_{2010/09}$ = 0.1497). At the output side we have a worrying result: Control $IC_{2010/09}$ = -0.07165. This is a result of the decrease in all categories of output: R&D results $IC_{2010/09}$ = -0.04857; Technological transfer results $IC_{2010/09}$ = -0.12006; Entrepreneurship outcome $IC_{2010/09}$ = -0.04633, which indicated that technological and innovative activities were not fertile: inputs are not being transformed into outputs at a satisfying rate. Total change, as it is expected to be, is negative: Total $IC_{2010/09}$ equals -0.0209, which is much worse than the previous 2-year period when total $IC_{2009/08}$ was 0.2073.

2011/10: On first glance it is clear when looking at Table 2, that the results are better than in 2010/09. Planning indicators $IC_{2011/10}$ equals 0.0259. This is only a slight improvement, which has not yet reached the great results from 2009/08. Anyhow, a positive tendency is good to be captured. These results are a consequence of: 1. increased investments in applied research and equipment, and 2.keeping values of all other indicators at the same level in 2011 as in 2010. Organizing indicators also improved: $IC_{2011/10}$ = 0.0142 (Infrastructure: $IC_{2011/10}$ = 0.0092; Public administration efficiency: $IC_{2011/10}$ = 0.11147; Cooperation support: $IC_{2011/10}$ = -0.07822). But, on the output side, we notice the decline again – Control $IC_{2011/10}$ = -0.05276. R&D results and Entrepreneurship outcome declined ($IC_{2011/10}$ equals -0.14512 and -0.10886, respectively), while only Technology transfer results were better: $IC_{2011/10}$ = 0.095685, mainly because the increase in Charges for the use of intellectual property (both payments and receipts). Total $IC_{2011/10}$ = -0.0042, which indicates to the negative trend in government performance in TIM.

Trends of changes of ICs for the Input, Process, Output and the Total ICs changes for the observed period are shown on Figure 2.

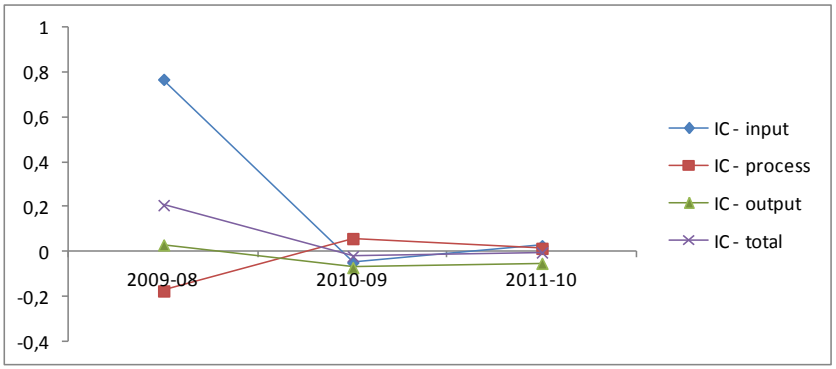

Figure 2: Trends of ICs of government performance in TIM (input, process, output, total) for the Republic of Serbia, period 2008-2011

5. CONCLUSION

Government as an important player and an element of the Triple Helix model, creates collaborative R&D projects and the necessary links among other elements, investing in development in different fields, regions and at different levels of a country. It is the key element in enhancing knowledge based economy that is largely based on efficient and effective technology and innovation management. Although government R&D investments could be vulnerable to a budgetary cut in times of economic difficulties, they are always present as incentives for the development of economy and society. Inputs, processes and outputs of government activity in Technology and innovation management are important to measure and analyse in order to determine correlations, achievements and weaknesses, as indicators relevant for the future activities and decisions. It is important to note that, by using the model developed in this paper, government impact in all three relevant spheres can be tracked, monitored and analysed for quick responding action with policies and strategy well adapted to the concrete TIM performance in practice.

In this paper, government performance in TIM is analysed and a model is created for its measurement and monitoring. One of the attributes of the model is its balanced structure enabling a systematic approach to the broad body of indicators already in use, oriented at better understanding the specific and most relevant role of the government in creating the innovative environment for supporting the basic technology and innovation management functions. In the model we classified the identified government TIM performance indicators into categories related to the three basic management functions - POC, also observed as the input, process and output, respectively, and show the relations that exist between these categories of indicators. Planning indicators refer to the investments in technological and innovative activities; organizing indicators refer to the technological and innovative Infrastructure, public administration efficiency and cooperation support, while control indicators refer to the country's R&D results, technology transfer results and entrepreneurship outcomes. Each of these categories and groups refer to the specific government TIM performance indicators, which are accessible in large internet databases such as the World Bank, OECD, UNdata, UNDP, and in the observed country's Statistical Office. In addition, we tested the created model in the case of the Republic of Serbia and have shown how the collected data can be analysed in order to measure changes, notice the interactions between the elements of the model and use the feedback as a support in making strategic management decisions in the area of TIM at the country level.

Nevertheless, this is not the final list of government performance indicators in TIM. This is the first attempt of the authors to create a systematic list of these indicators, which has to be re-examined, and potentially spread with more government performance indicators, which will be the subject of the authors' future research. The authors will also conduct further research of the other two components of the Triple Helix: University and Industry. This is necessary to complete the broader picture of the contribution and results of Triple Helix players in TIM at the national economy levels.

[3]University of Belgrade, Institute Mihajlo Pupin, lazar.zivkovic@pupin.rs

Abstract: *Over the past few decades knowledge-based development and innovation are recognized as an engine of the economy development. This created revolution in R&D activities and economy. In this paper the authors highlighted the importance of innovation for restructuring economies of Western Balkan countries. The results indicate that drivers of innovation in Western Balkan countries are generally less powerful than those in EU countries. Authors also presented policy measures that can be successfully implemented in order to improve communication between various stakeholders in the innovation process.*

Keywords*: innovation, innovation process, Western Balkan countries (WBC), mechanism for fostering innovation, small and medium sized enterprise (SME)*

1. INTRODUCTION

The core of the continuous innovation process is the commercialization of Research and Development (R&D) results. This means transforming an invention into product or service that will be sold on the market and provide return for the investor. Generally speaking, innovation potential of a country is determined by R&D activities, human resources engaged in them, institutions and regulations and use of information and communication technologies.

Innovation is important on different levels and for different reasons. On a country level, innovation is important as an engine of economic growth. It increases human wellbeing and employment. For companies, innovation improves productivity, enables development and shareholder return.

The data presented in this paper provide evidence of existing huge differences in innovation capacity of developing and developed countries. Developing countries still lag behind developed countries when it comes to number of researchers, R&D expenditures, number of scientific articles and patents, etc. This is the fact that restricts the scope of innovations available for commercialization.

Developing countries also have limited efficiency in the process of commercialization of R&D results. Lack of interaction between science and industry is major limitation of innovation process. Encouraging technology transfer from faculties to private companies is a strategy used by many countries in order to mitigate constraints of innovation process. Policy measures presented in this paper are being implemented with that purpose.

2. INNOVATION AS A KEY FACTOR OF ECONOMIC DEVELOPMENT IN MODERN SOCIETY

In the last few decades innovations have been identified as crucial driver of economic and social development. Theory of innovation was developed by Joseph Schumpeter during the 1940s and after that many authors began to explore this phenomenon. Many studies have showed that innovation has main role in acquiring comparative advantage in the individual company, as well as in the macro economy.

In a general case, "*there are only two ways of increasing the output of the economy: (1) you can increase the number of inputs that go into the productive process, or (2) if you are clever, you can think of new ways in which you can get more output from the same number of inputs"* (Rosenberg, 2004). Increasing productivity of the economy is a key for raising living standard. This productivity growth can enable rising wages of workers and increasing national per capita income. Innovation is essential for increasing productivity. In the long term, no economy can be competitive by just increasing inputs. The best way to raise living standard is to find new methods for combining natural, human and capital resources and increase productivity.

Innovation consists of the purposeful search for changes and the opportunities that such changes might offer (Drucker,1985). Innovation includes making change, creating new ideas and new opportunities. It is important to note that innovation and entrepreneurship are closely connected, so innovation is one of the instruments of entrepreneurship.

Joseph Schumpeter argued that economic development is driven by innovation through a dynamic process in which new technologies replace the old, a process he labeled “creative destruction”. In Schumpeter’s view, “radical” innovations create major disruptive changes, whereas “incremental” innovations continuously advance the process of change. Schumpeter proposed a list of five types of innovations: introduction of new products, introduction of new methods of production, opening of new markets, development of new sources of supply for raw materials or other inputs, creation of new market structures in an industry (OECD 2005).

An innovation is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations (OECD, 2005).This understanding is quite broad and includes not only the development of new technologies, but also improvements in business practices, relationships and organizations.

There are many studies explaining relationship between innovation and economic development and growth. Neoclassical economists treat innovation as key factor contributing to economic progress and long-term convergence (Fagerberg, 1994). Supporters of endogenous growth theory argue that differences in innovation potential create variations in economic performance and wealth of the nations. They also devote attention to the place of international trade in the growth process, including the transmission of innovations from the industrial economies to the less developed countries (Grossman & Helpman, 1991). However, it is important to take into account social and institutional perspective of an economy. In a study by Rodriguez-Pose and Crescenzi (2008) is shown how regional innovation capacity is shaped in interaction between R&D sector, economic, social and institutional sector.

Innovation has become extremely important factor in productivity growth. According to Boston Consulting Group, relative importance of innovation to labour and capital has been growing over time. This rate is especially high from the 1990s (The Economist, 2007).

Today, innovation is facing new challenges on global, national and organizational level. Innovative capacity is created in interaction between research, education and innovation. Perhaps the most important obstacle to innovation and commercialization of R&D results in insufficient collaboration between scientific and corporate sector. Industry and science relations have to be stronger to ensure that R&D activities anticipate market needs. Measures of encouraging university entrepreneurship can also help in fostering innovation activities in the economy.

3. POTENTIAL FOR INNOVATION IN DEVELOPING COUNTRIES

During the 2000s indicators that foster innovation in Western Balkan Countries (WBC) were generally less advanced than those in developed market economies. Although many developing countries have well-educated labour forces and good tradition of scientific research, many of them cannot compete with developed countries. In the following tables WBC are compared with selected EU countries using various indicators of science and innovation activities.

Number of researchers per million inhabitants from 2005-2011 in WBC varied widely across countries (Table 1). While in Croatia number of researchers was 1584, in Albania was only 148. These numbers are much lower than in selected EU member states in which average number of researchers was 2329,29. Countries members of EU-15 have much higher number of researchers per million people which indicates that WBC as well as new EU member states have to include more people in R&D activities in order to catch-up with developed countries.

Number of scientific and technical journal articles includes articles published in the following fields: physics, biology, chemistry, mathematics, clinical medicine, biomedical research, engineering and technology, and earth and space sciences. It is mainly in correlation with previous indicator in terms that countries with higher number of researchers have more scientific papers. Of course, this is not always a rule. For example, Slovenia and Bulgaria have more researchers than Serbia and Croatia, but have less scientific journal articles. However, these data should be considered with caution. The number of scientific and technical papers considers article counts from a set of journals covered by Science Citation Index (SCI) and Social Sciences Citation Index (SSCI). When interpreting these data for developing countries it is important to analyse if the improved number of scientific articles is result of including certain national journals in Science Citation Index or it is consequence of real increase in scientific productivity. Remarkable results in this area

have Germany and United Kingdom whose researchers published over 46000 scientific papers in 2011 (which is partially due to their large population).

Table 1: Science and technology indicators in selected countries

Country group/ country		Researchers FTE per million people (2005-2011)	Scientific and technical journal articles (2011)	Patent applications filed (residents + nonresidents) (2012)	Trademark applications filed (2012)
Western Balkan countries	Albania	148	27	11	2700
	Bosnia and Herzegovina	193	54	16	4517
	Croatia	1584	1289	251	7564
	FYR Macedonia	461	77	40	3275

Source: World Bank

Data on patents and trademarks show success of research, development and innovation activity in certain areas. It is actually a measure of innovation activity of a country that shows knowledge utilisation and transformation of knowledge into potential economic benefits.

Table 2: R&D expenditure in selected countries (% of GDP) from 2010-2012.

Country/ country group		2010	2011	2012
Western Balkan countries	Albania	n.a.	n.a.	n.a.
	Bosnia and Herzegovina	n.a.	n.a.	0,27
	Croatia	0,75	0,76	0,75
	FYR Macedonia	0,43	n.a.	n.a.
	Montenegro	n.a.	0,41	n.a.
	Serbia	0,79	0,77	0,96
New EU member states (selected countries)	Bulgaria	0,6	0,57	0,64
	Czech Republic	1,4	1,64	1,88
	Hungary	1,17	1,22	1,3
	Poland	0,74	0,76	0,9
	Romania	0,46	0,5	0,42
	Slovakia	0,63	0,68	0,82
	Slovenia	2,1	2,47	2,8
Selected EU-15 countries	Austria	2,8	2,77	2,84
	Germany	2,8	2,89	2,92
	Netherlands	1,86	2,03	2,16
	Sweden	3,39	3,39	3,41
	United Kingdom	1,77	1,78	1,72

Source: Eurostat
National Statistical Offices

Number of patents and trademark applications filed in 2012 is also modest in WBC compared to selected EU countries. Croatia and Serbia have highest number of patents (251 and 224), while in other countries in Western Balkan Region this number is very low.

R&D expenditures as a percentage of GDP in the Western Balkan Region from 2010-2012 were much lower than in EU countries (Table 2). Certain countries even have no statistical data that would allow calculating this indicator. This is a serious issue because absence of statistical monitoring means the inability to compare and improve this indicator. In 2012 in WBC higher R&D expenditure as % of GDP had Serbia (0,96) and Croatia (0,75). Most new EU member states have higher R&D expenditures, but still not as in EU-15 countries. Lack of investments in R&D (especially private ones) is partly a consequence of poor business environment, which reduces incentives for investing, especially when risk is high (which is characteristic of innovation investments).

4. DIFFERENT TYPES OF SUPPORT TO INNOVATION IN WB COUNTRIES

There are numerous examples of good practice in fostering innovation in European Union. Many of them are collected and described under the project WBC-inco.net – Coordination of Research Policies with the Western Balkan Countries (WBC-inco.net, 2011). In this paper will be presented policy measures that are suitable to apply in Western Balkan Countries. They are the following: Strategic Innovation, Innovation Officer, Innovation Voucher scheme, Soft Landing Platforms, Competition for Best Technology Innovation.

Strategic Innovation

Strategic Innovation has the aim to allow large number of small and medium-sized enterprises (SMEs) to improve their innovation capacities. Increasing number of innovative firms is crucial for developing countries which can be achieved by coaching and stimulating existing firms to develop strategic approach to innovation.

This methodology was developed by UNU-MERIT (The United Nations University – Maastricht Economic and Social Research Institute on Innovation and Technology) in the Netherlands while participating in an EU funded program (EdiSon) in which pilots had been performed in 15 Dutch SMEs. Because of the success in the 15 SMEs on the one hand and the policy choices that had been made in the Euregion Meuse Rhine on the other, UNU-MERIT developed a project proposal together with 3 other project partners in Flanders, Wallonia and Germany (WBC-inco.net, 2011).

The initiative enables management teams to re-develop their business strategy by putting priorities, making choices and implementing them. In that way, many SMEs are facilitated at micro level. It is conducted as 4 step intervention and final implementing phase in companies. These steps of intervention include interviews with top management, innovation scan and two strategic sessions with management team in a group. Implementing phase in companies facilitate trained consultants.

Strategic innovation implies that if one region wants to make improvements in innovation area, it is necessary to include large number of firms that will make changes on micro level. Crucial factor of success of this program is selection and training of consultants and interest of companies for the program. This approach is very effective and it usually gets high scores in the satisfaction surveys.

Innovation Officer

Innovation Officer is the approach that stimulates innovation in SMEs by enabling qualified staff. Innovation officers enhance innovation results and help in overcoming bottlenecks in SMEs operating. Philosophy of this scheme is that entrepreneurs should use knowledge to innovate, so they need new employee – innovation officer that will act as driver of innovation. This officer should detect opportunities for innovation and find ways for their effective implementation. To do this, he needs to have adequate knowledge about innovation processes and development. All plans he proposes should be reviewed by independent commission.

This method for enhancing innovation was developed in the Netherlands. It was part of larger programme – “Innovatie Zuid” which was financed by EU, the Dutch government and private businesses. The overall program was managed by Brabant Development Agency (BOM) and the implementer of this measure was Syntens, not-for-profit innovation intermediary.

Applying this method requires having good implementing agency. This agency should be independent, capable of problem definition and act as an intermediary between the entrepreneur and the innovation officer. First step of this approach is the initial conversation with SME and defining problem/opportunity. After that, intermediary agency writes innovation project and look for innovation officer. Innovation problem and innovation officer are being presented to independent committee which makes decision about the request. Innovation officer starts working, submits reports and gets salary from the SME. SME gets money back from the intermediary agency based on the innovation officer's report.

Innovation Officer Scheme is important because it can be applied in broad base of SMEs and not only in highly innovative ones. It stimulates creating innovative culture by enabling SMEs high-educated young professional.

Innovation Voucher Scheme

SMEs have generally very limited human and capital resources which do not allow them to develop their own know-how. This creates serious delays and missing important market opportunities. On the other hand, there is lot of available, already developed expertise in academic institutions and large companies that can be offered to SMEs. Since SMEs are not well informed about these external sources, they do not know enough to use this opportunity. Reducing this gap between knowledge institutions and SMEs is main goal of innovative vouchers.

Innovation vouchers are usually defined as small lines of credit provided by governments to small and medium-sized enterprises to purchase services from public knowledge providers with a view to introducing innovations (new products, processes or services) in their business operations (OECD, 2010). Such approach directly stimulates knowledge transfer, but also creates long-term relationships between industry and research institutions.

Research vouchers pilot project was developed in province Limburg in the Netherlands in 1996. It was implemented in cooperation with multinational company DSM dealing with chemicals and advanced materials. The goal was to allow SMEs to make use of knowledge accumulated in DSM's research sector. At first, there was limited number of vouchers given to companies for three days advice from DSM Research. After that, certain companies got vouchers to make use of DSM Research's expertise in certain areas. After this pilot many more voucher schemes were developed both in the Netherlands and the rest of the world.

The European Commission rewarded innovation vouchers as one of the best schemes for fostering innovation in Europe. This measure is widely applied because it is really flexible in terms that each region/ country can decide what type of knowledge will be offered under the voucher regime. This enables adaptation of the method to specific situation in certain region.

Soft Landing Platforms

Globalization and using new technologies have created new form of competition for countries and enterprises. In modern economy companies have to face with international competition and get into new markets. International operating increases growth, creates comparative advantages and long term sustainability. When changing business environment, companies are coping with various problems, especially when it comes to legal and tax systems, finding employees and clients, etc.

Conquering global markets will be more successful if companies have external support. Moreover, if that support comes from technology transfer intermediaries, there will be synergetic effect. Such services that help innovation led business to enter on foreign markets are often referred as Soft landing. Support services that Soft landing agencies offer should be flexible and focused on specific company's needs. Skills and contacts this agency has will enable companies faster and easier managing in foreign country. There are various types of services that soft landing offers: business planning, market analysis, finding partners, experts and personnel, access to funding, logistic, etc.

Soft Landing Platforms are created with primary goal to offer professional consulting services to companies starting operating on international level. However, this has proved to be a mechanism for improving innovative results of the company. The created collaborations with partners from different regions and countries contribute not only to the extension of their own networks, but also support the provision of conditions for international collaboration for economic growth. For businesses to innovate in this way, this has proven to be an effective mechanism for improving the innovative application of research results and for business development support to start-ups and existing SMEs (Kniejski, 2013).

Competition for Best Technology Innovation

Competition for Best Technology Innovation promotes entrepreneurial spirit in the domain of high-tech and gives support to people willing to commercialize their ideas and innovations. The competition is based on the philosophy that interaction of innovation and entrepreneurship are crucial for competitiveness of companies, universities and the economy as a whole. It mobilizes researchers, students, companies and innovative individuals to present results of their work.

Competition for Best Technology Innovation is successfully implementing in Serbia. It was initiated in 2005 by the Ministry of Science and Environmental Protection. The idea came from the Faculty of Technical Sciences in Novi Sad because they organized similar competition for their students in 2003. In 2007 this competition began to organize in the Republic Srpska, as a result of cooperation between Ministry of Science and Technological Development of Serbia and the Ministry of Science and Technology of Republic Srpska.

The competition has several phases. First, competitors have to register via internet and if they pass evaluation they get professional training on how to create innovative strategy for their product/service. Second phase includes creating business and marketing plan. Participants that show greatest potential and progress present their ideas publicly – at an exhibition, semi-finals and finals. Main criteria for choosing winner are: economic impact, novelty, growth potential and social impact. This competition has facilitated creation of more than 80 enterprises in Serbia and Bosnia and Herzegovina. It also helped in connecting and presenting to each other research and business sector.

5. CONCLUSION

Commercialization of R&D results and their conversion in profitable goods and services is important determinant of economic development and country competitiveness. Besides other factors, the scope of R&D activities depends on the number of researchers and academic institutions, level of investments in this sector, government policy measures, etc.

In a modern interconnected world, innovations are becoming international, so openness to foreign technologies and cross-border cooperation plays important role in fostering innovation. Innovation process includes various stakeholders and their relationships shape the effectiveness of the process. In order to ensure these linkages, there should exist organisations that support entrepreneurs in introducing products, finding financial resources and establishing new spin-offs.

Available data show that drivers of innovation in Western Balkan countries were generally less advanced than those in new EU members and developed EU economies. WBC still lag behind these countries in terms of number of researchers and scientific papers, number of patent and trademark applications, expenditures for R&D, etc. As a consequence, innovation process in WBC is facing with significant challenges.

In order to increase the effectiveness of converting R&D investments in commercial products, there are many policy mechanisms that can be implemented in WBC. Most of them are oriented on enhancing innovative culture and creating stronger links between research and business sector. Strategic innovation, Innovation Officer and Innovation Vouchers enable individual firms to re-develop their business strategy and orient towards innovation. On the other hand, Soft landing Platforms offer help in getting into new markets, but still the support is given by technology transfer intermediaries. Competition for Best Technology Innovation educates professional and general public about the importance of entrepreneurship and R&D.

Acknowledgment

Research presented in this paper was supported by the Ministry of Education, Science and Technological Development of the Republic of Serbia, under the project: "Research and Development of the Platform for Science Based Management of the Scientific and Technological Development of the Republic of Serbia", 2011-2014, reg. no. III 47005

POSSIBILITIES OF OPENING UP THE STAGE-GATE MODEL

Biljana Stošić[1], Radul Milutinović[2]
[1]Faculty of Organizational Sciences, biljst@fon.bg.ac.rs
[2]Faculty of Organizational Sciences, radul.milutinovic@fon.bg.ac.rs

Abstract: *The paper presents basic elements of the Stage-Gate and Open innovation models, and possible connection of these two, resulting in what is frequently called an "Open Stage-Gate" model. This connection is based on opening up the new product development process and integration of the open innovation principles with the Stage-Gate concept, facilitating the import and export of information and technologies. Having in mind that the Stage Gate has originally been classified as the third generation model of innovation, the paper is dealing with the capabilities for applying the sixth generation Open innovation principles in today's improved and much more flexible phases and gates of the Stage Gate. Lots of innovative companies are actually using both models in their NPD practice, looking for the most appropriate means of opening up the well-known closed innovation, especially in the domain of ideation through co-creation.*

1. INTRODUCTION

The need for lean, rapid and profitable new product/service development has never been more evident. In today"s business world, product life cycle is getting shorter, the competition is getting tougher, users are becoming more demanding, and therefore companies that do not innovate are losing pace with competition and slowly deteriorate.

A growing number of authors and leaders from different branches identified innovation as a key driver for achieving long-term success and profitability (http://www.prod-dev.com/stage-gate.php). Most of today's companies with great concern talk about improvement of their innovation performance in order to deliver sustainable growth and significant competitive differentiation (http://www.sopheon.com/industry-innovation/). However, it must be kept in mind that gaining competitive advantage by offering new product/service is not easy - in fact, it is estimated that about 46% of the funds, which company invests in the development and launch of new products/services is related to unsuccessful projects (http://www.prod-dev.com/stage-gate.php).

Having this in mind, the world's leading companies have revised their processes of product/service innovation, including critical success factors discovered through research of best practice, through introduction of the Stage-Gate new product/service development process. Based on various independent studies, which were conducted by leading consulting companies in the field of innovation management, it was concluded that 70-85% of the leading companies in the U.S. use model Stage-Gate for managing the entire process from idea generation to launching of new product/service to market (http://www.prod-dev.com/stage-gate.php).

Starting from this point, the paper is organized in tree main sections, first related to linear models of new product/service development, describing the development of innovation models through generations and the Stage-Gate model as a main representative of the third one; second related to open innovation model, its features and advantages; and third related to possible connection of previously mentioned models, discussing the ways of embedding the main principles of open innovation in the Stage-Gate model.

2. LINEAR MODELS AND STAGE-GATE

Innovation is identified as a key driver for strengthening of competitiveness, so that fostering innovation has become one of the key priorities in every company that strives to be the leader in the field. Globally, innovation appears to be the central element of today'sknowledge-driven economy, with domination of information-communactions technologies - ICT, as a key strategic dimension bringing completely new ways of communication and business. Even though the importance of innovation is recognized by most companies and they spend a lot of money on innovation, many of these initiatives do not generate reasonable profit or competitive advantage. Plenty of research in this topic reveals that the main problem does not lie in the invention part or the generation of innovative ideas, but more in the successful management of the innovation process from an idea to a successful product in the market (du Preez, Louw, 2008).Having that in mind, successful innovation demands a rigorous process for managing innovation, including a disciplined,

stage-by-stage approval process combined with regular measurement of every critical factor, ranging from time and money spent to the success of new products in the market.

When it comes to innovation processes from idea to commercialized product/service, literature proposes a lot of different models and frameworks. Basically, six generations of models can be found, from simple linear to increasingly complex interactive and network ones (Rothwell, 1992), up to new concept of open innovation (Table 1).

Table 1: Development of innovation models (adopted from (du Preez, 1992))

Model	Generation	Characteristics
Technology push	First	Simple linear sequential process, emphasis on R&D; market is the recipient of the R&D results
Market pull	Second	Simple linear sequential process, emphasis on marketing, the market is the source of new ideas for R&D; R&D has a reactive role
Coupling model	Third	Recognizing interaction between different elements and feedback loops between them, emphasis on integrating R&D and marketing – Stage-Gate process, – The Collaborative Innovation Process
Interactive model	Fourth	Combinations of push and pull models, integration within firm, emphasis on external linkages – Minnesota Innovation Research – Program (MIRP) model
Network model	Fifth	Emphasis on knowledge accumulation and external linkages, systems integration and extensive networking – The Creative Factory Systems Innovation Model
Open Innovation	Sixth	Internal and external ideas as well as internal and external paths to market can be combined to advance the development of new technologies

One of the most important elements of this classification is chronological review of models development, where shifting of models from conventional, unilateral, facing the own R&D solutions, via one-sided market orientation, to interactive combination of push and pull models, and contemporary, network models based on knowledge can be clearly noticed (Stošić, 2013).

The first and second generation models are linear models pulled either by market needs or pushed by technology and science. Coupling model as the third generation model recognizes the influence of technological capabilities and market needs within the company"s framework. Even though the coupling approach encompasses feedback loops it is essentially a sequential model. Cooper"s Stage-Gate model, which is in the focus of this research, can be looked at as the main representative of this generation. This model divides the product innovation process into series of stages – set of parallel activities, and gates - decision points between the stages. The fourth generation innovation process model, known as interactive model, observes the innovation process as parallel activities across organizational functions. The fifth generation or network models are the influenced by external environment and effective communication with external environment. The sixth generation of innovation models is open innovation models, which can also be seen as network models, but instead of being only focused on internal idea generation and development, internal and external ideas and paths to market can be combined to advance the innovation process (du Preez, Louw, 2008).

Having in mind the aim of this study, the following text will be describing the Stage-Gate model, Open innovation model and possibilities of their connecting i.e. the opening up of Stage Gate model.

Stage-Gate® is a trademark of R.G. Cooper & Associates Consultants Inc., a member company of the Product Development Institute. It stands for industry standard for excellence in new product/service development. This advanced, widely applied and recognized process, skillfully integrates a number of practices in an easy to understand recipe for success. It is characterized by a structure that engages users at all levels and functions, and consequently allows making good and effective decisions regarding further project extension, and impacts on quality and speed of innovation project execution.

The current Stage-Gate is a third-generation process, which incorporates six Fs (Cooper, 1994):

- Flexibility,
- Fuzzy,
- Fluidity,

- Focus,
- Facilitation,
- Forever green.
-

The first three Fs makes the process less rigid, enabling it to be scaled to various size projects and enabling stages to be overlapped and approved conditionally. “Focus” means that the process is connected to a strategy. “Facilitation” refers to specific role gate keeper, who ensures that the process is properly guided. As a final point, “forever green” suggests the continuous improvement of the process. Generally, these six Fs enables a more sophisticated process, but they also encourage more abuse of the process (Cooper, 1994).
Using the Stage-Gate model improves efficiency and reduces the risk of failure, regardless whether it is launching of new product or technology that could change the competitive image in the market, or introduction of new products that could generate additional income for the company, or defense of company"s market share by introduction of significantly improved product (http://www.stage-gate.com/resources_stage-gate_full.php).

Stage-Gate model is a business process for value creation that is designed for quick and profitable transformation of company"s best ideas into new products/services. Model as such generates an organizational culture that includes existence of the new product development process leader, strategic responsibilities definition, high-performance teams, focus on customers and markets, excellent solutions, compliance, discipline, speed and quality.

It follows that the Stage-Gate model provides a conceptual and operational roadmap for driving new product development, from idea to launch, i.e., blueprint for managing the process of product/service innovation, aimed at increasing efficiency and effectiveness. Stage-Gate approach decomposes innovation process in a set of phases that comprise a set of planned, multi-functional and parallel activities. At the entrance to each stage is a gate, which role is quality control and decision-making Go/Kill/Hold/Recycle to the process (Cooper, 2011).

Phases are activities undertaken by members of the team owning to gathering the information they need for project progress toward the gate. The phases are cross-functional and activities are undertaken in parallel to speed up the time to market. In order to provide risk management, parallel activities within a particular phase must be designed in a way to gather important information - technical, market, financial, operational (Stošić, 2013).

The model is structured in that way that in front of each stage is a gate, or decision point. The decision about whether an innovation project is going to pass certain gates perform, combined, both internal managers and external experts, so-called gatekeepers. Gates have a dual role. First, to check whether the project met all the criteria identified in previous gate and second, to check whether the project meets the criteria for the current phase.

Every gate includes following (Stošić, 2013):

- Elements that represents deliverables – results of actions from the previous phase;
- Criteria on which the decision on project are made;
- Outputs, representing the results of the decision (Go/Kill/Hold/Recycle).

There are many different predefined qualitative and quantitative criteria based on which the assessment of innovation project is made in every gate. Such criteria have to give answer on the following questions:

- Are the milestones connected to technology met?
- Does the project perform in accordance with time and budget?
- Could innovation concept reach potential benefits for end-users?
- Does the innovation concept coincide with pre-set goals and strategy?

Specific criteria are different from gate to gate and become more rigorous as the project approaches the development stage.

One of the innovation project characteristics is high risk level which to a large extent affects the innovation process stability and depends on the process stage. Consequently, it is useful to execute risk identification in a more precise and efficient way in order to respond in the right time and manner. This is the reason why it is important to choose the right gatekeepers and criteria within the gates to implement the project in line with planned. Different findings on SG benefits and weaknesses are summarized in Table 2.

Table 2: Advantages and disadvantages of Stage-Gate model

Benefits (http://www.stage-gate.com/resources_stage-gate_full.php)	**Common Errors and Fail-Points**(Cooper, 2008)
Accelerated speed-to-market	Gates with no teeth
Increased new product success rates	Hollow decisions at gates
Decreased new product failures	Who are the gatekeepers?
Increased organizational discipline and focus on the right projects	Gatekeepers behaving badly
Fewer errors, waste and re-work within projects	Too much bureaucracy in the idea-to-launch process
Improved alignment across business leaders	Too much reliance on software as a solution
Efficient and effective allocation of scarce resources	Expecting the impossible from a process
Improved visibility of all projects in the pipeline	
Improved cross-functional engagement and collaboration	
Improved communication and coordination with external stakeholders	

P&G is one of the companies which can be seen as a good example of applying the Stage-Gate model. It introduced the SIMPL™ model which consists of four main stages, where stages represent a set of current best practices in the form of key activities, and also clearly defined deliverables for project team (Figure 1). There are also four gates or decisions points in the model, which are comprised of a team recommendation and a management decision (Cooper & Mills, 2005).

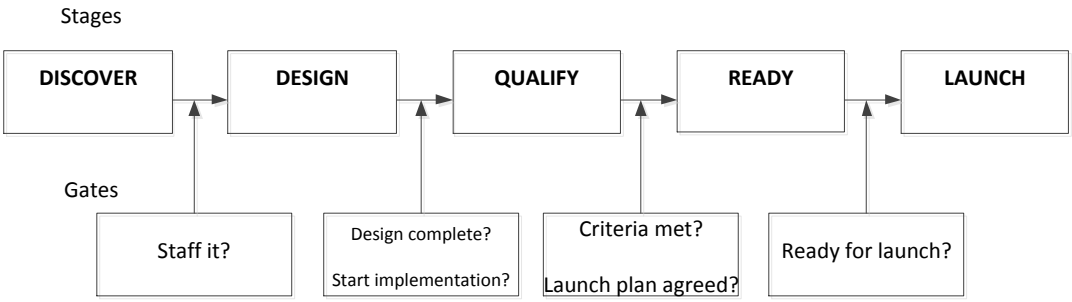

Figure 1: P&G"s SIMPL™ Process - An Idea-to-Launch Stage-Gate® Model (adopted from (Cooper & Mills, 2005))

3. OPEN INNOVATION AS A NEW PARADIGM

In today"s intensely competitive environment the main question is no longer why to innovate, but how to innovate. Bearing that in mind, innovation theory recognized that not all good ideas come from inside the firm, neither all good ideas emerged within the particular firm should be commercialized by that same firm (Gabel & Chesbrough, 2011).

Based on aforementioned, Henry Chesbrough coined the term “open innovation” to describe a paradigm that assumes that firms can and should use external ideas as well as internal ideas, and internal and external paths to market, as they look to advance their technology (Chesbrough, Vanhaverbeke and West, 2006). While Chesbrough (2003, 2006) partly admits the rich source of antecedents to the „open innovation paradigm", there are some authors such as Trott and Hartmann (2009) who claim this paradigm to represent just an old wine in new bottles, meaning repackaging and representation of concepts and findings presented over the past forty years within the literature on innovation management.

The model of open innovation is based on the movement of ideas across organizational boundaries. Valuable ideas can be generated externally (outside the organization) and internally (within the organization), which also refers to the output of the innovation process, i.e. placement of innovations to the market.

On the other side, the conventional internal model of closed innovation is based on the principle of control for the success of innovation and innovation projects. The organization needs to generate and control their own ideas in the same way as the functions units - production, marketing, finance. The main features of both models are shown in the Table 3.

One of the factors that led to abandoning the concept of the closed innovation is the mobility and accessibility of knowledge due to ICT. Therefore, employees" fluctuation is encouraging knowledge transmission, resulting in a higher throughput of knowledge between the organizations. This has changed the logic of modern innovation processes and models, growing from closed to open ones, through well-known principles given in Table 3.

Table 3: Features of Open and Closed innovation model (Chesbrough, 2003)

Closed Innovation Principles	Open Innovation Principles
The smart people in the field work for us.	If we create the most and the best ideas in the industry, we will win.
To profit from R&D, we must discover it, develop it, and ship it ourselves.	External R&D can create significant value: internal R&D is needed to claim some portion of that value.
If we discover it ourselves, we will get it to the market first.	We don"t have to originate the research to profit from it.
The company that gets an innovation to the market first will win.	Building a better business model is better than getting to the market first.
If we create the most and the best ideas in the industry, we will win.	If we make the best use of internal and external ideas, we will win.
If we create the most and the best ideas in the industry, we will win.	We should profit from others" use of our IP, and we should buy others" IP whenever it advances our business model.

For the successful implementation of this model, the organization should define the business in a way to use advantage of both internal and external ideas which can be improved through internal R&D, and to build an adequate business model which will provide greater value for the organization.

Key Factors to Implementing "Open Innovation" (Docherty, 2006):

- Broaden your view (where you look and your ability to see what"s there);
- Create alignment across the innovation ecosystem;
- Adapt an approach for your organization"s tolerance for risk;
- Put the focus on learning, not just results.

Many of the market leaders such as GE, Cisco, Adobe, Nokia, P&G, Spalding, Starbucks, successfully use the model of open innovation in order to improve their products/services, reduce the cost of R&D, solve technical problems and accelerate time to market (Stošić, 2013).

P&G has institutionalized its Connect and Develop program to ensure external ideas have access to the organization and that internal intellectual property is marketed to the outside. Aiming to speed and simplifying external innovation connections, P&G"s Connect and Develop program launched a new website, linking innovators directly to top company needs, and P&G business leaders directly to external innovation submissions. In the spirit of C+D, the web site was developed in collaboration with several external partners, which brought new innovative technology to the back-end of the site, enabling user submissions to directly feed into the business category leaders. This will allow P&G to review needs more quickly and more efficiently for strategic fit or scalability across the business.

4. POSSIBILITIES OF CONNECTING THE STAGE-GATE AND OPEN INNOVATION MODEL

Concerning the market needs and treat that internal R&D isn"t the engine of innovation anymore, left companies no options but to adapt their business if they want to stay competitive and not to miss opportunities any longer. Referring to that and the fact that a lot of external knowledge is now accessible, companies which have been using Stage-Gate model for their new product/service development make a great effort to improve their model, broadening it with open innovation features (Grolund, Ronneberg & Frishammar, 2010). It assumes accommodation of flowing the new ideas, intellectual property, technology or even fully developed products from external sources.

Companies which have moved to open innovation, also have to modify their Stage-Gate process, and consequently to modify their business model, making it more flexible in order to enable proper surrounding for networks of partners, alliances and outsourced-vendors. One of the best examples of Open innovation

Stage-Gate model usage is company P&G, which released SIMPL 3.0 version Stage-Gate system, designed to handle external ideas, technologies, and even fully developed products (Cooper & Edgett, 2008).

Using the open innovation in new product/service development implies its involvement in all three aspects of the innovation process, including ideation, development, and commercialization (Figure 2).

Ideation or Discovery stage: The first phase of the innovation process/project is always generating ideas - in the literature also known as ideation. The beginning of generating ideas process is always associated with the identification and understanding that somewhere there is a gap, i.e. new product characteristics, new elements of the business improvement process technology, a completely new business model (Cooper & Edgett, 2005; Cooper, 2011; Kahn, 2013; Stošić, 2013).This is the stage in which companies go across their borders looking for external information that could be helpful in satisfying customer"s needs, when it comes to ideas for new product/service development (http://www.stage-gate.com/resources_stage-gate_openinnovation.php). Many companies such as Starbucks, P&G, BMW, now use open ideation or co-creation, offering the possibility to customers to share their ideas by giving them problems the company is facing with or just giving them possibility to propose some new idea over the companies" sites.

Building the Business Case: Implies detailed market research, consumers" needs and desires, stakeholder analysis, concept testing, detailed financial and business analysis. As a result of the stage, a business case is obtained, i.e., defined the product/service, business justification and a detailed action plan for the next stage (Cooper & Edgett, 2005; Cooper, 2011; Kahn, 2013; Stošić, 2013). Concerning open Stage-Gate, this stage includes actions such as identification of missing internal capabilities, seeking for potential partners who will provide technological or marketing capabilities to develop and commercialize new product/service, developing an intellectual property strategy (http://www.stage-gate.com/resources_stage-gate_openinnovation.php).

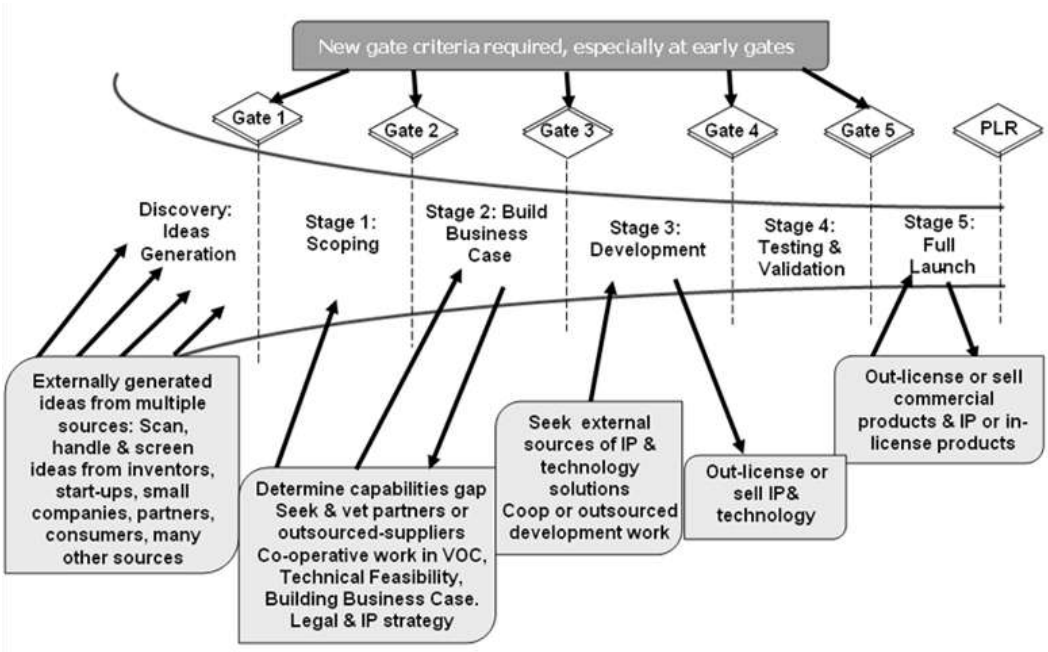

Figure 2: Open innovation Stage-Gate model
(http://www.stage-gate.com/resources_stage-gate_openinnovation.php)

Development stage: Within this stage comes to implementation of the action plan and development of new product or service. It is necessary to carry out various tests within the company"s laboratory in order to confirm that the product meets all the requirements (Cooper & Edgett, 2005; Cooper, 2011; Kahn, 2013; Stošić, 2013). Concerning the open Stage-Gate system, companies cooperate with suppliers or partners trying to solve technology and development problems and also try to get external innovations which have already been commercialized. Furthermore, companies can out-license or sell their internally developed technologies and intellectual property (http://www.stage-gate.com/resources_stage-gate_openinnovation.php).

Launch or commercialization stage: Start of full production and commercial launching of the product and its sales. Within this stage monitoring of the innovation project is carried out, as well as detecting and correcting mistakes (Cooper & Edgett, 2005; Cooper, 2011; Kahn, 2013; Stošić, 2013).On the other side, the open Stage-Gate system should enable the company to sell or out-license already commercialized products if

there is a possibility to gain more value elsewhere; or to in-license – purchase an already commercialized products for achieving new growth for the company (http://www.stage-gate.com/resources_stage-gate_openinnovation.php).

Speaking about gates and criteria they include, they must also be modified in the open Stage-Gate system. In this case, not having all the capabilities to develop or execute a project doesn't lead to a "Kill", but leads to seeking a partner to handle the missing elements. These modified criteria must be introduced, dealing with partner or supplier selection and their capabilities (http://www.stage-gate.com/resources_stage-gate_openinnovation.php).

Having been a leader in Open innovation model employment, P&G also made an effort to develop and introduce the *open Stage-Gate* model, frequently cited as SIMPL 3.0. This is the version of a Stage-Gate model and is a method used to drive products from idea to launch stages with clear go/kill criteria and timing requirements (Panduwawala, Venkatesh, Parraguez & Zhang, 2009). In addition, one of the examples that should be useful to mention is General Electric's open Stage-Gate named "Toll-Gate" (Stage-Gate system) for handling an open innovation, both out-bound and in-bound (http://www.stage-gate.com/resources_stage-gate_openinnovation.php).

5. CONCLUSION

In this paper we discussed the opportunities to make connection between the Stage-Gate and Open innovation model, to integrate the open innovation principles into a closed new product/service development model. As it is previously stated, open innovation principles infiltrate almost every stage of the Stage-Gate process, while recently the most popular engagement of open innovation is in the ideation phase. The companies through co-creation or crowdsourcing try to solve current problems or even try to somehow attract end users to propose their ideas through online or offline games or over the companies' sites.

Various papers confirm that opening up the new product development process, in this case Stage-Gate process can generate significant value. On the other side, its implementation can be very challenging. We presented both Stage-Gate and Open innovation model and emphasized the possible points of their association. When it comes to this connection, it should be pointed out that not only changes in the Stage-Gate process has to be made but also company's current business model and capabilities have to be put under examination. For this model, very important is dynamic view, where companies should continuously revaluate their business models and be aware of own capabilities in order to successfully leverage problems when engaging in external collaborations (Chesbrough & Schwartz, 2007).

The "Open Stage-Gate" model has many benefits, starting from the fact that this model systematically integrates the principles of open innovation with existing Stage-Gate processes; it increase companies' proficiency in outbound open innovation activities (selling intellectual property - licensing); it provides systematic application of open innovation principles; it helps managers to continuously evaluate and adjust companies' capabilities and business model, i.e. business model innovation; it allows systematic review and assessment of importing intellectual property from outside the boundaries. Involvement of external know-how and technology can contribute the company in many ways, such as to complete a product, add value to the product offering, speed up the innovation process and reduce development costs (Gabel & Chesbrough, 2011).

THE EVOLUTION OF MOBILE TECHNOLOGY IN RETAIL MARKETING CHANNELS IN THE REPUBLIC OF SERBIA

PhD Jelena Končar, full professor[1], PhD Goran Vukmirović[2], Sonja Leković, MSc.[3]
[1]Univeristy of Novi Sad, Faculty of Economics Subotica, jkoncar@ef.uns.ac.rs
[2] Univeristy of Novi Sad, Faculty of Economics Subotica, vgoran@ef.uns.ac.rs
[3] Univeristy of Novi Sad, Faculty of Economics Subotica, sonjalekovic@ef.uns.ac.rs

Abstract: *The evolution of retail institutions in marketing channels goes towards the implementation of modern information technology. The use of mobile technology is influenced by changes in buying habits and improvement of the buying experience of consumers on a global scale. Mobile commerce application has an increasing tendency with significant involvement in the whole electronic commerce in the market of developed countries. Retailers implement mobile technology tin order to get closer to consumers, to present their offers and become competitive. Offer becomes available in the global market thanks to mobile technology, which allows comparison of different retailers' offers by consumers. Modern mobile technology in the Republic of Serbia is an opportunity for growth of the application of mobile retailing in the country.*

Keywords*: marketing channels, mobile technology, retailing, globalization, internationalization*

1. INTRODUCTION

The application of modern technologies in the retail marketing channel is changing the structure of the channel, as well as the relations between participants in marketing channels. Retailers adapt to changes in the global market in order to reach the individual consumer, which is much easier with the implementation of new mobile technology. Changes in the mobile technology have an increasing impact on end-users in the Republic of Serbia, which is a potential that needs to be utilized.

The development of mobile technology in marketing channels set the following goals: continual evolution and trends of mobile technology in marketing channels, development and implementation of mobile technology in the process of globalization and internationalization, the use of mobile technology in the Republic of Serbia.

The main goal of this paper is to show implementation of mobile technology in modern marketing channels, all influenced by rapid technological changes in the global market. It should be noted that the use of new mobile technologies in the retail channel marketing aims to increase the competitiveness and reaching the end consumer. The research goals will be achieved by applying analytical, descriptive and comparative methods in data processing.

2. EVOLUTIONARY DEVELOPMENT OF NEW MOBILE TECHNOLOGIES IN MARKETING CHANNELS

The use of technology in marketing channels led to a closer relationship between all participants in the marketing channels, including connection with the consumer. The technological revolution in telecommunications, as well as changes in lifestyle of potential customers has enabled the development of mobile technologies in marketing channels. New mobile technologies have found their implementation in marketing channels, especially in retailing, because it is an attractive way for purchasing for some groups of consumers.

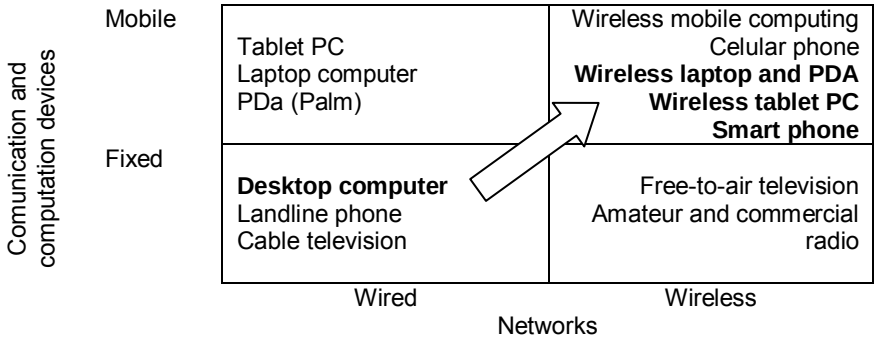

Figure 1: The development of the wireless mobile environments (Turban, King, et. al., 2010, p. 386)

Namely, the use of desktop computers and the necessity of connection of the computer to the Web, restricts those who want to obtain information about offers, or even do their shopping while on the way home, at work or in any other situation, when computer it is not available.

An additional factor which "pulls" the development of mobile application technologies are innovations in telecommunications and the emergence of new mobile devices with increasing performances, which exceeds the power of desktop computers. The evolution of new mobile technologies in marketing channels has led to the development of mobile environments. As it can be seen in Figure 1, the further development of the application of mobile technologies by consumers is influenced by the spread of use of mobile devices, especially smart phones with the characteristics of computers and tablet PCs, wireless laptops and PDAs that have a direct or wireless connection to the Web. Furthermore, mobile commerce includes any business activity conducted over the wireless network (Turban, King, et. al., 2012, p. 277).

In developed countries, the market share of mobile commerce in the overall e-commerce is rising from year to year, while in some countries show greater significance than the e-commerce. In the USA mobile commerce generated $41.68 billion of the total $262.3 billion of e-commerce sales in 2013, which was an increase of 68.2% from 2012 and account for 16% of total ecommerce sales (Forbes, http://www.forbes.com/, February 2013).

For the development of mobile commerce use by participants in marketing channels, it is necessary to access to adequate technical support for conducting transactions, the development of telecommunication network for rapid and secure exchange of information, adequate software support, applications that are customized and that are simply used by the user, and the willingness of all participants to accept the technology. Therefore, the infrastructure that supports mobile commerce requires the cooperation between multiple stakeholders such as mobile operators, service providers, manufacturers of mobile devices, Internet service providers, to the banking institutions and retailers and acceptance of technology by end-users, namely potential consumers.

In Figure 2 we can see the trend of exponential growth in sales via smart phones in the U.S. since 2012, with growth in the 2015th year, and an increase in the share of total e-commerce.

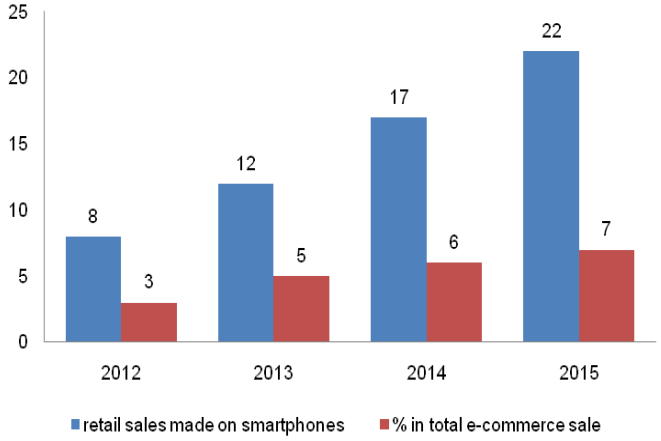

Figure 2: The U.S. Mobile commerce sale via smart phones in billions and share in total e-commerce sale with predictions in next years (Forrester Research, http://blogs.forrester.com/, January 2013)

In addition to high-performance smart phones, full use of smart phones means the existence of a developed telecommunication network. For the development of mobile commerce is crucial the evolution of mobile networks, and today we talk more about the implementation of 4G and 5G networks for mobile commerce. It is expected that transactions through mobile phones will rise to a thousand times until the 2020, influenced by the development of the new 5G network. The new technology should provide faster Internet at any time, video calls, instant access to on-line databases, creation of shopping lists, and buying via mobile devices will become more common (Končar, Leković, & Petrović-Katai, 2013, p. 122).

Smart phones with 5G technology have the possibility to choose the most secure data connections and ensure safe and fast transactions of mobile commerce. Data about the use of mobile devices, such as smart phones and tablet computers, shows their rise in share in turnover of retail marketing channel from year to year, and that tends to increase in the coming period, especially in developed market countries, such as the USA, Japan, Australia and so on. According to e-Marketer research in 2013 half the users of mobile

technology in the United States will have a connection to the Internet (Lovreta, Končar & Petković, 2013, p. 435).

Table 1: The U. S. Mobile commerce sale via smart phone and tablet (eMarketer, https://www.emarketer.com/, April 2013)

year / share	2012	2013	2014	2015
retail m-commerce sales	24.81	38.84	53.41	71.16
% change	82	56.5	37.5	33.2
% retail e-commerce	11	15	18	21

The use of smart phones in recent years is growing due to the multifunctionality, and the additional benefits are provided by tablet computers. Therefore, in the further development of new mobile technologies in marketing channels is important the usage of high-performance mobile devices. In the developed countries a large part of the mobile commerce transactions are conducted via smart phones and tablet computers, which affects the growth of the total e-commerce transactions.

3. BUILDING THE MOBILE RETAIL CONCEPT IN CONDITIONS OF GLOBALIZATION AND INTERNATIONALIZATION OF THE MARKET

Although the revenue from mobile retailing is relatively small, this concept begins to occupy an important place in the shopping experience in traditional retailing. Mobile retailing improves shopping experience and allows interaction between consumers and retailers on global market. Thanks to the mobile retailing, retailers have the opportunity to develop interactive relationships with consumers, to learn about consumers' individual needs in the best way, and appropriately and quickly respond to consumers' demands.

Gaining a significant role in the modern process of buying, mobile retailing is used in different business forms of retail sector. With mobile phones, smart phones, tablet computers and other mobile devices that have access to the Internet, buying process is easier because it is allowed to search products, locate store and products in the store, compare prices on the Web, and so on. By that, consumer has the opportunity not only to communicate with the retailer, but also transfer its experiences to other consumers globally, as all information is available on the Web.

The use of mobile technology in retail affects on the value of the sales, which is directly associated with factors related to end-users, ie. potential consumers. Factors that are relevant for the adoption of mobile technology are income per capita, the number of mobile phone users, the availability of technology, consumer buying habits, education and information literacy of users, and so on. There are different ways of application and use of mobile technology by end-users, ie. potential consumers. The application of modern mobile devices has an impact on changing habits and behavior of consumers. Consumers are using mobile devices to access the Web and come up with the necessary information about the offer, especially (Deloitte, October 2013, p. 20):

- 56% getting store locations,
- 54% check/comparing prices,
- 47% getting product information,
- 45% shop/browsing online,
- 40% checking product availability in a store or website,
- 36% get/using discounts, coupons, sales information,
- 32% scanning product barcodes to find more product information,
- 31% making a purchase online,
- 24% getting text messages or exclusive deals from retailers.

Based on the above, it can be concluded that the use of new mobile technologies in retailing has an impact on the achievement of competitive differentiation against the competition, in such a way that the information is available to potential consumers irrespective of the consumers' location. Location-based mobile commerce (the user is physically located at any place) is the key for offering relevant personalized services, which is the combination of personalization and location (Končar, 2008, p. 242).

Mobile retailing offers new possibilities to end consumers regardless of time and space. In combination with locating retail store or products, mobile retailing creates new value for consumers. The following years are considered crucial for the penetration of mobile retailing in the global market. In Table 2 is a growing trend in the mobile retailing in the United States, as well as a growth of the share in the total e-retail.

Table 2: Predictions of the US retail m-commerce sales 2011-2015, with the % sale and share in retail e-commerce sales (Forbes, http://www.forbes.com/, February 2013)

year / share	2011	2012	2013	2014	2015
retail m-commerce sales	13.57	24.78	41.68	56.72	75
% change	171.7	82.6	68.2	56.72	32.2
% of retail e-commerce sales	7	11	16	19	22

As it is presented in Table 2, as in the preceding parts, the United States leads the world in the application of mobile technology and mobile commerce. Retailers in the U.S. implement mobile commerce in their business. A large number of medium and large retailers in the United States recognize the importance of mobile commerce in achieving competitive advantage and positioning over the competition. However, it can be concluded that mobile retailing is a still a small percentage of the global e-commerce, or mobile commerce, and therefore have a little share in total retail trade. The only exception is Japan with advanced mobile retailing. Region with a high-paced growth of mobile retailing is East Asia, where growth is much higher than in Europe. A significant portion of electronic retail transactions in Japan are conducted through mobile devices, which is why this country is considered to be advanced in the application of mobile technology in retail.

4. THE CONCEPT OF MOBILE RETAILING IN FUNCTION OF THE DEVELOPMENT OF THE MODERN MARKETING CHANNELS IN THE REPUBLIC OF SERBIA

For the development of mobile commerce in the Republic of Serbia, a necessary factor is the implementation of the infrastructure of mobile commerce. Retailers in Serbia should take into consideration the advantages of mobile commerce for business development. The strategy of mobile commerce should be a support to existing businesses.

Using the latest generation of mobile telephony should improve and precedes the development of mobile commerce in Serbia. Mobile operators in Serbia conducted testing 4G mobile network in real conditions in April 2011. Bimonthly testing was performed in collaboration with manufacturers of mobile devices, companies Ericsson, Huawei and Nokia Siemens Networks, that have installed their equipment in multiple locations. Successful tests have shown that the mobile network in Serbia is fully prepared for the introduction of LTE technology and the launch of next-generation mobile telephony. Bearing in mind that only part of the frequencies intended for the use of 4G technology is in use at present, only after the completion of the digitization process, which will happen in 2014, use of a wider frequency range and 4G phones will be in use in our country (Končar, Leković & Petrović-Katai, 2013, p. 122). Croatia has started to operate a 4G network based on LTE technology that brings users up to ten times higher data rates than previously.

Table 3: Devices used for accessing the Internet in the Republic of Serbia from 2006 to 2013 (Republički zavod za statistiku, 2013)

year / device	2006	2007	2008	2009	2010	2011	2012	2013
PC	94.0	90.0	95.2	93.2	91.1	88.7	84.8	80.9
Cellular phone	-	26.6	24.8	25.4	21.8	15.7	37.2	46.1
Laptop	4.6	8.6	8.5	15.4	19.3	27.8	35.4	46.6
Game consoles	-	-	-	1.5	1.3	1.1	1.3	2.8
PDa palmtop	-	0.5	0.5	0.7	0.1	0.2	1.1	5.0
TV	-	0.2	0.1	0.2	0.1	0.4	0.8	3.5

As the main factor in the further development of mobile retail in Serbia is the number of users of mobile devices, as well as information literacy of users. Number of mobile phone users has increased to 86.9% (up from 83.9% a year earlier) in 2013 in the Republic of Serbia (Republički zavod za statistiku, 2013, p. 2). In Table 3 it can be seen that for access to Internet users mostly use PCs (80.9%, with a fall in the previous year), and for this purpose the mobile phone is used by 46.1%, an increase over the previous year from 37.2%. However, using a PC to access to the internet from year to year declines, while growth in the use of mobile phones, laptop and tablet computers recorded growth in the period 2006-2013. Based on the above it can be concluded that the growth of mobile phone use will continue in the future, as well as use of the Internet by users, as a necessary condition for the implementation of mobile commerce.

Additional prerequisite for the implementation of mobile retailing is the development of mobile payment systems. What is recognized is that mobile payment systems are developing in recent years in Serbia. Thus, in cooperation with mobile operators and banks is developed a system for mobile payments “PlatiMo”, through mobile phones. Also, very popular in the Republic of Serbia is voucher system “Qvoucher”, which acts as an electronic "supplement" for payment goods and services on the Internet. After only two years since the introduction of this system it has over 20,000 users and over 25,000 transactions per month.

Revenue from mobile retailing in Serbia is relatively small, but its aspect begins to occupy an important place in the shopping experience. Mobile retail is yet to show its full potential in generating growth across all retail channels, along with improving the buying experience by allowing greater interaction between consumers and retailers. Exploitation of mobile technologies will enable retailers to be oriented towards the user, potential customers, develop closer relationships and increasingly meet the needs of individual consumers.

5. CONCLUSION

Continual evolution of new technologies and trends in marketing channels, under the influence of global environmental factors, leading to innovation and the emergence of new mobile devices with increasing performance. Thanks to the mobile retailing, retailers have the opportunity to develop interactive relationships with consumers in the global market. The implementation of new mobile technologies in retailing has an impact on the achievement of competitive differentiation against competitors in marketing channels. The implementation of new mobile technology needs to improve and develop mobile commerce in Serbia. As the main factor for this development of mobile retailing in Serbia is a growing use of the Internet by consumers.

ADVANCED REAL ESTATE MANAGEMENT SYSTEM

Verka Jovanovic[1], Djordje Vukelic [2]
[1]Faculty of Informatics and Computing, Singidunum University, Belgrade
[2] iPro Solutions Ltd, Valletta Waterfront, Vault 14, FRN 1914, Malta

Abstract: *GIS and Internet services are one of the leading trends in the new developments of the information technology. Their impact could be seen in the different sectors of business and management. Very closely connected to the new paradigm of mobility, detecting the space/location is becoming one of the most important point for the different industries. Contrary to isolated use of technologies, Advance Real Estate Management System presents integration of GIS and Internet as one of new models in business management.*

Keywords*: GIS, Internet, Management, Real Estate, Model, Software*

1. INTRODUCTION

Information technology has shifted the paradigm of the global economy. In a macroeconomic sense, information technology affects the patterns of production, investment and employment. In a microeconomic sense, information technology changes business activities (Eui-hwan, 1999). The world is changing from the industrial age to the information age. The rise of information technology marks a more complex relations between space and time. The accent must be on the approach to treat the space and time as the key, integrated entities in the "new mobility".

Where people live? What they do? Where, when and how they go? And where, when, and how they spend their money are now key factors in the business success. From product development to distribution, marketing and sales, GIS technologies help companies identify, understand and serve their markets far more effectively than ever before (Winslow, 2002).

Space, place, location plays a key role in determining the type and nature of human activity. The space/location determinant is correlated with consumers' information needs, and product or service choices. Many previous papers from various fields have discussed the usage of space information in day-to-day business applications (Goodell & Syverson, 2007), (King, 2009), (Svantesson, 2007), (Briney, 2013).

However, as GIS technologies progress and spread across the globe, the more questions are arising. What can businesses do to stay ahead of the changes? Which technologies are the most efficient and flexible for different business models? What this type of the information could tell us about business processes and how do we use those insights to manage the same processes?

It is important to note, space/location as furthered by this renewed Internet industry has seemingly extended the influence of the 'social' as a driver of contemporary Internet innovations (Sap executive insight paper, 2011). Internet and surrounding communication technologies are becoming the key drivers in the innovations and new business models.

2. INTEGRATING GIS AND INTERNET TECHNOLOGIES FOR NEW BUSINESS MODELS

GIS's development has been more evolutionary, than revolutionary. It responds to contemporary needs as much as it responds to technical breakthroughs. Planning and management have always required information as the cornerstone. Early information systems relied on physical storage of data and manual processing. With the advent of the computer, most of these data and procedures have been automated. As a result, the focus of GIS has expanded from descriptive inventories to entirely new applications involving prescriptive analysis.

In the past, analytical models have focused on management options that are technically optimal. Yet in reality, there is another set of perspectives that must be considered, the business solution. It is this final sieve of management alternatives that most often confounds geographic-based decisions. These are not the usual quantitative measures amenable to computer algorithms and traditional decision-making models (Berry, 2000).

The step from technically feasible to business acceptable options is not so much increased scientific and econometric modelling, as it is communication. Basic to effective communication is involvement of interested parties throughout the decision process. This new participatory environment has two main elements—consensus building and conflict resolution. Consensus building involves technically-driven communication and occurs during the alternative formulation phase. It involves a specialist's translation of various considerations raised by a decision team into a spatial model. From this perspective, an individual map is not the objective. It is how maps change as the different scenarios are tried that becomes information. Often, seemingly divergent philosophical views result in only slightly different map views. This realization, coupled with active involvement in the decision process, can lead to group consensus (Berry, 2013).

However, if consensus is not obtained, mechanisms for resolving conflict come into play. The business-driven communication occurs during the decision formulation phase. It involves the creation of a "conflicts map" which compares the outcomes from two or more competing uses. Each map location is assigned a numeric code describing the actual conflict of various perspectives. For example, a parcel might be identified as ideal for a wildlife preserve, a campground and a timber harvest. As these alternatives are mutually exclusive, a single use must be assigned. The assignment, however, involves a holistic perspective which simultaneously considers the assignments of all other locations in a project area.

Traditional business approaches rarely are effective in addressing the holistic problem of conflict resolution. Even if a scientific solution is reached, it often is viewed with suspicion by less technically-versed decision-makers. Modern resource information systems provide an alternative approach involving human rationalization and tradeoffs. The dialogue is far from a mathematical optimization, but often comes closer to an acceptable decision. It uses the information system to focus discussion away from broad philosophical positions, to a specific project area and its unique distribution of conditions and potential uses (Berry, 2000). In this direction, GIS might have the unique ability to be the right solution.

GIS uses spatio-temporal (space-time) location as the key index variable for all other information. Just as a relational database containing text or numbers can relate many different tables using common key index variables, GIS can relate unrelated information by using location as the key index variable. The key is the location and/or extent in space-time.

Any variable that can be located spatially, and increasingly also temporally, can be referenced using a GIS. Locations or extents in Earth space–time may be recorded as dates/times of occurrence, and x, y, and z coordinates representing, longitude, latitude, and elevation, respectively. These GIS coordinates may represent other quantified systems of temporo-spatial reference (for example, film frame number, stream gage station, highway mile-marker, surveyor benchmark, building address, street intersection, entrance gate, water depth sounding, POS or CAD drawing origin/units). Units applied to recorded temporal-spatial data can vary widely (even when using exactly the same data, see map projections), but all Earth-based spatial–temporal location and extent references should, ideally, be relatable to one another and ultimately to a "real" physical location or extent in space–time.

Related by accurate spatial information, an incredible variety of real-world and projected past or future data can be analyzed, interpreted and represented to facilitate education and decision making (Rafi, 2011).

GIS technologies are not merely about space location, in this sense, and can be read as technologies of mobility. As Cresswell (2010) writes, mobility is ~~-t~~he entanglement of movement, representation, and practice". Physical movement, Cresswell continues, is the ~~-r~~aw material" of mobility. Beyond this notion, however, representations of mobility abound. Mobility is thus about the meanings of movement (or the absence of movement) (Cresswell, 2011). In this sense, mobilities demand the recognition of the spatiality of our worlded interactions, despite the ways in which space and time are ~~-t~~amed", to use Massey (2005), by some methods for measuring movement.

The rise of Internet technologies marks a further enabling of the turning of space into time, while also producing more complex relationships of mobility between the here and there. These geographies of information technology emphasize the ways in which technology imbricates in everyday life.

It therefore becomes apparent that new models cannot succeed in a business sense without integrated framework based on detailed knowledge of GIS and Internet technologies.

3. RESEARCH AND OBJECTIVES

This research aims to develop an effective response to the challenges currently faced by emerging GIS and Internet technologies and their influences in different new business models.

It is intended that the research findings will contribute to the development of a framework/model designed to support the creation of the software which could be effectively used to manage new business models.

These above aims raise the following core project objectives:

• To identify different location/positioning and communication technologies

• To propose ways in which these specific technologies may be combined

• To create software to manage new business model related with Real Estate and property market

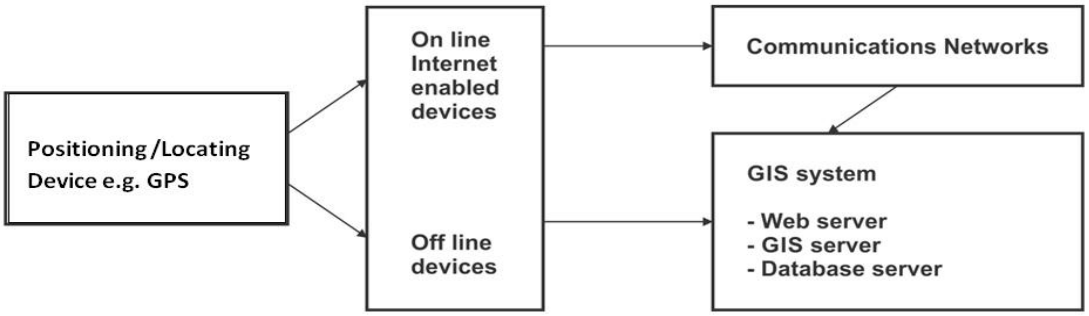

Figure 1. GIS and Internet technologies integrated with the communications networks

4. METHOD

HTML5 with Geolocation API was used and tested on the following the browsers and Geolocation service (including corresponding maps):

- Chrome - Google Location Services
- Firefox on Windows - Google Location Services.
- Firefox on Linux - GPSD
- Internet Explorer 9+ - Microsoft Location Service.
- Safari on iOS - Apple Location Services for iPhone OS 3.2+.
- Opera - Google Location Services.

The following code (JavaScript) was applied in the part of GIS in order to get the current location of the user:

```
// Current position
navigator.geolocation.getCurrentPosition(prcsGeolocation,geolocError,
{
timeout: 0,
enableHighAccuracy: true,
maximumAge: Infinity
}
);
//Tracking position
Id = navigator.geolocation.watchPosition(prcsGeolocation,geolocError,
{
timeout: 0,
enableHighAccuracy: true,
maximumAge: Infinity
}
);
```

Figure 2 Snippet of the code

The method of comparison was used with the following criteria:

- Accuracy of location
- Work in the different environments (in-door, bad weather conditions etc)
- The range of the different platforms and devices
- The level of adaption with open source software (like PHP, MySQL)

5. APPLIED GIS - ADVANCED REAL ESTATE MANAGEMENT SYSTEM

Malta is a southern European country in the Mediterranean Sea. With the area of 316 km2 and the population of 400000 people, Malta is one of the world's smallest and most densely populated countries. Malta's population density of 1,282 per square km is by far the highest in the EU, and one of the highest in the world [17- [Online]. Available: http://mt.wikipedia.org/wiki/Malt, 2014.]. Very limited space with population density and advance economy has a serious impact in many different sectors. One of this area is real estate or property market.

Malta with very good standard, historically always important geographic position, moderate climate, membership in Europe Union, is very attractive location for many people to buy or rent the property. The prices in last decade clearly indicates this trend. However, the micro location is increasingly becoming the key factor in the most of the business decisions related with the real estate system in Malta. It was clear the new information system needs to be in place, which represents not only the properties, but more the complete environment around the properties. The price is important factor, but the location is even more important.

The new system is based on GIS architecture with the following components:
- HTML5 with Geolocation API
- XML
- PHP
- MySQL

The main features of the system:
- Clear separation of the client and server side
- HTML5 and JavaScript enables all the platforms (Windows, PC, MAC) and devices (PC, SmartPhone, Tablet) to use the system
- Using XML as de-facto standard in exchange format
- PHP and MySQL as open source technologies

There are two parts of the application:
- Administrator part which is responsible for all input and updates of the data
- The part for Public user which could search for the property

Using HTML5 Geolocation API, which separates the implementation of Geolocation from the underlying devices, there are several benefits:

- There is a solution for the limitation of GPS (Chivers, 2013) which cannot work in bad weather conditions or in-door environment.

- Combining several methods of the positioning like GPS, A-GPS, Cell-ID, Wi-Fi (Reardon, 2005) etc, the accuracy of the coordinates is improved and it is available in all different environments.

- Web interface brings main advantage to avoid any limitation of using different devices with the different operating systems

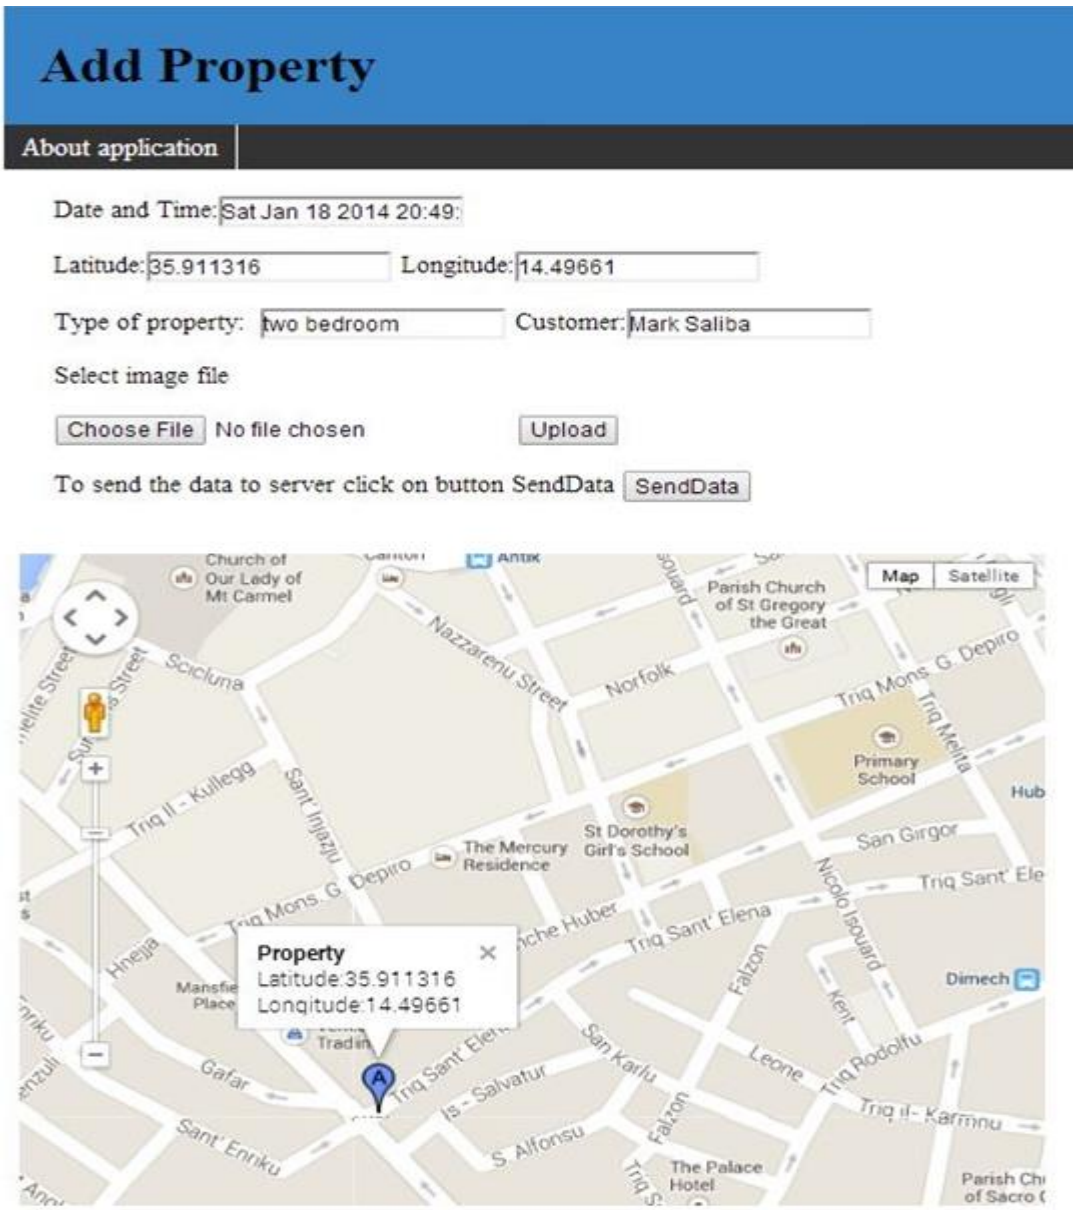

Figure 3. Add Property

Very important feature of the new system is the ability to add the objects which are located near the property. As it was mentioned, micro-location is becoming very important factor in any business decisions related with property.

How far is the post office? How far is the bank? But even more important the information about some small objects which usually is not available, like small supermarkets, green grocery shops, pharmacy etc.

Similar to the previous screen, adding the object located near the property is very simple process, getting the coordinates of the object, inputting the details of the object and send data to server.

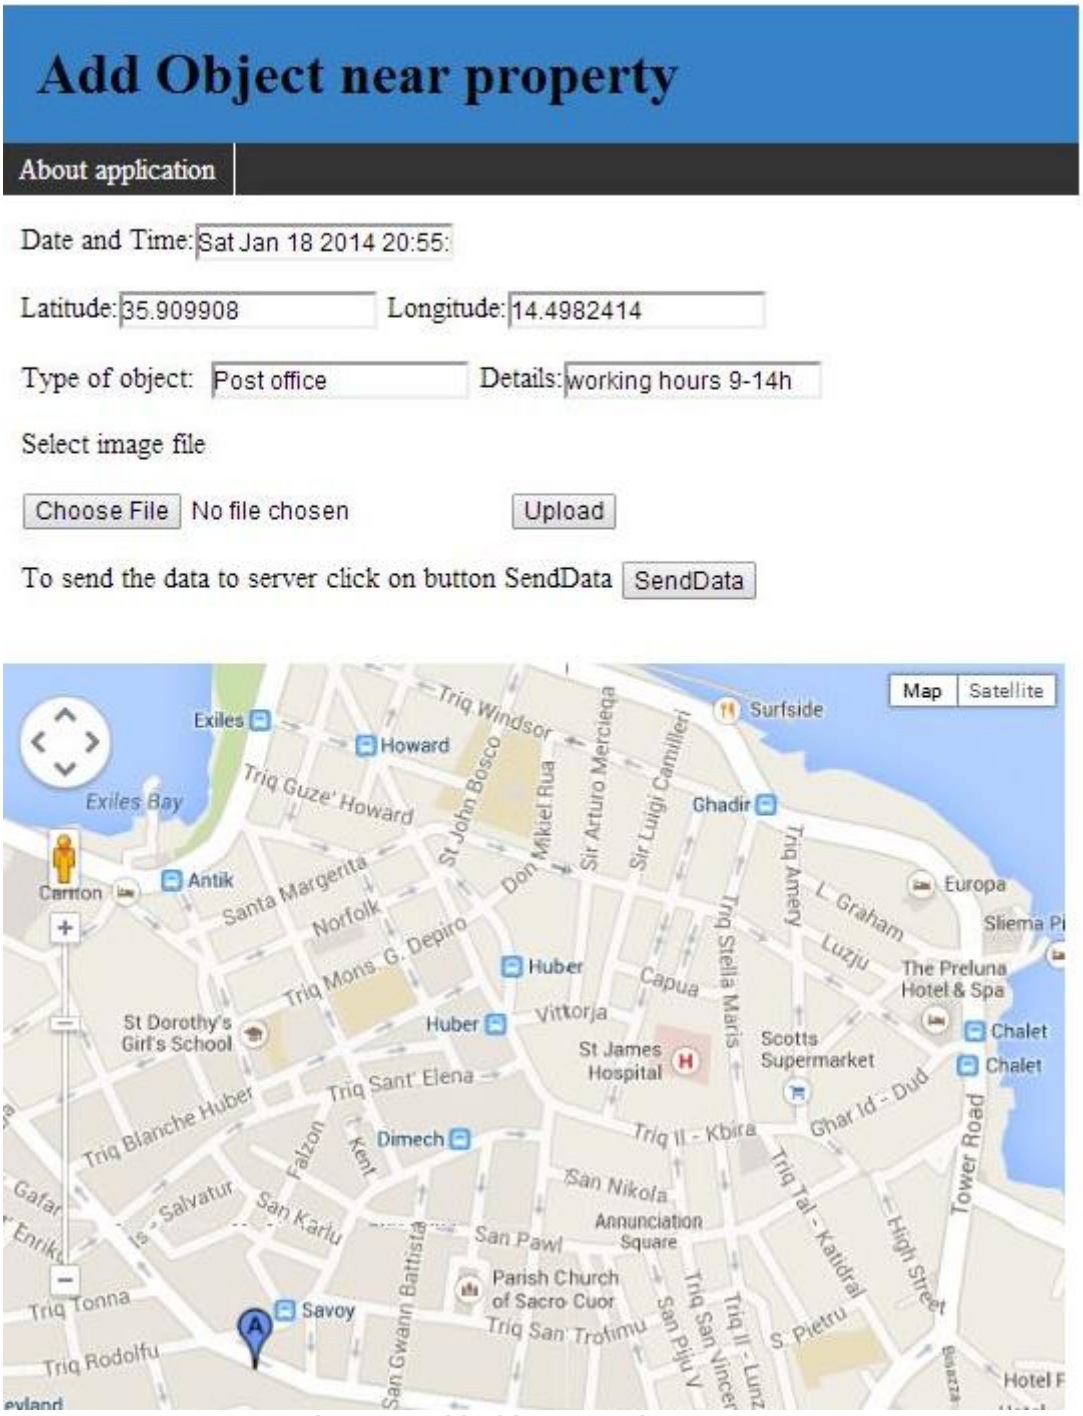

Figure 4. Add Object near the property

Public user of the application could use the search in two modes:

- Selecting the position of the map and inputting the search criteria like; find and show all the properties which are located in the distance of 500 m from this position and the value of these properties not to exceed 100 000 euro.

- Automatically getting the current position (show on the map) and inputting the search criteria like; find and show all the properties which are located in the distance of 500 m from this position and the value of these properties not to exceed 100 000 euro.

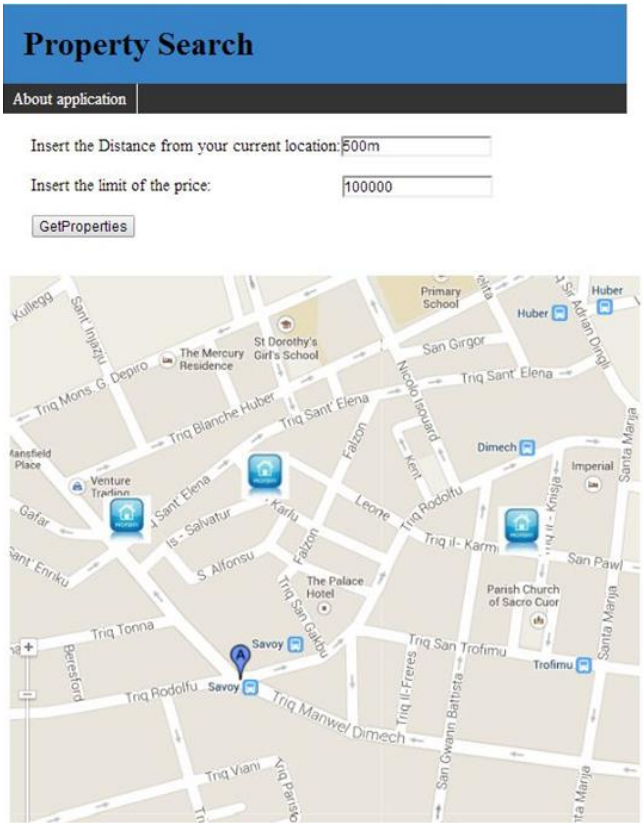

Figure 5. Property search

Figure 5. Shows three properties with above-mentioned conditions.

Figure 6. Property View

Clicking on one of these properties (exactly clicking on the icon which represents the property) from the Figure 5. the next screen (Figure 6.) will show the property.

The details of the property will be shown, like one or two images and the objects close to this property. The location of the objects and ability to see their position in a relation with the location of the property will give the new details about the property itself.

6. CONCLUSION

The new trends and developments of the information technology have very important or even the critical impact to all spheres of today's economy. Technological mobility, the characteristic of modern world, is changing the traditional meaning of the space/location. The new business models where the space/location

is critical will require integrated approach in combining different Internet technologies with the communications networks where GIS will be synergy integrator on the separate levels.

Advance real estate management system is one of the examples where this integrated approach is applied. Considering very specific conditions, the system is developed to be the tool to manage appropriate business model with over 3000 properties and over 7000 objects. The new research and recommendations will be to create the other prototypes of the software solutions based on the above-mentioned integrated approach, always considering business model as a critical factor.

CLOUD COMPUTING INFRASTRUCTURE APPLICATIONS IN COMPUTER SIMULATION

Mihailo Marinković[1], Sava Čavoški[2], Aleksandar Marković[3]
[1]Telenor Serbia, mihailo.marinkovic@telenor.rs
[2]MDS Information Engineering, scavoski@mds.co.rs
[3]University of Belgrade, Faculty of Organizational Sciences, aca@fon.rs

Abstract: *This paper presents possibilities for improving computer simulations using cloud computing infrastructure. Authors examine the types and good examples of cloud-based computer simulations, offering suggestions for the architecture, frameworks and runtime infrastructures which support running simulations in cloud environment. There are cases when Monte Carlo simulation can have more accurate outputs than analytical methods. In order to reach such accuracy and results precision, Monte Carlo simulation sometimes requires orders of magnitude more computing time. Such computationally intensive scientific problems can be solved by using the possibilities offered by cloud computing platforms as cloud computing has become the standard for providing hardware and software infrastructure. Authors present results of solution that uses public cloud infrastructure for executing simulation experiments and increased efficiency of simulation execution more than 300 times and still keeping costs at acceptable level.*

Keywords*: cloud computing, infrastructure, computer simulation, Monte Carlo simulation*

1. INTRODUCTION

In last couple of years, Cloud Computing has become a standard for delivering hardware and software infrastructure. It is based on a pay-per-use business model where resources are acquired only when really needed and customer pays only for resources actually used. Cloud computing represents the mechanism for dealing with the use of external services as part of the computational foundation (Tor-Morten, 2012). It provides scalable, distributed computer services as needed. The aim of cloud computing is to present a service layer for its users where all detailed logic is made transparent and drawn upon as needed. In general, cloud computing is recognized as an infrastructure where all underlying resources (storage, RAM, processors, load balancers etc.) are completely abstracted from the end user. This leads to the cloud provider/vendor to be in charge of performance, reliability and scalability. Gartner (2013) defines cloud computing as a style of computing in which scalable and elastic IT-enabled capabilities are delivered as a service using Internet technologies. The National Institute of Standards and Technology (NIST) defines cloud computing as “a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction” (Peter, M., & Grance, T, 2011). The same authors list three service models: Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS). Some authors extend this list with additional service models: Communication as a Service (CaaS), Database as a Service (DBaaS), Security as a service (SECaaS), Identity Management as a Service (IMaaS), Desktop as a Service (DaaS) (Schaffer, 2009) and Carroll et al. (2011) extend it further with: Monitoring as a Service (MaaS), Storage as a Service (STaaS), Compute Capacity as a Service (CCaaS), Hardware as a Service (HaaS), IT as a Service (ITaaS), Business Process as a Service (BPaaS).

Infrastructure as a Service (IaaS) service model brings possibility for outsourcing common elements of infrastructure like virtualization, storage, networking, load balancers etc. to a vendor of choice. The IaaS provider bills for the infrastructure services usage as per its service level agreement (SLA). One of the biggest benefits of IaaS is that it provides granular control, in which you can choose the core components for your infrastructure.

The starting hypothesis of this paper is that by using cloud computing technologies, researchers can increase efficiency of simulation experiment execution, decrease costs and improve computer simulation process in general. As in traditional computing environment, it is possible to execute all kinds of simulation experiments using cloud computing environment. This approach can make models accessible to a wider range of researchers, and data analysis of simulation experiments outputs can be performed in more improved ways.

2. LEASE OF HARDWARE INFRASTRUCTURE FOR SIMULATION LAUNCHING

Simulation is a process of creating abstract models of real systems and performing experiments based on these models. A computer simulation is a simulation performed by computer to reproduce behaviour of a system (Radenković et al. 2010).

IT infrastructure is the foundation for computer simulation, and has important impact on simulation execution efficiency, on process of simulation model development as well (Marinković et al. 2014). Recent development of virtual platforms and virtual platforms hardware infrastructure modified the way in which the applications, services and hardware are used on Internet. Cloud computing represents a new way for using infrastructure, hardware and software resources. We may differentiate between private, public and hybrid clouds (Figure 3). The well-known public ones are: Amazon, Google, Microsoft Azure and Salesforce. The private clouds are often developed within big companies, by using the virtual platforms (commercial: VMware, Citrix, or open source: Eucalyptus).

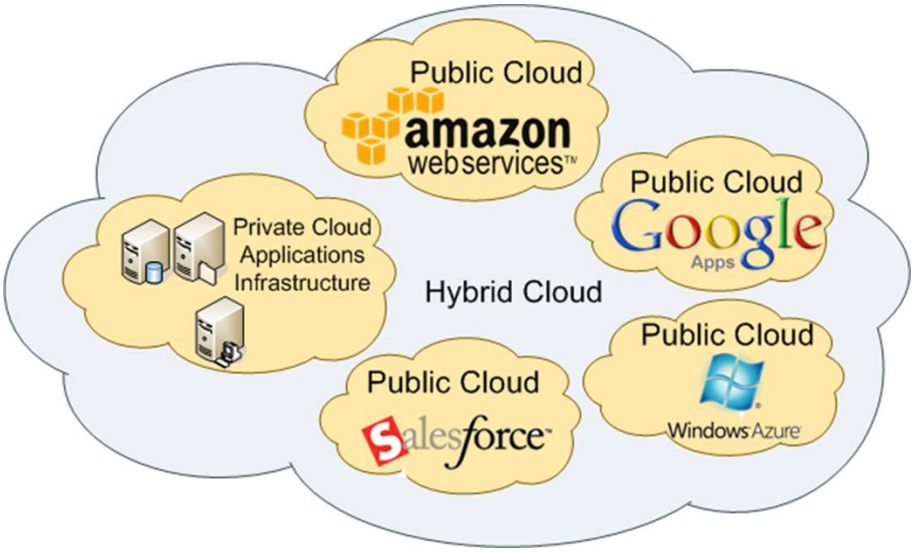

Figure 1: Types of clouds according to the development model (adopted from Slook, B, 2009)

In our paper we will present possibilities of using computing infrastructure offered by public cloud provider.

The use of cloud computing services has become inevitable in the majority of research institutions with the aim of fulfilling the need for increased IT resource and data storage capacities. The main three factors which influence the expansion of cloud computing use are the following:

1. Constant increase of IT resources and storage needs which lead to increased hardware and support costs;
2. Exponential growth of data used in research;
3. Greater use of Service computing which use Web 2.0 applications.

Along with IT infrastructure rented from cloud computing service providers, research institutions are starting to use applications accessible on the Internet, instead of traditional software installed on on local computers. This approach reduces IT system complexity, prices and maintenance costs.

Cloud Computing is most frequently related to lease of IT resources in public clouds (IaaS and PaaS service models). IaaS model includes leasing of virtual machines and data storage space, while PaaS model includes leasing of system software (operating systems, DBMS, application servers i and development tools).

The main components of any Cloud infrastructure are:

1. Hardware layer - including storage, IT and network infrastructure (EMC, IBM, CISCO, NetApp, HP, ...)
2. Virtualization layer - application of virtualization technologies: VMware, Citrix, Microsoft
3. Application layer – applications which are offered to users as a service.

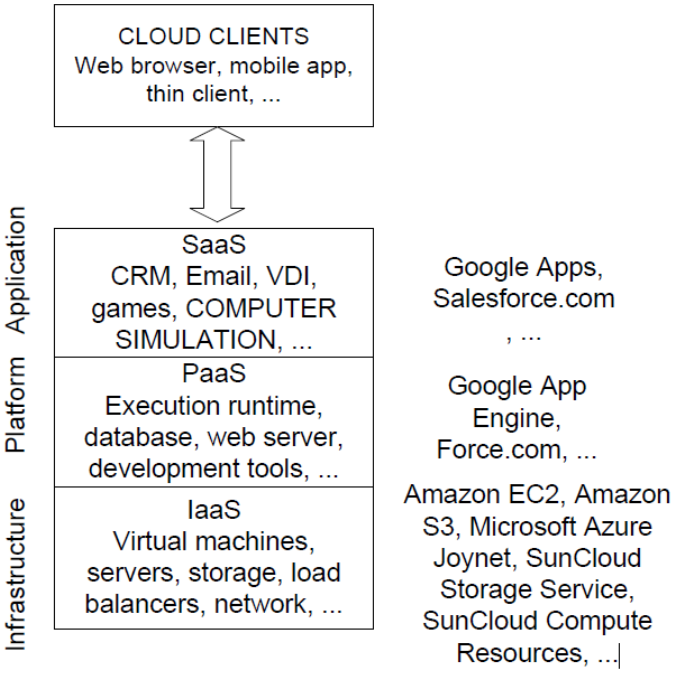

Figure 2: Service models of cloud computing (adopted from Peter Mell, Tim Grance, 2009)

Focusing on the lease of hardware and virtual hardware infrastructure, we can list three main aspects introduced as a novelty by Cloud Computing (Andrzejak et al. 2010):

1. User's impression that the resources are unlimited, which implies that there is no need for additional resources planning;
2. The ability to extend resources at any time and according to current needs;
3. The ability to lease IT resources for a short period of time (for example processors for an hour, data storage for one day) and their abandonment after the activity is finished.

Executing of simulation experiments of complex models has always been hardware demanding and time consuming. Also, necessary memory and storage space for storing results of such simulation experiments is extensive. By the rule, such experiments are demanding large databases which store numerous results of different experiments and their variations. Although they are usually structured, there is a great number of unstructured data output such as pictures, videos, etc. Additional challenge is put in front of researchers by using and processing the data resulting from simulation experiments.

We may conclude that computing infrastructure necessary for performing simulation experiments used to be one of most expensive components of simulation projects. Leasing of IT infrastructure from Cloud Computing service providers brings possibilities for performing multiple experiments which may be executed at the same time, in parallel, without the need of having own expensive IT infrastructure. Also in some cases, during the project implementation, researchers may need to change existing hardware performance by adding additional CPUs, memory and storage, and it is possible to be done during the very experiment. The virtual infrastructure provides business continuity plan, which means that the break-up of physical hardware does not influence the execution of the simulation experiment.

CLOUD INFRASTRUCTURE FOR EXECUTION OF MONTE CARLO SIMULATION

Poole, Cornelius, Trapp and Langton (2012) provide good examples for the implementation of the simulation experiment, by using the Monte Carlo simulation. This type of simulation is common in financial simulations field, and it can be implemented even in spreadsheet (Barjaktarović-Rakočević, et al., 2006, Marković, et al. 2005, Marković & Čavoški 2005). The users of Cloud infrastructure have the possibility to multiply calculations in a short time period within the Monte Carlo simulation experiments, which is the basis of the Monte Carlo simulation (Metropolis, N., & Ulam, S, 1949, Mahdevan, S, 1997). The classic infrastructure would require an expensive and specialized hardware. If it is not available it will be time consuming to

perform calculations. The new infrastructure model ensures the repetition of a great number (millions and even billions) of experiments within a very short period of time.

Poole et al. analysed the application of GEANT4 C++ tool for simulation of penetration of particles through geometrical shapes by using the Monte Carlo simulation. Flexible definition of geometry and adjustment of physical processes offer the user a high level of control and the ability to simulate a wide spectrum of radio therapy techniques with the aim of rapid and quality determination of therapy with cancer patients. In carrying out this study researchers used Amazon EC2 as the computing platform and Amazon S3 as storage. By using the Amazon public cloud the Monte Carlo simulation was significantly speeded up by increasing the number of instances of simulation experiment.

In our study, we have used Microsoft Azure cloud platform as infrastructure for performing simulation experiment. For the experiment task, we have chosen simple case of approximating the value of π using Monte Carlo simulation. Although, there are more complex and useful applications of Monte Carlo simulation, including financial, behavioural, mechanical ad nuclear physics problems, we wanted to focus on benefits provided by using Cloud Computing infrastructure, leaving model as simple as possible.

For approximating value of π using Monte Carlo simulation, we used the approach of approximating the circle with radius r=1 inscribed within a square, as presented in Figure 3. The area of the circle is $r^2\pi=1^2\pi=\pi$, and the area of the square is $(2r)^2=4$. A simple Monte Carlo simulation to approximate the value of π involves randomly selecting n points and finding the number of points that satisfy (red points, Figure 3). In the end, the value of π is approximated as π –
As the generation of points are independent events, we can split them on different nodes and represent them as generating pairs of random numbers in the range between 0 and 1 inclusively and perform validation if they fit inside the circle area by verifying

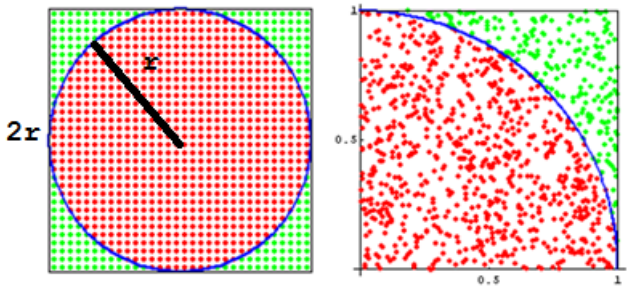

Figure 3: Circle inscribed inside of rectangle and points that fit inside, marked red

Implementation of the simulation software is done by using Java and JBoss application server including JBoss Messaging. The architecture consists of three different types of nodes: one manager node, JBoss cluster and multiple worker nodes and is presented at the Figure 4. Manager node starts and controls simulation experiment, splits simulation process into granular tasks, sends them in tasks queue and collects results from results queue, puts results together and produces final results of simulation experiment. JBoss cluster is in charge of delivery of tasks and results messages to and from worker nodes. Each worker node has the same piece of software installed and listens to tasks queue, performs incoming simulation task and posts back the result of task. The manager node split in tasks according to the necessary number of iterations per each task. Each task, before being sent to the tasks queue is assigned a unique identifier and is saved at the manager node. This way, if some worker node fails, that task is being resent to the task queue and gets delivered to other worker node for processing. In an asynchrony way, idle worker nodes take tasks from the tasks queue in order, one by one, executes necessary random numbers generation in iterations and posts results to results queue. After this, worker node is available for receiving new task from the queue and continues executing it. When all tasks are done, and manager node received all results, it can aggregate final result and calculate requested approximation.

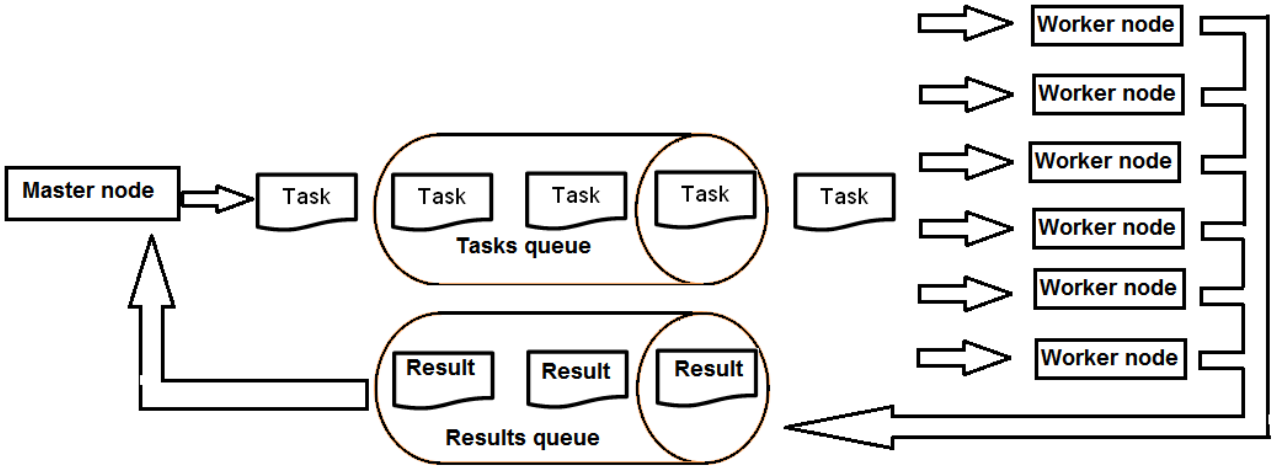

Figure 4: The architecture of simulation system

For comparison purposes, the experiment was conducted on single computer, HP ProBook 6440b, with i5 processor, having 2 cores at 2.4 GHz and 3GB RAM with sequential execution of random numbers generation and also in Microsoft Azure public cloud, on nodes with 2 virtual cores, and 3.5 GB memory. In order to get more accurate results, each simulation task is performed for 10 times and average results are presented in the Table 1:

Table 1: Performance and price comparison

Single computer			Cloud environment		
Number of points generated	Decimal Precision	Avg. Duration	Worker Nodes	Duration	Price (USD $)
100	1	**0,015 s**	2	2,24 s	0,27
1.000	1	**0,121 s**	2	3,45 s	0,27
10.000	2	**0,349 s**	2	4,82 s	0,27
100.000	3	**0,599 s**	2	5,01 s	0,27
1.000.000	3	**1,642 s**	2	7,96 s	0,27
10.000.000	3	**10,983 s**	5	21,72 s	2,74
100.000.000	3	105,354 s	5	**22,44 s**	2,74
1.000.000.000	4	19,944 m	10	**33,66 s**	5,48
10.000.000.000	5	2,648 h	10	**2,34 m**	5,48
100.000.000.000	5	1,042 d	20	**10,85 m**	10,95
1.000.000.000.000	5	11,003 d	100	**47,71 m**	54,75

These results are showing that working with small number of points generation makes more sense to be performed on a single computer rather than using multiple nodes cloud environment. This is most probably because of messaging overhead and time needed for synchronization between nodes. When number of random numbers generated for simulation goes over 100.000.000, 5 worker nodes perform this simulation task near 5 times faster than single computer. This speedup is more obvious when dealing with very large amount of random numbers generated (1.000.000.000.000) where 100 nodes finish this simulation task near 332 times faster, with quite acceptable costs (Figure 5).

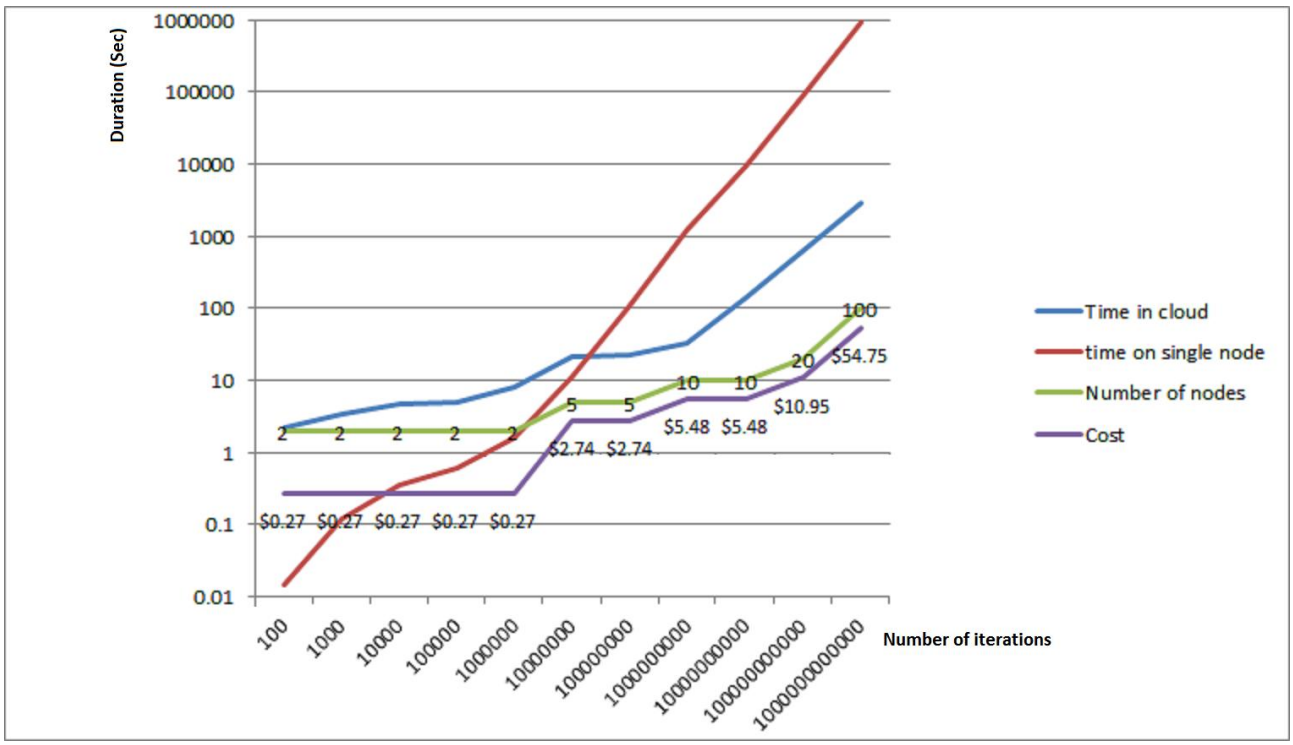

Figure 5: Experiment duration as function of number of nodes, cost and number of iterations

4. CONCLUSION

Earlier, most of the simulation software's paradigm was that each software user has his software copy installed on his computer. There was a strong relation between user, software and computing resources and this approach lacked scalability. By introducing virtualization and cloud environment, the way software is being developed and used has changed significantly. There is no more need for having own computing infrastructure. Distributed computing is now performed using multiple virtual machines rented from one or more cloud providers. As Fox et al. (2009), Harms & Yamartino (2010), De Assunção et al. (2009), Etro (2009), Kondo et al. (2009), Grossman (2009) and many other authors confirmed in their works, the use of cloud computing brings a significant reduction of IT cost. This is more obvious in cases where the system is used from time to time, executing tasks which require intensive computing resources usage, and then powered off. From results gathered during research, we can point out that, by using the public cloud infrastructure, the Monte Carlo simulation was significantly speeded up by increasing the number of instances of simulation experiment. As costs are linearly increasing as number of instances grows, in cases where time is a critical factor, by increasing the number of instances it is possible to speed up the simulation experiment execution with linear cost increase.

CASE STUDY

INCITING PHYSICAL ACTIVITY AMONGST YOUTH USING MODERN TECHNOLOGIES

***Abstract**: Technology is a double-edged sword: it contributes to sedentary leisure-time activities (e.g., playing sedentary computer games), but can also be used to incite physical activity and influence exercise behaviour. For years, people have been relying on pedometers, accelerometers, and heart rate monitors as their source of motivation. Global positioning system (GPS), geographic information systems (GIS), interactive video games, and persuasive technology could also be added to the list of recent technologies and approaches which were used for that matter. Additionally, some experts firmly believe that clinicians should rely on Internet-based physical activity interventions with aim to incite and positively affect exercise behaviour. Modern technologies could influence behaviour of the population, especially youth. This paper introduces the urge for mobilizing youth through sports and technologies. In attempt to achieve that key objective, people should be involved in everyday physical activities, but not necessarily brought to sports fields - instead sports should be brought closer to people. The vision is to challenge people's everyday activities with the sportive ones. Binding on a local level, global orientation shall be developed towards decreasing a negative trend of youngsters' illness, increasing an atmosphere of sport for all. This paper is a result of the cooperation between Faculty of Organizational Sciences and the National Olympic Committee of Serbia on conducting a 2013 case study dedicated to the incite of physical activity amongst youth by using modern technologies.*

***Keywords**: Modern technologies, youth, exercise, physical activity, sport, health promotion, mobile application*

1. INTRODUCTION

Nations around the world are growing into an inactive unhealthy population. Inactivity and passivity represent the main reasons for the obesity issues among the population of age 15-30.[1] The lack of time and small economic incomes often represents crucial excuses why people rather choose to stay at home and live sedentary lifestyle instead of practicing sports. It is important to learn how to perceive sport as a positive habit starting early in childhood days, otherwise this unhealthy behaviour would become a habit not easy to be treated. Encouraging citizens to practice and to be physically active as much as possible through a number of possibilities and activities is perceived as a common task. It is scientifically confirmed that daily physical activity secures a number of healthy and social benefits, while the populations' well-being is increasing. Making different sport disciplines part of a daily lifestyle in children's life, reflects a positive memory, habit and affection towards the active youth.[2] Taking for example the Olympic values as values which could easily be implemented in every aspect of human lives; we have to rethink what the possibilities are and how to strategically start resolving this very common global problem starting from the local level. Global aim in tackling physical inactivity is devoted to finding an efficient tool, best practice or experience. Young people today live in a world characterized by dramatic cultural, economic, social and educational differences; individual circumstances depend largely on where a person is born and raised. More than 800 million adults (where two-thirds of them are women) still lack basic literacy skills; at the other end of the spectrum, the use of information and communication technologies (ICT) is skyrocketing. On one hand, we are living in such era of modern technology where ICT plays an active role in everyday life. On the other hand, we have sport as a very efficient tool in promoting any idea and mission, and in addition, modern technologies as probably the most common instrument in today's families.

[1] According to the National and European Youth Low, people from 15 – 30 are considered to be youth.

2. PROBLEM IDENTIFICATION

Defined by numerous studies, Bauchard and Shephard suggested that physical activity refers to “any form of movement of skeletal muscles resulting in a substantial increase over the resting energy expenditure. Under the broad rubric we consider active physical leisure, exercise, sport, occupational work and chores, together with other factors modifying the total daily energy expenditure.”[3]

Formal organization of traditional sports is being pushed by nowadays trends, modern technologies and virtual reality. Physical education is a key component of high quality education and integral part of lifelong learning.[4] Not being physically active lowers the quality of education supported with negative health effects.

Current physical education curriculum does not provide experience necessary for personal and social development, which resulted in free time usually occupied by modern technologies and unhealthy lifestyle. In other words, physical education does not always succeed to promote healthy lifestyle and to motivate children and youth to practice sports in their free time. Following global and European trend, over 72% of youth in Serbia described physical education classes like monotonous and boring. Considering previously mentioned use of modern technologies, interesting results showed that students believe modern technologies could contribute towards improvement of physical education classes and extracurricular activities in their free time.[5]
According to the results of the latest Eurobarometer[6] survey on sport and physical activity, 59% of European Union citizens never or seldom exercise or play sport, while 41% do so at least once a week. Northern Europe is more physically active than the South and East. 70% of respondents in Sweden said they exercise or play sport at least once a week, just ahead of Denmark (68%) and Finland (66%), followed by the Netherlands (58%) and Luxembourg (54%). At the other end of the scale, 78% never do so in Bulgaria, followed by Malta (75%), Portugal (64%), Romania (60%) and Italy (60%).

The survey shows that local authorities in particular could do more to encourage citizens to be physically active. While 74% of respondents believe that local sport clubs and other providers provide sufficient opportunities for this, 39% think their local authorities are not doing enough.

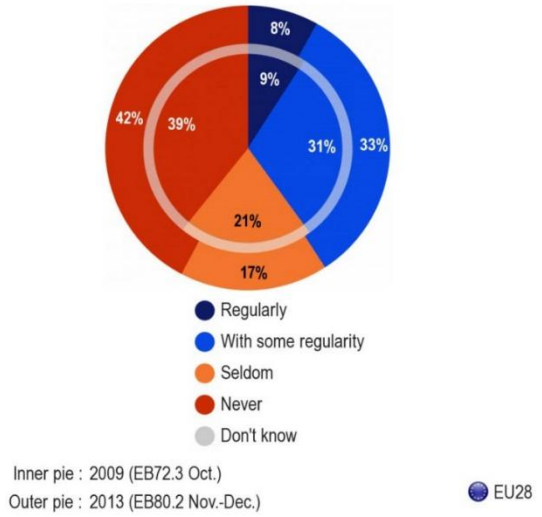

Figure 1: How often do people exercise or play sport?

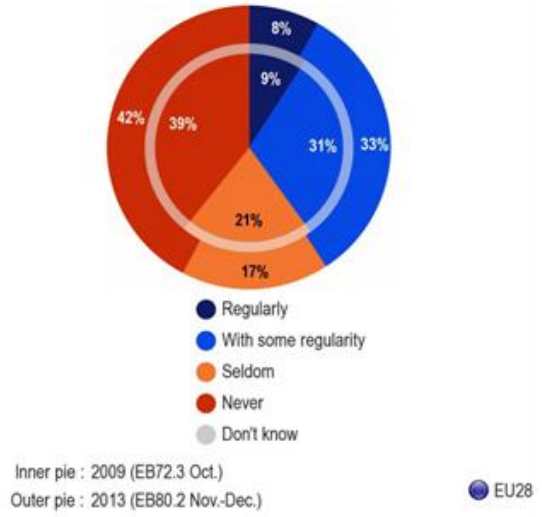

Figure 2: How often do people engage in other physical activity such as cycling from one place to another, dancing, gardening, etc.?

[5] Ministry of Sport and Education, Research Sport center of Serbia and National Olympic Committee of Serbia (2008), “Report: Study of current situation of school sport in educational institutions in Serbia” (p. 3-19), Institute for Education Quality and Evaluation, Belgrade, Serbia.
[6] Eurobarometer survey was carried out for the European Commission by the TNS Opinion & Social network in the 28 Member States between 23 November and 2 December 2013. Nearly 28 000 respondents from different social and population groups took part in the poll. The survey follows comparable surveys conducted in 2002 and 2009, and will contribute to providing data to support the development of policies to promote sport and physical activity.

On the other hand, the results of this survey are compatible with number of studies which shown that recent technological progress completely changed habits of youth.[7] Considering following information (Figure 1), another big problem regarding physical activity of children and youth is obesity.

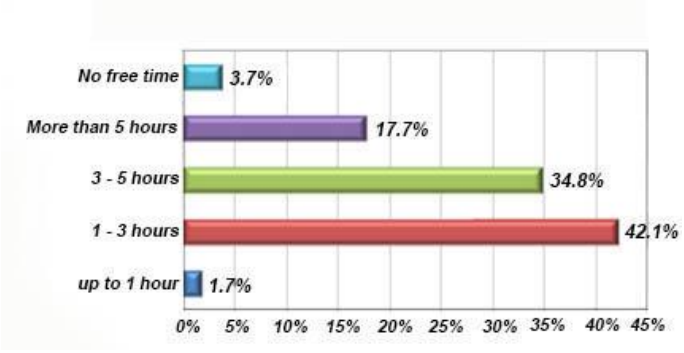

Figure 3: Free time of high school students in Serbia.

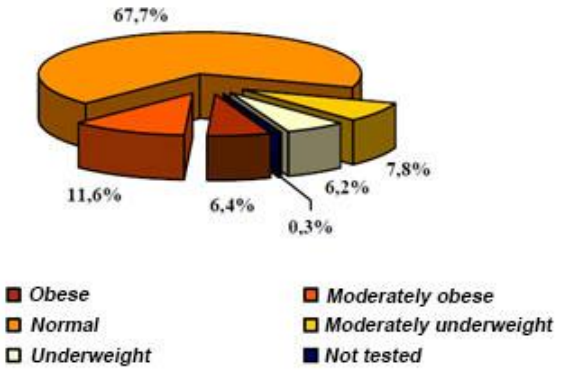

Figure 4: Percentage of children and youth (7-19 years old) by weight categories.

According to the study of health of Serbian citizens in 2006, two thirds of children and youth aged 7-19 were ideal weight (67.7%). Almost one fifth of youth (18%) were medium obese, which is an increase comparing to 2000. (Figure 3). Also, the number of underweight children (6.2%) decreased comparing to year 2000. (8.4%). Increased number of moderately obese and overweight children, caused by bad diet habits and lack of physical education presents significant health issue.

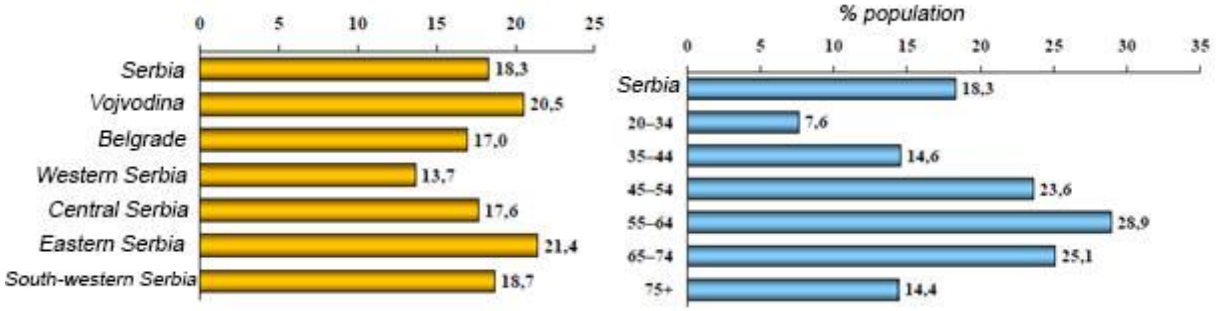

Figure 5: Percentage of overweight population regarding age and geographical region.

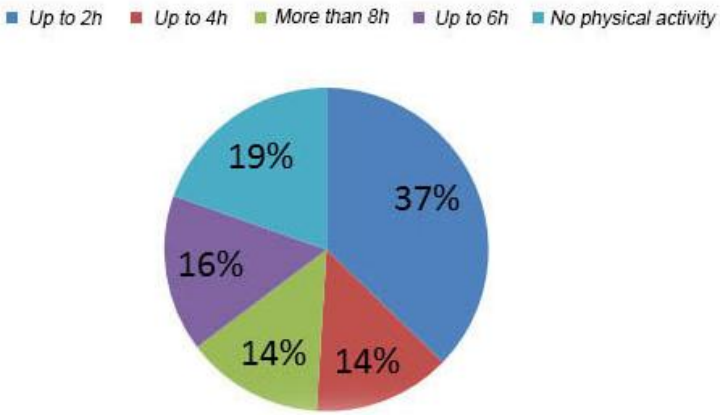

Figure 6: Physical activity of children and youth (15-25 years old) in hours per week.

The results of the Eurobarometer confirm the need for measures to encourage more people to make sport and physical activity a part of their daily lives. This is crucial, not only in terms of an individual's health, wellbeing and integration, but also because of the significant economic costs resulting from physical inactivity. The Commission is committed to supporting Member States in efforts to encourage the public to be more active. We will implement the recently adopted Council Recommendation on health-enhancing physical

[7] European Commission, (2009-2013), Eurobarometer survey (p. 20-193), European Commission's Directorate-General Communication, Brussels, Belgium.

activity and move ahead with plans for a European Week of Sport. The new Erasmus+ program will also - for the first time - provide funding for transnational initiatives to promote sport and physical activity.

3. RECOGNIZING THE NEGATIVE TREND VIA GLOBAL SPORTS INDUSTRIES

Several reports establishing a link between a lack of physical activity and health problems have been published all throughout Europe.

These studies show that health threats, such as chronic sicknesses, obesity, posture problems and also a reduction of the cognitive processes can be linked to physical inactivity. Especially young people´s lifestyles have shown a growing trend towards increasing sedentariness coupled with an inadequate diet. This combination of critical factors motivated the partnering organizations to propose a project, using physical activity and education, to promote an active, healthier way of life. The design of the activities has been originally developed for the German-Dutch EUREGIO project named GKGK.[8]

Particularly the age group of children and adolescents should be paid special attention to, as it is in the young years that the foundations are laid for a healthy lifestyle. Therefore play, sports and exercise should be conveyed and encouraged during youth in order to install a lifelong healthy lifestyle.

Numerous investigations have shown that it is far more cost effective and promising to invest in preventive measures by conveying and imprinting a physically active lifestyle, than the treatment of health problems – especially obesity.[9]

Sport as a physical activity is often in a shadow of elite sport. Matter of fact is that sport represents crucially important activity area in ones' life. Being committed to physical activity at early age, is influencing future development of healthy behaviour. Improving school sport is vital, therefore different examples of good practices from all over the globe following below.

Great Britain is an example of highly developed support to talented children and youth, as well as to talented sportive pupils. Their high - schools are running special educational program as a support for young athletes (*Junior Athletes Education – JAE*), but they also have a specialized colleges (*specialist schools*) as a support to talented young people in general.

Since 1994 Australia is developing a national program for identification of sportive talented youth, which has similar to the previous example, strong basics in educational system. Referring to the required annual students' tests for school's sport record, Talent information system has been upgraded while data could be used to grade talent of pupils for specific sports.

Taking into consideration these examples, researches which are done in the field of Serbia emphasize dimension that requires attention. More than half of the schools in Serbia don't meet the required needs for delivering the classes of physical education, specifically sportive halls and equipment.[10]According to this study, 36.5% of schools in Serbia doesn't have a required size of the sportive hall, while 48.5% has the small one (dimension less than 450 m2). Sportive hall that meet all required and proposed needs have only 15% of schools in Serbia, but still 107 schools are missing equipment. Positive impact of physical education is barely impossible, mainly due to the uneven and weak material and spatial conditions, followed by discriminatory valued work of teachers in sport. Abovementioned study presented one positive fact, too. Relying on statistics, pupils in Serbia are significantly more interested to practice sport and physical activity, compared to their generations in other European countries.

4. MODERN TECHNOLOGIES AND SPORT

Complex cultural situation in which young people are struggling to find direction in their lives or simply to survive, to improve their living conditions, and to develop their identities has been given various names.

[8] ENGSO Youth (2010), "Healthy Children in Sound Communities" (p. 2-14), ENGSO Youth, Berlin, Germany.
[9] World Health Organization (2007), "Nutrition, physical activity and the prevention of obesity" (p.17-33), WHO Publications, Copenhagen, Denmark.
[10] Ministry of Sport and Education, Research Sport center of Serbia and National Olympic Committee of Serbia (2008), "Report: Study of current situation of school sport in educational institutions in Serbia" (p. 3-19), Institute for Education Quality and Evaluation, Belgrade, Serbia.

Some call it the information or informational age, while others prefer the term technoculture1 or techno-capitalism, global media culture, or simply globalization, referring to the dialectic process in which the global and the local exist as "combined and mutually implicating principles". [11]Labels such as post-industrial, virtual and cyber society are also in use. The idea behind all these terms is that across the globe, ICT are playing a central role in young people's lives and in society at large.

Europe's youth are growing up in a connected world of internet access, mobile phones and electronic interactivity. Sport remains the most effective means for youth engagement and participation. Efficient use of media is the infrastructure for reaching and engaging youth today, where numerous studies from inside and outside of Europe document how young people are using various media sources as outlets to participate, share knowledge and – more generally – engage in societal matters.

The ubiquitous trend of using the Internet and mobile devices has imposed the IT solution as a logical realization mode of the project of integration of youth and modern technologies with aim to encourage physical activity. This will be the most effective approach to bring the services closer to our target group - **youth**, physically active and inactive individuals and groups. Even in our environment, youth is a group that is above average computer literate, i.e. they are regular Internet users, accustomed to finding, ordering and purchasing products and services through all networks. By comparison, the research shows that students often use computer, as 62.26% of students use computers on daily basis, and 23.13% of them use them several times a week.[12] The percentage of students who do not use the computer for more than one week is 11.6%, while the percentage of those who use the computer a few times a month is just 6.96%.

The development of the third and fourth generation of mobile technologies allows the appearance of new devices which successfully combine two important characteristics of mobile Internet: mobility and quality connection to the Internet. There is an increasing number of mobile phone apps for various platforms (Android, Windows Phone, iOS, Firefox and others) that are dedicated to monitoring of personal athletic performance (e.g. Sports Tracker, MapMyRun, CardioTrainer, iFitness, RunKeeper, etc.). A commonly used approach is relying on the embedded functionalities of the phone, such as GPS, which determines your current location on the map, accelerometer, which determines the speed of your movement, then, the mobile data transfer and the like. In recent years, another interesting approach is the use of wireless sensor networks bondable with smart mobile devices for the purpose of continuous monitoring and control of physiological human functions in sports. Good information for us is that our students have expressed great confidence in the computer and information technology (see Figure 3).

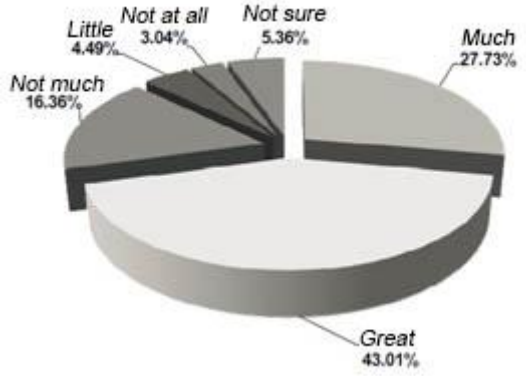

Figure 7: Confidence of students in computer and information technology.

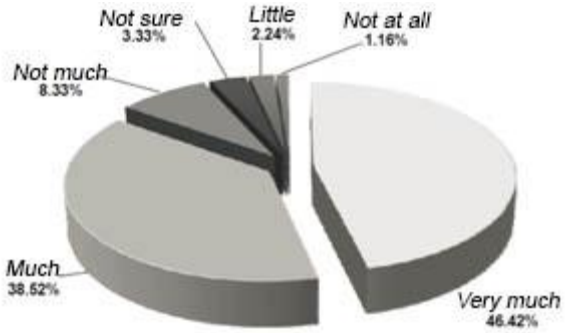

Figure 8: Students' opinions about how computers and ICT can contribute to the modernization and improvement of education process.

Also, 45.94% of students strongly believe that the future of education lies in information technology, and 29.93% of them greatly believe so, 10.22% somewhat believe so, 6.74% do not believe so and 7.17% of students are not sure about it.

5. TARGETED COMMUNICATION AND CAMPAIGNS

Reflecting on increasing the influence of physical education, every improvement of macro and micro long-term oriented interests towards creating systematically healthier nation and youth with clear sport oriented habits should have certain support from country where solution is proposed and realized. Engaging institutional support, but also media and industrial sector is obligatory in order to achieve high level of influence and to meet needs of the community in general.

Authors have identified good practices from European level to regional and national examples that combines modern technologies, young population, community and strong partnerships follows: **European Week of Physical Activity NOW WE MOVE campaign[13] (Europe), Fotomarathon (Germany), We Run Belgrade, the MUZZEUM project[14] (Serbia)**. All share a specific or general common goal of enhancing physical activity among nowadays population for a better and healthier future.

6. INFLUENCING THE REGION

The previous examples from Serbia have not focused on the integration of modern technology to mobilize the youth at the institutional level, with aim to make them like an active and healthy live. The projects were instead mainly focusing on training and adapting sports fields and facilities (tennis courts, mini pitches, multi-purpose courts, jogging track, gym and outdoor, etc.). Projects such as the "Paths of health" (2006), and "Let's improve sport in Vojvodina" (2010) of the Provincial Department of Vojvodina and local governments were directed precisely to this problem. A similar example is the action "What do you train?" (2009), launched by Coca-Cola Hellenic and the Coca-Cola Company with the organization ADFOR - Children's Forum, with the active support of the Ministry of Youth and Sports and the number of partners such as the Institute for Sport, sports Association of Serbia, National Office, Ada Ciganlija and UNICEF, with the aim to motivate those young people who were previously uninterested and insufficiently active to take an active role and play sports.

The study of the situation in educational institutions in Serbia in connection with school sport (2008), which the Ministry of Youth and Sports conducted jointly with the Institute for Quality Education and the Olympic Committee of Serbia, has led to significant results on the situation of school sport. The most popular sport in schools is volleyball, which is the most abundant of the extracurricular, sports activities. A total of 36.2 percent of schools do not have volleyball as an extracurricular activity; 75.7 percent of schools do not have athletics, which is a basic sport; furthermore, 89.6 percent of schools do not even have gymnastics as an extracurricular sports activity. Less popular sports activities, such as aerobics, karate, chess, archery or rowing, almost do not exist as extracurricular activities - this practice is present in between 0.2 and 0.8 percent of schools. Young people are most active at the age of 15-18, when they are involved in school and club sports and system activities (school competitions - School Olympiad, an annual National School Championships, youth sports leagues in the system of national associations). When it comes to educational profiles, the most active students are the ones from the Faculty of Sport and Physical Education, and from other faculties: FOS, the Faculty of Law, Faculty of Mechanical Engineering, Faculty of Electrical Engineering, Economics - mostly faculties who actively participate in the Student leagues, competitions among universities (University Sports Federation Serbia) and international student championships. However, all the problems related to the availability of sports facilities and sports equipment significantly hampered attempts to make youth more interested in sports, especially when it comes to the inactive part of the youth. It is therefore attempted to use modern means of communication and modern technology to approach the youth in helping them understand the need for this way of life. However, the fact that nearly 80% of respondents said they would like more information about the importance of individual exercises, healthy eating, self-training, and the like is very encouraging.[1]

7. CONCLUSION

Despite of number of studies and initiatives for raising up awareness, Eurobarometer in 2013 represented a pore picture where large proportion of adults in Western cultures are physically inactive, despite several decades of warnings and intentions about the potentially negative health consequences of a sedentary lifestyle. Weak points of the Eurobarometer can be revealed, for example the question on the existence of sport facilities should have been broadened. Even though a high percentage of people appointed that they

[13] The official webpage of the NowWeMove Campaign (2012-2020): http://www.nowwemove.com
[14] The official webpage of the Muzzeum project: http://www.muzzeum.com

had sports opportunities in their area, it would have also been interesting to find out more about the quality of the sport facility and if they offer the kind of sport that people actually want to engage in. Efforts to promote and increase physical activity so far have focused on identifying its determinants and designing interventions that might effectively empower regular physical activity. Following global trends in technology and linking them to sports, represents step forward and one of the crucial criteria in communicating and popularizing sport among youth.

Whether it is about usage of social media, mobile applications, internet services or other technological solutions in sport, implementation of such idea should contribute to healthy lifestyle among youth in general through practicing physical activity.

Support of the key stakeholders play an important role in realization of this initiative, starting with different approaches for gaining youth attention and how their interest in sport will be maintained in a long-term perspective. It continues with the importance of how such initiative will be financed and covered by media, supported by all necessary regulations. When it comes to institutional support, it should focus mainly on systematic activities (setting up the legal and formal regulations on youth sports, system software and infrastructure financing activities). University of Belgrade and National Olympic Committee of Serbia have long tradition of initiatives that are very well welcomed and strongly supported. The results and experiences (good ones and bad ones) are recommended to be used to develop specially tailored health-enhanced multi-actor-programs for the partnership of schools, sport clubs and universities on community level.
Legacy remains: developing more opportunities for all to engage in an active lifestyle in order to counteract physical inactivity and overweight/obesity.

8. WHAT'S NEXT: STUDENTS IMPROVEMENT

We have introduced to university students how global issue of inactivity is influencing the national perception, asking them for a sustainable and efficient solution(s).

Table 1: Solutions that solves problems and achieves goals

Problem	Goals	Solution
Inactive youth	Increase physical activity among youth	Interactive mobile phone sports application
Bad infrastructural condition and poorly equipped	Upgrade sports infrastructure	"I am running for school"
Increase of obesity and chronic diseases among youth	Reduce number of obese kids for 5% in next 3 years	Lectures, activities, special events

Best and unique solution introduced was a "TreninGO!" a mobile application for Android platform intended to youth, but also to general population.
According to the survey, majority of young population is not physically active, often spending less than 2 hours per week on physical activities. One of the biggest problems identified back then is that one third of the schools do not have sport halls and facilities and that the existing ones are in bad infrastructural condition and poorly equipped. On the other hand more than 50% examinees are using smart phones, and 60% of them are not familiar with the activities of the Olympic Committee of Serbia.
Through "TreninGO!" project, society will gain the chance to reach young population, and then to influence society, introducing the application through solutions that could meet and reduce above mentioned issues.

APPENDIX

1. STARTING APPLICATION

- Splash screen with logo of the application (TreninGO!), “Beat yourself” motto and partner logos.
- Application **Login** via **Facebook account, Google + or e-mail,** where basic information is applied to application.
- User can see profiles of his friends, and user can invite friends to join application.

2. USER PROFILE

- **Basic information:** User profile contains **photo** (1 additional can be chosen), **name, birth, gender and location**. User can also write something in “about me” field which is limited to 140 characters.
- **Statistics:** Several statistics are available for user – **total time** user spent doing sports, **total distance**, **total amount of calories**, **amount of hamburgers** user burned doing sports (total amount of calories / hamburgers calories value) and **average speed**.
- **Badges:** Doing sports and reaching specific goals, user can win the different badges visible on his profile, which could be shared on social networks. The examples of achievements are: **first run**, **fastest time**, **7 days doing sports in a row,** but also **two weeks of inactivity**.
- **Rating:** Users can rate other users according to their activity, and rating of each user is shown on user profile and presented with stars.
- **History:** History for the user activity is available for each day, week or month.

Figure 9: Splash screen with logo of the application (TreninGO!), "Beat yourself" message and partner logos.

Figure 10: Login screen of the application.

Figure 11: Profile screen that contains information about user.

3. NEWS FEED

- **Interaction:** In a NEWS FEED **user can see activities of his friends at the moment**, **the results they achieved** or **which sport event did they sign up**. After finishing sport activity user can share result on social networks.

4. CHOOSE TRACK, TEAM AND CHALLENGE

- **Chose Track:** Map shows all the tracks and sport courts. Each track has basic information such as name, length, ground type, rating presented with stars, average time and current king who holds the best time. The king is a person who made the best result (fastest time) for past two months. Users can add different tracks, sport courts, and outdoor sport machines on their own, and they can add photos. User can also write reviews and comments about sports locations. After choosing the track, user chooses if he wants to compete with some result which could be his best time on that track, or the best time of his friend, or the fastest time on track in general. After choosing the track and starting an exercise, user can see his progress on the map, current time, and time left for beating the best result. **Hint:** There is a welcome message when user enters the track for the first time. In order to add the track, user needs to run that track, so the starting and ending point could be defined.
- **Choose your Team:** User can create a sport event on a certain location and invite people to join. Other users have YES, NO, and MAYBE available as choices.
- **Choose the Challenge:** Challenges can include various sports and exercises for users. User will have different exercises programs available, which are provided by Serbian Olympic team. Users that choose challenge option will have different written tasks each day. Some tasks might include a video or a key message from the sportsman. During the challenge and after successfully finished task, different motivational and supportive pop up messages and push notifications could appear. After finishing the challenge successfully user gets special badge.

Figure 12: Screen that shows available tracks and challenges.

Figure 13: Screen that show map with current progress.

5. CHOOSE ACTION (GOOD CAUSE)

- Users can join different campaigns where they can for instance “Run for their school”. For each kilometre that users ran or walked, they donate specific amount of money for renovation or new equipment.
- Progress line shows how much money is raised, and how much is needed for renovation.
- All the data that users generate can be seen on the website after logging in.

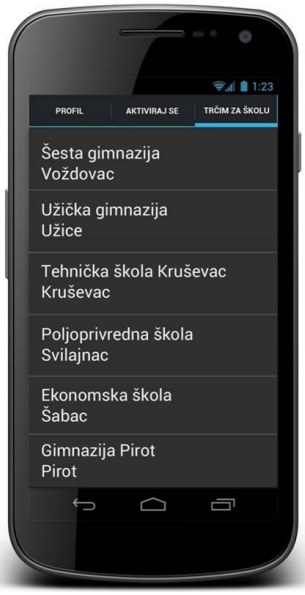

Figure 14: Screen that shows schools available for donation.

Figure 15: Screen that shows how much money is raised, and how much is needed for renovation.

ALFA BANK: DEVELOPMENT STRATEGY FOR NEW DIGITAL CHANNELS

[2] Faculty of Organizational Sciences, kristi.petric.92@gmail.com
[3] Faculty of Organizational Sciences, damvesna@fon.bg.ac.rs

Abstract: *Alfa Bank is one of the leading private Russian banks. This case study provides information about strategies that Alfa Bank is implementing in battling with competition, with special focus on new digital channels, as they represent a new business model for attracting customers. The authors present an overview of Russian banking industry, banks competing on this market, as well as an overview of customer segments and popular services. There is special focus on e-banking and electronic channels that Alfa Bank is using and how their implementation has helped the bank reach the leading position among privately owned banks, with further potential for development.*

Keywords*: Alfa Bank, bank industry, competitive advantage, new business model, digital channels*

1. INTRODUCTION

Maxim, director of e-business at Alfa-Bank, was spending sunny Saturday afternoon on the porch of his favourite café with his sister Anna. She moved to America 10 years ago, graduated from university there and is now working in a major U.S. company in the field of information technology. Maxim was glad to argue with her about latest technological innovations, improved gadgets, and cutting-edge technology. They started talking about E-banking and difference between America and Russia. For Maxim, it was hard to understand why Russians are so reluctant to pay via the Internet, but he was sure that in the future electronic channels will be the best way for bank to stay competitive on Russian market.
Next day he decided to set up meeting with board of directors. He thought that company's strategy for electronic channels is not clearly defined and in the future, using these channels may be best way for company to stay competitive. However, he was not sure how the company can use and improve electronic channels. He decided to start with setting up the goals:

1. Increase number of Alfa-Klik users from 20% to 30% in 2014
2. Increase number of Alfa-Mobile users to 15% in 2014

2. COMPANY BACKGROUND

Alfa bank is the leading Russian private bank by total assets, total equity, customer accounts and loan portfolio, founded in 1990 in Moscow, where it is headquartered today. Alfa Banking Group offers a wide range of products and operates in all sectors of the financial market, including corporate and retail lending, deposits, payment and account services, foreign exchange operations, cash handling services, custody services, investment banking and other ancillary services to corporate and retail customers. Its branch network consists of 617 offices in Russia and abroad, and it includes a subsidiary bank in Netherlands, and financial subsidiaries in the United States, the United Kingdom and Cypress. The bank employs over 25.000 people and provides services to over 109.000 corporate customers and 10.6 million retail clients. Throughout its history, Alfa Banking Group has considered its reputation as its most valuable asset. For this reason it was one of the first Russian companies to publish a Social report. In 2013, Alfa Banking Group also picked up awards: "The best retail bank" by Retail Finance; "The best internet Bank in Russia" in 2013 by Global Finance; the title of the Best Russian Bank providing private banking and wealth management services in 2013 by SPEAR'S magazine. (Alfa-Bank corporate site- Corporate Profile, 2014)

Alfa-Bank Russia has a mix of Western and Russian management which successfully combines international standards of business and corporate management with deep knowledge and expertise in the Russian market. Its franchise is supported by an extensive distribution platform with multiple delivery channels, including in-person service through branches and offices, and ATMs spread across Russia and the CIS, as well as remote access through internet and phone. Alfa Banking Group has always supported charities, Russian culture, the creation and development of programs for young talent, and corporate responsibility has always been a key component in its social policy. The most valuable asset of the company is its reputation.

(Alfa-Bank corporate site- Alfa Bank Governance, 2014; Alfa-Bank corporate site- Corporate Profile, 2014; Alfa-Bank corporate site- Annual Rreport, 31.03.2014)

Alfa Bank Finance Structure

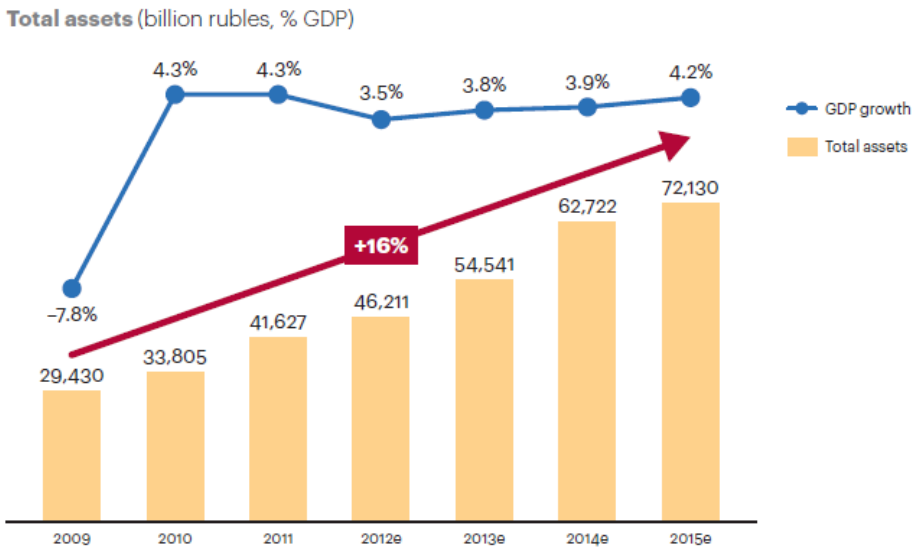
Net profit of the Alfa-Bank Russia for the period (2013) amounted to USD 900 million which is the highest reported annual profit in the history of Alfa-Bank Russia. Total equity increased by 16 % to USD 4.8 billion. Total operating profit before tax and provisions was USD 3.1 billion. High profit was driven by considerable growth in net interest income and fee and commission income reflecting excellent performance in all core business segments based on expanded customer base, portfolio growth combined with high quality of delivered services and operational efficiency. (Alfa-Bank corporate site- Alfa-Bank News, 2013)
The Alfa-Bank Russia net interest income increased by 33.5% to USD 2.3 billion in 2013 from USD 1.7 billion in 2012. The increase was mainly driven by growth in interest bearing assets, in particular retail loans. In the 2013 total assets of the Alfa-Bank Russia increased by 5.9% to USD 48.6 billion at December 31, 2013 from USD 45.9 billion at December 31, 2012. (Alfa-Bank corporate site- ABH Financial Limited, 31.12.2013)
In the funding structure of the Alfa-Bank Russia customer accounts remained stable at USD 26.7 billion as at December 31, 2013. Meanwhile, retail customer accounts increased by 17.8% to USD 14.4 billion as at December 31, 2013. (Alfa-Bank corporate site- Income statement, 11.04.2014)
As at December 31, 2013, cash and cash equivalents accounted for 12% of total assets. In addition, the Alfa-Bank Russia holds investment portfolio of highly liquid debt securities available for sale amounting to USD 2.1 billion. The Group has also access to secured and unsecured funding provided by the Central Bank of Russia. (Alfa-Bank corporate site- Annual Rreport, 31.03.2014)

3. BANKING SECTOR IN RUSSIA

Industry overview

Over the past six years, around 300 banks in Russia were taken over by large state owned or international institutions. Compared to other European countries, Russian market has grown with a CAGR of 27% from 2005 to 2010. There is even more room for growth on the Russian market, as banking sector assets represent only 75% of GDP, compared to 100% of GDP which is usual for developed economies. As shown in Table 1, growth projection is that by 2015 the market will grow by 16% compared to 2009.

Table 1: Future predictions for banking sector in Russia



With the majority of banks dominating the market being state-owned, private banks such as Alfa Bank need to find their spot on the highly competitive market by applying new business models and focusing on offering added value to their customers. There is also a trend of greater concentration by the larger banks (AT Kearney, 2013; Moody's Investor Service, 2013).

Customer segmentation

16 - 22 years old
This group includes students with first job (often part-time). They need short-term loans, money transfer services, simple forms of savings, as well as services related to tourism (purchasing insurance, multi-currency accounts, etc.), and cards. This group can be divided into youth, without special education, living outside the home, and youth with ongoing education.

25 - 30 years old
People this age are thinking about creating family, settling life, and therefore their needs are: targeted savings for purchasing houses, apartments, durable property and insurance for purchased property. Bank services popular for this group are: money transfers, opening a single account for family members, various forms of revolving credit, financial protection (insurance), account transactions via phone or internet.

28 - 45 years old
This segment includes people with established careers, steady, but still not free financial situation. Their goals are diversified: children education, family financial security and improving living conditions. Services popular for this group are long-term loans for purchasing durable goods and new houses, savings schemes for children and their parents, advices for insurance, savings and taxation.

40 - 55 years old
Goals and tasks of this group are very similar to the previous one. Representatives of this group are also supporting family and focusing on long-term products. However, a significant part of the income is spent on own and travel needs. The main features of this group are: revenue growth, reducing liabilities and pension planning.

Over 55 years old
This is the most robust and stable group of clients. Customers are characterized by the presence of large account balances. Necessary services for this group are: testamentary dispositions, financial consulting, trust capital management, operations related to tourism (purchasing traveller's checks, insurance, etc.), as well as credit cards.

Online bank users in Russia

The most active smartphone users are usually young people, as well as the more mature members of the middle class (men and women aged 23-37). They use Internet, pay and buy online more often than the others. On the other hand, in Russia, usage of e-banking depends on income. Among the users of "Alfa-Click" most customers are from the high-income group - more than 60% of all service users. The lowest percentages of users (35%) are customers from a group with income below average.

According to Alfa-Bank's research of customers, despite the active penetration of the Internet, electronic channels are still not popular in Russia. Alfa Bank has conducted research of customers who don't use e-banking. The study involved customers of Alfa-Bank and other banks, who don't use electronic services. Half of the clients (48%) had never heard of such a service as an internet bank. One fifth of these clients have the misconception about online banking and mobile banking, and only 16% of respondents have ever used online banking (mobile banking - even smaller percentage). The main reason why clients are not using electronic channels was that —there is no need to use them". This indicates that customers simply do not have enough information about electronic channels and they do not understand how and why they can use them.

There are seven segments of "non-users" of electronic channels: disinterested (25%), customers who call several reasons (25%), problem – having customers with difficulties of using/connecting to services and prefer personal contact with staff offices (12%), beginners who do not know about the possibilities of the service (12%), disloyal who are enjoying such services of other bank or are simply uninterested (10%), sceptics who do not trust to the security system of electronic channels (8%) and customers who do not have access to the Internet (8%).

E-banking in Russia

Market for electronic banking channels is increasing annually. In 2013 market volume in Russia was 15 million users, and the total amount of transactions by individuals through online banks was 591 billion rubles. In Russia, almost every large bank has an application for online and mobile banking. As shown in Table 2,

according to recent data, Alfa-Bank is positioned as the best online bank and the second ranked mobile bank in Russia.

Table 2: Internet banks rating - parameters: functionality and usability (Markswebb Rank&Report, 2014)

Ranking	Bank	Functionality	Usability
1.	Alfa Bank	A	4
2.	Bank24.ru	A	4
3.	Bank Saint Petersburg	A	4
4.	Russian standard	AA	3.5
5.	Moscow credit Bank	A	3.5
6.	Tinjkoff Credit Systems	BB+	4
7.	Svyaznoy Bank	BBB	3.5
8.	BINBANK	BBB	3.5

Ratings are indicating that the most successful e-banks, apart from Alpha Bank Online, are TCS Bank, Promsvjazj Bank, VTB 24, Bank - Saint Petersburg, Avangard, Sberbank, Russian Standard and others. TCS Bank doesn't have affiliates or branches, and all direct interactions are performed by courier. All the other activities are performed online. In 2013, this bank had more than 3 million customers. Customers have only Internet and Mobile bank at their disposal, and that's why this bank has the full suite of e-banking services and applications: full access to financial information on the card and the account, all payments and transfers and service management.

According to several publications, Promsvjazj was named as the best bank in Russia in 2013. Internet Bank PSB-Retail provides 24 hour client access to their accounts and full distant maintenance: paying bills, all the operations with cards, loan repayment and more. There are two versions of Internet Banking: informational (current account balance, deposits) and operational (full version of online banking). Bank VTB 24 offers, in addition to online and mobile banking, a service "Teleinfo" - an information service that can be used by calling a specific number. The most popular distant service in VTB 24 is internet bank. Number of users in the Internet bank "Telebank" exceeded 1.5 million users at the end of 2013. Sberbank has recently improved its services and now with large customer base is becoming leader. "Sberbank Online" is the largest Internet bank in Russia by number of active users (2.5 million people). Competitive advantage of Internet bank Sberbank is orientation on wide range of customers, including those customers that are not familiar with working with finances online. With "Sberbank Online" customers can view information on their cards, bills, statements, reports and receive mini-statements, open/close accounts deposits, make loan payments and more. There are two versions of Internet Banking in Sberbank: information and operational. (Promsvyaz Bank- Corporate site, 2014; PTB24 Bank- Corporate site, 2014; Sberbank- Corporate Site, 2014; TSC Bank- Corporate site, 2014).

4. ALFA BANK STRATEGY

The main goal of Alfa-Bank is to be the one and only bank for all customers, a part of everyday lives of Russians. Alfa-Banking Group's business model is focused on a rapid organic growth strategy, geographical expansion and further integration of business units and retaining of highly qualified staff. Main competitive advantages of company are customer focus and openness. According to research, number of customers of Alfa-Bank will increase by 13-15% in 2014. The main directions of growth are geographic expansion, strong positioning in new cities and the network development.
Main company's strategic goal is to:
• Maintain status as the leading private bank in Russia, while enhancing stability and profitability
• Set the industry standards in key areas such as customer experience, technology, efficiency and teamwork.
To achieve this, Alfa-Bank should focus on client with broad product offering for meeting customer's needs and customized approach to sales and services for target client groups. (Alfa-Bank corporate site- Annual Rreport, 31.03.2014)

5. ELECTRONIC CHANNELS OF ALFA BANK

Alfa-Bank is one of the first banks in Russia that started developing and investing in electronic channels. "Alfa-Click" appeared in 2003 as the most functional online bank in the country. In 2005, Alfa-Bank was the first to launch mobile banking in Russia. Now, Alfa Bank continues to develop its electronic channels, being one of the leaders in the Russian market and ratifying its title as the most innovative bank.

To ensure real-time innovations, department "e-business" was isolated in a separate division of Alfa Bank. And now, budget provided for electronic channels is distributed between: Operating part (IT support, 30% of total IT-budget) and Strategic part (R&D, about 70% of total IT-budget). In order to handle multiple operations, which are now carried out monthly in the Internet Bank —Alfa-Click", Alfa- Bank would have to build more offices and significantly expand the call center. On the other hand, electronic services generate a certain fee income and additional revenue of about $ 2.4 million (about 5 % of total sales of Alfa Bank). That is the main reason why Alfa Bank never stops the development of new opportunities in the electronic channels.

Every fifth customer of Alfa-Bank actively uses the Internet bank, and every twentieth mobile bank. On the other hand, the western banks have much better indicators, with every third person in the U.S. and every forth in Germany using a mobile bank. This suggests that there is room for growth with electronic channels in Russia.

Most popular “E” services among customers of Alfa-Bank are following: 1) Mobile and Internet billing; 2) Account Transfers; 3) Transfers to other customers of the bank; 4) Bank to Bank Transfers; 5) Operations with online wallet; 6) Utility Payment; 7) Online shopping.

Important part of business of Alpha Bank – is investing in security. The Bank is providing the optimum balance between comfort, mobility and safety. That is why "Alpha Click” has two-tier system of protection. That is also the main reason why Alfa Bank is in many ways ahead of competitors in terms of safety standards.

The most common way of return on investment in electronic channels for large banks is commission for the client's transaction. There are two type commissions:
• Client commission for holding payment,
• Partner commission for the reception of the payment (Alfa Bank corporate site-News, 2014; 1C: Enterprise 8, 2014; Alfa-Bank corporate site-Internet Bank, 2014; Mikhail Belov, 2013).

6. ALFA CLICK AND ALFA MOBILE

Alfa Click online bank is an innovative product developed by IBA for Alfa Bank. It is based on the IBA Internet Banking system. Alfa Click is providing its clients with a secure 24/7 access to their accounts, including deposit and card accounts, as well as deposit and loan products. Main Functionalities of Alfa Click, based on IBA report, are (IBA Group, 2014):

• Balance statement on all accounts of the client
• Detailed information on loans, deposits, and card accounts of the client
• Client account statements
• Payments for mobile services, internet and cable TV services , public utilities, and other goods and services registered in the Belarusian payment system Raschet (Payment)
• Payments for goods and services registered in the Belarusian payment system Raschet (Payment)
• Transfers between client accounts in a single currency, including loan settlements from the client's own funds
• History of payments and transfers done using Alfa Click and Alfa Mobile
• Templates for payments and transfers. A client needs to indicate payment details only once. Afterwards, it will be enough to choose a ready–made template, including the account from which the payment is made and beneficiary details
• SMS alert management : connect the service, change mobile phone number, switch off the service
• Password change
• Alfa–Bank news feed, feedback option.

Alfa-Mobile - is service that allows performing multiple banking operations, using Java-based applications that customers can download. The main functionalities are:
• getting detailed information about the accounts (available balance, recent transactions on the account, the arrears, etc.);
• paying for the Mobile operators and Internet service providers;
• making transfers between accounts (Alfa-Bank corporate site-Mobile Bank, 2014; Alfa Bank corporate site-News, 2014).

7. CONCLUSION

In order to remain competitive on the market, Alfa Bank has to find a way to retain current clients while honing an edge that makes Alfa Bank appealing to all potential customers. Maxim, director of e-business at Alfa-Bank thinks that the best way to do this is improving electronic channels. However, to do this, it is important to define strategy for electronic channels that will be aligned with the strategy of Alfa Bank, and to target potential customers that have potential to be the most frequent users of electronic channels in Russia. Also, arising question is, what is the best communication and pricing model for current services, and is there a way to improve services, based on best practise of foreign companies.

Abstract: *The case study presents marketing, communication and sales challenges and issues, faced by Slovenian startup company ZkotZ (Ltd.) which is operating on international markets. The ZkotZ (Ltd.) company was established in 2010 and is growing since. The case study is described from the stand point of Tina Šegota, Director of Marketing and Sales, and Anže Miklavec, founder of EQUA and CEO of ZkotZ (Ltd.). Today company operates on 12 markets and owns three brands. ZkotZ (Ltd.) company focuses on production and sales a variety of reusable bottles. The most valuable brand of the company is EQUA which represents reusable bottles. EQUA brand was the best selling product in Slovenian market in its category in 2011 and 2012. In Slovenian market EQUA brand quickly became a symbol not only for reusable bottles, but also for ecology, water and sustainable lifestyle. After great success of EQUA brand in Slovenian market, company's management team (three assistants) decided to develop marketing plan for entering CEE markets.*

At the time presented in the case study Tina is discussing EQUA brand development strategy for CEE markets with her CEO. Aside from them, Tina gathered a team to brainstorm about different market entry and positioning strategies. But the main issue Tina would have to face in the next six months regards development of the most appropriate strategy to successfully enter CEE markets and position EQUA as a premium brand in the reusable bottles segment. The task in front of Tina is even greater having in mind that company had been planning to launch the EQUA brand on Croatian, Hungarian, Slovakian and Czech Republic market in next the years simultaneously. So Tina needs to work hard, act fast and make quick decisions in order to create the most suitable methods and tools for entering these markets. But even though selected CEE markets are in a certain way similar to Slovenian market and have historically and politically connection, potential customers nowadays have different needs and desires in different markets. Therefore, company conducted a research and identified interesting trend - raising consciousness about negative impact of regular plastic bottles on health of customers on CEE markets. This trend appeared after customers from CEE markets started to implement more ecological and sustainable approach into their modern lifestyle. If the company does not identify correctly different customers' needs and desires, and does not incorporate mentioned values into branding, advertising and selling the EQUA bottles, the managing team is risking failure of entering CEE markets.

This case study will provide students with basic perspective of strategic marketing planning within a company. The case reflects marketing, communication and sales issues and challenges faced by Director of Marketing and Sales in an international company planning to enter CEE markets and expand its operations.

Keywords*: CEE markets, brand development, EQUA, bottles, sustainable, lifestyle*

1. INTRODUCTION

In a small modern house in the centre of Ljubljana one could get lost only by listening how Tina was smoothly switching from Croatian, Slovenian and English language. At one point Tina was answering an email in Croatian, providing information to a Slovene customer on the phone and in another second talking to her co-workers in English. It was a cloudy November afternoon just before the rain. Tina loved the smell of rain because it reminded her of the changes that will happened when she was discussing brand development strategy with Anže, founder of EQUA and CEO of the company ZkotZ (Ltd.). They were talking about different strategies: positioning, market entry, brand development etc. So, the main problem Tina would have to face in the next six months was to develop a strategy to successfully enter CEE markets and position EQUA brand as a premium brand in the segment of reusable bottles. The demand for results was very high and there was no space for mistakes nor time to waste. Tina had to work hard and think about the methods and tools for market entry that could be recycled for CEE markets. The company had been planning to launch the EQUA brand in: Croatia, Hungary, Slovakia and Czech Republic, in 2011 and 2012. Even though these markets were historically and politically interconnected, potential customers nowadays have different needs and desires.

In her position as Director of Marketing and Sales, Tina Šegota has been facing daily challenges of marketing, communication and sales since the very first day she started to work for the start-up company ZkotZ (Ltd.) two years ago. All those challenges were connected to branding, advertising and selling the EQUA bottle – a reusable plastic bottle for water which would enable people to be hydrated wherever they go.

In the beginning of the 21st century, bottled water was one of the most desired and purchased products in the world. But many countries, among them also countries from Central and Eastern Europe, have high quality tap water. The problem with regular plastic bottles emerged when customers started to implement more ecological and sustainable approach into their modern lifestyle. Today's customers started to notice a high percentage of regular plastic bottles in waste and countless studies about negative impact of different plastic moulds on their health.

Therefore, in 2010 Anže Miklavec, CEO of the company ZkotZ (Ltd.) decided to establish a new brand that would be related to ecology, water and sustainable lifestyle. Anže's team came up with an idea of reusable branded bottles for water that would be made from top quality plastic material and would represent the best alternative to regular plastic bottles which would enable customers to use tap water more frequently and save more money. The whole concept of the brand: its name, logo and slogan *For your health and nature's wealth* were carefully designed to highlight brand's mission and values and to repeatedly remind customers of two basic ingredients of the brand – ecology and water. But since EQUA brand hit the Slovenian market in 2010, it was a challenging task for the company's marketing team to launch it in Central and Eastern Europe markets and to make EQUA a premium band in the segment of reusable bottles.

> It was decided that Croatia would be the first CEE market where the company would try to launch EQUA brand. The reasons to firstly enter Croatia were numerous: it was Slovenian neighbouring country which provided cultural, historical, geographical and economical relations, and since Tina was born Croatian there were no communication problems at all. So, the choice was a little bit obvious.

Since Tina was facing a very demanding challenge, she was thinking that there had to be more than just a simple 4P's of marketing thought by numerous academic marketers for decades. While Tina was searching for most appropriate method for entering CEE markets, she came across 4E's of marketing or so called new marketing eco-system presented by worldwide advertising agency Ogilvy & Mather. The 4E's of marketing were presented as a replacement for each of the 4P's elements: from Product to Experience, from Place to Everyplace, from Price to Exchange, and from Promotion to Engagement and Evangelism. But she did not like the complete elimination of traditional 4P's, so after a careful taught, she decided that it would be the best to combine 4P's and 4E's to create a new brand development strategy for CEE markets. In the next six months she had to answer numerous questions. "What does a customer encounter while purchasing and using EQUA BPA free bottle?" While brainstorming with Anže, Tina repeated this question from her notebook. Moreover, she continued with reading the questions that were rushing through mind "how to use social media and other communication tools to present the product in a way to be seen by everybody? And with so much on the web being offered for free, how to justify the price of the product?" Tina finally concluded that "promotion isn't enough any longer. With so many communication channels, we can't just bombard people with messages and hope they'll pick them up. We have to figure out how to get customers to allow us into their attention spans. And we have to do it so unified that it would work on all CEE markets."

2. EMPHASIZE PRODUCT BENEFITS FOR BETTER CUSTOMER EXPERIENCE

EQUA's name consists of two words eco and aqua. The name stands for ecological, reusable and trendy products. In November 2011 there were only two products in the brand's portfolio: EQUA BPA free bottle 600 ml and EQUA BPA free bottle 400 ml. There were more than 20 different designs to choose from for BPA free bottles and they could be used for different purposes and at various situations: at home, in the office, during sport activities or even while having a walk through the city. On top, the bottles were very practical, light and easy to use on a daily basis. Slogan of the brand *For your health and nature's wealth* directly represents the message the EQUA BPA free bottles tent to communicate regarding health and ecology (MyEqua, 2013).

Anže decided that Tina would be the leader of the team to support entering the CEE markets. The team consisted of four people: Jana was a graphic designer; Helena provided web page support, marketing assistant Monika and Tina. On the first meeting, after team was put together, Tina was explaining the purpose of EQUA brand to her team "the first collection of EQUA BPA free bottles was designed with the desire of raising awareness about the importance of clean and safe environment and the influence it has on people's health. It also aims at showing that living a healthy and active lifestyle can be fun. But it is not just about fun, our care for nature is real so we decided to donate 10% of our net sales profit to the ecological

organizations. That way we can enable for our customers to make a contribution to better and cleaner environment." Moreover, she stressed out that "more importantly, we have to implement a special experience for a customer when using each EQUA product. It would be the best to combine EQUA's slogan and product benefits into a story."

The story of EQUA BPA free bottles

Back in the office in the middle of November 2011, the team worked constantly together for days trying to come up with the story for EQUA BPA free bottles (My Equa, 2013). After spending numerous hours talking about product benefits, potential customers and the brand, the team agreed that EQUA BPA free bottles would be presented as one of the best alternatives for regular plastic bottles. "Normally, unnecessary emissions are used for production, transport and storing of a regular plastic bottles. They are also harmful for the environment and have consequences to our health. But there are not any extra emissions used for production of tap water, which is simply the most ecological and the cheapest to drink," Tina said to the team.

While looking through the window in the office, Tina was thinking about EQUA's customers. She looked at her co-workers and said "O.K. girls, listen really carefully." Helena, Jana and Monika turned to Tina and listened to what she had to say. "Let's say that I am one of many potential customers of EQUA. I am a woman in her late twenties who mainly spends her working day in an office. My private life consists of regularly going to the gym, hanging with my friends in coffee shops, relaxing in wellness clubs, travelling and spending time with my family. So, I take care of my physique, my health and my expenses. Therefore, EQUA bottle would benefit me in many ways: I would always have a bottle of fresh tap water in the office and most importantly I would like to know that the bottles I drink from would not jeopardize my health." The team began to discuss the materials regular plastic bottles were made of and how it influenced the content of the bottle if used regularly. They agreed that the content from regular plastic bottles could become dangerous when consuming liquids from it. What makes the EQUA BPA free bottles more suitable to use is the material the bottles are made of and which does not contain harmful chemical compound BPA. Each bottle carried the "BPA free" certificate that guaranteed that consumption of the content from the EQUA BPA free bottles was 100% healthy and harmless for both human and environment.

"The EQUA bottles are meant for long-term use and are recyclable" Tina started to build the argument with her team. Since all EQUA bottles are made of high quality material Eastman Tritan™ copolyester, an amorphous copolyester derived from vegetable source, the bottles do not contain harmful chemical bisphenol A (shorter BPA). "While reading scientific papers, I came across some serious data which link BPA to changes that lead to breast and prostate cancer, allergies, and hormonal disorders. Therefore, we have to emphasize product's most outstanding features: its excellent toughness, hydrolytic stability, and heat and chemical resistance," Tina continued with the transformation of product benefits into the story for customers. "If I continue with my perspective as a potential customer, I would like to have a bottle that I could fill with hot and cold liquids, wash in a dishwasher and most importantly have it as an accessory wherever I go. For me it is important to put a statement out that I take care of the environment by not contributing to plastic waste because I drink from only one bottle all the time. This bottle is eco-friendly, it has a nice design that suits my style, it reminds me to drink water whenever I look at it and moreover, it is my new trendy accessory which fits into my bag," Tina concluded with her story.

Tina's co-workers agreed to the description they had just heard and the discussion continued with the descriptions of other potential customers: men, teenagers, pregnant women, young mommies and their children. At the moment there are more than 20 different bottle designs (see Figure 1) for both product sizes (400 ml and 600 ml). It was decided that the main story of EQUA BPA free bottles would unite the preservation of health and environment by emphasizing multiple situations where one could use the bottles. "The experience behind the EQUA BPA free bottles is in customer's wish to use the bottle as frequently as possible because one is taking care of his or her health and environment. The moment when a customer drinks from the EQUA BPA free bottle, he or she also influences life of others by contributing to better and cleaner environment for future generations. And this is the statement we want EQUA's customers to give to others," Tina added at the end of the meeting.

Figure 1: The most popular designs of the EQUA bottles

3. PROVIDE ENGAGEMENT IN EVERYPLACE

In CEE markets a discount group buying was really popular. Therefore, Tina saw an opportunity to firstly enter Croatian market by offering the product nobody knew through the biggest discount promotion website in Croatia – www.kolektiva.hr. “For EQUA the discount promotion represented the most suitable tool to reach the customers who are willing to buy a product for at least 50 % off. This will provide us with instant feedback and sales results” Tina explained her decision. Anže was very supportive of her decision since this would provide his team with instant feedback of what else could be changed in the presentation of the product. When presenting the product for the first time, it is of big importance to choose the most appealing images. Therefore, Kolektiva promotion had been prepared for two weeks. The images selected had to reflect the story of the product. In November and December 2011 it was hard to catch sunny days to take good pictures, but Jana was doing her best. As a graphic designer, she was in charge of all visual material of the product and she decided to portray happiness of EQUA’s customers. Tina loved that about her because she could relate to any customer and portray it in the best possible way (Company Report 2012).

At Monday morning in the middle of December 2011 the team gathered in a room with all material they prepared to launch the product in Croatian market (Moja Equa, 2013). Each member of the team had a mug full with coffee on the table and Jana started with the presentation of numerous photos of the product. “Since Croatian customers would be introduced to the product for the first time, it is of big importance to select the images which reflect its usage,” Tina interrupted Jana’s presentation. But there was no room for panic, since Jana did just that – she planned numerous photo shootings in detail to enable the representation of both the usage of the EQUA BPA free bottles and happiness of the customers. She presented numerous photos reflecting happy and smiling people using the product in various situations – at work, in school, during the workout, outdoors, in a coffee shop. “I knew I could trust your instincts. You did a great job,” Tina said to support Jana’s work from the past two weeks. Later the turn of presenting her work came to Monika, marketing assistant, who did a research of the Croatian market. This was not so hard for her, since she spent most of her life in Croatia and she could understand people’s lifestyle and preferences. She did a research of the market and discovered that Croatians like colourful and vivid pictures. Therefore, it was decided the most colourful designs would be used to present the product on the discount website due to the lack of promotion space offered (see Figure 2).

Figure 2: Presentation of EQUA's discount offer on www.kolektiva.hr

"It is true that a photo is worth a thousand words, but when introducing a product for the first time, it is essential to describe product's quality, purpose and customer benefits," Tina said to the team. For the past few days she was working on the structure of the text to have all features as a story (exposition, climax, resolution) and was planned to guide a reader towards the purchase. The exposition introduced the problem of plastic waste and excessive financial costs connected to bottled water. The climax introduced the EQUA BPA free bottles as the best alternative for regular plastic bottles which were essential core of both the problem of plastic waste and costly bottled water. Furthermore, consumers' benefits were expressed through the problematic of bisphenol A. Since EQUA bottles are BPA free, the product was presented as a healthy and environmentally friendly reusable alternative bottle suitable for everyday use. "But the most important details of the product were communicated in the resolution of the text. Here a potential customer will be introduced to variety of product's features which emphasize the benefits of using the product," Tina was explaining the structure of the text. "In the resolution of the text we reveal that the material the bottles are made from is top quality material that enables more than just drinking water from the bottle. It also enables hot drinks like coffee, tea or hot chocolate and cold and freezing drinks. EQUA BPA free bottles come in two sizes: smaller bottle holds 400 ml and bigger holds 600 ml, right? So, a potential customer can choose the size of the bottle that would satisfy his or her daily hydration intake: a smaller bottle is suitable for children since it is lighter and easy to hold, it suits smaller bags women like to carry around and it best suits bottle-holder in a car. A bigger bottle is more suitable for those who are in constant need for hydration like athletes and pregnant women, those who work in offices and do not have a constant supply of the water and to those who go hiking or travelling where water supply is limited," Tina went on with the explanation.

Jana's photo material and parts of Tina's text provided Helena with the material to put on EQUA's web page www.myequa.com (see Figure 3). Helena used the assistance of Monika and her good writing skills to launch the web page only 3 days before presenting the product to the customers by Kolektiva. The web page also featured links to EQUA's Facebook, Flickr, LinkedIn, Twitter and other social media channels where customer could engage with the team. Nonetheless, Tina liked that idea so she put the links to the EQUA's webpage and Facebook in the sidebar of Kolektiva's offer to furthermore encourage consumers to contact the team to get additional information of the EQUA and its products (Kolektiva.hr , 2013).

Christmas time was approaching very fast and Anže decided to give the team well deserved holidays. "See you in 10 days," he concluded the meeting in which the team showed him that everything was ready for launching the product. "We will start with the discount action in the beginning of January 2012 because we will have lots of work. So it is important for you to rest and enjoy time with your family and friends. In the beginning of the next year we will have a blast," he added.

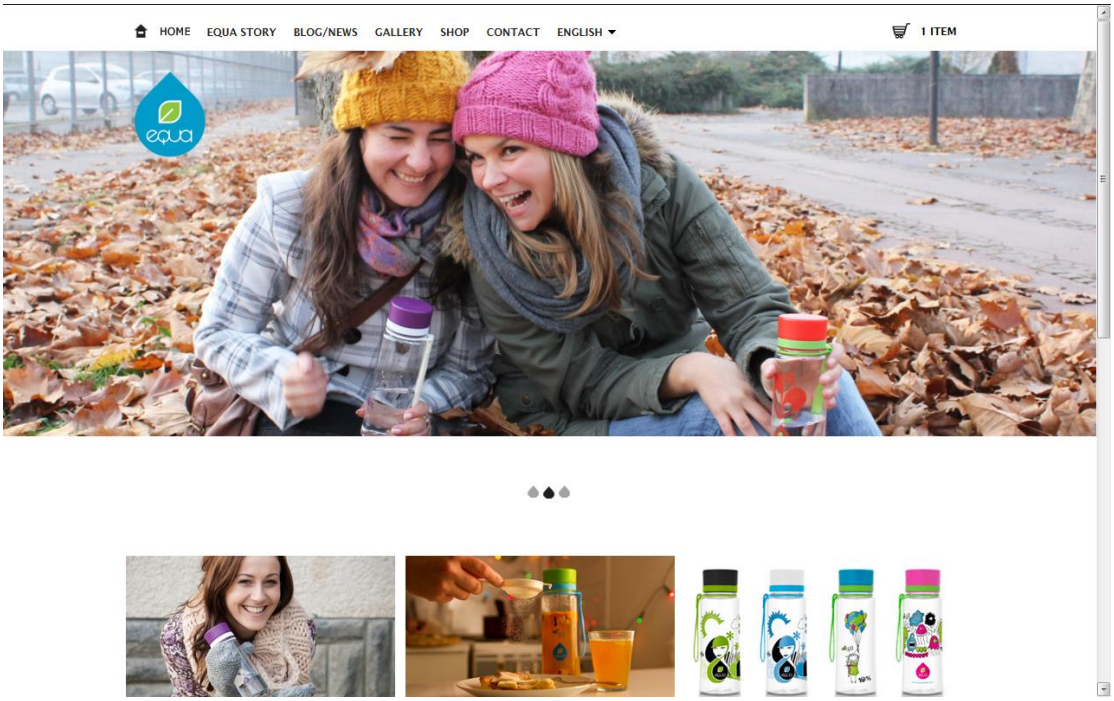

Figure 3: EQUA's web page (www.myequa.com)

And it was really a blast. Tina and her co-workers returned to the office on January 2nd, but all the preparations from 2011 were not forgotten. "It is time to go live with EQUA," Tina said at the beginning of the meeting were the support for market entry was discussed. It was decided that Monika would provide the support for social media channels and that she would answer all the questions customers would ask. Jana would support Monika with visual material and Helena would provide constant support for the web page and web shop.

Launching of the product happened on January 9th 2012 and in four days it reached enormous proportions. More than three thousand coupons offering one EQUA bottle for 50 % discount price were sold and after the offer customers were asking for more information about the product and where to buy it (Company Report, 2011). The EQUA BPA free bottles, with their appealing designs, became all consumers talked about on Facebook and at the same time encouraged each other to purchase it. Numerous buyers referred to the brand's official Facebook page EQUA Hrvatska to access additional information about the brand itself, its products and the story about bisphenol A. Consumers engaged in the communication by sharing numerous posts on their private Facebook pages and in private messages (EQUA Fan page, 2013). They recommended the product and, most importantly, they posted numerous pictures of themselves or their family members and friends using the product (see Figure 4). The team awarded customers' loyalty and was stunt by the reaction of their fans welcoming new fans.

"The result of this feedback was not only the proof of the successful communication strategy, but more, consumers' feedback resulted in increasing sales results in online store available on www.myequa.com," Helena presented results from web shop on the meeting the team usually had every Monday morning. "Moreover, we managed to do search engines optimization, advertise on Facebook and we invested a small amount of finances to Google AdWords," Tina briefly explained Helena's support in the launching process. "That enabled us to be seen everywhere in connection to online media," Tina added.

Figure 4: Consumer's engagement in EQUA Hrvatska Facebook page

4. TRANSFORM THE PROMOTION INTO ENGAGEMENT

Since online media played a big role in EQUA's brand launching story on the Croatian market, Anže wanted to hear how EQUA brand will caught people's attention in offline media. Anže added that "the results are outstanding but now we have to work even harder because not all people saw the product. We also have to promote EQUA in lifestyle magazines and we do not sufficient financial support for advertising."

Tina's analytical thinking helped her prepare for this, days ago when she was sitting in her office on Friday afternoon and was thinking about the results that team would have to present to Anže on Monday. Tina knew that the next step should be presenting the product to Croatian journalists. Several questions were on her mind "But how should we do it? Should we hire an advertising agency for PR or deal with journalists on our own? If we do it on our own, how could we get the journalists to love the product so much that they would write about it?" Tina was thinking while sitting in the dark. She left the office with these questions tangling her mind for the whole weekend.

On Monday, Tina came prepared with the answer, and started the meeting with explaining Anže following "we will face another challenge and do PR with all the help and knowledge we have *in the house*." "That means there is no need for help from an advertising agency and that we will take *do-it-yourself* approach in contacting Croatian journalists and try to make them love our product," she explained her decision. Anže stressed important fact "the only affordable financial investment in PR would be the bottles which could be compensated for the coverage." So, the Tina faced additional challenging questions: how to make journalists like and use the product, and how to present the product as a lifestyle accessory? But she was thinking very fast trying to recover some of the ideas she got during the weekend.

It was decided to communicate with *the message in the bottle*. The communication strategy had four steps. Firstly, the team had to choose the total of 20 editors-in-chief of lifestyle magazines and journalists covering the topics of health, trendy lifestyle and fashion. Secondly, the bottles with the most appealing designs for women were checked against all faults and prepared to be sent in special post-boxes. Thirdly, in each bottle was inserted a special personalized message for the receivers. The message described the product very briefly (no longer than two sentences) and offered a refreshing recipe of a delicious fruit smoothie that could be consumed from the EQUA bottle for breakfast or snack. And finally, the recipes were chosen carefully to include only exotic fruits (strawberries, pineapples, kiwi, and mango), because the team wanted the bottles to be presented as an exotic item in the market.

The packages for journalist were prepared in the next two days and sent out, but there was no place for rest for the team. Social media communication, web shop sales and production of visual material were constant ongoing processes in the office when Anže presented Tina with the next challenge. He showed up in her office in the middle of the week in January 2012 asking her "how will you justify the price of the EQUA BPA free bottles?" He continued putting the pressure on Tina by saying "if I were a customer, why would I buy the EQUA bottles for approximately 10 €, if I could drink tap water form regular plastic bottles which I get for free when buying bottled water for 0,60 €?" Tina looked out of the window; it was snowing that day, and knew she also had to prepare for that question. She asked Anže to give her one day to think it through and after Anže left her office, she looked at Ogilvy & Mather presentation of 4E's. The word *exchange* was tangling her mind for the rest of the day because she had to cope with very challenging question.

5. EXCHANGE THE BENEFIT FOR THE PRICE

The final element of 4P's of marketing included the price of a product. "A price is always a big problem: for a seller it is always too low and for a customer it is always too high," Tina taught. Since the price of a single EQUA bottle was promptly calculated and presented by Anže, Tina had to come up with the special preposition how to present product's price to the consumer. The EQUA bottle in a store would cost 9,95 € including VAT. A single bottled water could reach a price from 0,60 € to 4 €. "In consumer's mind it is cheaper to buy bottled water. The benefit for a customer is very simple – he or she would pay for the water and later on reuse its plastic bottle until it is not appropriate for further use," Tina was thinking out loud trying to figure out the way a potential customer would think. "I would also be outraged if one would offer me a plastic bottle overpriced by 150%. But I have to change this mind-set," she was determined to come up with the solution.

Tina started to think about the word *exchange* and what it meant in connection to the price, consumers, marketing and market economy. She invited Monika to join her in the office on Tuesday morning and they discussed the economic situation in Croatia. Monika said that her market research showed that "Croatians are very price sensitive. The economic situation in the country was not at its best and the country's GDP and average salary are lower in comparison to Slovenia." There was also a currency issue, since Slovenia adopted EURO in 2007 and Croatia is still in the process of negotiation for European Union membership for 2013. Therefore, there will be additional expenses with customs, transport and sanitary inspections that would influence the price. "But our customers will not understand this. They want to buy a cheap product no matter the problems we are facing now," Monika stressed Tina. After Monika exited the office Tina started to calculate the price. Taking into consideration all the costs, she entered Anže's office and started to present her solution.

"Anže, the price of the product in Croatian market should be lower than in Slovenia. The best psychological price one would pay for one EQUA bottle in a store would be 69,90 HRK for bigger bottle and 59,90 HRK for smaller bottle," Tina presented her calculations. Anže was not quite satisfied with the result because in Slovenia the price did not differ among sizes and when recalculated, Croatian customers would pay 0,65 € less than customers in Slovenia. "And if we take in consideration that Croatian VAT is higher than Slovenian VAT for 4 %, we lose lots of money," Anže expressed his dissatisfaction. Tina agreed with him but went on explaining that "Croatian market is double the size of Slovenian market which consequently means more quantities sold. And in the future if Croatia becomes a member of EU, all expenses will be transformed into profit." Anže give it a taught but he repeated to Tina the question from yesterday: "how will you justify the price of the EQUA BPA free bottles to potential customers?"

Tina was determined to explain the process. Firstly, the exchange Ogilvy & Mather were talking about would be expressed through the story of EQUA bottle. This is a key element when it comes to justifying the price of the product. "The main question is what a customer would benefit from the EQUA and we already emphasized that in our story," Tina stressed. "We delivered the story through all our communication channels and moreover, we already hinted the price when we offered 50% off on Kolektiva. So, I think our customers will not be so surprised to see that they would have to pay approximately 10€ for the EQUA bottle". Moreover, the added value of saving money when drinking tap water would be additionally stressed on the brand's webpage and social media communication channels. "We calculated that half a litre of bottled water is up to 255 times more expensive than half a litre of tap water. And I think that if we stress this information strong enough using every communication tool available and affordable to us, we can provide even additional economic benefit for our customers," Tina concluded with her explanation and Anže seemed quite happy with her answer.

6. WINDOW INTO THE FUTURE

Tina was aware that all CEE markets are not the same. EQUA brand entered Croatian market successfully, but Hungarian, Slovakian and Czech market were still to be entered:

> *The time was flying fast and it was already second Friday in February 2014. Tina set behind her table and looked at the picture of her team she kept on her desk. She was not needed to be reminded that there were still three more markets for EQUA brand to enter which could be so diverse that all effort put in Croatian market might not provide the company with desired results. April was approaching with the goal for EQUA to enter CEE markets and it was really difficult to try to repeat Croatian market activities in other markets. After all, Tina and her team did not know the language nor had personal insights into customer preferences for CEE markets. Tina used her knowledge from Marketing Management, Integrated Marketing Communication, Marketing Strategy and Human Resources Management class*

she had taken back at Faculty of Social Science, University of Ljubljana. She knew that market entry strategy depended on the decisions regarding hiring some help, but she was still illusive because she was struggling with the decision to hire some local advertising agency or an intern for each market. "If I only had more time to hire marketing assistants like Monika to provide some quality insights into CEE markets," she taught. "That would help me solve all question I have been struggling with: how to provide experience to customers, how to justify the price of the product and how to successfully deliver the news to local journalists," Tina left the office with that taught occupying her mind. She turned off the lights and locked the door of the office, since there was nobody behind her. All of her co-workers left for a drink in a small pub in the centre of Ljubljana where they usually hanged out after work. And Tina decided to join them, since a glass of premium wine would be a welcome distraction from all unanswered questions. She locked them in the office, at least till next Monday.

DESTINATION BRANDING
THE CASE OF BELGRADE - A FRIENDLY EUROPEAN CITY

Stanislava Bivolarević[1], Vesna Damnjanović[2]
[1]MSc Student, Faculty of Organizational Sciences, University of Belgrade, stanislava.bivolarevic@asp-poli.it
[2]Associate Professor, Faculty of Organizational Sciences, University of Belgrade, damvesna@fon.bg.ac.rs

Abstract: *This paper investigates the perception of Belgrade from perspective of people living in Serbia. The results show that promotion has not been as successful as hoped, and that Belgrade is still not seen as a modern city among the respondents. Quantitative survey has been applied with 458 respondents. The findings have identified Belgrade as the European city with three main characteristics: friendly, exciting and hedonistic city. Furthermore, positive and negative aspects of the city have been explored. Based on the results, we recommend framework for future development of destination brand identity. This study should contribute to researchers and practitioners working in the field of city destination branding.*

Keywords: *Belgrade, destination branding, residential perspective, friendly city, Europe.*

1. INTRODUCTION

There is a growing interest of exploring the nature and meaning of branding destination among practitioners and academics. The competitiveness among cities will increase in the future and brand experts should understand how to transform knowledge about corporate or product branding into place branding. (Ashworth and Kavaratzis, 2009). Recent studies have identified that the well-being and satisfaction of different stakeholders (residents, government, visitors, investors, entrepreneurs and media) have strong influence on the image of a city or place in general. (Riza et al., 2012; Baker and Cameron, 2008; Damnjanovic et al., 2009).

However, local people may be an important factor when distinguishing and selling a city as a destination brand. According to (Freire, 2009) local people or residents of the place are the crucial element of destination brand identity. Recent study by (Merrilees et al., 2012) also underlined residents as important stakeholders in the branding context, since residents perceive the city brand as a place to live. Moreover, local people may also be important providers of word-of-mouth promotion and place branding externally to visitors perception (Garrod et al., 2012).

Only few studies have examined the city branding of Belgrade. They are two strategies developed by city authorities, which support development of tourist strategy for Belgrade city in 2008 and 2011 (Eric et al., 2008; Vasovic and Alimpic, 2011). Previous study by (Bursac, 2006) has examined the brand identity of Belgrade among three respondents group: residents, visitors and city representatives. However, further investigation is needed in order to understand brand identity and brand image of city of Belgrade that will be a starting point for an improved brand positioning in the future.

2. SCOPE

Belgrade is described as a vibrant metropolis of 1.6 million residents situated in Southeastern Europe, on the Balkan Peninsula. The city is located at the confluence of two large rivers – the Danube and the Sava. It is the third largest city on the Danube (after Vienna and Budapest) and the fourth largest city in Southeastern Europe (after Istanbul, Athens and Bucharest) (Hirt, 2009).

Belgrade has received many interesting international awards that prove its potential as an attractive tourist destination. In March 2006, Financial Times declared Belgrade the “City of the Future in Southern Europe”, which was the outcome of the competition for foreign and direct investments (Stupar and Hamamcioglu, 2006). Moreover, in 2011 and 2012, Belgrade was promoted as one of the top ten travel destinations on Earth according to famous online tourist guide Lonely Planet, with the following explanation: “It is an interesting city that's full of hedonism, passion and finesse”. Recently, at the Summit of city leaders held in Dublin in July 2012, Belgrade was awarded a prize in the category of "Best Cities", and Belgrade The city mayor at the time, Dragan Djilas, received Manager of the Year Award by Europe Business Assembly.

This study aims at explaining the current Belgrade brand identity and image from citizens‟ perspective and provide directions of destination branding strategy. In particular, it is about the way Belgrade should be marketed in the future and what it will be able to offer to the internal and external stakeholders.

The three main research questions of this study are as follows: What are the main elements of the current brand identity of the city of Belgrade from residents‟ perspective? What are the positive and the negative brand associations regarding Belgrade? How can we apply obtained knowledge to Belgrade‟s promotional message in the future?

3. METHODOLOGY

Quantitative research was undertaken in June 2012 with a range of 458 local people. A questionnaire was created based on previous studies about destination branding (Oliver, 2005; Popesku et al., 2010). The survey was published and distributed electronically to residents in order to identify and analyze their attitudes and opinions about the city of Belgrade. The questionnaire was initially face-to-face tested among 20 participants, and after being modified, it was sent to several mailing lists and social networks. The form was composed of general questions regarding age, sex, and occupation, as well as statements related to city branding aspects. A number of questions was based on a five-point Likert scale with respect to the level of agreement with the stated characteristics of Belgrade, along with two open-ended questions asking respondents to provide first impression for the word “Belgrade” and to suggest suitable communication slogan for Belgrade as a tourism destination. Obtained data were analyzed using SPSS 17.0 statistical software. The study also included qualitative research methodology using summative content analysis which involves counting and comparisons, usually of keywords or content, followed by the interpretation of the underlying context.

4. ANALYSIS AND RESULTS

The aim of the survey was to explore and identify brand identity of city of Belgrade from the perspective of its residents, Serbian people. Thus, our surveyed sample is consisted of 97% of citizens of the Republic of Serbia, with 72% of all respondents residing and 11% living temporarily/occasionally in Belgrade. Gathered pool consists of 273 female (60%) and 185 male (40%) respondents. Respondents were mostly students (67%), followed by employed (25%) and unemployed people (5%).

Several aspects of Belgrade were analyzed: geographical level of familiarity with Belgrade, main characteristic of the city, positive and negative attributes regarding living, doing business, infrastructure, culture, economy, and leisure, as well as first associations when hearing the word “Belgrade”.

Results show that Belgrade is known regionally, in Europe (81% of respondents), while 13% of the surveyed people claim that people outside of Europe, around the globe, are also familiar with Belgrade and its key values and characteristics. This distribution should be carefully considered, since Belgrade, as the capital of Serbia, should be famous worldwide.

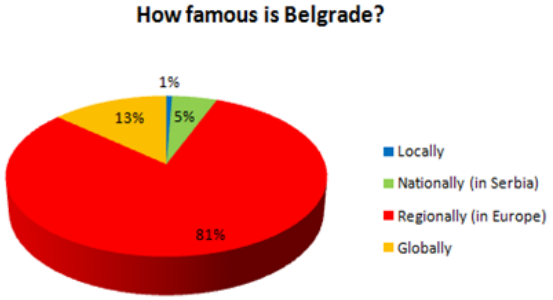

Figure 1. Level of familiarity with Belgrade

As for the main characteristic of the city, 33% of respondents stated that Belgrade is a friendly city. Next most frequent choices were exciting city (26%), hedonistic city (17%) and perspective city (13%). What is interesting is that two fewest chosen features are related to the aspects of modernity and safety of the city of Belgrade.

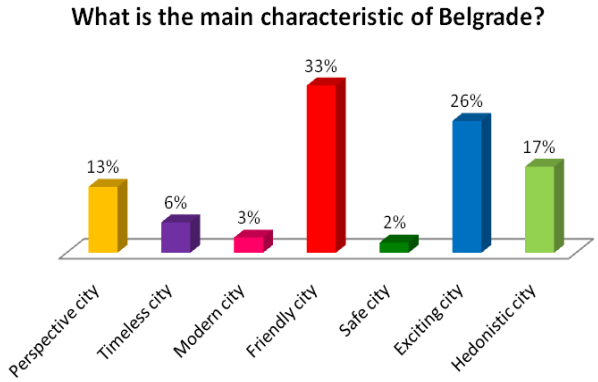

Figure 2. Main characteristics of Belgrade

Word association has been used in marketing to ensure that proper message is conveyed by names or adjectives used in promoting products. Therefore, the purpose of this type of question was to identify the main experience, through first word association test, of Belgrade among its residents. This question was open-ended and obtained answers were categorized in certain groups according to similarity among them. The most frequent answers (18%) were related to *"capital, metropolis, big city"* group. Having in mind the fact that Belgrade is one of the largest cities in Southeastern Europe and the main regional center in the Balkans, this answer is completely expected. It is not surprising that significant percentage (16%) of respondents answered that their first association belongs to the group of words *"my city, home, friends and family"*, since they either live or have spent time in Belgrade and thus, experience Belgrade as their hometown. Some authors (Tadic, 2010) claim that Belgrade's nightlife has spontaneously become the city brand, and evidential group of respondents (13,5%) is consentaneous with it. Having in mind that Belgrade is located at the confluence of two large rivers - the Danube and the Sava, and that many happenings take place on the rivers or by their side, a quite frequent (11%) answer *"rivers"* is not surprising. Eventually, a group of answers *"Kalemegdan, Pobednik"* was also common (10%). What is noteworthy is that in (Bursac, 2006), citizens also declared Kalemegdan fortress, Knez Mihailova Street, Republic Square, Skadarlija Street and confluence of the Sava and the Danube to be the most representative places in Belgrade.

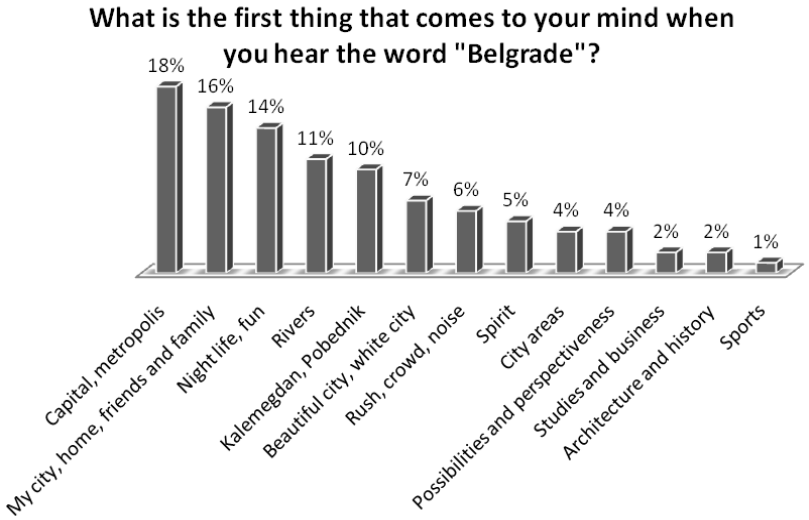

Figure 3. Brand perception of Belgrade

Summing up and analyzing all statements about Belgrade, conclusion about positive and negative elements has been created using summative content analysis. Namely, Belgrade has a lot to offer (European city, desirable tourist destination, hedonistic way of life and warm and friendly local people). Nevertheless, it is a metropolis and hence, has certain adverse aspects (inadequate promotion, poor traffic system, low standard of living and unclean city). What is encouraging is that all detected negative characteristics can be amended if adequate branding strategy is developed.

Table 1. Positive and negative elements of Belgrade

NEGATIVE ASPECTS	POSITIVE ASPECTS
INADQUATE PROMOTION City authorities do not promote Belgrade in a good manner. Negative image in world media.	**EUROPEAN CITY** Well-connected to other European metropolis. Regional center.
POOR TRAFFIC SYSTEM Poor public transportation system. Traffic jams.	**DESIRABLE TOURIST DESTINATION** Offers unforgettable experience. Good place for living. Rich history. Visitors gladly come back.
LOW STANDARD OF LIVING Lower standard of living in comparison to other European capitals. Not a city of glamour.	**HEDONISTIC WAY OF LIVING** Diversified fun content. Great nightlife. Tasty food and drinks. Good shopping and wellness.
UNCLEAN CITY Polluted city. Unclean and poorly maintained city.	**WARM AND FRIENDLY LOCAL PEOPLE** Pleasant and hospitable citizens. Citizens are proud of their Belgrade. City of future. City of youth.

5. TARGET CUSTOMERS

It is important to understand target customers from foreign countries who have visited Belgrade in order to create better image of the city in the future. According to the latest data from Belgrade Institute of Information and Statistics, annual turnover in 2013 was increased by 13% (put in numbers, 638.179 visitors), comparing to the 2012. Domestic tourists are up by 4% (120.778 visitors), and foreign visitors by 15% (517.401 visitors). Total number of overnights in 2013 is 1.409.037, which is an increase by 5% comparing to the results in 2012. Overnights of foreign tourists (1.016.739) is increased by 11%. Most off the foreign visitors in 2011 came from Slovenia (74.674), Montenegro (66.636), Germany (48.159), Croatia (50.625), Bosnia and Herzegovina (65.960), Italy (38.105), Romania (30.628), Bulgaria (28.054), Greece (26.400), Austria (25.245), Russia (25.236), Poland (21.548) and Turkey (19.196). In December 2013, number of foreign tourists has increased by 24% (40.889), comparing to December 2012. Number of overnights is up by 6%, comparing to same period last year (86.122), and overnights of foreign tourists is up by 15%. The most numerous visitors came from Slovenia, Croatia, Bulgaria, Bosnia and Herzegovina and Germany. According to the information from Belgrade Institute of Information and Statistic in 2013, the rising markets are Turkey (increase by 72%), Greece (increase by 36%), Russia (increase by 32%), Bulgaria (increase by 28%) and Poland (increase by 21%), which further create the initial pool of target customers for the future.

6. LIMITATIONS AND FURTHER RESEARCH

When interpreting the results of this study, a number of limitations must be considered. To start with, it is only focused on citizens, mostly on young people. Thus, results provide perception of residents as one target group that is considering destination branding. Further research should be directed on investigating different

target groups, examples being visitors and city representatives, since it will create valuable comparative analysis when identifying the brand identity and image of the city of Belgrade.

7. CONCLUSION

Throughout the paper the best necessary potentials of the city"s identity and city"s branding creation were investigated in order to understand what residents" perspective about city of Belgrade is like. Thus, both positive (European city, desirable tourist destination, hedonistic way of life and warm and friendly local people) and negative (inadequate promotion, poor traffic system, low standard of living and unclean city) elements of brand identity were identified. Belgrade possesses rich historical and cultural heritage, favorable geographical position, hospitable citizens and a lot of potential for a successful brand image. Kalemegdan fortress and Pobednik monument are among the top attractions of the city of Belgrade, as well as rivers and several more sights. Residents believe that the exciting nightlife, so called "spontaneous brand of Belgrade", is still among the best-known characteristics of Belgrade.

Vision of Belgrade identity (a.k.a. desired brand image) is showing positive city identity with integrated marketing communication strategy of the product destination portfolio (see Figure 4). What is valuable in these results is that positive elements could be used in future communication with external stakeholders and target groups. Nonetheless, adequate communication strategy and product destination portfolio towards interested parties should be developed in order to improve current brand image of the city. In that sense, it would be interesting to create portfolio offers that are customized for specific target groups, i.e. foreign tourists, diaspora, investors and media. We propose the city branding framework for long-term strategy that is to be further developed in the future studies. Our framework for city branding was created following the previous research study (Balakrishnan, 2008), which includes strategic destination branding model. More precisely, the author analyzed the creation of the country image for Dubai, a star in the east, and used the feedback for the improvement of the destination branding identity.

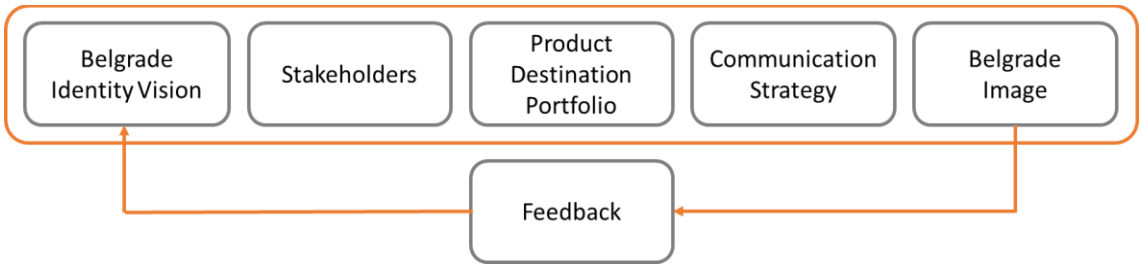

Figure 4. City branding framework for Belgrade

Furthermore, this research identifies inputs and necessities for developing branding strategy of the city of Belgrade, with an important emphasis on the inclusion of the perspectives of all stakeholders. Overall suggestion for the improvement of the current identity of the city of Belgrade is to establish a cooperation between city authorities on one side, and independent marketing and branding consultants on the other side. This setting would enable smooth definition of the key city identity elements, as well as creation and implementation of the adequate branding strategy based on the future vision of all city stakeholders. Our findings support the perspective that city branding should convey both the intention of city authorities and the experience of people (Zhang and Zhao, 2009). Based on the observations of the study, authorities of the city of Belgrade should provide a proper branding of this impressive city, as a friendly European city, with an aim of including the attitudes and beliefs of its residents, and exceeding the expectations of its visitors and other stakeholders.

Abstract: *Purpose of this paper is to inspire students and all other interested parties to think strategically and try to find best possible ways to restructure and improve business of a company, on the example of Serbian mid-size enterprise. Autogarant Ltd. was established in 1992, and after 22 years of successful business is official car dealer for 9 vehicle brands, has over 50 employees, 3 modern car showrooms and service workshops equipped with state of the art technology. Now, the company seeks for a new ways to strengthen existing business and form new business pillars in order to secure stable future growth.*

Keywords*: Automotive industry, new business pillars, strategy, improving sales performance, vehicles*

1. INTRODUCTION

In 1992 entrepreneur from Čačak decided to open a car service workshop in his hometown. He hoped that sometime in the future, that same car service workshop will emerge from small workshop to serious company in the area of automotive industry. After 22 years, that is exactly what Autogarant stands for - modern automobile retail center which includes retail showrooms and various workshops and other business units that are needed in order to provide top quality after sales services to end customers, with over 50 employees. With clear vision and great business decisions directed to growth and development, mainly through dealership contracts, Autogarant represents successful medium sized company with annual turnover of over 5,000,000€ and annual profit of over 100,000€.

However, if he wishes to continue with this steady growth and taking into account that primary activity of Autogarant is car sales and car dealership, it is necessary to devise a business strategy that will adequately mitigate and take advantage of decline in new cars sales. This negative trend of sales volume is not noticed only on Serbian market, but also throughout European car markets. Situation in automobile industry is far from ideal both for manufacturers and car dealers, so new strategies for adapting to existing trends are needed. Beside car market negative trends, emerging local competition and increased differentiation among buyers are also influential external factors that should be taken in consideration. With turbulent environment and limited resources, Autogarant must come up with an effective long-term business strategy which will bring more new clients or even markets, increase turnover and profit and, eventually, ensure the leader`s position for the company.

Question that arises for owner and GM of Autogarant is - how to increase the sales of existing portfolio (9 car brands) and which target groups should we focus in our marketing activities? On the other hand, is it possible to expand the scope of business and enter some new markets which company currently does not operate and how?

2. ABOUT COMPANY

Autogarant Ltd. was established in 1992, as a small car workshop for repairing all types of cars. This family business was successful since its foundation and was trying to constantly improve itself since the beginning. First major business expansion was becoming official car dealership for Fiat and Lancia cars in the territory of Western Serbia, after signing contract with Delta Automoto Ltd. After just two years, Autogarant Ltd. has become a leader in sales of new Fiat vehicles in this market, and maintained that position until today. In 2004 new car showrooms for Fiat and Lancia vehicles were opened. That same year the company has become official car dealer for Alfa Romeo vehicles.

Within the new business centre there is a showroom, service workshop, unit for painting works, spare parts store, car wash unit, and tire workshop for all the vehicles within the Fiat Group.

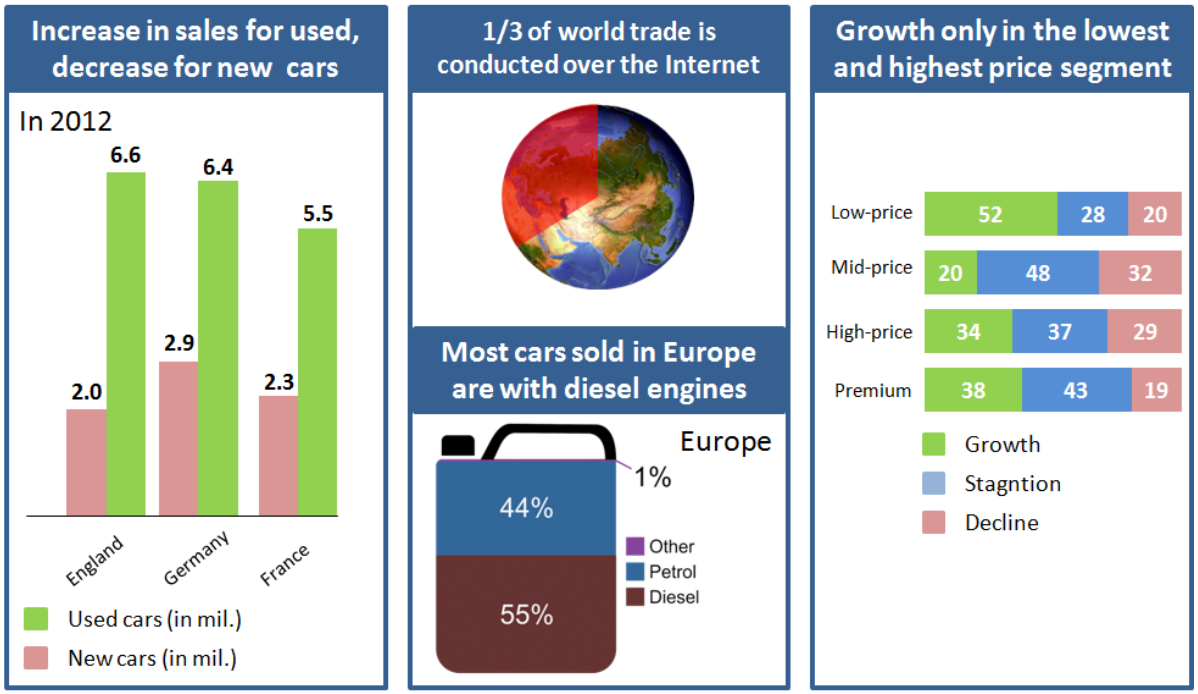
During 2007, new retail canter (showroom) was opened – Autogarant HONDA. After becoming official dealer of Honda cars, company continuously achieved remarkable results in the Western Serbia market.

All retail centres and business units are equipped with the state of the art technology, equipment and computer devices in order to provide high quality sales, and after sales services to the clients. In 2007 and 2008 there were significant improvements of after sales services. During 2009 Autogarant Ltd. has become official dealer for BMW and MINI vehicles. After this step vehicles portfolio was significantly increased, especially after dealerships for Dodge, Chrysler and Jeep vehicles were opened in 2012.

Summed up in a nutshell Autogarant Ltd. today is official car dealer for 9 car brands, it has 50 employees, 3 modern car showrooms, and several service workshops equipped with state of the art technology.

3. VEHICLE MARKETS OVERVIEW AND TRENDS

In this section we will look at the automotive industry of Europe, but also our country (Serbia) and comment some of the trends that we thought are interesting.



Source: European Automotive Survey 2013 – Earnst &Young; The European Used Car Market Report 2012 - BCA

Figure 1: Trends in Europe

As it is illustrated on the graphs above, on the three biggest markets in Europe, number of used vehicles sales significantly higher than the new vehicles sales. The predictions are that this trend will continue and that difference will be even higher in the years to come. As a result, car producers and dealers are suffering crisis and are constantly trying to adapt to these trends and prevent further drop in sales.

Some of the measures taken by them are: lowering production costs, technologies innovation (new materials, motors with lower fuel consumption, lower CO2 emission), they are using opportunities provided by government legislations concerning ecology, investing into promotional activities etc.

Interesting fact is that the largest number of vehicles sold on the European market has diesel engines. This is data that greatly differs from other markets, for example in Japan in 2012, less than 1% of vehicles sold have diesel engines (ICCT, 2013). Fact that should be taken into consideration is that one third of world trade is conducted over the internet.

As it can be seen on the graph above, largest growth is in low-price and premium car segments. This is very important data while defining product portfolio and marketing plans (Ernst and Young 2013).

As it is already said biggest growth in automotive industry is recorded in the segment of used cars. Regarding that we analyzed history of this segment since the year 2000.

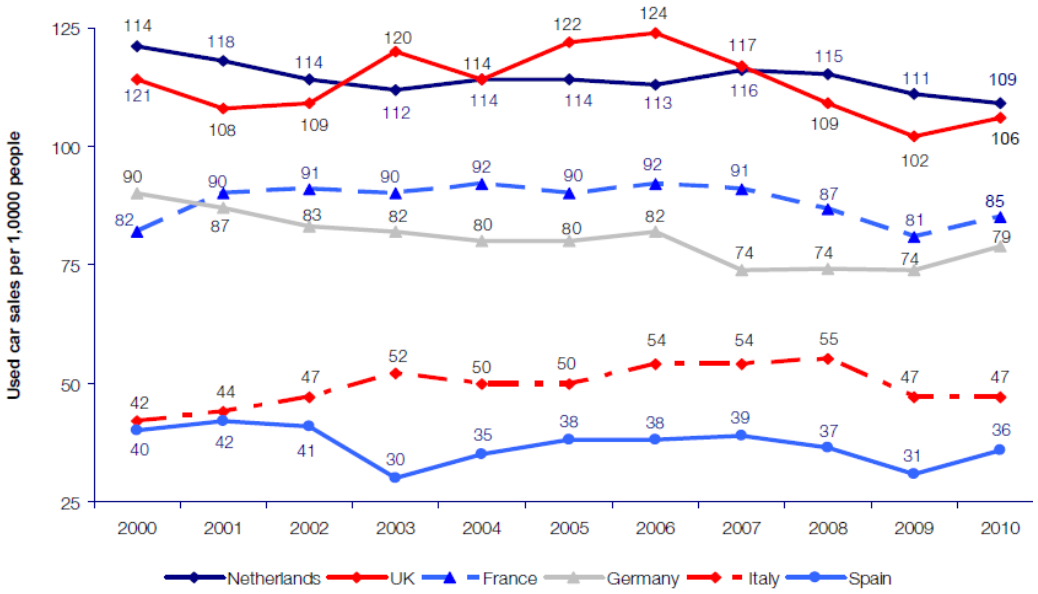


Figure 2: Used car sales per 1,000 people

On the graph above you can see used car sales per 1,000 people per year, in the largest European markets.

- France"s used car sales per 1,000 people rose from 82 to a peek of 92 in 2004 and again in 2006, dropping back to 85 per 1,000 people in 2010;
- Germany showed a steady drop in used car sales per 1,000 of the population, from 90 in 2000, to 74 in 2007 to 2009 – recovering 79 in 2010 as Germany"s used car volumes rose 420,000 units to 6.43 million last year;
- Italy, one of the „laggards", in terms of used car sales per 1,000, moved from 42 in 2000 to a healthier 55 by 2008, dropping back to 47 in 2009 and 2010 – less than half of the UK"s and Netherlands" performance for this key indicator.
- Spain"s used car sales per 1,000 people has fluctuated over the past 10 years, reaching low of 30 and 31 in 2003 and 2009 respectively – recovering to 36 in 2010 as used car volumes rose by 250,000 units. Nevertheless, Spain remains firmly at the foot of the EU 15 used car sales per 1,000 people.
- The United Kingdom"s used car sales per 1,000 of the population fell from a high of 123 in 2006 to 102 in 2009 – recovering to 106 in 2010, narrowing the gap with the Netherlands which took over top spot for this indicator in 2007 (BCA, 2012).

Thing that can be drawn as a conclusion, is the fact that in all countries, number of used vehicles sold significantly decreased during the economic crisis that has hit the entire automotive industry. After recovery of the European economy, since 2009, and 2010 steady growth was recorded within all states, and continued in later years. As it is already mention, now we have a situation where the number of used vehicles sales significantly exceeds the number of new vehicles sales.

If we look at the Serbian used car market, all of the trends are in line with current trends in the European market. In 2012 ratio of used vehicles and new vehicles sales was 5:1 in favour of used vehicles. The reason for this is, among other things, reduced purchasing power of the end consumers.

Result of this is expansion of this type of trade, and consequently an increase in the number of retailers, which can be divided into three groups. On one side we have the classic traders (selling cars on their car lots), the car dealers (in addition to the business with the new cars, they perform import and sale of used cars), as well as individuals that are importing vehicles for their own use.

4. COMPETITION

On the new car market, competition in Serbia is very strong. Given that there are over 60 authorized dealers, in this section we will look at the most important ones. In the first place it should be noted competitors covering an area of Western Serbia in similar segment cars.

One such company is Autočačak Ltd. established in 1991. The company was initially engaged in the sale and servicing of cars and it is the first private company which during 90s had a signed contract for the sale and servicing of Zastava vehicles. Later, on May 7 in 1996 the company became the general distributor and importer of Škoda vehicles on the territory of former Yugoslavia and in the next nine years Autočačak sold approximately 25 000 cars. The company still records significant sales of Škoda cars and represents Autogarant"s biggest competitor.

Another competitor is the Auto Centre Manik Ltd. which also has its headquarters in Čačak. AC Manik - ACM Ltd. is an authorized dealer and service centre for Audi vehicles. In addition to selling all models of Audi program, the company owns and service vehicles, and is well equipped with the latest technology and qualified staff. In addition to selling new vehicles, the company also sells used vehicles which give them a significant competitive advantage.

Next is Jevtović Ltd. an authorized dealer and service provider for Mercedes-Benz and Mitsubishi Fuso vehicle. This company has the most modern facilities and equipment for servicing vehicles in western Serbia and this represents their primary business. Because of the high quality service facilities and brands in portfolio, also represents an influential competition to Autogarant.

In addition to regional competitors, there are car dealers from all over Serbia, which represent significant direct competition when it comes to new car sales. On the other hand, as can be seen from the previous section, even more significant competition (although indirect) are the sellers of used cars, a lucrative segment which records significant growth on European car markets.

5. TARGET GROUP PROFILES AND DESCRIPTIONS

At first, B2B (A.) and B2C (B.) segments are separated, and further segmentation within these segment is applied in order to identify generic target groups.

A. Business to business segment:

1. Managers choice – includes management of successful international big and medium sized companies which operates on territory of Serbia. They search for quality, prestigious and premium price company"s vehicles. Management and GMs belong to the upper class and perceive car as status symbols and want to make a good impression, both within the company and externally, when interacting with business partners. Further these companies highly appreciate the quality and brand of the car, and their fleet must properly communicate and represent the values of the company. Furthermore, companies that belong to this segment usually have a clearly defined communication strategy that also prescribes the image of the company"s fleet for management .This is the premium segment, which means it is willing to set aside more money for top quality. Therefore, in order to attract this B2B target group and differentiate our offer from the competitors, it is necessary to propose certain benefits and after sales content. Company cars are used on a daily basis (trips to work, meetings, and business trips), so in addition to attractive terms of sale, both comfort and performance of the vehicle should also be emphasized.

Key values: status, top quality, brand

2. Salesman staff choice – also includes big and medium sized companies, but they need vehicles for operational staff, not management, usually employed in the sales or distribution sectors. The staff of the company needs practical and economical vehicles for performing basis activities. These companies mainly have already established and developed distribution network, which require a lot of fieldwork. Therefore, an employee of the company most of his working time spends in the company"s vehicle and has high daily transport mileage (such as staff employed in sales, supervisors, etc.). It means that besides price, as the main purchasing factor, fuel consumption, maintenance costs and warranty period represents also important factors. Further it is crucial to offer reliable cars with the right ratio of price and quality and to achieve a long-term cooperation by offering adequate after-sales services.

Key values: price, fuel consumption, warranty period

B. Business to consumers segment:

1. Premium segment – employed individuals over 30 years old with high income (over 1000€ per month) who belong to upper middle and high class. They are willing to invest more money into purchase of a high quality car which will properly represent their status in society. Beside basic need or transportation, when purchasing new car, they also consider various needs such as need for possession of expensive goods or well-known car brands and emphasize their higher status in society. Similar to Managers choice segment, this segment also perceives car as a sign of prestige.

Key values: status, high quality, premium price

2. Value segment – includes buyers who belong to middle class with average and above average income (from 400€ to 1000€). Their funds for purchasing new cars are limited, so for the money they tend to invest in car purchase, they seek to maximize the value they get, in return. This segment is extremely price-sensitive, thus price represents the primary criteria for purchasing vehicle. Beside price, low fuel consumption and low maintenance costs are also highly appreciated.

Key values: price, fuel consumption, maintenance costs

3. Family segment – includes employed married couples with small and underage children which look for practical and economical vehicles. Car is usually used in variety of purposes, from the daily commute during weekdays, the longer journeys during weekends and transport of the children. Therefore family segment particularly regards vehicles that are safe, comfortable (with usually five doors), spacious, and multifunctional, but also economical in terms of price and fuel consumption. They are also interested in accessories, such as additional safety gear like parking cameras, sensors, and locking system.

Key values: safety, comfort, practicality

4. Urban segment – mainly represented by younger population up to 45 years, which live in big cities and very often use cars urban environment where availability of parking spots is always an issue. Therefore, they look for small (usually 3 doors) and modern vehicles with low fuel consumption, suitable for everyday town rides and in price range of the given class. Beside this, we may further differentiate buyers which values characteristics and accessories such as attractive design and “green” technologies (eco-friendly technology such as reduced CO2 emission, engine modes for fuel saving etc.). This segment also includes youth population up to 25 years, who usually do not possess enough funds, so it is the parents who buy them cars. Further, beside price they also consider and appreciate customization options (if existing, like unique paint jobs, loud audio systems and other characteristics that will attract attention and make them stand from the crowd). Finally, they follow trends and they are not loyal to one particular brand and prefer to experiment with car brands.

Key values: practicality, design, accessories

5. Off-road segment – a specific niche market embodied through drivers who use car in special conditions and surroundings such as rural and off-road drive. They want strong, durable and safe vehicles which can be relied on and adapt to any weather or terrain unfavourable conditions. Cars must have excellent performances, to be safe and well equipped with additional gears for every kind of situations. Beside transportation need, these buyers also love to enjoy the feeling of ride and to test the limits of their cars.

Key values: performance, safety, accessories

6. TASKS

Based on the data given in the case study it is necessary to provide answers on following questions. Do not forget that the point of the case is to apply strategic thinking on Autogarant Ltd. possible future actions and not on the company"s analysis.

1. How to improve the business performance and sales volume of new cars (existing portfolio)?
    a. Which strategy would you propose to Autogarant owner and GM?
    b. Taking into account identified target groups (section 4), create a marketing strategy for the chosen target groups (choose one or more, it is up to you) for whom you think has a biggest potential.

2. Which new segments/markets would you recommend to Autogarant to enter in order to create new business pillars?
    a. Which strategy would you use when it comes to penetrating new segments/markets? Explain the strategy and necessary prerequisites for implementing the chosen strategy?

The accent is on your ideas, so feel free to propose creative but also realistic strategies. Every answer must have valid arguments and chosen strategies must aim to upgrade Autogarant position on market and bring additional profit to company.

Apstract: *We live in a time when globalization is an inevitable process. Globalization is characterized by a high degree of complexity. With a population of enterprises is relevant strategic approach to globalization of business. We talk about the highly integrated and electronically networked global economic system. Due to the fact that the international division of labor is becoming a central determinant of future economic development of each country, the knowledge in the field of international marketing are becoming a necessity in every business organization on the global market. Globalism, viewed as a business philosophy, based on an integrated, standardized system where people buy, sell, and share common products, services and ideas .*

Keywords: *strategic marketing, brand, finance, competition, Zara, H&M*

1.INTRODUCTION

Fashion is more than just a designer's whim. Fashion is a reflection of a given time, socially, politically, economically, and artistically. The changing styles show just as much about history and the time period as any history book. It reflects on what people think, what they valued and how they lived. Fashion is a statement, a way of living. Fashion is used in different ways such as clothing, culture, religions etc. (Wikipedia, 2013.)

The fashion industry is now one of the biggest industries in the world.The world clothing and textile industry (clothing, textiles, footwear and luxury goods) reached almost $2,560 trillion.

- The world childrens wear market is expected to reach beyond $186 billion in 2014, marking a 15 percent increase in five years.
- The world bridal wear market is expected to reach almost $57 billion by 2015.
- The world mens wear industry should exceed $402 billion in 2014.
- The world womens wear industry is expected to pass $621 billion in 2014.

American households spend, on average, $1,700 on apparel, footwear, and related products and services. In addition, a large number of people (4,2milion people) are employed in the fashion industry, the majority of the population, fashion is one of the hobbies and areas of interest.

2. STRATEGIC MARKETING

Strategic marketing is the process by which managers formulate and implement marketing strategies, in order to achieve the goals set in the given environmental conditions and the company .To marketing managers develop marketing strategies and manage them, according to (Filipovic V., Janicic R., 2010) they must concentrate on several marketing tasks including:

- Analysis of market opportunities and constraints;
- The choice of target markets;
- Development of the marketing mix;
- Analysis of internal factors, strengths and weaknesses of marketing and the company as a whole.

2.1. THE PROCESS OF STRATEGIC MARKETING

Strategic marketing involves the decisions and actions that are the result of :

a) analysis of the current situation;
b) development of new strategies or modifications to existing ones;
c) elaboration of the program of action for their implementation;

d) evaluate the effects of application .

2.2. MARKETING STRATEGIES FOR THE FASHION INDUSTRY

Fashion marketing techniques apply many of the same marketing strategies that large and small businesses use. Fashion marketing includes market research, advertising and promotion. Research gathers information about the market for a particular brand or product. Advertising helps generate sales, and promotion increases brand or product awareness.

Fashion marketing strategies based on the Internet:

Fashion Blogs

A big part of the online community includes blogs and social networks.

Online advertising

These strategies include creating online versions of printed magazines, banner ads, photos and articles about the brand.

Online interactive fashion show

It is possible to organize a series of small interactive show, with a series of image model where viewers can click on the picture to see more information about the layout, or even buy the product.

Marketing strategies fashion shows

Fashion show - organizing fashion shows is a classic marketing strategies in fashion, which provides a formal presentation of the production program selected public.

Press Release - fashion managers use the press release for publication of certain activities of a given brand. Statement delivered by the media and is one of the classic ways of informing the public about the intentions of the company.

Digital Media – They are used for research and promotion. The amount of information available to research pertaining to, and the possibility of two-way communication is the main advantage of using this strategy for promotion .

Product placement - This strategy involves techniques where the fashion products of a given brand promoted through television programs, broadcast and film or engaging public figures.

The choice of brand ambassador - Present influential people in the targeted group of potential customers who participate in the popularization of fashion products (David, F. (2013).

2.3. CREATIVE FASHION MARKETING STRATEGY

Viral marketing - viral marketing strategy in the fashion industry can be very effective, due to the effect of trust in the user that is advertising .

Guerrilla artwork - This is a strategy that includes the recent collaboration with artists in the creation of murals, graffiti and similar examples of street art, which the company addresses the street culture of their customers.

Strategy word-of-mouth - relies on effective communication brand values and beliefs of the company, which must be clearly communicated and accepted by the company to be properly transferred to customers.

3. H&M

In 1946 the company's founder Erling Persson was on a trip to the United States and came up with the business idea of offering fashionable clothing at attractive prices. In 1947 he opened his first shop Västerås, Sweden "Hennes", which exclusively sold women's clothing. "Hennes" is Swedish and means "for her" and/or "hers". In 1968 the hunting apparel retailer MauritzWidforss was acquired, which led to the inclusion of a menswear collection in the product range and the name change to "Hennes&Mauritz" (H&M). H & M Hennes&Mauritz AB comprises six independent brands: H&M, COS, Monki, Weekday, Cheap Monday and & Other Stories.

H&M is are tail that is looking to provide consumers with fashionable, high-quality clothing at the best price possible. They offer “fast-fashion”clothing, in other words from runway tracks in record time, and sell Europeanin fluenced clothing in the American market. Additionally, H&M carries clothing in avariety of categories including women‟s casual, men‟s business, children‟s wear, footwear and accessoriesThe company is the second largest clothing retailer in the world, and actively engages in E- retailing. H&M is also economically, socially, and environmentally sustainable (H&M, 2014).

3.1. H&M PERFORMANSE

Financials

The revenue chart started in 2004 at about $10 million, and has risen to about $16 million in 2008. Their profit margin dropped significantly from about 14.7% in 2004 to about 12.9% in 2005. Each year after that, the profit margin in creased again and is basically stabilized again at about 14.7% in 2008. From 2009 when the profit was $118 million, they increased the profit at $150 million in 2013.
H&M"s growth target is to increase the number of stores by 10–15 percent per year, and at the same time increase sales in comparable units.

Recent Expansions

H&M had started theirglobal expansions earlierthan Zara, so theyhavehad alonger time period ofsuccess in the performancearea. An articlein Business Week (2002) states that in theirfirst attempt at international expansion, H&M opened astorein London in 1976.When this article was written in 2002, H&M was leading the market versus its major competitors, Gap and Zara. According to the author, (Capell.K, Khermouch.G (2002) HIP H&m Business Week,(3807) 106-110), by the end of 2002, the company had plans to increase their number of stores to 844, which would have been an increase of almost 75% from 1996-2002. H&M opened 190 new stores in 2005, 2,325 stores at the end of 2011 and 2,629 stores at the end of August 2012, 2014 there are 3,200 stores in 54 countries.

The strong pace of expansion continues into 2014 with a planned 375 new stores net. The highest rate of expansion will be in China and the US. There is also great potential for expansion in other markets such as Russia, Germany, Italy and Poland.

Online expansion

H&M"s shop online is available in 10 European markets and the US. The easily navigated digital store is fully mobile-adapted since January 2013 and already very popular with our customers. Roll-out of shop online to other markets of the H&M Group will follow.
COS, Monki, Weekday and Cheap Monday offer sales online in 18 European markets while & Other Stories is available online in 10 European markets.
The online market is constantly growing and mobile shopping through the use of smart phones and tablets has become increasingly common. 64% of consumers are interested in scanning products with smart phones to get more information while 76% of consumers are interested in instant offers via smart phones for things they were already looking for. Additionally, popular mobile apps include mobile coupons, store information, mobile self-checkout and digital receipts.

Current Marketing Strategy-H&M

Current strategies that H&M are marketing to its consumer are thro ughamobile marketing campaign to promote the latest collection. In doing this mobile marketing strategy consumers receive SMS coupons, mobilebannerads placed on major portals and media sites.
To help gain customer traffic in the storeH&M has also used celebrities such as Karl Lagerfeld, Roberto Cavalli, ReiKawakubo, and Jimmy Choo to help increase sales. One of the major ad topics that H&M may market is the Fashion Against Aids campaign. The specific collection featured t-shirts, tank tops, and hoodeds weaters designed by Designers Against AIDS (DAA) and by several music artists including Rihanna, Timbaland, and Ziggy Marley. Nearly 25% of the sales from this collection went to HIV/AIDS prevention projects (Wikipedia, 2013).

Introduction

Zara"s history begins with the owner company, The Inditex Group.Inditex Group is a large company based out of Spainrunning around one hundred stores dealing with textile design. Inditex operates over 4,350 stores worldwide with brands like Massimo Dutti, Bershka, Oysho, Pulland Bear, Zara, ZaraHome, Uterque, and Stradivarius (Zara,2014).

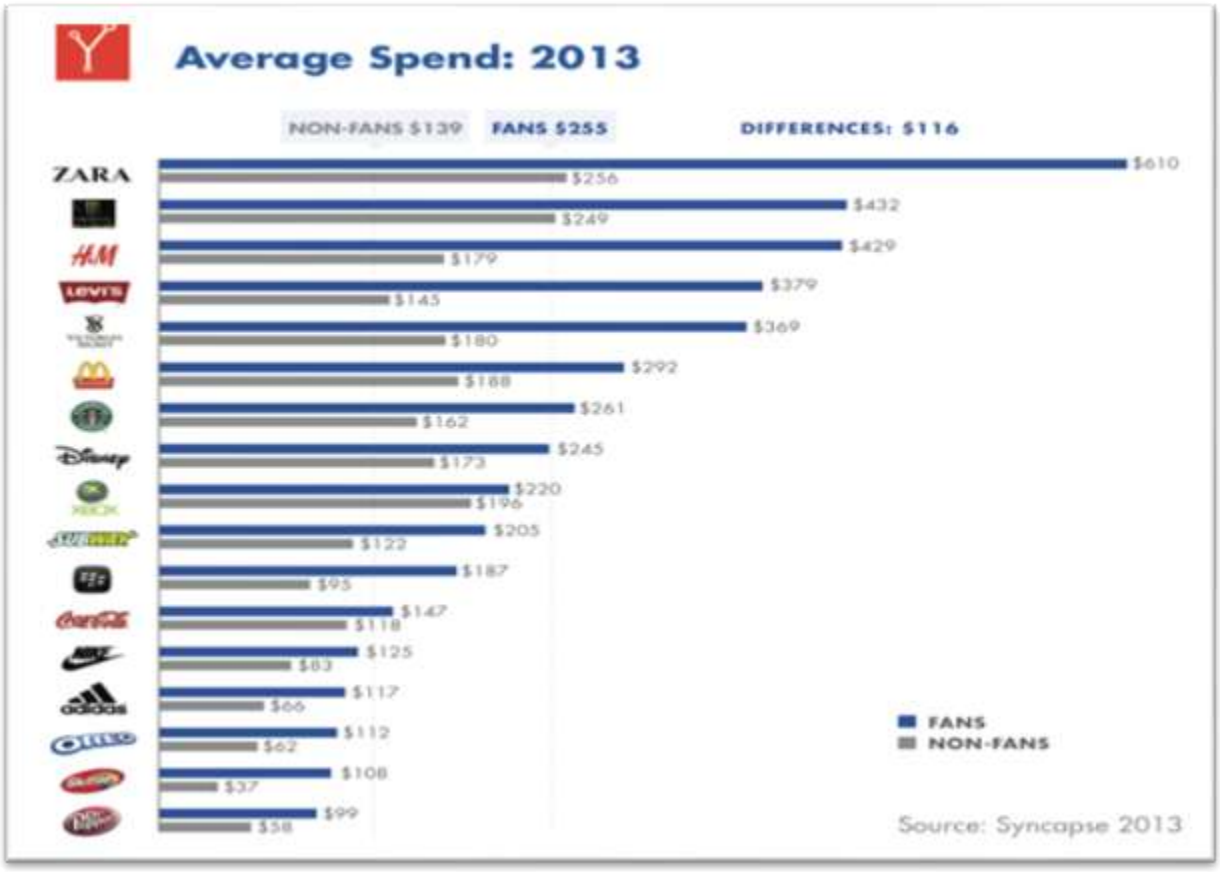
The company was found in the year 1963 by Amanico Ortega Gaona and by the year 2005 its holding group Inditex became world's fastest growing manufacturer of fashion clothing that was both affordable and trendy. It has over 2000 stores all over the world and plans to make that number double by the year 2011. The success story of Zara is based upon its business strategy that fostered creativity, innovation and flexibility in its business model and that is what differentiated Zara from it competitors and provided it with an edge and competitive advantage both at a local as well as at an international level. The very first shop of Zara was opened in the year 1975 in the city of Spain which is to date the home and central location to its headquarters.

3.2. ZARA PERFORMANCE

Financials

As Zara emerged from the company Inditex, this report includes some financials about Inditex. Their revenues started in 2004 with about $8 million and steadily roseto about$15 million in 2008. Inditex"s profit margin started off somewhat low in 2004 at 11.6%, and peaked in 2007 at 13.3%. In 2008, their profit margin is back down at 12.1%. In 2013, Inditex"s sales rose by 4.9% from the previous year to 16.72 billion euros ($23 billion), said Spanish textile titan Inditex, owner of global fashion brand Zara, Amancio Ortega.

Asia accounted for 20.4 percent of the company"s sales, overtaking its domestic market Spain at 19.7 percent, where consumer spending has plunged due to a double-dip recession that has left one in four people out of work. But despite stressing “strict control of operating expenses,” Inditex said business costs rose as it coped with a net 331 new store openings and higher sales in the year. Net profits edged up by 0.6% from the previous year to 2.38 billion euros in 2013 (Capell,K. (2008)



Recent Expansions

Zara"s parent company,Inditex, opened 448 new stores in 2005, By 2010, their global total was expected to bealmost 5,000 stores. The group boasted a worldwide empire of 6,340 stores in 87 markets at the

end of its 2013 business year,Zara now operates in 86 countries across the globe, in every continent, with total of 1,770 stores.
As one of the leading brands in the fashion industry, company profitability and growth is of course important. At the beginning of 2013, Inditex reported a 22% increase in their earnings as they expanded in many emerging markets such as China, India, and Indonesia as well as the online retail.
So far in 2006,Zarahas expanded cautiouslyin the United States, with only19 stores. At 2013 they include only 45 US stores. Meanwhile, their biggest competitor, H&M, has 91 stores in the US, which is still cautious (Zara, 2014).

Online Expansion

As the world is now becoming digital, many marketers initiate the digital marketing campaign. Many companies now engage actively to promote their products on social media like Facebook, Twitter, YouTube, or Instagram. Not wanting to be a laggard, Zara also created its own Facebook page, Twitter account, YouTube, and also Instagram accounts. More than 16 million people —likell Zara„s FB page and more than 300 hundred people followed Zara on Twitter, thousands of people also subscribed to Zara„s channel on YouTube. Unfortunately, it is not enough. Despite its availability on social media, Zara is not utilizing using these social media to do advertisements; therefore, these accounts are not really productive or useful for the company (Ghemawat, P., Nueno, J. L. (2012).

Current marketing strategy ZARA

The company„s vision as stated on the website:

“Zara is committed to satisfying the desires of our customers. As a result we pledge to continuously innovate our business to improve your experience. We promise to provide new designs made from quality materials that are affordable”.

Long-term Objectives
The company states on their website the following as their objectives in the long-term:

1.Save energy, the eco-friendly store:
They are implementing an eco-friendly management model in their shops in orderto reduce energy consumption by 20%, introducing sustainability and efficiency criteria. This management model sets out measures to be applied to all processes, includingthe design of the shop itself, the lighting, heating and cooling systems and the possibility of recycling furniture and decoration.

2.Produce less waste and recycle:
Zara recycles their hangers and alarms, which are picked up from their shops and processed in to other plastic elements. This is an example of their waste management policy. Millions of hangers and alarms are processed each year and both the cardboard and plastic used for packaging are also recycled.

3.Their commitment extends to all their staff, increasing awareness among the team members:
The Company holds In-company awareness campaigns and specific multimedia-based training programs to educate their staff in sustainable practices, such as limiting energy consumption, using sustainable transport and modifying behavior patterns.

4.Use ecological fabrics, organic cotton:
Zara supports organic farming and makes some of its garments out of organic cotton(100% cotton, completely free of pesticides, chemicals and bleach). They have specific labels and are easy to spot in the shops.

5. Use biodiesel fuel:
Zara„s fleet of lorries, which transport more than 200 million items of clothing a year, use 5% biodiesel fuel. This allows them to reduce their CO emissions by 500 tons. We can see from the objectives that Zara is aiming to be an environmental-friendly company. It is their top priority at least until the year 2020.

H&M SWOT Analysis

Strengths

- Leader in Global market (2nd)
- Affordable & high quality clothing
- Fast-fashion
- Throw-away fashion
- Strong presence in multiple markets (Women, Men,Kids…)
- Celebrity endorsements
- Strong social media presence
- Price does not effect quality
- Company website and blog

Weaknesses

- Brand awarenss of individual apparel brands sold in stores
- Fit is not consistent due to variety of manufacturers and supplies
- Customer service

Opportunities

- Promote current sustainability practices
- Increase word of mouth in both temale& male audiences
- Online market including social media
- Mobile Marketing

Threats

- Secondary competitors such as Express, Charlotte Rouse
- Primary competitors: Forever 21, Topshop, Urban Outfitters, Zara

Marketing mix

The 4Ps of H&M:

1.Product:
H&M"s business concept is to offer fashion and quality at the best price. Quality also means that the products must be manufactured in a way that is environmentally and socially sustainable. All goods are labelled with their country of origin. Prints on H&M"s goods shall not cause racial, sexual, political or religious offence.
2.Price:
The price strategy of H&M is designed based on their customers needs which is low price and high fashion. In fact, this is the one of the biggest challenges for H&M.
They combine fashion and cheapness by two steps: first, H&M outsources the production to countries where the labour cost is much lower. Second, the company also conduct strict cost control plan.
3.Place:
There are over 3200 H&M stores all over the world. The store is located in prime locations of the area with high concentration of visitors. Because the inventory for H&M is refreshed everyday (H&M, 2014), direct command is important for correct adjustment in more than 3200 stores. Besides stores, H&M starts to launch online sale in several areas. It was suggested that well-known fashion retailers have advantages of their brand to attract customers(Marciniak and Bruce, 2004). Therefore it is beneficial to take the initiative to launch online shop. And This step could satisfy online customers and complement the shortcomings of store sale.
4.Promotion:
H&M"s target customers are young women who want more fashion cloth at low price. Young people have plenty access to information. A multi-channel promotion strategy including advertising, internet

promotion, sales promotion was adapted by H&M. These multi-channel strategy increases the exposure of H&M. They promoted through Fashion outlets (i.e.magazines,blogs,retailer web sites). H&M hired celebrities in their campaigns.
The promotional actions of H&M focus on the two features. It is easy to find the posters of H&M are in fashionable style and always with the price of the clothes. On H&M"s website, price is put at obvious position. Although Zara and Gap, H&M"s main competitors, put the price online, they usually put it small. On the contrary, advertising of H&M always highlights the low price to build awareness of their low price (Capell,K., Khermouch,G. (2002).

4. CONCLUSION

In conclusion, Zara and H&M have much to accomplish internally and externally as companies. To be fully established as a brand both companies will need to alter some of the aspects they have already created to be where they are at today. Both brands are well known in certain are as of the world and have formed a strong brand identity. To keep growing each company will need to make some adjustments and some compromises so consumers are more exposed to the fashion brands. H&M has already formed are cognizable name in the U.S. by having selective advertisements and a strong apparel line. If the company wants to continue to be adominant trendy company then implementing the marketing plan that wehave come up with may help to spread the name to more consumers.To make a mark on the U.S. market, Zara has many changes that need to take place in order to do this. Both companies have astrong brand identity; they just need to be introduced in a different manner so consumers are aware of the irexitence. Both apparel companies have the ability to spread in the U.S and be highly successful. It is a huge risk, but it will not damage the name or the price to make their products available to more people.
