FOREWORD

We are very pleased to present the Proceedings of the XIV International Symposium SymOrg 2014, traditionally organized every two years by the Faculty of Organizational Sciences, University of Belgrade. This year's Symposium continues its tradition of being the premier forum for the presentation of research results and experience on the latest issues in management theory and practice. SymOrg 2014 brings together people from various disciplines to discuss current and emerging issues within the business models arena, including business, social, technical and content-related management topics.

The topic "New business models and sustainable competitiveness" chosen for this year's Symposium sparked strong interest among the professional and scientific community and elicited great response to the call for papers. The Proceedings include around 250 papers and contributions from more than 500 authors. The international reputation of the Symposium was once again confirmed through the announced participation of speakers and guests from abroad.

The mission of the Symposium is to share novel business model solutions that meet the needs of sustainable competitiveness and identify new directions for future research and development. It brings together prominent experts from academia, corporate and public sector and other relevant organizations and institutions. It is a unique opportunity for the most competent individuals and organizations to present their theoretical knowledge, experience, and their forecasts with regards to new global and local trends of management development in the business environment.

The Symposium aims to provide a unique international forum to facilitate the exchange of cutting-edge information. It is acknowledged that SymOrg has positioned itself as one of the major conferences of its kind in Serbia, in terms of size, quality of content, and standing of attendees. The Symposium particularly encourages the interaction of research students and developing academics with the more established community.

The peer-reviewed papers in this volume span the scope of topics explored at the Symposium. The Proceedings are a vital reference for students, scientists and managers working in this field and will provide valuable guidance for developing new business models in practice and maintaining sustainable competitiveness.

The broad topic of the Symposium has allowed for exploration of different aspects of these areas:

- New Business Models
- Business Intelligence and Decision Making in Management
- Business Psychology
- Communication Management and Social Networking
- Corporate Social Responsibility
- Education Management
- Electronic Business
- Entrepreneurship and Management of Small and Medium Enterprises
- Financial Management
- Health Care Management
- Human Resource Management
- ICT and Management
- Innovative Organization and Management
- International Management
- Knowledge Management
- Marketing Management
- Operational Research and Quantitative Methods in Management
- Operations Management
- Organization of Business Systems

- Performance Management
- Project Management
- Public Administration Management
- Quality Management
- Strategic Management
- Sustainable Development and Environmental Management
- Case Study
- Technology and Innovation Management

We want to thank the contributors and the reviewers who made this issue possible. We also thank the Faculty of Organizational Sciences, University of Belgrade for the generous financial support that made the Symposium possible.

Abstract: *One of the most challenging managerial attempts nowadays is undoubtedly strive for creation of a business model which would best integrate the organizational position towards the external adaptation and integral integration. This managerial process is a logical continuation of modeling the competitive advantage of a certain enterprise, in such a way that the organizational learning would best integrate the used, not the overall organizational knowledge, the flexibility of the organizational systems would determine the potential of the behavioral processes and that the changes oriented towards innovation would enable strategic positioning regarding the existing and potential competition.*

The prior objective of creating and further managing a business model is achieving an integrated and pro-active combination of elements that implement the needs of an organizational dynamism, in the process of problem analyzing of sustainable dimensions of the competitive advantage. Therefore, its ultimate target is managing a Customer – integrated Business model, as one that places an 'integrated importance' to the role of the customer within managing the organizational competitive advantage.

Key words: *Business model, strategic positioning, organizational inertia and dynamism, pro-activity and strategic flexibility, customer-integrated model*

INTRODUCTION

Business modeling and the process of managing it has emerged it's importance for an applicative usage from the mid 1960's when dynamic companies, such as IBM – in main framing the computer from industrial to predominantly personal, Sears Roebuck – in shifting from overall catalogue offer to a retailing specialized catalogues, Motorola – from consumer electronics - operating method to high-technology added value in telecommunications, mobile and internet based competitive model, IKEA - from immense non compositional to separate segmented business offer, and many others, have identified the necessity of *changing the dominant business logic*, with regards to the contingency analyses of the internal and external stimulus, determinants and obstacles for a prominent and recognizable sustained competitiveness.

Each organized effort for planning and implementing a certain *business model* integrates not only the organizational, but also the departmental level, especially to those organizational units which are most critical for a proper determination and combination of business elements whose relationship and inter-dependence forms the scope and depth of the competitive potential of any enterprise. In this context, business modeling is far more a process than a state, predominantly due to the needed changes, transformational or transactional, that shape the process of managing it.

1. METHODOLOGICAL DETERMINATION AND ELEMENTS OF BUSINESS MODEL

Despite the fact that applicative importance of business modeling has emerged from the mid 1960"s, up to the end of 1990"s their hasn"t been a unified and accepted methodological framework for *managing an organizational business model*, which inter-relates with the increase of the need for a planned, not an incidental organizational change, mainly focused on changes for adopting the strategies to the complex

environment. However, it is quite important to emphasize that *the concept of business modeling is far from applying the organizational strategy, or operative accommodation of strategic elements*. In detailing the desired nature and capacity of their business model, every organization focuses on their *particular combination of resources - especially the used knowledge, skills, capabilities and experience, on one hand, with the capacity for pro-active behavior, strategic flexibility and organizational inertia, on the other hand, both of them aimed at reaching the state of organizational dynamism*.

The fundamental logic of the business model is *finding out the key value – adding resources and capabilities and integrating them in accordance with the organizational strategy, structure, systems and human resources*. *Theoretical defining of a business model* presents a variety of methodological approaches, which determine it as the following:

- *The method of doing business by which a company can sustain itself through generating revenue* (Chesbrough & Rosenbloom, 2002)*;*
- *Firm's intended or actual response to how value is created or appropriated (*Magretta, 2002*)*
- *Design of organizational structures (Baden-Fuller & Morgan, 2010), such as boundary – spanning transactive structures (*Amit & Zott, 2001*);*
- *An operational tool expressing the business logic of an organization (*Osterwalder, 2004*);*
- *A convention between partners concerning the generation and sharing of value among stakeholders (*Verstraete & Jouison, 2007*);*
- *A firm's underlying logic and strategic choices to create and capture value within a value network (*Shafer, Smith & Linder, 2005*) and the most prominent and influencing definition in the business modeling literature is:*
- *An architecture for the product or service, an information flow, a description of the benefits for the business actors involved, and a description of the sources of revenue (*Timmers, 1998*).*

It is evident from majority of the above detailed definitions that business model initially *refers to using a „dual business developmental perspective*", in terms that it simultaneously stipulates, in our profound analyses, the following organizational counter-parts:

- *Pragmatism and innovative changes;*
- *Integrity and particularization;*
- *Management and leadership;*
- *Adaptively and pro-actively performing*
- *Short – term profit orientation and long – term business value maximization;*
- *Strategic choices and user generated operational context etc.*

Each business model integrates various *constitutional elements*, predominantly determined and described through the following Table:

1. The initial element of each business model is *value proposition*, which refers to the perceived value benefit, which a customer would get from the specific combination of the organizational products or services. It precisely determines *the quality features* which are prevalent for the customer from the organizational offer. This first element details *the cognitive offer view* which, in fact, is dominant for the perceived value from the transactions with the specified organization.
2. In order to accommodate the numerous products or services to the most particular customer demands, an organization has to undertake changes in order to position itself in front of the *target customer* – the model of interdependence starts from *identifying the customer portfolio which can be best served with organizational products and services* that have undergone transactional or transformational changes. The importance of this second business model element lies in *clear determination of the customer wishes, tendencies, motives, expectations, benefits etc.*, received with the act of purchasing the product or service.

.

Table 1 Business model elements

No.	Element of business model	Description
1.	**Value proposition**	*An overall view of the company's bundle of products and services*
2.	**Target customer**	*Segments of customers a company wants to offer value to*
3.	**Customer handling/distribution channel**	*Various means of the company to get in touch with it's customers*
4.	**Customer interfaces/relationship**	*Kinds of links a company establishes between itself and its different customer segments*
5.	**Value configuration**	*Arrangement of activities and resources*
6.	**Capability/core competency**	*Competencies necessary to execute the company's business model*
7.	**Partner network**	*Network of cooperative agreements with other companies necessary to efficiently offer and commercialize value*
8.	**Cost structure**	*Monetary consequences of the means employed in the business model*
9.	**Revenue model**	*A way a company makes money through a variety of revenue flaws*

Source: Adopted according to Osterwalder, A., Pigneur, Y. & Tuchi, C.L. (2005), Clarifying Business Models: Origins, Present and Future of the Concept, *Communication of the AIS,* Vol.16 (1), p.13

3. The process of achieving a *full alignment with the identified need*s, in a broader meaning of the word, includes a proper way of handling them, through the distributive channels. As a third element, *customer handling/distribution channel integrates all communicational approaches* in order to create a sense of satisfaction at a specific customer, in terms of mutual articulating, gestures, emphasizing common interest of both sides etc. The only exception of this element is at public tenders, in which case this element is included in the following one – customer interface/relationship
4. Each customer, as a member of various determined target customer segments, possesses different means of establishing and developing a closer relationship, which is done in the element *customer interfaces/relationship*. It implies that, with regards to the handling method, the complete relationship is build with an accent to the *stimulus for a customer segmented satisfaction*, which is highly important especially for the higher customer segments which want a clear distinction in satisfying their determined needs.
5. Very after the relations with the customers have been set up, the company should create a *specific combination for optimal usage of its resources and capabilities*, particularly processes and activities which add value for the customers, which is done in the fifth business model element – *value configuration*. It is important that each organizational configuration of resources and capabilities *must be unique* compared to other companies, as well as compared to various customer segments. It details *the capacity of the organization to be original* in satisfying its customers.
6. In certain circumstances, an organization could be able to integrate its resources and capabilities pro-actively, but would not bear the needed competencies for implementing the desired business model – it is the focal point of the sixth element, i.e. *capability/core competency*. As an applicative element, it stipulates that *core organizational competencies are expected to be sustained*, and therefore to influence to a *more complete delivering the promised organizational outcome* – benefit from the products or services for the customers.

7. *Partner network*, as an element of the business model refers to the undeniable truth that *each organization can not be specialized in every business function*. The tendency for finding out a solid and serious network of business partners would result in bringing about *higher quality of the performance for lower costs*. Its focus is towards an increased efficiency and at the same time commercializing the benefits that arises from the achieved value for the targeted customers.
8. It is useful to measure invested money in increasing the level of satisfaction of the customer segments. Therefore, in the element named *cost structure*, an organization makes efforts to *leverage the benefits*, in order to determine *which means of effecting value configuration are priority, and which are of a second level of importance*. The cost structure should not lower the promised quality level to the customers, and at the same time it is not expected to be based on a non-sustainable combination of resources and capabilities.
9. Finally, business model finalizes with creation of *revenue model* – which implies that an organization should determine *the level of risk exposure for different revenue flaws*, in order to enable itself to put priority to those that are best suited to the contingency combination of internal and external elements. The importance of revenue model is *categorizing the revenue flaws in accordance with the degree of prosperity and potential for influencing its competitive advantage*.

Every element of the business model influences to the fulfillment of the consecutive one, as well as to the overall effectiveness and efficiency of the created business model, in which, as *most creative and sensitive elements usually are perceived target customer, value configuration, building capability/core competency and partner network elements*.

A categorization of the elements of the business model which pays prevalent attention to *using transformational strategy for changes* is detailed as constituted of the following *integral business model elements (*Yip 2004):

- *Value proposition,*
- *Nature of inputs,*
- *How to transform inputs (including technology),*
- *Nature of outputs,*
- *Vertical scope,*
- *Horizontal scope,*
- *Geographic scope,*
- *Nature of customers,*
- *Organization of the model.*

The most important difference of the last model, compared to the first, previously detailed business model is in *the position of the customers*, which is on the 8-th level. The prior reason for it lies in the fact that *in strategic modeling of the business, customers are initially positioned, as an element which influences to all other elements*. In this context, customers on the 8-th level may manifest certain variability with regards to a closer integration of the resource/capability combination compared to the desired level of customer satisfaction.

Besides these 2 business model concepts, the most intriguing issue in creating and managing most efficient business model is in the *proper combination of resources and competencies, aimed at adding value to the organizational performance*. A model which pays most attention to it is named *RCOV model (Resources and Competencies, Value Proposition, Organization)*, in which *each combination of the resources and competencies is measured through its marginal influence to the customer quantitative and qualitative benefit*. The presentation of the approach, in combining the elements of this *configurative business model* would best be detailed on the following Figure:

It is evident that the *integration of elements of the RCOV business model is done through organizational and customer learning, socialization and acquisition of new customers, offer specification, production and/or distribution by the customers*, resulting in the *customer integrated character of this model*, although the very customer is not an element of the model, but may appear within the dimension external organization

Figure 1 The RCOV Business model (Demil & Lecocq, 2010)

.

2. MANAGING PRO-ACTIVITY, ORGANIZATIONAL INERTIA, STRATEGIC POSITIONING AND FLEXIBILITY FOR ORGANIZATIONAL DYNAMISM

In order to increase the level of successfulness, each business model is expected to execute certain *management criteria for success of a business mode (*Rasler 2010), among which, as most applicable, arise the following:

- *A pro-active business approach that turns out thoughts into looking for business and our marketing strategies to creating a need and away from a current business model where marketing focuses on fulfilling a need and waiting for the customer to ring,* undertaken through these *managerial steps:*
    - *Figuring out the company culture,*
    - *Putting a business plan in place,*
    - *Showing leadership, and*
    - *Recruiting and retaining top performers.*
- *Business model constitutes a change in company culture, one that allows us to plan and one that still maintains a sense of urgency. The new culture is about creating more opportunities and building relationships.*

Organizational pro-activity is higher at experienced organization, compared to young and start-up companies, in which the manifestations of *organizational inertia*, especially the structural one, emerge owing to the *managerial determination* (Marx 2008) that *less subject to structural inertia, young organizations may seem more adaptive than established firms, but their agility depends critically on the availability of resources to pursue multiple paths, aimed at reaching strategic continuity.*

The integration of pro-activity and organizational inertia leads to a proper determination and consecutive application of the concept of *strategic positioning for managing business models*, which is fundamentally consisted of the following constitutive elements (Porter, 1997):

- *The right goal,*
- *A value proposition,*
- *A distinctive value chain,*
- *Trade – offs,*
- *Fit among strategy elements,*
- *Continuity of direction.*

The managerial challenge is to inter-relate these elements in order *to achieve an organizational dynamism, from their predominant static character*, like it has been achieved in Ikea, Neutrogena etc. In doing so, an organization should initially attempt to achieve its *strategic flexibility*, a propulsive business concept that is theoretically determined as:

- *The ability to identify innovation opportunities, commit resources to new courses of action, or reverse unproductive resource deployment (*Shimizu and Hitt, 2004; Uhlenbruck, 2003).

Strategic flexibility is influenced by organizational structures and dynamic capabilities, on one hand, and on the other hand it influences the *organizational dynamism*, which in return is critical for creating and managing of *dynamic business model* through *reducing the structural complexity and making full use of a pro-active organizational culture*. Key determinant in the organizational dynamism are *dynamic capabilities*, which refer to:

- *A learned and stable pattern of collective activity through which the organization systematically generates and modifies its operating routines in pursuit of improved effectiveness* (Zollo and Winter, 2002).

In creating a *dynamic business model*, *dynamic capabilities are inter-related with the forms of knowledge* needed for anticipating and proper effecting of customer needs through structures and routines, on the following *managerial approach for their dynamic integration(*Mason and Leek *2008)*:

- *A relationship between the structures and routines is captured by a firm's business model,*
- *Exists a constant and iterative need for creating and sharing know-how to drive improvements to both structures and routines.*

Actual *dynamic change model* which fulfills the above detailed managerial approaches would best be presented on the following Figure:

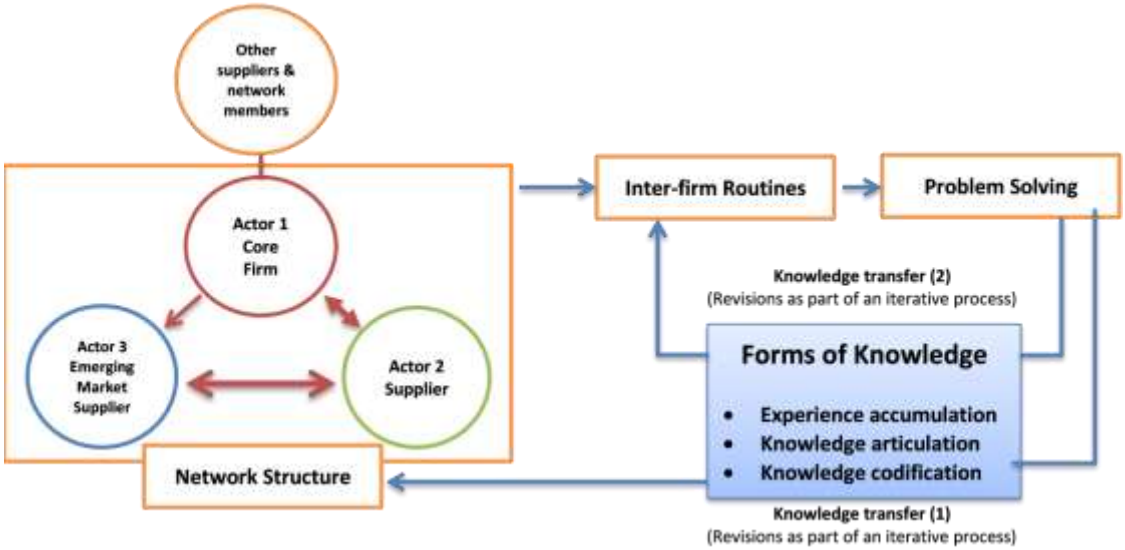

Figure 2 A dynamic Business model (Mason and Leek, 2008)

Fundamentally, in order to *manage pro-actively the dynamic character of the business model*, it is essential to *adopt the need and form of the knowledge to the internal combination of structures and routines, on one hand, and to the nature and depth of the needs of the specific external customer segment, on the other hand*

3. CONCLUSION

Each organized effort for planning and implementing a certain business model integrates not only the organizational, but also the departmental level, especially to those organizational units which are most critical

for a proper determination and combination of business elements whose relationship and inter-dependence forms the scope and depth of the competitive potential of any enterprise. In this context, business modeling is far more a process than a state, predominantly due to the needed changes, transformational or transactional, that shape the process of managing it.

However, it is quite important to emphasize that the concept of business modeling is far from applying the organizational strategy, or operative accommodation of strategic elements. In detailing the desired nature and capacity of their business model, every organization focuses on their particular combination of resources - especially the used knowledge, skills, capabilities and experience, on one hand, with the capacity for pro-active behavior, strategic flexibility and organizational inertia, on the other hand, both of them aimed at reaching the state of organizational dynamism.

Each business model integrates various constitutional elements, predominantly determined as: value proposition, target customer, customer handling/distribution channel, customer interfaces/relationship, value configuration, capability/core competency, partner network, cost structure and revenue model.

The most intriguing issue in creating and managing most efficient business model is in the proper combination of resources and competencies, aimed at adding value to the organizational performance. A model which pays most attention to it is named RCOV (Resources and Competencies, Value Proposition, Organization) model, in which each combination of the resources and competencies is measured through its marginal influence to the customer quantitative and qualitative benefit.

The integration of pro-activity and organizational inertia leads to a proper determination and consecutive application of the concept of strategic positioning for managing business models. Strategic flexibility is influenced by organizational structures and dynamic capabilities, on one hand, and on the other hand it influences the organizational dynamism, which in return is critical for creating and managing of dynamic business model, through reducing the structural complexity and making full use of a pro-active organizational culture.

Fundamentally, in order to manage pro-actively the dynamic character of the business model, it is essential to adopt the need and form of the knowledge to the internal combination of structures and routines, on one hand, and to the nature and depth of the needs of the specific external customer segment, on the other hand.

INNOVATIVE APPROACH TO THE ANALYSIS OF THE SPA TOURISM IN VOJVODINA (SERBIA)

Peter Harmath[1],Deniz Ahmetagić[2]
[1]University of Novi Sad Faculty of Economics in Subotica, Segedinski put 9-11, 24000 Subotica, Serbia, harmatp@ef.uns.ac.rs
[2]University of Novi Sad Faculty of Economics in Subotica, Segedinski put 9-11, 24000 Subotica, Serbia, ahmetagic@ef.uns.ac.rs

Abstract: *Along with other neighboring countries in the region of the Pannonia plane, Vojvodina (Serbia) lies on rich thermal springs which can be listed among the world largest. Contrary to the fact that the rich in water is equal, Important and urgent task is to include Spa centers in Vojvodina in an integral cooperation. Practice shows that economic growth can only be achieved by laying good foundations and having a network of common goals. Numerous weaknesses and errors were noticed, primarily in stakeholder analysis, benchmarking, organization and marketing which all hinder the possible development of the Spa tourism in Vojvodina. In this article, on the basis of the research problem, authors wish to highlight the importance of expansion of the methods and techniques which are needed and urgent for improvement and promotion of Vojvodina Spa tourism in the region.*

Keywords*: spa tourism, stakeholder analyses, foreign experiences, regional development*

1. INTRODUCTION

According to world assessment there are more than 71600 spas, employing 1.2 million people (European Spa Magazine, 2008) “Europe is the largest region of Spa tourism in the world with over 22607 spas and revenue of about 18 billion US dollars.” (Global Spa Economy, Report, 2007). According to most studies (Ellis, 2008) spa and wellness tourism based on thermal and healing springs will become a leading part of health tourism by 2015. Neighboring Hungary is very rich in thermal springs, about 80% of the total country lies on thermal waters; it is fifth in the world after Island, USA, Italy and Japan. Serbia is also in a favorable position, and it is rich in thermal springs. Spa tourism in Hungary has grown from 12.7 million to 16.1 million guests in the period from 2000-2004. According to the strategic development program of Hungary (Szechenyiterv), 74 spas have received state subsidies, out of which 60 spas used that subsidy by the end of 2006.

For comparison purposes the tourism region of Southern Pannonia Plane of Hungary and Vojvodina as a tourism region in Serbia will be observed. By comparing the two closest tourism regions (Southern Pannonia Plane – Dél Magyarországi régió and Vojvodina from Serbia) it already becomes noticeable that Vojvodina region makes only half of the revenue compared to the observed region in Hungary. (See tables 1 and 2). It should be mentioned that, as far as the tourism and spa capacities go, that is even the leading region in Hungary (cumulative data of the Danube region – Dunántúl. Table 1). Especially, we need to say that this is not related to the leading tourist region in Hungary.

Table 1: Number of tourist nights in Hungary, in period Jan-Sept 2012 (iKSH 2013)

Tourist region	I–III. quarter cumulative
Middle Hungary (Közép-Magyarország)	6110759
Middle Közép-Dunántúl	1995155
West Nyugat-Dunántúl	3539167
South Dél-Dunántúl	1823853
Dunántúl	7358175
Northern HungaryÉszak-Magyarország	1338761
Norther Pannonia valeÉszak-Alföld	1453362
Southern valeDél-Alföld	1009215
Vale and the NorthAlföldésÉszak	3801338
Hungary Total	17270272

Table 2: Number of tourist nights in Serbia, in period Jan-Sept 2012 (RZS, 2012)

Tourist region in Serbia	Number of tourist nights
Belgrade region	1084240
Vojvodina region	572491
Sumadija region and Western Serbia	2442740
Southern and Eastern Serbia	1076651
Republic of Serbia Total	5176122

The state of Hungary takes care of its, so-called, prominent tourist regions and destinations, and it offers additional financial aid and support when applying to EU funds for development projects. In the so-called "prominent" regions in the area of health tourism in Hungary belong Dél-Alföld (Southern Pannonia vale), Észak-Alföld (Northern Pannonia vale), Nyugat-Dunántúl (West Danube region) (ROP 2013).

In Hungary, the strategically defined tourism development goal (which had in itself the development of spa and wellness tourism) was followed by, among other things, by specific activities which included research of stakeholders in that niche and the development of cluster cooperation. Various studies point out the significance of real and thought-out planning, flexibility in forming development plans of spa center, logical thinking and an entrepreneurial spirit. On a bilateral plan between Hungary and Serbia the strategy of common approach to spa tourism is being formed under the name "Cooling Cubes" in the gravitational area of the Budapest-Belgrade highway. The project is so far entrusted to the Agency for regional development. Certain parameters in the area of finance and joint ventures are developed in such a way that they support the projects, and if necessary, secure the investment part (with the application on EU projects).

The goal of spa clusters is to set up cooperation between spas, businesses, social organizations, NGOs, all the way up to State level. Cooperation is spreading from bilateral to multilateral level when it is expanded to regions of Romania (connecting as the Spa cluster of Hungary's Southern region). With various arrangements of cooperation, we are closer to the goal of creating a common tourist brand, irrelevant of borders, because "our chance is in networking". (http://www.datekla.eu/index. php?ln=hu&cid=2021&id=44)
The starting hypothesis of work is that the ones who offer spa services in Vojvodina are not doing enough preliminary analysis of the potential stakeholders on different basis, and thus their communication with existing or potential investors is not attractive and the interest of starting investors is soon lost.

According to literature (Scott, Baggio, 2008), in most cases the examples of such data collecting is hard to find. Unfortunately, it is also noticeable that the generic methods of the stakeholder analysis are left out, let alone supported or expanded by additional methods and techniques. By researching these aspects we had to accept the fact that "some of our examinees do not accept our plea for cooperation" (Kovacs, Bacsi, Loke, 2012) which were the same problems that the researchers in Hungary came across.

One of the problems with the tender holders is that often they search for only one large investor (who then becomes the sole responsible person for the project). Those kinds of investors are always low in number. That approach can limit the circle of potential partners from the very start. That problem already occurred in spa Kanjiža (unsuccessful project of investment in the hotel and wellness park http://www.banja-kanjiza.com/node/3/Planovi) and with Master Plan Palić. Most investors are hard to accept the sole responsibility of the complete investment. Positive exceptions are for example the construction of the aqua park in Bački Petrovac where a Slovak company "Aqua term invest" invested 8.5 million Euros in the first stage of 2012. The Becej complex is also in the process of joint investment with the help of Aquaprofit from Hungary (Vital Spa). With more sophisticated research of potential stakeholders several smaller, secondary ones, could be found which could achieve the wanted potential for the start and maintenance of a project.

Even though destinations can be familiar to domestic tourists, they are still a mystery to foreign ones." (Smith, Pucko, 2010 page 278). An additional problem can be a rough approach due to the under-developed road infrastructure or a complicated route. There is also a possibility of a so-called "tunnel-effect" where the highway leads the travelers to major cities towards which the highway traffic is funneled. (Szügyi, Sefcsich, 2011) On the basis of this phenomenon spa Kanjiža, even Bečej near Tisa or spa Bezdan, spa Junaković and the municipality of Apatin near the Danube remain pretty isolated. Highways have positive gravity effects on tourist for big cities (centers).

2. MATERIALS AND METHODS

Successful projects based on the studies (Kovacs, 2012) are always founded on a well segmented market of supply and demand. Precise categorization of spas, (waters as a potential are sometimes referred to as hardware, sometimes as software) is the first step to attract someone with development ambition (of capacities and services). Good example for that is the spa Heviz from Hungary. By the way, the most recognition among guests get the spas with more healing properties or a health tradition like the most famous spas (e.g. Balatonfüred, Bükk, Debrecen, Eger,Gyöngyös, Gyula, Hajdúszoboszló, Harkány, Hévíz, Miskolc, Parád, Sopron, Zalakaros) and in the promotion of spa (historical ambience) buildings, and the quality of service, which makes Heviz one of the most recognized spa centers in the region.

According to literature (Smith, Puczko 2009) a general guideline of the development activities is given by the very classification of waters, as a leading content in spa tourism. Basic categories are: (Smith, Pucko, 2010 ,86):

- Mineral waters – which contain an amount of dissolved mineral content, minimum is 500 mg/l or 1000 mg/l
- Thermal waters – natural water which has at least 30° C or 32° C at the spring (this can vary from country to country)
- Healing waters – healing effect needs to be proven or based in the medical and therapeutic effects-evidence. (There are various attempts, but they mostly do not measure up to world unified standards, e.g. see Spa Evidence 2013). There is an action in Hungary to collect data on yet insufficiently analyzed waters, so they could expand their offer of medical treatments, or to create more attractive and smaller (less known) springs and to attract potential investors.

Stated categories of waters already create clear segments of potential tourists and potential investors. By the next segmentation, it is possible to better differentiate the circle of guests and gravity of other interested groups. The basic forms of spas are (Smith, Puczko 2009, 87)

- Spa as a place of healing with certain means and methods.
- Spa as a center of health for free time, rest and recuperation.
- Spa as the most important center of a region, intended for vacation.
- Spa as a sports center with special offers for various sports (winter, water, golf, riding, etc.)
- Spa as a cultural center.
- Spa as a congress center.

Nowadays management of spa and wellness capacities is becoming a more complex task, especially with the development of new products – services (with the ambition to attract new market segments). This task demands good definition and differentiation of spas, their infrastructural potentials as well as management and communication models. Management, marketing, organizational challenges – as problems, are only going to manifest and grow if behind it all is not an inherited natural wealth, or newly created conditions (infrastructural) which are often demanded by foreign tourists.

Spa or wellness center cannot contain everything in its offer. Setting a clear categorization is very important also for preforming a stakeholder analysis. Maybe the most encompassing categorization of SPA centers comes from ISPA 2006: (Smith, Pucko, 2010, 87):

- Club Spa – object that primarily offers fitness services, as well as some other services for ordinary spa users in the broader sense;
- Day Spa – object that offers beauty programs, fitness and wellness programs, without accommodation and the length of the service can be from one hour to the whole day;
- Spa hotels – offer accommodation for a few days with all (inclusive) programs designed to provide physical and spiritual balance;
- Holistic Spa – spas which offer alternative therapy and diets in an effort to make a positive change in their guests;
- Medicinal Spa – object that offers traditional and complementary therapy treatments and health protection, as well as other spa services and can be included as health institutions;
- Bath – spa constructed to use the natural mineral, medicinal or sea water which is on that location, offering hydrotherapy to their guests;
- Resort Spa – vacation place separated from cities and villages, spa location is set in the beautiful natural ambience, offering a wide selection of wellness services and top programs for guests;
- Sport Spa –offering spa services and special sport programs;
- Structural Spa – establishing an operational goal towards strict rules, which offers the guests the opportunity for reaching a certain goal.

The last segmentation of spa types is very important as a possible start basis and stakeholder analysis aspect. By going into these categories, from the aspect of certain spas or springs, we come to very clear possible interest circles from the supply as well as from the demand side.

Based on the preliminary statements authors suggest an approach by which multiple methods would be included into the research thus ensuring a clearer picture on the questions of spa tourism, and at the end sure recommendations on future activities needed to ensure positive results. In order to solve this core problem we suggest use of, parallel to the expert grading, other modern methods.

General overview of recommended/used methods for more complete – wider analysis of the stakeholders can be:

- Benchmarking,
- Stakeholder mapping,
- Social Network Analysis.

2.1. Benchmarking aspects

As the beginning step of the stakeholder analysis, we suggest contemplation of several benchmarking aspects which have been used with successfully managed projects in Hungary. This step helps in clearing crucial management and marketing questions, as: defining basic and side businesses, potential users, other financial as well as engineering aspects. It is important to mention that successful destinations have additional content in their service offer. General practice in benchmarking is to compare or take the best practice as the base value. Aspects can be various, and taking for example “Hungarian Spas”, which very much behind compared to spas from developed EU countries. Compared to German, Austrian, Italian and Slovenian centers of this type Hungarian spa are 15-20 years behind. (Kovacs, 2011) Benchmarking of spas is done on the basis of collected and calculated data (often) obtained from the very spa operators. Benchmarking of spas can be divided into three categories:

a. Spa profile benchmarking (Cohen, Bodeker, 2008, 55) - allows for the comparison of spa characteristics and quality. E.g. Number of spas, different spa types, location, size, facilities, business infrastructure, infrastructure and available capacities, offered services, price formation, etc. ... (Cohen, Bodeker, 2008,56)

b. Spa performance benchmarking (results) is related to comparison of various indicators: profit, expenses, guests, human/business potential,etc.

c. Ratios benchmarking – mainly the same indicators are observed as in spa performance benchmarking.

Additional valuable data can be obtained with analysis of local inhabitants. Primarily we can observe their attitude towards the spa and tourists (Kovacs, Bacsi, Loke, 2011, 59 tab. 3.3) and socio-demographic aspects of tourism sustainability in that location. Considering the effect which the spa would have on that region or city/community, socio-economic aspects, as well as other attractions in the vicinity or region as a potential for tourism development.

2.2. Stakeholder analysis

Stakeholders are, as interested initiators and carriers of the realization of the idea of the spa tourism, present in various groups from the world of economy, society and politics, for example:

- Tourists (different types, with different motivations), patients (at treatments, rehabilitation, etc.),
- The health care (institutions, professional employment, educational background)
- The academic sector- State and private universities, institutions, education centers and other science and research institutions from the corresponding areas,
- Regional administration and government officials (often in the role of regulators, creating strategies for the development of tourism, working out the layout of the facilities, decisions about marketing and advertising in tourism, building the infrastructure, promotion of tourism, the administration of the public income for tourism, the state- ministries (for example the ministries of economy, environment, agriculture. The education of the government organization and institutions)
- TOS,- National Corporation, - PUC Srbija Šume, PUC Vode Srbije, National resorts LTO
- One stop shop full service centers, centers for tourism, media of the local community, NVO
- Strategic and other investors, local and foreign and direct partners in PPP
- International agencies for development (International agencies for development, USAID, GTZ, EU, WB, UNDP, FAO, SIDA, WTO and others)
- Promoters of the development of tourism (Economic chambers, Marketing companies, non-government organizations)
- Industrial operators- (Tour operators, touristic agencies, hotels, B&B, other accommodation facilities, hostels, restaurants and cafés and other service providers, shops, traffic companies and other transport services.
- Gaming industry, etc.

- Agency and other tourism middle men – indirectly involves companies in the tourism value chain connected to operators and investors (e.g. outsourcing, organic and other foods, marketing services, financial services, software services, civil engineering companies)

All public companies in their nature do not have much motive for change. Gain that needs to represent the main moving force does not have such significance in the public sector. The concept of public sector is gradually changing towards creation of an efficient and profitable public sector and that demand is arising as a necessity. The public sector must remain oriented towards satisfying customers' needs in an efficient and responsible way." (Domazet, 2008)

Different subjects at a tourist destination (commonly marked as stakeholders, players, participants in the tourist business, etc.) are informed about each other, or about the cooperation and creation of various partnerships (not on the competition). Their potentials are measured also in the performance and capability of successful dealings in planned tourism development at that destination having one common goal – to secure highly qualified and integrated tourist product to a particular market. Considering these aspects, stakeholders in Hungary have presented themselves much more clearly and with more coordination, while stakeholders in the Vojvodina marketing strategy are not differentiated. In a researchers development project they are referred to as a unique opinion "group" – interviewee. Often municipalities and local authorities are faced with a difficult problem of transferring the public resources for the use in private sector. The problem is that then they are sold (privatized) or rented in various usage forms (e.g. concessions) by creating contract terms in PPP cooperation (e.g. very hard debates have been in Spa Vrdnik).

2.3. Social Network Analysis in Spa Tourism

In order to overcome stated problems, we suggest use of the Social Network Analysis methodology.
Stakeholder analysis can be improved with terms (measures) using Social Network Analysis methodology. These terms or sizes can easily be applied with stakeholder analysis in tourism (Scott, Baggio, Cooper C, 2008). (Measures such as size, inclusion, components, availability, density, centralization, symmetry, transitivity, etc.) Several possible indicators - measures for potential defining of networked stakeholders. Those measures and definitions can show the nature of a wanted or existing network of stakeholders in a very good way. (With this expansion we get the possibility of better comprehension of roles and characteristics of certain stakeholders. It is possible to achieve compatibility of various software tools (e.g. UCINET, GRADAP) when quantifying the stakeholder relationship or even simulating their mutual potential.

Some other measures, involved in Social network analyzes methodology, According to Typical Social Network Measures of Ties (Brass, 1995) E.g. Indirect links, the frequency, the stability, the symmetry, Typical Social Network Measures Assigned to Individual Actors (Brass, 1995) can be also useful when defined for determining the power of Degree, In-degree, Out-degree, Range (Diversity), Closeness, Betweeness, Centrality, Prestige, Roles, Star, Liaison, Bridge, Gatekeeper, Isolate. Including the measures of Social Network Analyses helps the accuracy of identifying the most powerful actors from the list of stakeholders. It can help to answer the questions, what emotional interest do they have in the outcome of work? Is it definitely positive or negative? What motivates them most of all? What information do they need? Especially in Serbia where the tourism management and the commercial tourism industry often represent two very different systems that operates on very different assumptions and requirements. but that usually claim to the same resources

3. RESULTS

Experience of Hungary and other countries as a comparison for the analysis of noticed errors in the development functioning of spas in Vojvodina (Serbia)

- Undefined regionalization in (spa) tourism – Spas in Europe show a tendency to develop into regional centers of health, with a more prominent advance on international markets where they are represented by the health system. Others are relatively isolated from crisis influences thanks to the characteristics of the health tourism, with a condition that they are continuingly perfecting their quality and service. Unclear segmentation in offer and demand is a poor attractor of consumers and potential investors are not targeted. Incomplete offer without support of a wider set of necessary functions results in a loss of competitive status.
- Development should be based on complex services (health tourism) – healing with healing waters.
- There is no list of stakeholders (missing) with local tourist organizations so the necessary actors in the spa tourism are not known. Tourist cluster Subotica-Palic has done certain research of stakeholder's circle including the degree of their interest and satisfaction but the results of that research are not recognized or included in any business politic (Izabel Lanji Hnis, 2013)
- Receiving funds for financing the function – Here it is a characteristic that spa visitors are mostly those people who go through a health security fund (those who are ill) and those who have enough money

for rest and relaxation – an important segment of Serbian tourism which has over 50% of accommodation capacities and makes more than 50% of sleep-overs from domestic tourists. The number of foreign visitors is very low and the number of sleep-overs is relative considering the number of sleep-overs achieved in spas abroad.

- Clouded and unclear privatization and negotiations on development projects. A mistake would be to limit the possibility of attendance of other investors, who see opportunity in tourism, from international investment funds to individuals – physical persons who wish to invest in their own small capacities (accommodations). For years there has been "covert communication" which destroys the group (of other) interested stakeholders, and instead to attract them it only makes the primary candidates quit up front. True example of this is Spa Palic and its unclear destiny. From a development point of view projects who work parallel on both wellness hotels and spa capacities should be preferred. If possible thermal springs should be included, and not fill the pools with ordinary city water. Negative example in Kanjiza is the projected Hotel Ana. Last changes in the project Spa Kanjiza are connected with so-called Vekerle project from Hungary. (http://www.magyarszo.com/hu/1920/vajdasag_magyarkanizsa/ accessed 22.04.2013)
- Undeveloped system of social security care and health expense covering. Institutions are neglected and financially they close business very difficult.
- There are further developments in domestic tourism in Hungary, with special interest in state subvention vouchers for excursions and tourist stays, which business owners can buy, as well as so-called mess-hall vouchers for the employed in public services, which affected the increase in the stagnant demand. Motivational aspects were recognized for employees in private, foreign and multinational companies which also contribute to the development of tourist demand. Influence of domestic tourist should not be neglected because Serbia has "low interest of foreign guests (from 2.8% to 4.5% in 2008!) While in Slovenia that goes over 54.6% in the same period." (Stojkovic et al, 2006 p. 297) Generally we can recognize the lack of possible communication lines between stakeholders and PPP forms which remain unknown.

4. DISCUSSION

It is necessary to define priorities. Results of comparison with Hungary show that more work is needed on a more complete development of health center offers, not only based on natural wealth. It is necessary to scientifically prove the healing properties of waters and other treatments and there has to be a correspondence of health and medical research with the development of health tourism with the support of further research. Parallel to that wellness services need to be developed, as well as hotel capacities. Good stakeholder analysis contributes to the development of effective marketing activities.

It is necessary to develop cooperation with international development agencies, which ensure funds for initial projects in tourism and similar businesses. Competition in the wider border region for investment in tourism is high, which demands additional efforts of creating attractive conditions for investors. That includes the preparation of master plans and efficient support for investors as well as clear investment offers. Every development project in Hungary was done parallel to the development of infrastructure. It is good to work on regional airports, highway construction, railway traffic, etc. The location preparation is important from a cultural and historical aspect (monuments, parks, music pavilions, etc.). For example, in Hungary at Spa-Lake Heviz, the park is among the leading content. Same thoughts apply to Serbia. "Presence of cultural, historical and sport potentials of a spa and its surroundings gives a whole integrated tourist product, where the quality of specific parts largely determines the quality of the total offer of that tourist destination" (Stojković, Pnajković Žikić 2006 , 297).

Complete management of a spa must unite all demands of a successful healing, or a medical aspect as well as a financial – marketing (business) aspect. Those are usually two very different areas. Because of that the success depends on team work and a talented leader. Management roles can be general or specific in certain areas. Careers are usually started with assistant managers and promoted to resource managers of certain areas (Cohen, Bodeker, 2009)

5. CONCLUSION

Foreign experience in achieving a national strategy of the development of health tourism should serve as a role model for the development of spa tourism in Vojvodina. For comparison we started with statistical data for the same period in Hungary and Serbia. It is useful to see the data for two tourist regions (Del Dunantul, and Del Alfold which borders with Vojvodina and lies on the same thermal waters as Vojvodina). It is obvious that using the same natural potentials Vojvodina lacks in the number of sleep-overs. 572491 in relation to something over one million in the tourist region DelAlfold (see picture 1).

Benchmarking several of stipulated problems of development projects (experience of spa capacities in Hungary) we can create a picture of possible stakeholders and possible method approaches for a more perfect analysis. Several of the preliminary findings are:

- Primarily, oversized ambition of increase in water surfaces (pools) need to be avoided, unequal to demand
- Too ambitious investment and development plans for complexes which are above capabilities (e.g. when a local interest capacity wants to become a national or an international interest without any proven potential for growth)
- Legal regulations need to exist as a basis for a healthy PPP
- International funds (management of projects) need to be monitored and used
- Communication with local community in a simple and comprehensive way, so that local hosts can be motivated for idea generation and acceptance. Projects of public relations (media campaigns, events, news, open days) for increasing local community awareness on the eco-tourism
- By targeting a wide circle of guests and offers potentials remain unused, and impossible to coordinate
- Instead of season offers, such as open pools, capacities should be developed which secure a more flexible interval of use, with additional services
- Multipurpose use of thermal waters (e.g. additional source of energy)

Social Network Analysis contributes to the development of human resources inside a branch, secures a systematic approach for valuing existing actors and their communication, as well as to simulation of possibilities of including new ones (from individuals to associations, networks, even on an international level). We recognized reasons for failed attempts in finding stakeholders and partnership building which can be interpreted more than this article allows. It is important to say that the success or failure of projects in much depends on the adequately defined and continuously renewed stakeholder circle. Many projects are not sustainable because they are not adequately promoted or insufficiently recognized in the circle of potential stakeholders. Those projects are not public enough and are promoted too narrow, or the very project does not include the interest elements of a wider circle of potential sides. Example for characteristic errors in stakeholder analysis is the investment plan in master plan Palic. Potential investors from Slovenia have come across the fact that the Lake Palic, in its present condition, is unattractive due to water pollution. There is a danger that similar aspects will make difficult or stop the finalization of projects in Spa Kanjiza. It is too ambitious to expect someone to invest and not to see the whole business environment. That can mean that the pools will contain clean water, but the nearby lake will be full of algae. Or in Spa Kanjiza the construction with unclear deadlines creates a picture of a constant construction yard not only for guests but also for those who want to do serious business in that tourist location.

[3]Ministry of Defence (SRB), Strategic Planning Department, vlada.mitic@mod.gov.rs

Abstract: *The concept of organisational capabilities is relatively a new approach to face with uncertainties and environmental complexity and dynamism. The paper explains the generic model of organisational capabilities development with specific reference to a nature and types of organisational capabilities, the capability development process and capability inputs. The purpose of the paper is to extend understanding of organisational capabilities and their influences on performances of organisations.*

Keywords*: organisation, organisational capability, development, concept, model.*

1. INTRODUCTION

Organisations increasingly operate in a dynamic and complex environment. To stay competitive in such an environment organisations have to develop capabilities that enable them to deal with core challenges and problems.

Current organisations need to build and sustain capabilities to respond effectively, efficiently and timely to contemporary needs, to build capability in advance of need when emerging needs can be reasonably anticipated, and to establish flexibility to cope well with the unexpected. A failure in organisational capability can have a strong impact on organisational performance.

By developing different types of capabilities, organisations become more or less able to compete successfully in different environmental circumstances. Organisational capabilities can be classified according to different criteria.

Organisational capabilities are not static, but are dynamic realities and should be always in the state of development and improvement. They are influenced by many factors and capabilities development should be well structured and a systematically managed process.

2. THE CONCEPT OF ORGANISATIONAL CAPABILITY

The concept of organisational capability is relatively a new approach to deal with organisational problems. A basic assumption is that organisations have specific ways of acting which are based on organisational capabilities that have been gradually accumulated and shaped within organisations. Organisational capabilities enable organisations to deal effectively in an organisation-specific way with key organisational problems (Dosi, Nelson, Winter, 2002).

Authors have different but essentially similar views on a definition of the term “capability”. Helfat (2006) points out that an organisational capability refers to an organisational ability to perform a coordinated task, utilizing organisational resources, for achieving a particular result. Saint-Amant and Renard (as cited in Rauffet, Da Cunha, Bernard, 2010) define organisational capabilities as know how to act, potentials of action which results from the combination and the coordination of resources, knowledge and competencies of organisation through the value flow, to fulfil strategic objectives. Robert Grant (2010) defines an organisational capability as an organisational capacity to deploy resources for a desired result. Grant emphasizes that resources are not productive on their own and a team of resources must work together in order to perform organisational tasks.

Definitions indicate that an organisational capability means the organisation’s ability to carry out activities to meet its objectives. The quoted definitions do not take into account a way of carrying organisational activities out. It is important to emphasize that activities should be performed and objectives achieved under specified standards and conditions. Standards are quantitative or qualitative measures and criteria for specifying the levels of performance of an activity. Standards are the acceptable level at which activities must be performed to assure successful achievement of objectives. Conditions are those variables of an environment or situation that affect the performance of activities.

Capabilities are crucial for organisations. They establish key aptitudes that organisations have to build in order to perform activities and accomplish objectives. Organisational capabilities come up from the synergy of organisational resources and organisational knowledge. They require the efforts of various individuals to be integrated with one another and with crucial equipment, technology and other resources.

The need to sustain and develop the organisation's capabilities provides a basis for long-term plans and decisions about key organisational factors. In addition, organisational capabilities coordinate and constrain short-term planning and provide a logical basis for the physical structure of the organisation.

It is necessary to keep in mind that modern organisations work in an unstable and rapidly changing environment. Because of that, organisational capabilities have to evolve and change over time. The ability of organisational capabilities to adapt over time makes important influence on the success of organisations. If capabilities are inert, organisation will gradually lose ability to perform activities and accomplish objectives.

Schienstock (2009) points out that in the literature there are many other related concepts which are not clearly distinguished from the "capability concept" as, for example, "core competencies" or "organisational capacities". The great number of organisational capabilities or core competencies mentioned in the literature indicates that scholars have not been able to clearly enumerate many general problems organisations have to deal with and for which they have to develop appropriate capabilities.

3. TYPES OF ORGANISATIONAL CAPABILITIES

Organisational capabilities can be classified in accordance with different criteria. Authors identify various types of organisational capabilities depending on the selected criteria.

Schienstock (2009) distinguishes five dimensions of organisational capabilities: (1) selective or strategic capabilities which enable organisations to adapt to a rapidly changing environment; (2) organisational or integrative capabilities, which enable organisations to cope successfully with the problem of combining organisational efficiency with organisational flexibility; (3) technical or functional capabilities, which enable organisations to perform and extent their characteristic output; (4) capabilities and understanding of market and demand characteristics, which enable companies to profitably sell their products or services and to invade in new markets and (5) ability to learn, absorb, transform and reflect on acquired information and experiences, integrating and cutting through all these. Schienstock points out organisations are heterogeneous and focused on the development of different organisational capabilities.

Jon Kay (as cited in Armstrong, 2011) emphasizes that competitive advantage of the organisation is determined by its capabilities. He noted two kinds of capabilities - distinctive capabilities and reproducible capabilities. Distinctive capabilities are those characteristics of the organisation which cannot be replicated by others, or can only be imitated with huge difficulty. Distinctive capabilities describe what the organisation is specially or uniquely capable of doing and establish a basis for competitive advantage of the organisation. Distinctive capabilities can exist in such areas as technology, innovation, effective leadership, teamwork, specific knowledge etc. Reproducible capabilities are those that can be bought or created by other organisations with appropriate management skills and financial resources. That kind of capabilities cannot be a source of competitive advantage. In order to build and sustain organisational competitive advantage distinctive capabilities need to be supported by an appropriate set of complementary reproducible capabilities.

One of commonly used approaches to selecting of organisational capabilities is a functional analysis. A functional analysis identifies organisational capabilities in relation to each of the principal functional areas of the organisation. For instance, there are operations capabilities, logistics capabilities, research and development capabilities etc. The specific capability which can be recognized within the general research and development capability is innovative new product development. In addition, an example for the specific capability within logistics is equipment maintenance.

The process approach is another way of organisational capabilities classification. In accordance with that approach, all organisational capabilities can be grouped into primary capabilities, support capabilities and management capabilities. Primary capabilities are related to primary organisational processes. Primary processes are end-to-end cross-functional processes which span across the organisation and create direct value to organisation's end clients. Support capabilities enable performing of support processes within organisations. Support processes do not directly provide value to clients but they are directly responsible for providing all kind of support and resources which are necessary for execution of primary processes. Performance of management processes which guide primary and support organisational processes is directly linked with management capabilities.

Regardless of the approach that is applied, identified capabilities are likely to be broadly defined and should be disaggregated into more specific capabilities. For example, the human resource management capability can be disaggregated into the recruitment capability, the HR appraisal capability, the career development capability etc. Grant (2010) suggests establishing of a hierarchy of capabilities where more general, broadly defined capabilities are formed from the integration of more specialized capabilities.

The Australian Public Service (APS) is one of good practice examples in organisational capability management. APS points out needs to build and sustain organisational capability to respond effectively (and at pace) to contemporary needs, to build capability in advance of need when emerging needs can be reasonably anticipated, and to establish resilience to cope well with the unexpected. APS develops following capabilities: leadership, stakeholder engagement, citizen engagement, innovation, policy development, strategic planning, program delivery and implementation, project management, governance, risk management, change management, workforce planning and staff performance management.

4. THE MODEL OF ORGANISATIONAL CAPABILITIES DEVELOPMENT

Contemporary organisations are aware of capabilities development importance to overall organisational performances. Capabilities development is a high priority for many of them but they have not yet figured out how to do so effectively and efficiently. The generic model of organisational capabilities development is shown in Figure 1.

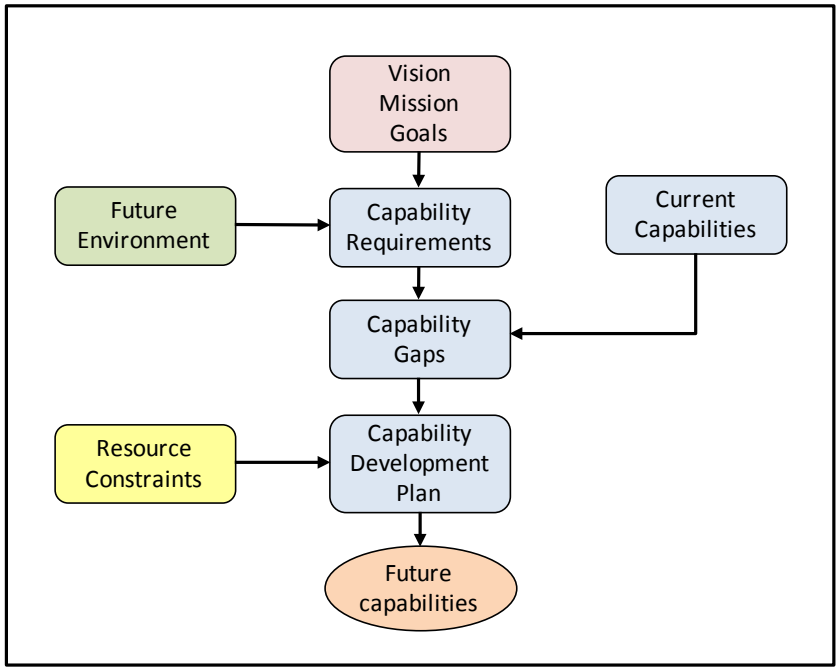

Figure 1: The generic model of organisational capabilities development

The basic step in the capability development process is an identification of capability requirements. That is probably the hardest part of the process and requires a combination of imagination and subject matter expertise. The purpose of this stage is to identify types and quantities of organisational capabilities required to accomplish given tasks and achieve defined goals and objectives.

Capability assessment is a stage that follows capability requirements determination. The purpose of the stage is to assess fulfilment of the previously identified capability requirements. Using the identified requirements and current organisational capabilities as primary inputs, capability assessment produce a list of capability gaps that require solutions and indicates the time frame in which those solutions are needed. It may also identify redundancies in capabilities that reflect inefficiencies. This stage of the process will also provide the relative priority of the gaps identified.

Development of possible approaches to solving (or mitigating) the capability gaps is the next step in the process. Planners develop options taking both materiel and non-material solutions into account. The development of realistic options is a crucial step in linking capability gaps to the scarce resources.

There is general agreement that organisational capabilities are result of the combined effect of multiple inputs. They cannot be built simply by purchasing new equipment or spending on R&D. Achieving necessary capabilities requires coordinated efforts in many areas and processes.

The main tool for organisational capabilities development is the capability development plan. This plan needs to be carefully developed to ensure that the organisation will have appropriate abilities and capacities to fulfil own mission and perform tasks. Some organisations formulate so called the capability strategy that defines what the organisation needs to do to develop and maintain its capabilities.

The implementation of the capability development plan follows its official approval by organisation's management. This is a very complex process which must be well prepared and led. Relevant bodies within organisation prepare the necessary partial plans and programs which would specify the capability development plan and support its implementation.

5. CAPABILITY INPUTS

Organisational capabilities are a result of the combined influence of multiple inputs. It is not the sum of those influences, but the synergy that arises from the way those inputs are combined and applied.

Defence institutions are the example of organisations which pay special attention to capability development. They identify different but similar the capability inputs. For instance, in the Australian Defence the fundamental inputs to capability are categorized and broadly defined as: personnel, organisation, collective training, major systems, supplies, facilities, support and command and management (Australian Department of Defence, 2012). Within the Canadian Defence a capability is a function of personnel, materiel facilities and procedures. In the United Kingdom, the military recognizes eight so called Lines of Development as a means of capability development: training, equipment, personnel, information, concepts and doctrine, organisation, infrastructure and logistics.

The Australian Public Service considers leadership, strategy and delivery as the most crucial areas of capability and key enablers of successful performance. The APS capability model (Figure 2) comprises 10 elements, grouped under the key enablers. The model provides a framework and common language for discussing and assessing organisational capability.

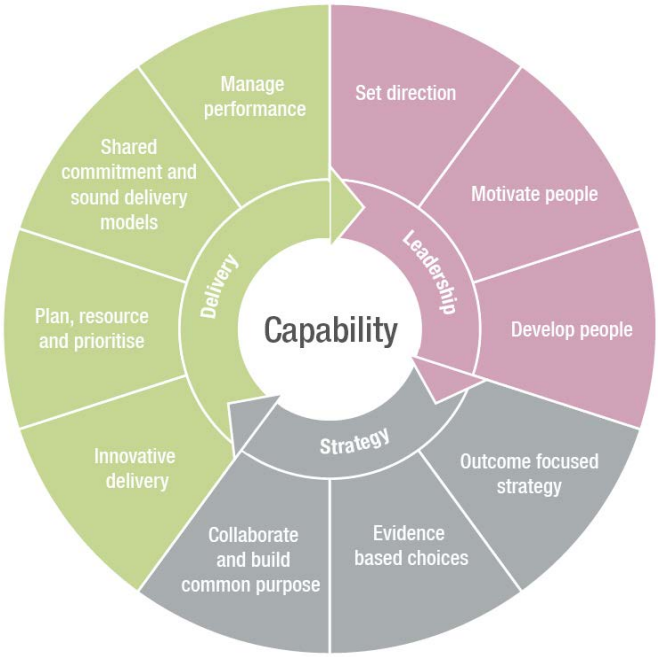

Figure 2: APS model of capability (Australian Public Service Commission, 2011).

Leonard-Barton (as cited in Gusberti, Viegas, Echeveste, 2013) describes the main components of the organisational capabilities by the four dimensions: knowledge and skills, technical systems, managerial systems, and values and norms. Capability Based Planning from the Systems Engineering identifies following capability inputs: people, process products, technology, and facilities.

As it can be seen from the discussed examples, scholars and practitioners have different views on capability inputs. However, most of them agree that organisational resources (human, material etc.) are fundamental

source of capabilities. Resources must be properly integrated and coordinated in order to produce capabilities. Organisational strategy, structure and management systems play a crucial role in resource integration and coordination.

Gusberti et al. state that resources are divided in technical systems and intangible resources or knowledge-that. Knowledge-that is expressed by knowledge contained in people and processes and can be acquired by training or education. The technical systems are essentially resources that were deployed by the capabilities in results and include products, technologies, facilities and materials. It can be divided in: (i) material resources; (ii) infrastructure, facilities, equipments, and information technology.

6. CONCLUSION

The traditional approach to organisational proceedings is based on establishing fixed structural arrangements which perform different tasks in order to achieve desired results. However, the complex and dynamic environment is characterised by rapid substantial and discontinuous change under which, to survive, organisations must be flexible and prepared for unexpected requirements and problems.

Such a situation requires a new organisational approach. Organisations need to focus on the creation and continuous development of specific capabilities that enable them to cope with uncertainties and new requirements in a much more flexible way.

Modern organizations should possess appropriate types of capabilities which enable efficient and flexible performance of tasks and activities in order to achieve desired results. The most important are capabilities which enable an organisation to perform key organisational processes and provide necessary outputs to clients. Also, organisations must develop an appropriate spectrum of management and support capabilities.

Development of organisational capabilities must be a result of a well arranged and managed process. The process of capability development consists of many activities which require an appropriate coordination and execution.

Organisational capabilities are a result of the synergy of multiple inputs but basic organisational resources are fundamental source of capabilities. Resources must be properly integrated and coordinated in order to produce capabilities. Organisational strategy, structure and management systems play a crucial role in integration and coordination of resources.

AKNOWLEDGMENT

Abstract: In the last three decades, public administration was struck by a wave of unprecedented reforms.The traditional model has come under the strike of strong criticism by citizens and the private sector, as well as theorists of governance. Basically, the reform lies upon the conclusion that the state has become too large and with too many responsibilities, and that the market offers superior mechanisms for more efficient delivery of public goods-and services. Therefore, political leaders found themselves under pressure from the public and the industry to increase the efficiency of government, reduce government spending and taxes, while maintaining a high level of public social services(Various*authors,*2002/03).

Programs of public administration reform which have made a strong impact on the international administrative policies are rooted in Westminster systems (Australia, New Zealand, UK and Canada) and the United States, countrieswhich are rightly considered the main representatives of the "New public management". A wave of administrative reforms actually started in the United Kingdom when in this country, a radical change was made in the program and methods of government activity and its administration so as to reduce the role of the government in economiclife, which led to a substantial consideration of the practice and concept of the existing system of public administration.

Keywords: *public management, public sector, reinventing of government, entrepreneurial country.*

1. FROM TRADITIONAL ADMINISTRATION TOWARDS A NEW PUBLIC MANAGEMENT

The reforms quickly spread in other countries, with the support and guidance of Bretton wood institutions that propagated the new public management, in order to reduce the role of the state in the production of goods and provision of servicesit.The non-existence of a state government that achieves satisfactory results was-considered a barrier to participation in the global economy, so the administrative reforms should provide a new system for the state, which would allow it to be properly globalized. The starting point was the premise that a strong, democratic state and globalization go together(Group of authors, 2002/03).Reforms included in this approach were aimed at reducing the number of administrative bodies and employees in the public administration, the elimination of the role of the state as a producer of goods and provider of services,-promotion of privatization, deregulation and decentralization, and fundamental changes in the nature of business of the government. A policy that was initially put the emphasis on maintaining macro-economic stability, stopping inflation, reducing budgetdeficits andpublic spending turned into a campaign for "reducing" and diminishingthe state organization, and thus its impact on the economy and society. The huge costs of social programs in Western Europe questioned the significance and sustainability of the welfare state that had been promoted and that had to be redesigned.

The need to improve efficiency in the public sector and to reduce public expenditure was accompanied by a package of measures which had the character of the introduction of market mechanisms in the public sector. Although success varies from country to country, these principles, however, can be regarded as the world trend. This trend was probably influenced by the value system whose construction was significantly impacted by multilateralorganizations, the media and civil society (Various authors, 2002/03).

Improvement of human resources in the public sector and the strengthening of institutionalcapacities of administration are not given equal attention as the liberalization of the economy.-Experience also points out the limitations of such a strategy. It has become obvious that macroeconomic programs are not sufficient to solve the fundamental problems of public administration. Moreover, the net effect of the adjustment policies was the neglect and weakening of strategic institutions, primarily of personnel systems in public administration, particularly in countries where the process of "state-building" is not over yet. The applicability of different models of the state raised the question whether the newglobal paradigm of public management is

being developed: New Public Management and the so-called "reinventing" government are the exact tools used in the process of improving public sector efficiency and reduction of costs " (Various authors, 2002/03).

2. NEW ADMINISTRATIVE PUBLIC SECTOR ENVIRONMENT

A.A hundred years ago the word 'bureaucracy' had a positive connotation: it signified the rational and advanced doctrine, i.e. the type of organization that was supposed to replace the arbitrary power of autocraticregimes. Bureaucracy introduced the same logic in state government, as the continuous production line introduced in factories. Hierarchical management and functional specialization, made it possible to effectively undertake such complex tasks. The bureaucratic model has functioned for a long time because it disabled basic problems that people then wanted to be resolved. It provided security from unemployment, which was characteristic of the previous period, stability, trust in the fairness and impartiality of the administration, standardized services that are suitable for all, which people needed and which they expected from the industrial era(Various authors, 2002/03).

Today, it does not exist anymore. We live in a time of globalmarket which represents an enormous competitive pressure on economic institutions.We live in an information society in which citizens obtain information almost as quickly as their politicians. We live in a knowledge-based economy in which educated workers do not put up with being commanded and demand autonomy in their work. Today, consumers are educated and aware of the quality standards of products and services and choices they have. In such an environment, bureaucratic organizations developed during the industrial era, both public and private, are letting us down. Today, organizations are turning to the specific needs of theconsumer, offering a wide variety of non-standardized services. They guide consultationsand incentives, which gives employees a sense of control, and even of "ownership". They develop an approach that would rather "empower" citizens, than to simply "serve" them, by giving them rightsand the ability to participate in the process, not just passively use services.

B."Empowerment" of citizens is a central motif in the managerial-doctrine. The hypothesis is that citizens are "damaged" by bureaucratic rules that limit choices and access to quality services. Moreover, it is assumed that the privatization, "the foreign supply" of public services and de-bureaucratization lead not only to greater satisfaction of citizens/consumers, but also to greater freedom and fullerdemocracy. In other words, "managerism"in terms of more efficient, entrepreneurial and results-oriented public sector management, opposes to administration bounded by rules.

Today, most state institutions still perform very complex tasks in a competitive environment that is rapidly changing, with consumers who demand quality and choice. In their iconic book "Reinventing government", David Osborne and Ted Gaebler stress out the following(Group of authors, 2002/03):"In a sense, this is a symptom of progress - a devastating crash that occurs when a new reality is faced with old institutions. Our information technology and our knowledge economy give us a chance to do things we never dreamed of fifty years ago. However, to take advantage of this opportunity, we need to clear out the ruins of our institutions from the industrial era and to build new ones."(Ristic, Z. 2012)

C.The origins of an activist, bureaucratic state, are practically the phenomenon of the twentieth century. The characteristics of the bureaucratic state were clearly, under the strong influence of Woodrow Wilson, defined by Max Weber in year 1920:

- there is a clear separation between politics and administration, and thus the clear role of political leaders (mostly of elected ones) and government officials (usually named)
- administration is to be permanent and predictable, and should function on the basis of written, unambiguous rules
- civil servants are employed on the basis of qualifications and are trained professionals
- the organization reflects the functional distribution of the workload and the hierarchical arrangement of tasks and personnel
- the funds belong to the organization, not individuals who work in the organization
- the main motivation is a sense of duty or of public interest, that transcends personal or organizational interests.

The perfecting of the traditional model of public administration came by applying the ideas of "scientificmanagement" based on the private sector, that have introduced effective operational methods based on the standardization of tasks, the principle of "one best way" to adjust the staff to the assignments and systematiccontrol of tasks, processes and people. These principles have easily adapted to the bureaucratic structure. Supplement to the traditional model was the application of knowledge in social

psychology, through the approach based on "interpersonal relations-".It is often compared with the approach of scientific management, but in practice, it scored higher efficiency in performing tasks, while paying attention to the need for motivation of workers rather than controlling and directing them (Ristic, Z..2012).

As an argument in favor of an activist state model there was the fact that state intervention was necessary for correcting the shortcomings and failures of the market. Level of control and state intervention varied considerably in practice: to the complete state ownership and market allocation. The decisive role was played by strong state bureaucracy. This activist model has been criticized by the traditional model of state bureaucracy and the government's inability to do its job properly(Group of authors, 2002/03).

D.While the welfare state justified itself by the need to remove the lacksof the market, the predominance of the above stated characteristics has led to a critical situation that requires the rectification of failures in the administration of the state (Group of authors, 2002/03).

- The Irresponsible state, whose abundant interventions limited the freedom of people to deal with their own affairs, developed a dependency instead of independence;
- Excessive state, where government has taken on too many powers, could not accomplish them efficiently and effectively;
- State of private interests, where the elite and the privileged groups exploited the opportunities that were offered by government jobs to meet their interests and maximize revenues.

The combination of criticism (inefficient bureaucracy and defective nature of activist government) produced a model of reform called "new public management". This model of reform is based on the assumption that large state administrations are inherently defective and useless, and that the market is better equipped than the state to provide most goods and services. Radical changes needed for bringing a transformed and entrepreneurial model of public management are implemented by the following(Group of authors, 2002/03):

1 Restructuring and reduction of the public sector, particularly by privatization,
2 Reorganization and "thinning" of the central public services,
3 The introduction of competition in the remaining public services, by use of internal markets, and contracting the provision of public services with the private sector, and
4 Improving the efficiency by realizing the concept of "value for money" by management based on the results achieved and audit of performance.

The new type of public management is characterized by:

1 The separation of the strategic policy from operational management,
2 Concern for the results, not the process and procedures,
3 Orientation towards the needs of citizens, and not the interests of the organization or bureaucrats,
4 Withdrawal from the area of direct service provision in favor of the role of "steering" or "empowerment", and
5 Altered, entrepreneurial management culture.

2.1. Birth of entrepreneurial state

A common thread for the solution of problems of governance was not hard to find: it was necessary to "re-invent" the mode of government activities in all segments and integrate the elements of a new organizational culture, primarily of entrepreneurial mentality. Most entrepreneurial governments encourage competition among providers of services (Various authors, 2002/03).

- They "empower" citizens by transferring control from the hands of the bureaucracy into the hands of society,
- They assess the success of the work of their organizations by focusing is on the results achieved, rather than on resources used,
- They are guided by the results and their mission, not by rules and regulations,
- They define their clients as "customers" and offer them a choice, for example, between different schools and educational programs,
- They prevent problems rather than react when they occur,
- They decentralize jurisdiction by developing participation,
- They prefer market mechanisms to bureaucratic ones
- They do not focus on self-provision of public services, but on catalyzation of all sectors - public, private and voluntary - into action, in order to solve the problems of the community.

A.The government and the company are completely different institutions. Business leaders are guided by profit: the leaders of the government are guided by the desire to be re-elected.

Companies receive most of their funds from their customers/consumers, while the statecollects most of the funds from taxpayers. Business is usually conducted in a competitive environment, while the states use monopolies, Osborne and Gaebler explain, and suggest that differences such as these create a completely different aspirations in the publicsector: "For example, the key question for managers in public institutions is not whether they deliver a product or generate profit but whether it satisfiesneeds, whether they are to the liking of elected politicians. Having in mind that stakeholders are behind politicians, managers in the public sector - unlike theircounterparts in the private sector - must always include the factor of stakeholders into their activities. "

All of these factors are combined to create an environment in which public sector employees see the risks and rewards completely different from employees in the privatesector. ‘’The government aspirations are focused on how not to make mistakes," said Lu Vinik from the Ford Foundation, "State budgets are encouraging managers-to waste money. If they do not spend their entire budget by the end of the fiscal year, three things happen: they lose money they were saving, they get less next year, and budget directors complain that they demanded more than they should in the previous year."

B. Models of the new government may be (Group of authors, 2002/03):

- Model 1 - "Market Government" - focuses on decentralization, salary based on performance and other operational techniques of the private sector.
- Model 2 - "Participatory Government" - emphasizes "thinner" organizational structure, total quality management, and teams.
- Model 3 - "Flexible government" - promotes virtual organization and temporary staff.
- Model 4 - "Deregulated government" - puts the emphasis on greater managerial freedom.

Each model is a product of various criticisms of the inadequacy of government, each offering different solutions.

C."For most of the leaders, there are only two ways out of the crisis in the public sector: either to raise taxes or cut costs. For almost three decades we are seeking the third option. We do not want a lower level of education, fewer roads, a lower level of care, but at the same time - higher taxes. We want better education, better roads, better health care, for the same or a lower amount of tax liability.
To be more precise, we need better governance/state management (Good Governance) - the process by which we collectively solve problems and meet the needs of our society, and this is why this forms a coherent whole, the new model of government(Ristic, K. and Ristic, Z..2014).

3.New Public Management

A.New Public Management is a worldwide phenomenon, but in different countries this term is understood differently in different situations. In the United States, this approach is characterized by the movement for "reinventing government" and the project designed bythe Vice-President Al Gore -"National Performance Review".The UK has started the Financial Management Initiative of Prime Minister Margaret Thatcher and continued with what is called Next Step.New Zealand has made the most drastic changes in the structure of government and managerial philosophy(Ristic, K. and Ristic, Z..2014).

It should be borne in mind that the search for new public management requires consideration of the role of the state. It is a fact that the state today is more an economic than a political agent. The crisis of legitimacy affects the political class and the administrative structures which are still based on the rule of law. Another fact is that identity and political history of every European country must be fully understood. Where there are management models, their implementation depends on their adaptation in a way that significantly varies-from country to country.The practice of the new public management is therefore proved to be very applicable in the Nordic countries, whose structures are characterized by a high level of decentralization, "guild" organizations and a rooted culture of social pluralism. Outside the Nordic countries, the implementation of new publicmanagementdestroys not only the administrative structures, but also the representative bodies of civil servants and service users.Reforms largely depend on the "clientelism"in Greece, the role of civil service unions in France, the politicization of jobs in the civil service in Austria, the role of political parties in Italy. New Public Management which promotes efficiency and flexibility, it is often in conflict with the massiveness and the inertia of legal norms.

B.New Public Management (NPM) - is a term used in many countries around the world. Seemingly, it describesa globaltrend of a certain type of administrative reform, but it soon becomes clear that in the

variousadministrative environments, it has different meanings. Even in the academic world, there is no consensus on what the term means. In any case, the term is somewhat faulty because its elements are not new, which is why there are charges that it is "new wine in old bottles." In addition, the reform of public management occurs in a wide variety of forms, in different-contexts, including the very different national priorities and needs. The transformation process in Central and Eastern Europe is just one of the examples(Ristic, K. and Ristic, Z..2014).

With the advent of managerism, the term "public administration" is rapidly replaced by the more popular "Public Management" even in many academic programs (e.g., human resource management). Essentially, the difference between these two terms is not so much in theirdefinitionas in the doctrine behind each of them. Although inthe Serbian language "management" easily translates as "administration", the nationalliteratureequally and interchangeably uses the term management. The translation of theterm "manager" - "administrator" does not fully comply with the spirit and practice of Serbian language,so the term 'director' is often used (which is in English, "leader")(Ristic, K. and Ristic, Z..2014).
The translation of the terms "New Public Management" and "Good Governance" can be a matter of discussion, as well as the translation of the term "public policy": we use the terms 'novi javni menadžment' and 'dobra vlada/vladavina. But what is the new public management? It is fair to say that it helped in highlighting the need to change the way the governments operate.

C.Two types of main concept of new public management emerged. According to the narrower concept, new public management is a marriage of two different streams of ideas. One stems from the new, institutional economics which examines new administrative principles such as competition, a wider choice for users of public services, transparencyanda strong emphasis on new mechanisms for motivating employees. The second stream stems from the application of the principles of private business management to the public sector. Practically, this narrow understanding of the new public management places the emphasis on contract management, the introduction of market mechanisms in the public sector and linking salary with performance.The main features of the reform of public management, for achieving the targeted result-oriented management are:transferring powers and providing flexibility, ensuring the results, control and accountability, the development of competition and choice, responsible provision of services to citizens, improving human resource management, use of information technology, improving the quality of regulation and strengthening the function of "steering" in the center.

A broader definition of the new public management has a more pragmatic approach, not looking at it from a philosophical perspective, but as a rational response to the pressures that the governments are facing. Since the pressures of globalization are similar in all countries, it would be expected that the reactions overlap to some extent. However, this does not mean that the implementation of the new public management in those countries will be identical. Such a broad definition does not impose a universal model, but makes the model of the new public management more transmittable from one country to another. This can involve a detailed radical reform of public management or individualadjustment depending on the institutional framework of those countries.

The term New Public Management is used to describe a management culture that emphasizes the central role of the citizen and user of services and accountability for results, suggesting structural or organizational choices that emphasize decentralized control across a wide spectrum of alternative mechanisms for the provision of public services, including quasi-markets in which the public and private suppliers compete for funds provided by investors and those in charge of public policy. New Public Management does not claim that the government or the management -should to stop doing certain jobs; it does not care whether the work is done or not, it is interested in getting the job done in the best possible way. The new public management was conceived as a means of improving the efficiency and accountability of political leaders, and it originates from parliamentary democracies with a strong executive leadership, centralized government and administrative law.

New Public Management can be seen as a "cascade chain of contractual relations", which leads to one manager (often aministry) interested in better results in areas where there are significant and relatively stable jurisdiction. Most of the principles of new public management-can be illustrated by the example of establishing semi-autonomous agencies for the provision of public services. The argument in favor of the existence of the agency is that those who should provide those services should be concentrating on their efficiency and quality, without disturbing the structures for the development of public policy(Ristic, K. and Ristic, Z..2013).

D.OECD study reveals that all member states are experimenting with some of the elements of the new public management, although the degree of implementation of these elements and the differences between them vary from state to state. Nonetheless, it soon becomes clear that the actual implementation raises different

difficult issues about the goals and outcomes. This is partly due to the strong orientation of new public management towards the economic value and its underdeveloped legal and political dimensions. Given the complexity and the fact that many reforms are still under way, virtually every state will have to make a careful assessment ofaspects which in any combination offer real progress in the light of its institutional and political context(Ristic, K. and Ristic, Z. .2014).
Public management must not only be a promotion of economic values. Before us is a task to put a stronger emphasis on products and outcomes in accordance with the political and legal principles of public administration. The emphasis placed-on these various principles and their connections will vary from country to country depending on their traditions and political and legal framework. This new paradigmcannot be reduced to a slogan, claimsBornis, and states that key ideas can be extracted(Ristic, K. and Ristic, Z..2014):

- The government should provide high quality service that will meet citizens' needs
- The autonomy of public managers, especially from the central state organs, must be increased,
- Organizations and individuals should be evaluated and rewarded based on how successfully they reach the required goals,
- Managers must ensure that they have at their disposal adequate human and technological resources needed to achieve the objectives
- Public sector managers must appreciate the value of competition and maintain open access to what in terms of services belongs to the private rather than to the public sector.

Two variants of the new public management - contract theory and the theory of empowerment - are intended to give the public managers the flexibility they need in order to improve results(Ristic, K. et al.(2013/2014).Those who adopt the theory of "empowerment" implicitly allow them to develop the skills of intelligent decision-making, to reasonably use the given flexibility and to be motivated primarily by intrinsic motives of working in public administration.It is necessary to support the vision of the public sector as an "organization in the process of learning" /0} which should constantly be progressing. Those who adopt the strategy of contracting, normally do this through precise, clearly written agreements on the results that leave little room for the kind of confidence present in the previous strategy, which motivates better results by special awards. There are no universal solutions to the public sector as a whole - different parts of the public administration require different systems of public management, depending, for example, on whether it comes to redistribution of resources, provision of services or the classic state activities. Some states, such as New Zealand and the United Kingdom, use contracts and incentives to "force managers to do their job." Others, such as Australia and Sweden, for example, "empower" their managers and thus "allow managers to do their job"(Ristic, K. and Ristic, Z..2013).

SUMMARY

New public management and "reinventing government" have significantly enriched the language of management with a number of new terms and graphic expressions.

- results, not the processes
- Downsizing, and now the rightsizing
- Lean and mean
- Contracting out, off-loading, outsourcing
- "Steering" rather than "rowing"
- "Empowerment" rather than serving
- Earning rather than spending

New Public Management is designed to continue to somewhat influence the development of the administration. The question is whether this impact can go beyond the field of methods and techniques into the field of value systems. It has to play a role in the ongoing efforts to implement "good government (governance)," primarily in the-developing countries. Therefore, it is important to understand the context, powers and limitationsof the new public management so the best could be taken from it.
The improvement of government performance is a complex undertaking. This means that differences have to be taken into consideration between people in different regions, at different times or for different issues of public policy. Every government, when it comes to improving the results, tries to make steps forward. Whenever government decides make a specific step, it needs a special strategy that will maximize its performance in this specific context.

NEW COSTING MODEL IN MINING INDUSTRY

Dragan Manojlov[1], CvjetkoStojanović[2]
[1]Deloitte Central Europe,dmanojlov@deloittece.com
[2]Rudnik i termoelektranaUgljevik, investicije@riteugljevik.com

Abstract:*The research introduces a kind of new costing model of handling of costs in developing and exploration i.e. full lifecycle of coal mining site. The new costing model in mining will use all good facts from previous approaches implemented in coal industry.Analytic and holistic approach is the tool used in this model in order to establish the new way of handling of business in mining companies. In order to create new costing model in mining industry, the comparative method is used for analysis of software solutions and description method in order to establish link between relations and rules in old mining models. Additionally, elaboration method is used in analysing of the costing model in RiTeUgljevik. An impact of EPR implementation on new costing model in mining is essential, because many processes in production of coal should be automatized in order to allow the cost tracking on analytic level (cube view). In this paper areexplained benefits from implementation of an adequate ERP system in mining industry.The benefits of creating the right costing model for mining company are substantial, not only in terms of cost reduction, but also in the ability to better focus resources, enhance value for extension of profit margin and newinvestments.*

Keywords*: Handling of cost, new costing model in mining, RiTEUgljevik, production of coal, ERP*

1. INTRODUCTION

The mining companies have significant costs in order to establish their business. One of the first types of cost is associated with the complex process of expropriation.

Developing of coal site lasts several years and include two main phase: Set up of coal site and Expropriation. Each phase require generating of significant costs. Mining companies carry out the various stages of development necessary prior to production over a long period of time, at high cost and in some cases with a high level of risk and uncertainty as to future commercial benefits. Adopting an appropriate accounting treatment for the costs incurred at each stage is therefore essential. Unfortunately, there is little specific guidance as to the extent to which costs associated with finding, acquiring and developing mineral reserves should be expensed immediately or deferred.

The special attention is paid on methods of handling of “externalities”, during production of coal, in the ways of multiple hazards for health and the environment. Accounting for the damages conservatively doubles to triples the price of electricity from coal per kWh generated, making wind, solar, and other forms of non-fossil fuel power generation, along with investments in efficiency and electricity conservation methods, economically competitive.

Generally, an expropriation from a landowner by the government typically involves the taking of privately-held land for a public purpose, such as the building of roads or improvements to existing roads, acquiring land for municipal expansion, acquiring land or an interest in land for the construction of public buildings, and so forth.

Where the minerals are beneath privately-owned land, the landowner has the right to be compensated for the interference with their land, and to take disputes with respect to compensation for their land to the provincially-appointed authority to determine compensation.

Also, there are many nus-effects for society from the expropriation phase. Typical sample of nus-effect have happened in New Scotia in Cannada in 2012.So, the Higgings family in Nova Scotia has lost their fight to prevent the expropriation of their land to a gold mining company.

The family runs a Christmas tree farm in Moose River Gold Mines. The provincial governmentexpropriated a section of their property. Australia’s DDV Gold Ltd. plans to start a $140 million open-pit gold mine and wanted the land.

On Friday, the Nova Scotia Court of Appeal unanimously dismissed an appeal by the family. That appeal backed an earlier Supreme Court judge who cleared the expropriation, which was ordered by Darrell Dexter's government in 2012(retrieved from: www.breakingthesilenceblog.com/general/family-loses-expropriation-case-against-gold-mine; 2013).

Apart from expropriation costs, the company must to count on many other costs for state authorities. One of these types of costs is concession. Normally, each country prescribes managing of access to coal via the mining concessions, to areas free for mining natural resources that do not belong to surface property and deposit`s owner.

In the case of mining laws, administrative procedures such as issuing of mining concession, approving operating plan and issuing permits or licenses to explore according to the water rights, the country authorities establish Mining authority. "In Germany, the classic procedure of mining license is the operation plan procedure, whereby the operator submits an operating plan to the Mining authority, which then examines it in order to ensure fulfilling of legal objectives (Schmidt, 2013)".

One review published in New York Academy of Sciences (AS, 2011) found out that the best estimate for the total economically quantifiable costs, based on a conservative weighting of many of the study findings, amount to some $345.3 billion, adding close to 17.8¢/kWh of electricity generated from coal. The low estimate is $175 billion, or over 9¢/kWh, while the true monetizable costs could be as much as the upper bounds of $523.3 billion, adding close to 26.89¢/kWh. These and the more difficult to quantify externalities are borne by the general public.

The third type of investment cost can be defined as activities performed in displacement of coal overburden layer. Measurement of overburden costs is very difficult. Generally, the cost depends of machines used to displace of this overburden layer. In practice, the machines in mining are segregated in two dimensions: Discontinuer and Continuer. Discontinuer is the name for machine which storage their production of coal on some medium (truck, train etc…) for transportation to Thermal Plant. Adversely, the coals are transported to Thermal production plant automatically by using of Continuer`s machines. RiTeUgljevik implemented only dis-continual way of transportation coal in further consumption of coal for production of electricity.

2. USE OF COAL

Coal is currently the predominant fuel for electricity generation worldwide. In 2005, coal use generated 7,334 TWh (1 terawatt hour = 1 trillion watt hours, ameasure of power) of electricity, which was then 40% of all electricity worldwide. In 2005, coal derived electricity was responsible for 7.856 Gt of CO_2 emissions or 30% of all worldwide carbondioxide (CO_2) emissions, and 72% of CO_2emissions from power generation - one gigaton = onebillion tons; onemetric ton=2,204 pounds (International Energy Agency, 2007). Non–power generation uses of coal, including industry(e.g., steel, glass-blowing), transport, residential services,and agriculture, were responsible for another 3.124 Gt of CO_2, bringing coal's total burden ofCO_2 emissions to 41% of worldwide CO_2emissions in 2005.

By 2030, electricity demand worldwide is projected to double (from a 2005 baseline) to 35,384 TWh, an annual increase of 2.7%, with the quantityof electricity generated from coal growing 3.1% perannum to 15,796 TWh(International Energy Agency, 2007). In this same time period,worldwide CO_2emissions are projected to grow 1.8% per year, to 41.905 Gt, with emissions fromthe coal-power electricity sector projected to grow 2.3% per year to 13.884 Gt(International Energy Agency, 2007)**.**In the United States, coal has produced approximatelyhalf of the nation's electricity since 1995,2and demand for electricity in the United States isprojected to grow 1.3% per year from 2005 to 2030,to 5,947 TWh.1 In this same time period, coalderivedelectricity is projected to grow1.5%per yearto 3,148TWh (International Energy Agency, 2007). Other agencies show similar projections;the U.S. Energy Information Administration (EIA)projects that U.S. demand for coal power will grow from 1,934 TWh in 2006 to 2,334 TWh in 2030, or 0.8% growth per year (Energy Information Administration. 2009).

To address the impact of coal on the global climate, carbon capture and storage (CCS) has beenproposed. The costs of plant construction and the "energy penalty" fromCCS, whereby 25–40% more coal would be needed to produce the same amount of energy,would increase the amount of

coal mined, transported, processed, and combusted, as well as the waste generated, to produce the same amount ofelectricity (House, Harvey, Aziz&Schrag, 2009). Construction costs, compression, liquefactionand injection technology, new infrastructure,and the energy penalty would nearly doublethe costs of electricity generation from coal plantsusing current combustion technology.

In order to perform and fulfilled the correctness, the mining company must to perform the demand analysis. This analysis was made for the development of coal mine safety monitoring system. It contains to build up the layout model of the standard coal mine underground production environment and set all kinds of underground transducers especially methane transducer. On this basis, the general design scheme of coal mine safety monitoring system was determined.

3. CAPEX AND OPEX COST IN „RITE UGLJEVIK“

Normally, the cost established in mining company can be divided on investment part, called Capex, and operational part called Opex. Capex cost are related to established and capital investment costs in mining operations, while Opex cost are related to daily production of coal.

Capex&Opex cost can be presented in terms of operation on the biggest mining company in Republic of Srpska “RiTeUgljevik”.

Capital mining investments, such as the project of opening mining site „Ugljevik - East“, are very complex due to the influence of various internal and external techno-economic as well as natural factors and constraints arising from social and economic environment. By investing in the opening of the mining site „Ugljevik - East“, the company „RudnikiTermoelektranaUgljevik“ (Mine and Thermal Power Plant „Ugljevik“) in the Republic of Srpska (Bosnia and Herzegovina), implemented previously defined goals of growth, developed policy and strategy of the company. This investment project required extensive financial assets, significant amount of other resources as well as time.

In order to assess the technical and technological, financial, market and social feasibility of the project, a Feasibility Study was made by the Center for surface mining, Belgrade, in 2013. This study contained a complex analysis of coal at the BogutovoSelo and Ugljevik East coal deposits, including all the components of sustainable mining, i.e., all the environmental and social impacts in addition to the economic impact. Production and technical data, designed in the technical part of the Study were used to design an economic model to determine the economic parameters of the project. Financial analysis is primarily based on planned production capacities of the mine, the investment and operating costs and the estimated selling price of coal. The amounts are given in BAM (KM), with the exchange rate of 1 EUR = 1,955 KM.

For the calculation of income, the price of coal of 44 BAM/t was used for the Thermal Power Plant (TPP) while the forecasted price of coal for general consumption was 65 BAM/t. The Price of 44 BAM per ton of coal for Thermal Power Plant is equivalent to the coal price of about 4.4 BAM/GJ, which is the average market price in Bosnia and Herzegovina and in the Republic of Srpska. The price of 65 BAM per ton of coal for household consumption is the price at which TPP Ugljevik is currently selling the coal.

According to the above study, there are not years with the negative financial result during the project implementation. Since this is an investment project which basically continues the current production with similar volume and similar costs, there are no negative financial results in the years of intensive investment. Instead, there is a significant decrease in net income in the period of repayment of interest on loan taken.

Based on the results of the Study (Center for surface mining, 2013), it can be concluded that the project is fully solvent, which can be seen from the cumulative inflow (2,267,361,382) and outflow (1,543,271,267). In addition to the observed dynamic indicators, the following static indicators were monitored as well:

- Profitability = Net Income / Total Investment = 9%
- Cost - effectiveness = Net Income / Total Income = 21%
- Reproducibility = (Net Income + Depreciation) / Total Investment = 13%

The average profit rate of the investment project is 28%.

The net present value of the project amounts to 160,369,022 BAM at a discount rate of 8%, while the internal rate of return (IRR) is 34.63% and return on the project investment is 10 years.The project is most vulnerable to changes in selling price, then to the production volume, and much less to the variation in the standardized materials, energy and investment cost.

By analyzing the turning point, a limit of the production level of 931,201 tons is defined, which is well below the planned average production level within the project lifecycle of 1,733,138 tons. The minimum price per unit of 30.63 BAM is also significantly lower than the forecasted average selling price of 44.60 BAM.

Dynamic sensitivity analysis indicates that in relation to selected key variables, the project is most vulnerable to changes in price and volume of production. Since there is a large difference between the planned and the minimum acceptable price, not even the largest analyzed deviations of 20% in comparison to the planned price,represent a hazard to the project.

From the point of impact onto the environment, the project is assessed as socially acceptable, while the sensitivity and risk analysis indicates that the project investments do not fall under the category of risky investments.

Opex costs are related to functioning of mining operation.It is very important to made distinction between Opex and Capex costs in mining industries.

Under the historical cost model, mineral reserves that result from a company's exploration activities do not appear as an asset. Information on mineral reserves is, however, vital to investors and analysts in predicting future cash flows and evaluating the prospects for a mining company. Thus, supplementary disclosure about mineral reserves outside the financial statements is important for a more complete appreciation of the value of the company.

Because quantities of minerals beneath the earth's surface cannot be known with absolute precision, reserves are usually categorized as "proven" or "probable," depending on the degree of confidence about the accuracy of the disclosed quantity. All of the companies we reviewed that disclose information on reserves provided quantities of proven and probable reserves, in some cases separately and in other cases combined. Many companies disclose in their annual reports information on mineral resources as well as reserves. Mineral resources are quantities of minerals for which there are reasonable prospects of eventual economic extraction. These are classified as "measured," indicated" or "inferred," depending on the degree of confidence. Only those parts of a company's mineral resources that have been determined to be economically extractable can be classified as reserves.

This distinction is important from an accounting perspective since only proven and probable reserves are used in calculating amortization on a unit-of-production basis and in measuring impairments. Most of the companies we reviewed state this explicitly in their financial statements, and those that do not are believed to follow this practice. Generally speaking, only proven and probable reserves are taken into account in determining fair values for acquisition accounting.

The resources used in mining production for RiTeUgljevik are fuel and electric energy. In 2012 year, there are cca. 50% of cost of machines (fuel&other energy costs and depreciation) of the total production costs. As the first stage of coal production, we gave basic coal. These basic coals should be cleaned. Afterwards, two sediments of coals are given: cleaned coal and dried coal.

In mining production, Opex phase, the production plan is essential. The production plan must to be in line with sales targets. Based on production plan, the company plans their resources (external and internal) on monthly and daily basic.

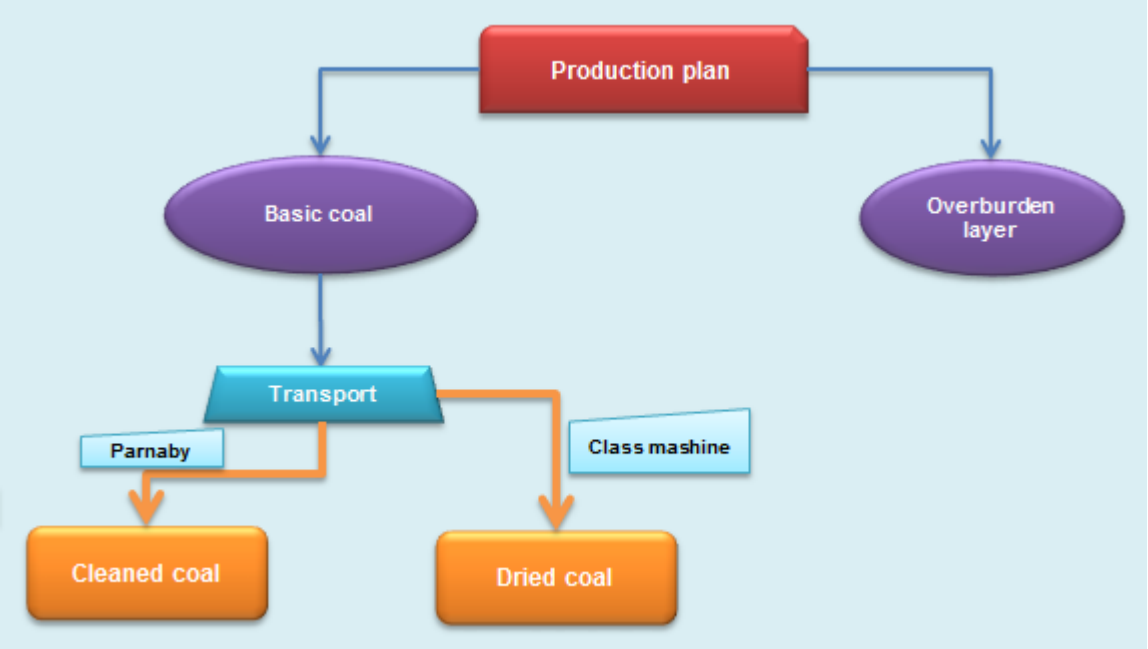

Figure 1: Production sheme in RiTeUgljevik

4. THE SOFTWARES IN MINING INDUSTRIES

There are two main players on worldwide level related to ERP software in mining industries: SAP and Oracle. The both software giants have derived solution for mining. Based on last research, ERP systemsearned more than 38% of total ERP software revenues in 2012 considering all companies world-wide (Pang, Dharmasthira, Eschinger, Motoyoshi and Brant, 2012). SAP and Oracle EBS offer up-to-date solution for mining processes. The choice of the right solution for companies is the last, but the most important stage in order to close the business model (Manojlov, Lutovac, 2012).

The common feature for SAP and Oracle is having a very good solution for mining, especially in cost calculation and measurement of maintenance costs. Oracle is launched Oracle`s mining solution map in order to better track costs and improve performances in business.

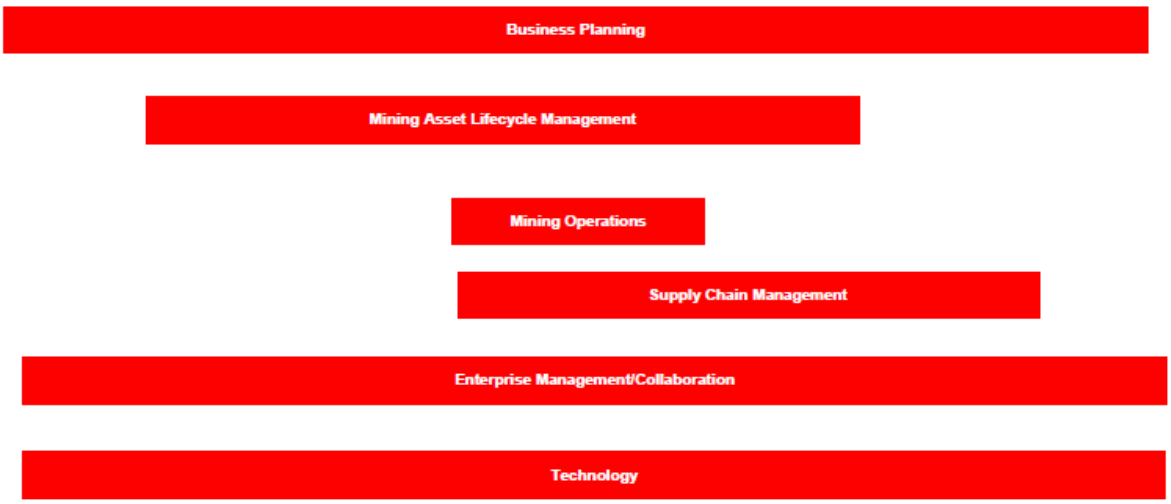

Figure 2: Oracle`s mining solution map

Oracle`s client called “Solid Energy” announce that investment in Oracle Enterprise Asset Management (eAM) is expected to yield rich dividends, enabling this capital-intensive resources enterprise to identify the true lifecycle cost of assets.

On the other hand, SAP deliver solution for mining called SAP for mining or IS-Mine. SAP for Mining consists of several technical components. One of these components is IS-Mine. The functions and tools delivered with IS-Mine are designed to handle the following key business processes in the mining industry:

Mining and primary distribution
- Maintain and optimize all mining processes
- Collect data on all mining processes

Secondary processing
- Plan long-and short-term production objectives
- Manage cost of entire supply chain
- Manage distribution processes

Normally IS-mine requires implementation of SAP ERP system previously. With SAP solutions, mining organizations can reduce operating expenses by improving efficiency in mining and processing operations, boosting asset uptime and utilization, enhancing overall logistics processes, and expanding efficiency improvements to areas like purchasing, finance, and controlling. For example, one mining company increased its overall equipment effectiveness by 75% by implementing SAP ERP (SAP AG, 2013). Additionally, mining companies can realize their sustainability strategy on safety and environmental compliance and help ensure financial success. With a clear view of profits and spending, they are in a better position to initiate internal improvement projects and drive effective negotiations with customers and suppliers. One copper mine realized a US$20 million reduction in stores inventory by implementing SAP ERP and reduced time from purchase order to requisition by 75% (SAP AG, 2013). Finally, with the SAP solutions, mining companies can realize a fast return on investment and reduce IT spending by integrating and standardizing enterprise software on a single platform. SAP solutions support organizations with acquisitions and mergers in a global environment and help them to overcome various localization issues in areas such as legal, finance, and HR when going global. SAP solutions help mining companies expand by providingthe security of long-term software vendor support. As an example, a tin mining company reduced the time required to create reports by 90% and the time required to close the monthly books by 40% (SAP AG, 2013).

5. NEW COST MODEL IN MINING COMPANY

Generally, new cost model in mining industry must to be tailored in order to cover operating and capital activities. The method is used to identify the cause and the connections between the cost inductors (cost drivers) and the cost of the activities by measuring the costs of the process the activities refer to and the cost objects. The main purpose of the method is reducing of cost and increasing of profit consequently. The basic prerequisite for the model is one final product i.e. coal.

There are several rules for implementation of new costing model for mining company:
- All costs collected on cost centers during the month will ultimately rest in the process centers.
- Costs will be moved to the process cost centers with various allocation methods.
- Overhead and utility costs will be allocated to Coal product through activity allocations during the period. At month-end, production activities will be revalued to actual and posted to Coal product. The allocation will be based on production statistics obtained from third-party systems. The management accountant will verify the production statistics before importing the data into system.
- All production orders will be settled to materials at month-end after all material movements, activity allocations and revaluations of activities have been processed for the period.
- All allocations will happen on a periodic basis.
- Differences between the moving average values/standard costs and actual costs on order related to Coal final product will be settled to materials at month-end after all material movements, activity allocations and revaluations of activities have been processed.

Table 1: The production in mining divided into two areas

Phase	Description
Production	It refers to all processes and activities related to surface stockpiling of mine. It starts with the hauling of mine from underground and ends at the surface

Shipping	Shipping refers to all processes and activities related to the shipment of coalmine to the various phase at the mining site

In order to give the correct cost in mining,the following workflow in costing is proposed:

1. Coal product order will be created to value the various phase:
   - Window coal mine.
   - High grade surface.
   - Medium grade surface.
   - Low grade surface.
   - High grade overburden layer.
   - Medium grade overburden layer.
   - Low grade overburden layer.
2. Cost collected in cost centers (one of the cost center will be shipment cost center) during the month will be allocated via activity allocation to the various orders in production.
3. The activity allocation to the various orders in production will be based on the production statistics data from the third party systems.
4. Raw material costs or additional mining costs will be allocated directly to the coal product order.
5. The coal product orders will settle to inventory at month-end.
6. Inventory valuation will be performed at the end of each period.
7. The moving average price calculated at the end of each period will be used for the next period.

All activities must to be in iteration with various users/departments in mining company. Normally, the controlling department would have some correction on period end closing activities; potential reversals of failed documents are expected in shipping, production and maintenance departments.

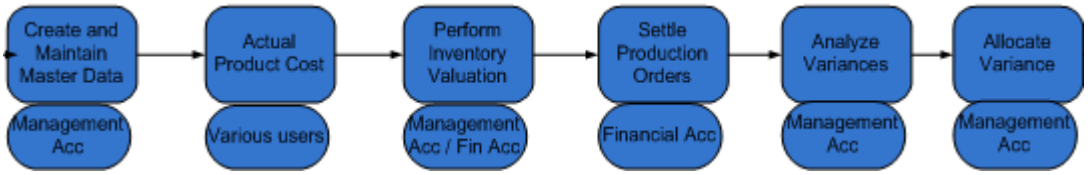

Figure 3: Departments in various phases of cost calculation

In product costing and inventory valuation, the calculation of inventory value is based upon a monthly weighted average. Each phase in coal mining will be numbered in accordance with the type of material and its stage of completion.Production costs will be derived from cost centersthroughallocation to coal product order

Apart from production orders, an investment order should take the main part in mining processes. There are two treatments of investment orders: the costs will be tracked via several accrual orders and accrual orders will be settled on periodic basis; the costs will be settled on fixed assets under construction and post on cost centers via depreciation after activation. The typical examples of these costs are: expropriation, the set up cost, initial concession for rented of mining site and overburden layer.

The presented model is very flexible. The modification of this model is possible and depends of specific of certain mining company.

6. CONCLUSION

The main benefit from establishing of new cost model in mining is cutting of cost in various phase of mining production. Segregation of production& maintenance costs in different phase and monitoring of variances is the base for the improvements of decision process.

Previous authors suggested “Phasing of coal processes” (Epstein, 2012), but nobody from them didn’t develop any comprehensive& analytical model for cost monitoring in different phase of coal processes

as well as presentation of these cost in final product. In this paper, a new modern approach is established through analyzing of all processes and conducting operations in mining companies.

The primary goal of thenew costing model presented in this paper is clear management picture of the cause of each cost. The model establishes the connections among the various cost inductors (cost drivers) in order to give the management the best option for manipulation of the costs. Additionally, themeasurement of the costs of activities is the backbone of the new costing model in mining companies.

The costing model takes into consideration the both capital expenses and operational expenses. The special attention is paid on treatment of costs of overburden layer during mining of coal.

The new costing model in mining company has analytic and holistic feature. It covers all phases in one lifecycle of mining company i.e. from set-up and expropriation till normal exploration of mining site. Also, activities in each phase in mining lifecycle have to be broken on many different parts for better monitoring of each cost.

Thispaper will be the starting point for mining companies to define their costing model and consequently expand their profit by cutting of costs in all phases of lifecycle of mining site. The next step will be practical validation of new costing model through implementation of the model in some mining company in Balkan region.

BUSINESS INTELLIGENCE AND DECISION MAKING IN MANAGEMENT

META-HEURISTIC BASED WRAPPER ATTRIBUTE WEIGHTING TECHNIQUES FOR NAÏVE BAYES CLASSIFICATION

Sandro Radovanović[1], Milan Vukićević[2] Milija Suknović[3]
[1]University of Belgrade, Faculty of Organizational Sciences, sandro.radovanovic@gmail.com
[2]University of Belgrade, Faculty of Organizational Sciences, vukicevicm@fon.ac.bg.rs
[3]University of Belgrade, Faculty of Organizational Sciences, milijas@fon.bg.ac.rs

Abstract: *Naïve Bayes is one of the oldest and mostly used data mining algorithms. This is because there are no parameter which needs to be adjusted in order to generate more accurate models. Still Bayesian learner sometimes underperforms due to assumption that all attributes have equal importance. Therefore, it is crucially important to differentiate attributes that influence positively on model accuracy from attributes that don't. In this research, problem of attribute weighting is addressed with four different metaheuristic wrapper attribute weighting techniques. Experiments are conducted on 25 UCI Machine Learning datasets. Additionally, two methodologies for identification of the best performing feature optimization techniques for data at hand based on meta-features (dataset characteristics) was proposed. Further, clustering, with optimized number of clusters, was used to identify similar datasets and relate obtained clusters with performances of different meta-heuristic attribute weighting techniques.*

Keywords*: Attribute weighting, Naïve Bayes, Meta-heuristics, Clustering*

1. INTRODUCTION

In last few decades many cutting edge classification algorithms are developed or improved. Still, naïve Bayesian learning is widely and successfully used many data mining applications like cancer classification (Wu et al., 2012), risk analysis in public procurement (Balaniuk et al., 2013), finance (Humpherys et al., 2011) etc.

Naïve Bayes algorithm is recently selected as one of the most influential algorithm in data mining and it is identified as one of the top 10 algorithm in data mining (Wu et al., 2008). Reason for that ranking is due to its advantage over other algorithms (Hand & Yu, 2001) which are easy to construct, without any setting or adjusting of complex parameters (which needs expert knowledge and experience using specific algorithm), computational and time effectiveness, ability to work with large datasets (big data), interpretability and intuitiveness (final users can understand created model). On the other side, in order to create reliable naïve Bayes model every possible combination of attribute values needs to be present and used for model training. However, this is mainly not the case because there are not enough data in the training set. This problem is bypassed with conditional independence assumption, which means that all attributes are conditionally independent between themselves. Unfortunately, this assumption is often violated, and the final model performance is often trapped in local optimum. Therefore, Bayesian learning can be improved by mitigating this assumption.

Since conditional independence can pose serious threat in many data mining application, two approaches are present in literature. First, conditional independence assumption is relaxed between class label and other attributes (Webb et al., 2012, Zheng et al., 2012). Second approach use attribute weighting techniques in order to calculate predictive value of attributes. This approach (Hall, 2007, Zaidi et al., 2013) can be viewed as process of discovering weight of attributes in order to reduce theirs impact on prediction accuracy due to conditional dependence.

In this research attribute weighting was used. Attribute weighting is process of selection weight vector which will be used to transform dataset values in order to improve predictive accuracy (Guyon et al., 2006). It is used in many data mining or machine learning problems because irrelevant or redundant feature may exists, which further leads to poor classification accuracy. Also, attribute weighting is used to deal with effects of the curse-of-dimensionality if problem contains many irrelevant attributes. In those cases attribute weighting is particularly useful because model training results in exponential increase in the required training data as the number of features are increased.

In this research several meta-heuristic wrapper attribute weighting techniques for Naïve Bayes were evaluated and compared. Namely, those are simulated annealing, variable neighborhood search, and evolutionary Search and particle swarm optimization. Experiments are conducted on 25 datasets obtained on UCI Machine Learning repository (Bache & Lichman, 2013). Additionally, a method for generalization of the

results based on the analysis of the dependence between attribute weighting performances and dataset descriptions (meta-features), which can be obtained on OpenML platform (van Rijn et al., 2013), was proposed. First clusters of datasets with similar characteristics were created. Then, attribute weighting techniques and their performances on different clusters was analyzed. With this approach data analyst should simply identify best attribute weighting algorithm for data at hand and to the best of our knowledge there are no researches that used similar approach. Second, a meta-model for prediction of performance for weighted naïve Bayes algorithm was proposed, which allows data analyst to see which attribute weighting technique will perform best for data at hand.

Even though many feature weighting methods were developed, most of them have been applied in the domain of nearest neighbor algorithms, but using these methods with naïve Bayesian learning received relatively less attention. There have been only a few methods for combining attribute weighting with naïve Bayesian learning (Huang & Wang, 2006, Hall, 2007, Huang & Dun, 2008, Lee et al., 2011).

The remainder of this paper is organized as follows. Section 2 presents weighted naïve Bayes algorithm. Section 3 reviews research methodology and presents results of experiment. In this paper, 4 attribute weighting techniques for Naïve Bayes for classification problems were evaluated. Conclusion and future work are described in Section 4.

2. THEORETICAL CONCEPTS

2.1. WEIGHTED NAÏVE BAYES ALGORITHM

General discussion of the naïve Bayes method, its pros and cons, are given in (Lewis, 1998, Wu et al., 2008). Weighted Naïve Bayes algorithm generalizes ordinary Naïve Bayes algorithm by introduction of attribute weight vector.

The naïve Bayesian learning uses Bayes theorem in order to assign a class label to a new instance. Let $A=a_1, a_2,..., a_n$ be values for feature $f_1, f_2, ..., f_n$ respectively of a new instance d. Let C be the target attribute where c represents the value under C domain. A new instance will be classified to the class with the maximum posterior probability. Mathematically, classifier is defined as follows:

$$V_{mad(d)} = argmax_c\ P(c)\ P\ (A|c) \quad (1)$$

Assuming that all attributes will be independent of the given class value.

$$P(A|c) = \prod_{i=1}^{n} P(a_i|c) \quad (2)$$

Therefore, the maximum posterior classification in Naïve Bayes can be presented as:

$$V_{nb(d)} = \text{argmax}_c\, P(c) \prod_{i=1}^{n} P(a_i|c) \quad (3)$$

Assumption that all features are conditionally independent does not hold in real world application and there have been some attempts to relax this assumption in naïve Bayesian learning. The most logical approach for relaxing this assumption is to weight attributes of given problem. It is shown in previous section that the accuracy of naïve Bayes algorithm can be improved by removing or weighting attributes. This makes sense if these attributes violate the assumption that attributes are independent of each other. When attribute weighting technique is applied to naïve Bayesian learning it can be formalized as follows:

$$V_{awnb(d,w(i))} = argmax_c\ P(c) \prod_{i=1}^{n} P(a_i|c)^{w(i)} \quad (4)$$

where $w(i) \in [0, 1]$

In this formula each attribute i has its own weight $w(i)$, where $w(i)$ presents significance or predictive value of attribute i with values between zero and one. It presents generalization of attribute selection problem (in attribute selection problems $w(i) \in \{0, 1\}$). Considering that attribute weighting can have infinite number of combinations. Therefore, use of intelligent search over space of values is required.

If weights are appropriate it can reduce the error of classification. For example, if some attribute does not have variance, the weight of that attribute could be set to zero, because it does not have any predictive value. Similarly, if there are at least two attributes, which are perfectly correlated between each other, then one of them is unnecessary. Therefore, weight of one of them could one and weight of other one zero. The other solution is to both of them have weight 0.5 ($1/a$ in general case, where a is number of perfectly correlated attributes).

In general, attribute weighting is strictly more powerful than attribute selection as it is possible to obtain at least the same result as attribute selection, due to generalization property.

2.2. WRAPPER FEATURE WEIGHTING OPTIMIZATION TECHNIQUES

In this research 4 wrapper attribute weighting techniques were analyzed:

- Simulated annealing (SA) is single unit local search metaheuristic that simulate process of annealing of solids and is best known for solving large combinatorial optimization problems. Analogy to physics, annealing is a physical process in which a solid in heated up a heat bath at a maximum temperature, where all particles of the solid randomly arrange themselves, followed by slowly lowering the temperature of the heat bath. This way, all particles of heated solid arrange themselves in the low energy ground state of a corresponding lattice (optimal state). In this research initial maximum temperature were 0.9, cooling to 0.4 with step of 50%. At each step 15 naïve Bayes algorithms were evaluated with maximum 20% Gaussian change of attribute value. (Laarhoven & Aarts, 1987)
- Variable Neighborhood Search (VNS) is also single unit local search metaheuristic which change neighborhood in order to avoid being trapped in local optima. It is well known for solving complex combinatorial problems (Hansen et al., 2010). Contrary to many local search metaheuristics VNS does not follow trajectory, but explore distant parts of feasible space and jump to better solution. This way most variables with optimal values will be kept and used. For exploring neighborhood another local search method must be used. In this setting as method that explores attribute weight space SA that use 10 naïve Bayes algorithms at each step was used. Additionally, three neighborhoods were used, each expanding its boundaries by 20%. (Mladenović & Hansen, 1997)
- Evolutionary Search (ES) is inspired by adaptation of many species to new-come problems and it is generalization of genetic algorithm. This adaptation is search for good enough solution over huge number of genotype (Hinton & Nowlan, 1987). It is population metaheuristic requiring number of units in population and number of generations. In this experimental setting three units were used evolving in 10 generations. In each generation tournament selection scheme were used with 25% size and 20% of variance as adaptation parameter. Crossover of unit is uniform. (Goldberg, 1989)
- Particle Swarm Optimization (PSO) is population metaheuristic inspired by simplified social model of bird flocking, fish schooling and swarming theory in general. Similarly as ES, it needs unit size and number of generations. It gained popularity because it is intuitive and became one of the most used population metaheuristics in general (Poli et al., 2007). In this research three units, which evolved in 10 generations were evaluated.

3. RESEARCH METHODOLOGY AND RESULTS

General idea of this research is to identify good performing wrapper optimization techniques for new datasets without the need for evaluation of all feature optimization techniques. And so, experiments are divided in two parts. First, datasets are clustered based on their meta-features. In order to determine whether there are connections between similar datasets (similar meta-features) and performances of different feature weighting techniques. Second, feature weighting techniques are evaluated by the means of the classification accuracy of Naïve Bayes on every algorithm. These performances are related to different clusters. Experiment was implemented in RapidMiner (Mierswa et al., 2006).

Data used in our experiments originate from UCI Machine Learning repository (Bache & Lichman, 2013) and list of dataset with basic details is shown in Table 1.

Table 1: Benchmark datasets from UCI repository used in this study

First part of this experimental study was clustering of datasets by their characteristics with K-means algorithm. In order to create better clustering several models with different number of clusters (from 2 to 5) and cluster quality is measured by Davies Bouldin index (Davies & Bouldin, 1979). Minimum value of Davies–Bouldin index indicates the best clustering solution. Optimal number of clusters based on Davies-Bouldin index is three. Cluster centroids are shown in Figure 1.

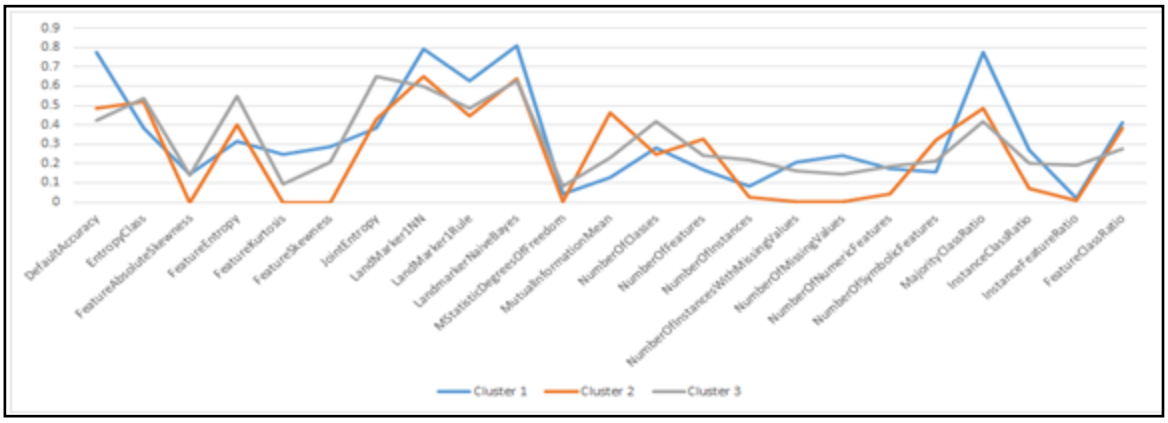

Figure 1: Values of cluster centroids

From Figure 1 difference between characteristics of datasets in different clusters.

First cluster is characterized by:

- High class imbalance - cluster have high values of LandMarker meta-features and MajorityClassRatio.
- Mising values - cluster have high values: NumberOfMissingValues and NumberOfInstances with missing values.
- High kurtosis and skewness.

Second cluster is characterized by:

- High number of symbolic and low number of numeric features.
- Low level of missing values.
- Low Instance/class and instance/feature ratios.
- Low kurtosis and skewness.

Third cluster is characterized by:

- Balanced classes - high values of FeatureEntropy and JointEntropyand low values of MajorityClassRatioand DefaultAccuracy.
- Large number of classes and instances.

Further, evaluation of each feature weighting algorithms on each dataset is performed. In order to prevent over training by feature optimization, each wrapper was trained and evaluated on 70% with 10-fold cross validation. Each dataset is divided into 10 subsets with the same number of different classes (stratified

sampling). Final evaluation of weighted Naïve Bayes performance is done on 30% of the data (unseen cases).

Table 2: Average accuracy and standard deviation of attribute weighting groups

First	8	3	2	5	7	
Second	7	5	1	9	6	

Performances and standard deviation are presented in Table 2 (cluster labels from previous experiment are also added). The best performance on each dataset was bolded, while second performance was presented in italic. The bottom rows show number of best and second best performances of each attribute weighting technique through all datasets. As we see default setting of naïve Bayes algorithm performed best 8 times and were second 7 times. The best attribute weighting technique was PSO, which performed best 7 times and second 6 times. ES performed best 5 times and were second 9 times. SA has also shown good performances having 3 best and 5 second best performances. VNS performed worst of tested metaheuristics having only two best performances and one second best performance.

Detailed analysis of the classification performances and clusters showed that on cluster 1 PSO have outperformed other algorithms, especially anneal and anneal-orig where difference was greater than 10% to second best and greater than 25% to others. On second cluster ES performed better than other algorithms, while on third cluster default naïve Bayes algorithm was mostly the best. This brings to conclusion that PSO performs well on highly imbalanced datasets, while ES performs good on datasets where there are low number of instances and high number of symbolical features.

4. CONCLUSION

In this paper meta-heuristic based attribute weighting techniques were evaluated in order to improve performance of Naïve Bayes algorithm. Four wrapper metaheuristic attribute weighting techniques were tested on 25 UCI datasets. Experiments showed that metaheuristic attribute weighting techniques in some cases improved performance of naïve Bayes algorithm. In order to generalize the results we clustered datasets by their meta-features (characteristics). Generated clusters identified groups where different metaheuristics performed well. Therefore, conclusion is that attribute weighting can influence performance of algorithm but also that it depends on dataset meta-features. In order to further generalize this assumption it is necessary to conduct all these experiments on more datasets As a part of our future work we plan to use described methodology on other algorithms (like SVMs and Neural Networks) Also, we plan to broaden the analysis with different types of attribute weighting techniques, such as statistical or information theory models.

Abstract: *The focus of this paper is the development of the Extract-Transform-Load (ETL) process, as one of the most crucial and demanding phases in the data warehouse development process. Because the development of these processes is extremely complex and time-consuming and requires significant financial resources, there is a growing need for its formalization and automation. Furthermore, it can be argued that this requirement becomes even more important in light of the constant changes in the business and technological environments and the demand for data warehouses to rapidly absorb these changes. A good deal of research effort has been dedicated to this issue and an analysis of the most relevant approaches has been given in this paper with the aim of exploring the possibility for the further improvement of ETL process development. To this end some open issues, which have not been fully addressed by the reviewed approaches, have been identified and discussed.*

Keywords*: ETL process, data warehouse, formalization, automation, MDD, DSM*

1. INTRODUCTION

The aim of data warehouse systems, as a specific type of information system, is to support the decision-makers in making better and faster business decisions in a constantly changing and increasingly demanding business environment, by providing them with the necessary tools for transforming business data into strategic information. In other words, in order to be competitive in such an environment the establishment of a data warehouse (DW), in which all of the relevant business data can be easily stored, processed and analyzed (i.e. transformed into strategic business information), becomes imperative. According to *(Jarke, Lenzerini, Vassiliou, & Vassiliadis, 2003)* data warehouses are expected to have the right information in the right place at the right time with the right cost in order to support the right decision.

The substantial body of existing research in the field of data warehousing has already significantly promoted the understanding of this domain and led to considerable progress being made with regard to the formalization and automation of data warehouse development. Various reference architectures have been proposed *(Golfarelli & Rizzi, 2009; Kimball, Ross, Thornthwaite, Mundy, & Becker, 2010; Linstedt & Graziano, 2011)* along with a number approaches for data warehouse development *(Luján-Mora & Trujillo, 2004; ; Mazón & Trujillo, 2008; Golfarelli & Rizzi, 2009; Kimball, Ross, Thornthwaite, Mundy, & Becker, 2010; Linstedt & Graziano, 2011; Corr & Stagnitto, 2011)* which provide guidelines for the use of particular architectures, prescribe the necessary activities and the order of their execution and recommend the artifacts that need to be created. At the same time, different data models have been developed specifically for the data warehouse domain, in order to enable the fulfillment of the specific requirements regarding the structuring of data, such as the Anchor Model *(Regardt, Rönnbäck, Bergholtz, Johannesson, & Wohed, 2009)*, Data Vault *Model (Linstedt & Graziano, 2011; Jovanović & Bojičić, 2012; Jovanović, Bojičić, Knowles, & Pavlić, 2012)* and the prominent Dimensional Model *(Kimball, Ross, Thornthwaite, Mundy, & Becker, 2010; Adamson, 2010)*.

In addition, research and practice have also focused on one of the most demanding phases in the data warehouse development process – the development of the process for the acquisition and integration of business data, its transformation into appropriate strategic business information and the subsequent storage of the transformed data in a format that facilitates business analysis (the Extract-Transform-Load process – ETL). The transformation process involves the execution of a set of activities through which the actual data transformations are achieved.

The design of appropriate ETL processes (which adequately fulfill their purpose) requires overcoming several challenges. First, it is necessary to integrate the available business data coming from diverse data sources which are usually very heterogeneous in nature (i.e. they may be based on different technologies, use various data models etc.). In order to resolve the numerous structural and semantic conflicts that may exist, a wide array of transformations must be performed. Furthermore, such transformed data must then be

translated into a form suitable for its further analysis. On the other hand, the sheer volume of data that is to be gathered, processed, stored and delivered, imposes strict constraints not only regarding the way the data must be structured but also with regard to the requirements related to the performance and scalability of data warehouse systems. Finally, these processes must be designed to be flexible so that they are able to respond to the constant changes not only in the state and structure of existing data sources (while at the same time allowing for the inclusion of new data sources) but also to the changes in business requirements (imposed by the dynamic business environment). A change in business requirements calls for new business analysis to be conducted, which in turn means that new strategic information must be provided. In other words, according to *(El Akkaoui, Mazón, Vaisman, & Zimányi, 2012)* in order to address the requirement for agile and flexible ETL tools (which can quickly produce and modify executable code based on constantly changing needs of the dynamic business environment) ETL processes must be able to easily identify which data is required and how to include it in the data warehouse. Taking this into consideration, it could be said that the manner in which these processes are designed and implemented significantly impacts the quality of the obtained information, and consequently the usability and success of the system as a whole. Moreover, it has been shown that as much as 70% of the time and effort invested in the development of data warehouses is spent on the development of ETL processes *(Kimball & Caserta, 2004; Kimball, Ross, Thornthwaite, Mundy, & Becker, 2010)*. Consequently, it is evident that an appropriate methodological approach for the development of ETL processes must be adopted.

Due to the fact that the development of ETL processes is extremely complex and time-consuming and that it requires significant financial resources, there is a growing need for the formalization and automation of their development and a good deal of research effort has been dedicated to this issue. An analysis of the most relevant approaches, proposed during the past couple of decades for ETL process development, will be given in this paper. However, it is also the aim of this paper to show that these approaches, despite their significant contribution, still have not managed to adequately resolve some of the problems inherent to this process such as: high development and maintenance expenses, low productivity, failure to adequately satisfy user requirements, etc. As previously stated, these problems stem from the complexity of modern business systems, frequent changes in the organizational and technological environment and the emerging need for businesses to adapt to these changes, especially in recent years in light of the pervasiveness of the Internet and the transition to e-business.

Therefore, an analysis of the most relevant approaches for ETL process development will be given in the following section and some open issues, which have not been fully addressed by the reviewed approaches, will be identified and discussed. This section is divided into two subsections which correspond to the actual phases of ETL process development, namely their specification and the subsequent implementation of the given specification. Finally, Section 3. concludes the paper and gives an outline of a possible solution to some of the identified issues which is intended as a subject of further work in this area.

2. ANALYSIS OF RELEVANT APPROACHES

The existing body of research on ETL process development is constantly expanding to respond to the growing need for the formalization and automation of the development. The leading approach to software development today is Model Driven Development (MDD). The main goal of MDD is to enable the automation of software development in order to increase development productivity, reduce development time and cost, and improve the quality and flexibility of the obtained solution. To this end it promotes the use of abstractions which enable the analysis of a problem at different levels of detail. MDD is based on the premise that the most important product of software development is not the source code itself but rather the models representing the knowledge about the system that is being developed. In other words, in MDD, models are primary software artifacts and the development process is automated through appropriate model transformations which should ultimately result in a concrete implementation i.e. executable code. In light of the complexity of ETL processes and the problems related to their development (as explained in Section 1.) it can be stipulated that they should be developed in accordance with the MDD approach. It should be emphasized that in order to enable automatic model transformations the models must be formal. Therefore, in the next subsections an analysis of the most relevant approaches proposed for the formal specification of ETL processes will be given as well as an analysis of the different approaches for the automated implementation of such specifications. Moreover some open issues will be identified and discussed.

ETL Process Specification

The first phase in ETL process development is the specification (i.e. conceptual modeling) of ETL processes. The main goal of this phase is to define “what” the software solution should provide in terms of its basic functionality. In other words, conceptual models are high-level abstractions representing the knowledge i.e. semantics of the system that is being developed. Since ETL process development presumes the active

participation of domain experts (as they possess the necessary in-depth understanding of the domain) the modeling languages, used for the specification of ETL processes, should be easily understandable not only to software developers but also to the domain experts. According to *(Fowler, 2010)* communication between software developers and domain experts is the most common source of project failure. Therefore, it can also be stipulated that the models should be expressed in terms of concepts specific to this particular domain i.e. the concepts and terms used by the domain experts. In addition, the modeling languages should also be as simple as possible (that is, they should provide a minimal set of necessary concepts) but at the same time semantically rich to enable the specification of the various aspects of the ETL process domain at the appropriate level of abstraction. Finally, if the modeling languages are to properly represent the domain concepts, along with their semantics, they should also include the rules of the domain to ensure the correct usage of the concepts. These rules should be included in the modeling languages to prevent structural and semantic mistakes.

Thus far, two distinctive approaches have emerged for realizing MDD, which differ primarily in the languages used for the specification of the models. One advocates the use of general purpose modeling languages (GPMLs) and their extension, while the other advocates the use of specially designed domain-specific languages (DSLs). It could be said that, in general, the existing body of research on ETL process development can be classified along the same lines.

Based on the premise that ETL processes can be regarded as a special type of business process, and emphasizing the need for standardization, the use of existing general purpose modeling languages (such as Unified Modeling Language – UML or Business Process Model and Notation – BPMN) has been proposed for the conceptual modeling of ETL processes. These languages have been appropriately extended in order to incorporate the concepts specific to the ETL process domain. More precisely, the extension of UML has been proposed in *(Trujillo & Luján-Mora, 2003; Luján-Mora, Vassiliadis, & Trujillo, 2004; Muñoz, Mazón, Pardillo, & Trujillo, 2008; Muñoz, Mazón, & Trujillo, 2009)*, while the extension of BPMN has been proposed in *(El Akkaoui & Zimányi, 2009; El Akkaoui, Zimányi, Mazón, & Trujillo, 2011; El Akkaoui, Mazón, Vaisman, & Zimányi, 2012).* However, it can be argued that since GPMLs were envisaged to support the description of the various aspects of any given business process in any given domain (in order to promote standardization) they include a large number of domain-neutral concepts which are defined at a low level of abstraction. According to *(Kelly & Tolvanen, 2008)* GPMLs do not raise the level of abstraction above code concepts. The complexity of these languages (i.e. too many concepts whose semantics are imprecise) along with the fact that they are often too technical for domain-experts to master, lead to a number of issues related to the acceptance, utilization and value of these languages. Furthermore, since the core GPMLs do not contain knowledge of a particular domain, different concepts could be used and connected regardless of the domain rules *(Kelly & Tolvanen, 2008).* In other words, it is up to the designer to know the semantic rules (e.g. the legal connections and structures, the necessary data etc.) and ensure that they are fulfilled when defining the specification. It can further be argued that the extension of these languages only adds to their complexity while most of the drawbacks of GPMLs still remain. Moreover, in order to extend these languages it is necessary to be familiar with their concepts in order to be able to identify those which can be specialized.

At the same time, the use of DSLs which are tailored to a particular domain has also been proposed in *(Vassiliadis, Simitsis, & Skiadopoulos, 2002, May; Vassiliadis, Simitsis, & Skiadopoulos, 2002, November; Vassiliadis, Simitsis, Georgantas, & Terrovitis, 2003; Simitsis & Vassiliadis, A methodology for the conceptual modeling of ETL processes, 2003; Vassiliadis, Simitsis, Georgantas, Terrovitis, & Skiadopoulos, 2005; Simitsis, Vassiliadis, Terrovitis, & Skiadopoulos, 2005; Simitsis, 2005; Simitsis & Vassiliadis, 2008)*. The main benefit of DSLs, according to *(Kelly & Tolvanen, 2008)* is that, unlike GPMLs, they raise the level of abstraction beyond current programming languages and their abstractions, by specifying the solution in a language that directly uses the concepts and rules from a particular problem domain. Furthermore, they state that with GPMLs it is not possible to know how and when to reuse data from models, check design correctness based on the domain, separate the model data into different aspects relevant in the domain and so on, for the simple reason that these are impossible to standardize as they differ from one domain and company to another. The aim of DSLs is to provide only a minimal set of domain-specific concepts, with clear and precise semantics, along with a set of strict rules controlling their usage and the way in which they can be composed. Since DSLs allow for the inclusion of domain rules (in the form of constraints) both the syntax and the semantics of the concepts can be controlled, thus incorrect or incomplete designs can be prevented by making them impossible to specify. Therefore, in comparison with GPMLs, DSLs are more expressive (i.e. they enable a precise and unambiguous specification of the problem) while at the same time being more understandable and easier to use by domain experts (since they do not include unnecessary general purpose concepts). In addition, the use of such languages facilitates communication among the various stakeholders (from both the business as well as the technical communities) thereby promoting teamwork which is one of the main principles of current agile approaches to software development.

It can, thus, be concluded that since DSLs allow for the formalization of semantically rich abstractions (which capture the existing knowledge and experience in the ETL domain) they are more appropriate for the formal specification of ETL processes.

On the other hand, taking into account the complexity of ETL processes, it is obvious that the various aspects of an ETL process (e.g. the control flow, the data flow, etc.) should be modeled separately else the specification would lead to an overly complex, convoluted model, in which all of the various aspects of an ETL process are interwoven. Though such approaches have been proposed, it should be noted that in most of them the authors have only focused on some of the aspects of an ETL process. Specifically, in *(Vassiliadis, Simitsis, & Skiadopoulos, 2002, November; Simitsis & Vassiliadis, 2003)* an approach for the "conceptual" modeling of ETL processes (i.e. for the specification of the mappings and the transformations needed in an ETL process) is given which, however, does not enable the specification of the execution order of the transformations. Next, in *(Vassiliadis, Simitsis, & Skiadopoulos, 2002, May; Vassiliadis, Simitsis, Georgantas, & Terrovitis, 2003; Vassiliadis, Simitsis, Georgantas, Terrovitis, & Skiadopoulos, 2005; Simitsis, Vassiliadis, Terrovitis, & Skiadopoulos, 2005)* the authors move their focus to the "logical" modeling of ETL processes in order to describe the data flow i.e. to describe the route of data from the sources towards the data warehouse, as they pass through the activities. The authors then state that it is actually the combination of the data flow (i.e. what each activity does) and the execution sequence (i.e. the order and combination of activities) that generates the semantics of the ETL workflow. Consequently, in *(Simitsis, 2005; Simitsis & Vassiliadis, 2008)* they propose a semi-automatic transition from the conceptual model to the logical model, along with a method for the determination of the correct execution order of the activities in the logical workflow using information adapted from the conceptual model. The approach proposed in *(Trujillo & Luján-Mora, 2003)* also deals only with the static aspect of an ETL process and the authors then expound on the proposed approach in *(Luján-Mora, Vassiliadis, & Trujillo, 2004)* to allow for tracing the flow of data at various degrees of detail. In *(Muñoz, Mazón, Pardillo, & Trujillo, 2008; Muñoz, Mazón, & Trujillo, 2009)* the authors recognize the need for the modeling of the dynamic aspects (i.e. behavior) of an ETL process and therefore propose an approach in which the elements of an ETL process are specified at the highest level of abstraction while, the flow of sequence of activities of an ETL process (i.e. the control flow) is specified at the lower level of abstraction. Finally, in *(El Akkaoui & Zimányi, 2009; El Akkaoui, Zimányi, Mazón, & Trujillo, 2011; El Akkaoui, Mazón, Vaisman, & Zimányi, 2012)* the authors propose an approach which allows for the modeling of both the control flow and data flow. However, it can be argued that the use of a single modeling language (be it an extended GPML or a DSL) would not be conducive since it would include a vast amount of disparate concepts. It is therefore stipulated that each aspect of an ETL process should be modeled by a separate language, which should include only the concepts which are relevant for that particular aspect, thereby keeping the languages straightforward and easy to use. These languages would then constitute a conceptual framework for ETL process specification.

As a final point it should be emphasized that some of these approaches do not provide explicit concepts which allow for the formal definition of the semantics of the data transformations. For example, in *(Vassiliadis, Simitsis, & Skiadopoulos, 2002, November; Simitsis & Vassiliadis, 2003; Luján-Mora & Trujillo, 2004)* notes or annotations are used for the explanation of the semantics of the transformations (e.g. type, expression, conditions, constrains etc.), while in *(Trujillo & Luján-Mora, 2003)* even the actual attribute mappings are defined through notes. Since in these approaches the authors allow for the notes to be given in a natural language (and often without any restrictions on their content) they do not represent a formal specification. However, in order to enable automated development, MDD requires that the models be formally expressed. It can therefore, be stipulated that it is necessary to provide the means for formally specifying the data transformation semantics and the approaches proposed *in (Muñoz, Mazón, Pardillo, & Trujillo, 2008; El Akkaoui & Zimányi, 2009; El Akkaoui, Zimányi, Mazón, & Trujillo, 2011; El Akkaoui, Mazón, Vaisman, & Zimányi, 2012)* have, to some extent, managed to address this issue.

ETL Process Implementation

The second phase in ETL process development is the actual implementation of the ETL process specification. It should first be emphasized that only a few approaches exist which enable the automated development of ETL processes in the context of MDD. Generally, in order to enable the automation of the development in accordance with MDD, it is necessary to first map the domain concepts to design concepts and then on to programming language concepts. The way in which the actual automation of software development is achieved (Model Driven Architecture - MDA or Domain Specific Modeling - DSM) is another point of difference between the general purpose approach and the domain-specific approach.

In the MDA approach, software development can be partially or fully automated through the successive application of model transformations, starting from the model representing the specification of the system (i.e. the conceptual model) and ending in a model representing the detailed description of the physical

realization, from which the executable code can ultimately be generated. The development of ETL processes in accordance with the MDA approach is proposed in *(Muñoz, Mazón, Pardillo, & Trujillo, 2008; Mazón & Trujillo, 2008)*. Thus, the conceptual models are defined as platform independent models – PIM which are then automatically transformed into platform specific models – PSM (through a set of formally defined transformations) from which the code (necessary to create data structures for the ETL process in the corresponding platform) can be derived. However, since the PSMs must be specially designed for a certain technology of ETL processes (i.e. each PSM must be based on the resources of a specific technology) the proposed approach presumes that a metamodel must be manually defined for each specific tool in order to create the transformations from the proposed conceptual model to each deployment platform. On the other hand, the MDA approach in general, is based on the refinement of models through successive model transformations, yet this process usually also requires that the automatically generated models be manually extended with additional details. These manual extensions could lead to a discrepancy between the original and generated models (i.e. the original models would become obsolete). This discrepancy is further emphasized when the modification of models, that were previously created by partial generation, is required. Since the correct modification of these models remains an unresolved issue, MDA advocates using a single GPML, namely UML, at all the levels (thereby lowering the abstraction levels of models) which not only entails all of the previously discussed issues regarding the use of GPMLs for modeling ETL processes, but also brings additional complexity to the development of model transformations *(Fowler, 2010)*. Thus, an improvement of the proposed approach has been suggested in *(El Akkaoui, Zimányi, Mazón, & Trujillo, 2011)* to directly obtain the code corresponding to the target platform, bypassing the need for the defining of an intermediate representation (metamodel) of the target tool. Thus, the conceptual model can be automatically transformed into the required vendor-specific code to execute the ETL process on a concrete platform.

On the other hand, in the DSM approach the implementation is automatically generated from the specification (which can be modeled using domain-specific concepts) by code generators which specify how the information is extracted from the models and transformed into code. In other words, the generator reads the model based on the metamodel of the language and maps it to code. The generators are also domain-specific (i.e. they produce the code according to the solution domain) since, according to *(Kelly & Tolvanen, 2008)*, this is the only way to enable full code generation i.e. the generation of code that does not need to be additionally modified. Usually the code generation is further supported by a domain-specific framework which provides implementation concepts, closer to the domain concepts used in the specification, thus narrowing the gap between the solution domain and the problem domain that would otherwise need to be handled by the code generator. The main benefit of DSM according to *(Kelly & Tolvanen, 2008)* is that generators, along with framework code, provide an automated direct mapping to a lower abstraction level (i.e. there is no need to make error-prone mappings from domain concepts to design concepts and on to programming language concepts) thus providing full code generation instead of resulting in a partial implementation. Because the generated code can be compiled to a finished executable without any additional manual effort, the specification (i.e. model) in fact becomes truly executable.

It can, thus, be concluded that, if the goal is to formalize and automate the development of ETL processes to a significant extent, the DSM approach should be adopted not only, because it allows for the formalization of semantically rich abstractions in a form which can be reused, but also because it enables the automatic generation of executable code from models representing the specification of the system. On the other hand, the modeling concepts of GPMLs do not relate to any specific problem domain on the modeling side while on the implementation side, they do not relate to any particular software platform, framework, or component library. Furthermore, MDA assumes the existence of several models at different levels of abstraction obtained through progressive refinement (which can be both automatic and manual) thus automation is usually only partially achieved. An additional benefit is that in the DSM approach, both the models and the code generators can be easily changed (and the code then only needs to be regenerated) which makes the development process more agile. Finally, according to *(Kelly & Tolvanen, 2008)* domain-specific approaches are reported to be on average 300–1000% more productive than GPMLs or manual coding practices.

As a final point, it is argued that the application framework (supporting the implementation of the ETL process specification in the DSM approach) should define specific implementation concepts which are more close to the real domain concepts introduced in the DSLs used for the specification of ETL processes. If both the specification and the application framework use formal concepts close to the real ETL domain concepts the transformation between them can be fully automated, thus significantly increasing development productivity and efficiency while lowering the development and maintenance costs. In other words, by elevating the semantic level and supporting it technologically development can be significantly automated and fewer steps will be needed to implement the abstract specifications. Furthermore, the obtained solutions would have good performances and be scalable and maintainable yet, at the same time, flexible (i.e. they could be easily extended to adapt to the constant changes in the environment and new requirements).

It should be noted that the approach, closest to fulfilling all of the posed requirements, is proposed in *(El Akkaoui & Zimányi, 2009; El Akkaoui, Zimányi, Mazón, & Trujillo, 2011; El Akkaoui, Mazón, Vaisman, & Zimányi, 2012)* in which the authors have even provided built-in mechanisms to validate the syntactic and semantic correctness of the created models. However it is based on the use of a single modeling language which is built by extending a general purpose modeling language, namely BPMN.

3. CONCLUSION

An analysis of the most relevant approaches proposed during the past couple of decades for developing ETL processes, as one of the most crucial and demanding phases in the data warehouse development process, has been given. It can be concluded that these approaches have not managed to adequately resolve some of the problems inherent to the ETL development process, especially in light of the need for the formalization and automation of the development. Several issues, which have not been fully addressed by the reviewed approaches, have been identified and discussed.

First, it can be stipulated that ETL process development must be based on abstractions as they are the only valid methodological means for overcoming complexity. Moreover, it can be argued that semantically richer abstractions are desired for the specification of ETL processes because they can capture greater knowledge thereby increasing productivity and efficiency *(Greenfield, Short, Cook, & Kent, 2004)*. Furthermore, since a greater level of automation is sought it is also necessary to formalize the existing knowledge and experience in such a form that would allow for its reuse. The possibility of reuse further increases productivity and efficiency, while at the same time lowering the cost of data warehouse system development. In addition to overcoming complexity, abstractions are also represent a means for capturing similarities and differences (i.e. achieving a separation of concerns) thereby allowing for parts of the system with the same functionality to be specified and then implemented independently from the specification which, ultimately, enables their reuse.

Since domain experts play a key role in the specification of ETL processes (as they possess an in-depth understanding of the domain i.e. the semantics of the data that is to be transformed) the models should be expressed in terms of concepts specific to the particular domain (i.e. the concepts and terms used by the domain experts). In addition, the modeling languages should be as simple as possible (i.e. they should provide a minimal set of necessary concepts) but at the same time semantically rich to enable the specification of the various aspects of the problem domain at the appropriate level of abstraction (i.e. as stated in *(Greenfield, Short, Cook, & Kent, 2004)* the more general an abstraction, the wider its application, but the smaller its contribution). On the other hand, they should also be formal in order to enable automatic model transformations. Thus, for the formal specification of ETL processes, the use of DSLs is preferred over the extension of GPMLs since they provide only a minimal set of semantically rich domain-specific concepts which makes them more approachable to domain experts. Furthermore, in order to reduce the complexity of the ETL process specification, the different aspects (e.g. the control flow, data flow, etc.) should be modeled separately. The rationale for introducing several languages, instead of just one, is to reduce the complexity of the ETL process conceptual model by separating the different aspects into different models while keeping the languages straightforward and easy to use.

The implementation of these abstract specifications is another crucial aspect. By elevating the semantic level and supporting it technologically development can be significantly automated and fewer steps will be needed to implement the abstract specifications. In other words, if both the specification and the application framework use formal concepts close to the real ETL domain concepts the transformation between them can be fully automated.

The focus of future research is to define a novel approach for ETL process development and the aim of this solution would be to automate this development to a significant extent. To this end the DSM approach would be adopted for the development of ETL process since it allows for the formalization of semantically rich abstractions in a form which can be reused and enables the generation of executable code from models representing the specification of the system. In order to reduce the complexity of the ETL process specification the different aspects of an ETL process would be modeled separately using several DSLs. In addition, a specific application framework would be introduced to support the implementation of the specification. The proposed approach would, thus, be based on a formal specification of ETL processes and its automated transformation into this application framework. By defining implementation concepts which are close to the real domain concepts the semantic level of the solution would be significantly elevated. Ultimately, the automated transformation between the specification and the application framework would additionally increase development productivity and efficiency as well as its flexibility.

Abstract: *One of the major issue in Serbian Government is public electronic procurement (public e-procurement) which is significant electronic service in electronic government (e-government) in Serbia. In this paper, the main phases of public e-procurement with an accent to bidder selection phase are described. The process of selection of the most suitable bidder in public e-procurement may be reduced to a multi-attribute decision making, because it includes both qualitative and quantitative factors. In order to select the most suitable bidder, it is necessary to make a trade-off between these tangible and intangible factors, which can pose conflict. For an efficient bidder selection in public e-procurement, an electronic decision support system (e-DSS) based on fuzzy Analytic Hierarchy Process (FAHP) is proposed and implemented in Java programming language. The paper describes the main architecture of e-DSS and practical application of this system in a case study from the public administration sector in Serbia. Upon definition of basic criteria and sub-criteria, a hierarchical tree is structured, while priority weights are obtained using e-DSS. The bidder with the highest priority is chosen as the most suitable one.*

Keywords*: Bidder selection, Multi-attribute decision making, DSS, Fuzzy analytic hierarchy process, Decision makers.*

1. INTRODUCTION

The information society as a new qualitative step in the development of human social life is characterized by extremely fast growth in the use of new capacities enabled by information and communication technology (ICT). Worldwide phenomenon of using ICT, especially the Internet, Influenced transformation of all life processes, including functions of the public administration. Governments could not stand aloof from these trends and is forced – just as the private sector – to implement innovations and to explore new possibilities (Heeks, 2003; Stragier et al., 2010;). The communication in public administration is increasingly taking place over the Internet, which is used as a potential channel for distribution of information and is becoming more and more a permanently open government information window (Bobar, 2013). Modernization of public administration by using ICT, as a principle of public administration reform (Public Administration Reform Strategy in Serbia, 2009) enables that the traditional form of public administration is transformed into electronic form as much as possible. The development of the Internet has contributed to the traditional model of public administration translates into an electronic model which leads to the concept of electronic government (e-government). Public e-procurement, as one of the significant electronic services of e-government, which refers to the relation of government towards businesses, should be implemented as web electronic service because it increases transparency and reduces costs in the work of public administration, at the same time. Therefore, in this paper, the attention is given to the concept of public e-procurement and design of fuzzy e-DSS for bidder selection in public e-procurement.

The bidder selection in public e-procurement may be reduced to a multi-attribute decision making where we have a number of quantitative (price, distance, delivery time) and qualitative (quality, technological capability, finances), often conflicting criteria are considered. Presence of qualitative criteria in public e-procurement led to using the fuzzy methodology because public e-procurement may be described as uncertain. FAHP represents a systematic approach to choosing alternatives and solving problems by means of a concept of fuzzy set theory (Zadeh, 1965) and AHP method, which is implemented by using triangular fuzzy numbers (Chang, 1996). In this paper, we use Chang's (1992) extent analysis method as a base for implementing e-DSS for bidder selection in public e-procurement.

The paper is organized as follows: Chapter 2 covers the background of public e-procurement. Chapter 3 explains the Chang's extent analysis method. In Chapter 4, we shortly described process of design and implementation of e-DSS based on mentioned Chang's extent analysis method. The e-DSS is applied in

order to solve the problem of selecting the most appropriate telecommunications equipment bidder in the public administration sector. The work is ended with conclusive remarks in Chapter 5.

2. PUBLIC E-PROCUREMENT

In this paper, public procurement means the procurement of goods, services and work by the government authority, in the manner and under conditions prescribed by the Public Procurement Law (2012). The public e-procurement is the process of purchasing goods, works or services electronically, usually over the Internet (Bobar, 2013). Public e-procurement consists of two main phases: pre-award phase and post-award phase (see **Figure 1**).

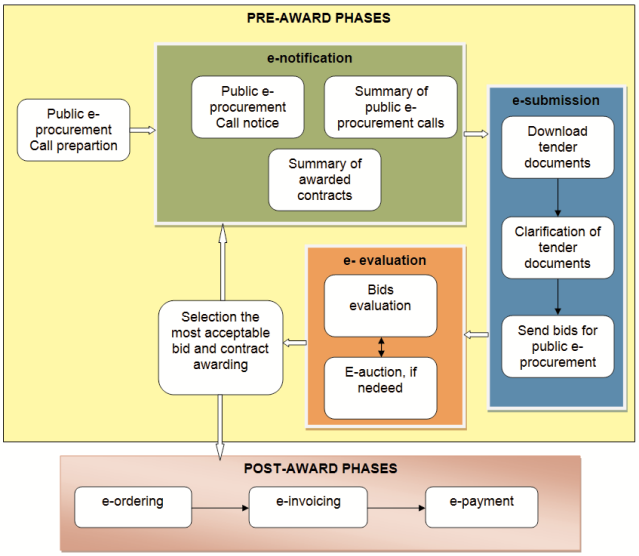

Figure 1: The phases of Public e-Procurement in Serbia

Pre-award phase has sub-phases which described by Bobar (2013). *Call preparation for public e-procurement* is a phase where contract authority creates tender documentation with all conditions and criteria. *E-notification* is a phase that provides online publication of call for public procurement, review of all public procurement calls (previous, current and future) and of all contracts which are awarded in past procurement process. *E-submission of bids* is a phase that ensures the online access to tender documentation, whether through an Internet site of a government institution or through separate software created for that purpose. Bidders can review documentation online or download it. This phase enables possible addition clarification of tender documentation on bidder's request. After completing the documentation and creating the bid, the bidder sends it to the contracting authority, also electronically (upload). *E-evaluation* is the most important phase of public e-procurement which ensures maximum uniformity for evaluation of bids based on predefined criteria. In evaluating bids it is possible to use the electronic auction or multi-criteria decision making methodologies which will be integrated into the background of the public e-procurement software. The result of the evaluation of bids is a recommendation of the most acceptable bid and awarding of the contract to a bidder who offers the most acceptable bid. *Selection of the most acceptable bid and contract awarding* is a phase where contract authority decides for a bid based on results from e-evaluation phase and after that creates a contract with selected bidder.

Post-award phase has following sub-phases (Bobar, 2013): e-ordering, e-invoicing and e-payment. *E-ordering* is a phase in which a contract is drafted, after which, the bidder must supply an electronic catalogue of his products or services and the contract authority made an order. Based on the catalogue, the contract authority will place an order, by submitting it to the bidder who will confirm the order electronically. *E-invoicing and e-payment* are the phases that ensure a uniform link between the accounting systems of the contract authority and bidder, allowing for the invoice to be directly forwarded from the bidder's accounting to the contract authority's accounting for payment.

The selection of the most acceptable bid and contract awarding is one of the most important phase in public e-procurement where evaluation of bids and selection of the most acceptable bid is conducted by applying the criteria of lowest price or of the most economically advantageous tender (Public Procurement Law, 2012). For this selection, many various mathematical models and operations can be used for decision making, such as weighting coefficients, the analytic hierarchy process (AHP) or fuzzy logic. In view of this,

the process of selection of the most acceptable bid can be viewed from the perspective of decision making phenomena, where selection of the most acceptable bid based on different criteria, in fact, represents the objective of a decision making problem. In the process of public e-procurement, alternatives are the bids or bidders who possess specific resources that they wish to place in the service of satisfying the purchaser's needs. Criteria are attributes for describing offered alternatives and they indicate the extent to which individual alternatives realize the set objective. Very frequent criteria for public procurement by government institutions are offered price, quality of offered goods or services, payment terms, delivery period, references, etc. (Public Procurement Law, 2012). In this paper, we present an illustrative example of the application of the specific e-DSS based on FAHP in the process of public e-procurement of telecommunications equipment for use by a government institution.

3. METHODOLOGY OF FAHP

Let $X = \{x_1, x_2, ..., x_n\}$ is an object set and $G = \{g_1, g_2, ..., g_m\}$ be a goal set. According to the method of Chang (1992) extent analysis, each object is taken and extent analysis for each goal g_i is performed, respectively. Therefore, *m* extent analysis values for each object can be obtained as $M_{g_i}^1, M_{g_i}^2, ..., M_{g_i}^m$, *i=1,2,..n*. All the $M_{g_i}^j$, *j=1,2,..,m* are triangular fuzzy number. The Chang's extent analysis (Chang, 1992) can be described as follow: The value of fuzzy synthetic extent with respect to the i^{th} object is defined by $S_i = \sum_{j=1}^{n} M_{g_i}^j \otimes \left[\sum_{i=1}^{n}\sum_{j=1}^{m} M_{g_i}^j\right]^{-1}$. In order to obtain $\sum_{j=1}^{n} M_{g_i}^j$ it is necessary to perform the fuzzy addition of numbers in the matrix such that $\sum_{j=1}^{n} M_{g_i}^j = \left(\sum_{j=1}^{m} l_j, \sum_{j=1}^{m} m_j, \sum_{j=1}^{m} u_j\right)$ and to obtain $\left[\sum_{i=1}^{n}\sum_{j=1}^{m} M_{g_i}^j\right]^{-1}$ which is performed by using the operation of fuzzy addition of all values such that $M_{g_i}^j$, *j=1, 2, m* $\sum_{i=1}^{n}\sum_{j=1}^{m} M_{g_i}^j = \left(\sum_{i=1}^{n} l_i, \sum_{i=1}^{n} m_i, \sum_{i=1}^{n} u_i\right)$.

The vector $\left[\sum_{i=1}^{n}\sum_{j=1}^{m} M_{g_i}^j\right]^{-1}$ is determined as $\left[\sum_{i=1}^{n}\sum_{j=1}^{m} M_{g_i}^j\right]^{-1} = \left(\frac{1}{\sum_{i=1}^{n} u_i}, \frac{1}{\sum_{i=1}^{n} m_i}, \frac{1}{\sum_{i=1}^{n} l_i}\right)$. The degree of possibility of $M_2 = (l_2, m_2, u_2)$ and $M_1 = (l_1, m_1, u_1)$ is defined by

$$V(M_2 \geq M_1) = hgt(M_1 \cap M_2) =$$

$$= \mu_{M_2}(d) = \begin{Bmatrix} 1, & if & m_2 \geq m_1 \\ 0, & if & l_1 \geq u_2 \\ \dfrac{l_1 - u_2}{(m_2 - u_2) - (m_1 - l_1)} & other & \end{Bmatrix}.$$

To compare M_1 and M_2, we need both the values of $V(M_1 \geq M_2)$ and $V(M_2 \geq M_1)$. The degree of possibility for a convex fuzzy number to be greater than k convex fuzzy numbers M_i, *i=1,2,..,k* can be defined as $V(M \geq M_1, M_2, ..., M_k) = \min V(M \geq M_i)$, *i=1,2,..,k*. If we assume that $d'(A_i) = \min V(S_i \geq S_k), k \neq i$, *k=1,2,..,n,* then the weight vector is given as $W' = (d'(A_1), d'(A_2), ..., d'(A_n))^T$ where A_i, i=1,2,..,n is a matrix with n elements. Using normalization, the normalized weight vector is given as $W = (d(A_1), d(A_2), ..., d(A_n))^T$ where *W* is not fuzzy number.

4. DESIGN AND IMPLEMENTATION OF e-DSS BASED ON FAHP

Using steps of FAHP described in Chapter 3, and using JAVA technology, an e-DSS based on FAHP is proposed. **Figure 2** represents a UML class diagram of FAHP module. Basic elements of this module are classes *Criteria* and *Alternative*. They are generalized from abstract class Element. Class *FuzzyNumber* represent a triangular fuzzy number. Classes Degree, *SyntheticExtent, Result* and *FinalResult* help classes for calculation of fuzzy AHP. *Calculate* is an abstract class which represents the template method software pattern. It is generalized to classes *FuzzyAHP* and *ChangFuzzyAHP*. Because of this template method, this software module can be extended with new methods, not only fuzzy AHP's, but methods like fuzzy TOPSIS or any other method that requires pair wise comparison of each pair of factors in the same hierarchy level. *Util* class is a singleton that provides a single point of access to this module.

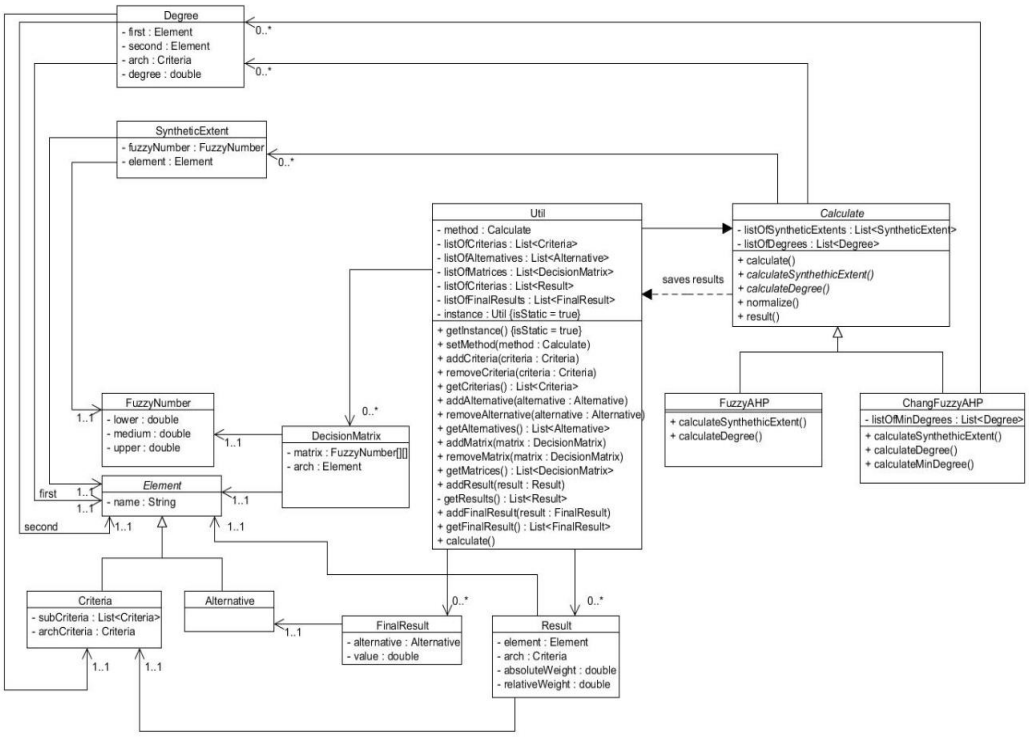

Figure 2: The Class Diagram of e-DSS

An example of program code for *ChangFuzzyAHP* calculation gives as follows:

```
public class ChangFuzzyAHP {
        private List<SyntheticExtent> listOfSyntheticExtent;
        private List<Degree> listOfDegrees;
        @Override
        public void calculate() {try {calculateSyntheticExtent();
                calculateDegree();
                calculateMinDegree();}
        catch (Exception ex) {
                Throw new Exception(ex.getMessage());}}
        …
        public void calculateDegree() {
                double value = 0;
                for (SyntheticExtent se : listOfSyntheticExtent) {
                for (SyntheticExtent visitingSe : listOfSyntheticExtent) {
                                if       (!se.equals(visitingSe)       &&       se.getElement().getArch
().equals(visitingSe.getElement().getArch ())) {
                                if                (se.getWeight().getMediumValue()                    >=
visitingSe.getWeight().getMediumValue()) {    value = 1;
                                }      else      if      (visitingSe.getWeight().getLowerValue()      >=
se.getWeight().getUpperValue()) { value = 0;
                                }    else    {value    =    (visitingSe.getWeight().getLowerValue()    -
se.getWeight().getUpperValue())          /          (criteria.getWeight().getMediumValue()          -
se.getWeight().getUpperValue()          -          visitingSe.getWeight().getMediumValue()          +
visitingSe.getWeight().getLowerValue());
                                }
Degree degree = new Degree (se.getElement(), visitingSe.getElement(), se.getArch(), value);
                        listOfDegree.add(degree);}}
```

This e-DSS is created as a part of electronic platform for public procurement in Serbia and it helps commission for public procurement to make quick and good decision for bidder selection in public e-procurement process. In the next section, the application of the proposed e-DSS on a real life problem is given.

4.1. Application of e-DSS in bidder selection in public administration sector in Serbia

As a case study, in this paper, described e-DSS is applied to the selection of a most suitable bidder in public e-procurement of transmission frequency repeaters which allow for area coverage without GSM signal or with a very weak signal inside public administration buildings. For that purpose, contracting authority formed commission for public e-procurement which consists of experts from the Technical Department. After the public opening of the bids, commission for public e-procurement selected three bidders (B_A, B_B and B_C) who met the legal requirements for participation in public e-procurement. Evaluation and selection of the most economically advantageous bidders among these three bidders is based on criteria and sub-criteria showed in **Figure 3**.

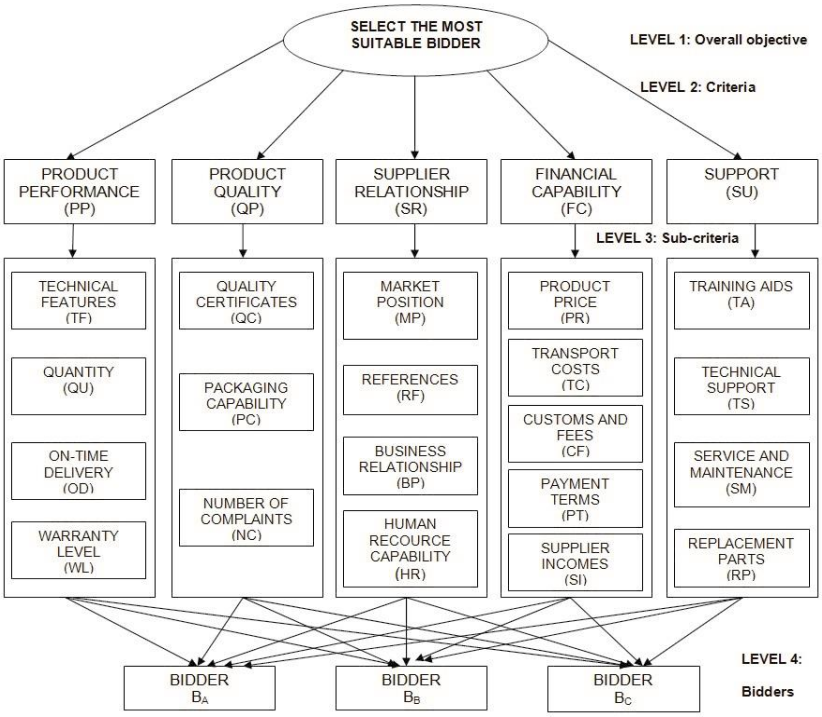

Figure 3: Hierarchical tree dedicated to bidder selection problem

All criteria and sub-criteria that may affect the selection of the best telecommunications equipment bidder have been determined using Public Procurement Law in Serbia (2012) and in cooperation with experts from the Technical Department of the contracting authority. The priority weights of each criterion, sub-criteria and alternatives from **Figure 3** are calculated using e-DSS based on FAHP method. Comparison of criteria, sub-criteria and alternatives is facilitated for the experts by means of a Linguistic Importance Scale (**Table 1**). Within **Table 1** (Kilincci and Onal, 2011), linguistic variables are converted into triangular fuzzy numbers.

Table 1: Linguistic scale of importance

Linguistic scale of importance	Triangular fuzzy scale	Triangular fuzzy reciprocal scale
Equal	(1,1,1)	(1,1,1)
Weak	(1/2,1,3/2)	(2/3,1,2)
Fairly strong	(3/2,2,5/2)	(2/5,1/2,2/3)
Very strong	(5/2,3,7/2)	(2/7,1/3,2/5)
Absolute	(7/2,4,9/2)	(2/9.1/4,2/7)

The experts from Technical Departments are involved in the comparison process. The ratings of the three bidders by technical experts under all criteria are given in **Table 2**.

Table 2: The ratings of three bidders by technical experts under all criteria

Criteria	PP	QP	SR	FC	SU
PP	Equal	Weak	Fairly storng	Weak	Fairly storng
KP	Weak	Equal	Very strong	Weak	Very strong
OP	Very strong	Absolute	Equal	Very strong	Weak
FK	Weak	Weak	Fairly storng	Equal	Weak
PD	Very strong	Absolute	Weak	Weak	Equal

Using data from **Table 1**, linguistic variables from **Table 2** can be converted to triangular fuzzy numbers (see **Table 3**).

Table 3: The fuzzy matrix for main criteria according to commission for public e-procurement

Criteria	PP	QP	SR	FC	SU
PP	(1,1,1)	(2/3,1,2)	(3/2,2,5/2)	(1/2,1,3/2)	(3/2,2,5/2)
QP	(1/2,1,3/2)	(1,1,1)	(5/2,3,7/2)	(1/2,1,3/2)	(5/2,3,7/2)
SR	(2/5,1/2,2/3)	(2/7,1/3,2/5)	(1,1,1)	(2/5,1/2,2/3)	(1/2,1,3/2)
FC	(2/3,1,2)	(2/3,1,2)	(3/2,2,5/2)	(1,1,1)	(1/2,1,3/2)
SU	(2/5,1/2,2/3)	(2/7,1/3,2/5)	(2/3,1,2)	(2/3,1,2)	(1,1,1)

The e-DSS uses the hierarchy tree from **Figure 3** for creating hierarchy into system (see **Figure 4**) and uses fuzzy numbers from **Table 3** (see **Figure 5**) and automatic calculates final results (see **Figure 6** and **Figure 7).**

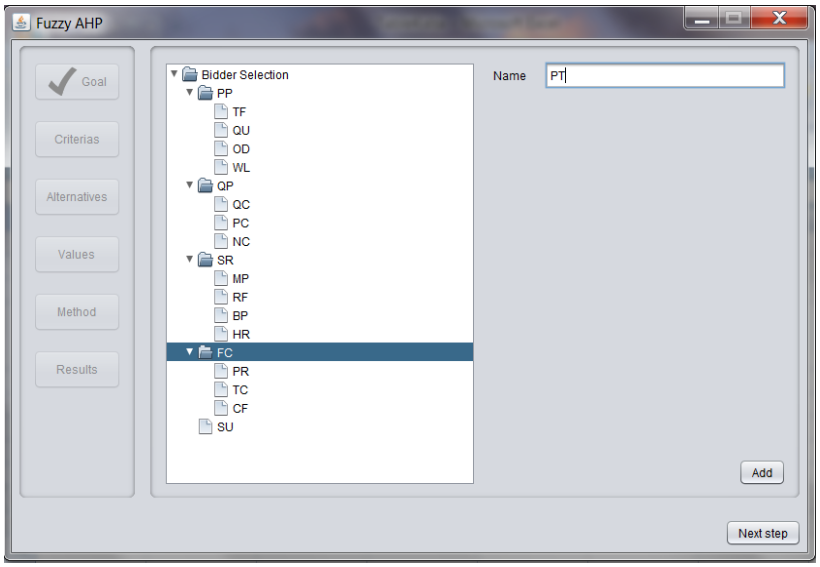

Figure 4: Creating hierarchy into e-DSS

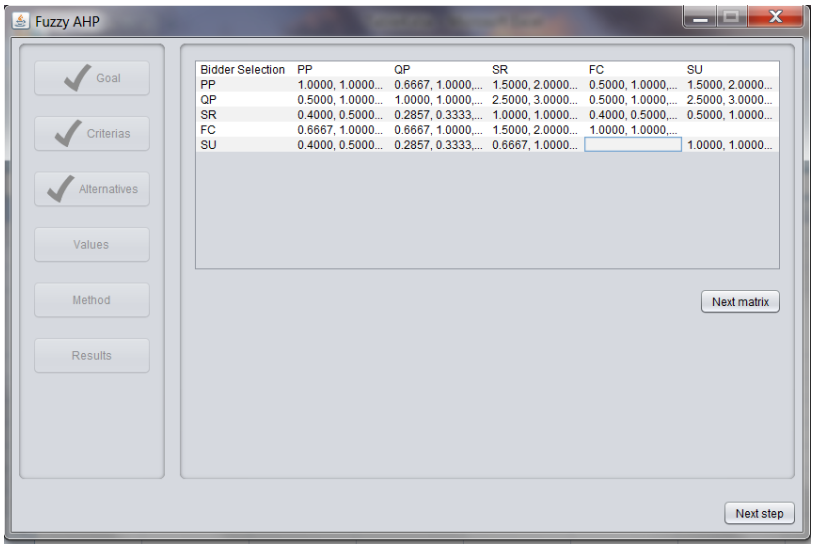

Figure 5: Creating of fuzzy matrix of criteria comparison

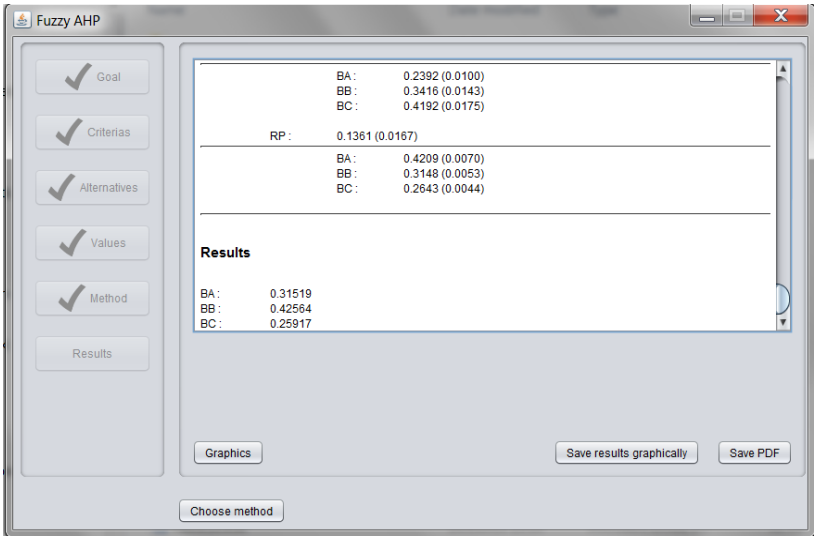

Figure 6: The final results

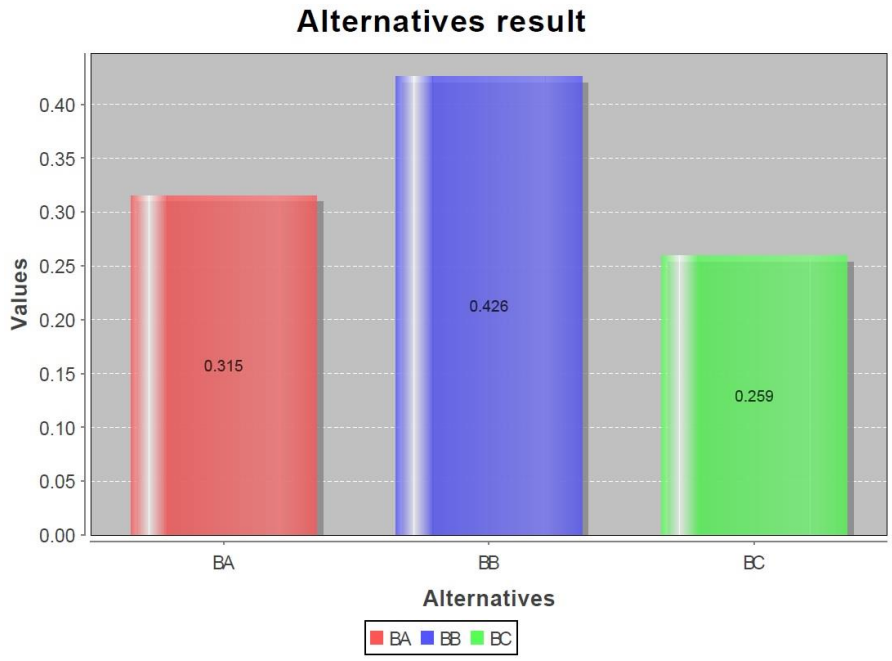

Figure 7: The Alternatives Order – the graphical representation

Analysis of results from **Figure 7** shows priority weightings for alternatives (0.31, 0.43, 0.26). According to the final results, we may conclude that bidder $\mathbf{B_B}$, with a total priority value of 0.43, is the most suitable bidder for this public e-procurement. The supplier $\mathbf{B_A}$ comes second with a total priority of 0.31, while supplier $\mathbf{B_C}$ ranks lowest with a total priority of 0.26.

5. CONCLUSION

Public procurement represents one of the key areas where electronic methods are used that significantly simplifies the procurement process, particularly in the government sector, which is known for lengthy procurement procedures (up to 6 months) (Bobar, 2013). This process can possible to transform from the traditional form into the electronic form by using ICT. This contributes to costs reduction, enabling efficiency and high level of transparency and as a result we have savings for economy subjects and government authorities. The basic benefit of using the system of public e-procurement is the possibility of consolidating numerous information systems into a single place by establishing a standardized purchasing method and supplier interface (Bobar, 2013).

The bidder selection in public e-procurement is one of the key phases of this process. This selection represents a multi-attributes decision making problem which includes both qualitative and quantitative factors. In order to select the most suitable bidder, it is necessary to make a trade off between these tangible and intangible factors same of which may conflict. This paper proposes an electronic decision support system for bidder selection in public e-procurement. This system is developed JAVA technology in combination with FAHP and it represents a part of the complex electronic platform for public procurement in Serbia. With the application of fuzzy numbers, the FAHP method has clear advantages over other similar methods. It effectively improves the flexibility of the conventional AHP in dealing with the uncertainties and ambiguities associated with the judgments of different decision makers. This paper has shown the practical usage of e-DSS to make bidder selection in one real-life case study of public procurement in Serbia. In this paper, five essential criteria and twenty sub-criteria have been analyzed for three alternatives, i.e. bidders. Essential criteria and sub-criteria have been determined according to Serbian Public Procurement Law and in cooperation with experts from the Technical Department. Comparison of essential criteria, sub-criteria and bidders has been facilitated through Linguistic Importance Scale, while weighting has been performed by means of the FAHP method.

It is worth to mention that e-DSS platform is extensible, so new modules can be created and applied. Additionally, user could select which module (method) to use in which public e-procurement.

Further research will be directed towards the inclusion of other methods of the multi-attribute decision-making, such as fuzzy TOPSIS and fuzzy PROMETHEE into described e-DSS in order to get more precise results.

ACKNOWLEDGMENT

The authors would like to thank Sandro Radovanovic, Ph.D. student at Faculty of Organizational Sciences, for his contribution in developing described e-DSS, helpful comments and useful discussion regarding this research.

Abstract: *The field of the research of this paper is the analysis of concept of data mining methodology and possibilities of improvement of model of decision making. There will be presented the practical application and best practices of data mining methodology with overview to influence and benefits it brings to management of modern companies. There will be presented the benefits that the decision makers have by the use of models of decision making from the field of business intelligence. Research in this paper will be focused on importance and application of data mining methodology in business system. There will be described the model of application of business intelligence with the use of modern software architecture. The goal of the research is proving that data mining concept has strategic importance in increasing the effectiveness of decision making.*

Key words: *Data Mining, Decision Making, Knowledge.*

1. INTRODUCTION

Decision making is very important and complex function of management that demands the methods and techniques that simplify the process of choosing one of more alternatives. In modern business the challenge is finding the possibilities for improvement of decision making of managers. Managers' decisions directly affect the making of profit, business and positioning of company at the market, etc.

Business intelligence is very important field in the phenomenon of decision making. In modern business it is the challenge to analyze and find the possibilities for improvement of process of business intelligence, in order for overall improvement of business decision making. The paper will be presenting the business intelligence concept, its methods and techniques, as well as their influence to improving the model of decision making.

In order to support decision making in organizations in modern businesses, the most often the concept of business intelligence has been in use. Business intelligence is defined as the pull of information technologies, organization rules, as well as the knowledge and skills of the employed in organization that together generate, write, integrate and analyze data, with the goal to get to the knowledge needed for decision making. The goal of business intelligence is to give support to strategic planning.

2. BUSINESS INTELLIGENCE IN MODERN DECISION MAKING

Systems of business intelligence combine operational data with analytical tools in order to give the descriptive meaning to that data and to give to the manager competitive information. The term *Business Intelligence* has replaced the terms systems for decision making, executive information systems and management information systems. The concept of *Business Intelligence* has been defined as:

Systems of business intelligence combine techniques of collecting data, data warehousing and knowledge management with the help of analytical tools, in order to present the complex internal and competitive information to decision makers. (Negash, 2004).

Mission of application of business intelligence is to give support to strategic and operational planning. Its most often use is in management of performances inside company, optimization of relationships with users and creation of reports for management. With the help of techniques and methods of business intelligence, the data has been transferred to useful information, and with the help of analyses of skilled analytics, that useful information has been transferred to knowledge. Business intelligence has been used to understand the possibilities inside the company. The possibilities are modern tendencies, future market positioning and technologies. There are also the steps and behavior of competitive organizations analyzed. Business

Intelligence provides that complex data transfer to useful information that is presented as characteristic knowledge for decision makers. The goal is to improve the timeline and data quality during decision making. Business intelligence is the system made of technical and organizational elements that give its users useful information for analysis to make effective decision making and support to management, in order to improve the organizational performances (Isik et al. 2013). Business intelligence continues to be the priority in many organizations and possibilities that provide are useful and interesting to management of companies. Companies fight to use and make logical large amounts of data that generated externally and internally. Business intelligence has become key component to many companies, as well as the topic of research of many academic institutions. Possibilities of business intelligence are critical functions that help organizations to improve performances and adapt to changes.

Data mining (Suknović, Delibašić, 2010) is the scientific discipline that has the goal to reveal in data certain rules, models and rules based on decision can be made. Data mining are methods, techniques and algorithms from different fields such as statistics, mathematics, data bases and it has been provided for processing of large amounts of data. Rules and patterns that achieved in this way have been in use later for business decision making, generating new ideas and generally influence to competitiveness of systems. Data mining is the technology that puts together traditional methods for data analysis with sophisticated algorithms that process the large amounts of data and open possibilities for research and analysis of new types of data.

In the paper there will be presented the model of business intelligence applied into real problems of modern decision making. The goal of the presented model is the description and the pointing to importance and benefits of concept of business intelligence, its methods and techniques that has in customer relationship management. The goal of the model is the application of business intelligence for creation the headlines for management of companies, in order to increase the efficiency and effectiveness of process of decision making.

3. MODEL OF APPLICATION OF BUSINESS INTELLIGENCE BY THE USE OF MODERN SOFTWARE ARCHITECTURE

In the paper there is the model of application of business intelligence on real business problem of modern decision making by the use of modern software architecture. Software “Orange” presents very popular data mining tool that serves as help to managers in decision making process. Orange, as very convenient and user-friendly software, has numerous data mining options for data processing, such as creation of model, testing, data visualization, application of model, etc. One of the most important technologies of data mining is CRISP-DM methodology. This methodology consists of following phases:

1. Business understanding
2. Data understanding
3. Data transformation
4. Modeling
5. Evaluation
6. Deployment of model

Orange has options for each of this phase of CRISP-DM methodology. In the paper it has been described the example of business problem if the buyers with certain attributes are convenient or not for marketing and CRM activities of companies. It has been shown the preparation of data in order to create the successful model of classification of buyers if they are CRM convenient or not. There is the validation of the project solution, as well as its application in practice.

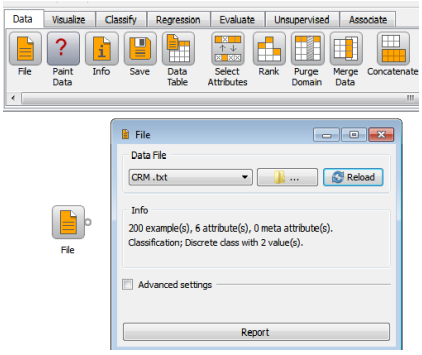

Figure 1: Desktop of Software Orange with Beginning Step of Data Input

On Figure 1 there is the desktop of Orange software. On toolbar there is the main menu with project functions. Application software Orange has numerous Data Mining functions: data processing, visualization, classification, evaluation, association rules. On desktop the input is the table consisting of data put to the node for further processing.

	Age	Sex	Income	Risk	Repurchasing rate	Complaints	CRM Convenient
1	23	F	HIGH	HIGH	0.792535	0.031258	yes
2	47	M	LOW	HIGH	0.739309	0.056468	yes
3	47	M	LOW	HIGH	0.697269	0.068944	yes
4	28	F	NORMAL	HIGH	0.563682	0.072289	yes
5	61	F	LOW	HIGH	0.559294	0.030998	yes
6	22	F	NORMAL	HIGH	0.676901	0.078647	yes
7	49	F	NORMAL	HIGH	0.789637	0.048518	yes

Figure 2: The Overview of the Table with Attributes of Buyers with Node Data Table

Business problem that will be presented is the data analysis about buyers by using the Data Mining methodology in order to get the most suitable solution in the field of customer relationship management. Therefore, it is needed to carefully process the data got by research about buyers attributes. On Figure 2, there is the part of the table with 6 attributes (age, sex, income, risk, repurchasing rate, complaints) where there are the 200 cases and none of the missing data. There are different data types, numerical and categorical. Output attribute has two values – *yes* and *no*. It has been analyzed if the buyers are convenient for companies' efforts in customer relationship management - CRM (yes) or not to continue the business communication (*no*).

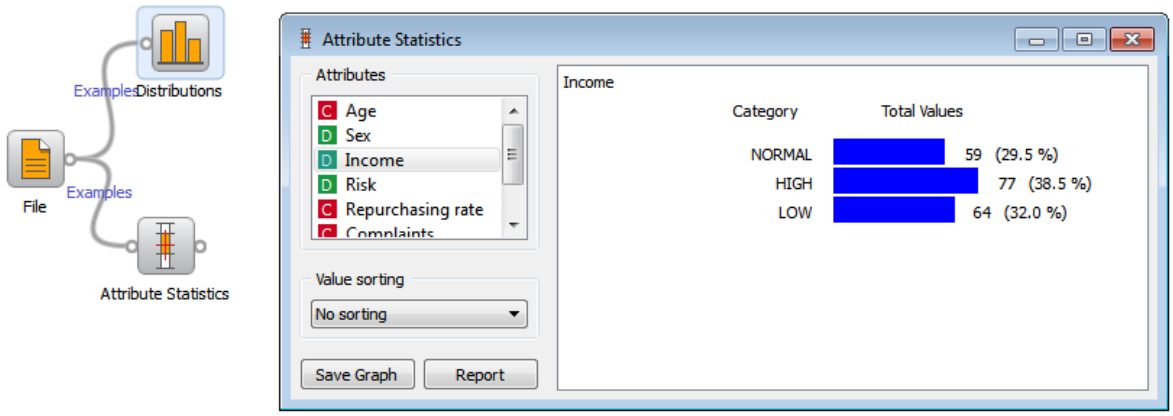

Figure 3: The Overview of Data Visualization

The Figure 3 shows the example of data visualization in Orange with the node *Attribute Statistics*. The user is getting the possibility of graphical overview of chosen attributes, in order to see the pattern. On the example the conclusion is that the biggest percentage of company's buyers (38.5%) has high income, than 32% follows with lower income and the least are buyers with normal (average) income. The conclusion is that there should be made different marketing and CRM activities that are later directed towards certain buyers' category. Data visualization can be successfully finished by node *Distributions*.

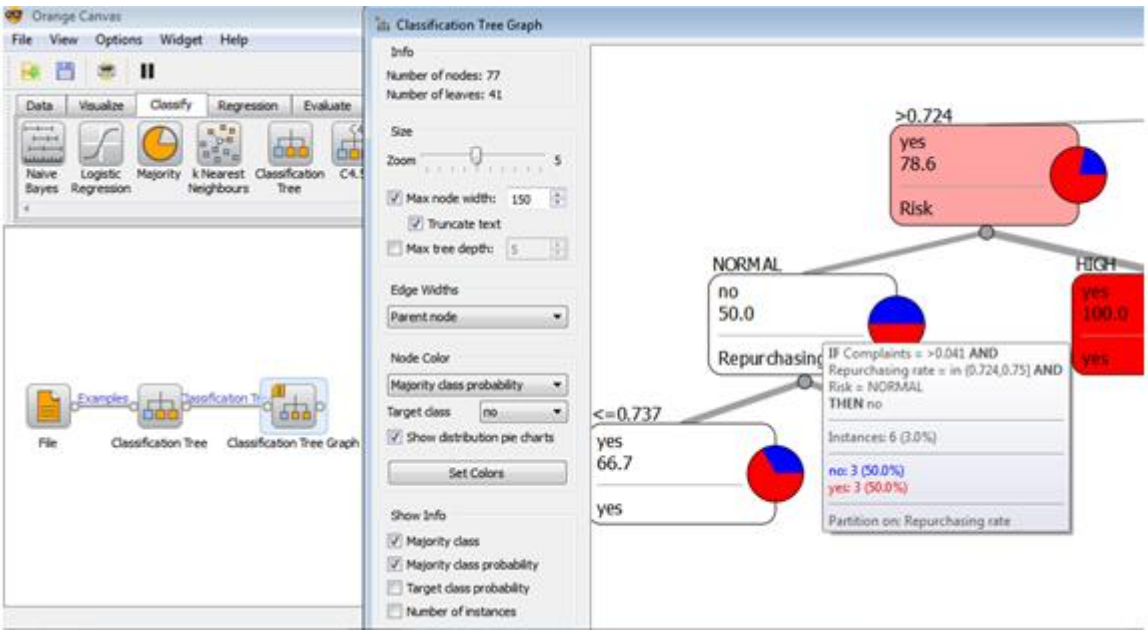

Figure 4: Generic Tree Graph

Classification problem is the problem of creating the way of classifying objects (cases) into right class. There are many algorithms for creating the classification model, and these are available through nodes of *Classify* group. One of the most popular and most precise way of classification in this program is through node *Classification Tree.* Data file should be connected to node Classification Tree, which is later connected to node Classification Tree Graph, in order to generate the classification tree. On this example there is the classification of input data given by research of buyers' attributes (age, sex, income, repurchasing rate and complaints). Data has been processed in order to get the outcome information about buyers' classes. Information about the buyers if they are CRM convenient or not, are in the outcome in created class. The goal is creating the knowledge should the companies invest in CRM and marketing activities towards certain buyers or not, depending on what class they belong to.

The model shows the path through the CRM convenience of buyers has been determined. Having CRM and marketing as very important segments of companies' budget, the presented model of business intelligence application can be of significance importance for savings and creation of the most suitable business solution that will maximize the profit.

If percentage of complaints is higher than 0.041% and repurchasing rate is 0.724 with normal risk, than the conclusion is that the buyer is not CRM convenient. However, certain limitation should be taken into account - the relationship with data from past was 50:50%.

Before using the model, it is recommended to validate its quality, in order to get the level of safety which can be applied. Process where the quality of model has been tested by using data is the validation. In order to complete the validation, node Test Learning has been used, that demands input training and test data, as well as the classification tree. Training data are those based on which the model of classification has been built, whereas test data are new data that check the quality of the model. Validation of built model of business intelligence applied to real business problem from field of CRM and marketing proves the higher level of safety in decision making.

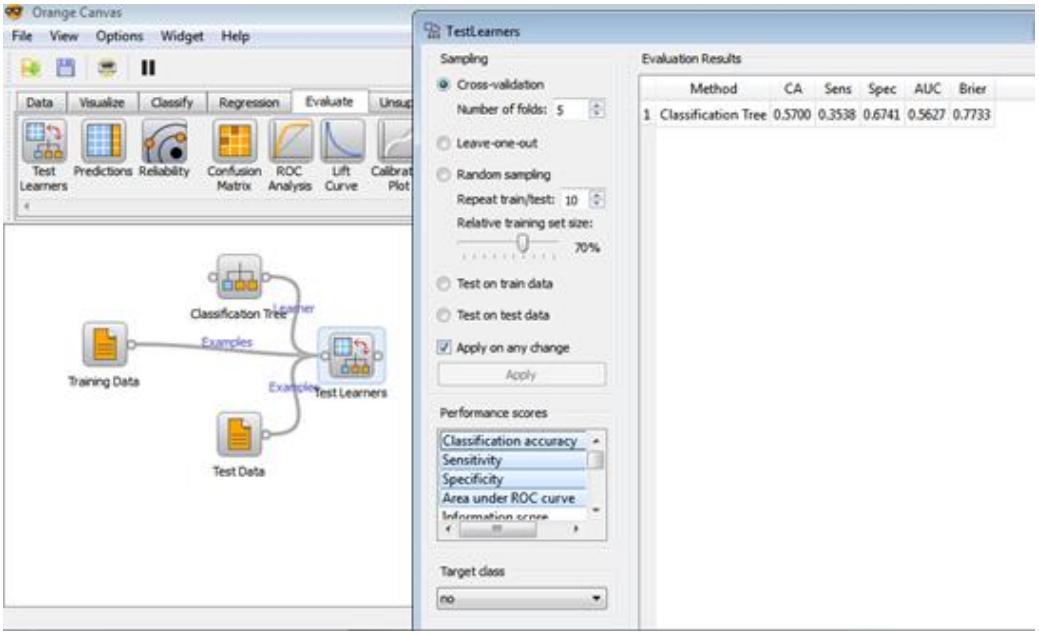

Figure 5: Validation of Model Quality with Node Test Learners

In lower left angle of dialog box Test Learners the user can specify what method to check the quality model (Classification Accuracy, Sensitivity, Specificity...). The most often used is the Classification Accuracy, which shows the accuracy of classification of 57%. When the accuracy is not satisfying, before the application of model there are corrections or creation of new model.

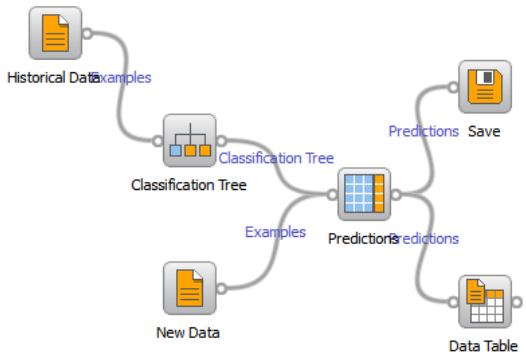

Figure 6: The Process of Function of Node Predictions
in Model Prediction

Classification model can be used in the future for prediction if future buyers based on attributes should have marketing and CRM efforts of the company or not. Furthermore, the node File that imports new data towards the node Predictions applying data mining in making patterns. At the end, the nodes Data Table for overview of given data and node Save for saving the same.

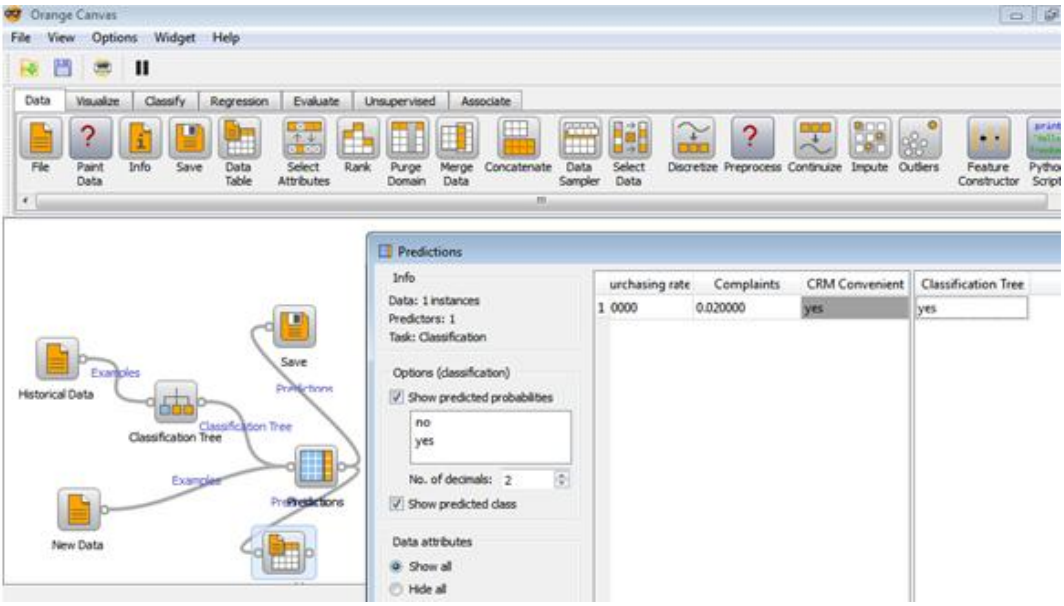

Figure 7: Model Application

On Figure 7, there is the application of classification model. For the buyer that has following attributes – age 43, female, normal income, risk normal, repurchasing rate 0.8, percentage of complaints 0.2, there is the conclusion of model that buyer is convenient for marketing and CRM activities of the company.

4. CONCLUSION

Business Intelligence concept has strategic importance for modern decision making. Data mining, very important and popular part of business intelligence, improves the effectiveness of decisions of managers in business system. Modern software architectures improve the finding of the most suitable solution of data mining methodology that has the application in different fields of business decision making: in marketing, customer relationship management, human resource management, etc. In the paper the model of business intelligence has been described that improved the quality and effectiveness of decision making management.

In order to be successful, data mining techniques need to become integral part of bigger business processes. Overall business strategies should be oriented to using the techniques of business intelligence. Increasing the effectiveness of decision making as complex process of getting the decisions that best fit certain criteria can be helped by the use of data mining techniques. Managers should have modern, interdisciplinary knowledge from the fields of information technologies, data mining and customer relationship management in order to get the most suitable business decisions for certain business challenges.

Abstract: *This paper analyses skier movement data on Mt. Kopaonik, Serbia, and identifies movement patterns using process mining and spectral clustering. Movement patterns allow ski resort management to improve organisation of the ski resort, as well as to examine the injury risk of each movement pattern, making it possible to distinguish safe and unsafe movement patterns on the mountain. In this paper we focus on identifying movement patterns and leave injury risk analysis for further research. For discovering patterns we use a recently proposed process mining methodology. We apply it on the analysis of the event logs of ski lift gates entrances. As skiers movements are highly diversified, a method for robust clustering methods was preferred. The process starts by calculating a similarity metric between traces generated from the event log. Afterwards, a robust estimator based on that metric is calculated, an affinity matrix is created, and a spectral clustering method is applied. Traces (movement patterns) were calculated for two skiing days. We used Adjusted mutual information (AMI) to identify movement patterns that are valid on both days. The most frequent skiing patterns, represented in the form of a process model are suitable for further quantitative and qualitative analysis.*

Keywords*: skiing, movement patterns, process mining, spectral clustering*

1. INTRODUCTION

The reasons for finding patterns in skiers' movement are numerous. Ski resorts can analyse frequent skier trajectories, detect bottlenecks, improve capacities of ski lifts; all resulting in increased level of security and end-user experience for skiers.

Every skier's entrance through the ski-lift gate is being recorded through RFID technology in a central database. The question is how to use this big data to discover knowledge? Currently there are only a few papers that analysed this kind of data (Kisser, Goethals, & Wrobel, 1996), (D'Urso & Massari, 2013)

Process mining is an emerging field that lies between data mining, computational intelligence and business process management. One of its primary activities is to discover processes hidden in event logs (Aalst, Process Mining Manifesto, 2012).

Discovery of movement patterns in this paper is based on clustering skiers' paths into previously unknown groups, so that cases would be highly similar one to another, compared within those groups, but as much as possible different, compared between the groups. The final result of this process is a discovery of common characteristics of skiers in those groups, represented in the form of a process model.

One extra problem, regarding this kind of data, is that these kinds of processes are highly diversified, and it is very difficult to choose which cases should be included in a distinct cluster as every one of them could be the cluster itself. Therefore, the most commonly used clustering methods and similarity measures do not provide satisfactory results if they are applied on raw data (Medeiros, et al., 2008). To overcome this problem, a robust similarity measure that was recently proposed in (Delias, Doumpos, Manolitzas, Grigoroudis, & Matsatsinis, May 2013) was used to pre-process the data for the spectral clustering. Other clustering approaches applied in process mining problems can be found in (Veiga & Ferreira, 2010), (Song, Günther, & Aalst, 2009), (Jung, Bae, & Liu, 2009), (Bose & Aalst, 2009), (Luengo & & Sepúlveda, 2012), however the method used in this work is preferred because it proposes a way to deal not only with high variability but with large number of unique paths as well and skiers' movements appear to be such a case. This highly diversified and chaotically connected kind of process, in process mining terminology is called a spaghetti-like process. As the volume of unique paths in this kind of data is very high, it was necessary to use robust methods for clustering. The illustration of a real process of skier movements is shown in Figure 1.

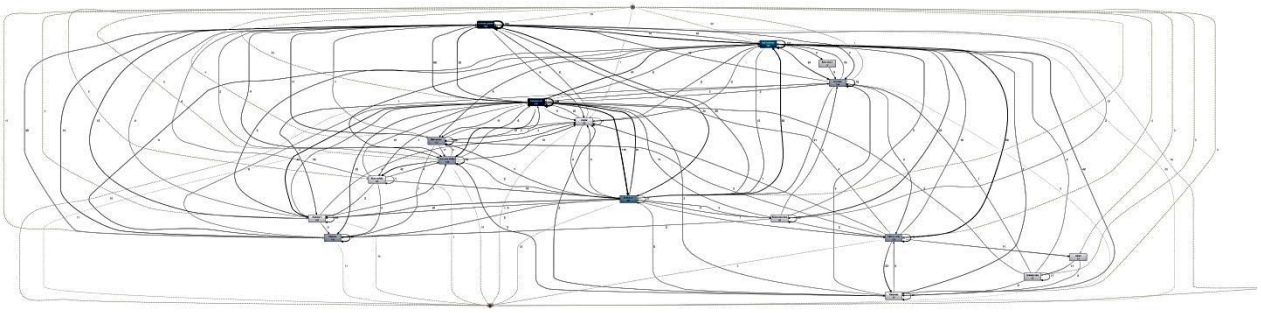

Figure 1: Real flow of skiers on the tracks – illustration of a spaghetti-like process, generated with Fluxicon Disco process mining software

About location and ski gates

Mt. Kopaonik is one of the largest mountains in Serbia, located in the central part of the country. Its highest point, Pančić's Peak, is 2017 m (6617 ft) above sea level. On average, 200 sunny and 160 days of natural snow coverage per year make Kopaonik the major ski resort of Serbia, with skiing season usually lasting from early December until late April, depending on the weather conditions.

It has total of 25 ski lifts with capacity of 32000 skiers per hour, equipped with RFID scanners collecting the data about skiers' pass.

Regarding Kopaonik's beautiful ski-tracks, there are 15 easy, 10 medium, and 7 difficult tracks, sorted by difficulty into three categories, respectively from easiest to the most difficult – Blue, Red, and Black. All tracks are connected one to another. Tracks "Karaman greben", "Pančićev vrh" and "Duboka" have installed systems for artificial snowing.Track "Malo jezero" is suitable for night skiing.

The map of the ski-tracks (figure 2):

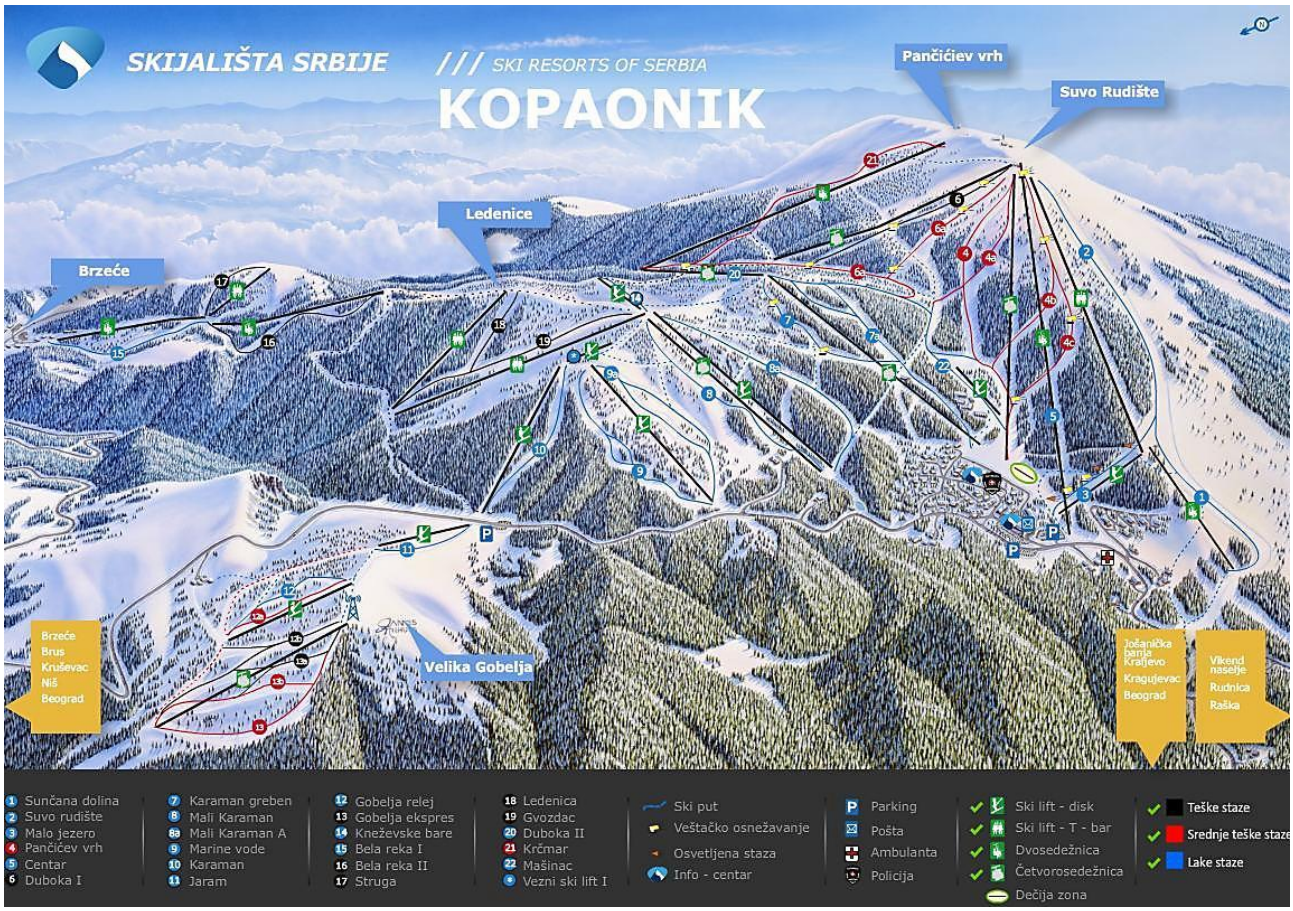

Figure 2: Map of ski-lift gates and slopes

2. METHODOLOGY

The methodology used in this paper was recently proposed by (Delias, Doumpos, Manolitzas, Grigoroudis, & Matsatsinis, May 2013), and consists of five steps. We added the last two steps in order to be able to compare skiing trajectories between different days. The steps are:

- Step 1: Creation of the Event log from the RFID ski-lift gate entrance scans
- Step 2: Creation of traces from the Event log
- Step 3: Calculation of cosine similarity of activities' and transitions' vectors
- Step 4: Calculation of the robust similarity matrix
- Step 5: Spectral clustering (through calculation of the eigenvectors and eigenvalues of the similarity matrix)
- Step 6: Using adjusted mutual index (AMI) calculation for analysing pairs of clusters on different days, and
- Step 7: Creation of the most representative cluster process model based on AMI analysis.

For the purpose of this paper, we have analysed two event logs for two representative, successive, skiing days, generated from ski-lift gate entrance RFID scans.

The process starts with data pre-processing. First, the Event log is being created transforming the data collected from RFID scans. The structure of this event log used for process mining is provided in Table 1. The Skier column/attribute represents an ID for the case in the process mining terminology, the Location attribute represents an Activity ID (node on the graph, ID of the track), and every row (instance) represents a single event. After grouping these rows by ID, ordered by timestamp, we get the whole case trace. Traces are vectors representing cases (skiers), and its components representing sequence of visited places (tracks). All these data are mandatory and minimum for process mining, although event logs could hold additional information for analysis of different perspectives (Aalst, Process Mining Manifesto, 2012).

Table 1: Structure of the Event log based on the data collected from the RFID scans

Skier	Location	Complete.Timestamp
341468	59	8:59:46
…	…	…

When traces are known, it is possible to calculate vector of frequencies of visited places (activities) and transitions (movement from location x to location y). This information is used in the next step to calculate similarity matrix of activities and transitions using cosine metric, which compares similarity of two vectors (Formula 1). These two similarities are later joined into overall similarity, where similarity of cases based on shared activities weights 40%, and similarity of cases based on transitions weights 60%. In this work, the weights are inferred arbitrarily, while a slight advantage is given to transitions similarity, because the activities set is rather small and is quite probable to have skiers visiting the same gates. Afterwards, the robust similarity is calculated using local densities concept (Chang & Yeung, 2008), so that outlier traces (low-frequent ones) could be more easily spotted and could avoid influencing the clustering process. However, we have to mention that even infrequent traces are clustered. The main idea is that if an object is surrounded with more objects, we should promote its chances to be grouped together with its neighbours. The measure used for estimating local density is given in Formula 3.

$$SIMactivities\ (Ti,Tj) = \frac{a(i)\cdot a(j)}{|a(i)||a(j)|}\frac{\sum_k a_k(i)\times\ a_k(j)}{\sqrt{\sum_k a_k(i)^2\times\ \sum_k a_k(j)^2}}$$

$$SIMtransitions(Ti,Tj) = \frac{a(i)\cdot a(j)}{|a(i)||a(j)|}\frac{\sum_k t_k(i)\times\ t_k(j)}{\sqrt{\sum_k t_k(i)^2\times\ \sum_k t_k(j)^2}} \quad (1)$$

$$s(Ti,Tj) = Sij = Wa\cdot SIMactivities(Ti,Tj) + Wt\cdot SIMtranstitions(Ti,Tj) \quad (2)$$

$$l_i = \sum_{j \in \aleph_i} S_{ij} \text{where } \aleph_i \text{ is neighborhood of an object i} \tag{3}$$

$$s'_{ij} = s_{ij} l_i l_j$$

After visualisation, we get the image of similarity of filtered data, represented by heatmap where cells coloured green represent the least similar cases, black coloured medium, and the red coloured the most similar cases. (Figure 3)

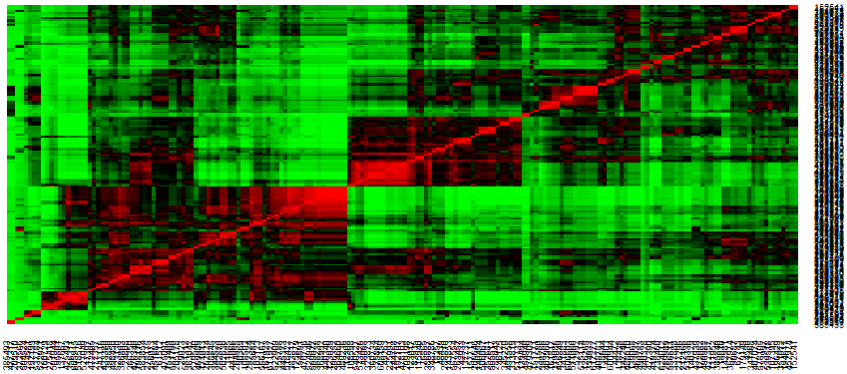

Figure 3: Heatmap representing cases similarity

The next step is to run spectral clustering. Spectral clustering is a methodology which analyses Laplacian matrix and finds its eigenvectors and their corresponding eigenvalues, so the dimensions of the space could be reduced to a lower dimension subspace which best represents a view on the data we are analysing. After this analysis, for chosen number of eigenvectors, k-means clustering algorithm was run with the same seed value, so the process could be fully repeatable. The concept of spectral clustering is similar to principal component analysis, as the idea is to find the variables which bring the highest information gain (highest variability) if used, although it is based on the graph theory, instead of covariance calculation (Luxburg, 2007).

In the next step, eigenvectors, and their values are being plotted to determine how many eigenvectors should be used to represent the data in the best possible way. The number of eigenvectors included in further analysis represents the number of dimensions of a new subspace. From Figure 4 and 5, which represents previously mentioned plot of eigenvectors and corresponding eigenvalues, it is still difficult to tell the best number of eigenvectors (clusters) to use, as there is no obvious cut-off point.

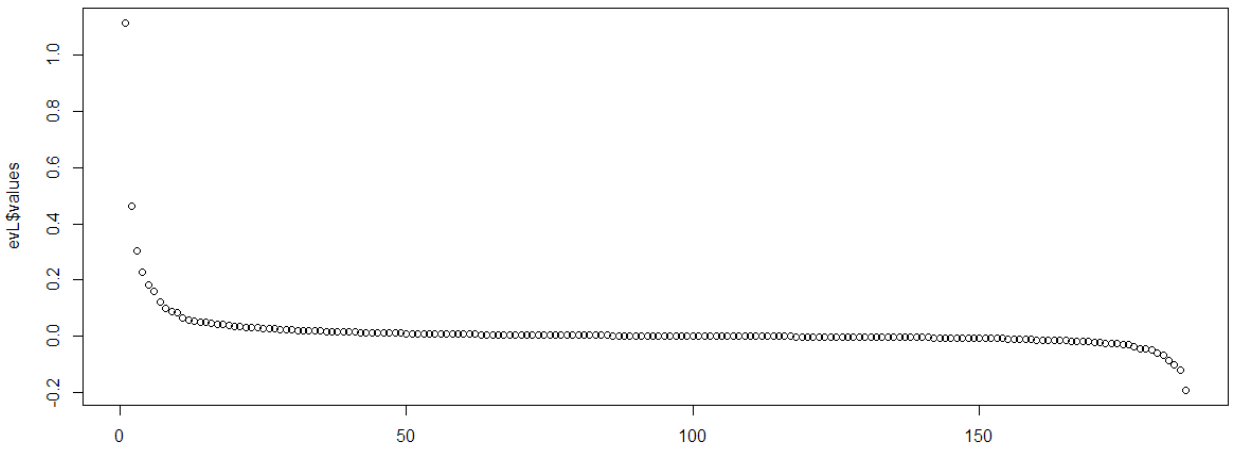

Figure 4: Eigenvectors and eigenvalues plot – all eigenvectors

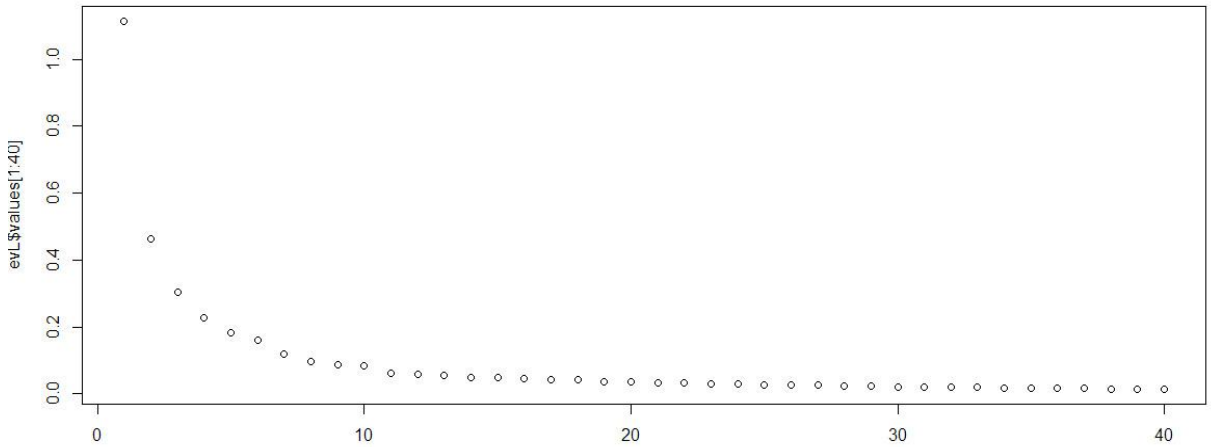

Figure 5: Eigenvectors and eigenvalues plot - first 40 eigenvectors

Therefore, we run k-means algorithm iteratively for clusters size 2 to 20, as 20 seems to be the theoretically best cut-off point, although practically may not be, and finally save the clustering results for each cluster size.

Once again, this process is repeated for the data regarding second day of analysis.

Having generated from 2 to 20 clusters for each day of analysis, we exclude the cases not contained in data for both days, for both groups of files containing information about clusters. Later on, we compare similarity of clusters using adjusted mutual index (AMI), which is based on combinatory measurement of clusters' similarity, and plot the results (Xuan Vihn, Epps, & Bailey, 2010). As it can be seen in Figure 6, the best representatives are cluster size cases where the AMI value is highest – scenario 1: two clusters, scenario 2: eight clusters. Therefore we generate process models for each of these cases

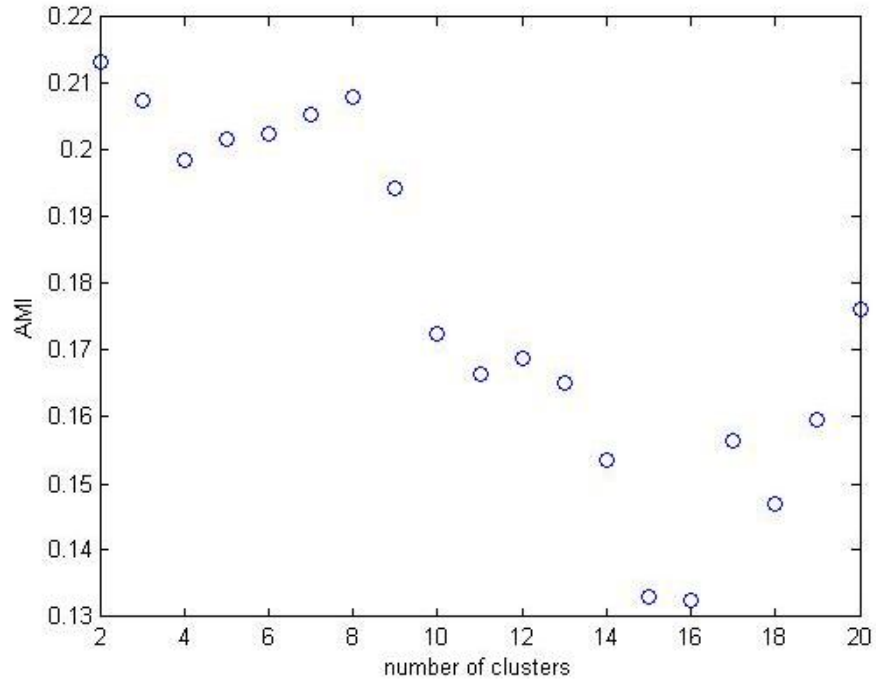

Figure 6: AMI graph

3. RESULTS

For scenario 1, where there are two clusters, we have obtained process models represented with Figure 7 and Figure 8. For the reason of better legibility, Figures 9 and 10 are also given. They represent the same models from Figure 7 and 8 but at the higher level of abstraction. We would like to stress that these figures are not generated with usage of any additional metrics or filtering cases, but with changing the level of details shown at the process map.

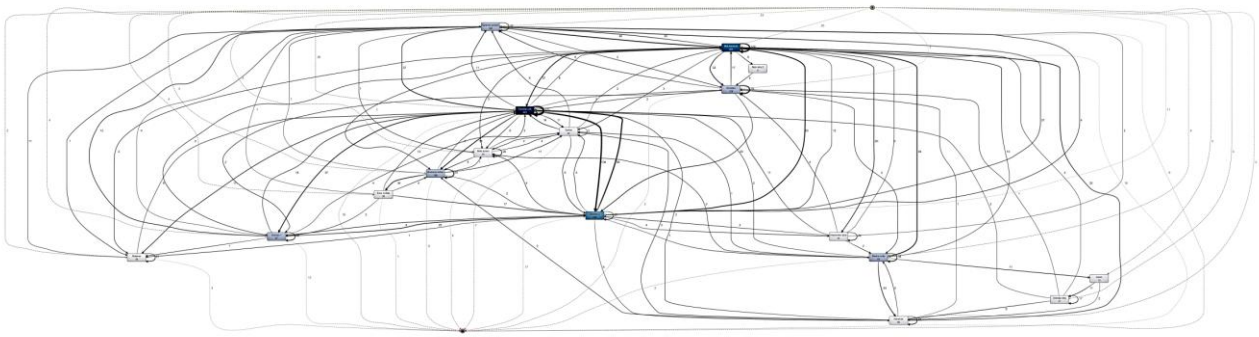

Figure 7: Full detail process map of Cluster 1 from Scenario 1, generated with Fluxicon Disco, 100% of activities, and 100% of paths visible

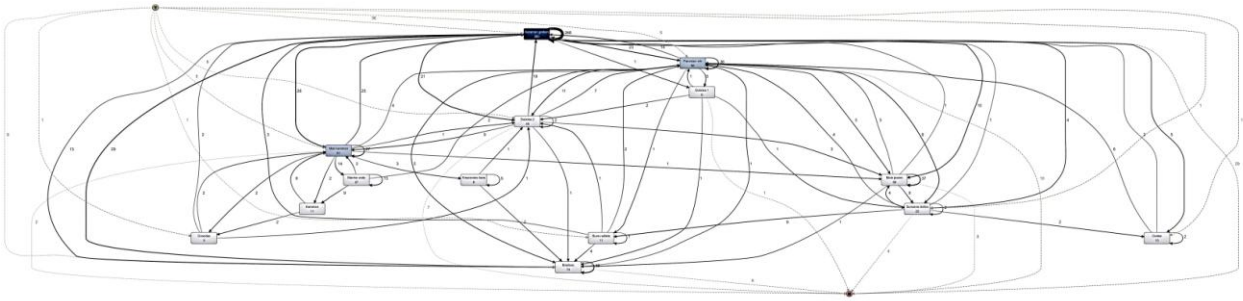

Figure 8: Full detail process map of Cluster 2 from Scenario 1, generated with Fluxicon Disco, 100% of activities, and 100% of paths visible

In cluster one (Figure 9), there are 63% of the cases (skiers), and they generate 69% of the events (passes through gates) in the Event Log.

In this cluster, it is noticeable that Ski-lifts (represented as nodes in Figure 9) “Pancicev vrh”, “Mali Karaman”, and “Duboka 2” are the most frequently used (in Figure 9 skiers’ pass frequency represented as arcs). Also, the biggest part of the skiers (30-50%, depending on the location) is using the same ski-lifts over and over again.

Some of the strongest patterns, besides previously mentioned loop-a-likes, are:

- Karaman greben ->Pančićev vrh
- Pančićev vrh ->Duboka 2
- Duboka 2 -> Mali Karaman
- Mali Karaman -> Marine vode
- Mali Karaman ->Kneževske bare

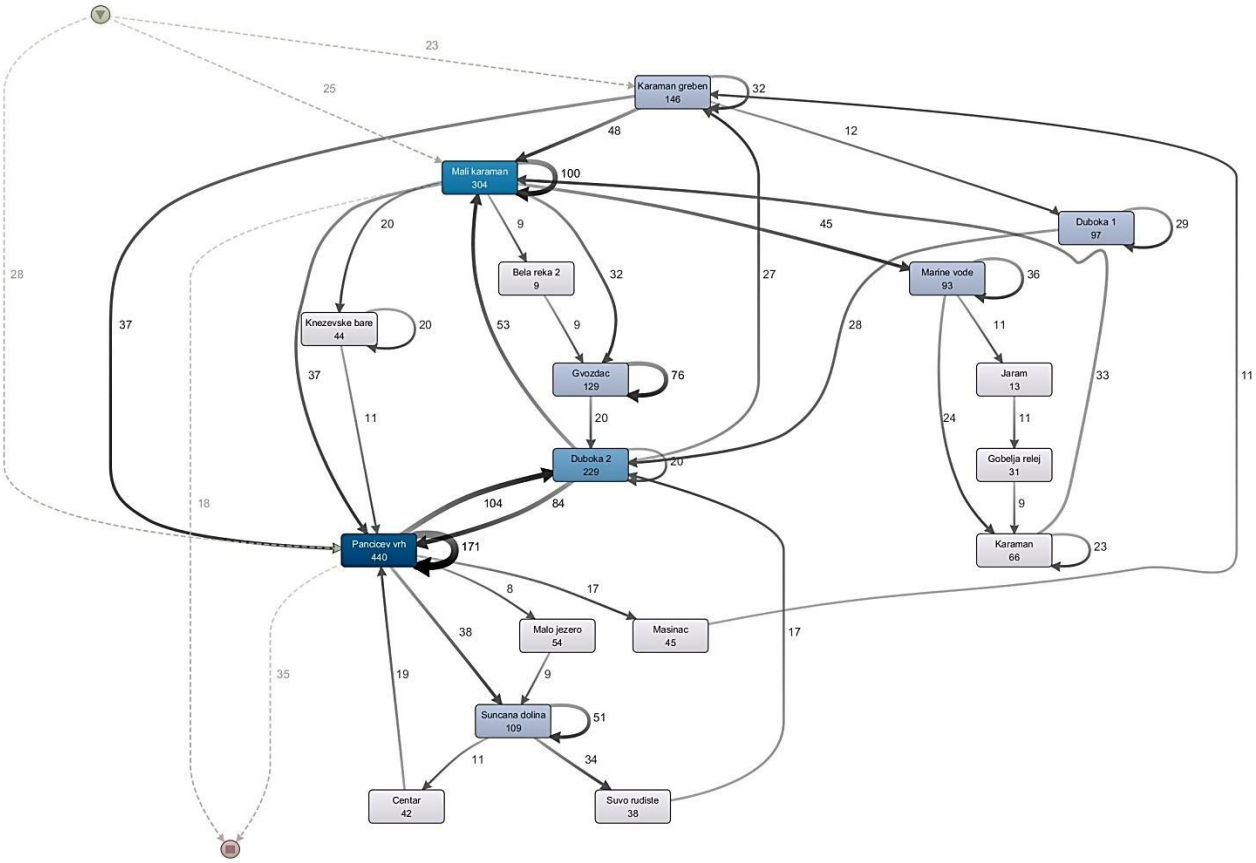

Figure 9: Higher level of abstraction of Cluster 1 from Scenario 1, generated with Fluxicon Disco, 100% of activities, and 20% of paths visible

In cluster two, 36% of the cases (skiers) generate 30% of the events (passes through gates) in the Event Log (Figure 10).

The most used ski-lifts in this cluster are Karaman greben, Pančićev vrh and Mali karaman.

Some of the strongest patterns discovered in this cluster are:

- 65% of skiers using Karaman greben ski-lift are returning over and over again
- 40% of skiers go from Masinac back to Karaman greben
- Karaman greben ->Karaman mali
- Karaman greben ->Pančićev vrh

The same kinds of models are generated for Scenario 2, but are left out due to space constraints.

As an illustration of capability for performance analysis of the process, figure 11 shows mean time skiers spend on paths, for cluster two. This kind of information is very useful for detecting bottle-necks. Figure 11 shows most popular paths (as time spent on them is noticeably longer than on others):

- Karaman greben -> Malo jezero (on average, skiers spend 6.3 hours on it)
- Karaman greben -> Centar (on average , skiers spend 9.4 hours on it)
- Knezevske bare -> Masinac (on average, skiers spend 5.8 hours on it)

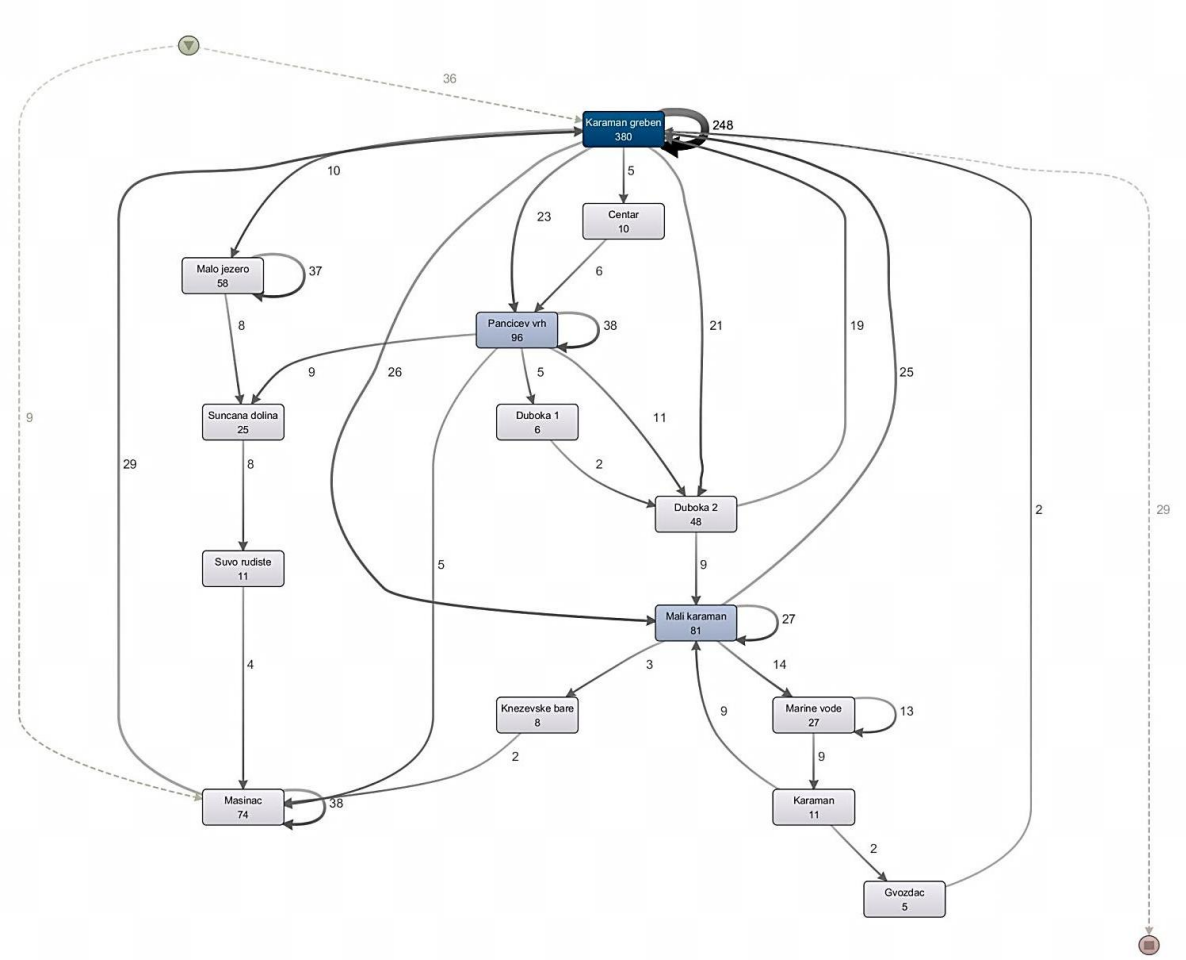

Figure 10: Higher level of abstraction of cluster 2 from scenario 1, generated with Fluxicon Disco, 100% of activities and 20% of paths visible

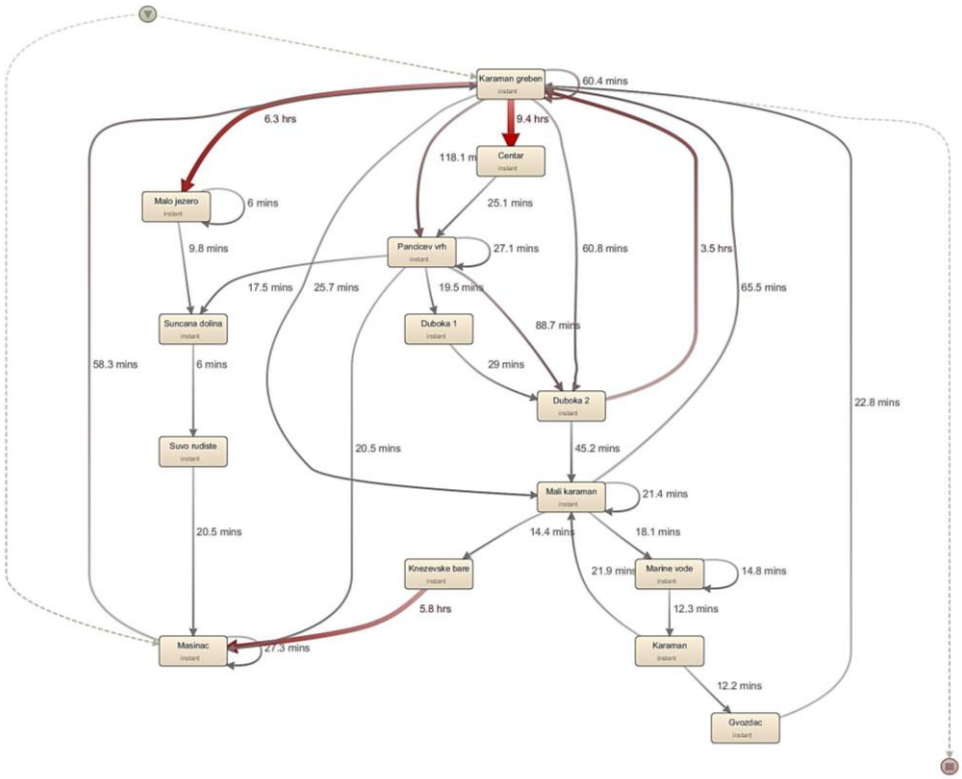

Figure 11: Average time spent on paths for cluster 2, scenario 1, generated with Fluxicon Disco, 100% of activities and 20% of paths visible.

4. CONCLUSION

In this paper we have analysed skier movement data on Mt. Kopaonik, Serbia, and have identified the most frequent movement patterns using a recently proposed spectral clustering process mining methodology which analyses event logs searching for underlying processes, supported with robust similarity metric for heterogeneous data filtering.

As there are only a few of papers analysing this kind of data, the results acquired are even more important from both theoretical and practical point of view, especially because analysing noisy data is in particular difficult from process mining perspective, due to fact that high variability in processes is caused by human behaviour, which is thereby often irrational and hard to understand or predict. Therefore, in such inconsistent and long-distance connected, spaghetti-like processes, it is very challenging for the most commonly used algorithms to discover suitable clusters, and additional data cleaning is necessary for successful analysis. The main advantage of using robust similarity metric for this task lies in fact that it is very easy to understand and implement, it is efficient, and its settings are highly customisable to a new instance of problem, which is very important due to fact that data are analysed on the daily basis which causes frequent changes in data.

Although using the movement patterns for examination of injury risk is not in the focus of this paper, as we have only focused on identifying movement patterns and left injury risk analysis for further research, it is a topic of uttermost importance for future extensions of this paper. The results of this paper are also suitable for further quantitative and qualitative analysis, as movement patterns allow ski resort management to improve organisation of the ski resort by analysing frequent skier trajectories, detecting bottlenecks, improving capacities of ski lifts; all resulting in increased level of security and end-user experience for skiers.

DATA ANALYSIS AND SALES PREDICTION IN RETAIL BUSINESS

Suzana Djukanovic[1], Milan Milic[2], Milos Vuckovic[3]
[1]Faculty of Organizational Sciences, University of Belgrade, Belgrade, Serbia
suzy.89@live.com, milicmil@gmail.com, mvuckovic70@yahoo.com

Abstract: *Sales drive the business. Sales forecasting helps in setting right objectives and making crucial strategic decisions. It is of the vital significance for a business both in short- and long term strategy. It is an effective marketing and management tool used to put consumer behavior into a predictable pattern, thus reducing various cost categories by creating intuitive campaigns and incentives to stimulate the sales in periods of low season and boost the sales when sales peaks are expected.*

In this paper the goal was to make predictions on sales volumes for retail chain Walmart. The dataset was derived from the Kaggle competition which is active until 05.05.2014. We propose a model for sales forecasting with a weighted mean absolute error (WMAE) in range between 3.455 and 25.546 which makes this paper ranked between 186th and 399th on the competition among more than 500 competetors. The model was derived using SVM algorithm, which showed the best result with least WMAE, comparing to other algorithms we tested (linear regression, Neural Net, W-lBk, k-NN).

Keywords: *Sales forecasting, trends, seasonality, exponential smoothing, data analysis, RapidMiner, SVM*

1. INTRODUCTION

For this competition Kaggle presented several datasets from Walmart, with a challenge to create a prediction system of weekly sales in retail departments, according to given set of historical data, parameters and key indicators.

Thorough data analysis showed that it is extremely difficult to make a proper prediction for this model. We have noted the presence of seasonality and discovered trends which vary from department to department. In this case, it turns out to be beneficial to use a smoothing process to compensate for the sharp discontinuities that will inevitably occur (Ian H. Witten, 2005). Each department's behavior is often different from behavior of its own store, and factors that affect the sales in stores, not necessarily have the same impact to a single department sales, thus imposing the need to put one more step in prediction process – taking into account some factors not previously defined in problem setting.

In section 2 we have examined the basic setting of the problem, datasets and main factors, detected the presence of various trends and dependencies, and implemented multiple research methodologies, including SVM validation in RapidMiner, program capable of many data mining tasks (Matthew North, 2012), LES method (linear exponential smoothing) in Excel, as well as a new model we proposed which tracks the cross-functional dependencies between sales trends of several factors respectively.

First algorithm we applied in RapidMiner for this case was Linear regression, which commonly delivers excellent accuracy. However, it is not applicable in this problem due to seasonality & trend presence.

Section 3 presents the results we got with chosen approach, explained the complexity of the problem and defined next steps to take.

2. EXPERIMENTAL DESIGN

In this section we explained the formula of WMAE presented in Kaggle competition and analysed the importance of several parameters in Walmart datasets. Next we tried to discover some trends in data and, finally, we presented the project we created in RapidMiner in order to achieve the desired objective.

2.1. EVALUATION

The main data is divided in two main tables: training table, with dataset consisting of 421.570 rows of data, and test data sample with evaluation on a part of test sample which is unknown.

Accuracy is evaluated by a formula for weighted mean absolute error (WMAE). We did not pick this formula, it was imposed by Kaggle as such. The formula includes number of records in a recordset of a single department and defines weight so that the week in which some holiday occurs has 5 times bigger weight than the ordinary week:

- *wi* are weights.
  (w = 5 for a holiday week, 1 otherwise)
- n is the number of rows
- $\hat{y}_i$ is the predicted sales
- *yi* is the actual sales

$$\text{WMAE} = \frac{1}{\sum w_i} \sum_{i=1}^{n} w_i |y_i - \hat{y}_i| \quad (1)$$

2.2. DATA

Data is presented as weekly sales per department. There are 45 stores in total, counting 99 departments in each store. This gives the total number of approximately 4.445 departments (there are some departments without sales data) to create individual sales forecast for.

Parameter set includes: 4 big national holidays in USA (Super Bowl, Labor Day, Thanksgiving Day, Christmas), promotional markdowns for 5 different product categories, store size and store size categorization, unemployment ratio, consumer price index, fuel price and air temperature. Column [weekly_sales] is given for each department of the store for a period from 05.02.2010 to 26.10.2012, and the main task is to predict the weekly sales for each department of each store for a period starting from 05.11.2012 until 26.07.2013.

The importance of holidays should be observed with caution, since for some holidays there is evident sales peek, while for other holidays there is no significant change in sales.

Values in markdown columns, representing the amounts of promotional discounts per store (not per department), are the real challenge, since their appearance seems to be random, and the data seems incomplete.

Other factors (store size, CPI, unemployment, fuel price and air temperature), show slight but stable changes in time. Fuel price actually presents the selling price of fuel within Walmart stores. It is valuable to know that selling boost in these retail stores always starts with „Black Friday“, Friday that comes few weeks before Thanksgiving Day (beginning of November), and this high seson in sales usually ends after Christmas. Similar situation is with Super Bowl (usually 6th week of the year), in which case the sales jumps week or two before the final game. These informations may further relativize the true weight of holidays.

2.3. TREND DETECTION

The observed dataset is considered in light with time series with seasonality, which will further help in choosing the proper methodology and algorithms. All tables with raw data are imported in Microsoft Access. Trend analysis is conducted in Microsoft Excel. For that purpose several new attributes are created in a form of derrived date fields which are supposed to shape and support trend analysis: week, month, quartal, year. We have created a relational model, connected stores, departments, holidays and weeks by ID, and cross joined primary tables in Access, in order to get comparable time series, as shown in Table 1. As we can see, data is not consistent, since some sales data in starting weeks of 2010 are missing. One possible solution was to crop the missing weeks and put the dataset in a range between weeks 6 and 43. In table 2 we observed the sales fluctuations during holidays.

Table 1 - Weekly sales by department

Dept	Week	Total	2010	2011	2012
1	1	16,567.69			16,567.69
1	2	32,878.64		15,984.24	16,894.40
1	3	35,724.80		17,359.70	18,365.10
1	4	35,719.63		17,341.47	18,378.16
1	5	41,971.67		18,461.18	23,510.49
1	6	83,578.75	24,924.50	21,665.76	36,988.49
1	7	137,986.76	46,039.49	37,887.17	54,060.10
1	8	108,565.64	41,595.55	46,845.87	20,124.22
1	9	58,880.40	19,403.54	19,363.83	20,113.03

Table 2 - Cumulative sales during holidays by departments

holidayName	Dept	2010	2011	2012
Christmas	96	609,498.66	589,757.47	
Christmas	97	517,062.60	516,222.42	
Christmas	98	220,397.35	259,031.46	
Christmas	99		6,460.01	
Labor Day	1	679,750.43	685,912.02	700,311.48
Labor Day	2	1,991,188.88	2,037,339.92	2,076,768.16

holidayName	Dept	2010	2011	2012
Labor Day	3	753,846.33	885,746.06	1,024,883.43

Since each store consists of 99 departments, it was interesting to examine if there is a trend present in this particular view. Figure 1 shows remarkable pattern in sales by same departments. Apparently, same departments have similar revenue levels:

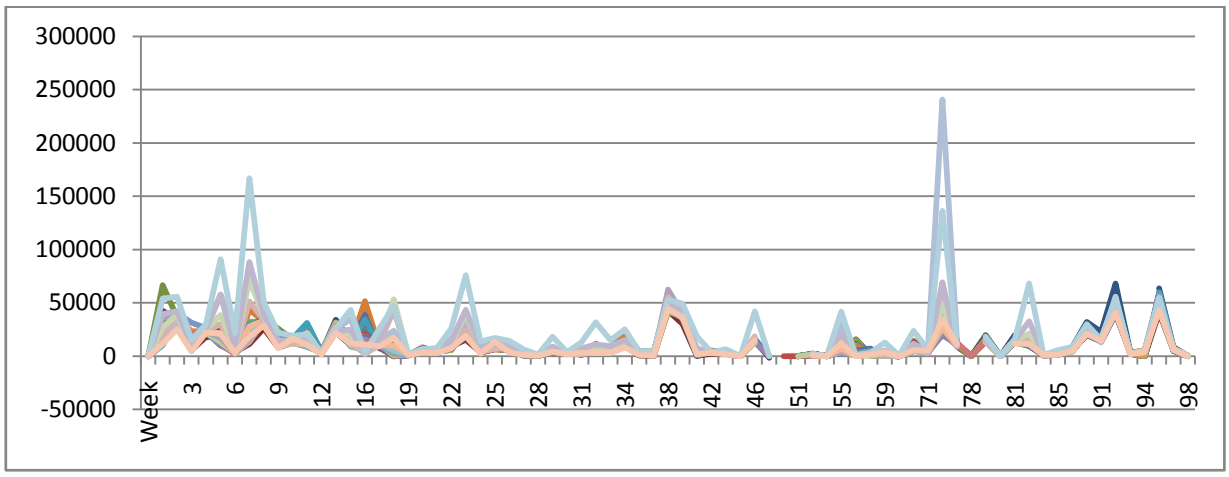

Figure 1 - Revenue trend for departments of all 45 stores

Table 3 shows annual changes in store revenues:

Table 3 - Cumulative sales in stores with % annual changes Y-2-Y

StoreID	2010	2011	2012	<> 2011	<> 2012
1	56,532,123	58,099,051	60,842,028	2.77%	4.85%
2	72,813,654	69,715,352	72,644,475	-4.26%	4.02%
3	14,218,013	14,715,512	16,118,525	3.50%	9.87%
4	72,380,275	78,634,279	82,674,554	8.64%	5.58%
5	11,315,820	11,649,619	12,647,859	2.95%	8.82%
6	58,946,026	57,201,270	59,437,292	-2.96%	3.79%

Figure 2 shows that there is no correlation in sales trends between departments of the same store whatsoever:

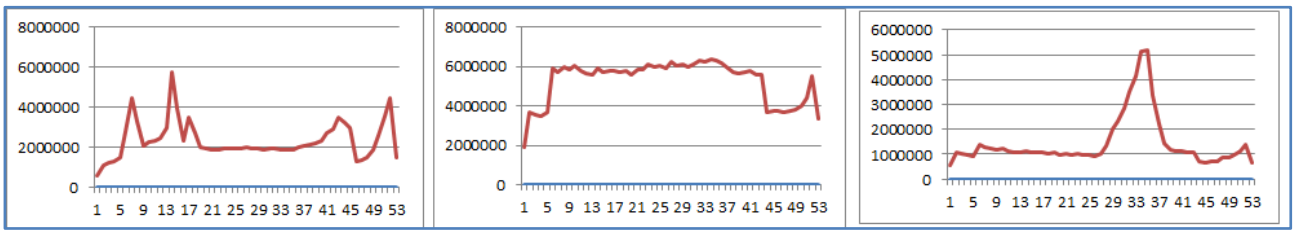

Figure 2 - Correlation existence analysis of sales in different departments within the same store

Figure 3 gives evidence of weekly sales correlation of same departments of different stores, and Figure 4 showes that this trend is being repeated in time, only with slight deviations.

Figure 5 brings the strongest evidence of trend existence. Each of 45 stores shows the same pattern in sales. Different behavior of store sales comparing to department sales adds to the complexity even more. To explain how complex problem really is, we managed to get prediction in RapidMiner only for a single store only (not for each department as originally required by Kaggle).

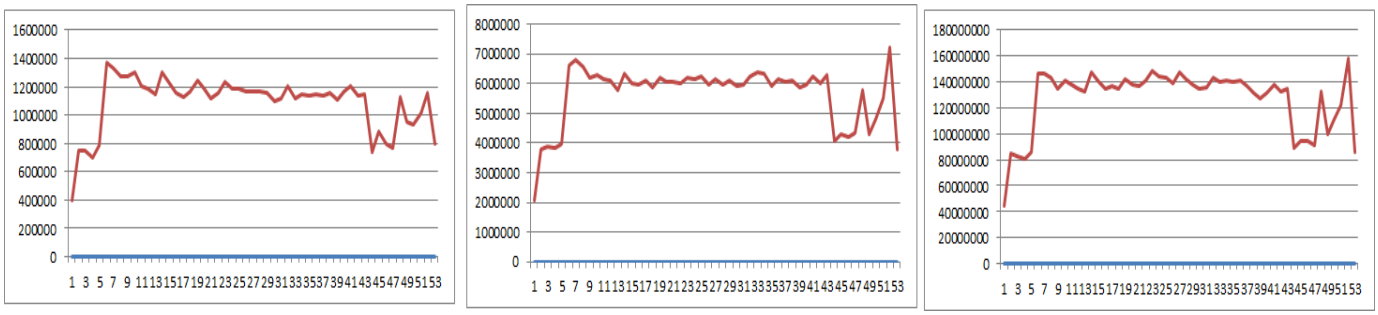

Figure 3 - Correlation existence analysis of weekly sales in stores 1, 2 and 3

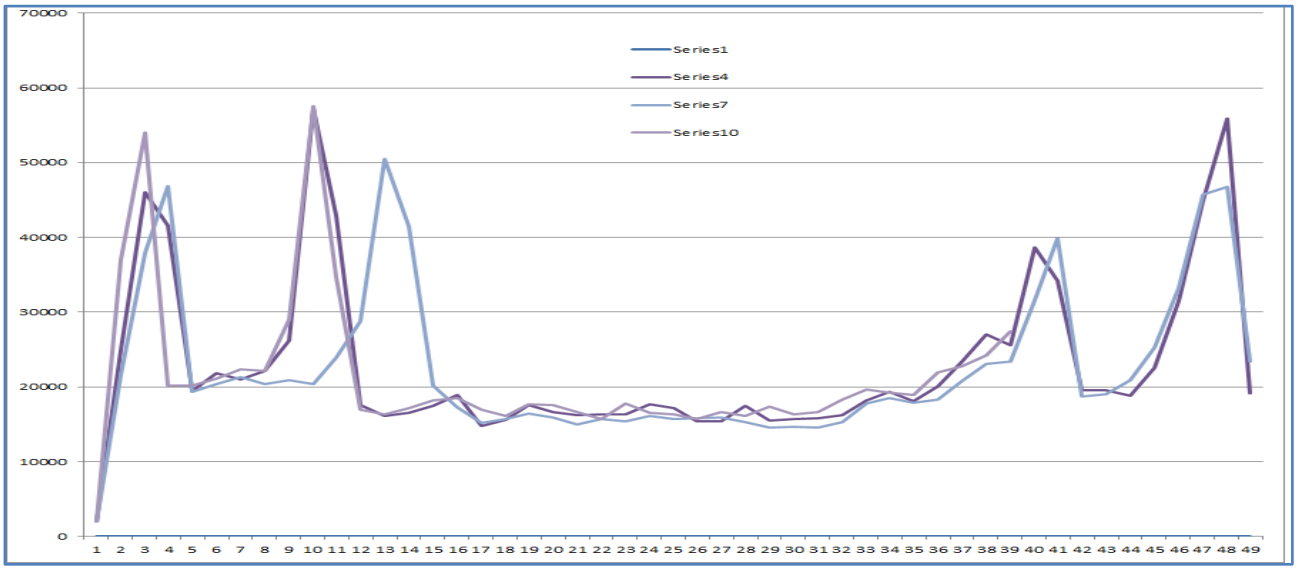

Figure 4 - Sales trend by weeks for a period 2010 - 2012 (weeks 6-43)

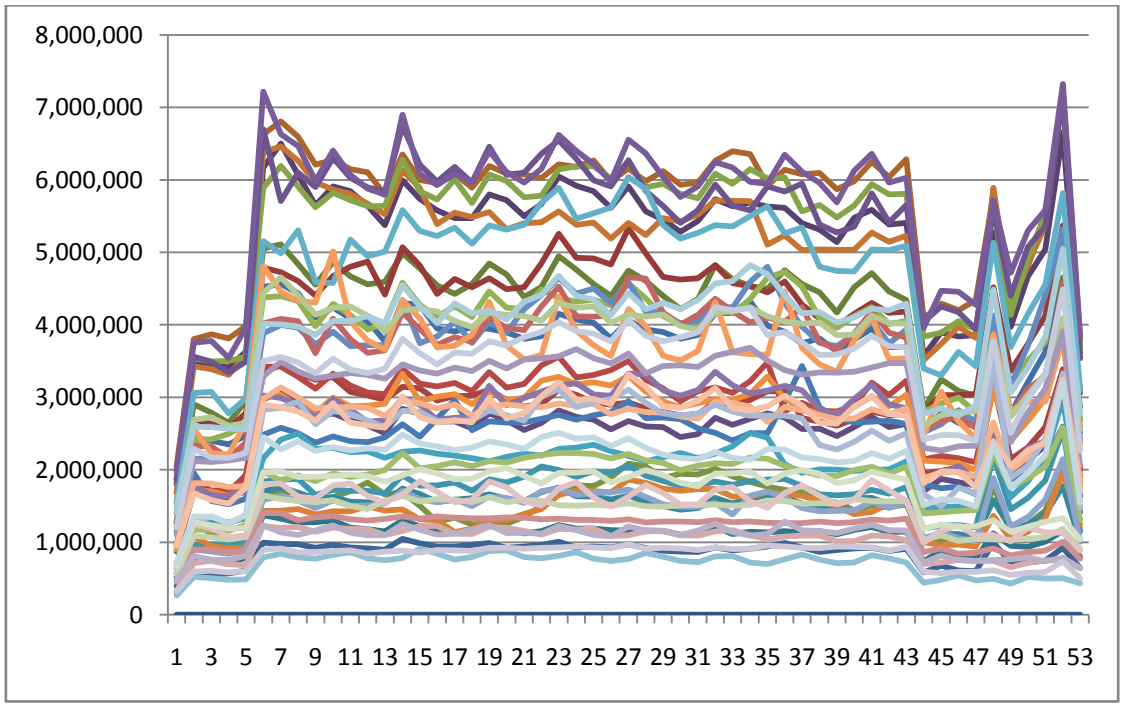

Figure 5 - General sales behavior in all stores

2.4. RESEARCH METHODOLOGY

Existence of time series with seasonallity combined with multifactor influence makes this problem complex in choosing a proper prediction methodology and algorithm. With regard to observations specified in previous chapter, we choose to test our work both in RapidMiner and in Excel. Unfortunately, due to the complexity of this problem, in Excel we did not include other factors except sales in time series.

2.4.1. MODELING IN RAPIDMINER

In modeling phase, we examined several methods to determine which model gives the best performance and least WMAE. Normalized data is processed in RapidMiner with following algorithms: SVM - support vector machine, linear regression, k-nn. In order to create a prediction model in RapidMiner, algorithm is trained with transformated data from file **TrainData.csv**, by implementing sigmoid kernel type.

Multiple error testing with SVM operator in RapidMiner showed the best results. Forecasting approach based on SVM model proves effective and feasible (Wu, Qi, 2009).

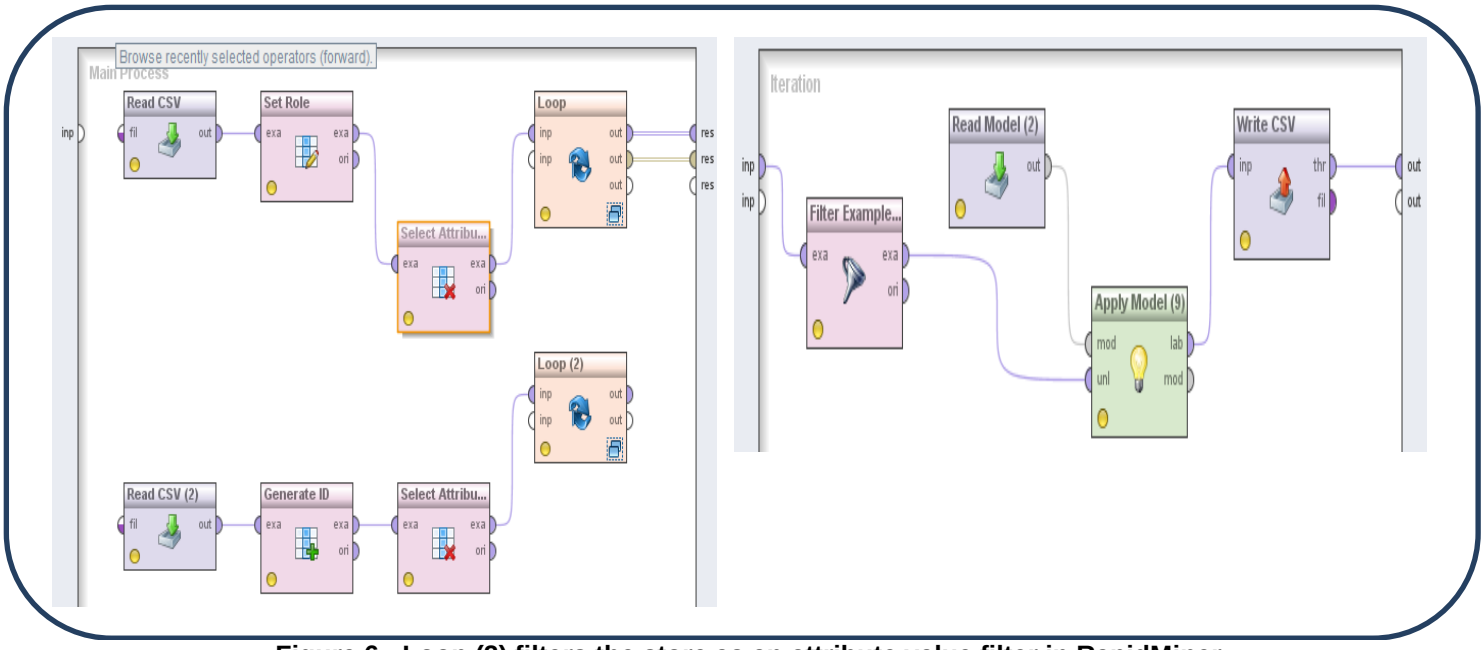

Figure 6 - Loop (2) filters the store as an attribute value filter in RapidMiner

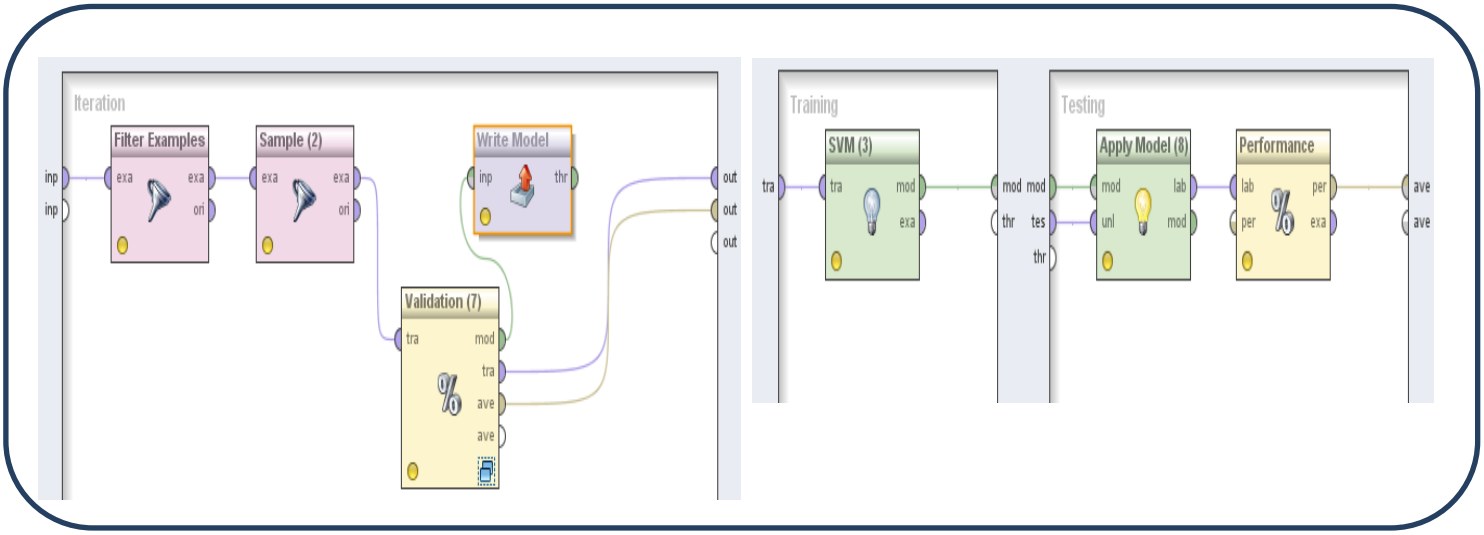

Figure 7 - Loop filters the store as an attribute value filter with 0.4 sample ratio, validated by SVM operator

As shown in figure 7, by using iteration macro, algorithm iterates 45 times, passes each store separately, and validates the model 10 times. To secure model to get through each store, we have put a filter example set by ID attribute value [store]. After each iteration, the model is saved at the store level. We have

tested the algorithm with data from file **TestData.csv**, by reading each model respectively. Finally, we saved the results of prediction in resulting **csv** file.

2.4.2. MODELING IN EXCEL

We have also examined various methods for implementation in Excel: moving average, linear approximation, least square regression, second degree approximation, flexible method, weighted moving average, linear smoothing, exponential smoothing, exponential smoothing with trend and seasonality.

Based on multiple testing and preliminary results, we decided to create several models: LES (linear exponential smoothing), seasonality moving averages, and multifactor dependency equation.

LES requires the number of periods best fit plus two years of sales data, and is useful for items that have both trend and seasonality in the forecast. You can enter the alpha and beta factor, or have the system calculate them. Alpha and beta factors are the smoothing constant that the system uses to calculate the smoothed average for the general level or magnitude of sales (alpha) and the trend component of the forecast (beta). (JD Edwards, 2013).

To get results with LES algorithm, we have ignored sales data for 2012 to create LES model based on two previous years only, 2010 and 2011. Then we compared results for 2012 proposed by LES, with actual sales. To implement LES, we have inserted moving average and divided it with sales value in order to get seasonality ratio for each week. Then by using denormalized and again normalized seasonality index we tried to make adjustment necessary to calculate LES formula which includes Alpha constant (Table 4).

Table 4 - Linear exponential smoothing with seasonality adjustment and alpha constant

Week	Year	Sales	Trend Mov.avg	Seasonal. ratio	Seas.idx	Seas.adj.	Irregular	LES Forecast	LES Error	Reseason. forecast		Alpha	RMSE		Denorm. seas.index	Normaliz. seas.index

Next model we examined is Moving average with seasonality adjustment. At first, we have calculated the seasonality factor by comparing each week sales with average sales for a given period between 2010 and 2012. Afterwards we implemented desasonality calculation for each repeating week in a period. Then we used Excel Forecast function which includes trend detection with prediction. Such result is finally used to take seasonality back in the model and to fine tune the prediction (Table 5).

Table 5 - Moving average with seasonality

Time	Week	Year	Sales	Week	1 Factor	2 Deseas	3 Forecast	4 Reseas		2010	2011	2012	2013	
1	6	2010	21,084.08	6	0.96	21,884	20,936	20,170	1	21,084	17,240	21,619	20,170	-6.70%

The final step in Excel prediction efforts is model we have created and named Multifactor Dependency equation. We have conducted the same methodology of cutting 2012 data to make prediction based on 2010 and 2011 sales and to eventually compare the results with actual 2012 sales.

We presumed that, in this particular case, sales has its various dimensions in time series. In other words, it can be viewed from different perspectives as percentage in sale change – by year, company, store, department, week, previous year, year before previous year, etc. Assuming that each dimension has its impact to the actual sales, we used some of them to create weights, namely importance factors as a

percentage of total sales factors (for example, we presumed that company sales trend has impact of 10% to the total department sales, store sales 20%, etc.), as shown in Table 6.

Table 6 - Multifactor dependency equation as a combination of single factor changes in time as weights in %

3. RESULTS

3.1 RAPIDMINER RESULTS

With lack of time to create the accurate prediction set for more than 4.400 individual data entities respectively (which is now more technical than methodological challenge), we have managed to get with SVM operator an error within range from 3.455 and 25.546, over a store, and not over departments.

Since the competition is still underway (ends on 5th May), with more than 500 teams competing at the moment, first team on the leaderboard scores 2.421. Our best projected WMAE score of 3.455 at the moment brings us at 186th place, with a note that this result has a big range deviation from 3.455 to 25.546.

3.2 EXCEL RESULTS

In Excel we have achieved results with different models based on week sales for a single department, as requested by Kaggle. However, we did not have enough time to process sufficient number of iterations before getting stable results, neither to check our prediction values with WMAE formulation.

By setting a different strategy, we made independent 2012 forecast and compared such 2012 sales prediction with real 2012 sales values. Results of weekly sales forecast by departments with three different methods showed following deviation from the real 2012 data:

- LES - 3.61%
- Multifactor dependency equation - 4.61%
- Moving average - 5.56%

4. CONCLUSION

After numerous attempts to get accurate predictions through RapidMiner and Excel with dozens of different algorithms, we concluded that RapidMiner provides best result with SVM algorithm, while in Excel models we have examined, we could only calculate deviations in prediction comparing to the actual data.

In both cases, data understanding is the key of picking the right implementation methodlogy. The complexity of this particular project has intensified the challenge we are facing. After carefully reviewing all aspects of data behavior, results we got upon various algorihms chosen are just the base for our future endeavours to make our predictive models even more accurate.

In general, plan is to divide data to smaller fractions at certain criteria (by departments, by seasonal periods, by holidays, etc.) and then to run numerous iterations to get the numbers in our sample stable enough to submit the final results to Kaggle.

Furthermore, since we started with a very small portion of a sample, and in this case only few iteration are processed respectively, we expect to get far more better results in days to come.

ACADEMIC DASHBOARD FOR TRACKING STUDENTS' EFFICIENCY

Sonja Išljamović[1], Srđan Lalić[2]
[1]Faculty of Organizational Sciences, University of Belgrade, sonjaisljamovic@gmail.com
[2] Statistical Office of the Republic of Serbia, srdjan.lalic@stat.gov.rs.

Abstract:*The use of modern technological resources and teaching aids, as well as the adjustment of teaching content to students, in order to achieve better results in the adoption and application of knowledge, may represent a good basis for the development of contemporary concepts of education in the 21st century. In order to achieve this, it is necessary to detect, define and analyze existing patterns of behavior and students' learning. Today, there are a large number of software products for facilitating and improving the quality of learning. Computer applications in education system introduce unique technical, managerial and most importantly pedagogical issues. Using business discovery platform QlikView, application developed in this research, should be beneficial to both, students and professors at the university. Application allows academic staff to identify good students and students who need additional tutoring, analyze current study success and make strategy for further curriculum development.The relation database model is based on data collected from student admission service of Faculty of Organizational Science, University of Belgrade.*

Keywords*:knowledge-based application, educational data mining, higher education*

1. INTRODUCTION

Education, and in particular higher education, is at the heart of the Europe 2020 Strategy and of Europe's ambition to become a smart, sustainable and inclusive economy: it plays a crucial role in individual and social advancement; and, with its impact on innovation and research, it provides the highly skilled human capital that knowledge-based economies need to generate growth and prosperity.Globalization and technological development are radically changing the landscape of higher education. While world economies push for stronger competitiveness, creating and attracting top talent represent one of central objectives of world-renowned higher education institutions.

Higher educational institutions are important parts of our society and playing a vital role for growth and development of nation and prediction of student's performance in educational environments is also important as well. Student's academic performance is based upon various factors like personal, social, psychological etc. Educational data mining concerns with developing methods for discovering knowledge from data, that comes from educational domain. The Data Mining tool has accepted as a decision making tool which is able to facilitate better resource utilization in terms of students performance.Many higher education institutions are committed to increase the quality of their courses to attract and retain the very best students. For propose of this paper a student data from Faculty of Organizational Sciences, University of Belgrade has been taken and some of educational data mining methods have been performed, in order to extract useful information from available data set and providing analytical tool to view. The result of study is aimed to develop an interactive data mining so that present education system may adopt this as a strategic management tool.

In this paper, the introductory part will present related works and background of the methodology in area of educational data mining software. The basic concepts of QlikView software platform and developed Academic Dashboard for Faculty of Organizational Sciences will be presented in the central part of the paper. The final part of the paper defines the guidelines for further development and adaptation of higher education system to the necessities of a student.

2. METHODOLGY AND TECHNOLOGY BACKROUND

Data mining in the field of education (Educational Data Mining - EDM), as a new field of research, has developed in the last decade as a special area of application techniques and tools for detecting regularities and correlations in the data (data mining), with the aim of analyzing the unique data types that appear in educational system for solving various problems of educational and instructional improvement process

(Romero & Ventura, 2007; Romero & Ventura, 2011). Educational data mining (EDM) is an interesting research area which extracts useful, previously unknown patterns from educational database for better understanding, improved educational performance and assessment of the student learning process (Moucary, 2011). EDM is engaged in development, research and application of methods to detect regularities in the data in the database in the field of education, which would otherwise be difficult or almost impossible to analyze and determine the dependency patterns of behavior and learning among students, primarily because of the large amount of data (Romero et al., 2006). Reasons of good or bad students' performances belong to the main interests of teachers and professors, because they can plan and customize their teaching program, based on the feedback. EDM could be used to improve business intelligence process including education system to enhance the efficacy and overall efficiency by optimally utilizing the resources available. The performance, success of students in the examination as well as their overall personality development could be exponentially accelerated by thoroughly utilizing data mining technique to evaluate their admission academic performance and finally the placement (Agarwal et al., 2012).

Data mining has several tasks such as association rule mining, classification and prediction, and clustering. Classification is one of the most useful techniques in data mining to build classification models from an input data set. The used classification techniques commonly build models that are used to predict future data trends. EDM consists of a set of techniques that can be used to extract relevant and interesting knowledge from data. Traditionally, academic researchers have used statistic models and methods in order to predict the success of the students. Today, there are many different approaches about classifying the students and predicting their success, such as linear regression, cluster algorithms, decision trees artificial neural networks, (Wook et al., 2009; Guo, 2010; Stathacopoulou et al., 2007; Wu et al., 2008; Isljamovic et al., 2012). For development of all mentioned data mining methods and model is need adequate software support, in whole process form collecting data to result visualization.

Technological development has provided base for developing software with new functionality. Teaching process records constant improvements through the use of ICT (Arenas-Marquez et al, 2012). Nowadays, providing students with services they expect is more challenging than ever before. Some of those services are ability to track current students' achievements and results, planning next semester, conducting optimal selection of exams based on preferences and results, operational planning, like attending colloquia, exams, participations in projects and practices etc. Also, that kind of software is attended for professors in order to track effectiveness of students (individually, by teams or by generation) and for planning and adapting curriculums in order to meet future interest of students, (Coll et al., 2008). Software scope and architecture may vary and below is an overview of the most significant solutions.

The first group of software represents large commercial software solutions which integrate data collection, ETL process and results representation. IBM company provides personalized software package SPSS for students and teachers. This software integrates different types of data analysis, data mining trend research and quantitative methods for measuring efficiency. As well, IBM developed SPSS Clementine (Clementine, 2014)which represents specialized software for data mining. SAP offers solution to support the work of students and teachers. Integral parts of this software are: Student Lifecycle Management, Teaching and Learning, Learner achievement Measurement and Tracking and Educational Performance Analytics (SAP). This software is a feature-rich, both for the students' and teachers' work. Student can plan and monitor present liabilities in the current semester, but also software allows professors to plan classes and the necessary resources (personnel, classrooms, technical resources), to monitor the presence of students (status of their obligations, progress, rating), to define grade scale, to evaluate test in-time and to send test results to students, to propose future courses based on interest of students, to optimize study process and to carry out large number of statistical analyzes.Microsoft offers multiple solutions to support students and teachers by personalizing product from the Dynamics family or using dedicated software like: Communication and Collaboration, Device Management, Web Portals, E-learning and Tracking Institutional effectiveness for Higher Education. These software solutions allow quick and easy connection and communication between students and teachers through various types of devices, easy scheduling obligations both students and teachers in accordance with number of registered students, retention of various records. Using this software, teachers can easily perform different analysis, support online teaching, testing and decision-making.

In the second group, of public domain data mining tools exist variety solutions such asWeka(Weka, 2014) andRapidMiner (RapidMiner, 2014). All these tools are not specifically designed for pedagogical/educational purposes and it is cumbersome for an educator to use these tools which are normally designed more for power and flexibility than for simplicity. However, there are also an increasing number of mining tools specifically oriented to educational data such as: Mining tool (Zaïane and Luo, 2001) for association and pattern mining, MultiStar (Silva and Vieira, 2002) for association and classification, KAON (Tane et al., 2004) for clustering and text mining, Synergo/ColAT (Avouris et al., 2005) for statistics and visualization, Listen tool

(Mostow et al., 2005) for visualization and browsing, Sequential Mining tool (Romero et al., 2006) for pattern mining, Simulog(Bravo and Ortigosa, 2006) for looking for unexpected behavioral pattern. All these tools are oriented to be used by a single instructor or course administrator in order to discover useful knowledge from their own courses. So, they don't allow a collaborative usage in order to share all the discovered information between other instructors of similar courses (contents, subjects, marks). In this way, the information discovered locally by teachers could be joined and stored in a common repository of knowledge available for all instructors for solving similar detected problems.

In this paper, we describe an educational data mining tool based on association rule mining and collaborative filtering for the continuous improvement curriculums and it directed to teachers non experts in data mining. The main objective is to make a mining tool in which the information discovered can be shared and scored between different instructors and experts in education. This paper will present custom developed applications based on both existing data, collected from student admission service of Faculty of Organizational Science (University of Belgrade) and the required functionality. Technology used for this solution is QlikView.

3. QLIKVIEW TECHNOLOGY STRUCTURE OF DATA MODEL

QlikView represents new patented software engine, which compresses data and holds it in memory, where it is available for immediate exploration by multiple users. QlikView delivers an associative experience across all the data used for analysis, regardless of where it is stored, (Harmsen, 2012). For datasets too large to fit in memory, QlikView connects directly to the data source and generates new views of data on the fly. QlikView's patented core technology, associative experience, and collaboration and mobile capabilities, make able to work with a lot of questions, passing by traditional hierarchical models, with created an associative network which works similar to human brain. Empowering the information workforce to derive insights from data helps organizations streamline, simplify, and optimize decision making, (Harmsen, 2012).

In primary frontend-backend architecture, on which is based QlikView solution, as data layer (Infrastructure resource) will be used relational database to record data on students of the Faculty of Organizational Sciences. Using OLDB connections, QlikView server will establish communication with the database with students data within specific time intervals (monthly level or after completion of the exam period). Once the connection between QlikView and elementary student database is established, the application will use the Associative Query Language (AQL) to download data from the relevant tables, necessary for the operating and usage, and after that it will be stored in its own memory. In addition to downloading data, backend part of application will be provided with ability to define application logic, rules for establishing a link between the data (in accordance with already defined relational model), as well as methods and privileges for using the application. Within the frontend, according to the rights they have, each user will be able to access the application and review it available reports and data.

Similar to QlikView usage in public or private sector, we developed QlikView Academic Dashboard for Faculty of Organizational Sciences, University of Belgrade, in order to help educational professionals and students to maximize data governance and optimize their intellectual investments by discovering how QlikView is used at a granular level in educational sector. With this application and resulting knowledge, professors and students can introduce more manageable and repeatable educational processes, as well as address data lineage and impact analysis questions on more efficient way. Approach of developing an integrated system for students and teachers has considerable benefits for improved data quality, mainly due to the fact that integration obviates the need for complex interfaces (Berkhoff et al., 2012).

The data contained within this application represents student personal, demographic and academic data, collected from student admission service of Faculty of Organizational Science, University of Belgrade. Using this data we can analyze the demographic and socio-economic student structure and success at the University.Developed relation data base model consists of 15 objects and more than 50 attributes.

Using the student data, professors will be able to monitor students' achiness and success by each study program, student gender, finished high school, exam, semester or science filed. Application allow professors to analyze current study success, but also to predict future success performance based on average exam performance from other students whit same background. Professors in addition can use developed application as an advisor system, in order to define new curriculum or in planning of faculty promotion activities. This application, also, takes advantage of security level setup using section access to show different views of the data, including two basic views: a professor view and a vice dean view.

4. RESULTS - ACADEMIC DASHBOARD FOR FACULTY OF ORGANIZATIONAL SCIENCES

Academic Dashboard for Faculty of Organizational Sciences allows professor and administrative staff to view and monitor student performance at undergraduate level, with ability of breakdown pass through demographic data such as gender, ethnicity, class standing and province of residence. Using these data fields they can identify trends and also can get an overall picture of the demographic breakdown of the faculty and students.

Teaching staff will be able to monitor success of students in each of the courses for which they are responsible. Data for each subject will be available in different time units: specific examination period, semester, school year, calendar year etc. Teachers will be able tofollow up students' success on multiple courses, for example group of courses for which a particular teacher is in charge. As it shown in Figure 1, professors can keep an eye on data such as GPA, average study length, entrance exam points by country, region and high school type for each generation of students.

Figure 1. Students' success by Region

In order to identify, for example correlation betweenstudy program and study success by different success criteria, on both global (GPA, average study length, average entrance exam points) and individual (exam, semester, specific examination period) level, it is allowed just by selecting adequate view, time period and desired variable, as it shown on Figure 2. Professor can switch to a chart view of GPA and see the disbursement of current GPAs on student, course or exam level, and with that like organized data, professors can look for trends in GPAs and get a high-level view of how students are performing. Selecting from the list boxes on the left side of dashboard, they can filter the data down to a single student or to results on particular course in one examination period.

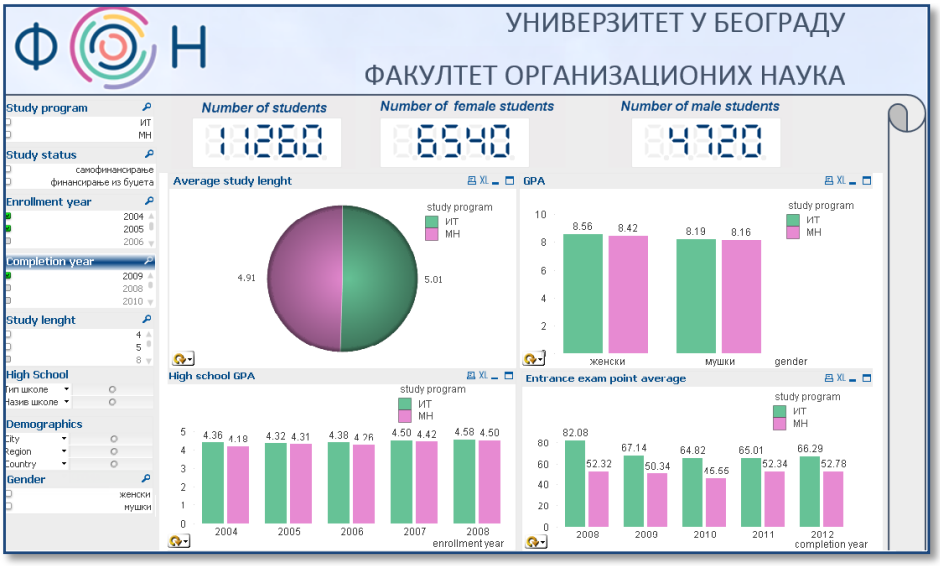

Figure 2. Detailed success statistic by study program

Observing student profile a professor or educational office stuff, as administrator, can see the academic data for any of the students enrolled in the faculty. Once the administrator identifies a single student, he/she can then get a look into that student's current academic state on more detailed level. Data such as cumulative GPA, declared major and minor, courses taken, remaining courses needed to fulfillment major requirement, and address information. As an advisor, this data is useful in helping the student plan for the upcoming semesters and also to be able answer any questions that the student may have regarding his/her academic standing. Through continuous monitoring of students during their studies, at an early stage, teachers can perceive students with good potential and students who need extra help in order to improve their results. The best students can be offered extra activities, for example additional courses, participation in scientific research and projects.

Academic Dashboard for Faculty of Organizational Sciences allows special functionalities and views for vice deans, which will have access to all student data, such as:

- Review the success of all students,
- Review the results of the each exam and examination periods,
- Summary and analytical review of students success by study program,
- Summary and analytical review of examination performance for all students by funding student status,
- Performance summary of students by student gender,
- Students performance summary by region and district from which the student came to study,
- Study performance by type of secondary high school and the particular high school that the student has completed,
- Parallel comparison of student success from one high school to success of students from other high school of same high school type or from same region (Figure 3),
- Parallel comparison of one student success with all student in study generation or with group of student with similar characteristic,
- Parallel comparison of the two sets of data according to the selected data criteria,
- Identification of enrollment trends by region or district, high school type or high school success, gender or study program.

That kind of observing students' success can be of great significance in determining trends in faculty performance and curriculum overview success.

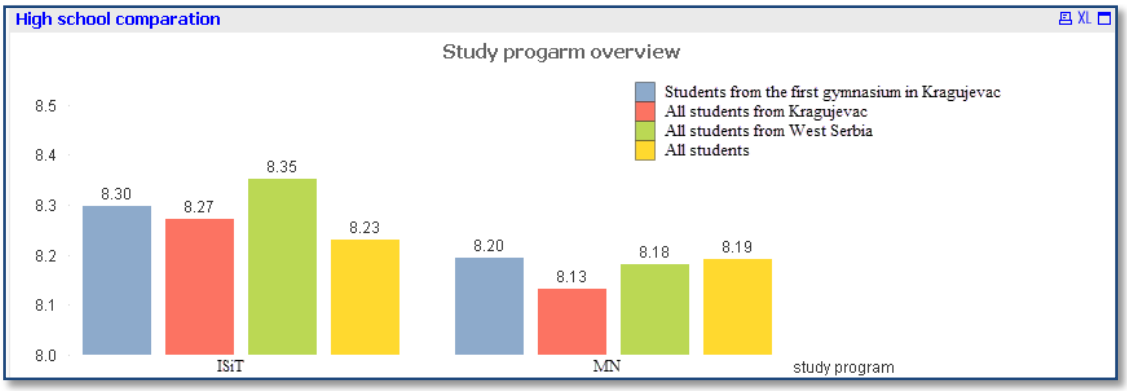

Figure 3. Comparison of GPA by specific high school students and other students

Another important benefit of this software represent fact that it is provided as SaaS(Software-as-a-Service), which is defacto increasingly important paradigm in information technology and also provides education systems as a service for enhancing processes in higher education (Masud& Huang, 2013). This functionality enables professors with an easy-to-use application, for which utilization they only need web browser and permitted access to application.

5. CONCLUSION

The main goal of this work was present developed application with ability to automatically discover useful, complex features in the context of educational data mining at faculty level. These features would at once elucidate the underlying structure of the raw data to the researcher, while at the same time hiding the complexity of this structure from the model so that the whole application could be fed into even simple model without introducing intractable complexity. In addition, developed Academic Dashboard is sustainable, easy to use and with automatically reloaded data always up to date, giving opportunity to academic personal with no expert knowledge to used it on every day basis.

Presented system model for analyzing and monitoring study performance in this paper, can represent a good basis for improving the process of higher education. The developed system aims to provide professors with tracking functionality in order for continuously monitor students' achievements. Also, application allows them to compare students' success categorized by courses, science-education groups or exams periods. Based on these information professors can determine the patterns of students' aspirations and needs, which can directly improve the process of education.

In addition to relations that indicate dependency between of students and their success, the developed system (based on QlikView in- memory solution) allows as well identification of relationships that are not directly related to the success in studies. Example for previous would be possibility for linking student with list of elective courses and optional seminaries, that they have chosen. This possibility provides students with advisory tool for choosing courses in the following semesters, gives guidelines for further scientific and professional development of each individual and also contributes to the prediction of the expected popularity of the elective subjects in the future.

Directions for future research are further improvement of the system in terms of development of modules for prediction students' success and implementing QlikView application Academic Dashboard on higher study level, such as master, specialist or doctoral studies. There is no one-size-fits-all approach, that will allow complete data analysis on all faculties, but at start level, developed application can present very good basis and point of start for further development of integrated application for whole university.

ANALYSIS OF RUNTIME DIFFERENCE BETWEEN RAPIDMINER AND CUSTOM IMPLEMENTATION OF SIMPLE COLLABORATIVE FILTER BASED RECOMMENDER SYSTEM

Milan Mihajlovic[1]
[1] mihajlovic.milan@live.com

Abstract: *This paper demonstrates creation of simple recommendation engine in Rapidminer and implementing it in C# programming language – as well as their strengths and weaknesses, through analysing time performance. Data used in this paper is a subset of Netflix Prize (Bennett & Lanning, 2007), comprising of roughly 1.27 million ratings made by around 4000 users for near 3000 movies. Recommendation quality was average, with AUC of 0.85 for both implementations. Time measurements showed drastic difference between tools used, with more than 60% runtime decrease when comparing C# to Rapidminer.*

Keywords*: Recommender systems, Rapidminer, C# recommender system implementation, Recommender system performance,*

1. INTRODUCTION

The idea for this paper came after observing the ease with which people with only basic computer training can make data mining models using pre-made software solutions. With some data science background, it was possible for a non-programmer to create a system which gave back somewhat accurate results. However, the question arose – are there any drawbacks to creating models using these tools? Several parameters were considered to possibly show differences, but they were all discarded. Prediction performance measures (accuracy, precision and recall, ROC curve) depend on the quality of the model chosen, and should be the same regardless of which type of implementation is used. On the other hand, CPU, memory and disk usage, as well as overall runtime appear to be most adequate performance measures for this case.

Interest in performance analysis of data mining systems is usually focused on the system's content – on accuracy, recall, and similar. There are almost no scientific papers that are concerned with system performance from the aspect of the runtime, and no side-by-side comparison of such performances for tool-based systems.

For this paper, the test is comprised of a simple recommender system implemented as similarly as possible in Rapidminer and in C#, and measuring the times required for implementation and average runtime. Prediction performance, as well as CPU, memory and disk usage are skipped in this paper.

The expected results are that the runtime of recommender system custom-built for single purpose should be less than the runtime of a tool-based recommender system. However, the implementation time for the tool-based recommender system should be drastically lower than for custom-build system.

2. IMPLEMENTATION ENVRIONMENTS

Rapidminer is an open-source platform which can be traced back to the year 2001, when it was still known as YALE ("Yet Another Learning Environment", developed at the Technical University of Dortmund) (Mierswa et al, 2006). In the thirteen years since its beginnings, Rapidminer has become number one of the foremost software packages for data analysis (Piatetsky, 2013). Some of the reasons for this surely lie in its affordable pricing and high availability to students, but also in the high level of generic approach adopted by the creators. This allows for a wide variety of combinations and easy extensibility, making experimentation, modification and upgrades of existing systems a painless and quick process.

On the other hand, this generic approach comes with a cost, in the form of a large overhead that occurs during runtime.

C# is an object-oriented programming language developed by Microsoft, and is an integral part of the .NET framework. With the first appearance during the July of 2000, it predates Rapidminer by a year. It is one of the top programming languages used in the world (currently ranked in the 5th place according to TIOBE Index for April 2014 (TIOBE Software B.V., 2014)). The recommender engine presented in this paper is built from the scratch, and can be made to fit perfectly to all aspects of the data model.

Both implementations were run on the same hardware specification[1], with Windows 8.1 Pro as the operating system.

[1] AMD Athlon™ II X2 260 processor @3.20 GHz, 2 x 4GB DDRAM3 @1600MHz CL10 latency, SSD Sata3 storage

3. DATA AND ALGORITHM SPECIFICATION

The problem considered is a textbook example of recommender engine implementations – the one of recommending movies to users, based on their previous ratings, and ratings of other users. The data used in this paper is a subset of the Netflix challenge (http://www.netflixprize.com/), no longer freely available due to privacy issues. Dataset contains around 3000 movies, as well as around 1.2 million of user ratings. The ratings are given in the `[MovieID, UserID, Rating]` format. The data for users is not explicitly given – we only have their IDs and ratings, but there are around 4000 distinct user IDs.

Algorithm chosen for recommender engine is k-nearest neighbors. The algorithm is based on learning by analogy, that is, by comparing a given test example with training examples that are similar to it. The training examples are described by n attributes. Each example represents a point in an n-dimensional space. In this way, all of the training examples are stored in an n-dimensional pattern space. When given an unknown example, a k-nearest neighbor algorithm searches the pattern space for the k training examples that are closest to the unknown example. These k training examples are the k "nearest neighbors" of the unknown example. "Closeness" is defined in terms of a distance metric. For this paper, the distance metric chosen is the Euclidean distance.

Recommender system that is considered in this paper is a user-based collaborative recommender. Collaborative recommenders try to predict the value of items for a particular user based on the items previously rated by *other* users, based on the "similarity" to the user (Adomavicius & Tuzhilin, 2005). For this dataset, the recommendation application tries to find the "neighbours" of user - other users that have similar tastes in movies (shown by rating the same movies similarly). Then, only the movies that are most liked by those neighbours would be recommended.

4. IMPLEMENTATION

Recommender engines are not the part of the default Rapidminer 5 installation, but they are freely available as an extension. After the installation, we have to choose among 20 options for recommender system that suits our needs. Since the recommender that will be implemented in C# is the simple K-NN collaborative filter, based on the similarity of users, that option is chosen. The implementation process for Rapidminer is straightforward and takes a short while – the entire process is done in less than five minutes. The Rapidminer recommender system process is shown on Figure 1.

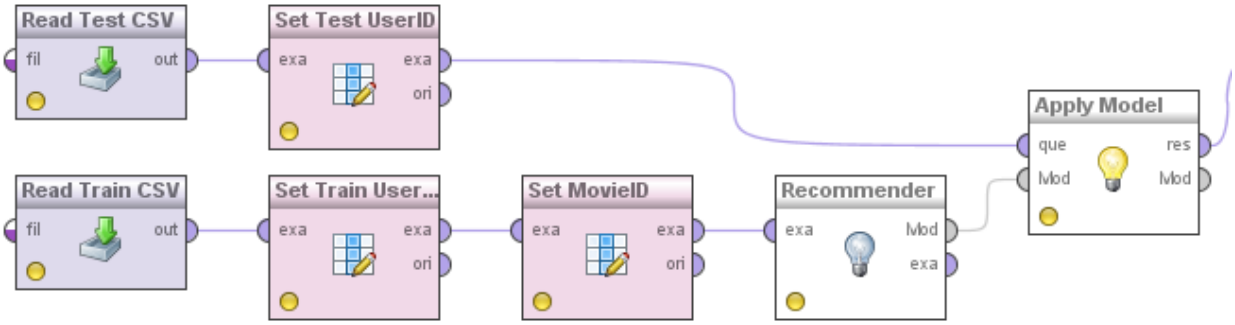

Figure 1 – Rapidminer recommender system process

After the configuration, we are able to run the process, and get the recommendations for our test User. Runtime for Rapidminer process is on average between 9 and 10 minutes, after which the recommender system gives recommendations for all supplied User examples.

Implementation of the recommender engine in C# is more open to choices, but for this paper, the choice is a simple WPF (Windows Presentation Foundation) user interface, together with filesystem access to data. Domain classes are shown in Figure 2.

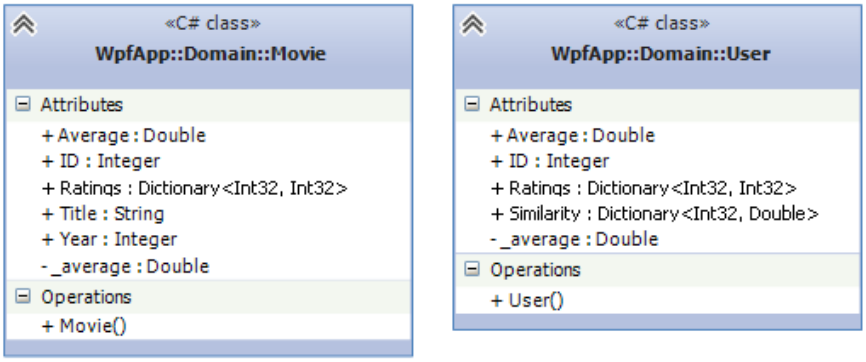

Figure 2 - C# domain classes

For computation of K-NN the distance chosen was Euclidian, based on the following equation (1)

$$d = \sqrt{\sum_{i=0}^{n}(x_i - y_i)} \tag{1}$$

With d being the distance between users, x_i first user rating for movie with `MovieID` i, and y_i second user's rating for movie with the `MovieID` i. Computations were done only for movies for which both users have given ratings.

The implementation time for C# was considerably longer, taking around 8 hours of work. But unlike the Rapidminer process, custom implementation allows us finer control over the dynamic program execution.

Runtime for reading the data and learning the model averages on around 3.5 minutes, a drastic improvement compared to Rapidminer results. This is probably the result of custom-made domain classes which do not have the requirement to conform to generic data model, eliminating some of the overhead.

Also, while Rapidminer solution allows only for batch processing, with the renewed learning process for every new batch, the C# solution allows for continual iterative process in which the model is learned only once at the application startup, and all further changes and queries are handled dynamically at runtime, creating new possibilities for further time savings.

For easier comparison, some of the noted aspects of this study are shown in Table 1.

Table 1 - Comparison of C# and Rapidminer implementations

	C#	Rapidminer
Initial implementation time	≈ 480 minutes	≈ 5 minutes
Initial implementation knowledge	Data-mining, basic programming	Data-mining
Runtime (data load and model learning)	≈ 3.5 minutes	≈ 9.5 minutes

5. CONCLUSION

Rapidminer's fast initial implementation makes it a good choice for models that are not yet fully defined. The ability to change the model without a significant investment in time is one of the key advantages when initially building a model. Also, the knowledge necessary for creating a recommender engine in Rapidminer is strictly tied to Data sciences, making it possible to non-programmers to use. The ability to implement Rapidminer models in Java programs adds to their usability by removing the batch-only limitation. However, even with that limitation removed, overhead caused by generic approach to data is not removed, and runtime should remain unchanged.

On the other side, that overhead makes implementation of the recommender engine in C# (or a similar programming language) possibly worth the cost. Taking only time into consideration (initial implementation time and runtime per batch), it is possible to see a point in time where C# solution will be more time effective compared to the Rapidminer.

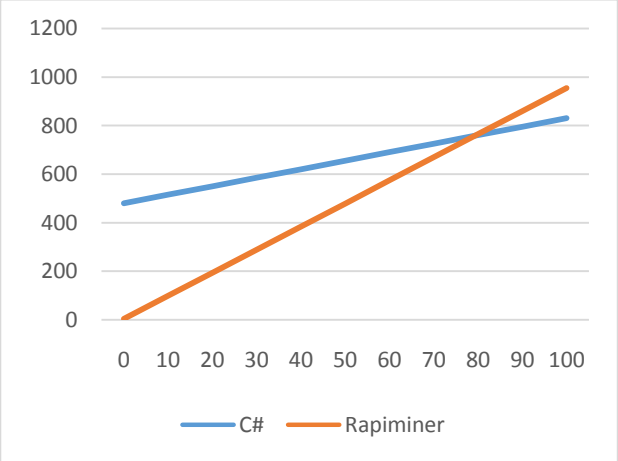

Figure 3 - time spent per number of batches

This paper does not suggest one approach to the other. It is imperative to understand the complex nature of data analysis, and realize there can be no one simple approach to all the problems. However, deeper understanding of options will hopefully allow for better decision making concerning choices of implementations of small-scale recommender engines.

Abstract:*This article proposes a classification model for a challenge that Ford has provided on Kaggle site. The goal of the research was to design a binary classifier to detect whether a driver is alert or not. Using a different algorithms (Decision tree, k-NN, Neural Network and Naïve Bayes) on a sample of the dataset thatis consist of about 600.000 data points we made a model, and for evaluation we used Rapid Miner (accuracy and Area Under the Curve). The best performance gave k-NN algorithm (for k=7) with the value for AUC=0.920 on training set. Also we have concluded that the biggest positive influence on the results of the process had adding weights to each attribute, and the most important group of attributes is environmental attributes (E1-E11).*

Keywords*:Ford Kaggle competition, Driver Alertness model, Rapid Miner, AUC, Neural Network, k-NN*

1. INTRODUCTION

There are activities that disturb the driver's attention while he is driving and can lead to accidents. These activities can be making or receiving phone calls, sending or receiving text messages, engaging in a conversation with other passengers in the car, eating while driving, also fatigue and drowsiness can be dangerous for all road users. (https://www.kaggle.com/c/stayalert) Our goal was to design a detector/classifier that will detect whether the driver is alert or not alert, employing any combination of vehicular, environmental and driver physiological data that are acquired while driving.
We have decided to work on this project because drivers who are not alert are threat, and there are a lot of accidence caused by them.

During our research, we monitored the results and the selected algorithms in two works that we found. Authors of the first paper are Louis Fourrier, Fabien Gaia and Thomas Rolf from Stanford University. In order to assess algorithms they mainly used two types of evaluation criteria: The accuracy of our algorithm and The Area Under the Curve (AUC). Their first step was to run their three algorithms (Naive Bayes, Logistic Regression, SVM) on the initial data set of 30 features. Out of the algorithm their implemented, the Naive Bayes with Gaussian Distribution fitting is clearly the most accurate one (Accuracy 90% AUC0.844)

In second research work Tayyab bin Tariq and Allen Chen have used Logistic regression, SVM, Naive Bayes, Neural Network, Random Forest, Logistic regression with feature selection. In the end, their simple logistic regression using 2 or 3 features selected via forward search presented the best results, with AUC around 81 percent and putting them in the top 15 on the Kaggle leaderboard.

Our project has three sections. First, we have done data processing (normalization, generating attributes, and attributes weights), then we chose algorithms (Decision tree, k-NN, Naive Bayes and Neural Net), and in the third phase we have done elevation of results (accuracy and AUC).

2. EXPERIMENTAL SETTING

The dataset that Ford has provided consists of about 600.000 data points. As we have already said, there are three types of attributes – physiological (P1-P8), environmental (E1-E11) and vehicular (V1-V11) (https://www.kaggle.com/c/stayalert/data). The problem was that we did not have the information about the names of attributes, and what they actually represent.

Because of the large number of data points we decided to use sample of whole dataset, and we used 10% of it to learn algorithm behavior.

The algorithms that we have used are:

1. **Decision tree** – It is an algorithm that is used for classification on both nominal and numerical data and to create a classification model that predicts the value of a *target attribute* (often called *class* or *label*). (Quinlan, 1986)
2. **Naive Bayes** classifier is a simple probabilistic classifier based on applying Bayes' theorem (from Bayesian statistics) with strong (naive) independence assumptions.
3. **K Nearest Neighbor**(k-NN from now on)is one of those algorithms that are very simple to understand but works incredibly well in practice. Also it is surprisingly versatile and its applications range from vision to proteins to computational geometry to graphs and so on. In pattern recognition, the k-Nearest Neighbors algorithm (or k-NN for short) is a non-parametric method used for classification and regression. In k-NN classification, the output is a class membership. An object is classified by a majority vote of its neighbors, with the object being assigned to the class most common among its k nearest neighbors. In k-NN regression, the output is the property value for the object. This value is the average of the values of its nearest neighbors. Both for classification and regression, it can be useful to weight the contributions of the neighbors, so that the nearer neighbors contribute more to the average than the more distant ones. K-NN is a type of instance-based learning, or lazy learning, where the function is only approximated locally and all computation is deferred until classification. The k-NN algorithm is among the simplest of all machine learning algorithms. The basic k-Nearest Neighbor algorithm is composed of two steps: Find the k training examples that are closest to the unseen example. Take the most commonly occurring classification for these k examples (or, in the case of regression, take the average of these k label values).A shortcoming of the k-NN algorithm is that it is sensitive to the local structure of the data.(Cover & Hart, 1967)
4. **Neural networks** try to mimic the human brain by using artificial ‘neurons’ to compare attributes to one another and look for strong connections. An artificial neural network (ANN), usually called neural network (NN), is a mathematical model or computational model that is inspired by the structure and functional aspects of biological neural networks. In most cases an ANN is an adaptive system that changes its structure based on external or internal information that flows through the network during the learning phase. Neural networks are usually used to model complex relationships between inputs and outputs or to find patterns in data. In this network, the information moves in only one direction, forward, from the input nodes, through the hidden nodes (if any) to the output nodes.(Haykin, 1994)

We decided to use this algorithm because we have already found some results of this Ford’s competition obtained with some others algorithms (Logistic Regression, SVM, etc.)

For the evaluation we have used two types of evaluation criteria:
The **accuracy** of our algorithm, which is calculated as in formula below:

$$\text{Accurecy} = \frac{(TP + TN)}{N} \qquad (1)$$

TP - True Positive
TN - True Negative
N – Number of data points in sample

The **Area Under the Curve (AUC)** – it presents a measure of discriminatory power of classifiers. It is very good for measuring performances of binary classifiers and it takes values from zero to one. When value is above 0.5 it is a positive class prediction, and when is between 0.7 and 0.8 it is a good classifier, between 0.8 and 0.9 very good, and above 0.9, it is excellent.

Validation of model, which is used to prevent over fitting, was done using 10-fold cross validation. This means that original dataset was divided to 10 disjunctive parts, from which 9 subsets were used for training of model and remaining one for test. This process is iterated 10 times, each having different subset for testing the model. (Kohavi, 1995)

3. RESULTS

In Table 1 results that were obtained using mentioned algorithms on theAlert dataset are shown.

Table 1: Performance of algorithms on Alert dataset

Algorithms	Accuracy	AUC
Decision Tree	66.56% ± 0.28%	0.603 ± 0.003
K-nn	69.17% ± 1.9%	0.500 ± 0.000
Neural Net	**82.94% ± 1.09%**	**0.880 ± 0.007**
Naive Bayes	64.31% ± 0.56%	0.812 ± 0.006

After the first section, where we used sample of original dataset, without any data processing, we can conclude that the best performance was obtained by the Neural Net algorithm. Other three algorithms had approximately same accuracy, but the values for AUC were different. For k-NN algorithm AUC was 0.500, and that means that it is on the border between positive and negative class prediction. Also, we must emphasize that in k-NN algorithm, k was 1.

We continued our research, and the next step was adding operator Attribute Weight in our validation. The operator Attribute Weight by Information Gain calculates the weight of attributes with respect to the class attribute and the higher the weight of an attribute, the more relevant it is considered.

In Table 2 are shown weights of each attribute and in the Table 3 new results for each algorithm.

Table 2: Attribute Weights

Attribute	Weight	Attribute	Weight	Attribute	Weight
P1	0.0738	E3	0.2286	V2	0.0516
P2	0.0151	E4	0.1689	V3	0.0298
P3	0.0070	E5	0.1118	V4	0.2511
P4	0.0070	E6	0.2955	V5	0.0150
P5	0.4457	E7	0.8297	V6	0.4782
P6	0.4548	E8	0.6597	V7	0.0000
P7	0.4548	E9	1.0000	V8	0.3515
P8	0.0000	E10	0.9658	V9	0.0000
E1	0.1883	E11	0.0384	V10	0.5038
E2	0.1064	V1	0.5120	V11	0.7725

After obtained attribute weights, we concluded that physiological (P) and vehicular (V) attributes were generally less important (except V1 = 0.5120 and V11 = 0.7725). And the most important attributes in the process of discovering whether the driver is alert or not alert, are environmental attributes (especially E9= 1).

Environmental attributes are more important and that means that should pay attention on environment more than physiological and vehicular factors on driver's attention. Otherwise, in environmental excited much more things that will distract attention of driver (human commercial or natural weather conditions, but this can be explained in more details in another project).

Table 3: Performance of algorithms with attribute weight

Algorithms	Accuracy	AUC
Decision Tree	66.56% ± 0.28%	0.603 ± 0.003
K-nn	87.43% ± 1.9%	0.500 ± 0.000
Neural Net	**82.94% ± 1.09%**	**0.922 ± 0.007**
Naive Bayes	64.31% ± 0.56%	0.802 ± 0.006

When we put attribute weights, we got some new results. Neural Net algorithm, again, gave the best results, and with accuracy of 82.94%, and value for AUC = 0.922 we can say that is an excellent classifier. Also, we

would like to point out that giving weight to each attribute had a positive influence on the results, and it is something that is really important for this problem.

The next that we wanted to examine is how the relationship between the attributes effect on the results, so we generated some new attributes. To be able to generate new attributes, we needed to normalize our data and to define what we want to present. To achieve the relevancy of new attributes we used relation between average size of the same group of attributes (physiological, environmental and vehicular). After the normalization of the data we have generated following attributes:

1. **E/P** = ((E1+E10+E11+E2+E3+E4+E5+E6+E7+E8+E9)/11)/((P1+P2+P3+P4+P5+P6+P7+P8)/8)
2. **E/V** = ((E1+E10+E11+E2+E3+E4+E5+E6+E7+E8+E9)/11)/((V1+V10+V11+V2+V3+V4+V5+V6+V7+V8+V9)/11)
3. **P/V** = ((P1+P2+P3+P4+P5+P6+P7+P8)/8)/((V1+V10+V11+V2+V3+V4+V5+V6+V7+V8+V9)/11)

Result of this fasa of research are shown in Table 4:

Table 4: Performance of algorithms with attribute weight and three new attributes

Algorithms	Accuracy	AUC
Decision Tree	66.56% ± 0.27%	0.603 ± 0.003
k-NN	91% ± 0.17%	0.500 ± 0.000
Neural Net	**86.25% ± 0.56%**	**0.920 ± 0.003**
Naive Bayes	64.16% ± 1.12%	0.809 ± 0.006

From the table above (Table 4) we can conclude that new attributes had not an influence on the results of process. As we can see there are not any relevant changes. The best results are still got from the Neural Net algorithm.
Also, we have noticed that accuracy for k-NN algorithm was good, bud the value for AUC was constantly on the border, so it was something that we wanted to examine. So we have tried with other valesfor k. The results that we have god were great, and the best were for k=7.

Table 5: Performance of k-NN algorithm for k=7

Algorithm	**Accuracy**	**AUC**
k-NN (k=7)	**90.38% ± 0.17%**	**0.958 ± 0.006**

To summarize everything above we have used a chart which is presented on Figure 1:

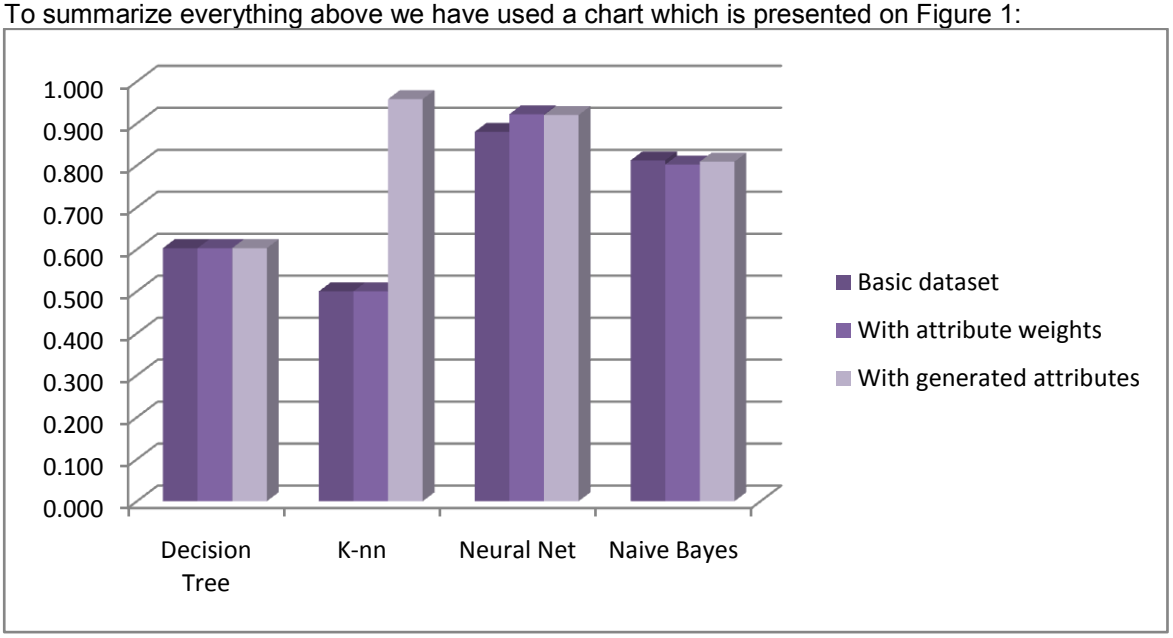

Figure 1: Chart with all values of **AUC** for all algorithms that has been used

From Figure 1 it can be noticed that best results gave **k-NN** algorithm for k=7, with accuracy about 90% and value for AUC= 0.958. We must not forget about results obtained with Neural Net algorithm – accuracy 86.25% and AUC=0.920 who also were excellent.

As we it was already mentioned, we used Rapid Miner for evaluation. Our process in Rapid Miner is presented on Figure 2.

The first thing that we needed to do was to take a sample of dataset. All attributes had a different values and different range, and because we wanted to make some new attributes the normalization was the first thing to do. After that, in the validation operator we put an operator for attribute weights, and k-NN algorithm. We also specified the value for k, an as it was mentioned the best results were with k=7,and the distance between vector was calculated with Mixed Eucledian Distance (Figure 3). At the performance operator we specified that we want our results to be shown by the accuracy and the value of AUC.

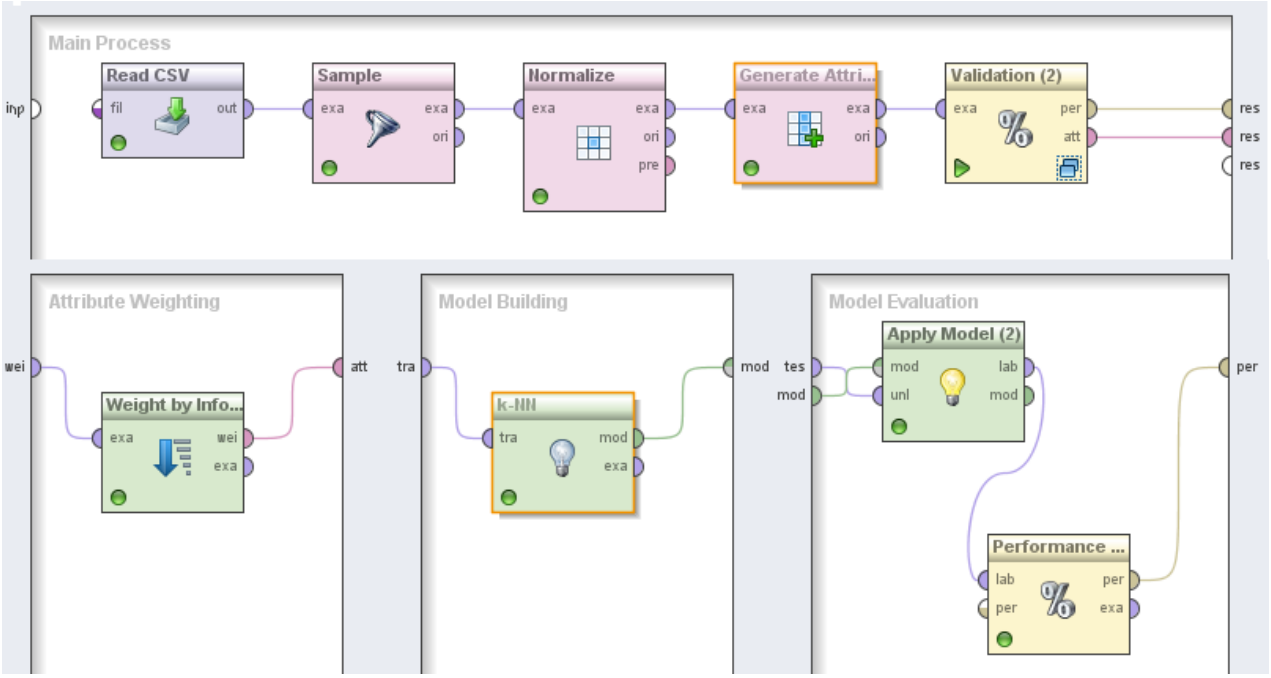

Figure 2: Process in Rapid Miner

4. CONCLUSION

There are lots of accidents and driving while not alert can be deadly. Using the program Rapid Miner we wanted to find out the best solution of Ford challenge. In our project we have worked with many algorithms - Decision tree, k-NN, Naive Bayes and Neural Networks. After our analysis the best experimental results are obtained from k-NN algorithm. k-NN gave us two moments which is able to predict values of numeric attributes, accuracy (90%) and AUC (95%). Also, Neural Net obtained good results, accuracy (86%) and AUC (92%)

We, also, conclude that the biggest positive influence on the results of the process was adding weights to each attribute, and the most important group of attributes is environmental attributes (E1-E11).
We were expecting the new attributes to have some positive influence on the model, but it was not the case. It turns out that relation between the averages of a same group of attributes has no influence for this research.

At the end we would just wanted to remind you – STAY ALERT!

Abstract: *Credit risk is the primary risk facing financial institutions. In this paper, the focus is on the individuals whom are in the need of a loan, rather than on corporations and other institutions. In this project, we had 10 attributes and 250.000 examples on which we managed to predict whether or not the client defaulted the loan in the next two years. The data set was provided by www.kaggle.com, as part of the contest 'Give me some credit'[1]. Using several different algorithms we were able to get the best AUC score of 0.813.*

Keywords*: Forecasting, RapidMiner, data analysis, loan prediction, feature weighting.*

1. INTRODUCTION

Historically, credit scoring systems were built to answer the question of how likely is it for credit applicant to default by a given time in the future. Different modelling techniques can be used to build such systems-discriminant analysis, logistic regression, partitioning trees, mathematical programming, neural networks, expert systems and generic algorithms[2]. The methodology is to take a sample of previous customers and classify them into a certain category, depending on their features, for instance, number of open credit lines and loans, debt ratio, and belated payments, supported by certain personal information such as age, number of dependants, and monthly income. The tool utilised for the purpose of the project is RapidMiner.

Credit scoring problem is often tackled with different data mining techniques and algorithms. (Huang et al., 2007) proposed hybrid GA-SVM algorithm that can simultaneously perform feature selection task and model parameters optimization by combining genetic algorithms with SVM classifier. Experimental results showed that SVM is a promising addition to the existing data mining methods.
(Vukovic et al., 2012) proposed a case-based reasoning (CBR) model that uses preference theory functions for similarity measurements between cases. Additionally, they used a genetic algorithm in order to select the right preference function for every feature and set the appropriate parameters. The proposed model is compared to the well-known k-nearest neighbour (k-NN) model based on the Euclidean distance measure on three different benchmark datasets. They showed that, in some cases, newly proposed algorithm outperforms the traditional k-NN classifier.

(Hsieg, 2004) proposed an integrated data mining and behavioral scoring model to manage existing credit card customers in a bank. A self-organizing map neural network was used to identify groups of customers based on repayment behavior and recency, frequency, monetary behavioral scoring predicators. It also classified bank customers into three major profitable groups of customers. The resulting groups of customers were then profiled by customer's feature attributes determined using an Apriori association rule inducer.
(Lee et al. 2002) proposed a study in which they explored the performance of credit scoring by integrating the back-propagation neural networks with traditional discriminant analysis approach. As the results reveal, the proposed hybrid approach converges much faster than the conventional neural networks model. They have reached the conclusion that the credit scoring accuracies increase in terms of the proposed methodology and outperform traditional discriminant analysis and logistic regression approaches.
(Martens et al., 2007) provided an overview of the rule extraction techniques for SVMs and introduced two others taken from the artificial neural networks domain, Trepan and G-REX. Their experiments show that the SVM rule extraction techniques lose only a small percentage in performance compared to SVMs and therefore rank at the top of comprehensible classification techniques.

(Huang et al., 2006) understood that the problem of imbalanced class distributions can lead the algorithms to learn overly complex models that overfit the data and have little relevance. Their study analyzes different classification algorithms that were employed to predict the creditworthiness of a bank's customers based on checking account information.

In this study we evaluate different classification algorithms on the real world credit scoring dataset that is recently used on Kaggle's "Give me some credit" competition[3]. We compared the performances of seven single and ensemble algorithms. Additionally, we used Evolutionary and Particle Swarm Optimization (PSO) algorithm for feature weighting in order to identify the most influential attributes and hopefully improve model performance.

2. PREDICTION OF CUSTOMER CREDIT DEFAULT – „GIVE ME SOME CREDIT"

In this section we propose a method for prediction of customer credit default. The data is collected from Kaggle competition and contains real world credit scoring examples from www.kaggle.com. Example set contains 250.000 examples, among those 150.000 is training set, and another 100.000 is testing data set. The basic description is given in Table 1.

Table 1: Basic description of variables

Variable Name	Description
SeriousDlqin2yrs	Person experienced 90 days past due delinquency or worse
RevolvingUtilizationOfUnsecuredLines	Total balance on credit cards and personal lines of credit except real estate and no installment debt like car loans divided by the sum of credit limits
Age	Age of borrower in years
NumberOfTime30-59DaysPastDueNotWorse	Number of times borrower has been 30-59 days past due but no worse in the last 2 years.
DebtRatio	Monthly debt payments, alimony, living costs divided by monthly gross income
MonthlyIncome	Monthly income
NumberOfOpenCreditLinesAndLoans	Number of Open loans (installment like car loan or mortgage) and Lines of credit (e.g. credit cards)
NumberOfTimes90DaysLate	Number of times borrower has been 90 days or more past due.
NumberRealEstateLoansOrLines	Number of mortgage and real estate loans including home equity lines of credit
NumberOfTime60-89DaysPastDueNotWorse	Number of times borrower has been 60-89 days past due but no worse in the last 2 years.
NumberOfDependents	Number of dependents in family excluding themselves (spouse, children etc.)

It can be seen from Figure 1 that cases are highly imbalanced 1:14. This is important to notice because algorithms and evaluation techniques for this kind of data are specific. This will be more thoroughly explained later. Figure 1 shows the data set summary:

Role	Name	Type	Statistics	Range	Missings
id	att1	integer	avg = 75000.500 +/- 43301.415	[1.000 ; 150000.000]	0
label	SeriousDlqin2yrs	binominal	mode = 0 (139974), least = 1 (10026)	1 (10026), 0 (139974)	0
regular	RevolvingUtilizationOfUnsecuredLines	real	avg = 6.048 +/- 249.755	[0.000 ; 50708.000]	0
regular	age	integer	avg = 52.295 +/- 14.772	[0.000 ; 109.000]	0
regular	NumberOfTime30-59DaysPastDueNotWorse	integer	avg = 0.421 +/- 4.193	[0.000 ; 98.000]	0
regular	DebtRatio	real	avg = 353.005 +/- 2037.819	[0.000 ; 329664.000]	0
regular	MonthlyIncome	real	avg = 6670.221 +/- 14384.674	[0.000 ; 3008750.000]	29731
regular	NumberOfOpenCreditLinesAndLoans	integer	avg = 8.453 +/- 5.146	[0.000 ; 58.000]	0
regular	NumberOfTimes90DaysLate	integer	avg = 0.266 +/- 4.169	[0.000 ; 98.000]	0
regular	NumberRealEstateLoansOrLines	integer	avg = 1.018 +/- 1.130	[0.000 ; 54.000]	0
regular	NumberOfTime60-89DaysPastDueNotWorse	integer	avg = 0.240 +/- 4.155	[0.000 ; 98.000]	0
regular	NumberOfDependents	integer	avg = 0.757 +/- 1.115	[0.000 ; 20.000]	3924

Figure 1: Example set descriptive statistics

It can be noticed that there are 29.731 missing values under the attribute *MonthlyIncome*, and 3.924 under the attribute *NumberOfDependants.* The solution for the first issue was removal of the instances with missing

values, and as for the second, we used an operator Replace Missing Values which had replaced the missing instances with average value. After the completion of these steps, we got the final data set that has 120.269 instances with no missing values.

From the original attributes showed in Table 1 we derived several new attributes in order to inspect if some aggregated attributes can provide more information to the algorithms, compared to original ones. These are:

Table 2: Derived attributes

Variable name	Description
Debt	MonthlyIncome*DebtRatio
CumulativeLateness	Sum of all lateness
WagesPerCapita	MonthlyIncome/NumberOfDependents
AgeDiscretized	Age is discretized in three categories: Young (under 35), Middle age (between 35 and 60), Old (above 60 years of age).

2.2. Algorithms

Because of the imbalanced nature of dataset we evaluated several ensemble algorithms, since they often showed good performance on this kind of data[4]. Additionally, we compared algorithm performances with single algorithms. Brief descriptions of algorithms used in this study is given in Table 3.

Table 3: Types of used algorithms

Type	Algorithm	Description
Ensemble	Random Forest	Learns a set of random trees, i.e. for each split only a random subset of attributes is available. The resulting model is a voting model of all trees.
Ensemble	Bayesian Boosting	This operator trains an ensemble of classifiers for boolean target attributes. In each iteration the training set is reweighted, so that previously discovered patterns and other kinds of prior knowledge are "sampled out".
Ensemble	Meta Cost	This operator uses a given cost matrix to compute label predictions according to classification costs.
Ensemble	Bagging	Bagging operator allowing all learners.
Single	Naive Bayes	Returns classification model using estimated normal distributions.
Single	Decision Tree	Generates decision trees to classify nominal data.
Single	Perceptron	Single Perceptron finding separating hyperplane if one exists.

2.3. Evaluation

Because of high class imbalance and binary class type, classification accuracy is not suitable for measuring performance of algorithms, since it gives misleading results, on this type of data. In our case, classification accuracy would give the accuracy of 93.05% forth majority algorithm, i.e. if algorithm predict always negative case (person will return credit). Even though this accuracy is high, it doesn't reflect the success of the model, since in this case is more important to predict positive cases (identify persons that will not return the credit). This is the reason we used Area under curve (AUC measure) for algorithm evaluation. It represents the area under Receiver Operating Characteristic (ROC) curve - graphical plot which illustrates the performance of a binary classifier system as its discrimination threshold is varied. ROC curve is created by plotting the fraction of true positives out of the total actual positives (TPR = true positive rate) divided by the fraction of false positives out of the total actual negatives (FPR = false positive rate), at various threshold settings[5]. The true positive rate, or recall, is calculated as the number of true positives divided by the total number of positives. The false positive rate is calculated as the number of false positives divided by the total number of negatives.

2.4. Experiments and results

In the first process, we evaluated performances of all algorithms on all available attributes. AUC is measured based on 10 fold cross validation with the stratified sampling. It builds random subsets and ensures that the class distribution in the subsets is the same as in the whole dataset. In our case of a binominal classification, stratified sampling builds random subsets in which each subset contains roughly the same proportions of the two values of class labels. Stratification is the process of dividing members of the population into

homogeneous subgroups before sampling. Afterwards, simple random sampling or systematic sampling is applied within each stratum. This often improves the representativeness of the sample by reducing sampling error. This enables correct interpretation of AUC values. Imbalanced class distributions can lead the algorithms to learn overly complex models that overfit the data and have little relevance. It is known that class imbalance problem can be successfully solved with under-sampling techniques[6]. In this experiment we evaluated every algorithm on different sub-samples:

Table 4: Evaluation of algorithms on basic data set

Algorithm/Sample (class 0/ class 1)	**111911/8357**	**50000/8357**	**30000/8357**	**8357/8357**	**5000/8357**	**2000/8357**
Random Forest	0.5	0.500	0.575	0.792 (0,667)	0.642	0.0
Bayesian Boosting- Decision stump	0.5	0.570	0.570	0.771	0.715	0.5
Meta Cost - Decision stump	0.511	0.571	0.646	0.668	0.775	0.697
Bagging - Decision stump	0.505	0.570	0.615 (0.773 DT, 0.748)	0.644	0.739	0.626
Naive Bayes	0.801	0.797	0.797	0.795	0.797	0.789
Decision Tree	0.719	0.500	0.500	0.773	0.715	0.701
Perceptron	**0.775**	**0.812**	**0.813**	0.814	**0.812**	**0.737**

After the conducted experiment with basic attributes, we started another analysis, but this time we utilized derived attributes, hoping to get better results. Those results are presented in Table 5:

Table 5: Evaluation of algorithms on data set that contained derived attributes

Algorithm/Sample (class 0/ class 1)	**111911/8357**	**50000/8357**	**30000/8357**	**8357/8357**	**5000/8357**	**2000/8357**
Random Forest	0.5	0.5	0.593	0.803 (0,737, 810)	0.794	0.5
Bayesian Boosting	0.502	0.631	0.664	0.789(0,708)	0.737	0.5
Meta Cost	0.54	0.587	0.657	0.758	0.757	0.776
Bagging	0.513	0.579	0.625	0.692	0.743	0.579
Naive Bayes	0.79	0.789	0.782	0.782 (0,68)	0.784	0.789
Decision Tree	0.5	0.5	0.546	0.753	0.753	0.753
Perceptron	**0.809**	**0.809**	**0.809**	**0.807 (0,756, 803)**	**0.811**	**0.81**

It can be seen from Table 4 that different samples influence on algorithm performance and that Perceptron in all cases gives the best results (around 0.81). Perceptron is a type of artificial neural network. It can be seen as the simplest kind of feed-forward neural network: a linear classifier. From this we can conclude that Perceptron successfully solves imbalance data problem on all sub-samples. This indicates that Perceptron could be trained on smaller sub-samples (in order to reduce time cost) without worsening the performance.

It can be also be noticed from Table 5 that ensemble algorithms showed the best performance when data is completely balanced (8.357 negative and 8.357 positive cases). As expected, Decision Tree algorithm showed the worst results especially when the data is imbalanced (111.911 positive and 8.357 negative cases).

In the second experiment we used feature weighting techniques (Evolutionary and PSO) in order to identify the most influential attributes, and hopefully, to improve model's performance. In order to prevent overtraining of models (because of optimization of attribute selection) we used Wrapper X-Validation operator that divides data on training and test samples. Training sample is used for estimating performance of different classifiers on different feature subsets. Models built on features with best estimated performance are returned to Wrapper X validation and evaluated on unseen data.

In Table 6 the results for evolutionary feature weighting are showed.

Table 6: Evolutionary feature weighting

Attributes	*Random Forest*	*Bayesian Boosting*	*Meta Cost*	*Bagging*	*Naive Bayes*	*Decision Tree*	*Perceptron*
RevolvingUtilizationOfUnsecuredLines	1	1	0.2	1	1	1	0.4
AgeDiscretized	0	0	0	0.4	0.4	0	0
DebtRatio	0	0	0.6	0	0	0	0.8
MonthlyIncome	1	1	0.6	1	1	1	0.6
Debt	0	0.6	0.4	0.4	0.4	0	0.4
NumberOfOpenCreditLinesAndLoans	1	0.8	0	0.6	0.6	1	0.2
NumberRealEstateLoansOrLines	0	0.8	1	0.2	0.2	0	1
WagesPerCapita	1	0.6	0.2	0.8	0.8	1	0.4
CumulativeLateness	0.4	1	1	0	0	0.8	1
AUC	**0.744**	**0.788**	**0.744**	**0.716**	**0.779**	**0.771**	**0.757**

It can be seen from Evolutionary feature weighting that Bayesian Boosting gave the best performance by the means of AUC (0.788) and the most important features were *RevolvingUtilizationOfUnsecuredLines*, *MonthlyIncome*, *CumulativeLateness*. It is interesting to notice that *RevolvingUtilizationOfUnsecuredLines* and *MonthlyIncome* had the highest relative importance in 5 out of 7 algorithms, and this indicates that these attributes are generally important for this problem. In Table 7 the results for PSO feature weighting are showed.

It can be seen from PSO feature weighting that Perceptron gave the best result (around 0.8). PSO gave the highest weights for *Debt and WagesPerCapita*, while the attributes with lowest importance were *MonthlyIncome* and *NumberRealEstateLoansOrLines* (below 0.2). Similar performance (0.796) was obtained by Random Forest (0.796), but the most important attributes were *CumulativeLatence* and *RevolvingUtilizationOfUnsecuredLines*, while the lowest weight was *RevolvingUtilizationOfUnsecuredLines*. Still, general conclusions about most important features cannot be made since other features were often identified as important in the other algorithms (e.g. *AgeDiscretized* was the most important feature in Bayesian Boosting and Bagging, while *Debt* was most important feature for Naive Bayes and Perceptron).

From previous results and discussion we can conclude that *RevolvingUtilizationOfUnsecuredLines* has the biggest influence on the problem (by both PSO and Evolutionary algorithms). *MonthlyIncome* also showed high relative importance in Evolutionary, but very low with PSO. In contrast to Evolutionary algorithm PSO gave higher importance to *Debt*, instead of *MonthlyIncome*.

3. CONCLUSION AND FUTURE WORK

In this research, we evaluated several classification algorithms and feature optimization techniques for client loan default in the next two years. The best performing algorithm was Multilayer Perceptron that showed AUC score of 0.813 in combination with evolutionary feature selection technique. As a part of our future work, we plan to evaluate different algorithms and other sampling techniques (such as random sampling, systematic sampling, cluster sampling). Additionally, we plan to improve performance of classification algorithms by using different techniques for imputation of missing values.

Abstract: *This paper describes the application of the ANP multicriteria method in modeling and quantitative analysis of major determinants and their relative weights in regard to benefits, opportunities, costs and risks (BOCR). In this way we estimate all the effects of the choice of appropriate strategies for the successful introduction of the concept of open innovation in the banking sector of Serbia. Based on the obtained results, the paper demonstrates the possibility of using ANP method to support effective decision-making in a complex business environment, as it provides a comprehensive, quantitative, and objective approach to all relevant, tangible and intangible factors in a decision-making process.*

Keywords*: Multi-criteria ANP method, BOCR, Serbian banking sector, concept of open innovation, effective decision-making.*

1. INTRODUCTION

Management of an organization is profoundly based on a decision-making process. Adoption of appropriate business decisions in a dynamic business environment is vital at all managerial levels, bearing in mind that each decision makes a significant impact on a company's business. Due to pronounced changes in business environments, functioning and survival of companies is becoming increasingly more complex, and the responsibility for decisions much greater. A wrong decision can have irreparable loss to an organization (Čupić & Suknović, 2010; Lawrence & Pasternack, 2002). Therefore, effective decision-making in complex conditions is a cognitive process that involves developing a logical, systematic and comprehensive approach, which requires the incorporation of multiple available data and alternatives, as well as qualitative and quantitative factors into a decision-making process itself, using appropriate tools and decision support systems (Drucker, 1967; Čupić & Suknović, 2010; Wood & Bandura, 1989; Heizer & Render, 2010).

In recent years the financial sector has been in the process of revolutionary transformation caused by a number of phenomena such as: global economic integration and regionalization of markets, development of knowledge-based economy, intense competition, regulatory pressures, a growth of sophisticated consumer requirements, technological innovations, political and demographic changes, volatile and turbulent business environments. The selection of effective strategies for sustainable competitiveness, growth and development of the organization, as well as creating superior values for customers and shareholders, have always represented a challenge for the banking sector. However, in the modern business environment the choice becomes increasingly complex. In order to respond adequately to the challenges of the external environment and to find appropriate strategies for sustainable competitiveness, growth and development of organizations, as well as timely response to a short-term phenomenon in the everyday pressures of business, the banking sector needs to develop the capacity to adapt to all the changes and to redefine existing business strategies without any delay (Fasnacht, 2009; Huo & Hong, 2013).

One of the competitive strengths of organizations and a key driver to maintain high profitability is an innovation (Drucker, 1988; Christensen, 1997). According to Löfsten (2014), organizations with a strategy of innovation gain a platform for better business performance. Due to pronounced pressures from the environment, the success of innovation has become very uncertain, and the question is whether the innovation and innovative processes in closed business environments are sufficient for sustainable competitiveness, growth and development of organizations in the 21st century? Chesbrough (2003) argues that companies from different business areas significantly changed the approach to innovation, so that the recently proposed concept of innovation management, the concept of open innovation, has become a key strategic element for the commercialization of innovation, the basis for the reduction of operating costs and increase of profitability in the conditions of the new era. Moreover, the model of open innovation has been recognized as an important driver of sustainable growth and development of organizations in all industries (Gassmann & Enkel, 2004).

As a new business paradigm, this concept represents a fundamental change in generating and managing intellectual property; it is based on a holistic approach to innovation management that involves

"systematically encouraging and exploring a wide range of internal and external resources as new innovation opportunities, consciously integrating the research possibilities and resources of a company and a wide exploitation of these opportunities through multiple channels of distribution" (West & Gallagher, 2006).

Introducing the concept of open innovation in the banking sector in Serbia is a very challenging and complex task, given that banks are traditionally closed systems, and the fact that the concept of open innovation, in addition to its benefits and opportunities, is correlated with costs and risks as important indicators for the assessment of important determinants based on which a final decision on the strategy implementation model of open innovation in the banking sector of Serbia is to be made. To this end this paper presents Analytical Network Process (ANP) based on the BOCR (Benefits, Opportunities, Costs and Risk) model as a method for decision support in a complex business environment that provides a comprehensive, quantitative, and objective approach to all relevant, tangible and intangible factors in the decision-making process.

2. DECISION MAKING IN BANKING

In today's business environment characterized by complexity and dynamism of the business environment, banks are facing different decision-making problems at every managerial level, and it is a particular challenge for strategic management in making appropriate strategic decisions on which the survival, growth, and development of banks depend. This problem is even more noticeable due to uncertainties and risks, as well as the strong influence of political-economic, social, technical, institutional and cultural factors.

Business environment of the banking sector has drastically changed over the last 20 years, which has led to significant changes in the banking sector (Fasnacht, 2009). Today, the banking sector is in a period of transformation and consolidation due to the changes imposed by this century, which are primarily reflected in deregulation and financial liberalization, privatization and advanced information and communication technologies. Over the last ten years a large number of countries in transition have faced these changes, which required significant structural reform of the financial system, which reflects in the reduction of the total number of banks and an increased number of foreign financial institutions. By the end of 2000 fundamental changes in the banking sector followed in Serbia as the banking sector was ruined during 1990s. The process of reform and reconstruction of the banking sector has resulted in significant positive effects such as neutralization of financial loss, improved structure of banks, restored confidence of customers in the banking sector, especially in relation to citizens' savings, entry of the foreign capital resulting (in addition to recapitalization) in greater competitiveness by adopting new knowledge and experience from international markets, the application of international accounting standards, strengthening the capital base, as well as significant increase in employment (NBS, 2005). The 2008 global economic crisis spilled over from developed markets into the banking sector in Serbia as a result of close connections between financial markets, thus leading to the structural weaknesses of the banking sector. The recession, which started in 2009, represented a serious challenge for the banking sector in Serbia, and the banks are still struggling with it today.

Searching for answers to comprehensive technological and regulatory changes, more and more demanding customers, as well as the phenomenon of globalization and the global economic crisis, financial institutions are faced with the problem of inadequate organizational structure. In recent years this sector began with the consolidation of organization, creating a new business model adapted to the conditions of the 21st century. New trends in the economic environment have imposed the need for banks to constantly innovate, revise business models and revitalize the trust of customers in order to survive, keep sustainable competitiveness, long-term growth and development (Luftenegger et al., 2010).

3. CONCEPT OF OPEN INNOVATION IN THE FINANCIAL SECTOR

Chesbrough defines open innovation as "alternating use of meaningful inputs and outputs of knowledge to accelerate the internal innovation process and increase the market for external use of innovation" (Chesbrough et al., 2006). Additionally, Chesbrough et al. (2006) explains the concept of open innovation as "a paradigm which assures companies that they can and should use both external and internal ideas in the same way, and both internal and external paths to market to advance their technology". However, the model of open innovation is more than the use of external ideas and technologies in innovation management. To get a competitive performance on the open market, the concept of open innovation means a new way of thinking based on openness, flexibility, sharing of intellectual property, investment in the global foundation of knowledge and integration with customers, suppliers, partners, universities and other stakeholders, with the aim to incorporate new knowledge, ideas and resources from the external environment (Chesbrough, 2003a; Laursen & Salter, 2006). Also, according to the authors, the concept of open innovation is vital for achieving operational excellence and increase profitability (Fasnacht, 2009; Schmitt et al., 2013).

The conceptual framework of action toward a successful implementation of open innovation model in the financial sector is based on three basic guiding principles: a transition strategy from a closed to an open innovation model, dynamic managerial practices, and appropriate corporate culture of open innovation (Fasnacht, 2009).

Transition strategy towards the model of open innovation involves changing business models that are based on openness and flexibility, a holistic approach, as well as the integration of customers through appropriate architecture and business strategy. In the open innovation model, customers are at the core of the business focus (Fasnacht, 2009; Teece, 2010).

The shift in the transformation from a traditional organization characterized by vertical hierarchical and bureaucratic structure with the functional structure orientated to product development, into an organization that follows the principles of flexibility, openness, and a customer-oriented business model, represents a major challenge for managers in the financial sector. With that in mind, competitive advantage can be achieved if the management of the financial sector understands how to use resources and opportunities as an integrated system. Innovation strategy as well as growth strategy should be flexible enough so as to enable the organization to properly respond to changes in the ubiquitous environment. More importantly, building and strengthening confidence, which becomes increasingly important both for interfunctional relationships within organizations and with stakeholders in the external environment, implies the creation of new ideas, development of new skills and a dynamic management approach (Chesbrough et al., 2006; Fasnacht, 2009; Teece, 2010).

In addition, incorporation of employees' intellectual capital in the open innovation model and the organizational capability to ensure an appropriate business culture towards open innovation is essential for the banking sector. Otherwise, the organization's inability to provide a supportive organizational culture is the biggest barrier to innovation and profitable growth. Unlike the traditional model which features a closed command and control systems, creating a learning and innovation culture within an organization is the basis for the development of performance and profitability growth (Fasnacht, 2009). The development of a new brand of innovative management and an intensive collaboration have become a necessity in financial institutions in order to timely react to all the changes and challenges of this era (Huff et al., 2013).

As with any new concept, initial research is based on case studies, which cannot guarantee the success of applying the concept in practice (Huizingh, 2011). With that in mind, this paper includes a quantitative analysis of significant determinants and their relative weights with regard to benefits, opportunities, costs and risks in order to measure all effects of the choice of appropriate strategies for the successful introduction of an open innovation concept in the banking sector of Serbia.

4. ANP METHOD BASED ON BOCR MODEL

The method that is most commonly and widely used in the decision-making process is the AHP - Analytic Hierarchy Process method. After the wide application of the AHP method in various fields and in complex business environments, the need for the creation of new methods in the decision-making process has arisen because over the time it was observed that a large number of problems in the decision-making process cannot be represented by a hierarchical structure which is the basis of the AHP method. Thus, the AHP method evolved in the ANP method - Analytic Network Process.

4.1. Analytic network process (ANP)

Analytic network process (ANP) is a newer multi-criteria decision-making method representing a modified and improved model of the AHP method, also developed by Saaty T. '96. (Saaty, 1999). As a generalization of AHP method, the ANP method takes into account the dependency between the elements of the hierarchy, thus making this method more realistic when calculating results. The ANP method is based on the development of a network that spreads in all directions and includes cycles between clusters and loops within the same cluster (Saaty, 1999). In addition, this method enables establishment of connections not only between clusters but also between the elements contained within them. Moreover, it enables a demonstration of inner dependence through the establishment of interactions and feedback between elements in the cluster. Similarly, the ANP method enables a demonstration of outer dependence establishing relationships and feedback between elements from different clusters. In addition, the ANP method enables the connection of whole clusters (Saaty, 2005; Saaty, 2008). Thus, the ANP method is an upgrade of the AHP method based on modeling the complexities arising from the feedback connections between the elements of structured decision-making problems. This method allows the modeling of functional interactions of criteria and alternatives in the model, resulting in greater accuracy in obtained

results, and it can be used in two ways: by BOCR model (controlled hierarchy) or network model (system). In this paper, we have applied the BOCR model which is detailed in section 4.1.1.

4.1.1. BOCR model

Complex decision-making process usually requires an analysis of a decision against benefits (B), opportunities (O) as a potentially good chance that may result in future, costs (C) that may arise, and risks (R) that could potentially follow the decision (Saaty & Vargas, 2001; Saaty, 2009). From this it can be concluded that the benefits and costs refer to a short-term period, while the opportunities and risks refer to a long-term period. In addition, benefits and opportunities represent profit, while costs and risks represent loss of the decision. Figure 1 is a summary of the BOCR model observed in regard to the period of activity, as well as the final outcome of the decision.

BOCR model represents a controlled hierarchical structure of the ANP model. In such a structure, a global goal is at the first level, at the second level are criteria and sub-criteria (clusters of elements and their relations) on the basis of which alternatives, located at the third level, are evaluated. The hierarchical structure is very similar to the structure of the AHP method, but the essential difference of the BOCR model compared to the AHP method is that the BOCR model is based on the feedback from the entities at higher levels (Saaty, 2005; Saaty, 2008; Saaty 2009).

Once a hierarchical structure of the goal, criteria, sub-criteria and alternatives is established, we move on to the next, most important phase which is performed by a paiwise comparison. Comparison of alternatives and criteria is performed for each of the BOCR factor, and this modeling allows the existance of more interdependencies between elements that are defined by the BOCR criteria (Saaty, 2008; Saaty 2009).

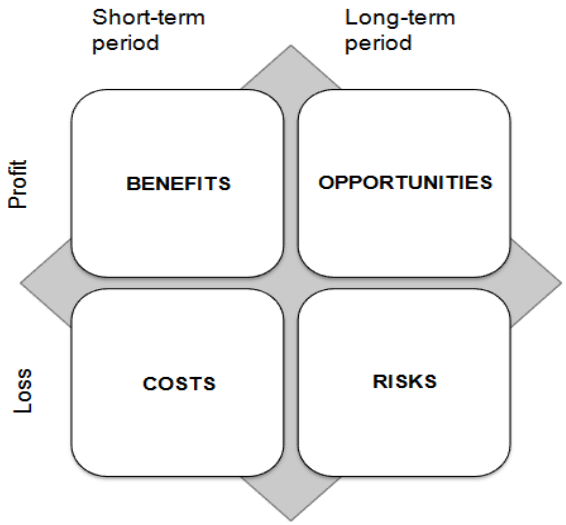

Figure 1: Summary of BOCR model in relation to the period and the final outcome of the decision (Source: Authors)

The comparison is made using a nine-point Saaty's scale as shown in Table 1, in which the rank 1 indicates equal importance between the two elements, while the rank 9 indicates the absolute importance of one element over another against which it compares (Felice & Petrillo, 2010). Reciprocal values shown in Table 1 represent the respective opposite values.

Table 1: Saaty's nine-point scale (Felice & Petrillo, 2010)

The intensity of importance shown by numerical grade	Definition	Reciprocal value
1	Equally important	1
3	Weak dominance	1/3
5	Strong dominance	1/5

When pairwise comparison is completed, the results are synthesed. To obtain the results, the following matrixes are used (Saaty & Ozdemir, 2005; Saaty, 2008):

1. Unweighted supermatrix is a matrix containing the priorities / weights obtained by pairwise comparison of elements in accordance with the inter-dependencies between the elements.
2. Weighted supermatrix is a matrix obtained by multiplying the unweighted supermatrice by cluster priorities / weights. Cluster priorities are shown in the Cluster matrix. Priorities in the matrix clusters are obtained by pairwise compersin of clusters in accordance with the dependencies between clusters. By this method a weighted matrix becomes a stochastic matrix in which the sum of each column equals 1.

3. Limit supermatrix is a matrix obtained by potentiating weighted supermatrix.

Figure 2 shows an example of a supermatrix.

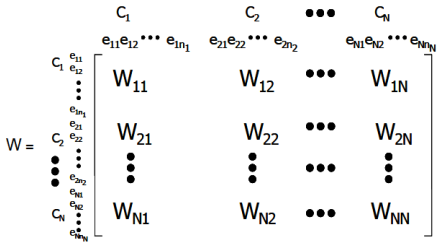

Figure 2: Supermatrix (Saaty, 2008)

In this model, C_x *(x=1, 2, … , n)* represents the hierarchy, while the elements are shown as e_{x1}, e_{x2}, … , e_{xn} (Saaty, 2008). Supermatrix is composed of so-called block matrix, W_{ij}, which shows the impact of each *i*-th element of the hierarchy on the *j*-th hierarchy. Figure 3 shows a supermatrix consisting of blocks.

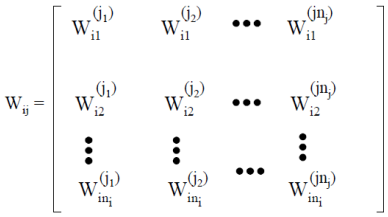

Figure 3: Supermatrix block (Saaty, 2008)

Unweighted matrix is obtained by assigning a weight to a supermatrix, which is calculated using a pairwise comparisons of elements. By forming unweighted matrix, the pairwise comparison of clusters is performed. Following this comparison, a multiplication of blocks of unweighted matrix by corresponding cluster weights is performed, using the following formula:

$$\bar{W} = a_{ij} * W_{ij} \tag{1}$$

where:
$\bar{W}$ – weighted matrix,
a_{ij} - appropriate weight,
W_{ij} - blocks of unweighted matrix (Sekitani & Takahashi, 2001).

In order to obtain the weights a_{ij} in the ANP method, the limit process is used $\lim_{v\to\infty} S^v$, but the weight vector of object *u* is the solution of the equation $S_u = u$ only if S is a random (stochastic) matrix, which is necessary in the ANP method (Sekitani & Takahashi, 2001). If the weighted matrix has zero values, it indicates that there are no interdependences between the clusters. Further, by the exponentiation of weighted matrix to the point of convergence a limit matrix is obtained. In the limit matrix all rows have the same value. Clusters which indicate other clusters must be pairwise compared to understand their impact on the clusters. To this end a cluster of the matrix is used. Comparison is made in regard to the criteria in columns and a comparison of all clusters whose value is not zero, and which are listed below these criteria, is carried out (Sekitani & Takahashi, 2001; Saaty & Ozdemir, 2005; Saaty, 2008).

To obtain the final result, during the synthesis of the whole model, the final ranking of alternatives is obtained. There are two ways to calculate the final rank of alternatives. The first may be the use of "multiplicative" formula: *BO/CR* which means that the product of the benefit-priority (B) and the opportunity-priority (O) vectors is divided by the product of the cost-priority (C) and risk-priority (R) vectors. By applying this formula there are no negative results of final priorities. The multiplicative method obtains marginal values, so that these results are considered short-term. Another way to calculate the final ranking of alternatives is the use of "additive" formula: *bB+oO-tT-rR*, where the values of *b, o, t* and *r* are priorities from the ranking model, and *B, O, T* and *R* are calculated in the same way as in the first approach. In this case the final solutions can be negative. The results obtained in this manner are considered long-term (Saaty & Ozdemir, 2005; Saaty, 2008).
When analysing the results in the BOCR model, we seek for a solution with the greatest benefit, and with the greatest opportunity to meet the control criterion. Unlike criteria *B* and *O*, which tend to the maximum value, the other two factors, cost and risk, require the solution with the lowest values. While observing the costs and risks, we should strive for a solution that carries the lowest risk and lowest cost. Additionally, in some cases,

we should take into account the alternative with the highest ratio of *BO/CR*. After the results are obtained and the most appropriate decision is made using the ANP method, we can conduct sensitivity analysis using "what-if" analysis (Saaty & Ozdemir, 2005; Saaty, 2008).

5. APLICATION OF THE METHOD IN BANKING AND THE ANALYSIS OF RESULTS

This chapter reviews the applications of the ANP multicriteria method in modeling and analysing relevant alternatives and their relative weights in regard to benefits, opportunities, costs and risks (BOCR), in order to assess all effects of the selection of appropriate strategies for the successful introduction of open innovation concept in the Serbian banking sector. The assessment was made on the basis of knowledge and professional experience of the authors of this paper; and for problem solving the software package *Super Decisions*[1] was used.

5.1. The structure of the BOCR model

Decision-making problem is decomposed into a controlled hierarchical structure, as shown in Figure 4, at the top of which is the main objective which is the development of the concept of open innovation in the banking sector. At the second level there are four criteria that reflect both positive and negative impacts on the ultimate goal, and they are: benefits (B), opportunities (O), costs (C) and risks (R). Each criterion contains a set of sub-criteria derived from the broader literature.

The criterion *benefits* (B) includes the following sub-criteria: reducing time-to-market, reducing the risk of guessing what the market wants, profiting from ideas from the external environment, reducing operating and research and development costs.

Under the criterion of *opportunities* (O) there are five sub-criteria: potential for the productivity development, potential for synergy between internal and external innovation, potential to increase profitability, the possibility of achieving sustainable growth and development of the organization and the ability to achieve competitive advantage in the market.

The criterion *costs* (C) contains the following sub-criteria: investment in the development of information technology and infrastructure, investment in the development of intellectual capital of managers and employees, investment in new business models and coordination costs.

The criterion *risks* (R) has four sub-criteria: brain-drain, lack of control and increased complexity in an open innovation model, possible release of classified information, unclear definition of strategies that employees cannot fully understand.

The development of the concept of open innovation (OI) in the Serbian banking sector can be achieved by choosing one of the sets of alternatives which are derived from the broader literature. It will, then, form the basis for the choice of an appropriate strategy for successful introduction of OI in banking, and it comprises: development of ambidextrous organization, building learning organization or knowledge-based organization, development of organizational culture as a platform for introduction of the concept of OI, the development of open, flexible and service-oriented business model, developing "digital banking", proactive role of innovation management along with the development of a new set of management skills, integration of employees in the innovation process, integration of internal and external knowledge into the developing process of products and services, improvement of internet technologies as a multi-distribution channel, developing an open architecture based on the use of "smart" mobile phones, the development of intellectual property (IP) of generators and associates including external stakeholders such as customers, universities, agencies for research and development, suppliers, and the development of intellectual property markets.

The *Super Decisions* software package uses a dual-layer BOCR model in which the main goal is located at the top of the hierarchy, while benefits, opportunities, costs and risks represent control criteria, i.e. control network. Within each control criterion B, O, C and R, there are two clusters. One cluster includes all alternatives, while the other comprises the sub-criteria. Both clusters within each of the control criterion include elements. Within the clusters of alternatives, the elements are the set of all alternatives, while in the second cluster the elements are a set of corresponding sub-criteria among which internal and external connections are established.

[1] www.superdecisions.com

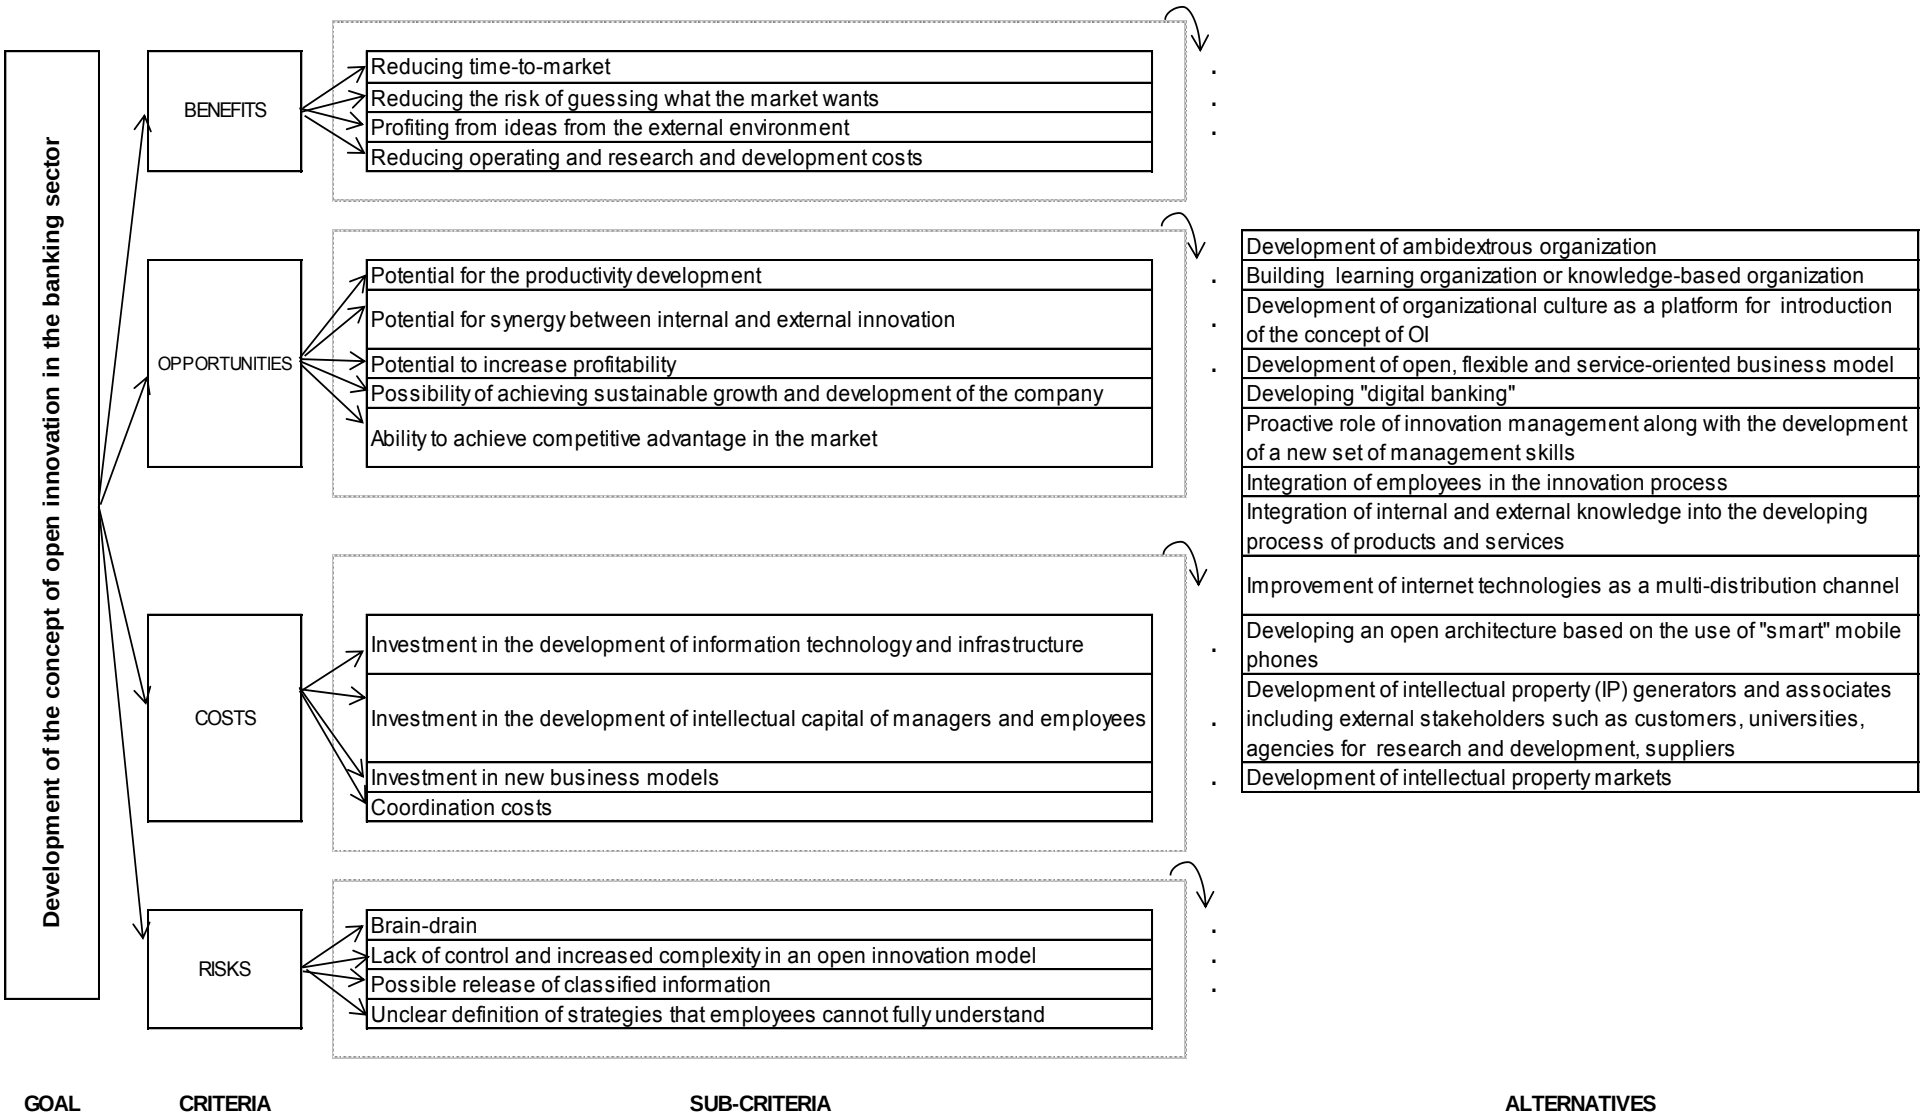

Figure 4: BOCR model (Source: Authors)

5.2. Analysis of results

Setting priorities of alternatives in the BOCR model involves pairwise comparison according to pre-defined connections between the elements and clusters within the control criterion. In the model presented in this paper, in assigning relative weights in relation to benefits, opportunities, costs and risks, the highest rated alternatives in regard to benefits and opportunities represent the greatest benefits and the greatest opportunities to meet the criteria. In contrast, in the evaluation of costs and risks, the highest-rated alternative is the one that causes the greatest costs, i.e. potentially carries the greatest risk. The results of pairwise comparisons are proved to be consistent.

After determining priorities within each of the control BOCR criterion, the synthesis of results within each control area network (BOCR) is performed, followed by the synthesis of the results of the overall model. By synthesis of the results of the overall model the final priorities of alternatives are obtained, i.e. the final ranking of options for decision-making. In this paper we have used additive formula: ***bB+oO-tT-rR***, which is considered to give long-term results.

Results obtained by software package *Super Decisions* can be expressed in three ways: 1) *Ideals* - priority list of alternatives defined in regard to an instrument that has the highest priority value, 2) *Normals* - vector of priorities in a normalized form and 3) *Raw* - priority vector of alternatives obtained after the synthesis of all impacts and the calculation of a limit matrix. The results of the final synthesis of alternatives are presented in Table 2.

Table 2: The final priorities of alternatives for decision-making

Alternatives	Ideals	Normals	Raw	Priority
Building a learning organization	1.0000	0.1354	1.0000	1
Development of ambidextrous organization	0.9264	0.1254	0.9264	2
Development of IP markets	0.8467	0.1146	0.8467	3
Integration of internal and external knowledge in the development process of products and services	0.8231	0.1114	0.8231	4
Development of IP generators and associates including external stakeholders such as customers, universities, research and development agencies, vendors	0.7583	0.1026	0.7583	5
Building "digital banking"	0.6033	0.0817	0.6033	6
Imrovement of Internet technology as a multi-distribution channel	0.5394	0.0730	0.5394	7
Development of open, flexible and service-oriented business model	0.4481	0.0606	0.4481	8
Proactive role of innovation management along with development of a new set of management skills	0.4361	0.0590	0.4361	9
Integration of employees in the innovation process	0.3748	0.0507	0.3748	10
Development of an open architecture based on the use of "smart" mobile phones	0.3660	0.0495	0.3660	11
Development of organizational culture as a platform for the introduction of the concept of open innovation	0.2655	0.0359	0.2655	12

The concept of a learning organization is based on the proposition that every organization that operates in a dynamic, technologically prominent and knowledge intensive environment must establish mechanisms for continuous learning, improvement and adaptation in order to strengthen competitive advantages. In addition, this concept allows greater flexibility for organizations, continually increasing their own capacity in order to achieve better business results and enhance them for finding new ways of managing and adapting to the increasingly difficult foreseeable circumstances in a turbulent environment.

Based on the results reported in Table 2, the highest ranked alternative in regard to benefits, opportunities, costs and risks is the alternative *building a learning organization*, i.e. *a knowledge-based organization*. The second most important alternative is the *development of ambidextrous organizatio*n, followed by the alternative *development of intellectual property markets*. On the fourth and fifth place of priority are alternatives which suggest integration of both internal and external knowledge in the process of product and service development, as well as incorporating stakeholders and external experts in the innovation process. Alternatives according to the final priority are also presented in Figure 5.

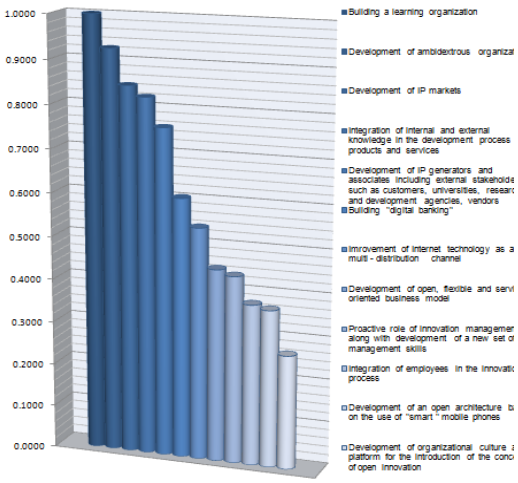

Figure 5: The final priorities of alternatives (Source: Authors)

Furthermore, in order to survive and obtain a long-term growth and development, banks should be developed into organizations that are able to simultaneously achieve harmonisation in current operations on

one hand, and on the other hand to effectively adjust to changes in the required environment, i.e. to become ambidextrous organizations.

The development of ambidextrous organizations implies a change in the management approach, which is, in the modern business environment, based on a systematic and holistic approach to management. In addition, in order to minimize market failure and the lack of adequate performance, the banking sector needs to find new ways of managing innovation and redefine existing strategies of innovation. In an effort to strengthen competitive advantages, closed concept of innovation has become inadequate to successfully generate profits from innovation. In addition to connecting various functional areas of the innovation process within an organization, it is necessary to develop a market for the exchange of intellectual property, to make innovation networks by linking various participants in the creation of superior value. The key business processes need to engage customers, representatives of research organizations, universities, partners, suppliers, and even competitons.

The authors of the paper maintain that these five alternatives are the most important elements for the successful introduction of the concept of open innovation in the banking sector of Serbia. Also, the authors are of the opinion that each company needs to adjust the priority of alternatives according to their own capacities and predefined strategic goals.

6. CONCLUSION

This paper presents the ANP method in multi-criteria decision-making which is used to carry out a quantitative analysis of alternatives and their relative weights in regard to benefits, opportunities, costs, and risks, thus performing an objective assessment of factors that affect the final decision.

According to the results obtained by the ANP method, the highest ranked alternative in regard to benefits, opportunities, costs and risks is the alternative *building a learning organization*, i.e. *knowledge-based organization*. The second most important is the alternative *development of ambidextrous organization*, followed by the alternative *development of intellectual property markets*. On the fourth and fifth place of priority are alternatives which suggest integration of both internal and external knowledge in the process of product and service development, as well as incorporating stakeholders and external experts in the innovation process.

Thus, for the successful introduction of the concept of open innovation in the banking industry, and with the aim to survive and enable long-term growth and development of the banking sector in Serbia, the authors are of the opinion that the sector needs to focus on building a learning organization concept that allows organizations greater flexibility, continuous increase of their own capacity in order to achieve better business results and empower companies for finding new ways of managing and adapting to the increasingly difficult-to-predict circumstances of a turbulent environment. Also, knowledge is a pre-requisite for the success of business as well as the imperative to conditions imposed by 21st century.

In parallel, the banks need to be developed into organizations that are able to simultaneously achieve harmonisation in current operations and to effectively adjust to changes in the demanding environment, i.e. to become ambidextrous organizations. In addition, in order to minimize market failure and a lack of adequate performance, the banking sector needs to redefine existing business strategies of innovation by developing intellectual property markets and continually incorporating internal and external knowledge in the innovation process.

Based on the obtained results, the paper demonstrates the possibility of the ANP method to support effective decision-making in complex business environments as it provides a comprehensive, quantitative and objective approach to all relevant, tangible and intangible factors in the decision-making process.

Subjective assessment of the authors in the process of the evaluation of alternatives is a potential constraint to the paper. However, this work can contribute to theorists and managers in the fields of decision-making, business decision-making, innovation management, and banking sector. In order to find a proper application in practice, future research on the concept of open innovation should include testing on a larger number of samples of different stakeholder groups.

[3] Faculty of Information Technology momirmilic153@gmail.com

Abstract: *In this research paper, based on the systematic study of the relevant literature and research performed in chosen companies in Serbia, with different types of activities, production processes and the ownership structure, on a representative sample, the methodological aspects of the implementation process of ERP system have been evaluated. The process of implementation and usage of ERP system has been researched and analyzed, emphasizing: the extent and factors which are influencing the implementation and usage of ERP solutions by the company users, business factors that influence the selection of ERP solutions analyses, ERP solutions presentations of different providers for midsize companies, comparison of the development phases of ERP solutions, analyses of the cost performance improvements, and the motives for the introduction of ERP solutions to companies in Serbia.*

Keywords: *ERP system, implementation, information system, company.*

1. INTRODUCTION

The goal of the research study was to gain insight into the research aspects of the Critical Success Factors (CSF) in the project management implementation of the Enterprise Resource Planning (ERP) systems in certain companies in Serbia. ERP solutions today are playing a major role in standardization, rationalization and automatisation of processes. [1] To accommodate today's challenging and competitive business environment, companies are introducing ERP systems in order to achieve the capability to plan and integrate company resources, and to be prepared to respond to all customers' requirements. This research study is attempting to systematically investigate the ERP literature and to identify the advantages in the world market, markets in the region, organizational culture and critical success factors of ERP implementation. The study aims to improve understanding of the critical factors that influence the success of ERP implementation in Serbia. Famous authors Boddy, D. Boonstra, A.& Kennedy, G. (2008) emphasize that ERP coordinates all activities, decision making and knowledge among different business functions, levels and units in anticipation of increasing efficiency and service. [4] ERP also provides direct access to current operational information to the management by enabling the integration of customer information, financial data, standardization of production processes and inventory reduction improving level of companies decision making, enabling the IS connection of the suppliers and customers with the internal IT processes. [5]

2. ERP CHARACTERISTICS

The below given figure 1 represents the percentage of unsuccessful and successful implementation, as well as the extended deadlines in a research period of ten years. The research showed that a large percentage of projects, whether it is the introduction of new or upgrade of existing IS, are not completed timely or the estimated cost increased.

Organization Standish Group International Inc. performed a study which concluded that 28% of all corporate IT development projects are abandoned before completion, 46% of projects is not completed within the stipulated time, estimated cost and in the expected volume. [13] Even when ERP solutions were being implemented, a large percentage of omissions are shown in implementation of the ERP (35%); also it is shown that the implementation of ERP is not completed within the stipulated time, with an increase of the estimated costs or estimated time (55%). The same source shows that only 10% of ERP implemented projects are being successfully installed. [3]

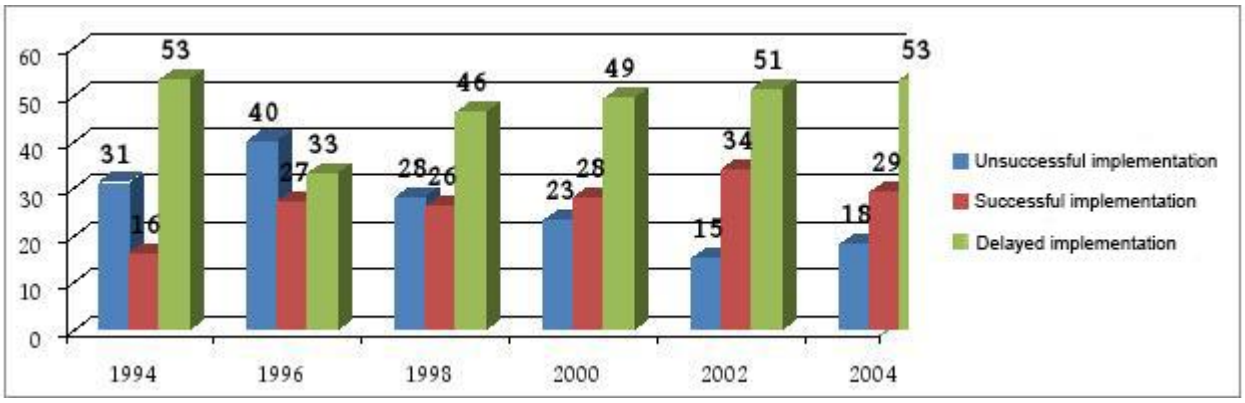

Figure 1: The success of ERP implementation [21]

Standish Group's research highlighted that, on average, there is 25% of successful ERP implementation, and that the planned implementation time, on average, was increased for 202%, exceeding the estimated budget by an average of 214%. [21]

The ERP Solutions recognize the following characteristics: [17]

- prepared software solutions designed for the client / server architecture, regardless of whether they use conventional or Web clients,
- connection of the most of the business processes in the company,
- processing of the major part of the company's transactions,
- utilization level of the database in which each data is recorded only once,
- provision of the access to data in real time to all users of the solution,
- recording and processing the majority of transactions in the company,
- enabling the design of different types of production (single, continuous and procedural) and different production environments (custom production, warehouse, assembly and a combination of mentioned environments).
- ERP solutions broke down the inefficiency of independent systems linking data in order to support multiple business functions, which are shown in Table 1.

3. IMPLEMENTATION OF ERP SYSTEMS

Projects for the implementation of the ERP systems shall be adjusted to the specific needs of the companies and business systems in Serbia. Many authors, such as Adur et al. (2002), and Akkermans Helden (2002), Bancroft et al. (2001), and Florin Bradford (2003), Estaves et al. (2002), Jarrar et al. (2000), Khan (2002), Mabert (2003), Sternad (2005) and others, are exploring the affecting factors on the successful implementation of ERP solutions. They came to the conclusion that conditions under which the selected ERP solution is going to be implemented shall be organizationally prepared within the stipulated time and the estimated costs. This means that companies have to be aware of the Critical Success Factors of ERP implementation. [20]

Five largest providers of ERP solutions have in their offer ERP solutions shown in Table 1.

Table 1: ERP solutions for medium-sized companies [2]

Company	Focus on the activity (type of the activity	ERP solutions
Infor	Footwear and textiles, automotive, chemical and food industries. ICT industry, equipment industry. Insurance, metal and plastics, shipbuilding, electrical industry, paper industry, water supply, heating, communications, management facilities, financial services, healthcare, hospitality, public administration, retail, food processing.	COM, BPCS, ERP LN, ERP LX (BPCS), MANMAN, MKManufacturing, KBM, MAXCIM, CAS, PEMS, Masterpiesce, Infinium, Prism, Protean,BAAN,Visual, TRANS4M,Xpert, XA, Syteline, Adage, System21, A+, FACTS, SX.e, Anael, Sun Systems and Varial.
Microsoft Dynamics*	Automotive, chemical, high-tech and electronics, oil and gas, procurement, manufacturing, food and shoes.	Microsoft Dynamics AX, Microsoft Dynamics GP, MicrosoftDynamicsNAV, MicrosoftDynamics SL.

Oracle	Banking and financial services, communications, healthcare, high technology, public sector, education, research, retail, supply, aerospace and defense, automotive, chemicals, mechanical engineering and building construction, manufacturing, and food processing and footwear	E-Business Suite, Peoplesoft Enterprise, JD Edwards Enterprise One, JD Edwards World.
Sage Software	Distribution and retail, automotive, construction, distribution, high tech, design, nonprofit organizations and government, health care, food and shoes	SageAccpac ERP, Sage MAS 90/200/500,Sage Pro ERP, Sage PWF ERP, SageERP X3ProcessSuite, Sage ERP X3Discrete Suite, SageERPX3 Distribution Suite.
SAP	Aerospace, automotive, chemical, engineering, construction, high technology, equipment and components, military products, mining, oil and gas	R/3, SAP Business Suite (includes SAP ERP),SAP Business One, SAP All-in- One, SAP Business By Design.

Legend: * Industry Solutions are sold to partners. The most prominent are Fullscope (to AX), Tectura and Hitachi Consulting (to AX).

The main features of the concept of governance, used applications, methodological approaches, technologies and a brief description of the development of ERP solutions are summarized in the following Table 2.

Table 2: Comparison of the developmental stage of ERP solutions [10, 15]

	1950 Editing stock	1965 MRP	1975 MRP II	1990 ERP	2000 ERP II
Characteristics	Economic ordering stock	Comprehensive planning of production	CIM, EIS	Complete design, OLAP, flowcharts, e-mail	Portals, BI
Menagerial concepts			TQM, JIT	The principle of best practice	SCM, CRM, SFA, e-commerce, SaaS
Oriented applications	Inventory control	Operational Planning and Control	Integration	Internal efficiency	Connect to applications from various organizations
The methodological approach	Manual systems	Scientific Solutions	Simplicity	Business Solutions	Virtual Business Solutions
Technology involved	Machine language	Third-generation programming languages (Fortran, COBOL)	Open Systems, 4th generation programming languages (eg SQL)	GUI, objects, components, TCP / IP	WAP, VoIP.
Hardware	Mechanical	Batch processing	Minicomputers and workstations	Client / Sertver, LAN	Distributed Network

Description (Focus on Performance)	Orientation to performance. Management control in the process of ordering and timely warnings. Provided they fill a variety of techniques, supply coordination, and report on actions.	Focus on sales and marketing. Designed for process planning based on sales. MRP programs are generated drawings for production planning, work control and inventory management.	Focusing on the strategy of producing and providing quality. Programs MRP II helps production management in supply chain planning and manufacturing process (product planning, parts purchasing, inventory control and management costs).	Focus on the integration of applications and customer management. Designed to improve the capabilities of internal business processes in the value chain of the company. Integrating the core business activities and support activities.	Focus on agility and global environment. Expansion of ERP solutions at all organizational systems enabling e-business. Enabling access anytime, anywhere to all partners; Inclusion of modules such as SCM, CRM, SFA, APS, and so on.

Today's ERP solutions are the result of three factors: the progress in hardware and software development (processing power, memory and communication), development of a vision of an integrated IS and changes in the organization from functional to process-oriented companies. [14]

The integrated IS or the ERP may lead to a more efficient business processes which cost less and in addition have the following advantages: [6]

- ERP enables easier global integration: language and cultural barriers can overcome automatically.
- ERP not only enables integration between people and information, but also eliminates problems with upgrades.
- ERP enables management of the operation, not only monitoring. This enables that all information are available to managers, allowing them to focus on improvement of the process.

Scott and Vessey emphasize that the ability to integrate all aspects of ERP have the strategic impact on the organization. [19] In terms of speeding up the restructuring of business processes to operate globally, it can be rapidly adapted to competition changes and thus can enable the integration of data throughout the organization. In terms of technology the installation architecture shall be speeded up, and that architecture is scalable and flexible and enables cost reduction in terms of the lease rather than in IS construction. [7] The company Aberdeen Group (2006) says that in order to have the successful ERP implementation it is essential to measure it in connection with the business benefits.

The following Table 3 shows the cost of performance improvement.

Table 3: Costs of performance improvement [1]

	small Businesses (<$ 50 Million)	Medium-sized companys ($ 50 Million - 1% Billion)	Large companies (> 1 Billion)
Reduction of the inventory costs	13.9%	14.5%	18.1%
Reduction of the operating costs of production	12.8%	12.8%	15.4%
Reduction administrative costs	13.4%	16.4%	11.4%
Full improvement and timely shipping	20.2%	21.0%	13.0%
Improved consistency of production schedules	19.3%	17.3%	12.1%
Average	15.9%	16.4%	14.0%
Cost in comparison to the percentage improvements	$ 389	$ 347	$ 130

Famous authors Motiwalla, L.F. & Thompson, J. (2009) emphasize that the advantages and limitations of the system shall be monitored from the business point of view, where results can be tangible or intangible, as well as short-termed or long-termed. [15]

Advantages and limitations of ERP system solutions are: [8]

- The integration of data and applications between functional areas of the organization (one entry of data and the ability to use data in all applications enhances the accuracy and quality of data).
- Easier maintenance and better support systems, IT professionals are focused on only one solution, and consequently on better support and the needs of the user.
- The unique user interface between different applications means less training for employees, increased productivity and easier movement of workers between business functions.
- Provides better security of data and applications through a central hardware, software and networks.
- The complexity of the installation, adjustment and maintenance of the system increases, which require specialized IT professionals for hardware, software and networks.
- Standardization of hardware and software is difficult to achieve.
- Transmission and data conversion from the old system to the new system can be time-consuming complex process.
- Employee training for IT ERP system can cause resistance and can reduce productivity in the first period.

Business advantages and limitations of ERP solutions are: [9]

- The flexibility of the organization which can respond quickly to changes in the environment (i.e. sales growth thus maintaining market share in the industry).
- Easier collaboration and teamwork to access information from different functional departments.
- To facilitate networking and exchange of data in real time between partners in the supply chain can improve the efficiency and reduce the cost of products and services.
- Higher quality of service to customers due to faster and better information flow within the organization.
- Improving business process trough re-engineering of the business processes.
- Staff training on the new system leads to additional costs.
- Amended business applications and department boundaries can cause resistance to the ERP system.
- Reduction of the cycle times in the supply chain from raw materials to product sales.

Kalakota, R.& Robinson, M. (2001), as the main advantages of ERP in the production stress out [12]

- part-time planning (95%),
- Part time delivery (10% – 40%),
- Part time production (10% – 50%),
- lower inventory levels (10% – 25%),
- reduction of delays in delivery (25% – 50%)
- increased productivity (2% – 5%).

There are six most common reasons why businesses and business systems need to implement ERP solutions, namely: [18, 19] the need for a single platform, process improvement, data visibility, reduction of operational costs, increased customer response and improved strategic decision-making. These reasons are related to each other and as a common platform they provide new opportunities for continuation of creation of significant results, as shown in Figure 2.

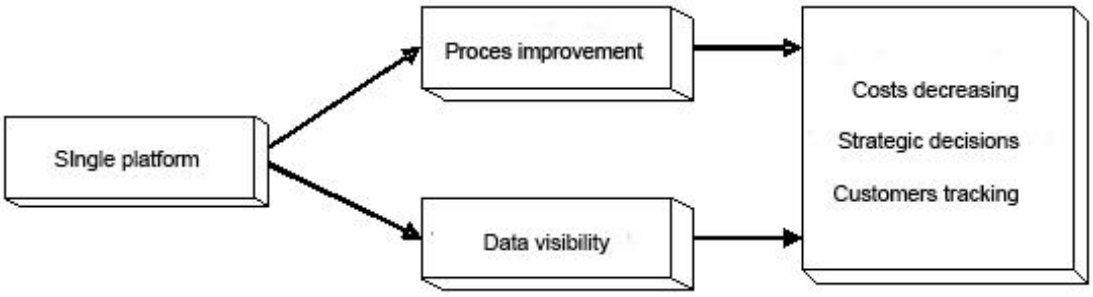

Figure 2: The motives for the implementation of ERP solutions [19]

The company or organization may decide to implement a new IS and thus to overtake competitors. This can be done through the following strategies: [16]

1. Cost leadership strategy where we become the manufacturer with the lowest cost per unit because IS reduces the cost of business processes and customers and suppliers cost.
2. Differentiation strategy where, with the help of IS, products / services can be differentiated.
3. Innovation Strategy where a unique product / service is being developed or integrated as a single performance in the markets.
4. Growth Strategy which significantly increases the production capacity of the company, accelerating the expansion of global markets, accelerating investment in new products and services, etc.
5. Alliances strategy which can be used to establish business relationships / alliances with customers, suppliers, competitors, consultants and other companies.

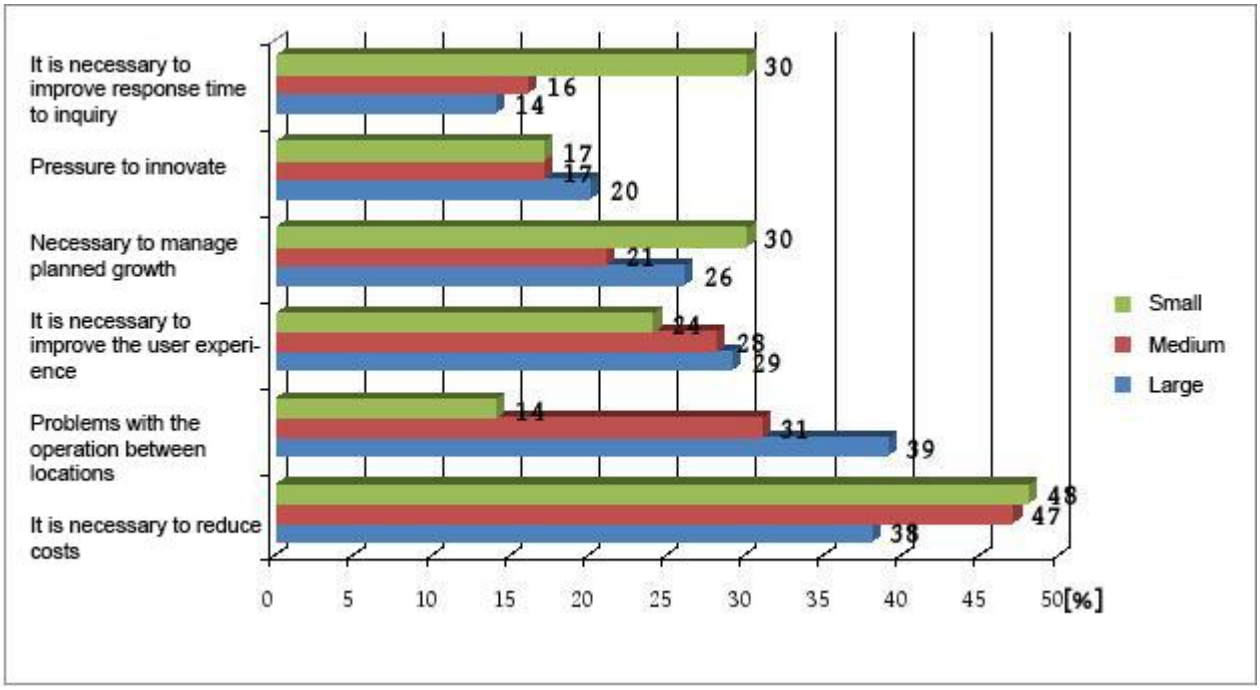

Figure 3: Business factors that influence the selection of ERP solutions [11]

The previous figure 3 showed that for small businesses and organizations the most important factors are cost reduction, the need to manage the expected growth of the organization and improvement and response time to customers. For medium and large companies and organizations the most important factors are cost reduction and solving problems of interoperability between locations.

4. CONCLUSION

Projects which include implementation of the ERP systems shall be adjusted to the specific needs of the companies and business systems in Serbia. The theoretical and practical part of the research shall be concluded with the presentation of the results of analysis of the installation of the implementation of ERP solutions in Serbian companies. In this research paper a study of methodological aspects of project management and ERP system implementation and installation is presented, where it is especially highlighted: comparison of developmental stages in ERP solutions, business factors that influence the choice of ERP solutions, motives for installation of ERP solutions, business benefits and limitations of ERP solutions, cost performance and thorough analysis of ERP solutions for midsize companies. The paper is presented as an important studious analysis which can help in the project management of ERP system implementation in companies, and help them to identify and allocate strategic resources for the successful implementation of the system. The realization of the project of introducing an ERP business information system, as a key resource, is always a complex and expensive with far-reaching consequences for the company. [6] However, no matter how long the project is being implemented, periodically in virtually all businesses and business systems, the complete project can often fail, mainly due to ignorance and disregard of the rules of governing such projects.

Investment in Business Information System is an important item in the cost of the organization and should be calculated within the budget. [8] In addition to financial moment, of the utmost significance are time and effort that management and employees shall invest in the project especially in organizations that already have negative experiences on previous similar projects; the staff can express its opposition to even start with the implementation if conditions are not completely provided in respect to complete project implementation. Also, what is rarely discussed is the price or lost profit if the company or business system does not implement a new concept of modern integrated ERP system. The longer the companies postpone the procurement and implementation of modern business system, their presence in the global market will be postponed, the profit and savings as a result of new system will not be made, neither the company will achieve a competitive advantage over the competition.

AN APPROACH TO A SURVEY SYSTEM AS A CORPORATE TOOL

Aleksandar Ivanović[1], dr Dušan Vujošević[1], dr Ivana Kovačević[2]
[1] The Union University, School of Computing

Abstract: *In the world dominated by data acquisition and evaluation, this paper is working on an idea of making data collection from survey participants manageable and simple. The proposed survey information system would allow companies and home users to define their own surveys to analyse and evaluate the opinion of survey participants. It should help them in obtaining some specific knowledge from the overall population without using the conventional off-line surveying methods. It aims to have a higher level of usability than similar available systems.*

Keywords*: data collection, survey, usability, decision support, public relations, local data storage*

1. INTRODUCTION

This paper proposes a concept of survey information system allowing companies and individuals to get data from the broad public. We argue that surveys should be introduced in organisations to allow easier decision making. Our concept should enable companies and users to define their own surveys and use the data obtained to get to different conclusions without harming the privacy of the end user.

The role of easily conducted surveys cannot be underestimated in a world where the amount of data is overwhelming. Google, one of the biggest data giants today, was processing more than 20 petabytes of data per day in 2008, as it was pointed out at the time (Dean & Ghemawat, 2008). Today, we are faced with the problem of data often seeming useless at a first glance. Much of the information is of little use on its own to end users, even if they were allowed to take a look. Most of the data is considered private and/or tools of the trade.

At the same time, all of the giant companies strive to collect a variety of data about their users, rivals, the usage of their programs and the like. In order to properly use the data, the information are backed up and restructured for data warehousing and analysis. The question of good date organisation, retrieval and analysis arises frequently (Vujošević D. et al., 2012).

The surveys performed today are usually very intrusive and aggressive, such that the usual reaction is dismissive. Having a system only for the purpose of surveys should ease the use and make the data more intelligible. Since the only activity of users will be completing and making surveys, the data obtained should be with less noise.

2. SURVEYS IN THE CONTEXT OF WEB AND USABILITY

Over the last thirty years, the technology for utilizing surveys has changed. The first e-mail surveys emerged in the 1980s and the initial web-based surveys in the 1990s. Schonlau et al. (2001) discussed that the services available could be found to meet the needs of a marketing research professional. Today, the web has grown so much more, giving the access to a wider public. The field of web research has been populated by companies such as AAPOR (American Association for Public Opinion Research, www.aapor.org) and CASRO (Council of American Survey Research Organisations, www.casro.org).

Online surveys are used for a variety of purposes. There are surveys purely conducted for entertainment, others conducted for public opinion evaluation and some even influencing decisions.

Today there are very little E-mail surveys. In most cases the data is obtained from a web form, and it is directly inserted into a database after which it can be analysed by data scientists.

As outlined in previous studies by (Joel R. Evans, 2005), there are numerous strengths and weaknesses to web surveys. The strengths that will be mentioned here are global reach, convenience, ease of data entry and analysis, and low administration cost.

Global reach is an ambiguous trait, such that it is useful depending on the scale of the research in question. For localized surveys, additional restrictions based on location of the participant should be implemented. It is undeniable that the global reach is otherwise invaluable to the large-scale research, whereas the regular paper-and-pen or telephone surveys would be very expensive and inherit some other issues on their own.

Web surveys are also perceived as convenient. They can be completed at one's own leisure, without peer-pressure and time constraints.

Since data is streamlined by forms, there is no chance of corrupted data, such as multiple choices in a single choice question. Data can easily be accessed and analysed. This streamlining also allows a variety of data inputs, as previously outlined (Joel R. Evans, 2005). Another highlighted advantage of online surveys is that they can be made more flexible, visual and interactive. The user can be drawn in by the sheer aesthetic of a survey, simplicity of input and multimedia content.

It is also possible for the interviewers to be absent and online surveys typically do not require any personal presence. This can avoid the effect of the interviewer, which can in some cases cloud the data (Bobby Duffy & George Terhanian, 2005).

The overall sense of individualism can be increased by personalising each survey to the participant, allowing a greater degree of potential involvement in completion of tasks and questions. The online surveys also have one key advantage – they can be completed at the leisure of the participant. The participant chooses when to start the survey, possibly pause it and complete at a later time. This brings out a potential issue for surveys where time passed between questions can be of great importance to the data, which we will discuss at a later time.

The survey response rate, also known as completion rate, is often taken as a measure of goodness (Schonlau, M., Fricker, Elliott, & M.N., 2001). Survey response rates can be calculated according to several different computation formulas (The American Association for Public Opinion Research, 2008). As it is pointed out (Kiesler, Sproull, & S, 1986), the respondents of online surveys exhibited fewer completion mistakes and fewer missing entries to a statistically significant degree. This allowed more complete data and truthful conclusions.

As technology becomes more available, the potential for online surveys increases as well. In developing countries this development provides the ability to survey quickly and efficiently. The administration costs decrease and the ability to reach a large group of individuals is key to conducting large surveys.

3. CURRENT SOLUTIONS

With the expansion of data and the need for knowledge, many solutions have been constructed to ease the acquisition and analysis of data. Most of these solutions are offered in the form of software as a service with a variety of subscription plans.

The current solutions have many different choices of features and payment options. These can be summarized by outlining the common features of the survey services:

- Basic users – Usually also considered 'trial'. There is an imposed limit on the amount of surveys/questions/participants.
- Personal users – Intended for personal use and small businesses. There can be an imposed limit on amount of surveys or participants. Some providers also offer integration via web windows, allowing surveys to be placed on other sites. This set of features is usually charged per month.
- Small firms – This subscription usually has neither imposed limits on surveys, nor on participants. There are greater tools for analysis offered, such as SPSS integration. Some additional optional features are also added, such as: question randomization and random assignment, among others. This list of additional features may vary from site to site.
- Large firms – This subscription method, usually having very little restrictions in terms of analysis and generation, seems not to have limits as compared to other subscription plans. It is intended for corporations and large firms. It can offer added-value features such as hosted internet domains.

The trend of software as a service might discourage occasional personal use. Besides, it certainly could limit the applicability of a survey in the case it turns out to be interesting/rewarding/engaging to the participants and becomes more widespread.

4. THE CONCEPT OF OUR APPLCATION FOR SURVEY CREATION

With the expansion of web and the applications moving from desktop to their web-based counterparts in the recent years (Vujošević & Kovačević, 2006), the appropriate choice for our application will be a web interface A web-interface requires a web-server and hosting services, which will have impact on the overall cost of maintaining such a service. The background data collection will be handled by an integration of database with a web-application. Upon completion of a survey, the data will be stored in a table that can be evaluated and analysed.

The data storage will be based on a relational database management system. It will consist of the following core tables (as shown on the Figure 1):

- Users – Storing the user data such as names, surnames, date of birth and any data useful for research
- Surveys – Each survey having a single user that created it, which can be shown to other users.
- Questions – Each question belongs to a unique survey, consisting of the text/picture for text.
- AnswerType – A pre-defined list of the answer types such as single choice, multiple choice, plaintext.
- Answers – Each row consists of an answer text, each answer belongs to a specific question.

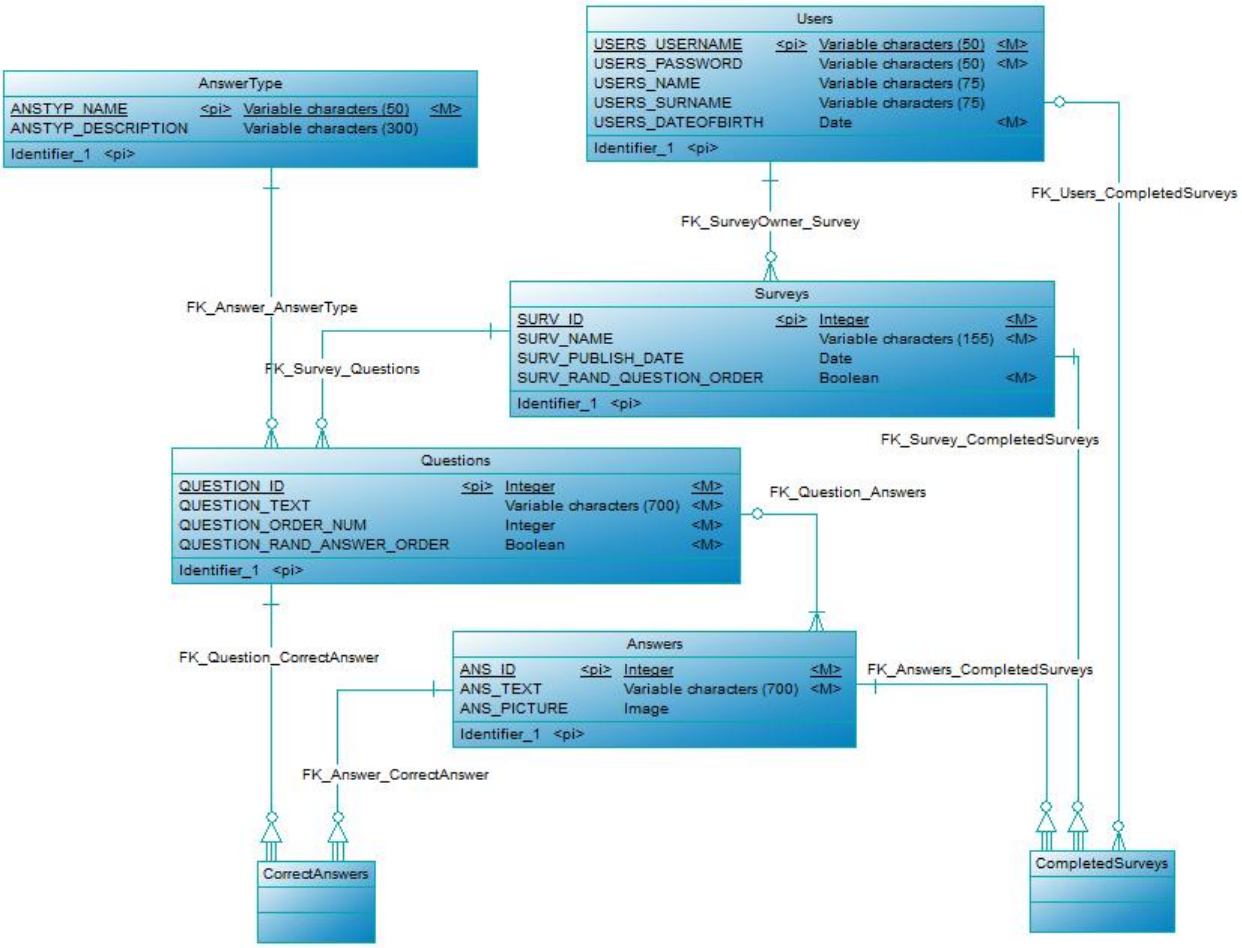

Figure 1: The data model of the proposed survey application

This would allow each survey to be data-driven, so that users could define their own surveys, their own questions, answers and correctness. The application itself would be web based, and the interface for defining surveys would also be accessed through a browser.

Allowing users to register and create surveys at first resembles a social network site. This could set apart our proposed solution in comparison with the current solutions. A social network site is defined (Boyd & Ellison, 2007) as a web-based service allowing individuals to:

- construct a public or semi-public profile within a bounded system
- articulate and update a list of other users with whom they share a connection

- view and traverse their list of connections and those made by others within the system

The one main difference would be the connection between the users – other sites call these "friends" or "followers" among others. In the proposed system, the only connecting medium between users would be the actual surveys.

In the present, the users are very much accustomed to using browsers in accomplishing nearly everything. This would mean that we expect that a minimal time will be needed for users to understand the usage of our application.

The final usability of the survey information system will be dependent on the interface design, which should be addressed during implementation. The greater the usability, the more will the system be accepted.

5. USER INTERACTION IN THE PROPOSED CONCEPT

Currently, there are three types of users planned for our system:
- Visitor User – This user is not registered, and as such is able to browse other surveys, but he is unable to submit a new survey or complete surveys.
- Registered User – The user has created a profile on the application and therefore is recognised. This user is able to complete surveys at his own accord.
- Survey Submitting User – This user has all the functionalities of the registered user with the addition of the ability to create surveys for others to complete.

The difference between a Registered User and a Survey Submitting User could be handled by the Administrator or by the initial setting of the system.

In the social-network aspect of the tool that could be hosted on the internet for wide use, corporate and personal alike, the difference between a Registered User and a Survey Submitting User would be handled by the system. For example, a user that has completed some arbitrary number of surveys set by the Administrator gains the ability to create surveys. This would encourage all new users first to get acquainted with the system, by completing surveys and learning how to use the interface, and at the same time, gaining insight which surveys were more enjoyable and which were less enjoyable, perhaps understanding how they should create their own surveys.

In a corporate use of the tool, the Survey Submitting User could be designated by the management to create an instance of survey to gain some wanted insight about their employees. This would allow a centralised source of surveys within a corporation and avoiding unnecessary traffic of unwanted surveys.

6. POTENTIAL USES IN COMPANY DECISION MAKING

Modern management needs to be able to make quick decisions in real time. The ability to make decisions that have the greatest impact could be supported by this proposed system. The upper management could define a survey for the employees to complete and then they could evaluate the data.

This would provide a modest to immense magnitude of increase in productivity of each decision (because it would be based on real data). It would allow the management do define and tune their surveys to its best potential.

It should be noted that while there are other solutions to surveys, they usually depend on storing that same data somewhere else, which no longer makes it safe for the company. We argue that the data storage must be within the company. Thus, one of the main advantages of a local survey application would be that the internal data of the company would stay within the company. The proposed solution would be self sufficient in the data storage, evaluation and generic applicability. The implementation of this system is not limited to a single instance on the web. Companies could have their own local, internal copies of the application, allowing them to keep track of the data and its usage.

Defining who can and who cannot create surveys would also be a feature, such that only specific users could define surveys. This limit would allow the control of survey-creating and evaluation to specific individuals, do prevent unnecessary or excessive surveys within the company.

As pointed out (Bobby Duffy & George Terhanian, 2005), the speed of response are considerably shorter in the case of web surveys. This gives an additional edge of speed to the upper management when attempting

to asses data. Face-to-face surveys with employees can be more insightful, but the web surveys allow greater accumulation of data in a much shorter space of time, thus allowing faster decision making, i.e. a decision making with more impact.

The system could also be used by companies' public relations management to conduct their own surveys of the public. The users participating could be the company's clients, which would mean the company already has some demographic data that would aid in the analysis of the results. In contrast to the face-to-face surveys, the company could reach a much greater public.

7. FURTHER RESEARCH

In the following months, tests should be made with a prototype system for defining surveys and completing surveys. It should allow the concept to be tested and some new features should arise.

The interface concepts will be rigorously tested and experimented. The interface must be able to support a critical mass of users with minimal effort.

8. DISCUSCUSION AND CONCLUSION

There are systems in place for online surveys, offered by major companies, such as Google. But none of these allow the portability of being a single-unified system on the web, while still maintaining the possibility of having separate applications entirely in the company or local storage.

In contrast to face-to-face surveys which can be sampled from a fairly comprehensive database, online surveys reach into a much greater pool of potential participants. While databases exist for local participants, there is no way of knowing who will participate in a survey online. There is no online database of everyone who exists, and while it is being argued whether that is a step in the right direction, there is no real way to gauge the data, except for being based solely on the honesty of the participant.

The issues in the demographic aren't the only thing that needs to be addressed. The behavioural and attitudinal differences need to be addressed as well. The participants must be motivated in some way in order to give thought and proper participation in each question and task. Another problem with online surveys is that they can be perceived as 'spam' and annoying. This can also deter not only potential participants, but also willing participants.

There are also issues based on privacy of participants, some participants would like to remain anonymous. That would mean disclosing some of their data to the creator of the survey, and yet allowing participants the sense of privacy. It is known that factors such as age and education can be an effective tool in gauging the data from a survey, and disclosing this data could violate the privacy of a participant.

It is also being discussed that the computer literacy of participants can be a key factor. It has been argued (Roztocki & Lahri, 2003) that the researchers in the field of IT tend to prefer Web-surveys, while researchers from other fields preferred the traditional pen-and-paper format. While the conclusion reached was that the non-IT fields leaned as much to the Web-based survey as the IT researchers did, the computer literacy of the participants could prove to be a potential pitfall. The surveys would have to be designed in such a way that a potential control group would be able to complete it, with the average levels of computer literacy. Today, however, the average computer literacy is much higher than it was five years ago, and this might prove to be much less an issue in the future.

IMPLEMENTATION OF DATA MINING TECHNIQUES IN CREDIT SCORING

Marijana Sitar, Jelena Rašeta, Anja Klešćek

Faculty of Organisational Sciences, anja klescek@hotmail.com

Abstract: *Credit scoring is a technique that is mostly used by banks in order to decide whether to grant credit to customer or not. Its increasing importance can be seen in everyday life and study after study has shown that credit scoring is a vital part of a modern financial system. Credit score prediction is of great interests to banks as the outcome of the prediction algorithm is used to determine if borrowers are likely to default on their loans. This in turn affects whether the loan is approved. In this paper we described an approach to performing credit score prediction using random forests, an operator in RapidMiner. The dataset was provided by www.kaggle.com, as a part of the contest "Give me some credit". Our model, based on random forests, was able to make rather good predictions on the probability of a loan becoming delinquent. We were able to get an AUC score of 0.845190.*

Keywords: *credit scoring, banking, RapidMiner, classification, imbalanced data, random forest, AUC*

1. INTRODUCTION

The field of data mining has been growing due to its enormous success in terms of broad-ranging application achievements and scientific progress, understanding (Venkatadri, 2011). The last two decades have seen a rapid growth in both the availability and the use of consumer credit. Until recently, the decision to grant credit was based on human judgment to assess the risk of default (Thomas, 2000). The growth in the demand for credit, however, has led to a rise in the use of more formal and objective methods (generally known as credit scoring) to help credit providers decide whether to grant credit to an applicant (Akhavein, 2005). This approach, first introduced in the 1940s, has evolved over the years and developed significantly (Rimmer, 2005). In recent years, the progress in credit scoring was fueled by increased competition in the financial industry, advances in computer technology, and the exponential growth of large databases.

In this report we analysed the problem of credit scoring. Credit scoring algorithms, which make a guess at the probability of default, are the method which banks use to determine whether or not a loan should be granted and they are generally based on statistical pattern-recognition techniques.

As we did a research regarding models that were used for the competition on Kaggle's "Give me some credit" data set, we noticed that for the problem of classification other competitors used Blended model, decision three, different usage of attributes. Also, it is important to mention that they used different programs such as R, Viscovery, SAS, SQL etc. We created a model using the RapidMiner program, and its operators: W-Logistics, SVM, AdaBoost Decision Tree, Naïve Bayes and Random Forest, but the best results were achieved with Random Forest operator invented by Breiman and Cutler.

2. CASE STUDY

We obtained the data for this problem from the Kaggle challenge website (http://www.kaggle.com/c/GiveMeSomeCredit/). The website provides two data files - one for training and one for testing. The training data file consists of 150,000 cases. The test file contains 101,503 cases. The intention is that we test our classifier on the test data and submit our predictions via Kaggle's online submission process.

Each sample contains 11 attributes and one class attribute (*Table 1*). The data set has missing values and is class imbalanced (there are 139,974 cases with "0" as a class value and 10,026 cases with "1" as a class value).

Table 1: Data set

Variable Name	Description	Type
SeriousDlqin2yrs	Person experienced 90 days past due	Y/N

	delinquency or worse	
RevolvingUtilizationOfUnsecuredLines	Total balance on credit cards and personal lines of credit except real estate and no installment debt like car loans divided by the sum of credit limits	percentage
age	Age of borrower in years	integer
NumberOfTime30-59DaysPastDueNotWorse	Number of times borrower has been 30-59 days past due but no worse in the last 2 years.	integer
DebtRatio	Monthly debt payments, alimony, living costs divided by monthly gross income	percentage
MonthlyIncome	Monthly income	real
NumberOfOpenCreditLinesAndLoans	Number of Open loans (installment like car loan or mortgage) and Lines of credit (e.g. credit cards)	integer
NumberOfTimes90DaysLate	Number of times borrower has been 90 days or more past due.	integer
NumberRealEstateLoansOrLines	Number of mortgage and real estate loans including home equity lines of credit	integer
NumberOfTime60-89DaysPastDueNotWorse	Number of times borrower has been 60-89 days past due but no worse in the last 2 years.	integer
NumberOfDependents	Number of dependents in family excluding themselves (spouse, children etc.)	integer

3. DATA PREPARATION

Reviewing the data set, we found that there are 29,730 cases with missing values for certain attributes. Testing the performance of the model, we found out that the elimination of cases with missing values achieved better performance compared to replacing the missing values with the average.

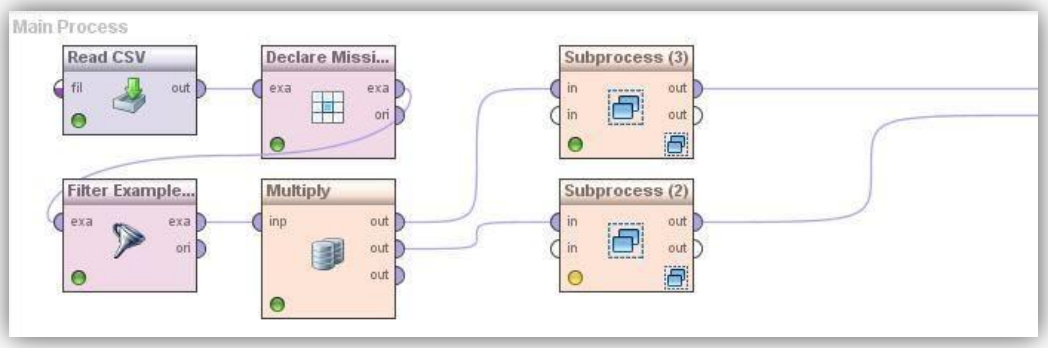

Figure 1. Data Preparation

Afterwards, examining the number of cases with “1” as a class value compared to the total number, we came to the conclusion that the data set is imbalanced. To solve this problem, we used clustering. We applied K-means algorithm on the cases with “0” as a class value to reduce their number to 6580. We divided the data set into two sets i.e. one set with the “0” as a class value and the other with “1” as a class value.

In order to get better performance of our model, we have reduced the data on 10%, because the algorithm for clustering indicated a problem in creating 6580 clusters. Then, we extracted centroids into the new data set and merged it with the set containing the cases with “1” as a class value using the operator *Append* in RapidMiner.

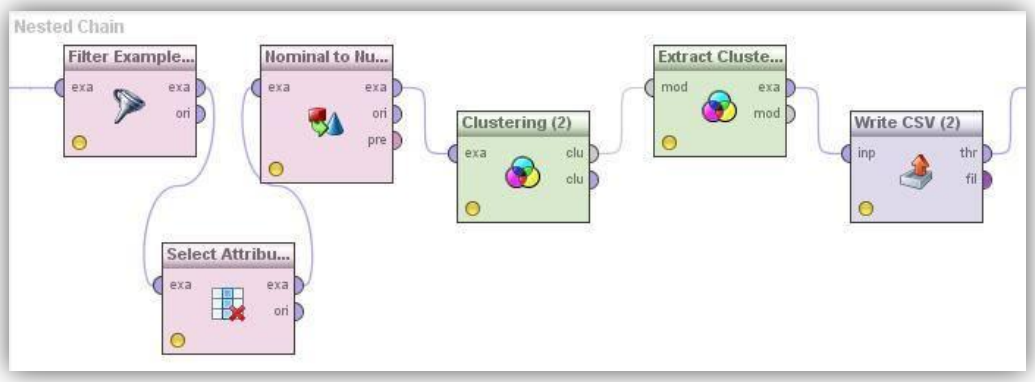

Figure 2.Subprocess 3 - clustering

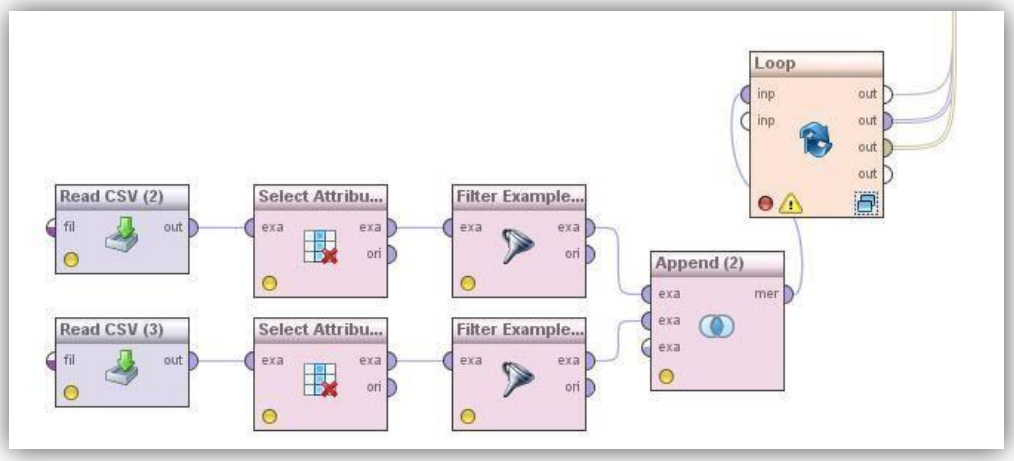

Figure 3.Merging data sets

For better understanding of the data set, we used operator *Correlation matrix* in order to determine which attribute influence the most on the output and how they are correlated.

attribute	weight
NumberOfTime30-59DaysPastDueNotWorse	0
NumberOfTime60-89DaysPastDueNotWorse	0.005

3. MODELING AND EVALUATION

For classification we used the operators: Naïve Bayes, AdaBoost Decision Tree, SVM, W-logistic and Random forest. We also tried to use the weight of the attributes to optimise the classification, but the result was much worse.

A Naïve Bayes classifer is a simple probabilistic classifer based on applying Bayes' theorem (from Bayesian statistics) with strong (naive) independence assumptions (Akhtar, Hahne, 2012).

Decision tree is a flowchart-like tree structure, where each internal node denotes a test on an attribute , each branch represents on an outcome of the test, and each leaf node holds a class label. The topmost node in a tree is the root node. This representation of the data has the advantage compared with other approaches of being meaningful and easy to interpret (Han, Kamber, 2006). AdaBoost operator tries to build a better model using the learner provided in its subprocess. AdaBoost, short for Adaptive Boosting, is a meta-algorithm, and can be used in conjunction with many other learning algorithms to improve their performance (Akhtar, Hahne, 2012).

SVM learner uses the Java implementation of the support vector machine mySVM by Stefan Rueping. This learning method can be used for both regression and classifcation and provides a fast algorithm and good results for many learning tasks (Akhtar, Hahne, 2012).

W-logistic - Class for building and using a multinomial logistic regression model with a ridge estimator and performs the Weka learning scheme (Rapid-I GmbH, 2008).

Random forest generates a set of a specifed number of random trees i.e. it generates a random forest. The resulting model is a voting model of all the trees (Akhtar, Hahne, 2012).

Result

For model evaluation we used AUC score because the accuracy is not precise when the class atribute is binary and the data set is class imbalanced.

By using operator Random forest, we got the highest ranking on Kaggle with an AUC score of 0.845190. As a reference, the top team got an AUC score of 0.869558.

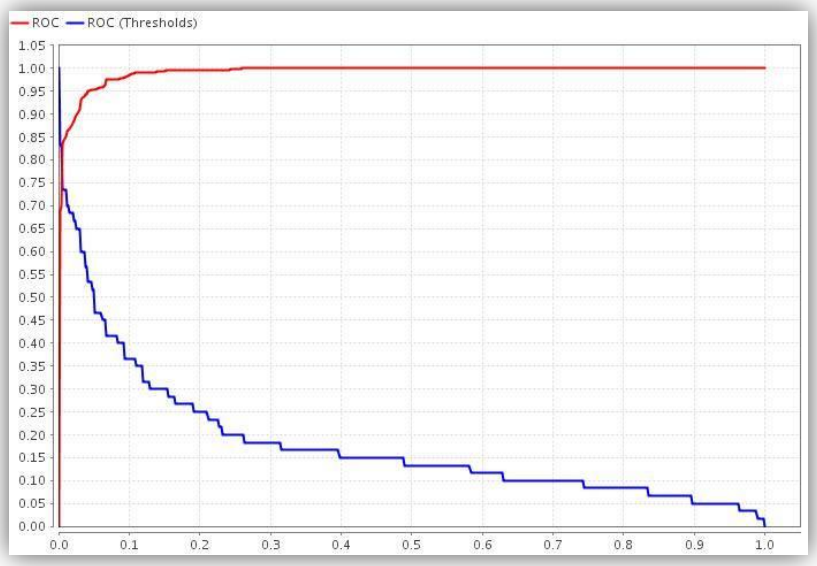

Figure 4.AUC in RapidMiner

4. CONCLUSION

To date, there exists no specialized algorithm coping with both the imbalance and largedata problem in loan default prediction, mostly because of the imbalanced datasets.In our work, we have presented a data mining model which applies classification methods using different algorithms for credit scoring. The most important part of our work was data preparation where we have used clustering. Clustering helped us to create balanced data set on which we applied Random forest algorithms. Using the knowledge gained during this project, there are a number of areas for possible improvement. Since data mining is a fast-growing area, there are numerous new techniques and programs that could be applied not only in credit scoring, but in all problems based on Big data, statistics and artificial intelligence.

WALMART RECRUITING – STORE SALES FORECASTING

Nikola Stojanović[1], Marina Soldatović[2], Milena Milićević[3],
Faculty of Organizational Sciences, University of Belgrade, Belgrade, Serbia

Abstract: *Forecasting sales is one of the most important task of every business. Based on that prediction resources can be allocated, so business can generate bigger profit. In this research the goal was to forecast weekly sales of 45 Walmart stores, each having around 90 departments. We used Rapid-Miner software and its several key processes and operators that were the most suitable for this particular problem. Forecast had to be made based on 15 attributes, on 421570 examples. This problem, although complex, is more difficult because data has seasonality effects making predictions highly unstable. Using several different machine learning algorithms we were able to get the best WMAE score of 11.517,09.*

Keywords*: Regression, Algorithm, Forecasting, Data Mining, RapidMiner*

1. INTRODUCTION

Walmart is the world's largest retailer, operating in 27 countries and offering a wide variety of goods and services. Our goal was to forecast Walmart's weekly sales with least absolute error. The sample contains data of 45 stores in various regions, each store having around 90 departments. Regression problem was complex, and it required an appropriately complex methodology. We had used software package RapidMiner (Mierswa et al., 2006), making sure we chose the most suitable operators and processes for our problem.

Paper (Krause-Traudes et al., 2008) presents a use case of spatial data mining for aggregate sales forecasting in retail location planning. The forecast of potential sites is based on sales data on shop level for existing stores and a broad variety of spatially aggregated geographical, socio-demographical and economical features describing the trading area and competitor characteristics. The model building process was guided by a-priori expert knowledge and by analytic knowledge which was discovered during the data mining process itself. They used SVR (Support Vector Regression) data mining technique against the traditional state-of-the-art gravitational Huff-model. Findings reveal that the data mining model highly outperforms the traditional modeling approach.

Paper (Parikh, 2013) presents data mining based solution for demand forecasting and product allocations applications. This paper proposes two data mining models, Pure Classification model and Hybrid Clustering Classification model. Pure Classification model uses k-Nearest Neighbor Classification technique, and Hybrid Clustering Classification first uses k-Mean Mode Clustering to define clusters and then k-Nearest Neighbor classification to find k most similar objects.

In research written by (Napagoda, 2013) author was using support vector machine (SVM), Gaussian Process, Multilayer Perceptron, Linear Regression and SMO Regression. Based on the evaluation results they concluded that SMO regression and Linear Regression algorithms are better suited for forecasting web site related information and also using Linear Regression on pre-processed data gives more accurate results.

In paper (Hulsmann et al, 2012), the performance and limitations of general sales forecast models for automobile markets based on time series analysis and Data Mining techniques were analyzed. The models were applied to the German and the US-American automobile markets. The Support Vector Machine (SVM) turned out to be a very reliable method due to its non-linearity. In contrast, linear methods like Ordinary Least Squares or Quantile Regression are not suitable for the present forecasting workflow.

2. EXPERIMENTAL SETUP

The sample data has been downloaded from www.kaggle.com competition is Walmart Recruiting – Store Sales Forecasting and data from the real world. It consists of 2 comma separated values data sets - one for training purposes and one for testing. The training data contains 421.571 comma values, while test data has 115.065 comma values.

Table 1. Data description

Attribute	Description	Data Type
Store	ID of the store	Polynomial
Dept	ID of the department	Polynomial
Date	Week of the year	Integer
Weekly_Sales	Sales for the given department in a given store for given week	Real
IsHoliday	Binary values representing whether the week is a special holiday week or not	Bit
Temperature	Average temperature for given week in the region where store is located	Numerical
Fuel_Price	Cost of fuel in the region for a given week	Numerical
MarkDown i (i=1,…,5)	Anonymized data related to promotional markdowns that Walmart is running. MarkDown data is only available after Nov 2011, and is not available for all stores all the time. Any missing value is marked with an NA.	Numerical
CPI	The consumer price index in region of store for given week	Numerical
Unemployment	The unemployment rate in region of store for given week	Numerical

Our output attribute is Weekly Sales. Linear regression, and most other regression algorithms, allows only numeric values only, so polynomial attributes are converted to numerical attributes. MarkDown 1-5, represents promotional discounts for the following holidays:

Super Bowl: 12.02.2010, 11.02.2011, 10.02.2012, 08.02.2013.
Labor Day: 10.09.2010, 09.09.2011, 07.09.2012, 06.09.2013.
Thanksgiving: 26.11.2010, 25.11.2011, 23.11.2012, 29.11.2013.
Christmas: 31.12.2010, 30.12.2011, 28.12.2012, 27.12.2013.

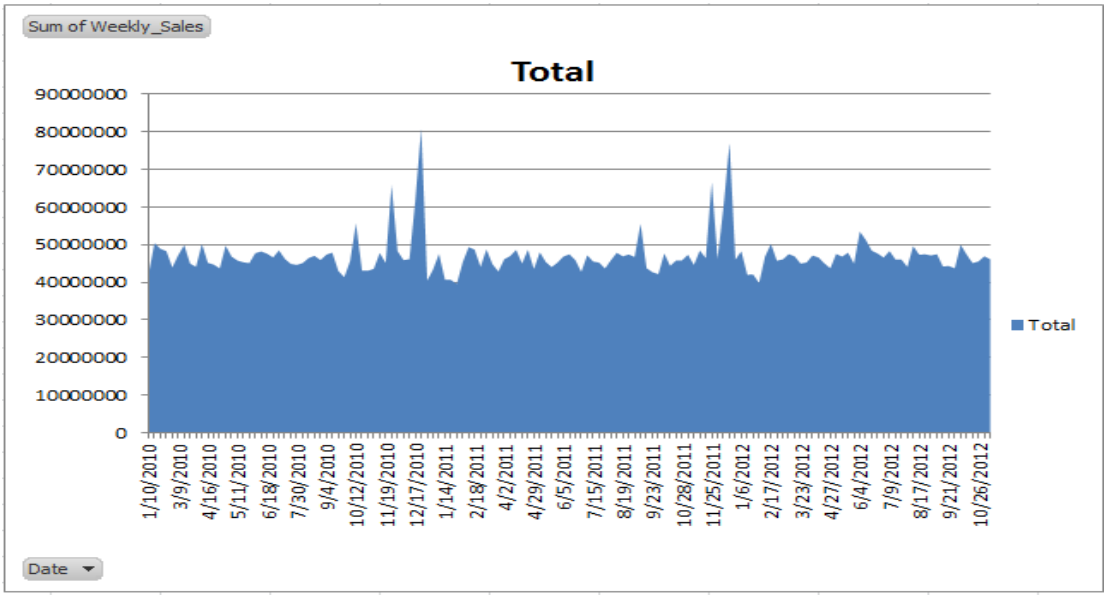

Figure 1. Weekly sales by time

Based on Figure 1 it can be seen that sales forecasting have high seasonality which is presented with peaks in December 2010 and January 2012. Shortly after that sale drops, this is seen in January 2011 and February 2012.

3. MODELING

In this paper, several linear regression algorithms to forecast weekly sales was used. Experiment is conducted in Rapid Miner as its inner operator structure allows easy setting up of the experiment. The experimental process was organized in 3 levels. On the first level we used Loop operator. This operator iterates over its subprocess for a specified number of times. The subprocess can use a macro that increments after each iteration, which, in our case, was 45 times. On the second level we had defined operators within the Loop operator and set the iteration on stores.

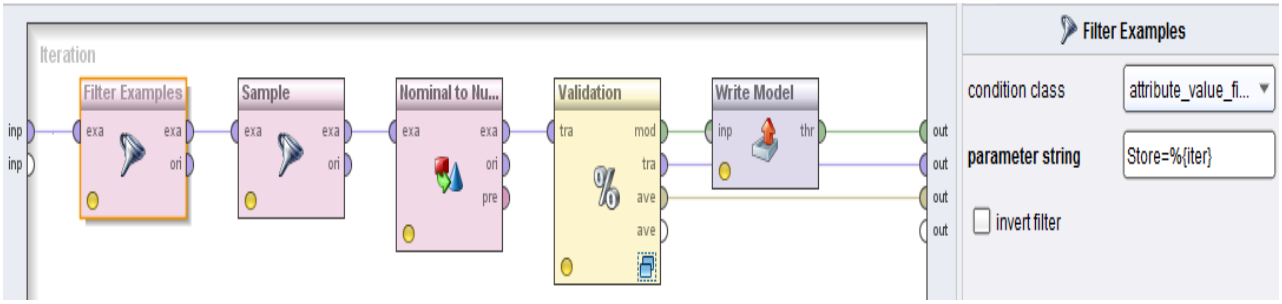

Figure 2. Inner operator structure of the Loop

On the third level we measured classification accuracy of every algorithm which is evaluated through 10-fold cross validation. The X-Validation operator is a nested operator. It has two subprocesses: a training subprocess and a testing subprocess. The training subprocess is used for training a model. The trained model is then applied in the testing subprocess. The performance of the model is also measured during the testing phase. On this level we used several linear regression algorithms to get the least absolute error.

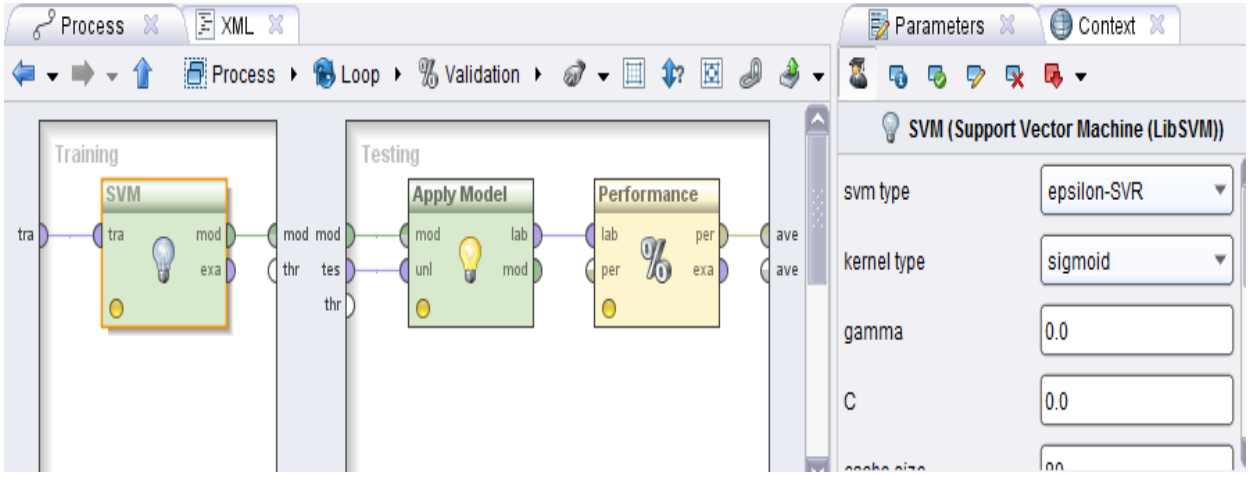

Figure 3. Inner operator structure of the X-Validation

Algorithms which we used were K-NN (k-Nearest Neighbor), W-Isotonic Regression, Linear Regression, Neural Network and SVM (Support Vector Machine (LibSVM)).

K-NN operator generates a k-Nearest Neighbor model from the input ExampleSet. This model can be a classification or regression model depending on the input ExampleSet. W-Isotonic Regression learns an isotonic regression model. It picks the attribute that results in the lowest squared error and missing values are not allowed. It can only deal with numeric attributes. Linear Regression is a technique used for numerical prediction. Regression is a statistical measure that attempts to determine the strength of the relationship between one dependent variable (i.e. the label attribute) and a series of other changing variables known as independent variables (regular attributes). Neural Network operator learns a model by means of a feed

forward neural network trained by a back propagation algorithm (multi-layer perceptron). Neural network is a mathematical model or computational model that is inspired by the structure and functional aspects of biological neural networks. SVM (Support Vector Machine) is supervised learning model with associated learning algorithms that analyze data and recognize patterns, used for classification and regression analysis. SVM training algorithm builds a model that assigns new examples into one category or the other, making it a non-probabilistic binary linear classifier (Mierswa et al, 2006)

4. RESULTS

SVM algorithm gave the best results:

Table 2. Results

Model	Absolute error
SVM (Support Vector Machine)	11.517,09
Neural Network	11.899,511
W-Isotonic Regression	14.1807,728
Linear Regression	14.528,238
K-NN (k-Nearest Neighbor)	20.633,996

The Support Vector Machine (SVM) approach represents a data-driven method for solving classification and regression tasks (Fawcett et al. 1998). It has been shown to produce lower prediction error compared to classifiers based on other methods like artificial neural networks, especially when large numbers of features are considered for sample description. We have used the test data for the testing process. Using the Loop operator gave us 45 models, each model representing one store. Then we used the Append operator, which merged all models into one model, which we then used to get the final result.

.

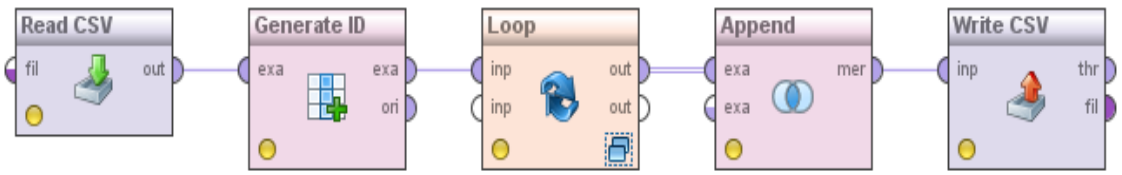

Figure 4: Final process – testing

5 .CONCLUSION AND FUTURE WORK

Preparing the data for our weekly sales forecasting project required us to replace missing values with zeros and identify the most relevant attributes for our goal output attribute. The validation process gave us 45 models which we then merged into one final model, using the Append operator. We then tested the final model and got the result (Picture 4). During the modeling phase we used several Rapid Miner's algorithms, where SVM gave us the best result, scoring the absolute error of 11.517,09.
Our conclusion is that Walmart's weekly sale is on a gradual rise a week prior to holidays. It rapidly increases during the Labor Day, Thanksgiving and Christmas holidays.

Our goal was to forecast weekly sales of 45 Walmart stores. We used Rapid Miner software and its several key processes and operators that were the most suitable for this particular problem. We needed to analyze factors and their impact on the process of sales forecasting. In order to find the solution with the least

absolute error, we tested linear regression models such as: K-NN (k-Nearest Neighbor), W-Isotonic Regression, Linear Regression, Neural Network and SVM (Support Vector Machine (LibSVM)).

We plan to detect outliers and execute same experiment again. Also, we plan to optimize parameters of algorithms, such as SVM, since performance is highly dependent on value of complexity parameter C and kernel type. Additionally, we plan to use more algorithms such as Gaussian Processes and neural networks.

Abstract: *The main of this paper is to propose a model for sentiment analysis that can recognize emotion in specific words, phrases and sentences. Usually, database form platforms for microblogging are used for this kind of research for model learning, but also specially prepared for specific problem. In this paper a sentiment analysis movies reviews database from movies critics portal is used. Classification models have ben developed. The best model had the following results: accuracy is 51,06%.*

Keywords*:Text mining, Sentiment analysis, Classification, K-NN, Rapid Miner*

1. INTRODUCTION

Knowledge about what people think and feel is a prerequisite of good decision making. Before the Internet Age people relied on opinions and experiences of others during decision making, but now experiences are more available either about making choices which film to watch, product critics or even comments about some places (Lee, Pang, 2008). These short comments are especially interesting for sentiment analysis which is a part of text mining. Analysis tends to discover authors attitudes using machine learning and language analysis (Yessenov, Misailovic, 2009). Microblogging services such as Twitter, Yahoo, Facebook, Tumblr (Pak, Paroubek, 2010) and movie and books critics are used as databases for analysis. Textual information can be categorized into two main types: facts and opinions. Facts are objective expressions and opinions are usually subjective expressions (Liu, 2010).

Text mining is a new field in computer science which combines techniques of data mining, machine learning and language processing for data discovery and knowledge management (Feldman, Sanger, 2007). Sentiment analysis is becoming more and more popular in recent years because it is applicable in business environment through customer feedback analysis in form of a product critics, organization's reputation management in public, but also in new campaign planning (Yessenov, Misailovic, 2009).

In this paper sentiment analysis is based on short critics of movies from portal "Rottentomatoes" (www.rottentomatoes.com). For contest proposes, main goal is to achieve the best predicting results meaning to achieve the best accuracy in predicting sentiments using operators which provides this kind of results. Also,it is very important to understand concept of Text mining and what kind of results it is providing ,to understand operators of text mining for purpose to make the best predicting model and achieve best possible accuracy . Idea behind contest is based on critics from which we can create model that can predict emotions that are incorporated in it, and hence makes classification easier. Database has been downloaded from portal "Rottentomatoes" which presents movies and allows readers to make comments. Besides mark which movie gets from every author, there is also possibility of putting fingerprints such as "rotten" or "fresh".

2. BUSINESS UNDERSTANDING AND DATA UNDERSTANDING

The data has several columns: Phrase ID, Sentence ID, Phrase and Sentiment. Phrase can include one word, several words or even a whole sentence (Figure 1). Every phrase has its unique ID while based on sentence ID we can conclude if several phrases are part of the same sentences. Sentiment presents an exit and takes value on scale from 0 to 4, where 0 is extremely negative emotion and 4 is extremely positive. According to database the most frequent value is 2 which analysis confirmed as modus.

Besides 4 columns, database has 156000 records and it is important to underline that every record does not represent logical phrase. It is possible to find phrases made of articles like "A" and "The".

PhraseId	Sentiment	SentenceId	Phrase
1	1	1	A series of escapades demonstrating the adage that what is good for the goose is also good for the gander , some of which
2	2	1	A series of escapades demonstrating the adage that what is good for the goose
3	2	1	A series
4	2	1	A
5	2	1	series
6	2	1	of escapades demonstrating the adage that what is good for the goose
7	2	1	of
8	2	1	escapades demonstrating the adage that what is good for the goose
9	2	1	escapades
10	2	1	demonstrating the adage that what is good for the goose
11	2	1	demonstrating the adage
12	2	1	demonstrating
13	2	1	the adage
14	2	1	the
15	2	1	adage
16	2	1	that what is good for the goose
17	2	1	that
18	2	1	what is good for the goose
19	2	1	what
20	2	1	is good for the goose

Figure 1: Presentation of data

3. DATA PREPARATION

It is necessary to reduce data sample because of huge amount of records, precisely 156 000 records in database,which is beyond capacities (working memory) of RapidMiner. In this research this amount of records has been reduced, and it takes 6% of records. Moreover, irrelevant data such as SentenceID and data made of articles has been removed. Attribute Sentiment is marked as label. Also, it is necessary to transform attribute Phrase from Nominal to Text using special operator or during data import.

4. MODELING AND EVALUATION

Operator Process Document (Figure 2) from data was used during the process of modeling with the aim to execute tokenization. Suboperators used in process are Tokenize, Filter Tokens by Length, Stem and Filter Stopword (English) (Figure 3). Operator Tokenize recognize everything that is not a single letter as a special word (Token) meaning that option “non letter” is on. For filter Tokens operator minimal word length is setup to be 3 characters (because of words like “bad” which can carry strong emotion) and for maximum 25 characters. For word rooting Porters algorithm for “stemming” is used. At the end an operator for removing English stopwords is applied.

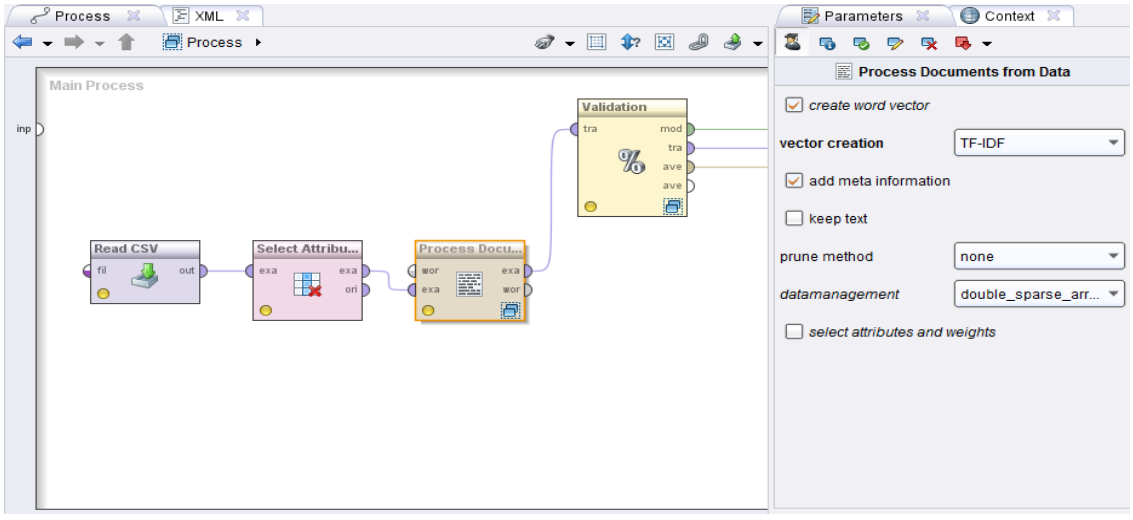

Figure 2: Process Documents from Data

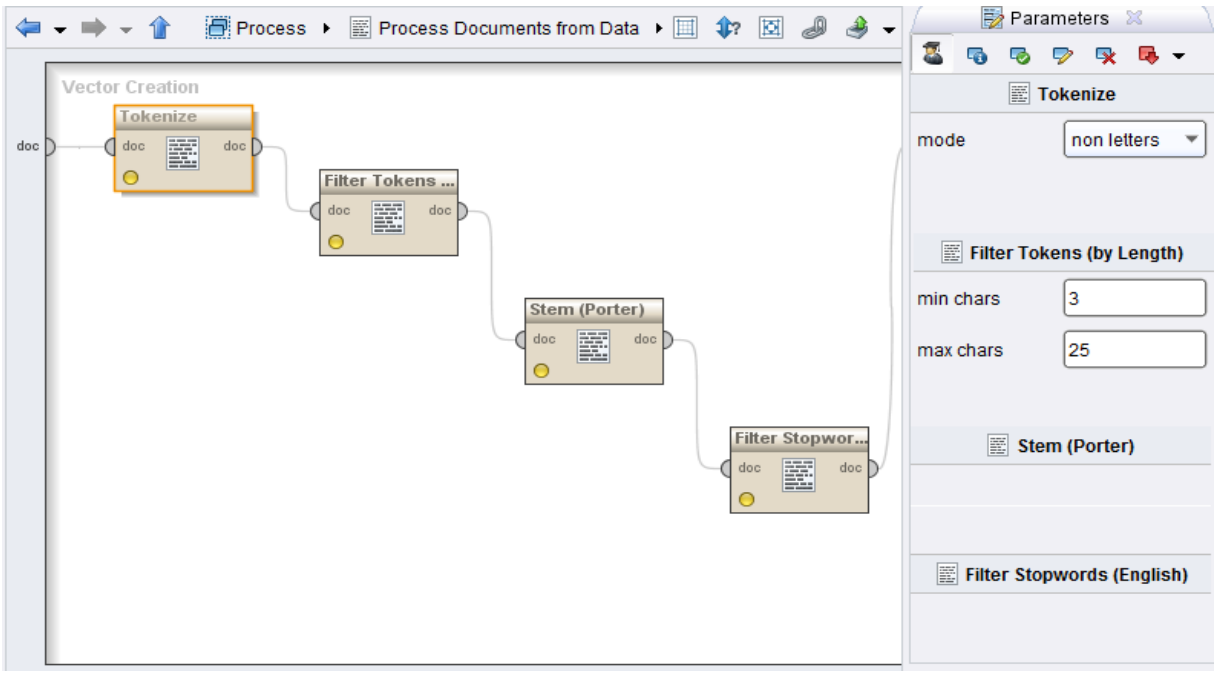

Figure 3: Process text suboperators

Several models for classification were used: k-NN, W-IB1 (Weka classifier) and Naive Bayes (Table 1). It turned out that using operator Naive Bayes takes shorter time for execution, but accuracy gained is lower comparing with two other operators (operator W-IB1 and operator Naive Bayes). Operator W-IB1 achieves precision as k-NN, but W-IB1 operator needs lot more time. So, k-NN operator, based on principle of neuron network, is used in this case. For assessment of optimal number "k" the Optimize Parameters node was used while for measure type "Cosine Similarity" has been used.

For model evaluation, operator Validation(X-Validation) has been used. Number of validation is setup to 5 and the sample was stratified. Criteria of goodness was "accuracy" (according to contest propositions). The best result for predicting accuracy using operator k-NN was 0.53 on 6% of sample set (Figure 4). For operator Naive Bayes best accuracy achieved (in best case) is 0.22.

Table 1: Comparing result of 3 operators

MODEL		Time	Accuracy
K-NN	K = 1	1:59	49.39% +/- 1.29%
	K = 2	2:00	49.46% +/- 1.29%
	K = 3	1:52	51.06% +/- 0.57%
	K = 4	1:37	50.38% +/- 0.68%
W-IB1		16:43	accuracy: 49.20% +/- 1.09%
Naive Bayes		0:31	20.37% +/- 0.93%
	Laplace correction	0:32	20.37% +/- 0.93%

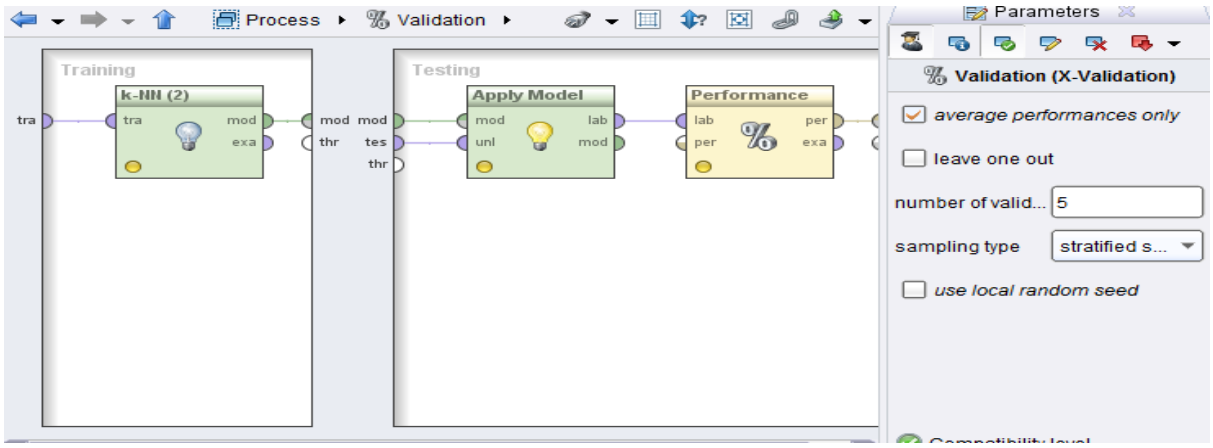

Figure 4: Usage of k-NN operator

5. CONCLUSION

Comparing results, conclusion is that operator k-NN is the best choice on this data set in order to get as much accuracy as it is possible and gained accuracy for k-NN is 51,06%(+/- 0,57%) using cross validation. Thanks to optimization operator optimal number 3 for k is gained. For data preparation it is necessary to use process document with operators Tokenize, Filter Tokens, Stem (Porter) and Filter Stopwords.

Suggestion for further studies refers integration for more different database comments from similar portals and that could provide higher accuracy for predicting results and also monitoring correlations between self-evaluation comments by authors and marks that model has given.

Abstract: *This paper aims to explain which algorithm is the best for predicting bonds price using RapidMiner. Whole work is based on CRISP-DM methodology. This research was cinducted on real data from competition on Kaggle. Accent was on reducing and preparing data for modeling. Through this paper we focused on popular algorithms for prediction, that are available in RapidMiner-open source data mining environment. Main goal was to compare different algorithms and find one which minimize the absolute error.*

Keywords*: Bonds price, Prediction, Linear Regression, Neural Networks, Support Vector Machines, Data Mining Forecasting, Rapid Miner*

1. INTRODUCTION

In nowadays technology financial institutions are able to produce huge datasets that build a foundation for approaching these enormously complex and dynamic problems with data mining tools. One of the most enticing application areas of data mining in these emerging technologies is in finance, becoming more amenable to data-driven modeling as large sets of financial data become available. In the field of finance the extensive use of data mining applications includes the area of forecasting stock market, pricing of corporate bonds, understanding and managing financial risk, trading futures, prediction of exchange rates, credit rating etc. (Murthy, 2010).

We used RapidMiner (I. Mierswa, 2006) for implementing research process. RapidMiner is a software platform developed by the company of the same name that provides an integrated environment for machine learning, data mining, text mining, predictive analytics and business analytics. It is used for business and industrial applications as well as for research, education, training, rapid prototyping, and application development and supports all steps of the data mining process including results visualization, validation and optimization (Markus Hofmann, 2013).

Scientific research aimed at gaining insights on the future, related to a high-importance domain such as business evolution, has the main goal of finding a way to minimize the risks and reduce the insecurity pressure in a business world affected by the economic crisis. Companies have turned to knowledge, processing and analyzing information in order to realize short-term or long-term forecasting based on powerful software applications. In this paper we used supervised learning algorithms (Banica L., 2012). The goal of a supervised learning algorithm is to obtain a classifier by learning from training examples. A classifier is something that can be used to make predictions on test examples. This type of learning is called "supervised" because of the metaphor that a teacher (i.e. a supervisor) has provided the true label of each training example (Elkan, 2013).

In Performance comparison of time series data using predictive techniques are focused on methodology used in applying the Time Data Mining techniques to financial data calculating currency exchange rates of US dollars to Indian Rupees. Four models were used: Multiple Regression in Excel, Multiple Linear Regression of Dedicated Time Series Analysis in Weka, Vector Autoregressive Model in R and Neural Network Model using NeuralWorks Predict (S. Saiglas, 2012).

Nowadays, many current real financial applications have nonlinear and uncertain behaviors which change across the time. Therefore, the need to solve highly nonlinear, time variant problems has been growing rapidly. These problems along with other problems of traditional models caused growing interest in artificial intelligent techniques. Comparative research review of three famous artificial intelligence techniques, i.e., artificial neural networks, expert systems and hybrid intelligence systems, in financial market. Results show that accuracy of these artificial intelligent methods is superior to that of traditional statistical methods in dealing with financial problems, especially regarding nonlinear patterns (Bahrammirzaee, 2010). Regression

modeling, while presenting a potential black box solution to the issue with market timing, has proven to be both flexible and robust relative to a static trading rule (Harvey, 2014).

2. FINANCIAL FORECASTING AND ALGORITHMS FOR PREDICTION

Regression analysis is one of the most widely used techniques for analyzing multifactor data. Linear regression attempts to model the relationship between two variables by fitting a linear equation to observed data where the relationship between the variables can be described with a linear model. Linear regression is a predictive model that uses training and scoring data sets to generate numeric predictions in data. It is important to remember that linear regression uses numeric data types for all of its attributes. For long time linear regression was very common algorithm for prediction tasks. But, now are more typical methods such as neural networks, support vector machines (SVM) (North, 2012).

Advantages/limitations of linear regression model:

1. Linear regression implements a statistical model that, when relationships between the independent variables and the dependent variable are almost linear, shows optimal results
2. Linear regression is often inappropriately used to model non-linear relationships
3. Linear regression is limited to predicting numeric output
4. A lack of explanation about what has been learned can be a problem (Douglas C. Montgomery, 2013)

2.1. Neural Networks

Several linear and nonlinear statistical models were proposed in the literature to solve the problem of financial phenomena forecasting. (Clements, 2004)Forecasting accuracy is one of the most important factors involved in selecting a forecasting method. Besides, nowadays artificial intelligence (AI) techniques are becoming more and more widespread because of their accuracy, symbolic reasoning, flexibility and explanation capabilities. Among these techniques, particle swarm optimization (PSO) is one of the best AI techniques for optimization and parameter estimation (Hadavandi E., 2010). Neural networks have become increasingly popular in finance as financial services organizations have been the second largest sponsors of research in neural network application. An accurate forecast into the future can offer tremendous value in areas as diverse as financial market price movements, financial expense budget forecasts, website click through likelihoods, insurance risk, and drug compound efficacy, to name just a few. Many algorithm techniques, ranging from regression analysis to ARIMA for time series, among others, are regularly used to generate forecasts. A neural network approach provides a forecasting technique that can operate in circumstances where classical techniques cannot perform or do not generate the desired accuracy in a forecast. Neural networks offer a modeling and forecasting approach that can accommodate circumstances where the existing data has useful information to offer, but it might be clouded by several of the factors mentioned above (Omidi A., 2011). Neural networks can also account for mixtures of continuous and categorical data. These attributes make neural networks an excellent tool to potentially take the place of one or more traditional methods such as regression analysis and general least squares. Thus, neural networks can generate useful forecasts in situations where other techniques would not be able to generate an accurate forecast. In other situations, neural networks might improve forecasting accuracy dramatically by taking into account more information than traditional techniques are able to synthesize. Finally, the use of a neural network approach to build a predictive model for a complex system does not require a statistician and domain expert to screen through every possible combination of variables. Thus, the neural network approach can dramatically reduce the time required to build a model (Edward R. Jones, 2004). Artificial neural networks (ANNs) have been popularly applied for stock market prediction, since they offer superlative learning ability. They often result in inconsistent and unpredictable performance in the prediction of noisy financial data due to the problems of determining factors involved in design (Kyoung-jae Kim, 2012).

2.2 SupportVector Machines

SVMs were developed by Cortes & Vapnik for binary classification. SVMs represent a powerful technique for general (nonlinear) classification, regression and outlier detection with an intuitive model representation (Hamel, 2011). Support Vector Machine (SVM) is a relatively new learning algorithm that has the desirable characteristics of the control of the decision function, the use of the kernel method, and the sparsity of the solution (Meyer, 2012). SVMs are currently a hot topic in the machine learning community, creating a similar enthusiasm at the moment as Artificial Neural Networks used to do before. SVMs nowadays have become a popular technique in flexible modelling. There are some drawbacks, though: SVMs scale rather badly with

the data size due to the quadratic optimization algorithm and the kernel transformation. Furthermore, the correct choice of kernel parameters is crucial for obtaining good results (Yuan, 2011).

2.3 Bonds and Financial Forecasting

A bond is a fixed interest financial asset issued by governments, companies, banks, public utilities and other large entities. Bonds pay the bearer a fixed amount a specified end date. A discount bond pays the bearer only at the ending date, while a coupon bond pays the bearer a fixed amount over a specified interval (month, year, etc.) as well as paying a fixed amount at the end date. A bond that provides a standard against which the performance of other bonds can be measured. Government bonds are almost always used as benchmark bonds. Also referred to as "benchmark issue" or "bellwether issue". More specifically, the benchmark is the latest issue within a given maturity. For a comparison to be appropriate and useful, the benchmark and the bond being measured against it should have a comparable liquidity, issue size and coupon (Investopedia, 2014).

The bond price prediction can help banks and financial institutions to build their portfolio in diversified manner. Using the trade price, the investor can assume not only the price of that bond, but can also the interest rates, and hence, has a very useful tool in his hand for investment purpose, thus making decisions about whether to invest or not, and if invest then when to invest (Diebold, 2006).

3. DATA AND METHODOLOGY

Data mining becomes a cutting-edge information technology tool in today's competitive business world. It helps the company discover previously unknown, valid, and actionable information from various and large databases for crucial business decisions (Bramer, 2013).

Data Mining methodologies have been evolving over time. In today's ever-changing economic environment, there is ample opportunity to leverage the numerous sources of financial data now readily available to the savvy business decision maker. This data can be used for business gain if the data is converted to information and then into knowledge (Kantardzic, 2011). Data mining processes, methods and technology oriented to transactional-type data have grown immensely in the last quarter century. There is significant value in the interdisciplinary notion of data mining for forecasting when used to solve bond price problems. The intention of this talk is to describe how to get the most value out of the myriad of available data by utilizing data mining techniques specifically oriented to data collected over time (Hui Li, 2012).

Investors use predicted bond trade prices to inform their trading decisions throughout the day. In this paper we want to show how linear regression can be used to predict the next trading price of a US corporate bond. We use bond price data provided through Benchmark Solutions and Kaggle.com[1], which includes variables such as current coupon, time to maturity, and details of the previous 10 trades, among others. Regression models are useful and understandable models which are used for prediction and data fitting.

One of the most enticing application areas of data mining in these emerging technologies is in finance, becoming more amenable to data-driven modeling as large sets of financial data become available. In the field of finance the extensive use of data mining applications includes the area of forecasting stock market, pricing of corporate bonds, understanding and managing financial risk, trading futures, prediction of exchange rates, credit rating etc.

This research was driven by CRISP-DM methodology. The CRISP-DM (CRoss Industry Standard Process for Data Mining) reference model for data mining. It contains the phases of a project, their respective tasks, and their outputs (Suknović Milija, 2010).

1. Business understanding
2. Data understanding
3. Data preparation

[1]http://www.kaggle.com/c/benchmark-bond-trade-price-challenge/data

4. Modelling
5. Evaluation
6. Deployment

Every phase of this life cycle is important, but most time takes to prepare data. The data preparation phase covers all activities to construct the final dataset (data that will be fed into the modeling tool(s)) from the initial raw data. Data preparation tasks are likely to be performed multiple times, and not in any prescribed order. Tasks include table, record, and attribute selection, data cleaning, construction of new attributes, and transformation of data for modeling tools (Galit Shmueli, 2011).

In this project the model was built up to predict the Benchmark Bond Trade Price. This price will be the estimated price at which the US corporate bond or government bond might trade at. The data set consisting of current coupon, time to maturity and a reference price was used for price prediction. Details of the previous 10 trades were also used for prediction (Kaggle, 2014).

We saw that this dataset comprises 61 columns of attributes. These parameters include the row ID (can be used for time series analysis), the bond ID (there is data for almost 8,000 different bonds), current coupon, previous trade prices, and more. The output variable is the trade_price column, as this is the value that we are trying to solve for.

The idea was to make smaller set, that will in a good was represent our whole set of training data. Originally set had over 700 hundreds instances, but we were using several data mining techniques to get smaller set. We prepared our data through: data reduction, handling missing values, inconsistent data, and attribute reduction. First, we reduced size of data set with sampling – relative sample with sample ratio 0.01. Cases with the missing values were removed; did not make sense to impute, considering type of date. We did not detect any outliers, also idea was to make some clusters, and then to split data sets for analysis, but there is more than 800 types of bonds, so that did not make sense to implement. Negative values were in attribute reporting_delay (The number of seconds after the trade occurred that it was reported – so it is impossible to be negative) and we removed cases with negative reporting_delay value. For attributes, first we checked correlation – because similar attributes act in same way, dropping out one of the correlated attribute, we lose little information, but speed algorithms a lot. Before implementing correlation operator in RapidMiner, we had to make sure that all data was numerical. Original set had 61 attribute, after correlation process 31 regular attribute and one special attribute – label. After we removed correlated attributes, we wanted to try weighting attributes. We selected all attributes, except label trade_price, and using generate weight LPR operator – but, we had not found any relevant result. Next step was using Principal Component Analysis - where we have reduced 32 to 14 attributes (components). PCA variance threshold was 0.99 – it means that 99% of previous data set was described with 14 new components – more than that number will give same results, as it is shown in *Figure 3.* Although we reduced the processing time, we have also made our prediction accuracy worse, so we decided to do modeling on data set after correlation.

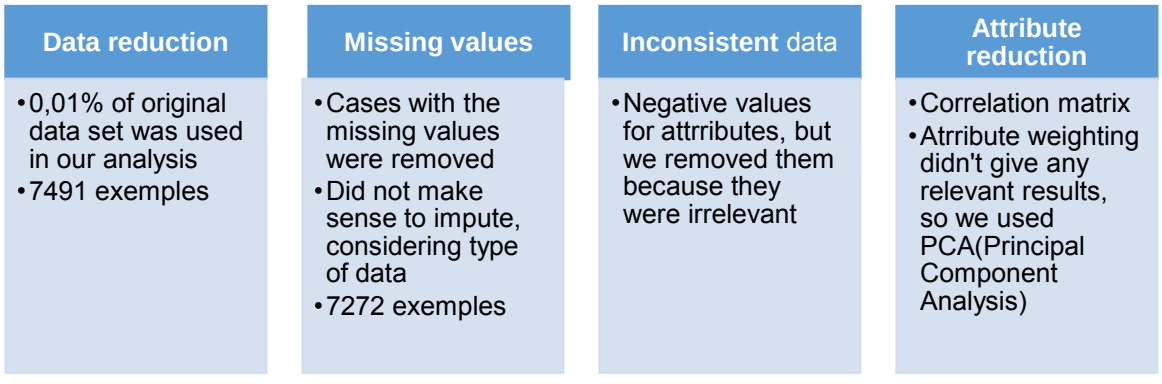

Figure 1: Data preparation

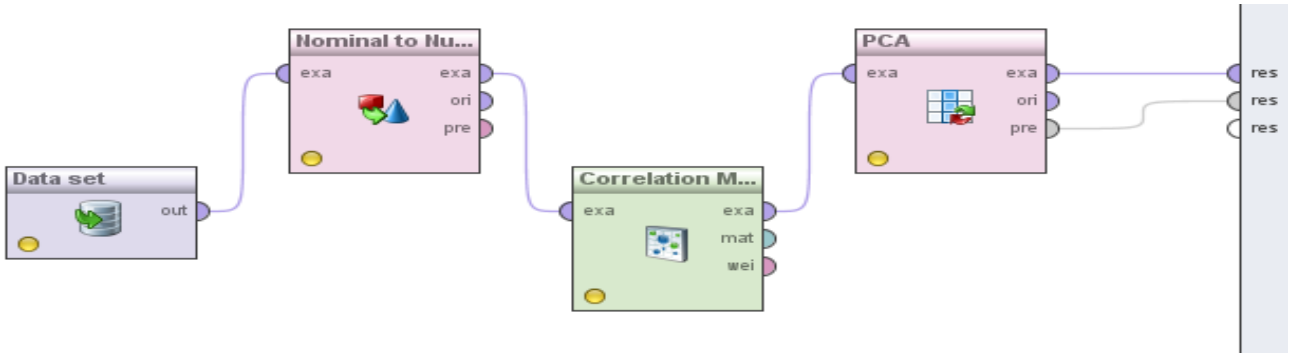

Figure 2: Principal component analysis

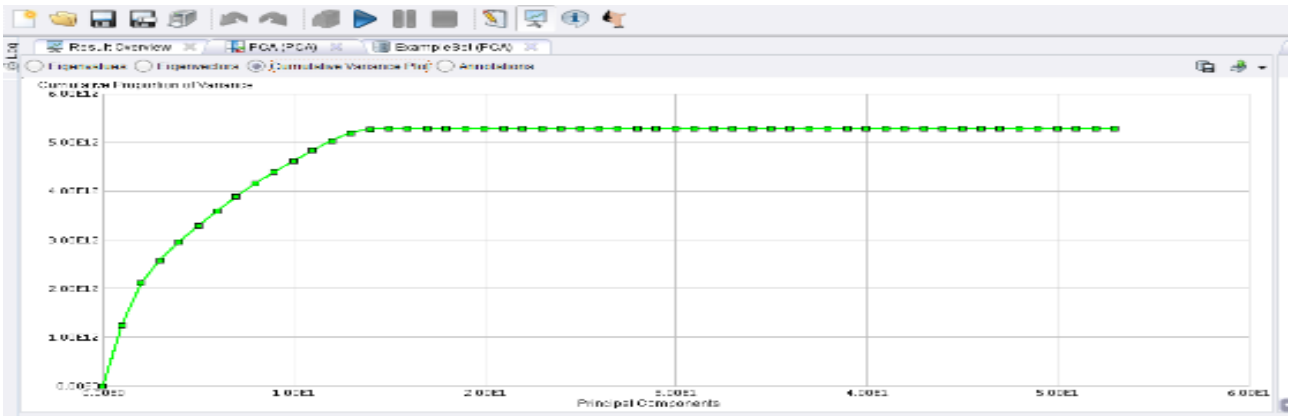

Figure 3: Cumulative variance plot

3. MODELING, EVALUATION AND RESULTS

Previous we have explained how we prepared our data, and here we focused on models, their performances and results of our work. Performance evaluation was conducted using mean absolute error. We wanted to show which algorithm gives the lowest absolute error and forecasts the best next bonds trade price. Whole, main process is shown in *Figure4, Figure5, and Figure 6.*

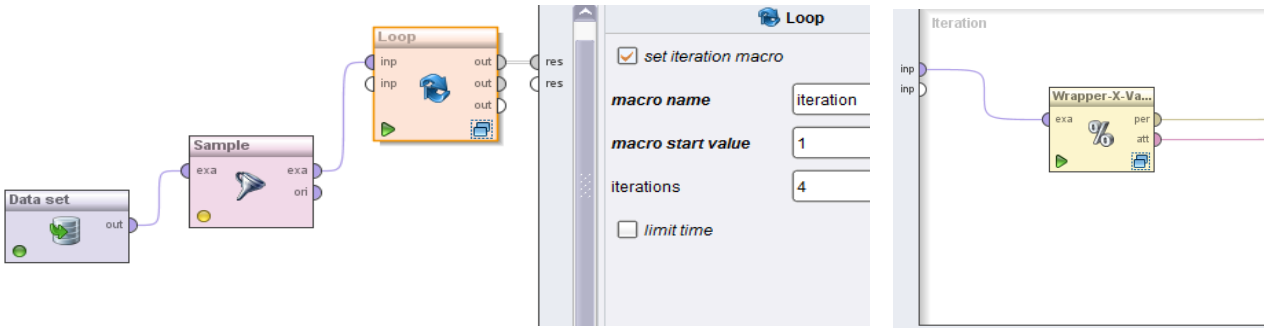

Figure 4: Start of a main process - loop operator

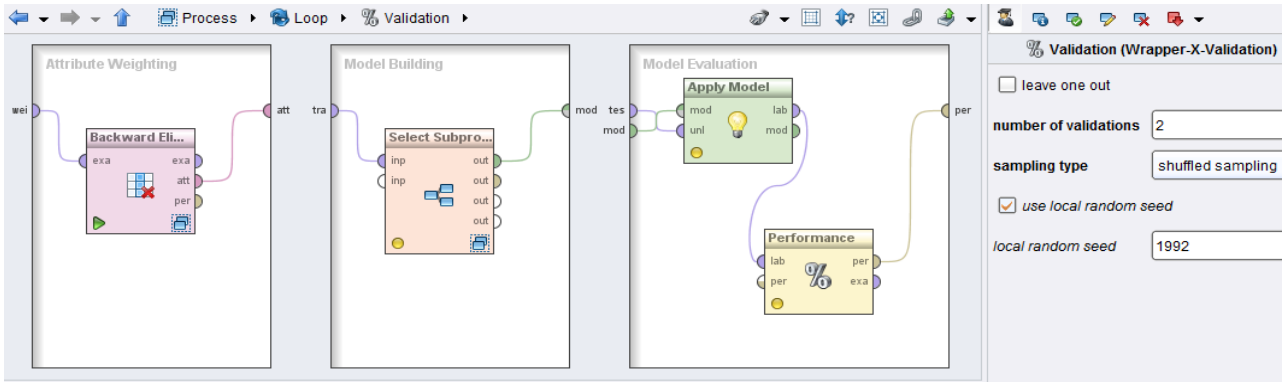

Figure 5: Wrapper-X-Validation

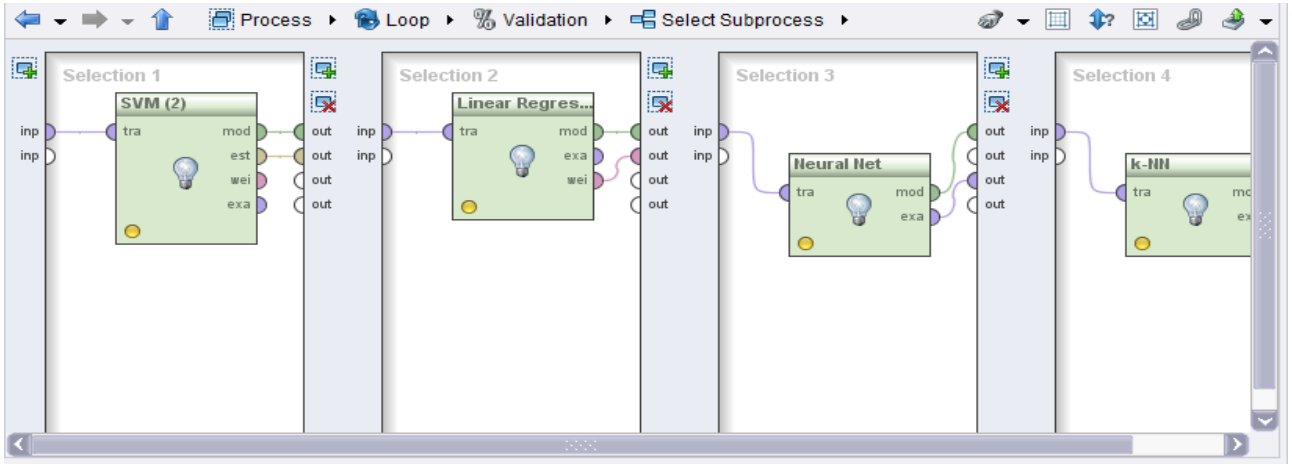

Figure 6: Algorithms

We have compered our results, which are shown in next table:

Table 1: Attribute optimization

		Optimize Selection	Forward Selection	Optimize Selection (Evolutionary)	Backward Elimination	PSO
ALG1	SVM	2.058+/-0.210	8.679+/-0.615	5.937+/-0.414	5.430+/-0.156	6.185+/-0.811
ALG2	Regression	0.807+/-0.027	5.728+/-0.263	5.742+/-0.318	4.618+/-0.164	5.053+/-0.211
ALG3	Neural net	1.328+/-0.084	7.48+/-1.033	7.467+/-0.734	6.213+/-0.289	7.915+/-0.831
ALG4	K-NN	6.128+*-0.053	8.805+/-0.532	9.108+/-0.798	8.035+/-0.196	7.694+/-0.027

Our goal was to discover which algorithm in RapidMiner gives the best results in prediction of bonds price. Our focus in this paper was on linear regression, neural nets, support vector machines, k-nns. But main thing was using real data sets and reducing them to applicable size. As we can see in *Table 1*, regression algorithm gave best results for our prepared data. That was no expected, but sure there is something we could improve in our preprocessing of the data. When compered our results with results from data mining tool called Eureka. They have got most accurate solution 0.547 absolute error. Having our possibilities as students in mind, the result was satisfying. It means that that this model can predict the future trading price of

a bond with an average error of only $0.807. We supposed that neural networks and support vector machines would give better results than simple linear regression, but we were wrong.

4. CONCLUSION AND RECOMMENDATION

In this paper we tried to do data preparation and algorithm optimization in order to minimize the absolute mean error of predicted trade price for bonds. Not expected, but linear regression was better than support vector machines and neural networks. We have tried to implement almost every available technique for data preparation, but RapidMiner is not good enough in processing financial data. Despite that, the results were pretty acceptable. The recommendation for future work is to try different kind of validation and optimization in other suitable programs. Also, it is important to inspect every possible technique of data preparation – selection and optimization of attributes, reducing data in way to improve results.

STOCK MARKET TIME SERIES DATA ANALYSIS

Nikola Peric
Faculty of organizational sciences, University of Belgrade, nikolasp91@gmail.com

Abstract: *Financial market is very dynamic and unpredictable environment. It is becoming more and more complex since the amount of data is growing rapidly. These data besides increasing too fast, also change quickly. Algorithms of data mining and time series analysis can be used extensively in the field of finance to help financial forecasting. The ability to predict direction of stock price accurately is crucial for market dealers or investors to maximize their profits. The aim of my research is to compare approaches and different data mining techniques that were used in past, related to time series analysis in finance and to analyze each of them. In the end, I will draw a general conclusion and propose solution that I think is good enough in struggle with time series analysis in order to help better future forecasting and making more profitable business decisions.*

Keywords*: Time series analysis, Data mining, financial market, Support Vector Machine, forecasting*

1. INTRODUCTION

A financial market is a market in which people and entities can trade financial securities, commodities, and other fungible items of value at low transaction costs and at prices that reflect supply and demand. Securities include stocks and bonds, and commodities include precious metals or agricultural goods. Nowadays financial market is defined as a very unstable and unpredictable place, that is expand constantly according to Ou, P., & Wang, H. (2009). Data mining and time series analysis are very popular in the field of finance. They are often used as major factors of competitor's advantage. The key area of application of time series analysis is in forecasting. In Tsay, R. S. (2005) the author draw general conclusion that time series data provide useful information about the financial market generating the time series, such as: stock exchange indices, share prices, index values, trading volume, etc.

Time series analysis and data mining have a strong relationship. Data analysts have to be familiar with data mining techniques and algorithms so that they could do the financial tasks and understand financial problems and results properly. Researchers in the data mining field have focused their efforts on obtaining algorithms in order to deal with huge amounts of data (Kacprzyk, Janusz, Leonid Sheremetov, and Lotfi A. Zadeh, 2007). It is amazing how volume of information in the world has grown over the last two decades. In the 1990s data analysts worked with terabytes of data by using RDBMS (Relational database management system) and Data Warehouse and today they are faced in their work with exabytes of data. Classical example for this is data from the astronomy science, and especially images from earth and space telescopes (Wang, J. (Ed.), 2006). The main techniques used today to work with and store this large amount of data are no-sql and key/value paradigm. The amount of data grew 1000000% in last twenty years (1 exabyte = 1000000 terabytes (TB[1])). We can see the trend of constant and rapid growth of information and this is the thing that will definitely complicate work of data analysts in the future.

Data Mining has found increasing usage in financial areas that need to work and analyse large amounts of data to discover knowledge, patterns (Wang, K., Zhou, S., & Han, J, 2002) and future trends in business in order to improve its position on the financial market. In Marketos, G. D., Pediaditakis, K., Theodoridis, Y., & Theodoulidis, B. (2004) the authors concurred that data mining techniques and algorithms provide some capabilities required in cases where the evolution of the existing data need to be observed through the time dimension. For a stock market as a specific area of finance it is very important to use advantages of Data Mining approach. This will help and support stock market traders in their main function, by suggesting possible stock market trading transactions and better business decisions.

Financial forecasting is very popular among data scientists. In the literature several data mining approaches were developed for a financial forecasting. Zafra-Gómez, J. L., & Cortés-Romero, A. M. (2010) in their research propose using of CHAID (Chi-squared Automatic Interaction Detector) for analyzing the financial condition of local authorities in Spain. Support vector machine (SVM) and Neural Net are very popular tools for prediction. Wang, J., Xu, W., Zhang, X., Bao, Y., Pang, Y., & Wang, S. (2010) propose using of these techniques as a method for crude oil market analysis and forecasting. Kim, K. J. (2003) suggest using of support vector machine (SVM) as a promising method for the prediction of financial time series. Batyrshin, I. Z., & Sheremetov, L. B. (2008) in their work describe a new technique of time series analysis based on a

[1] 1 TB = 1000000000000 bytes = 10^{12} bytes

replacement of time series by the sequences of slopes of linear functions approximating time series in sliding windows by using MAP (Moving Approximation). For a stock market prediction authors like Bose, I., & Leung, A. (2009) suggest exertion of machine learning for problems of stock index movements, change of exchange rates, and variations of bond prices.

In this research I am exerting data mining techniques for the problem of data series analysis. I have used four different approaches (Neural net, Support vector machine, Naive Bayes and K-NN classification) at the same data set and compare results that I got in every individual analysis. I also worked with specific dataset from a period of Global Financial Crisis that hits stock market. I am trying to forecast and predict the future trends of daily closing values of the stock.

2. FINANCIAL TIME SERIES ANALYSIS

A time series is a sequence of data points, measured typically at successive points in time spaced at uniform time intervals. It can be used only in cases where the past is observable. Time series analysis is the analysis of data organized across units of time and it is widely used in financial institutions. According to Nanni, M., & Spinsanti, L. (2010) time series analysis is based on the extraction of trends and other behavioral models that are then matched to the current situation to forecast future values. Results that these analyses provide are highly important since they can lead to a large potential for analytical studies and they can be the key competitive advantage in business.

Bose, I., & Leung, A. (2009) defined financial time series as sequence of financial data obtained in a fixed period of time. The key area of application of time series analysis in finance is in forecasting. Movement of stocks in the financial market is a typical example of financial time series data. At the stock market the main question that time series analysis should provide answer is: What is the likely future price of this stock? The answer to this question will help stock market traders to decide whether they should buy or sell stock.
Financial time series data is a promising area of research. It is definitely that it is going to be more and more popular among data scientists. Future is something that we want to predict for centuries and this methodology is just one way in future forecasting related to financial area. Financial time series data is quite different from traditional data that data scientist handle every day. For this reason working with financial time series is a bit harder but if you know how to use data mining techniques, understand algorithms that you are using and know how to interpret the result of analysis it is a big benefit for you and your company.

3. STOCK MARKET

Stock market is the market in which shares of publicly held companies are issued and traded either through exchanges or over-the-counter markets. Also known as the equity market, the stock market is one of the most vital components of a free-market economy, as it provides companies with access to capital in exchange for giving investors a slice of ownership in the company.

There are many factors that play significant role at the stock market. Each stock is not only characterized by its price but also by many others variables. All those variables are not independent; they are related to one another. In the analysis we have to check relationship between them, not only to do individual research. The main variables that can be identified at the stock market according to Marketos, G. D., Pediaditakis, K., Theodoridis, Y., & Theodoulidis, B. (2004) are shown in the table below.

Table 1: Stock variables

Variable	Description
Price	Current price of a stock
Opening price	Opening price of a stock for a specific day
Closing price	Closing price of a stock for a specific trading day
Volume	Stock transactions volume(buy/sell)
Change	Opening and closing stock value difference
Change (%)	Percentile Opening and closing stock value difference
Maximum price	Maximum stock price within a specified time interval (day, month etc.)
Minimum price	Minimum stock price within a specified time interval (day, month etc.)
Adjusted Closing Price	A stock's closing price on any given day of trading that has been amended to include any distributions and corporate actions that occurred at any time prior to the next day's open

Many researches in the field of finance including Marketos, G. D., Pediaditakis, K., Theodoridis, Y., & Theodoulidis, B. (2004) and Taylor, S. J. (2007) showed in their works that there are some factors that have big influence in the price of the stock. These factors are usual in everyday business with stocks and we could identify them as following:

Table 2: Possible stock price influence factors

Influence Factor	Description
Volume	How many dealings are taking place
Business Sector	The sector in which a stock belongs
Historical Behaviour	Fluctuation of a stock over time
Rumours	There is a rule suggesting to "buy on rumors sell on news" so that may cause some unpredictable behaviour
Book (Net Asset) Value	The accounting value of a company
Stock Earnings	Percentile difference of the stock price value over a period of time
Financial position of a company	The financial status of a company
Uncertainty	Are there any unpredictable factors?

All the above mentioned factors are proof that time series analysis and forecasting at the stock market are very complex.

4. PREDICTION OF STOCK MARKET

Stock market prediction is the attempt to predict and determine the future value of a stock traded at the financial market. The successful prediction of a stock's future price could yield significant profit.

4.1 Data

The dataset that I used for this research is NASDAQ[2] prices from the January 1, 2011 till the 15 April, 2014. I also worked with S&P 500 (^GSPC) [3]dataset that contains data from the stock market at the period of Global Economic Crisis, period from 2007-2008.

Table 3: A part of data set that i have used for this research

Date	Open	High	Low	Close	Volume	Adj Close
4/14/2014	18.01	18.13	17.72	17.82	72500	17.82
4/11/2014	17.92	18.03	17.72	17.76	51400	17.76
4/10/2014	18.36	18.44	18	18.02	78600	18.02
4/9/2014	17.84	18.22	17.84	18.21	51800	18.21
4/8/2014	18.1	18.12	17.6	17.8	131000	17.8
4/7/2014	18.06	18.06	17.8	17.99	91900	17.6
4/4/2014	18.71	18.71	17.97	18.01	137100	18.01

4.2 Experimental setup

In this research several regression algorithms are used:

Support vector machine (SVM) – this algorithm can be used for both regression and classification and provides a fast algorithm and good results for many learning tasks. It takes a set of input data and predicts, for each given input, which of the two possible classes comprises the input, making the SVM a non-probabilistic binary linear classifier. An SVM model is a representation of the examples as points in space, mapped so that the examples of the separate categories are divided by a clear gap that is as wide as possible.

[2] http://finance.yahoo.com/q/hp?s=QQQX+Historical+Prices
[3] http://finance.yahoo.com/q/hp?s=^GSPC+Historical+Prices

Neural Net (NN) - an artificial neural network (ANN), usually called neural network (NN) is a mathematical model or computational model that is inspired by the structure and functional aspects of biological neural networks. A neural network consists of an interconnected group of artificial neurons, and it processes information using a connectionist approach to computation (the central connectionist principle is that mental phenomena can be described by interconnected networks of simple and often uniform units). In most cases an NN is an adaptive system that changes its structure based on external or internal information that flows through the network during the learning phase. Modern neural networks are usually used to model complex relationships between inputs and outputs or to find patterns in data.

K-nearest neighbor (k-NN) – this algorithm is based on learning by analogy, that is, by comparing a given test example with training examples that are similar to it and it is one of the simplest of all machine learning algorithms.

Naïve Bayes - a Naive Bayes classifier is a simple probabilistic classifier based on applying Bayes' theorem (from Bayesian statistics) with strong (naive) independence assumptions. According to Congdon, P. (2003) the advantage of the Naive Bayes classifier is that it only requires a small amount of training data to estimate the means and variances of the variables necessary for classification.

In this experiment the time series model is created by using already mentioned algorithms and time series operators. The model applies algorithm on training data which are uploaded from data set and try to forecast the value of attribute that we have already marked as output. That output is something that we want to predict and it is called label. In this experiment label attribute is Close (daily closing price of a stock). The parameter series representation defines how the series data is represented. In this experiment encode series by examples approach is used in which the series index variable (e.g. time) is encoded by the examples where each example encodes the value vector for a new time point. . For this model it is also important to decide how many days ahead we want to do forecasting. In this research it is decided to forecast next day closing price and for this it was used time series parameter horizon (value of this parameter was set to 1). Step size is set to 1 and it means that each row of input data was processed. Another very important operator that has been used in this experiment is windowing. This operator allows work with multivariate value series data and that was something that is needed since data set was made of 7 attributes. It also transforms a given example set containing series data into a new example set containing single valued examples. For this purpose, windows with a specified window and step size are moved across the series and the attribute value lying horizon values after the window end is used as label which should be predicted.

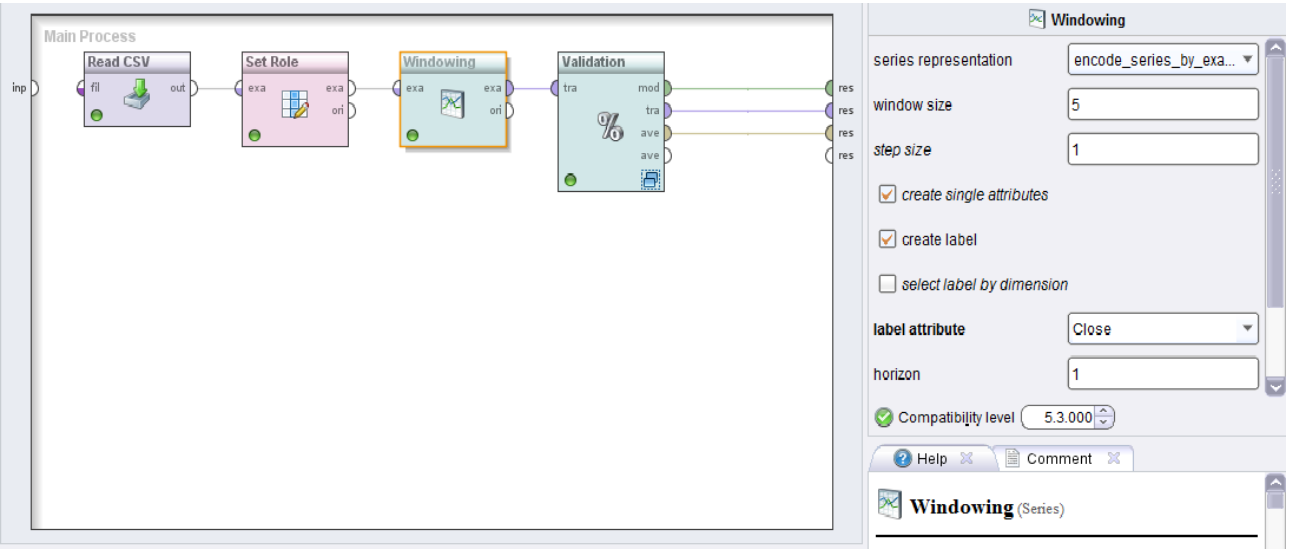

Figure 1: A part of experiment and example of using windowing operator

4.3 Evaluation and result

The results from previously described experiment are showed in table 4.

Table 4: Summary result of prediction performances for NASDAQ data set

Algorithms	Accuracy	Deviation	Rank
SVM	0.744	0.22	1
Neural Net	0.68	0.243	2
K -NN	0.533	0.242	3
Naive Bayes	0.455	0.295	4

The Figure 1 shows that closing price of stock is something that changes very quickly and unpredictably. In 2011 there was a trend that these prices extremely go up – down, but in 2013 there was a good period of time when closing prices were only growing. This is another indicator how hard is working with financial time series and how difficult is to create patterns for stock market.

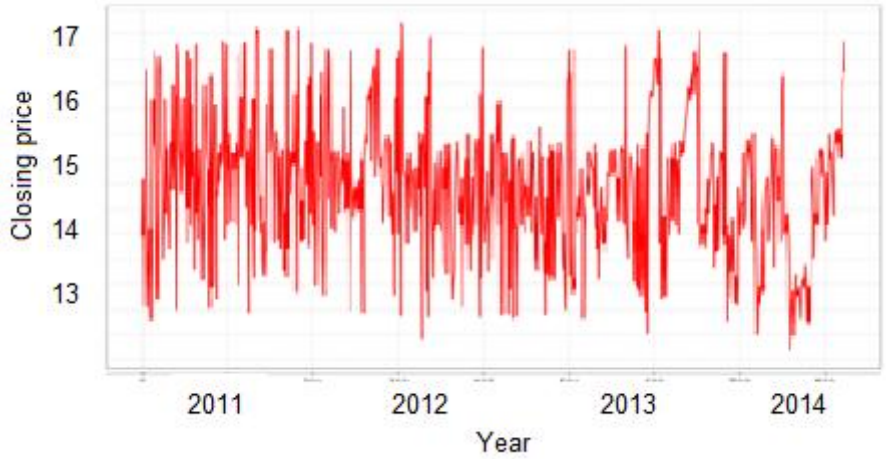

Figure 2: Daily closing prices of NASDAQ Stock Market

The result that I got while I was working with S&P 500 (^GSPC) data set were not so good. Even pre-processing data and doing parameter optimization could not help in increasing my model performance. After complex analysis I have discovered that the reason for this lies in the fact that this data set is from the period when Global economic crisis hits whole financial market and also stock market as a part of it.

5. CONCLUSION

This paper presents results of four different techniques of data mining to forecast movement direction of daily closing price of stocks from NASDAQ stock market. Prediction rate of these models vary from 45% to 75%. Support Vector Machine (SVM) and Neural Net outperform other two models since their algorithms guarantee to efficiently obtain global optimal solution which is unique. Other models may be reliable for other markets, but in this case they did not show satisfactory result. SVM and Neural Net are recommended for forecasters of stock prices and the better model, SVM, is more preferred.

Future work could include modelling the same problem by combining these approaches with other data mining techniques (e.g. fuzzy logic). The upwards/ downward tendencies can be considered as event types and be combined with others (e.g. Central Bank announcements). For stock market dealers it is not only important to know whether stock price will go up or down, but also how much will be that change. The key thing in working with stocks is to predict trends on time. The aim is not to buy cheap stocks, but these that have an upward tendency. Therefore, it will be good to combine all different approaches into the one solution that will help all participants at the stock market in their everyday work and provide them valuable information about future tendencies and possible results.

Abstract: *This paper provides a detailed analysis and comparison of different methods used in order to forecast possible bankruptcy of companies within the Republic of Serbia in the next year. We collected data for the 52 different companies in our country and calculated financial ratios based on Altman's Z-score model for each company in order to use these ratios as inputs in further analysis. Firstly, we used neural networks for prediction and tested how successful they are when it comes to this kind of problem. We applied pattern recognition and probabilistic neural network. Afterwards, we used regression analysis and tried to find most appropriate one for our data set. We used linear and logit regression models with different variants of dependent and independent variables. Finally, we mutually compared the results of each of the proposed models used for forecast of companies' bankruptcy*.

Keywords: *Altman's Z–score, Pattern recognition, Probabilistic neural network, Linear regression, Logistic regression*

1. INTRODUCTION

During the last decade considerable effort has been invested in the complex and demanding analyses of companies financial reports, in order to define more certain business strategies in the future. More accurate determination of company"s future market position is attempted by analyzing and studying the financial data of the company using many different kinds of analyses.

Successful management of the company"s business is always a very challenging task because of the frequent changes and volatility in political, social, financial and economic domain. Every business decision that is made brings both financial and business risks. There is always a possibility to have really bad business results, due to poor business decisions, that sometimes could even lead to the bankruptcy of the company. That needs to be prevented.

In this study we demonstrated different methods and models which are capable of forecasting the probability that company might bankrupt in the future. Every prediction of this kind aims to improve the company"s business performance.

So far, in literature and previous studies many mathematical models and techniques had been used to provide probability for the company"s departure into bankruptcy. Among the advanced techniques of data analysis, which are suitable for forecasting the probability of bankruptcy, it is possible to single out regression models and artificial neural networks. Regression models are very often used to determine correlation between several factors influencing the observed phenomena. On the other hand, neural networks, compared to multivariate regression techniques, have a completely different approach in solving this kind of problem. So far, the neural networks were successfully used in a variety of financial areas (McNelis 2005), such as the determination of credit risk, forecasting of stocks, pricing actions on a given day, the prediction of success in the financial market, etc. Our goal is to compare these two approaches and to determine which one is better in forecasting probability of company"s bankruptcy.

In order to solve the problem of bankruptcy prediction using neural network and regression we selected software Matlab 2012.

2. REVIEW OF COLLECTED DATA

For the purposes of this study, data from the 52 companies registered in the Republic of Serbia were collected. Within selected companies there are 26 companies which are still active and 26 of them went bankrupt or are in the process of bankruptcy. All data are taken from official website of Agency for Business Registers (2014), because it is mandatory to have data from regular annual financial statements. Among these reports there are balance sheet, income statement and statistical annex for a given year. All data

necessary to calculate the indicators included in the model of financial statements are related to the period of two years before the bankruptcy proceedings started.

3. ALTMAN'S Z-SCORE MODEL

One of the most cited and most used model for predicting bankruptcy of enterprises is E. I. Altman's model. In his work, Edward I. Altman (1968) introduced the Z-score, which is a linear combination of the five selected financial ratios. Presented statistical model uses accounting information in order to predict the probability with which one company will go bankrupt in next year or two. All the necessary data can be obtained from financial reports.

It was necessary to determine which financial ratios can show possibility of bankruptcy most precisely, as well as a weight for each selected indicator. Edward I. Altman used multivariate discriminate analysis for model formulation, which is not that popular such as regression analysis in this area, but it was very successful at the end. In his research, E. I. Altman used data for 66 companies from which one half got bankrupt and the other half not. From 22 financial indicators used by multivariate discriminate analysis he chose 5. Using these 5 indicators he formulated next Z score:

$$Z = 1{,}2T_1 + 1{,}4\,T_2 + 3{,}3T_3 + 0{,}6T_4 + 0{,}999T_5 \qquad (1)$$

Where:
T_1 = Working Capital / Total Assets;
T_2 = Retained Earnings / Total Assets;
T_3 = EBIT (Earnings before Interest and Taxes) / Total assets
T_4 = Market Value of Equity / Book Value of Total Liabilities
T_5 = Sales / Total Assets

The original work of Edward I. Altman referred to public manufacturing companies with total assets of more than a million dollars. Later on, the field of application of Z-score was significantly extended to other types of companies. The value of obtained Z-score is interpreted differently depending on the type of the company for which is calculated. In 2002 Altman introduced new versions of Z-score model, Z_1 and Z_2. They differ from previous one in that they are applicable both in public and private manufacturing companies, but also in non-manufacturing and service providing companies. Also, when calculating quotient T4 instead of Market Value of Equity, he used Book Value of Equity. Model for private manufacturing is as follows:

$$Z_1 = 0{,}717T_1 + 0{,}847\,T_2 + 3{,}107T_3 + 0{,}42T_4 + 0{,}998T_5 \qquad (2)$$

The weights of coefficient are different from the first presented model. It may be noted that the third and fifth coefficient are minimally changed which means that their influence remained almost the same.

On the other hand, for non-manufacturing companies and emerging markets the model as follows is given:

$$Z_2 = 6{,}56T_1 + 3{,}26\,T_2 + 6{,}72T_3 + 1{,}05T_4 \qquad (3)$$

A characteristic feature of this model is that doesn't take into account ratio of sales and total assets, i.e. T5, just because it comes to non-manufacturing companies. Therefore, the ratio of net working capital and total assets has dramatically greater impact than in previous models. Also, the quotient of EBIT and total assets has coefficient more than twice greater compared to the two previous models.

Seeking for the critical value that would represent the border between healthy companies and those who are in crisis, Altman has concluded that the value of 2,675 of Z-score is dividing companies into two groups on the best possible way.

In his further work, after detailed analysis, Altman is pointing out that for public manufacturing companies original model also applies, and if the calculated value of Z-score is less than 1.81, probability that a given company will go bankrupt is very high. If Z-score takes value from interval 1.81-2.99, then given company is in so-called "grey" zone and probability for bankruptcy is 50%. Finally, if the value of Z-score is greater than or equal to 2.99, the company is in safe zone and has very little chance of going bankrupt within year or two.

On the other hand, for the private manufacturing companies the boundaries are somewhat lower. For private manufacturing companies grey zone is between 1.23 and 2.9 and for non-manufacturing is 1.1-3.75.

After research it was found that the performance of bankruptcy predictions using the first presented Altman's Z-score is about 72%. In a series of tests and studies in next 30 years it has been established, on larger sample, that the performance of bankruptcy predictions within one year is actually between 80% and 90%,

with an error of the second level of 15% - 20%. Error of second level refers to the classification of the companies that didn't bankrupt in bankruptcy group.

The aim of Z-score model is not to predict when exactly the company will bankrupt, but to point out certain similarities with companies that have already bankrupted. The value of Z-score should be used as a warning and indicator of potential instability of the company.

4. ANALYSIS OF OBTAINED RESULTS FOR ALTMAN'S Z-SCORE MODEL

Table 1: Statistical successfulness of Z-score model

Model	Bankrupt and classificated into B	Not bankrupt and classificated into A	Bankrupt and classificated into A	Not bankrupt and classificated into B	Grey zone	
					Bankrupt	Not bankrupt
Z-score	Z<1,81 **24 (92%)**	Z>2,99 **18 (69%)**	**0**	**2 (7%)**	**2 (7%)**	**6 (23%)**
Z_1-score	Z_1<1,23 **21 (81%)**	Z_1<2,9 **6 (23%)**	**0**	**2 (7%)**	**5 (19%)**	**18 (69%)**

(A is a group of active and B is group of bankrupted companies)

Z-score model correctly classified 81% of companies in active or bankrupt group. From analyzed data may be noted that no company with Z-score greater than 2.99% went bankrupt in next year.
The revised Z_1-score model has been adjusted to the today's market at the beginning of this century in the way that weights of the parameters used for bankruptcy predictions have been changed. Each of these models has been defined in the United States. As seen in previous table, Z_1-score model didn't give expected results for our market. It can be noticed that great difference between markets exists and it's almost impossible to define universal model that would fit each market. Z_1-score classified barely 21% of successful companies in correct group of active manufacturing subjects. Also, model classified even 69% of companies in grey zone, even though they were doing business successfully. From this we may conclude that our market isn't on high level of development such as global market, therefore it is not mature enough for analysis using newer Z_1-score model. The older Z-score model has proven as much more precise. Considering that our data set contains only manufacturing companies, Z_2-score model is not applicable at the moment.

5. BASIC CONCEPT OF NEURAL NETWORKS

Neural networks are artificial systems made to recognize the rules that connect complex data in order to formalize existing correlations between given input and output data. Neural networks can even recognize laws that are, due to their complexity, hard to be seen by humans. Neural networks are characterized by parallel and fast information processing and large number of elements namely neurons of networks.

The structure of neural network

The structure of neural network shows the way in which the neurons of a network are linked together. In most of topology one can see the input, output and hidden layer neurons. Neural networks differ by how many hidden layers they possess, but it does not need to have a hidden layer of neurons.

Neural networks training

Before using neural networks for problem solving, they need to be prepared, i.e. trained. Training of neural networks is a process of passing appropriate data set through the network. The values obtained at the output are to be compared with expected values. Weights of connections between neurons are to be modified in order to reduce the difference of actual and desired outputs. This process is based on the observed differences.

The network learns the received data until it is able to provide an output that is in accordance with the set criteria (the number of training epochs or error tolerance).

Application of neural networks

In this study we used popular Pattern recognition that is based on feedforward neural network and Backpropagation learning method as well as Probabilistic neural network (PNN). PNN is multilayered feedforward network, which is driven from the Bayesian network, probabilistic directed acyclic graphical model, and Kernel Fisher discriminate analysis.

PNN have three layers. They are often used for classification problems, because of their ability to map inputs to outputs, even if their mutual relation is hard to define. Also, probabilistic neural networks train really fast, because training is performed in one pass of each training instance, rather than several as with recurrent networks.

Architecture of probabilistic neural network is composed of input, radial basis, competitive and output layer. Radial basis layer record the difference between input vector and training vector. In this way, the vector, whose elements show how close inputs to the training inputs are, is obtained. The nest layer crates the sum of these contributions, for each category, and creates new vector of probabilities that describes the belonging of each instance to specific group. At the end, complete transfer function returns 1 for belonging class and 0 for other classes.

Feedforward neural network - Multilayer perceptron network for pattern recognition usually consists of three layers, input, hidden and output, but it depends of the complexity of the problem. Sometime there is a need for more complex network, with more than one hidden layer. Numbers of neurons in input and output layer are determined by the concrete data and its structure. These numbers are easy to define for each classification problem. On the other hand, number of neurons in hidden layer, depends of complexity of problem. Even though, in literature, there are many different opinions how to compute number of hidden neurons, there is no generally accepted formula.

Pattern recognition is based on backpropagation supervised learning algorithm. Backpropagation is really successful in classification problems (Chaudhari, 2010) and it is the most widely used method for training neural networks. Through algorithm learning minimum error function is defined, by using the method of gradient descent. Difference between target values and resulting output is computed is sent back trough the network in order to adjust the weights of each connection in network. Training network is based on minimization of this difference through iterative process.

6. ANALYSIS OF OBTAINED RESULTS FOR NEURAL NETWORKS

In order to predict probability of company bankruptcy we created two neural networks: multilayer perceptron and PNN. Inputs in both of neural network are financial ratios from Altman's Z model, and the output is class in which company belongs. Class indicates weather that company is active or bankrupt. Thus number of neurons in output layer is two and in input layer is five.

As we already said, data set consists of 52 companies which are registered in Serbia. In collected data there are 26 active firms and 26 bankrupt. In our case, we have five financial ratios in Altman's Z model therefore there are five neurons in input layer. On the other side, in output layer there is two neurons, because we are trying to classify each company in group of active or bankrupt firms. For hidden layer, we decided to use 10 neurons in only one layer.

Pattern recognition NN

First, we created pattern recognition neural network which used *Scaled Conjugate Gradient* for training. Data set was randomly divided in three groups: one for training, one for verification and one for testing network's performance. Our goal was to create new model that could better establish the correlation of the Altman's five financial ratios.

After training pattern recognition neural network for ten times, we got average training error of 0,03172. For computing training error we used method of least squared error. Neural network was trained so it could predict probability that company is going to bankrupt, for new data. Neural network successfully predicted bankruptcy for **82%** of new companies, with variance of **0.78**.

When we look closely to results we can see that pattern recognition mainly made mistake in classifying company's that are in Altman's gray zone. From this we can conclude that pattern recognition gave the similar significance to financial ration as Altman's Z score.

Probabilistic neural network

Second neural network that we created was probabilistic neural network. Average successfulness after 10 trainings and after usage of network for predictions under new data is **90.7%**, with variance is **0.55**.
Interesting comparisons:

Table 2: Examples of instances classification

T_1	T_2	T_3	T_4	T_5	Z score	Group	PNN
0,333229	0,341265	0,081139	0,659928	0,576239	2,11702	2	1
0,275887	0,170856	0,166042	0,296366	1,263757	2,558514	2	2
-0,03522	0,10808	0,128135	0,268307	1,334494	2,026038	2	2

In column *Group* there is 1 if company got bankrupt and 2 if company is still active. Column PNN shows group in which company was classified by neural network. It may be noticed that for the first company PPN is wrong and Z-score classified it in grey zone. PNN classified next two companies correctly, even though Z-score said they are in grey zone.

7. INTRODUCTION TO LINEAR REGRESSION

Regression analysis is statistical tool used for investigation of relationships between variables. Usually it is used to ascertain the causal effect of one variable on another. In this kind of research investigators often asset statistical significance of the estimated relationships which is actually the degree of confidence that estimated relationship is close to real relationship.

Regression is data mining function that is used for predictions.

Linear regression is one of the simplest regression models. It attempts to model relationship between two variables (dependent and independent) by fitting a linear equation to observed data. Before working with this regression, it is important to determine if certain significant association between two variables.
Linear regression has this form of equation: ***Y = a + bX,*** *where* **X** is independent (or explanatory) variable and **Y** is dependent variable. The slope of the line is **b**, and **a** is intercept (a=Y when X=0)

Logistic regression (logit regression) is a type of probabilistic statistical classification model where **X** (independent variable) can be numerical or categorical and Y is often coded as 0 („doesn"t belong to a group") or 1 („belong to a group"). Logistic model is based on linear relationship between natural logarithm (**ln**) of the odds of an event and numerical independent variable.
Logistic regression has the equation:

$$L = ln(o) = ln\left(\frac{p}{1-p}\right) = \beta_0 + \beta_1 X \quad (4)$$

Where Y is binary and represents the event of interest (response), coded as 0/1 for failure/success,
p is the proportion of successes,
o is the odds of the event,
L is the *ln*(odds of event),
X is the independent variable,
β_1 and β_2 are the Y-intercept and the slope, respectively, and
Ɛ is the random error.

8. ANALYSIS OF OBTAINED RESULTS FOR REGRESSION ANALYSIS

Linear regression

We decided to use **linear regression** and to test how successful it is when it comes to comparison with neural networks. In our first iteration we set financial ratios as independent variables:
T_1 = Working Capital / Total Assets;
T_2 = Retained Earnings / Total Assets;
T_3 = EBIT (Earnings before Interest and Taxes) / Total assets
T_4 = Market Value of Equity / Book Value of Total Liabilities
T_5 = Sales / Total Assets.

Altman"s Z-score was set as dependent variable. Furthermore, multidimensional surface was created and based on that surface each instance was compared in sense of: is the result of function in one point under or below surface. Every instance under surface represents company that didn"t go bankrupt. Other way around, every instance below surface went bankrupt. Thus we got results as follows: 19 instances were classified in wrong groups (both bankrupt in active, and active in bankrupt). That means our linear regression was wrong in 36,54% of cases, and successful in 63,46%.

In further detailed analysis of results and comparison between regression results and Z-score we observed interesting facts:

- From 19 instances which were wrongly classified, Z-score gave correct results in 12 cases, which is around 63%.
- Only one instance we got wrong result both for Z-score and linear regression.
- In 6 cases where linear regression was wrong, Z-score classified in grey zone. Interesting observation here is that we have more cases when Z-score was sure will it go bankrupt or not while regression was wrong (12 cases), than when Z-score was in grey zone and regression was wrong (6 cases). Even though Z-score is more flexible and conservative because of grey zone existence, in this certain case, Z-score was more sure and showed better results alone than in combination with linear regression.
- On the other hand, from two cases when Z-score was wrong, we got improvement with linear regression in one case, which represents 50%.
- Whenever Z-score classified instance in grey zone and it was active in real, regression model was wrong with classifying it in bankrupt group. Other way around, whenever Z-score classified instance in grey zone and it was bankrupt in real, regression model classified it right, i.e. in bankrupt group. Therefore, whenever Z-score classifies an instance in grey zone, regression will classify it in bankrupt group.

In our **second iteration** we used the same input parameters but we didn"t use Altman"s Z-score as output parameter. Instead, we used concrete binary values for bankrupt (1) and active group (0) as output parameter. In this case our linear regression gave better results, and it was successful in 73% of cases, which is better than in first iteration.

In this case we noticed further facts:

- Wrong classifications are all the same. All 14 wrong cases have to be in bankrupt group, but our model classified them in active group.
- There was no mistake when it comes to group of bankrupt companies. But also, it is not the case that all really bankrupt companies are wrongly classified, just 14 of them.
- Using this model we can know for sure that all companies which were classified in bankrupt group will go bankrupt in next year. But we cannot be sure if all companies classified in active group will remain solvent in next year. We can claim that in around 63% of cases.
- If we compare all wrongly classified instances by regression with Z-score, we can conclude that in 86% Altman classified these instances in correct bankrupt group and 14% in grey zone. Therefore, after using regression model we should consider Altman"s Z-score and if it shows possibility of bankrupt, it may be very strong signal for caution.

As a **third iteration** for linear regression, we tried to adjust Altman"s Z-score to financial data for companies that are doing their business in Republic of Serbia. We kept financial ratios that Altman determined as the most important for bankruptcy predictions, but we changed weights of these ratios in our model.

Now, our regression has input parameters as follows: as independent variable we set financial ratios, and dependent variable is group to which companies belong (active, or bankrupt). Considering that we received new coefficients of linear combination for financial ratios from linear regression, this result is observed as a new model for bankruptcy prediction. The results of this model are interpreted as Altman"s Z-score model. It has been noticed that new value of Z-score has lower volatility than the real Z-score. Therefore, intervals that Altman defined in his work are not adequate now. If the intervals remain the same, all bankrupt companies will be well classified in appropriate group. However, if we look into active companies, we can see that new model doesn"t recognize them as active, but in grey zone or in group of bankrupt companies. Based on analysis of given results we concluded that intervals defined for Altman"s Z-score model are not appropriate now for new model given by linear regression. Empirically we defined new lowest limit as 1,11 and the highest limit as 1,41 for grey zone. Now we used these new intervals and based on them we will classify companies which will go bankrupt or will continue to operate successfully. New grey zone interval is now significantly smaller, but that was expected since we already mentioned that volatility of new Z-score is lower.

In this way, we got the model that should be better suited to companies in Serbian market. This score successfully predicted bankruptcy for 81% of companies, while on the other hand for active companies it predicted correctly that will not go bankrupt in 83% of cases. In grey zone there are now 10% of instances which is better than in first case when we had 15% in original Altman"s model. Updated Altman"s model is slightly better than the first, which is not defined for our market.

Logit regression

In **logit type of regression** analysis we used the same parameters as inputs, which are financial ratios. As output parameter in **first iteration** we used 1 for bankrupt group and 2 for active group. In this way, our logit regression classified well 79% of cases.

After deeper analysis of results, we have noticed:

- The same situation as for second iteration in linear regression happened. Actually, all wrongly classified instances are from group of bankrupt and this method classified them in group of active. Unlike linear regression (second iteration) we now have lower number of incorrectly classified which shows that logit regression is better model for our data set.
- If we compare Z-score results first we may notice that logit regression was successful in the cases where Z-score was incorrect. If we consider all grey zone instances from Z-score classification, in 75% our logit regression gave more precise and correct results. Therefore, whenever our Z-score classifies one instance in grey zone, we can consider logit regression to be surer what will happen when it comes to the solvency in next year.

Important information here is that we couldn't forward Altman's Z-score results as dependent variable because Z-score can have negative value, but logit regression always expects positive values. When Z-score gives this negative parameter that means company has really bad business results and soon bankruptcy can be expected.

In **second iteration** we tried to improve results so we involved probability of belonging to a group. We forwarded financial ratios as independent variable and belonging groups as dependent variable. After calling logit function we got 6 coefficients which we forwarded to a general form of logit function. Then we calculated value of function in one point and this result represents probability of belonging to one of the groups. Since we got result between 0 and 1 of a function in one point, we had somehow to define to which group each instance belongs. Therefore, we set a border of 0.5 in order to classify each instance. The truth is that border we set is really rough and we are losing information how close one instance to another group, but this is was only one logical way to define groups. In this case, our model was successful in 100% of cases.

9. COMPARISON OF USED MODELS AND ANALYSIS

In the table below we summarized all results and it can be noticed which method gave the best results.

Table 3: Summarized results for all methods

Name	Successfulness
Linear regression – Altman	63,46%
Linear regression – groups	73%
Linear regression – adjusted Z-score	82,69%
Logit regression -groups	79%
Logit regression – probability	100%
Pattern recognition NN	82%
Probabilistic NN	90.7%

We can see once again that Logit regression with probability was successful in 100% of cases. To be reminded, we set 0.5 as border in this iteration and, as we mentioned, this is really rough boundary. That's the reason we cannot be completely confident that in each case in future this method will give correct results. On the other hand, probabilistic neural network stands out as very good in bankruptcy predictions with successfulness result above 90%. This, now, means that probabilistic neural network can classify next company in future in correct group if appropriate input parameters are submitted. Therefore, everyone has to be sure if correct inputs are given to the network. Only in this way we can expect correct results.

10. CONCLUSION

As we said in previous chapter, probabilistic neural network was the most successful considering all factors and facts. Now we can use our network to classify every company with accuracy of 90.7% which can be very good indicator for business operations in next year for each company.

After researching neural networks and comparing them with regression analysis, we drew the following conclusions:

- Neural networks have possibility to modify themselves and easily adapt to different kind of problems. That's why they can learn fast and give accurate results.

- Neural networks can implicitly detect complex non-linear relationships between independent and dependent variables, which is for regression a bit harder. If a complex non-linear relationship exits, neural network model will adjust weights by itself in order to reflect these nonlinearities. Therefore, it is empirically proved that neural networks may provide tighter model than conventional regression (Tu, 1996)

Even though neural networks can model complex relationships and give pretty good results, still they are like black box. That"s why we cannot get an answer from neural network *why did one company go bankrupt?* or *why is still active*? These answers depend on various factors, such as management"s decisions, state of the market etc. That"s why it will never be possible to create perfect model which is successful in every single case. But, it is possible to seek for the best possible model, and for bankruptcy predictions of companies in Republic of Serbia this model is probabilistic neural network.
This research is based on small data set because of impossibility to gather more digital records in our market. For further analysis it is certain that data set has to be greater, but these results can give significant basis and can show good scientific directions for bankruptcy predicting.

Abstract: *It is inconceivable that any organization could function properly, without agreed actions of its subjects. However, harmonizing opinions as important factor of group decision-making process, have not attracted sufficient attention in the contemporary literature. In this paper, we have identified, described and explained some of the possible methodological problems that arise in the process of harmonizing attitudes of the subjects of organizations in the group decision-making process.*

Keywords: *Decision-making process, group, coordination, organization, human resources management,*

1. INTRODUCTION

Making important decisions in the interest of the organization is not a simple product of thinking, the conclusion about what is the most beneficial for the organization at one time and long-term, what to do and how to do it at certain point... Specifically, in order to come to any conclusion about what represents the interest of the organization at some point, in order to make proper decisions, it is necessary to carry out the process of harmonization of the attitudes of important subjects of organization. One must not ignore the fact that the potential subjects - participants in the group decision-making process, can be bearers of various interests by themselves. Some interests are clearly internal, others external. In the process of finding the common interests of the group and making appropriate decisions, a lot of adjustments are required and they are taking place in various stages and phases.

2. DECISION MAKING AS AN IMPORTANT FACTOR IN MANAGING AN ORGANIZATION

If we try to find a common characteristic of all existing organizations, regardless of their type of activity, sectoral affiliation or business volume, we would undoubtedly come to the conclusion that an important part of their organization and functioning are primarily these subjects - people who form them. Irrespective of this fact, the personnel function in modern organizations is often unfairly overlooked, because the rapid technological development has put greater focus on the technical equipment and problems that arise from it. This trend is one of the main causes of the emergence of the crisis in the organization's operations and functioning.

People are the ones who manage the organization, make decisions and implement them. Management of each organization can be viewed as a complex process that involves several sub-processes, namely: planning, organizing, leading and controlling. Each of these sub-processes implies the adoption of a large number of decisions .

Randjić, Jokić and Lekić (2007) discuss that decision-making or decision-making process consider choosing between two or more alternatives (options) (p.81). But decision-making is not something that is done only by managers. Every individual in an organization is constantly involved in some form of decision-making while performing his tasks, as he is often in a position to select one or more options .

In this paper, we have especially focused on decision-making process in the domain of managers, concerning the planning, organization, management and control. In the planning process based on the environment analysis, directions of development are determined, objectives are positioned, and strategies are identified, selected and implemented. Decisions on organizational design and organizational structure are made in organizing. Management is conducted through implementation of a series of decisions that link motivation and communication with coordination (commands and instructions). Control involves continuous monitoring in order to determine deviations (errors), in order to take preventive and corrective actions.

Decisions that are dealing with the important issues of organization can be made individually or in the groups, depending on the number of people who take responsibility for decisions. This separating is conditioned by the situation that some decisions by its nature must be made by group, such as decisions on the adoption of key documents that define work rules of organization, such as statutes, regulations, or decisions on strategic ways of development and so on. While in individual decisions, one person makes a decision in accordance with the responsibilities and powers, in group decision-making there is a principle that the more people there is, the more they know, and at the same time, group decisions are opportunities for better understanding of the situation.

Regardless of whether decisions are taken individually or collectively, the ultimate goal is to make best decisions, that will lead organization to it's desired state. Therefore, in the process of decision-making, there is a task for management to contribute to a healthy organizational climate, to enable expression of positive potential of individuals, to channel potentials and resources and thus ensure high quality decisions.

3. CONCEPT AND IMPORTANCE OF A GROUP DECISION-MAKING

Contemporary environment impose complex issues to organizations, that need to be solved quickly. Organizations are forced to constantly adapt to the new requirements of the environment, changing markets and target groups. These conditions require the joint efforts of entities belonging to a particular organization, in order to devise the best solutions.

Jarić, Ćurčić and Jagodić (2009) point out "As more and more complex problems are appearing, interdisciplinary knowledge is required for their solving, but such knowledge is hardly to be possesed by an individual. Interdisciplinary knowledge can be found and achieved within the team" (p. 60). The need for the organization of teams and teamwork occurs at all levels, regardless of the organizational structure of the organization and hierarchical levels of decision-making. *Drucker (1996) discuss that development and expansion of the organization's activities, slightly overcome the power and capabilities of a single person in the decision-making process, and there appears a need for the establishment of the management team. Such teams are based on mutual understanding, and to achieve it, there is a lot of work to be done (p. 133).*

A prerequisite for achieving significant effect of teams that bring together actors of organization in the decision-making process is their positive acceptance by the leaders of the organization. These teams should not be considered as a threat to the authority of organization's management, but as an important factor of achieving the interests and goals of the organization. It is an indisputable fact, that the power of the team is greater than the sum of the powers of its members.

It is important to point out the differences between teams and groups. Each team represents a group, but each group is not a team. The main difference lies in the fact that the group work means the work of professionals who work in the organization and that their work is performed in accordance with the general laws of the organization, while the teamwork approach is used when you need to form a team of experts and solve a particular complex problem. Teamwork gives the opportunity for team members to be actors who are not employed by an organization that needs to solve particular problem, and usually when a solution is founded and task is completed, team would be disbanded.

Since we can consider that the objectives of group and team work are identical, namely that both increase the effectiveness and efficiency of common work, we have decided that in our paper we should use the concept of group decision making, which would also apply to decision-making entities in teamwork.

Both groups and teams make common group decisions in certain decision-making procedures. All decision-making procedures have their advantages and weaknesses and it is same for group decision making.

Identified advantages are the following:

- Overall knowledge of the group is greater than the knowledge of the individual, so there is a greater pool of knowledge and information that is focused on problem solving;
- It is possible to develop more alternative solutions for problems;
- Participation in decision-making increases the acceptance of the decision by the members of the group;
- For employees who participate in decision making, a need is developed to implement group made decisions.

Identified disadvantages are the following :

- The decision making process is much longer than in case of individual decision-making, and because of this sometimes in situations of crisis, group decision-making is not applicable;
- In case of disagreement, it is possible to hurt the feelings of the participants in the decision-making process;
- Bulk opinion does not mean that it is the best opinion;
- There is a risk of domination by one person or several of them, in which case opinions of other group members are not respected;
- There is a tendency for pressure in order to create agreement and consensus, and then there is a restraint of group members;
- Competition among group members becomes more important than the solution of particular problem, which leads to unnecessary backlash and sabotage of the process of adopting the decision;
- Also, there is a tendency of accepting the first solution that leads to consensus, without worrying about whether is that solution good enough or not.

All mentioned advantages and disadvantages of group decision making are showing us the importance of the process of harmonization of the attitudes of the subjects involved in the process of group decision making. Hence the need in our work to pay a special attention to methodological problems of harmonizing opinions of the subject - participants in group decision making.

4. TERM - ADJUSTMENT OF ATTITUDES

Adjustment is a social reality that can be seen in everyday life. It is a form of communication between two entities, where each of these two entities has its own attitude that differs in part or in whole of the the attitude of another entity. These attitudes may be different in form, content, relevance and orientation and can express perceptions, facts, judgments, conclusions, forecasts, expectations and so on.

Rečnik srpskog književnog jezika (1967) defines that "To agree means to bring one another into compliance. Agree means even unify and lead in the match (p. 223)". In everyday practice, there is a feature to equate harmonization and alignment . Although they appear similar, and often the explained one to another and vice versa in the literature, these terms can differ significantly. The difference between the concepts of alignment and harmonization, in terms of methodology, is reflected in the fact that reconciliation is only possible first phase alignment, and not his synonym.

We will focus our work on the process of adjusting attitudes of subjects - participants in group decision-making, that can occur in the following ways:

- polemics, if the views are opposed,and the adjustment of attitudes are made through proving and refuting certain attitudes of entities;
- the use of premises and knowledge, if subjects of adjustment act with the intent to agree, they point out common positions and soothe opposite.

5. AIMS OF ADJUSTMENT OF ATTITUDES IN PROCESS OF FINDING THE INTERESTS OF ORGANIZATIONS

Kukoleča (1972) discuss that each aim is a reasonable definition of a desirable, probably possible situation. The existence of the target is a prerequisite for the emergence of a new organizational system, and the individual and the society over the resulting system achieve articulated goal. Hence, certain principles are based on the characteristics and importance of each specific goal, which should be adapted to the structure, and functioning of the particular system, to achieve concrete goal (p. 221).

Mala politička enciklopedija (1966) points out that "In an embodiment of the process and goals of an organization there are two key moments, namely finding interests of the organization and its implementation. The term "interest" comes from the Latin word interesum, interesse, which means participating in something, be interested" (p. 390).

This is confirmed by the fact that the interest must:

- identify;

- classify;
- select;
- be articulated as interests of such organization;
- get approval of the competent entities, to proclaim itself as the interest of the organization;

Termiz and Milosavljević (2000) point out that "Exercising the interests of the organization is moving from the sphere of thought in the realm of facts and actions, so that the organization is trying to achieve by its collective power the idea about itself interest" (p. 20).

Decision in group decision-making should be preceded by adjustment of attitudes, ie achieving mental, psychological, emotional and rational agreement about:

- problems;
- solutions (problem solving).

Goals of adjustments are to overcome initial differences in attitudes and behaviors between the entities of the organization are to provide their common functional activity. That is one of the reasons why they can not be classified as targets in general. It is entirely appropriate to classify them, according to the areas to which they apply, and by the order of their implementation. According to the level of decisions that need to be aligned, goals can be divided into: strategic goals; operational goals and specific (instrumental) goals.

The ultimate goal of the implementation of process of adjustment of the attitudes of the subjects participating in group decision making is overcoming differences of attitudes which should be the part / content of the decision . This creates the prerequisite for ensuring actual compliance on important issues that are often related to current and future challenges, it increases efficiency, effectiveness, efficiency, rational use of resources , adaptability and flexibility of the system and the alignment of its components with the future development needs.

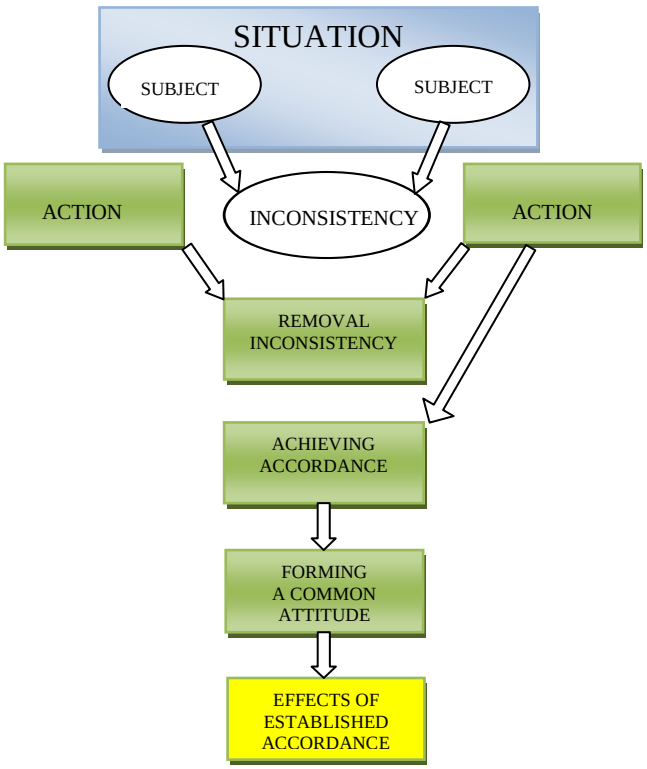
6. METHODICAL PROBLEMS OF ADJUSTING ATTITUDES

Adjustment, as well as every social process, is taking place in certain conditions. Conditions here imply the existence of a number of subjects and other factors that significantly influence the course and outcome of the decision-making process. One subject of adjustment , usually a manager, ascertains that there are certain needs of the organization for making important decisions. Because an individual, regardless of his expertise and position in the organization may not be able to independently make important decisions, or he is just seeking confirmation of his already formed opinions, he is forming a team of experts in order to make common - group decision that will be the basis to solve existing and potential future problems. Accordingly, he takes the following steps:

- Ensures associates in direct meeting those needs;
- All parties involved in the process of adjusting are informed about what are the conditions for meeting those needs;
- Forms a narrow group of people that will help him to evaluate options to meet the needs of decision;
- Defines the goal.

Yukle G., (2006) discuss that phases of adjustment are, as follows:

• Establishment of idea;
• Articulation of idea in to the initiative;
• Argumentation of the initiative;
• Making proposals for decision;
• Gain insights into counter-initiatives and counter-arguments;
• Debate the arguments from the perspective of the validity and according the criteria of benefit and damage;
• evaluation of the arguments;
• reaching agreement in ways how to evaluate arguments;
• development of a common attitude - unanimous decision (or compromise).



Scheme 1: The general model of adjustment process

Subjects - participants in the process of group decision making process, during of adjustment of their attitudes, in principle, attempt to reach a common attitude, but on this way they can find themselves in different situations. At first it may happen that managers who initiated and formed a team to solve some important problem and make decisions regarding it, through formall adjustment and consultations, just seek confirmation of their attitude. In the most severe variant, they demand the acceptance of their own attitude as a fundamental (paradigmatic), and its development into operational purposes.

Second possible situation is characterized by the occurrence that no one participant in decision-making group has not strongly formed attitudes, so there appears equal sharing of available notifications, assumptions, premises and arguments and while studying them, they formulate together an attitude as a structured consent - where disagreements were removed. This second situation is certainly better and helps to achieve a real consensus on an important issue.

However, adjusted attitude, formulated through the process of adjustments is not the final attitude without dissidence. Every attitude, even adjusted is achieved through at least two phases: the first is the interpretation of the attitude, and the second is the application of the attitude, its implementation in the process of communication, values and rules of behavior and action.

Interpretation of attitude includes:

• understanding of attitude and statement;
• understanding of the essence of the meaning of attitude - linked with the reality of social practice that points to.

Adjustments of attitudes, unfortunately, does not always accomplish such a level of accordance, especially not when it comes to very large differences in paradigmatic attitudes, or attitudes concerning the vital interests and values.

When large differences are subject of adjustments of attitudes, then adjusted attitudes are compositioned. The compromised common attitude, as a rule is attitude which is arising out of any loosening of parties - participants of group decision-making, according to rule that he is the one which has less power and it can to go to his damage. Compromised attitudes, no matter how clearly stated, are always subject to interpretation. The reason for this is, that most often both subject of adjustments are putting efforts to the interpretation and application of the attitude, in order to improve their position.

Achieving compliance is not an easy process and does not always end with success. Particularly significant are the problems of emergence of rapid consensus and the emergence of a quasi consensus. Emergence of rapid consensus is characterized by the adoption of the first or loudest alternative solution. Other alternatives are not given enough attention. Quasi consensus is characterized by adoption of a resolution by the members of the group, although they personally do not accept it by themselves. The reasons for such action may be: deference of opinion to authority or the majority, the desire not to jeopardize the harmonious atmosphere in group, or being subject to internal and external pressures to make decisions. This false consensus have negative impact on the quality of decisions, and the cohesion of the group.

In addition to building a consensus, alternative method of making decisions in the group would be the use of voting procedures. Their use typically precedes an exhaustive discussion of options and that means that members are well informed about their characteristics.

There are several voting procedures, but in practices most often used procedure is absolute majority. In the event that a group can not decide between two alternatives, conflict can be solved using this method. However, when choosing among several options, the method of absolute majority may be inefficient procedure and thus, prolong the final selection. The characteristics of this method are that decisions are made on the basis of majority support of an opinion, in which are the procedure established in advance and clear. The process is quick and proposals are clear, and members are opting for and against it. The aim of the discussion is to provide support to one option and denies the other, not to find the best solution. This decision may be the product of concessions.

There are also situations where the end result of the process of adjustments of attitudes during the group decision-making, is imposed attitude. One can not a priori have a negative orientation toward imposed attitude. There are two extreme terms concerning imposed attitude. Firstly, least common feature of such imposed attitude is acceptance of other people's attitude because of the force of argument and genuine notification that the caller was not enough known before adjustments. It could be said that these are extremely rare situation in ordinary circumstances, because each entity - a participant in the process of adjustments is preparing in advance to participate in the coordination of attitudes. Collecting information on the contents and characteristics of attitude of other subject in the process, is inevitable in order to guide their own behavior in the process of group decision making.

When the subjects of group decision making have no equal positions in the process of adjustments of attitudes, under normal circumstances, in fact, there is no true adjustments. Power of authority to establish final attitude is available to the competent authority, executive, manager. Their authorization in this regard are:
• to obtain necessary information for the formation of the attitude;
• to express, indicate the expert knowledge about the problem and its solution;
• to develop appropriate activities in the promotion and implementation of competent superior's attitude.

Methods of adjustments of attitudes in this process, in which the head of the organization has a regulating position, can legally be as follows:
• information;
• professional indication;
• some explanation;
• ability to influence the interpretation and during the execution;

7. **CONCLUSION**

Opting for the treatment of this subject, we were aware that we could not include, within this study, all issues of complex process of adjustment, nor we could adequately resolve it through science. So we started from the basic, scientifically validated and generally accepted knowledge. The complexity of this process is reflected in the fact that it is influenced by many factors and environmental conditions as well as the numerous parties involved in it.

We conclude that the methodological problems of adjustments opinions are numerous, but the process of adjustments is a good way to overcome initial differences of opinion with regard to the adoption of some important decisions for the organization. Adoptation of the quality group decision is preceded by true adjustment of attitudes, ie. achievement of mental, psychological, emotional and rational consensus on problems and solutions, ie. ways of solving problems.

Abstract: *Observing job performance in the context of individual behaviour leads scholars to encompass in their measuring conceptions not only activities closely linked to tasks but also those that accompany performance, commonly called contextual. Inspired by endeavours to assess job performance on broader model, there is an attempt to develop and empirically verify scale of work behaviour. Scale was based on 5 theoretically defined indicators divided into two broader categories: behaviours related to the (1) results and to the (2) manners of conduct. Finally, principal component analysis showed structure of eight main components, that explains 64% of total variance. They are labelled according to the related items. Scale distribution does not deviate from normal with Internal consistency of Cronbach`s alpha=.79.*

Keywords*: work behaviour, psychological tests, self-assessment scale, Internal (consistency) reliability, Principal component analysis*

1. INTRODUCTION

Acknowledging the theoretically postulated idea that job performance should not be defined solemnly on achievements of employees, there is an initiative to develop empirically verified scale for assessing the concept of work behaviour that encompasses all activities leading to the final accomplishments.

As a matter of fact, existing paradigm of conceptualizing job performance considers wider framework. It includes all behaviours present in work context leading to the specific achievement and describing the way how work has been performed by employee (Jex & Britt, 2008). It analyses not only the results but also the manner of engaging in activities connected with the work process. It also takes into account different behavioural episodes according to the level of relevancy for organizational goals (Motowidlo, 2003).

We consider the fact that job performance comprises actions that go beyond the frame of employment`s formal demands. Bialek and colleagues (1977) claim that employees spend less than half of working hours engaged in activities given in their job description. Therefore, work appraisals should not be based on homogeneous, one-dimensional constructs. Rather, a more complex method of assessment that incorporate all key processes involved in achieving the work tasks, should be developed and applied.

2. THE CONCEPT OF WORK BEHAVIOUR

Motowidlo (Motowidlo, 2003) believes that there are, at least, two conceptual and practical advantages of observing performance in the context of individual`s behaviour, rather than linked to its results. First, there are some situational factors that modify the effects. Second, there are some psychological processes and principles that govern the course of action during the performance of the tasks. Since performance is expected organizational value of employees` contribution, results are seen as conditions that are changed by it, behaviour is the means of contributing organizational value by changing those conditions (through results).

Different conceptualizations of job performance and work behaviour are present in literature. Some of them are relevant for this study and their common qualities are universality and complexity. General definitions enable to include in concept all those behaviours that are not directly connected with concrete work tasks. Also, they cover these behaviours that contribute, as well as those that peril, the achievement of professional and organizational goals.

Campbell (1990) has categorized work behaviour according to the direction of influence on organizational effectiveness as: (1) productive, that contributes to the organization, and (2) counterproductive behaviours, that impair organizational, and interests of its members. Accordingly, productive work behaviours are related to the work performance, organizational citizenship behaviour and innovation (Jex & Britt, 2008). On the other side, different definitions of counterproductive behaviour could be integrated in one broad definition that explains it as: "*total expected value to the organization of behaviours that are carried out over a*

standard period of time with the intention of hurting other individuals or the organization as a whole and that have negative expected organizational value" (Motowidlo, 2003, 48).

Models of work behaviour commonly distinguish behaviours that are closely related to the work tasks and those that accompany performance. So, Murphy (2004) differentiates work behaviour according to the course of impact and its relation to the core activity, on those: (1) closely associated with the task, (2) considering human relations, but also (3) causing absenteeism, destructive and risk behaviours. Waldman and Spangler (1989), for example, develops integrative model of work behaviour that focuses on: personal characteristics (experience, abilities), effects (feedback information, job security) and environmental factors. These models tend to offer valid predictors. Work behaviour on individual level is seen as a consequence of job complexity (task requirements), knowledge and working skills (based on abilities and experience) and employee`s consciousness (personal characteristic) while operating on job (Jex & Britt, 2008). Studies have confirmed that cognitive ability predicts better technical skills and work effort, whereas some personal features are better predictors of contextual work behaviours as discipline (Pulakos, Broman & Hough, 1988).

Similar, Borman and Motowidlo (1993) emphasis that there are two sorts of work behaviours: (1) those directly linked with task performance and (2) those called contextual. Task performance considers activities that could be found in formal work description and refers to the working role. Contextual behaviours contribute to the organizational effectiveness due to the psychological, social and organizational work context. So, effects of contextual activities are executed via impact on others, increasing personal willingness to engage at work activities and through activities that has impact on organizational resources. These contextual behaviours serve to ease communication, sustain social interaction, reduce tension and disturbing emotional reactions, and are of highly importance to the issue of team work (Jex & Britt, 2008).

Van Scotter and Motowidlo (1996) describe the manner how contextual work activities contribute to the organizational effectiveness by shaping organizational and social environment that facilitate task activities. It is believed that those contributions have general value that is present in every each job and organization, while work activities linked to the task varies from job to job. So, distinction between contextual and activities tightly connected to the task, is of theoretical, as well as of practical significance, due to the fact that they are probably determined by different antecedents. Specific knowledge, skills and abilities are better determinants of someone's behaviour while completing job tasks. On the other hand, dispositional factors are better predictors of contextual work behaviour.

Arvey and Murphy (1998) claims that one should be careful with the idea of developing a new construct of contextual work activities. It defines something that is not in the job description, but if we formalize it as part of the job description, then it loses its specificity. However, researches shown that this theoretical construct has its empirical confirmation (Coleman & Borman, 2000). Factors linked to the job task, as well as, contextual ones, independently, contribute to the work outcomes (Barrick & Mount, 2005). Also, it was found that personal variables are in higher correlation with contextual activities (Pulakos, Broman & Hough, 1988).

Recognition of the existence of contextual work behaviour, not strongly tied with formal work goal, jet essential for organizational performance, requires some methodologically valid approach of measuring its contribution. Here is an endeavour to include in the scales of measuring job performance contextual aspects and to develop an instrument that could be used in variety of settings by mixing different theoretical concepts.

3. MEASURING WORK BEHAVIOUR

3.1. Theoretical and methodological considerations

It is not uncommon to assess job performance based on one narrow specific aspect of work activity based on outcome. However, the idea of perceiving job performance as a "*property of multiple, discrete behaviours that occur over some span of time*" (Motowidlo, 2003, 39) is very popular. As a matter of fact, the whole domain of practice, that envelops processes of defining, measuring, assessing and giving feedback with the objective to improve performance, exists. Defining a work process in behavioural terms enables accessing and measuring it. As *Nelson and Quick* (2006) posted, *measuring the work outcome is an activity of appraising appropriateness and effectiveness of someone`s work activities in specific context.*

Consequently, different conceptions of measuring work behaviour exist. Borman and Motowidlo (1993) are among the first scholars to claim that there are two sorts of work activities both of particular importance for

task achievement: operative and contextual ones. Further, authors distinguish five types of those, so called, contextual activities: (1) readiness to voluntarily complete tasks that are not part of the formal job demands, (2) persistence with additional enthusiasm and effort that is necessary for successfully accomplish working goals, (3) supportative actions toward colleagues and cooperation, (4) obeying organizational rules and procedures even when it does not go in one`s behalf, (5) acceptance, support and protect of organizational goals. Coleman and Borman (2000) observe this concept from the empirical point of view and parse it on 27 items from which they extract 3 factors: (1) interpersonal support, (2) organizational support and (3) consciousness and initiative related to work tasks.

Those behaviours that are not strongly tied with the formal work goal and often called contextual became an inspiration for many researchers. For example, in case that those actions are not part of the formal system of appraisal and compensation, if they are rather optional and result of employee`s initiative, then it is often seen as the phenomenon of Organizational citizenship behaviour (OCB). It is first introduced by Organ in 1977 to define those *behaviours that are not part of the formal job description and that are not prescribed by work role*, but rather "*self-initiative behaviour that contributes organizational effectiveness and benefit and that are not directly and explicitly rewarded*" (Organ, 1988, 4). Also, some distinctions are made between OCB directed toward the colleagues (for example, expressing altruism) and toward the organization (consciousness and loyalty).

Nevertheless, operationally defining work behaviour is not an easy task. The main problems are its inherent multidimensionality and its dependency on different factors. Therefore, it is necessary to clearly define the subject, the criteria and purpose of appraisal and methods for systematically observing targeted subjects and their behaviour on work. Also, potential predictors, conditions facilitating or aggravating work process, and epistemological problems of assessment (accuracy, reliability and validity), should be considered.

Job behaviour is assessed: (1) to determine if a person is suitable for some job (selection), and (2) to determine if a person perform it well (evaluation). Appraisal could be theoretical, informal or highly formalized with significant consequences on compensation, promotion, retribution, dismissing, selection, training, and so on. According to the purpose we chose criteria, methods and sources of assessment. Studies show that there are significant differences in evaluation results in function of measures that are taken as criteria, job that are evaluated, and also of purpose of evaluation (Nelson & Quick, 2006).

Although almost 95% of all appraisals in work context are based on evaluations of superiors, it is believed that when evaluating OCB and similar concepts, more relevant evaluators are subordinates and clients. Also, in theoretically inspired researches, self-appraisal is acceptable (Cardona & Espejo, 2002). The question of accuracy is highly dependent not only on criteria but also on the appraiser. On the other hand, reliability depends on phenomenon`s stability which is not the case. It is believed that past work behaviour is a good predictor of future work behaviour but it relies on the factor of experience. So, the concept of dynamic criteria should be introduced, considering the obvious fact that the work behaviour is changing over time. It is also one of the reasons why correlation of two measures of job performance decreases in function of time and it produces the, so called, problem of work behaviour temporal instability (Sturman, Cheramie & Cashen, 2005).

3.2. Empirical objectives and procedures

The main objective of this paper was to develop an instrument for measuring work behaviour that is strongly rooted in theory and then verify its practical value and metric features through application. This instrument was conceived as five degree Likert type scale with 27 items. Appraisal of work behaviour is left on performers themselves. It is justified with theoretical goals of the study with no practical implications on subjects what so ever.

Inspired by theoretical ideas and methodological experience of other researchers (Slemp, 2013; Kahya, 2007; Coleman & Borman, 2000), we decided to develop an instrument for measuring work behaviour postulated as a wider concept of job performance, based not only on its effects but according to the idea of contextual relevancy. It was expected that it would be able to measure the excellence of work behaviour in totality and in its complexity. The additive nature and capability of instrument to give one single measure is going to be examined by alpha coefficient of internal reliability of the scale.

On the other hand, there is also an assumed structure of operationally defined concept that distinguishes at least two categories representing the work behaviour domains. First one considers activities associated with

main working processes and therefore items should describe the manner of accomplishing professional tasks. Second indicator should refer to the behaviours only indirectly associated with job tasks. In this

context, interaction with colleagues and attitudes toward organization should be taken into account. It is important because it was found that performance is very much dependent on those qualities. The question of how many varieties of contextual activities exist remains open. This postulated structure of work behaviour concept was tested using Factor analysis, precisely, method of Principal components that extracts from original set of items, components that share common variance (Kovačić, 1998).

The procedure of testing the instrument was conducted on 100 employees from five Belgrade IT companies. Respondents are all with similar educational background and they are working on tasks of similar complexity and content. Actually, they are engineers employed on positions of IT managers, system administrators and software developers. Gender structure is slightly biased, with 62% of males and 38% of females.

3.3. Defining scale`s rationales

Work behaviour self-assessment scale is based on previously mentioned Borman and Motowidlo`s concept of work behaviour (1993), as well as on Coleman and Boreman`s empirical verification (2000). Some items are inspired with popular Organ`s concept of citizenship behaviour (Organ, 1988).

Finally, five degree Likert type scale measures work behaviour taking into account: (I) behaviours related to the final job result, although it depends on majority of mentioned factors and as well as on factors we did not include. Here, (2) quality of work is equally important (2 items) as (3) quantity of accomplished tasks (2 items). Further, there are evaluations of episodes of behaviour that are called (II) contextual, explaining the approach to work (manner in which work has been done), implicitly describing employees' attitudes toward job, colleagues and organization. Here, we distinguish between (3) behaviours expressed during the task accomplishment - directly connected with performing working tasks (core activities) (9 items), (4) behaviours referred to the psycho-social (contextual activities) (7 items) and (5) organizational aspects of work (contextual activities) (7 items).

Indicators of work behaviour that are directly attached to the job performance refers to the employee`s persistence with enthusiasm, when additional effort is necessary to accomplish the task, regardless the work conditions. It includes taking an initiative to do whatever is necessary to achieve goals even if they are not a part of the regular duties. There are also tendencies to find extra tasks after fulfilling regular obligations, developing individual knowledge and skills by one's own means and resources. Also, accuracy, reliability and goal oriented qualities should be mentioned. Accordingly, we could mention motivational aspects in this context.

Psycho-social domain of work behaviour encompasses questions of providing help to co-workers by coaching, advising, replacing and doing some part of their tasks, adjusting to their schedules, offering emotional support, as well as cooperation, courtesy, timely informing, expressing consideration, generating motivation, respect and trust. Finally, it could be seen as related to the organizational citizenship behaviour conception, especially that aspect that is directed toward the one concrete employee (colleague), opposite to the indicators of organizational work side. Behaviours associated with organization contribute to the whole organization by representing organization with good image, voluntary organizational promotion, loyalty even in crisis, consciously supporting organizational mission and goals, willingly obeying organizational rules and procedures.

5. TESTING A WORK BEHAVIOUR SELF-ASSESMENT SCALE (WBSAS)

Distribution of scores on scale is normal. One sample Kolmogorov-Smirnov test showed that we could retain null hypothesis due to the fact that there is no statistically significant deviance from normal distribution (AS=99.81; SD=11.47; N=100; p=.43). Internal consistency for 27 items given in the Likert type scale, was Cronbach`s alpha =.79. It represents the measure of homogeneity and internal reliability (low level of obtained measurement error). This measure could represent the level of excellence of someone`s work behaviour as it is seen by him. This measure could be used in studies as an indicator of work behaviour and it could be associated with other psychological variables, as it is the case with one recent study where it is correlated with satisfaction (Kovačević, Čizmić, 2012). Nevertheless, it is possible to approach to the instrument as it is a composite of different dimensions that describe the content of the concept.

Principal component analysis is mostly used for constructive validation, i.e. comprehension of the structure of operationally defined notion. Intercorellations between manifest variables (27 original items of Work behaviour scale) imply lesser number of latent variables that are extracted *with retaining the maximum possible variability at the same time* (Kovačić, 1998, 187). Based on Guttman-Kaisser reliability criteria, eight orthogonal components were extracted (varimax rotation). They give approximation of variation structure of original variables. Total explained variance is slightly above 64 %, which is rather satisfactory. Except first

component that explains about 10% of total variance, components have almost the same amount of explained sample differences. Percentages of possible variances are given in the Table 1.

Table 1: Percentage of explained variance

Component	Percentage (%)
I	10.16
II	8.76
III	8.14
IV	8.12
V	7.81
VI	7.29
VII	7.02
VIII	6.72
Total	64.03

Componential saturation with the scale`s item is given in the Table 2 and it provide us with the information how this components should be comprehended, as well as how real structure of theoretically conceived composition of scale looks like.

First component that explains about 10% of total variance is saturated with items which classification in theoretically defined indicators is rather heterogeneous. Here, we have an item of work quality that overcome the expectations of superiors and work persistence despite the obstacles, but also a high saturation with items provoking enjoyment in informal interactions with colleagues and effort to protect colleagues from personal dissatisfaction, which seems to be mistakenly categorized in organizational aspects. Also, there is a relatively expressed saturation with items that describe a manner of performing task and willingness for professional development. Due to its multiplicity, we named this category **(I) The general work behaviour indicator** (items: 21, 5, 2, 12, 13, 19).

Second component is explained with four items that mainly refer to the relations with colleagues – collegiality and punctuation (meeting deadlines). So, this component is called **(II) Collegiality and devotion** (items: 16, 6, 15, 11) in contrast with third component that is saturated by items with negative connotation of collegiality and psycho-social aspects: distrust and conflicts with colleagues and unwillingness to help. So it is called **(III) Uncooperativeness** (items: 18, 17, 14). Fourth component is strictly defined with organizational aspects of work behaviour, expressing positive attitude toward organization and readiness to protect its image and interest. Thus, it is called **(IV) Organizational loyalty** (items: 24, 25, 26, 27). These items could be incorporated with the organizational aspect of the concept of organizational citizenship behaviour.

Fifth indicator is highly saturated with two items referring to the quality and quantity of work done, so we named it as **(V) Efficiency and effectiveness indicator** (items: 1, 4). It is almost opposite to the component defined by items indicating tendency toward absenteeism that is labelled as **(VI) Skiving indicator** (items: 10, 9, 20). Seventh factor is not consistent. There is an item articulating indifference and lack of information toward the organization and organizational public representation and an item about the quantity of work done that goes beyond average. We called this factor **(VII) Organizational indifference** (items: 22, 3, 23). At the end, eighth component is characterized by willingness to work overtime and undertaking tasks that goes beyond one`s responsibility. So, it is a question of **(VIII) Personal conscientiousness indicator** (items: 8, 7).

Table 2: WBSAS`s components` saturation with items

Items/components	I	II	III	IV	V	VI	VII	VIII
1. I have better results than my colleagues	.01	-.13	.16	.07	**.85**	0	.01	.12
2. Quality of work that I`ve done usually goes beyond superiors `expectations	**-.6**	.05	.25	0	-.42	-.13	.28	.21
3. I usually complete more tasks than average	.08	-.19	.36	-.04	-.45	.01	**.53**	-.08
4. In my business hours I overcome organizational norms	0	.14	-.12	-.11	**.83**	-.19	-.01	.02
5. I try to complete job despite the obstacles	**.63**	.15	-.04	-.09	.03	0	-.06	.11
6. It is important to me to finish job within expected deadline	.2	**.69**	-.01	.09	.1	-.28	-.25	.23
7. I usually avoid to take more tasks than it is required	.02	-.11	.10	-.1	-.06	.1	-.02	**-.69**
8. It is not hard for me to work overtime just to finish work adequately	.18	.08	-.1	.12	.08	.16	-.08	**.73**
9. Sometimes I come late at work	.04	.03	-.03	-.19	-.13	**.69**	-.09	.2
10. Sometimes I can`t continue to work unless I spend more time on break	.08	-.04	.28	-.06	-.05	**.70**	.29	-.15
11. If I finish my job before the end of the work time, I usually find myself some extra tasks	-.11	**.48**	-.06	.15	.32	.34	.14	.16
12. I never stay after work, unless it is explicitly requested by superiors	**-.58**	.15	.09	-.01	0	-.21	.11	-.54
13. I am willing to attend some extra course If I find it useful for my professional development	**.57**	.41	.16	.05	.05	.31	-.05	.08
14. It is not hard for me to help a colleague if I realize that he has too much to do	.29	.35	**-.38**	.17	-.16	.30	-.28	.14
15. I always share information with my colleagues	.24	**.62**	-.29	.09	-.09	-.06	.02	-.13
16. If any of my colleague have some problem I am willing to help	.21	**.72**	-.27	.11	-.03	.11	-.25	.1
17. Experience taught me not to believe my colleagues	.05	-.18	**.75**	-.05	-.13	.14	-.07	-.11
18. I often have conflicts with my colleagues	-.21	-.16	**.76**	-.05	.03	.09	.06	-.14
19. I try to protect colleagues from my bad temper	**.54**	.09	-.29	-.13	-.14	.01	.35	-.26
20. I am not eager to change my plans in order to coordinate with co-workers	-.27	.04	.5	-.24	.17	**-.36**	.32	0
21. I enjoy casual activities that company organize	**.67**	.23	-.07	.08	-.15	-.13	-.05	.22
22. I often overlook some important information in media about the company I work for	-.09	-.10	-.03	.07	.07	.12	**.78**	-.08
23. It seems that my acquaintances know better than me what is happening in my company	-.39	-.21	.1	-.17	-.15	-.32	**.47**	.17
24. When I speak about my organization with people outside the organization, I mention only positive things	-.10	.14	-.1	**.79**	.08	-.04	-.04	.03
25. It bothers me when people criticize what we do in our organization	-.01	.14	.04	**.72**	-.14	.12	.13	.20
26. I do not know what should happen so that I decide to leave the organization	.05	-.19	-.15	**.70**	0	-.38	.01	.10
27. Even when I do not agree with organizational procedures and rules I strive to obey them	.09	.28	-.04	**.51**	.05	-.08	-.33	-.05

6. DISCUSSION AND CONCLUSION

Learnt componential structure of instrument could be improved by analysing the saturations of components with representative items, expecting to, by removing or replacing some items attain higher internal consistency and better explanation of the concept. As a matter of fact, this operational definition of work behaviour could give a good insight to the real content of the notion. It indicates that it is a subject of complex composition that integrate some personal aspects as conscientiousness trait (VIII), attitude toward

organization (IV, VII), motivation and inclination to counterproductive behaviour (VI, III), as well as organizational citizenship like behaviours (II, IV). Also, there is a measure of efficiency and efficacy as the description of finial result (V). There is also a general factor of job performance with the highest impact on work behaviour`s variance and on evaluation (I). This general factor could be seen as if it expresses the manner how the work is done. It explains mainly contextual activities.

Finally, we might see this operationally defined work behaviour concept in the theoretical framework of Borman and Motowidlo (1993) where there is an distinction between task and contextual behaviours, with the conception of Borman and colleagues (2001) who categorized job performance into a personal, organizational support and conscientious initiative. Consciousness is also a predictor of job performance in Barrick an Mount`s (2005) model of performance. We should not forget the Organ`s (1988) concept of organizational citizenship behaviour and Coleman and Boreman`s (2000) methodological endeavours. Afterwards, there is an idea for further researches based on this conception trying to conduct a confirmatory factor analysis using structural equation modelling similar to the existing contemporary attempts where the idea of proactive approach to job is considered (Slemp, Vella-Brodrick, 2013). As a matter of fact, those researchers distinguish three domains of crafting: task, cognitive and relational, with the idea to introduce three factorial concept of job performance and correlate them with relevant variables. Similarly, Kahya (2007) proposed a concept of following dimensions: task performance, interpersonal and organizational citizenship and job dedication, associated with criteria of physical effort, environmental conditions and hazards.

Although scale could be considered applicable according to the fact that its structure relatively coincides with expected theoretical structure of the concept, the question of its final composition remains open. As a matter of fact, validity of the concept is not yet systematically analysed and due to the fact that it considers multiple correlations with different related instruments and real behaviour observations, we left this important metric aspect for future researches. Also, objectivity issue could be examined by correlating the results gained by self-assessment and assessments from other sources. There is also a potential for gender issue to take into consideration and the question of different job characteristics.

Abstract: *Leadership, as a new style of management, implies changes in a number of psychological characteristics of a leader, his knowledge and behavior. This paper discusses the psychological characteristics of leaders as carriers of positive change and new values, as well as the bearers of a complex process of leadership, which refers to a change that starts from the definition of the current and existing, towards the vision of the possible.*

Keywords: *leaders, psychological characteristics, leadership.*

1. INTRODUCTION

Leadership is a process that captures the attention of many years. According to Bennis and Nanus (1985), there are over 350 different definitions of leadership, as a result of hundreds of studies conducted in the twentieth century. Being a complex managerial activity, leadership can be defined as a process of creating positive change and new values (Grubić-Nešić, 2008), as well as a process of influencing others to work in order to achieve the organization's objectives. Leadership is considered to be a shaping process of individual and group behavior, system of designing and directing teamwork, way of human behavior motivation, communication and negotiation system. Being a change agent, a leader alters the company culture. The change agent should recognize disproportion between the organization size and age, new conditions and organizational culture model. The leader should develop his technical expertise through education and experience, and initiate and monitor organizational changes. For example, organizational culture change implies the leader's activities towards destruction of the old culture elements and promotion of new elements that will form the basis for the new behavior.

2. PERSONAL CHARACTERISTICS

The correlation between personal characteristics and leadership marked theoretical approaches to leadership in the early twentieth century by the theory of the Great Man, which evolved into the trait theory of leadership. The term trait is widely used to emphasize human attributes, including ability, motives or behavioral patterns. The trait theory of leadership does not make assumptions about whether leadership traits are inherited or acquired. It simply asserts that leaders' characteristics are different from non-leaders' ones. At the beginning of the twentieth century, psychological study, and later there were numerous discussions on trait approach, including Cowley's (1931), which summarized the views of trait theorists in the leadership approaches. The trait-based approach was challenged in the middle of the last century when, after a thorough examination of literature, a prominent theorist Ralph Stogdill concluded that a person could not become a leader by possessing a combination of traits. Trying to discover the character traits of leaders, the researchers within this theory group (Stogdill, 1948) used the two approaches, namely: comparison of the personality traits of leaders and non-leaders, and of successful leaders and unsuccessful ones.

According to the first approach, studies have shown that, as a social group, leaders are generally smarter, more open and more self-confident than non-leaders. However, there are some divergences because there are people who possess all of these psychological traits, yet never become leaders. Stogdill believed this because the research showed that no traits were universally associated with effective leadership, whereas situational factors were also influential. It has been shown that the traits are of great significance. Six traits on which leaders differ from non-leaders are the following: drive, desire to lead, honesty and integrity, self-confidence, cognitive ability and business knowledge.

Despite a series of good assumptions defining the trait theory of leadership, the research results related to the personal qualities and leadership were inconsistent and often disappointing. The literature review leads to the conclusion that the trait approach has been abandoned among leadership researchers. Zaccaro, Foti, and Kenny (1991) noted that trait explanations of leader emergence were generally regarded with little esteem by leadership theorists.

The primary source of skepticism towards the trait approach is often associated with Stogdill's (1948) influential statements. Although Stogdill detected consistent relationships, he concluded that leadership was not a matter of passive status or mere possession of certain combinations of traits. As Bass (1985) noted, after Stogdill's examination, the analysis of the specific situations was a dominant factor. Indeed, Hughes, Ginnett and Curphy (1996), commented that any trait effect on the leadership behaviour would depend on the situation. Even today, with a renewed interest in various explanations of attitudes and behaviour, there remains pessimism about the relationship between trait variables and leadership. House & Aditya (1997) concluded that there were few traits associated with the effective leadership.

Reviewing the literature on theories of personality traits, Bass (1985) noticed two distinct questions: which traits distinguish leaders from other people and what is the magnitude of those differences? Despite the considerable research on this topic in the past century and previous meta-analytic views, (Lord et al., 1986), surprisingly little consensus has emerged to respond the two questions raised by Bass.

Leaders must gather, merge, and interpret large amounts of information. These requirements are higher today than ever because of rapid technological change. Therefore, it is not surprising that leaders must be intelligent enough to design appropriate strategies, solve problems and make correct decisions. Charisma, creativity, originality and flexibility are qualities with a little less clear evidence of the leadership importance. Effective leaders may be charismatic, but this feature may be important only for political leaders. Effective leaders can be more creative than others as well, but there is no consistent research that proves it. Flexibility and adaptability may be important features in the present turbulent environment. Leaders must be able to make decisions and solve problems quickly, and initiate rapid changes.

Effective leaders are proactive. They make choices and implement actions that lead to change, rather than just react to changes and wait for things to happen, they show a high level of initiative. Instead of sitting and waiting in vain for fate to smile upon them, leaders should challenge the process. Leaders are oriented towards achievements; they are ambitious, energetic, persistent and proactive. They have a relatively strong desire for achievement, which becomes the motive for further engagement because it draws satisfaction from the successful performance of ongoing tasks, excellence standard achievements and development of better ways to get things done. To maintain a high drive for achievement and progress, leaders must have a lot of energy. Achievement motivation is caused by a range of mutually conditioned factors, like personal characteristics (attitudes, needs, interests, aspirations, abilities, personality traits, internal motives), but also the job type and characteristics (type of work, degree of self-control, responsibility, autonomy, complexity of work, creativity). Working long, intense work weeks for years requires an individual to have a psychological, mental and emotional vitality. Leaders, as opposed to non-leaders, have much more strength and endurance, and generally are active, vital and constantly in motion. Leaders possessing willpower and persistence are better at overcoming obstacles than the others.

Research shows that leaders have a strong desire to lead. Leadership motivation includes a desire to influence others and is often equated with the need for power. People with high leadership motivation think a lot about influencing other people, winning arguments and being a greater authority. They prefer a leadership rather than a subordinate role. Willingness to take responsibility, which coincides with leadership motivation, is another trait that can be seen in leaders. The psychologist Jon Bentz (in Kirkpatrik & Locke,1991) describes successful leaders as those who have a powerful competitive drive for the position, authority, and need to be recognized as people of influence. Effective leaders empower others to increase their own power. They do not see power as something that is competed for but rather as something that can be created and distributed to followers without diminishing their own power. Successful leaders should be ready to implement power over subordinates, tell them what to do and appropriately use positive and negative sanctions.

Leader with a personal power motive seeks power as a target in itself. These individuals have little self-control, are often impulsive and focused on collecting evidence of personal prestige. Gaining power only for the purpose of dominating others may be based on self-doubt.

A leader of a socialized power motive uses power as a means to achieve desired goals or a vision. Its use is expressed as the ability to develop networks and coalitions, gain cooperation with others and resolve conflicts in a constructive way.

Individuals with a socialized power motive are more mature than those with a personalized power motive. They exercise power more for the benefit of the whole organization and are less likely to use it for manipulation. These leaders are also less defensive, more willing to take advice from the experts and have a

longer-range view. They use their power to build up the organizations and make them successful. The socialized power motive takes into account the followers' needs and results in empowered, independent followers.

Self-confidence plays an important role in decision-making and gaining the trust of others. Obviously, if the leader is not sure of what decision to make, or expresses a high degree of doubt, then his followers are less likely to trust him and be committed to the vision. Not only matters the leader's self-confidence, but its perception in others. Often, leaders engage in impression management to maximize their image of competence; by projecting self-confidence they enhance the confidence of the followers. Self-confident leaders are more assertive and determined, which gains the confidence of others in decision-making. This is essential for the effective decision implementation. Even when decisions turn out to be incorrect, the self-confident leader admits the mistake and uses it as an opportunity to learn, often by building confidence in the process.

In order affect employee motivation, the leader must be intrinsically motivated, and know how to motivate others by rewards and punishments, based on a good distribution system of earnings, applied consistently and relied on the results of performance appraisals.

3.BIG FIVE AND LEADERSHIP

Overall, the results of meta-analysis show that Extraversion, Conscientiousness, Openness, Agreeableness and Neuroticism are useful traits or characteristics in relation to leadership. Collectively, the results support the importance of the five-factor model in the study of leadership. Previous studies do not withstand the test of time, but there is an idea of not only which traits are relevant, but also why that is so. Is Neuroticism negatively related to leadership, since the neurotic individuals are less likely to be found in leadership positions, because they are less inspired, or because they have lower expectations of themselves or others? Similarly, Extroverts may be related to leadership because they are more willing to talk, while talk and garrulity are strictly related to leadership emergence. Alternatively, it may be that others implicitly expect leaders to be extraverted. Implicit views of leaders expect them to be sociable (outgoing) and assertive (forceful, aggressive, aspiring). Extraverts could be better leaders due to their expressive nature or the contagion of their positive emotionality. The authors used the five-factor model as an organizing framework and meta-analyzed 222 correlations from 73 samples. Overall, the correlations with leadership were Neuroticism, Extraversion, and Openness to Experience, Agreeableness, and Conscientiousness. Results indicated that the relations of Neuroticism, Extraversion, Openness to Experience, and Conscientiousness with leadership generalized in that more than 90% of the individual correlations were greater than 0. Extraversion was the most consistent correlate of leadership across study settings and leadership criteria: leader emergence and leadership effectiveness (Judge, Bono, Ilies, Gerhardt, 2002). Open individuals may be better leaders because they are more creative and are divergent thinkers, because they are more willing to take risks, while their tendencies for esoteric thinking and fantasy (McCrae, 1996) make them more likely to be visionary leaders. Agreeableness may be weakly correlated with leadership because agreeable individuals tend to be passive and compliant (Graziano & Eisenberg, 1997) but can also be helpful. Conscientiousness is correlated to leadership because conscientious individuals have integrity and engender trust so they excel at process aspects of leadership, such as setting goals (Hogan et al., 1994).

Communication of a leader is a balanced, harmonized communication, first with itself, with its own emotions, and then with other people. Most psychological theories agree that it is impossible to build adequate communication with others, if own dilemmas are not, before that, recognized, clarified and established. And, on the other hand, it is important to avoid reluctance to admit those dilemmas in front of others and constantly look for solutions which can be achieved. The high level of successful communication with oneself means accepting yourself, not worshiping oneself, but realistically accept oneself and it implies a willingness to work on oneself, self-confidence, self-esteem, self-control...

Personal integrity is a consolidated functional activity of a number of traits, skills, and abilities that make up a harmonized whole. The integrity is manifested in the behavior in which the words do not differ substantially from the work and thoughts of conduct. The value system that people of integrity have is stable and based on sincere beliefs that were adopted without calculated needs. Work on oneselves integrity means working to unify different image of oneself, such as the ones that our family, friends, acquaintances or enemies have.

4.CONCLUSION

In the process of leadership, the relationship between leaders and employees is established through work and action, i.e. through action and results, and not through command and control or hierarchical dominance and subordination, which are related to the traditional leadership model. In modern societies with advanced technical and technological bases, organizational structures and cultures permeated by psycho-sociological aspects, the phenomenon of leadership is very important. Most of leadership theories unreservedly accept the attitude that performance and satisfaction of followers are the outcomes of the leader's actions. The important feature of attributive approach is to warn us of the possibility that leadership is only an illusion, or, perhaps, a mere belief. Companies need leaders who do not try to anticipate the future so much as create it. New organizations require different management and a new employee. Perspectives on leadership development is on learning leadership and developing of employee.

Abstract: *In recent years, online games are becoming increasingly popular as a way of entertainment. Many of these games offer the option of purchasing items within the game with real-life money. Since they gather a large number of players, these games are a substantial source of profit. The goal of the present study is examining the factors related to the players' choice to purchase virtual items or not. The factors studied were motivation for playing online games and loyalty level. The sample consisted of 1000 online game players. Chi-square analysis and ANOVA were conducted on the data. Significant differences were found between the players who buy virtual items and those who do not regarding the motivation type and loyalty level. The players who are primarily motivated by leisure are significantly less likely to buy virtual items. Furthermore, it was shown that the players who purchase these items are significantly more loyal than those who do not. We discussed the results in the context of previous findings and offered possible directions for further study.*

Keywords*: online games, virtual items, motivation, loyalty*

1. INTRODUCTION

The Internet has become a part of everyday life and with time it is becoming a necessity in the life of every individual. The Internet is used for a wide variety of purposes: providing information, communication, socialising, business transactions, education and entertainment. It facilitates the interaction between geographically distant individuals, which has contributed to the creation of enormous interactive networks which do not represent only sets of users but settings within which various social activities occur in the virtual environment. An increasing number of online video games have emerged especially on popular social networks which, apart from impressive graphical and technical features, offer the possibility of playing the game in the real time accompanied by the interaction with other players. Internet users visit sites with online games more frequently and stay there longer than on any other web pages (Beak et al., 2004). The data suggest that only in the USA and Great Britain, 120 million people play an online game at least once a week, of which 81 million people play them daily and that the trend increases annually (ISG, 2011). The access to the games is significantly facilitated and encouraged by the development of mobile technologies and the availability of telephones which have the capacity to support the use of wide variety of web applications.

Online games in the most general sense represent a virtual environment with an Internet connection and a large number of players. In other words, they are computer games in which the interactions of Internet users are processed by an Internet connection (Ho & Wu, 2012). In the context of social networks such as Facebook, online games mostly represent simple applications easy to use and understand which lay emphasis on mutual cooperation and communication between players and are frequently called social games (Chang & Chin, 2011). Since online game market steadily increases, its economic potential has become obvious. Until recently, online games used to generate income only by advertisements on their pages. However, due to their growing popularity a possibility of direct profit has arisen (Beak et al., 2004). Certain games sell online accounts and take prepayment for participating on monthly or multi-monthly bases (Oh & Ryu, 2007). However, another mode of profit is becoming more frequent. It is made on the games which are essentially free and which are found on social networks. Users do not have any obligation to pay for participation, yet, within the game, they are offered a possibility to purchase various virtual items with real money. Virtual items refer to various types of objects, such as avatars, decorative articles (furniture, clothes, backgrounds, music) or virtual currencies which exist within the game (Lehdonvirta, 2009). Their purpose is the enhancement of the user's profile as well as the improvement of the performance during the game. They usually cost between several cents and several dollars (Kim et al., 2009). This way of charging has proven to be more profitable, due to the fact that it is not obligatory and that free games attract a greater number of users who, on the other hand, are more inclined to spend small amounts of money to buy a certain item within the game if it occurs periodically. Furthermore, it has been indicated that more frequent payments of small amounts of money are related to the extended game usage with respect to paying a long-term

subscription which implies spending a large amount of money at once (Nojima, 2007). This way the game attracts a great number of users and establishes a community with a great total paying capacity. Accordingly, a higher profit is earned and the game gains popularity. Numerous Internet companies earn more than 100 million per year in this way (Kim et al., 2009; Oh & Ryu, 2007).

The most frequently purchased item is virtual money i.e. currency which is valid within the game and can be used to buy virtual items (Oh & Ryu, 2007). Approximately 50% of users of Facebook, the most popular social network, play social games, of which 2-6% purchase virtual items. Although this percentage is low in relation to the total number of players, the profits of Internet companies are high. Social games industry earned 3, 65 billion dollars in 2010 of which 60% originated from the purchase of virtual items (Crowdpark, 2012). The number of people who buy virtual items has increased in comparison to the period of few years ago and there are indications that the increase will continue in future (ISG, 2011).

It is clear that virtual item sales in games have a great financial significance, and most researches which dealt with this topic were focused on marketing and economic aspects (Guo & Barnes, 2009). Customer preferences were examined, most frequently regarding the attributes of virtual items aiming to improve the design, develop the game which will be enticing and position it well in relation to its competitors. So far, a small number of researches have dealt with the purchase of virtual items from a psychological perspective and there is still a lack of explanatory models and adequate measurement instruments in this field (Guo & Barnes, 2009; Lehdonvirta, 2009). There are few data about the psychological factors which underlie the purchase of virtual items with real money. Therefore, the aim of this research is to examine psychological factors related to this phenomenon.

Most frequent reasons for playing social games are challenge and leisure. People play games because the process itself is attractive and demands engagement (Prensky, 2002). The games are designed in a way that they tempt users do be engaged in them actively and continuously, provide the feeling of engagement and improvement, ensure a quick and constant feedback, and set goals which are challenging enough to keep the interest but not too difficult to detract users. All of that occurs in a friendly but competitive social environment where users can share their success with friends, call attention to their accomplishment on the leaderboards and thus improve their social status in the virtual community. Considering the social aspect of these games, efficacy at problem solving serves as a criterion for comparison with other players and it is related to the individual's self-esteem. Individuals will participate in the game as long as they perceive that they are able to overcome the obstacles and achieve goals which the game sets. Players will tend to maximise their achievement in the game in relation to others (Voreder et al., 2003).

Different researchers suggested categorisations of motives which initiate users into playing online games, based on empirical research. Wood and associates (Wood et al., 2004) distinguish pleasure and relaxation, challenge and excitement as well as social contacts and acquaintance as the most frequent reasons for playing online games. Yee divides motives for playing into three basic categories: achievement, social motive and escapism (Yee, 2006a, 2006b). A similar typology of motives is offered by Wu and associates, who distinguish overcoming the challenge, making friends, killing time and leisure (Wu et al., 2008). One of the latest and most comprehensive classifications was suggested by Li who distinguishes seven motivation categories for playing games: applying knowledge and skills, identification with the theme of the game, fantasising, competition, leisure, social interaction and escape from reality (Li, 2012).

Perceiving a certain product as useful, valuable in emotional or social sense is assumed to have a great influence on users' decision to purchase some virtual item. In other words, key factors on which the purchase decision depends are the product functionality in the sense of practicality, the emotional reaction which the product enhances and an estimate that it will contribute to the status in the virtual social group (Kim et al., 2009). Certain authors distinguish decorative and functional items: decorative mostly stay in permanent possession and have only aesthetic value, while functional items serve for progression in the game and easier goal accomplishment but they are consumable, which means that the players have to repurchase them (Lehdonvirta, 2009). It is established that the value of a certain item will be evaluated differently depending on the motivation which initiates the individual into participating in the game (Kim et al., 2009). For example, the need for achievement and exploration is positively related to the perceived functional value of the virtual item, which leads to the purchase (Li, 2012). Players mostly want to perform the tasks and goals in the game and they are prepared to pay to accomplish that (Crowdpark, 2012). It is established that the players are actuated to purchase virtual items by advancement in the hierarchy within the game and positioning in relation to playmates, exploration of new content and and adjusting the game to one's own preferences (Kim et al., 2009). Similar findings were also obtained in the study of a popular game – World of Warcraft - which indicate that the main virtual items purchase motivators are customisation and accomplishment (Guo & Barnes, 2012). In one of rare comprehensive studies of a large number of online games, it was established that there are certain differences between the users who purchase virtual items

and those who do not in two of four examined game motivation categories. In fact, those who purchase virtual items more often play in need of competition while those who do not purchase them more often play for leisure. It was revealed that there is no difference between users who play for mental exercise or social interaction (ISG, 2011).

Even though they are a significant factor, it was established that mere examination of preferences and motivation cannot entirely explain the variations in recurring purchases by the same user. From a business standpoint, the literature and research recognise the significance of user loyalty for generating profit and positioning in relation to competition (Cheng & Chou, 2011). A survey of different website users confirmed that the largest number of Internet users exhibit a tendency towards loyalty to certain web technologies. Loyalty in the context of business on the Internet is defined as a user's preference for a certain web technology and its continuous use. It was established that loyalty is positively related to the probability of repeated purchase (Anderson & Srinivasan, 2003). Since users can choose between various competitive offers which exist on the Internet and can satisfy their needs, loyalty represents a significant factor in generating profit (Cheng & Chou, 2011; Reichhfeld & Schefter, 2000). It was revealed that the active and constant users of a certain game purchase virtual items with real money more often than the ones who are not (Guo & Barnes, 2009; ISG, 2011). On the other hand, there are findings that players who have the need for novelty and who are not committed to a particular game are not inclined to participate in the same online games for long and spend money on them (Nojima, 2007).

This study deals with examining the association of virtual item purchase and motivation and loyalty of the players. We attempted to consolidate the findings of previous researches as well as a psychological and IT approach in the perception of this phenomenon. Knowing relevant psychological factors and their effect would facilitate developing online games which would be enticing to users and thereby more profitable. Moreover, regarding the lack of research on this topic in our region, this study has the potential to record all feasible peculiarities of the Serbian sample concerning this phenomenon. Relying on the existent findings, we assumed that there would be significant differences in the type of primary motivation for playing between players who purchase virtual items with real-life money and those who do not. At the same time, we expected that the participants who purchase virtual items would more often be motivated by competition and winning than the ones who do not and that the ones who do not purchase them would more often be motivated by relaxation and entertainment. In view of the lack of clearly formulated theoretical models in this field as well as adequate empirical findings, there were no presupposed specific connections between purchase and other types of motivation for playing. Furthermore, we assumed that there would be significant differences in the level of loyalty to online games between the players who purchase virtual items and those who do not. Specifically, we expected that the participants who buy virtual items would be significantly more loyal.

2. METHOD

The research sample consisted of 1000 participants (N= 1000), users of online games. The games involved were two popular online games. By type, they are knowledge quizzes and also include elements of social interaction. After accessing the game, a pop-up window appeared inviting the players to participate in the research. The research was in the form of a short questionnaire with multiple choice closed-ended questions. As recompense for research participation, the participants received a certain amount of virtual currency which is used in the two games. In order to control giving random answers, the participants who completed the questionnaire faster than two seconds per question on average were excluded from the analysis.

Given that there are numerous various types of motivation for playing in the literature, in order to establish which types of motivation are the most prevalent among the users of this type of games, a pilot research was conducted on a random sample of 50 users. The participants were asked open-ended questions which demanded that they specify the main reasons why they play online quizzes. By content analysis, the answers were classified into four categories which could comprise the largest number of answers. Those categories are: 1) competition; 2) intellectual motive; 3) social motive; and 4) leisure. Competition includes motives which are related to pleasure in competing with other people, achieving victory and accomplishing a

high ranking with regard to other players. Intellectual motive is related to desire for knowledge acquisition and improvement as well as for practising cognitive functions such as attention, memory, deduction and similar. Social motive comprises desire for meeting new people and socialising with acquaintances and friends by playing the games. Leisure relates to the desire for boredom elimination, relaxation and entertainment. After we described these four types of motivation, we asked the participants to select among them their primary motive for playing the games.

Subsequently, the participants were asked to complete a short questionnaire specially designed for the purpose of this research which examined their level of loyalty to the game. The questionnaire consisted of Likert items where the total score was taken as a loyalty measure.
Purchase was operationalised as a dichotomous variable. Information about whether each of the participants uses real-life money for virtual item purchase within the game is automatically registered from the administrators' database of the games included in the research. Given that, according to different researches (Crowdpark, 2012; ISG, 2011), players who purchase represent a very small part of the total population of players, the sample is composed of an equal number of players who purchase and players who do not in order to facilitate comparison of these two groups.

Chi-square analysis and analysis of variance were conducted on the data in the statistical program SPSS for Windows.

3. RESULTS

Contingency table analysis for the purchase and motivation variables confirmed that there are significant differences in primary motivation for playing between users who purchase virtual items with real-life money and those who do not, χ^2 (3) = 9.85, p< .05. Table 1 shows frequencies of motivation types indicated by the users who purchase and the ones who do not purchase and Table 2 shows values of χ^2-statistics for each type of motivation in relation to categories of purchase variable.

Table 1: Frequencies of motivation types among players who purchase and who do not purchase

	Primary motivation					
		Competition	Social motive	Intellectual motive	Leisure	Total
Purchase	Do	163	7	201	129	500
	Do not	146	9	172	173	500
	Total	309	16	373	302	1000

Table 2: Values of χ^2-statistics, degrees of freedom and p-values for each type of motivation in relation to purchase

Motivation	χ^2	df	p
Competition	0.94	1	ns
Social motive	0.25	1	ns
Intellectual motive	2.26	1	ns
Leisure	6,41	1	< .01

When examining Table 2, one can see that significant differences between the players who purchase and the ones who do not purchase exist only when considering the leisure motive. Namely, there are significantly more participants who do not pay for virtual items with real-life money among the ones who indicated leisure as their primary motive for playing.

In order to test the hypothesis that there are differences in loyalty between users who purchase virtual items and the ones who do not, analysis of variance was conducted on the data (ANOVA). By Levene's test, it was established that the homogeneity of variance condition of the dependant variable (loyalty) was satisfied, W (1, 998) = 0.45, p>0.05. The analysis of variance results indicate that there is a significant association of the examined variables, F (1, 998) = 14.68, p< .001. The participants who purchase virtual items achieved a significantly higher score on the loyalty scale than the ones who do not purchase them.

4. DISCUSSION AND CONCLUSION

The obtained results support the hypothesis that the users who do not purchase virtual items are more often primarily motivated by leisure than the users who purchase them. This finding, as well as the absence of significant differences when the intellectual and social motives are considered, is consistent with the results of the ISG research (2011). Moreover, the results support the hypothesis that the players who pay are more loyal. As opposed to that, the results did not confirm the expectation of significantly more frequent presence of competition as a primary motive among players who purchase virtual items.

One of the possible reasons for the absence of the expected outcome is the type of the games included in the research. Both games are knowledge quizzes and competitive element is inevitably present during every playing. The players aim to give the correct answer or accomplish a task before the other player who is playing simultaneously. At the end of each segment, the achieved results are compared, and at the end of the whole game one of the players is declared the winner. Since the games of this format are almost impossible to play without an element of competition, it is likely that they attract competitive users more than

the other games in which this element is possible to avoid. In that case, variations in decision to purchase virtual items couldn't be explained by competitiveness but other factors, such as, for example, loyalty or users' financial capability.
The finding that users who pay are more loyal is consistent with the results of previous research (Guo & Barnes, 2009; ISG, 2011; Reichhfeld & Schefter, 2000). Prensky postulates the existence of a two-way association between these variables: the players who invest money in the game will not tend to give up their investment. Continuing the game, the players will be able to ascertain the progress after a certain time and gain the impression that the invested money has paid off, which will encourage them to keep spending and investing in the game (Prensky, 2002).

Further research which would deal with this topic should consider the type of the game when examining the association of motivation and paying. Previous research established the association of paying with competitive and leisure motive (ISG, 2011). While every game can represent leisure to people who play it, the same does not apply to competition. In some games competition is inevitable (quizzes, card games and other games in which there are an unambiguous winner and loser), in some it represents a matter of choice (the games in which interaction with other players is optional) while in others this element is minimal or non-existent (real life simulation games in which there is not an outcome to achieve, but the emphasis is on expressing individuality and creativity). It would be interesting to examine which variables best explain the variations in paying in games which are at the ending points of this continuum, i.e. in cases when the variability of the competitive motive is reduced to minimum (almost inevitable in one and almost non-existent in the other case). Furthermore, in future research, more salient information could be obtained if the participants are not asked to decide on their primary motive but allowed to estimate the degree of presence of different types of motives. In that way, we would have an insight into possible influences of different combinations of motives on virtual item purchase.

Moreover, we could obtain additional insights by checking whether there is an association between loyalty and a certain type of motivation for playing, i.e. whether the players primarily led by one type of motives are more loyal than the players led by different motives. This finding can have implications for further development of online game industry. Since users' loyalty is one of the key factors in generating profit (Cheng & Chou, 2011; Reichhfeld & Schefter, 2000), it is expected that the developers of online games will attempt to make their products attractive for a large number of people. Possible revelation of the association of loyalty and motivation type could influence the design of future games and lay emphasis on the elements within the game which can satisfy a certain type of motivation.

Abstract: *Complex organizational changes involve different approaches and different ways of thinking and behaving of employees, such as greater responsibility for personal career and greater importance given to human capital in work processes. The key to successful business is not found only in work and creative potential of employees, but in their personal engagement as well, which is related to the process of career development. As a highly complex and dynamic concept which is based on needs, aspirations and preferences of employees, the development of career differs with respect to personal characteristics of employees and their positions within the organization. It is of utmost importance to be aware of employees' personal characteristics (such as the locus of control, work styles, degree of self-esteem), importance of organization to the employee, development goals of the organization, and social environment. Successful development of employees is possible with the analysis of development plans and understanding of employees' needs. To attract, retain and motivate employees, as well as to enable their personal development, is a challenge for an organization which growth depends on the characteristics of people who make that organization.*
In this paper, main characteristics of the process of development of employees' careers is studied from the aspect of personal indicators in order to identify which personal factors set the direction of career development which contributes to more successful personal and professional development.

Keywords*: Personality, personal characteristics, career development, employees, organization*

1. INTRODUCTION

One of the most important characteristics of modern business is that without competent people neither society nor organization can be healthy, so the development of employees is a permanent process and investment in the future of many organizations.

In an era of knowledge where strong international competition prevails, Blustein (2006) noticed that the career development which aims at acquiring new knowledge and skills becomes increasingly important as a link between an individual and organization; it becomes the determining degree to which employees are attached to an organization. In order to be successful in the achievement of goals and development, the organization should be focused more on individual goals and interests of its employees, and on arranging, planning and achieving growth by developing its employees.

Today, career is a complex concept that modern management is facing. The need to follow worldwide trends because of the globalization poses challenge to employees to care for their education, creativity, and productivity with the aim of positioning themselves in the organization.

2. CAREER DEVELOPMENT

According to Arturu and Rouseu (1996), the traditional career considered only from the aspect of hierarchical advancement is fading and disappearing because contemporary organizations tend to be more flexible in modern business, more dynamic, and economically efficient in an uncertain and unpredictable future. Casto (2000) claims that career should be viewed as permanent development of personal competences in order to secure employment opportunities and remain satisfied with the job, as well as to be prepared for making decisions and taking responsibility during one's career.

Arnold (2001) sees employees as the capital which must be constantly encouraged, directed, and provided with opportunities for growth; he points out that training given at work place is one of the most popular forms of management development. Bacanli (2006) claims that the organizations which learn and overcome the obstacles in the process of learning create conditions for development and engagement of all individuals.

Development of career in modern business is a big challenge for individuals because there are no standards but just a few regulations that can be regarded as guidelines. Individuals primarily take responsibility for

career development, education and training. This leads to interest in education and professional development of employees because it is necessary to constantly encourage employees by creating individual feeling of self-actualization and actual purpose of participation in business collaboration.

The focus is given to employees who create portfolios with their achievements, competences, self-evaluation and building of social network.

2.1. Professional development of employees

Professional development refers to advancement in the business life of an individual. A continuous professional development means work experience which is logically organized in time and planned in such a way to broaden the knowledge and improve the skills of employees (Hicks-Clarke & Iles, 2000). Professional development is a process which needs active participation and investment of the employee as well as the organization that this employee works for. On the other hand, the purpose of this process is professional acknowledgment and employee's feeling of accomplishment, but also improvement of organization and increased employee's contribution to the achievement of organizational goals by means of professional development (career development, education in company, professional orientation, and system of advancement).

The need for professional development can be recognized in the fact that person always seeks for improvement and strives for changes which will have positive effect on that person's professional development. If the key factors for professional development exist, then the organization generates motivation, pleasure, efficiency and equal development. In order to ensure successful process of professional development there should be fair expert choice of candidates which involves proposition of candidates, evaluation of their characteristics, decision making and monitoring of career development.

2.2. Career planning from the aspect of an individual

The importance of career lies in the fact that career is the strongest and most obvious link which joins individual and organizational goals and interests. Career planning is a process which enables an individual to identify and implement the steps and actions necessary for achievement of career goals. Career development involves career planning, development of possible career paths, activities related to training and development, promotion, promotion criteria, assessment, consulting and encouragement of mentoring which is designed based on personal characteristics of employees. By planning the career, employee takes responsibility for his/her own development by identifying and taking necessary steps and actions for achievement of professional goals. By encouraging the planning and development of career, the organization shows that it cares about its employees, which is a strong motivation for their development.

Career planning helps individuals to understand their personal goals and aspirations and their own identity, to make decisions based on information, to be committed to what they do and to control the changes in their career, both planned and unplanned changes. Thus, it is important to consider a synthesis of biological (hereditary) and social (acquired) characteristics of a person because they build physical, mental, sensor, psychomotor and other biological properties, knowledge, skills, habits and social characteristics (Palmer,2004).

Career has both subjective and objective dimension. Subjective dimension is related to attitudes, interests and motives of individuals, and objective dimension is related to the conditions provided by organization, workplace structure and advancement criteria.

3. INFLUENCE OF PERSONAL FACTORS ON PROFESSIONAL DEVELOPMENT OF EMPLOYEES

Every organization, regardless of the nature of its business, is composed of members of that organization – individuals. The employee is expected to take an active role in the organization in order to control his/her career and its development successfully. It is the individual who should draw the organization's attention to his/her needs and aspirations, and who should be active in looking for the ways to fulfill them. Career development of an individual is not necessarily connected to a single organization. According to Spencer and Harris-Bowlsbey (2014), every employee in an organization is the instrument that organization uses for achievement of its goals. Likewise, employees should see the organization as their instrument to achieve the goals related to their professional development and advancement. The best way to achieve mutual goal is when personal professional goals are similar to those of the organization. In order to analyze the organizational processes and functioning of an organization, the behavior of individuals who work in that

organization should be analyzed first. By observing the behavior of each individual, certain characteristics that this person exhibits in community can be seen. People behave differently inside an organization, and those differences are mainly due to differences in their personalities. That is why it is of utmost importance for the management to define and be aware of the characters of all employees. Apart from understanding the behavior of someone, it is also important for the management to accept the fact that everyone is different, and to match the job with person as much as it is possible. Also, it is necessary to recognize person's characteristics and dimensions which will influence the development of employees and use the potential of other employees. When planning career development, the basis for that plan is person's characteristics. In the beginning, both employee and organization need to familiarize themselves with the strengths and weaknesses so that they could adjust the development to those strengths and weaknesses. Behavior and profile of an organization are the result of relation between personalities and behavior of its members.

3.1. Personality and personal characteristics

Personality is commonly defined as a unique combination of characteristics of a person, seen from this person's behavior and communication with other people. The most important fact is that it is a combination of characteristics which single this person out from other people in his/her surrounding. Also, another important fact is that the person's character is formed and expressed during the interaction with other people. Those interactions in someone's life create this person's character but they also serve us for evaluation of someone's personal characteristics. Judge, Higgins, Thoresen, Barick (1999) noticed two basic factors of personality are inheritance and environment where person is maturing, as well as the situations this person has experienced.

- Inheritance includes factors which influence personality by birth. Those are physical qualities, gender, temper, energy level, biorhythm, etc. Genetic inheritance is an important factor in this group.
- Environment includes several factors which influence the personality. This group includes those influences that occur during one person's growth and development. Those are family (as the most important factor shaping one's personality), belonging to certain social group (social class, profession), and belonging to a nation and national culture.
- Situation is not as important as inheritance and environment but sometimes it can be of huge importance to person's development. The influence of a situation is more of a correction type because it can rarely create a characteristic if a person does not already have it, but it can emphasize some hidden characteristic that this person has not been aware of.

Most personality research has been focused on discovering characteristics and personality traits. Personality traits are permanent characteristics which describe the behavior of a person. The Big Five Model gives the most significant classification of personality traits and characteristics according to John & Srivastava (1999). After a long research of several thousands of characteristics, five basic dimensions were selected based on which all characters can be distinguished.

1. Extrovert-introvert (sociality or openness) - degree to which person is sociable and satisfied with relationship with other people. Extrovert people are sociable and open, communicative and friendly towards other people. Introvert persons, are unsociable and closed people, and they are less willing to take part in social interactions.

2. Amiability – this dimension refers to: cooperativeness, warmness and trust, but on the other hand it is also marked with antagonism, coldness, doubt. This trait shows tendency of a person to be agreeable and keep good relationship with others.

3. Consciousness- this dimension shows reliability and trust, but on the other hand it also shows disloyalty and distrust. This trait describes a person who is careful, scrupulous and persistent.

4. Neuroticism – this dimension, on the one hand, shows emotional stability, safety and calmness, and on the other hand it shows nervousness, uncertainty, depression. People who are adjusted or emotionally stable are calm, stable, relaxed and feel safe.

5. Openness- this dimension of personality shows creativity, originality, curiosity, openness to new experiences, imagination, and un-conventionalism and risk proneness. At the other end of this dimension, there is closeness, conventional person, conservatism, lack of imagination, aversion towards risk.

One of the well known classifications of personality types is the one defined by Judge et al.,(1999). They observed dimensions of personalities in the context of their development. He determined that every person's

personality was developed from immature to mature based on certain dimensions. Schermerhorn, Hunt, and Osborn (2005) determined that this development occurred in cycles and not continuously, and he set the hypothesis about those cycles: up to the age of 18, from the age of 18 to 30, from 30 to 45, and from 45 onwards. Dimensions of mature and immature personality can be seen in the following table:

Table 1: Dimensions of mature personality (Schermerhorn, Hunt, Osborn 2005)

Mature personality	Immature personality
Active	Passive
Independent	Dependent
Different modes of conduct	Single mode of conduct
Deeper interests	Minor interests
Long-term perspective	Short-term perspective
Executive position	Subordinate position
Self awareness and control	Lack of self awareness and control

3.2. Matching of personality and job

According to the description and dimensions of personality, it can be concluded that people are different and that individuals cannot be categorized as being better or worse for some jobs (Judge & Bono, 2001). The fact is that all people are different. However, we cannot say that employees' characteristics are not important for an organization. According to Holland's theory, although all characteristics of people are legitimate, they have to be adjusted to the work that employees do. Although all personality traits are equal they are not equally good for all positions. Matching of personality traits to job requirements increases both productivity and job satisfaction. In case that a manager forces an employee to do the job which requires personality that is totally opposite of the personality of that employee, the employee will be dissatisfied and frustrated regardless of the fact that this type of job can be attractive to someone else. According to Holland's theory, there are 6 main personalities which have corresponding jobs.

Realistic – prefers to work in the field of civil engineering, agriculture, architecture; *Investigative* – prefers the following jobs: biologist, chemist, dentist, vet, programmer; *Artistic* – prefers the jobs of: artist, musician, poet, interior designer, writer; *Social* – prefers jobs of: social worker, counselor, police officer; *Conventional* – prefers jobs of: teller, clerk, typist, data input; *Enterprising* – prefers jobs: lawyer, business director, politician, TV producer.

3.3. Career and working styles

1. Perfection – people who set goal to work perfectly and to be perfect must not make mistakes and in that way they renounce their right to be average. This person strives for perfection in one aspect of life which is important for him/her or in more aspects. The person devotes a lot of energy to these aspects, which is why it is difficult for him/her to perform other activities. Perfection can be comparative, which means that an individual wants to be better than the others, or non-comparative, when an individual does not compare himself/herself with the others but tends to be the best at what he/she does. Perfectionists are not productive because they waste considerable time irrationally on achieving good results for something that is not necessary. These people can suffer from obsessive disorder or depressive disorder. They need help in order to be able to develop the personality which they can use to distinguish between optimum and maximum.

2. Strong personality – these people tend to show their strengths and not weaknesses, they are proud of their persistence, strength and resolution. This type of behavior is common in our country where life has been cruel to people and they are exposed to danger of not being able to ever lead better lives. These people prepare themselves for cruel life and in that way they renounce the right to enjoy. They often develop antisocial personalities; they have paranoid tendencies and suffer from psychosomatic disorders.

3. Arduous work – these people work constantly regardless of the fact whether their work is visible or not to other people and in that way they pose limitations on going on holidays and having fun. People often choose this type of work when they want to avoid pessimistic mood, loneliness and boredom. These people are afraid of being rejected and do not allow themselves to have rest. They often suffer from chronic fatigue, heart attack due to being extremely tired, spine problems, depression (Katic et al.,2013).

4. Pleasing– these people stick to the principle that they should not oppose the others and have to fulfill their wishes. There are two extremities: according to the first extremity, the imperative is to please the other people and according to the second extremity, the imperative is to please them. This type of person is narrow minded and often looses social power, avoids conflicts by withdrawing from a conversation with other people and remains separated from her/his wishes. Due to their behavior, these people are often in danger of suffering from depression and psychosomatic disorder. These people should be persuaded to realize that they are not responsible for the other people‘s feelings and that their wishes are very important. The model of assertiveness training can influence on the changes.

5. Speed – the imperative of speed is of particular importance in urban western societies. An individual is extremely fast and effective in everything he/she does, but he/she can easily become bored. These people believe that normal and low work rates are undesirable. The basis here is productivity and efficiency. These people are limited because they have problems with handling all social situations where things are performed at normal or low work rates. These people choose professions which require speed such as journalism, television, stock market, medicine. They are constantly exposed to stress and there is an increased risk of suffering from hypomania, psychosomatic disorder and cardiovascular diseases. The most important for these employees is the fact that they have to behave in accordance with their nature because in that way they will feel better and have right attitude about themselves and the environment around them.

3.4. Personal values

Personal values represent beliefs that certain modes of conduct or existential conditions are desirable from personal or social aspects in comparison to the opposite modes of conduct or conditions. Therefore, values represent an ideal condition or mode of conduct which we are striving for. Values show what people believe is good and what is bad. Every value has content and intensity. Content of value shows the things that people believe are good and important, and intensity shows how good and important those things are. An individual system of values is developed when individual’s values are ranked based on importance and then connected. The value system shows the values which are important for individuals and the values which individuals believe are good and which are bad, as well as which values are important, less important and the relationship between them. As such, individual value system is the best in showing predisposition of an individual to behave in a certain way. Values develop in early childhood and they are set early in people’s lives. Family is a factor which has the largest influence on the development of values in every person. Apart from the family, environment also affects development of values. Hollander (1971) noticed values are rather stable and difficult to change. The reasons for this are: they are set in early childhood which makes them resistant to changes, and, over the time, they are placed into sub consciousness and people keep them even when they are not aware of that; alteration of values requires radical change of people’s attitudes about the world, which is rare and difficult.

3.5. Locus of control

It defines the extent to which people believe they can control their own destiny. People are different with respect to the feeling of control that they have over their lives. Some people believe that they are affected by their actions and that they build their own lives. They have internal locus of control because they believe that they have the control. On the other hand, some people believe they do not have the control over their lives and they are affected by activities of the other people or destiny. They have external locus of control because they feel that their lives are beyond their control. In organizations according Blau (2011), those who have external locus of control are, as a rule, less satisfied with job, more absent from work, less dedicated to work and have strong tendency to obey orders and authority. People with internal locus of control have better performances at more complex jobs such as job of a manager and all expert jobs.

3.6. Self esteem

Self-esteem is the extent to which an individual respects and appreciates himself/herself and his/her abilities. Self esteem is related to self efficacy which shows an extent to which an individual believes in his/ her individual abilities. People with high self-efficacy greatly appreciate their abilities and according to that they can have high self esteem. People with high self esteem believe that they are able to perform difficult tasks. This is why they are highly motivated, prone to take risks and they are more satisfied with their jobs (Judge & Bono, 2001). If some difficult and risky job has to be done in an organization, people with high self esteem and self-efficacy should be chosen. People with low self-efficacy and self esteem will show tendency to be dependent upon other people and they will be less satisfied.

3.7. Self-observation

Self-observation is the extent to which an individual is aware of his/her characteristics and abilities to adjust his/her characteristics and mode of conduct to the situation. People with greater extent of self-observation are more aware of themselves and their environment. These people pay more attention to the behavior of other people in the organization. Therefore, they are more aware of the situation around them. However, even if they have higher ability to adjust to the environment, these people are promoted and change workplace more often.

3.8. Abilities

Abilities are defined as mental or physical capacity of an individual to perform certain tasks or jobs. People's abilities are of particular importance for understanding of behavior in an organization because they affect the individuals' performances and organizations as well.Judge and Bono (2001) indicated abilities can be divided into two main groups:

- Intellectual abilities are part of general intelligence and they include the following abilities: verbal, numerical, reasoning abilities, abilities to deduce, to notice relations, to remember, to manage in space and ability to perceive.
- Physical abilities comprise two groups of abilities: motor and physical abilities. Motor abilities represent abilities to physically manipulate things in the surrounding and they include the following: reaction, speed of the arms… Physical abilities represent an individual physical shape and strength such as: static strength – ability to lift certain weight.

3.9. Employees' attitudes

When entering an organization, employees do not renounce their old, previously acquired characteristics, but they change, adjust and improve them partially (Driver,1982). Employees have influence on organization and its aims and organization and management have influence on employees, their interests, development and behavior. Employees' attitudes to work and organization are of particular importance for management. Attitudes have three components:

- Emotional component,
- Cognitive component,
- Behavioral component.

Attitudes can be defined as relatively stable group of feelings, beliefs and behavioral predispositions towards some certain object.

4. CONCLUSION

Career advancement means that individuals analyze their weaknesses and strengths, learn about the ways to develop or overcome them by analyzing aspects of internal motivation for set goals in careers. People, their needs, preferences, motivation and satisfaction become the center of attention in business, considering the fact that we have come to the conclusion that human capital represents major tool of the competitors' abilities and advantages on the global market. Personality represents complex psychological structure which requires knowledge in personality psychology so that their career development could be affected. Accordingly, this paper focuses on the analysis of psychological traits of employees that affect their careers.

Assessment of personality by using five-factor model of personality provides information on significant personality indicators that affect job performance. Adopted attitudes of employees, that are seen through locus of control, attitudes, working styles, self-esteem, self-observation, and employees' expectations are conditioned by personality traits, which further leads to assuming the responsibility for career management. Strengthening of organizational culture and climate, in order to establish criteria, is necessary, as well as establishing the criteria for employees' development so that employees could build portfolios of their own achievements and abilities. Business reason for the mentioned concept lies in the productivity of employees which is the result of more realistic dedication of employees to the career development.

RESEARCH INTO ATTITUDES ABOUT SOCIAL CHANGE AND GLOBAL MODELS OF GOVERNANCE[1]

Slobodan Miladinović[1]
[1]The Belgrade University, Faculty of Organizational Sciences, miladinovic@fon.bg.ac.rs

Abstract: *This paper presents the results of the empirical research "Cultural orientation of actors/students, interethnic relations, national identity and the culture of peace in the Balkans" performed within the macro project "Tradition, modernization and national identity in Serbia and the Balkans in the EU integration process" (179074). They are related to attitudes about democracy, social change and global management. The key issue of the research is how people perceive functionality of democracy and whether they are satisfied with the situation and do they support the democratic process and democratic institutions. From the findings we can see that the authoritarian legacy consciences burden the citizens of Serbia greatly, and in particular the examined population - university students. Confirmation of this was seen in the finding that the majority of respondents believe that the best global management model is technocracy. This leads us to the conclusion that our society still does not have a fully developed and mature political culture since the people are still inclined to accept (personalized) authorities that are ultimately reflected in the state and the holders of state power rather than citizens and their associations.*

Keywords*: change, democracy, technocracy, authoritarianism*

1. INTRODUCTION

The beginning of XXI century can be considered as the period of the third wave of democratization (Huntington, 1991), the period characterized by accelerated breaking up with authoritarian systems and the consolidation of democracy at the global level. The third wave was initiated in 1974 with the democratic changes in Portugal and continues to this day. The process has been accelerating since the second half of the eighties. Authoritarian regimes transit to a democratic form and parliamentary elections are becoming freer and more open. The number of countries in which democratic electoral system is evolving (multi-party parliamentary democracy) has more than doubled in the last three decades. It seems, at least when it comes to the beginning of the XXI century, that this is the age when democracy is, at least nominally, becoming a global political norm rather than one of the possible choice. But in the new democracies, as it is the case with us, it appears, as a general problem, that they still retain an authoritarian heritage since the democratic norms, values and practices are still a great uncertainty for many actors of social change, starting with political and economic leaders, political parties, civil` associations and to the ordinary citizens. It takes time for people to adapt and accept democracy as a form of global management and government of the state and society. So in order for democratic systems to be functional it is important how the citizens themselves perceive their functionality among other things, e.g. if they are satisfied with the situation and whether they support democratic process and democratic institutions. Therefore, it is nothing strange that the new democratic society has a lot of problems in the way of democratization.

The aim of this paper is to determine the extent Serbian citizens support the democratic system and democratic institutions, e.g. to what extent do people experience democracy as the optimal form of global management. Therefore, we conducted a survey of social attitudes of citizens relating to the acceptance of democracy as a system of global management, relationship to social changes and issues if the social subject should be managed by the state.

A variety of factors affect citizens' satisfaction with the democratic process (McAllister, 2008). One of them relates to the institutional aspects of democracy. This is especially true when it comes to whether the elections can provide representation in the establishment of their will, and whether that can ensure the quality of the electoral process, which will be reflected to the effects of the election activities of citizens. Second, support for the democratic system takes into account a responsibility and performance of the system, i.e. whether the system is effective in providing good management, as well. It should be taken into account whether the occasional and temporary convergence of political parties in order to create coalitions

[1] This paper was written as part of the project "Tradition, Modernization and National Identity in Serbia and the Balkans in the Process of European Integration" (179074) which is implemented by the Centre for Sociological Research, Faculty of Philosophy in Niš, and funded by the Ministry of Education and Science of the Republic of Serbia.

limits the choice to citizens. Third, the consequences of political participation and political involvement of the citizens to political efficacy are important.

Here will be analyzed the results of the empirical research "Cultural Orientation of Actors/Students, Interethnic Relations, National Identity and the Culture of Peace in the Balkans" performed within the macro project "Tradition, Modernization and National Identity in Serbia and the Balkans in the EU Integration Process" (179074) in the implementation of the Centre for Sociological Research, Faculty of Philosophy, University of Niš, which is financially supported by the Ministry of Education and Science of the Republic of Serbia. The study was a survey type and realized in the area of South and Southeastern Serbia (summer 2013) on a sample of 818 students of the University of Niš. The sample is proportional to the composition of students and includes three groups of students: (1) students of social sciences and humanities, (2) students of technical and technological sciences and (3) students of medical and natural sciences and mathematics, by years of study and educational institutions.

2. SURVEY DATA ANALYSIS

Many years even decades-long crisis facing the Serbian society has endangered the stability and functionality of the society to the extent that the issue of fundamental social transformation became a development imperative. Of course, there may be different types and different political contexts in which transformation may take place. Today, the broader public often raises the question whether it is better for our society to establish a democratic or an authoritarian form of political organization. Of course, this is a false dilemma considering that the current social practice has shown that democracy has many advantages over other forms of political organization. Every form of authoritarian government favors particular social subjects to the detriment of some others while democracy strives to articulate different interests. Of course, democracy may have specific problems and go through developmental difficulties and even "children's diseases" but at the end of the development path however shows socially favorable results which for various forms of authoritarian government generally it cannot be told.

Revisiting the concept of political power often corresponds to the dominant value patterns in the society among which we would emphasize the global type of national culture and within it the issue of organizational and political culture as particularly important. (Mojić, 2010). Unfortunately, in the society of Serbia during recent history dominated patriarchal and traditional cultural patterns within which authoritarianism (Kuzmanović, 1994, 1995) and nationalism (Miladinović, 2006, 2007; Popadić, 2010) played a particularly significant role. This context dictated in many respects the type of organization and political culture and attitude towards work cultivated in our society. It is no coincidence that the personal authorities were easily accepted in these areas and built cults of leaders on the basis of them (Kuzmanović, 2010). Rather than democratic solutions characterized by the free elections and a parliamentary form of government there are often present personal authorities who frequently promoted populism and hid themselves behind the idea of technocracy in a public arena. The essence of a technocratic government, which is supposed to represent the rule of experts, is that they, despite their expertise, they are not politically neutral for general benefit, but they support various authorities and their ideologies and interests clans. Authoritarianism as a value framework and personal power as a political practice are in the firm coupled with the demagogic action that was done in parallel demagogic rhetoric and concrete action designed to satisfy the low passions, and launch the broad masses support (Stojanovic, 2011).

Authoritarianism, cult of leaders and demagogic actions triggered mass as inarticulate subject which is easy to manipulate. In such circumstances, the power of mass gives legitimacy to the leader and theirs will is seen as a general people will. It has long been known that when ideas mastering the masses become the driving force that can fundamentally change the social circumstances. The key problem is that the charismatic leaders with a skillful manipulative rhetoric present their ideas as ideas of the masses and thus get an enormous social power that presents as a legitimate political will of the people and their every move as the fulfillment of the peoples will (Miladinovic, 1994).

The recent political history has shown that every social crisis, whether economic or political, is an introduction to the period in which the leader has grown over the society. The Second World War and the period of revolutionary construction led to the cult of Josip Broz. After his death, the political crisis has led some nationalist leaders in the political arena (Bowman, 2004; Denitch, 1996; Miladinović, 1994):. Ideological turmoil, in the conjunction with the birth of multi-party system, brought to the surface a larger number of potential candidates who play on personal charisma and fought for the position of undisputed leader of the nation. The period after the 2.000 year is a period of temporary calm. It seemed that the leaders go down in history, and vacuum is filled with new social and political patterns. However, the crisis at the end of the first decade was favorable for the fact that citizens of Serbia turned again to personal authorities and give the support to the cult of personality at the beginning of the second decade of the twenty-first century. At this

moment it is a thankless task to predict the outcome of the current social and political turmoil. It can be reliably argued only that there are all necessary conditions to establish the cult of the charismatic leader and his personal power. What will be realized from it depends on a number of political, economic and cultural factors that set the tone of current events.

Table1: To what extent do you agree with the following attitude:

To what extent do you agree with the following attitude:	Strongly Disagree (1)	Tend to disagree (2)	Neither agree nor disagree (3)	Tend to agree (4)	Completely agree (5)	Mean	Std. Deviation	N
Democracy may have its problems, but it is better than any other form of government	12,84%	11,60%	31,73%	28,89%	14,94%	3,21	1,210	806
Undemocratic order is sometimes better and more efficient than democratic	14,88%	15,62%	39,24%	19,19%	11,07%	2,96	1,178	806
Democracy is the same as anarchy	29,19%	24,26%	30,54%	9,85%	6,16%	2,39	1,177	806
For people like me it does not matter what kind of political system they live	47,41%	13,92%	22,41%	8,13%	8,13%	2,16	1,318	806

With the aim to determine the tested population attitudes towards democracy we asked respondents to declare themselves to which extent they agreed with the four statements (Table 1):

1. Democracy may have its problems, but it is better than any other form of government
2. Undemocratic order is sometimes better and more efficient than democratic
3. Democracy is the same as anarchy
4. For people like me it does not matter what kind of political system they live

It turned out that is the highest compliance exists with the first claim. Even 43.83% of respondents believe that democracy is better than any other form of government, although it may have its problems. If we take into consideration dominance of authoritarian patterns in the value structure of the society in Serbia, this finding seems to be very good. However, it does not provide developmental perspective of Serbia. The problem is that one in four does not endorse this attitude and one in three does not have clearly defined opinion on this issue. Even among those who agree with this statement dominate is the caution about the claim that democracy is the best form of governing a society (28.89% tend to agree but only 14.94% completely agree). This answers configuration suggests there is a poor subjective potential for adoption and development of a democratic political ideas and system in Serbia.

The largest numbers of the respondents are not in a state to respond about their own compliance with the claim that the undemocratic order is sometimes better than democratic (39.24%). There is an equal number of respondents who refuse and accept this attitude (about 30%). Within the structure of those who reject this essentially anti-democratic attitude, half of them reject it completely but the other half do it mainly. This configuration of responses indicates that there is very good potential for the acceptance of non-democratic forms of governing a society. This finding is not surprising given that previous studies have shown a very high presence of authoritarianism in the value structure of the population of Serbia (Kuzmanovic, 2010).

If we sharpen the previous attitude and say that democracy is the same as anarchy, then we have a slightly more favorable response configuration. Now willingness to defend democracy shows more than half of the respondents (53.45% of which 29.19% completely) while 30.54% are indecisive. So, there are only 16.01% of those who directly admitted that democracy and anarchy can be equated. In the structure of those who equate democracy and anarchy are 6.16% of those who completely agree this attitude. Ultimately, this is about the potential for acceptance of extremist political organizations and their ideologies. This potential can be extended from the current six percent to a significantly higher number in times of crisis. Moreover, here is a potential core for extremist forces first line support in any context of escalation of social conflicts and their transmission from parliament and factory halls to the streets. This number can grow up in a short time and take on alarming proportions by skillful political manipulation and attempts to establish the cult of the charismatic leader, as it was seen in Serbia and former Yugoslavia in the nineties.

The last statement "for people like me it does not matter what kind of political system they live in" expresses political apathy. Political apathy may be considered as an expression of saturation with political events or dissatisfaction among citizens about social perspective or inadequate party and electoral offer and the entire political elite (Stojiljkovic, 2011) as the "lull before the storm." In our case, only 16.26% of respondents expressed a direct political apathy supporting such attitude. Half of it (8.13%) accepted this attitude completely. It should be added that 22.41% of those who cannot opt which in total are 38.65% of potentially apathetic citizens, i.e. those who might want to take off from any political activity. On the other hand there is the majority of 61.33% of the respondents who do not accept political apathy as a way of his personal relationship with the government of the state and society. An interesting finding is that almost half of the examined population completely rejects this claim. This means there is a great potential for political activism in the Serbian society, and that the citizens are very interested in the politics and political perspectives of the society.

Table 2: Which of the following statements best describes your opinion:

Which of the following statements best describes your opinion:	
The whole organization of our society must be radically changed (in revolutionary action)	25,31%
Our society must be completely changed through a reform	52,21%
Our present society must fight vigorously against any changes	7,74%
I do not know	14,74%

A democratic society is essentially a dynamic society. A dynamic society is a society that is willing and able to change itself quickly and create new forms of social behavior. Of course, it is important to the changing of society that there are no subjective forces that would be carriers of changes. It is common understanding that the younger and more educated, which includes our respondents, are more willing to accept and initiate social change. Therefore, we offered them to choose an attitude that best reflects their relationship to a global social change (Table 2). Offered attitudes exemplify the following orientations: a radical change (radical cut - a revolution), gradual change (reform), resistance to change and the absence of change attitude. The modal response was that the society should completely change through a reform. So, every second respondent accepted reform, gradual changes, as the best solution to the current social problems. On the other hand, one in four respondents thought that the best pattern of social change is a radical revolutionary action. The key difference between these two versions is the duration of the transformation process. While, on the one hand, the reform involves long duration process on the other side revolution implies a relatively short-term action. A revolution brings stormy and very dramatic changes almost as a rule while the reform is not necessarily the case.

It is an interesting finding that even 7.75% of the respondents think that our society must fight vigorously against any changes. They advocate for the status quo, for preserved existing situation of social relations. We need to add 14.74% of those who declare that they cannot opt for any of the available variants.

So almost 85% of students have a clear vision of the pace with which the social transformation is supposed to happen and more than half is for gradually changing social relations.

Table 3: Who in your opinion should manage the state:

Who in your opinion should manage the state:	
A strong leader who is not limited by Parliament and elections	17,04%
Experts who know best what is good for the state	60,49%
Army	3,33%
The government and the parliament elected in free elections	19,14%

Respondents were also given to declare themselves within which global government model changes should happen (Table 3). We asked them the question: "Who should manage the state?" and it was given as standard variants authoritarianism (strong leader who is not limited by Parliament and elections), democracy (the government and parliament elected in free elections), technocracy (experts who know best what is good for the country) and militarism (the army). The answers are surprising. The modal response was based on the idea that the state should be managed by technocracy i.e. experts who know best what is good for the state. Technocracy as the best model of state government adopted by more than half of respondents (60.49%).

The second ranked was the answer that the best model of state management is a democracy that declared one in five respondents (19.14%). Authoritarianism is accepted by 17.04% and militarism by only 3.33%.

Thus, the technocratic model is three times more desirable than the democratic model of state management and government. Here, in our example, we recognize the authoritarian heritage in accepting the authority of experts. The key disadvantage of the technocratic model compared to the democratic is that professionals are given carte blanche confidence to make strategic decisions and the bulk of the population is excluded from the decision-making process. Technocracy is a kind of the minority educated professionals tyranny over the majority of less educated members of society. It should be noted that technocracy does not necessarily produce socially valuable results. It can be linked to any political or economic strength of society and defend its own interests, or simply take care about their own interests primarily. The point is that global politics should be left to the democratically elected government that will be able to articulate the interests of all stakeholders of civil society and ensure the protection of minority interests in the broadest sense of the word. Experts should be left to perform the individual specific tasks that require professional competence and thereby achieve socially valuable effect.

But it seems to be, the much greater problem is that one in five respondents accept authoritarianism either in any form of government of a strong leader who is not limited by Parliament and elections or in the form of militaristic government.

In the next step (Table 4) we crossed questions that show the attitude towards change and attitude that defines the optimal model of change. There is statistically significant relationship ($p = 0.000$) of low intensity between these two variables (Contingency coefficient C=0.23 and Cramer`s V=0.13). Most frequently accepted combination is the one that connects the reformist view of social change with the technocratic model of governance. Concretely, 65.3% of the supporters of reform course accept technocratic model of governance as the best, or 56.4% of the supporters of technocracy accept the reform course. Another cell of the table which contains interesting results is one in which even 58.1% of the supporters of the democratic model of governance accept the reform course of changes. Of course, acceptance is not bidirectional, as only 21.4% of reformists accept democracy as the optimal model of governance. It is also interesting results in the row where intersects supporters of revolutionary change (radical cuts) given that more than half of supporters of radical change (56.4%) also preferred technocratic model of governance, while on the other hand, only about a quarter of supporters of technocracy accept the radical changes. It is interesting that 44.3% of supporters of the status quo accept the government of technocracy.

The table can be viewed either in vertical columns or in horizontal rows only. If we look at the vertical columns, we see that on the one hand one third of the supporters of the authoritarian model of governance advocating the radical course and in the other hand the next third advocating the reform course. It is observed that within this group it is twice more of those who oppose any change (16.2% of supporters of authoritarianism to 7.6% of supporters in the general population. It is observed that within this group, the share of those who oppose any change is twice bigger (16.2% of supporters of authoritarianism to 7.6% of supporters in the general population).

Supporters of technocratic model are mainly directed towards the reform course (56.4%), while a quarter of them (23.6%) accept the radical cut.

A third of the supporter of militaristic model of governance prefer radical cuts (33.3%), a quarter of them prefer reform change (25.9%), while the same number of them are undecided. It is interesting that there are the most of those who do not have a clearly defined attitude toward the preferred dynamic of social change (25.9% compared to 14.9% of the total population) among the supporters of militarism. It seems that the militaristic attitude towards choosing a subject of change occurs as an expression of profound social hopelessness considering that a large number of supporters of this form of government either want quick, radical change or just do not know what would be good for the society, the state and the economy and they found force that can bring order in the society in the army.

It has already been noted that three fifths of the supporters of democratic government model accept technocrats. It should be added that one in five believes that social problems can be solved in the best way applying radical cuts.

Analyzed by horizontal lines we observe that a technocracy is the modal choice of supporters of radical changes (56.4%). In addition to this, almost a quarter of them advocate an authoritarian model of governance. The presence of the acceptance of democracy and militarism in this group is significantly less

Two-thirds of reformist oriented respondents accept the technocratic model of global management and government, while only one-fifth of them accept a democratic model. Other models of governance (authoritarianism and militarism) barely have supporters in this segment of the population

Table 4: Cross tabulation: Who in your opinion should manage the state * Which of the following statements best describes your opinion:

	Who in your opinion should manage the state:				Total
Which of the following statements best describes your opinion:	A strong leader who is not limited by Parliament and elections	Experts who know best what is good for the state	Army	The government and the parliament elected in free elections	
The whole organization of our society must be radically changed (in revolutionary action)	23,5% 35,3%	56,4% 23,6%	4,4% 33,3%	15,7% 20,6%	100,0% 25,3%
Our society must be completely changed through a reform	11,6% 36,0%	65,3% 56,4%	1,7% 25,9%	21,4% 58,1%	100,0% 52,2%
Our present society must fight vigorously against any changes	36,1% 16,2%	44,3% 5,5%	6,6% 14,8%	13,1% 5,2%	100,0% 7,6%
I do not know	14,2% 12,5%	59,2% 14,5%	5,8% 25,9%	20,8% 16,1%	100,0% 14,9%
Total	16,9% 100,0%	60,5% 100,0%	3,3% 100,0%	19,2% 100,0%	100,0% 100,0%
χ^2=42,946	C=0,23	V=0,13	p=0,000		

Slightly less than half of the opponents of social change (44.3%) accept technocratic model as the best model of governance, while more than a third of them (36.1%) support the authoritarian model of governance.

The distribution of those who declare not to know which the model of governance would be optimal is almost identical as in the general population. The only visible difference is related to supporters of militaristic model which are almost twice more than in the total population (5.8%).

4. CONCLUSION

Now we can return to the question how people perceive functionality of democracy and whether they are satisfied with the situation and do they support the democratic process and democratic institutions. From the findings we can see that the authoritarian legacy burden the conscience of citizens of Serbia greatly, and in particular the examined population - university students. Confirmation of this was seen in the finding that the majority of respondents believe that the best global management model is technocracy. This leads us to the conclusion that our society still does not have a fully developed and mature political culture since the people are still inclined to accept (personalized) authorities that are ultimately reflected in the state and the holders of state power rather than citizens and their associations.

Technocratic system can be considered as a transitional form between classical authoritarianism, which may be embodied in personalized authority or in authoritarian institutions such as the army in a very limited context, and democracy which is represented with the government and the parliament elected in free elections. In this case it is masquerading as professional competence of their carriers so that it can be easily uncritically accepted as a system of governance which is better than authoritarian personnel governments or military administration in periods of turbulent social upheaval which also impairs the democratic nature of the social system at the same time. The problem is that a technocratic government is not the same as a democracy. Technocratic government and management of society is just one more model of authoritarian rule. The difference compared to other authoritarian models is that the technocrats hide behind the professional competencies what inspire some confidence, but it does not mean that there is an existential interest of experts to work for the common good. Technocrats are not controlled by numerous mechanisms of broader social control backed by the citizens. Technocrats are controlled by centers of alienated social power and behind them can stand very different authorities.

The expansion of political freedom (democracy) achieves different effects on economic growth (Barro, 1999). The positive thing is that democratic institutions enable control of the government, which limits the potential

of public servants to accumulate personal wealth or to do the unpopular policy. Negative is that more democracy encourages redistribution of income from the rich to the poor, and the growing power of different interest groups. Therefore it can be considered that the net effect of the growth of democracy is uncertain.

On the other hand, practice shows that economic development embodied in the higher standard of living promotes democracy. This relationship is clearly shown when a democracy is presented through the electoral rights and civil liberties and impact, and the living rate through the growth of gross domestic product per capita, access to primary education and reducing the gap in education of male and female population and the growing importance of the middle class etc.

STORYTELLING AS AN ORGANIZATIONAL CHANGE MANAGEMENT TOOL

Željana Pavićević[1]
[1]University of Belgrade, Faculty of Organizational Sciences, zeljana.pavicevic@yahoo.com

Abstract: *Organizational change is one of the most studied phenomena within the domain of organizational theory. Further, overcoming resistance to change is pointed out as a critical success factor in the successful implementation of an organizational change. Over time, academics and practitioners have developed a variety of tools and methods to cope with the employees' resistance to change. This paper presents one of the contemporary corporate tools that has been successfully deployed for such purposes - storytelling. The advantages and disadvantages of the usage of storytelling during the organizational change process are pointed out and avenues for future research are provided.*

Keywords*: organizational change, resistance to change, storytelling*

1. INTRODUCTION

Although the method of storytelling as a communication strategy is well known among theorists, there is not many documented research endeavours on the application of these methods during the process of organizational change.(Simmons, 2001; Wiggins, 2009; Oreg, 2003.) In this paper I will briefly summarize the scope of contemporary research and relevant publications on the corporate storytelling. By doing so, I aim to demonstrate the ways in which the use of storytelling can be an effective form (and even more effective than some other forms) of communication during organizational change. As such, corporate storytelling should secure the support from the employees, especially when it comes to the implementation of strategic goals. In order to demonstrate its power, storytelling will be put in contrast to the traditionally used internal communication channels during the period of organizational change. Research has shown that employees have a greater affinity for changes because of the application of storytelling, mainly due to the fact that stories can be, and often are in this context, associated with their experience and knowledge.

Due to the importance of this topic, for both business and academic community, as well as the great interest in this topic and broader research area in general, this paper aims to highlight the specificities of the method of storytelling in organizations, with an emphasis on organizations that are going through the process of organizational change.

2. CHANGES AND CHANGE MANAGEMENT IN ORGANIZATIONS

Organizations are nowadays faced with high level of complexity and uncertainty in various fields of business due to the fact that economic and social unrest are changing the game, often more rapidly than one can observe. Unfortunately, many companies are designed to operate in conditions where there is no change, or when operating effectively at "full speed" means consistently keeping up the track on the past actions. In that respect, changes are often seen as something that must be overcome, controlled, as a simple break in the known world, not as a new "norm" that needs to be properly managed.

This new "norm" refers to the fact that organizational agility and flexibility have to be developed; organizations need to be able to constantly adapt and change in order to meet diverse economic and competitive challenges. Truly agile organizations are able to meet these changes and challenges through the implementation of different organizational projects that allow them to adapt, to continually be assessed by an educated and informed leadership, and in a way that is common and normal for all employees (Change Management Institute, 2012). To sum up, companies need to develop and strategically apply sophisticated change management practices.

Change management can be defined as a process of constant renewal of the direction of the organization, its structure and its ability to adapt to the needs of internal and external clients (Moran and Brightman, 2001). According to Burns (2004) changes are always present - existing part of organizational life, both on the operational and strategic level. Therefore, there should not be any doubt about the importance of opportunities to be identified on where the organization needs to be in the future, as well as how to manage changes in a way which will make that happen. Finally, organizational changes cannot be separated from

organizational strategy or the other way around (Burnes 2004; Rieley and Clarkson, 2001). Organizational change is one of the building blocks of the corporate strategy.
Although it is difficult to establish any kind of consensus on the framework for the management of change, there seems to be agreement on two important issues. First of all, it is accepted that the pace of change has never been greater than in the current business environment. Secondly, there is a consensus that changes caused by internal or external factors come in all shapes and sizes and therefore, can potentially affect all organizations in all industries. Hence, the significance and the relevance of the topic get constantly reinforced.

3. RESISTANCE TO ORGANIZATIONAL CHANGE

The basis for the success of organizational change is their acceptance by employees. In the context of his work Kubler-Ross (1973) argues that people faced with loss or change go through five stages of "grief" namely: anger, denial, bargaining, depression and acceptance. This indicates the essential aspects of change management in an organization. Wiggins (2009) uses this model for the purpose of communication and support during the period of change which again indicates that it should be adapted to the stage in which the employees are concerned. For example, after the news about the change have been communicated, employees must be given the information that would oppose their potential (and most likely to happen) rejection. After they receive the information, they experience a sense of anger, negotiating and entering into a state of depression, which actually requires different types of support within each of these phases. At the end of the cycle, once employees start to accept the new situation, they need a vision of the future – the one that can make them dedicated and committed to the new circumstances.

On the contrary, some other researchers advocate a different approach in the research on change governance, arguing that individual reactions are complex, different and unpredictable. One representative of such thinking is Oreg (2003) who suggested that the resistance to change is based on the personality and the context in which the change occurs. In his initial study (Oreg, 2003), the author developed and tested a scale called "The scale of resistance to change (RTC)" which is conceptualized as a stable personality trait. In this study, Oreg came to a positive and significant relationship between the individual RTC results and their affective and behavioural resistance to specific organizational changes with which they are faced.

In addition to personal settings that affect the level of resistance caused by organizational changes, Oreg (2003) also showed that the context variables played a significant role. Trust in management has proven to have a strong effect on cognitive and behavioural resistance, which is pointed to the importance of good governance in a time of change. Similarly, studies have shown that a large amount of information about changes given to individuals resulted in a worse evaluation of changes and increased the ability to act against them. This latest finding has led Oreg (2003) to suggest that there will be an optimal amount of information that can be given, after which the employee will feel satisfied. He also suggests that if the change has a negative impact on the individual, it would not be surprising that more information about the change increases the resistance to it. This study highlights the importance of another management approach in connection with the communication strategy.

On a day-to-day basis, the engagement of an employee relies on the effectiveness of internal communication through the exchange of information between employees and management and employees among themselves. Such an internal communication takes place on three distinct levels: the daily management of employee relations, strategic plan for realisation of the mission of the organization, and project management (Cheney and Christensen, 2001). In the times of change, employers need to successfully shape and manage information throughout these three levels of communication, in order to maintain and support amplifiers of positive employees' attitudes (Gots and Wilson, 2001).

4. THE CONCEPT OF STORYTELLING

Corporate storytelling is the process of transferring messages that form a new angle or reinforce the opinion or behaviour using narratives about people, organizations, past, visions of the future, social cohesion and work in general.

Stories are one of the most important motivational tools known to a man. Useful, anytime and anywhere - from the Bible to contemporary comedians - stories explain, entertain and motivate. Through jokes, tragedy and comparisons, they make us laugh, sadden, or inspire. In business, good communicators use storytelling to sell products, generate ideas, develop and nurture a corporate culture. Kyle and Jacobson (1999) remark that the story can communicate vision and build a sense of common goals as well as create a sense of

community among different people. Certain situations are perfect for storytelling, such as new beginnings or calming employees during crisis.

Kaye and Jacobson (1999) identify a typical three-step sequence that holds the key to the power of storytelling:

- *The story*. One person tells the story while one or more others listen.
- *The understanding.* Both parties begin to gain a deeper understanding of something that was previously known only superficially.
- *The shared meaning.* Groups use the shared meaning of one thing as a metaphor or shorthand for the broader understanding of other things.

Organizations are dependent on effective communication as drivers of success. Storytelling already plays an important role in the world of organizations, businesses and modern politics. Stories can be used internally by the organization in order to motivate people and create a memorable message for employees (Madlock, 2009; Marques, 2010). Traditionally, stories in the workplace have been used to highlight the safety and well-being, and reduce risk. From an employer's perspective, the expansion of the value of corporate storytelling is the potential to persuade, motivate and inspire staff, especially in the period of change, which strengthens the internal loyalty (Simmons, 2006).

The key advantage of using stories as a communication strategy during organizational change lies in the fact that management can use the corresponding narrative in order to understand employees (their wishes, expectations, ambitions, general attitudes and attitudes in relation to a respective organizational change etc.), without compromising the goal of communication (Harrison, 2008). The common opinion is based on the fact that the pure logic between management and employees may be significantly improved through storytelling, thus making it easier for employees to adapt to a change and the new emerging organizational reality.

Another important advantage is the universal need for the use of storytelling in contact with members of the organization who have different interests and learning styles. Many large organizations have a great range of stakeholders. The stories provide a flexible framework for the narrator to present objectives in accordance with interests of certain stakeholders (Dowling, 2006). We can see that storytelling is not only a communication tool aiming at employees but all other relevant internal, and potentially also external stakeholders.

5. STORYTELLING AND CHANGE MANAGEMENT

According to Fleming (2001), the role of the leader is to challenge the cosy and outdated beliefs, selectively discarding them, and providing new insights into the attitudes and existing organizational practices. However, most leaders can confirm that this is easier said than done. The following story confirms these claims to a great extent (James and Minnis, 2004).

> *"The young Presbyterian minister looked out on his congregation with satisfaction as he noted the apparent enthusiasm in their faces. He had expected the subject of his sermon – change - to ruffle some feathers and he had embarked on it this morning with no small degree of consternation. He had just finished outlining his new initiatives for the church and, to his delight and surprise, his established (some would say mulish) congregation looked to be responding enthusiastically. Emboldened, he decided to go a step further than he had planned for the morning by asking his parishioners to signify their individual readiness for the fresh ideas. "If you're with me," he enthused, "get up and move to a different pew and take a look at things from a whole new perspective." The response: no movement, except for some head shaking and even a little vocal refusal. One congregant's declaration captured the sentiment of the group in a nutshell: "I'm all in favor of the church making changes, but that doesn't mean I want to change."*

The lack of commitment of employees is the main reason why a program of organizational change fails. Successful change requires a new general behavior of all members of the organization, but employees usually react in the opposite way, with anger, denial, doubt and anxiety. Theorists generally agree that the key to overcoming this resistance is open communication. The most common barrier to organizational changes is the top management who hold tickets to unto in its hands. The change is frequently experienced emotionally by the employees, and task of the leaders is to spend their followers through uncharted waters. The challenge is to involve employees in the current changes so that they feel as participants and not as

targets. This requires leaders to engage not only the technical but also the human side in an effort to change. They can build consensus with strong relationships instead of using the power that their positions bring. In contrast to positional power, where the results are achieved by emphasizing rank, power relations strengthen new projects through the involvement of leaders and provide information to those who will be affected by the changes.

Further, leaders more often consider human emotion as a potential threat, rather than as a potential opportunity for engagement. As the process of creativity stories can be used as a symbolic tool for persuading others to change their views and consider new beliefs. Aristotle talked about the three pillars of persuasion:

- *logos* - that appeals to the intellect;
- *pathos* - indicating emotions;
- *ethos* - which appeals to the credibility of one who convinces.

Intellect and emotion are strongly related, but not always aligned. Emotions have the ability to affect the intellect. The right time, well directed story, can cause emotions to transform the point of view of the employee and motivate the desired response. Mark Walton (2003) calls the stories that affect the change "strategic narratives". Walton (2003) describes a three-step process to develop a strategic story. The first determines what the desired end is - what we want the audience to take. The second one - establishing strategic story should provide a positive view of the future that the audience should imagine. Thirdly, develop a story line that meets the specific needs of the audience, their desires and goals. Annette Simmons (2001), on the other hand, wrote that the need for a demonstration of the benefits of compliance with the changes should be understood – it is the key aspect of this plot. When listeners believe that their needs are understood, linking actions or commitment to the plan provides multiple and significantly higher chances for success.

6. STORYTELLING AND RESISTANCE TO CHANGE

It is the fact that storytelling is a way for the suppression of organizational change, but not a substitute for changes in policies, programs, budgets, incentives, staff, measurement and other actions that are necessary for prolonged periods during the transformation of a large organization. Storytelling is just a tool that can be used to implement these measures in the first place. It helps inciters of changes to communicate the changes to all levels. Storytelling connects employees and managers in order to support the changes that seem strange and threatening.

There are a number of reasons why stories can be effective to change organizations:

- *Storytelling is natural and easy*. The ability to tell and follow narrative is a capacity that happens at such an early age - around the age of two or three years of age - that one is tempted to call the capability innate, or at least a natural, capacity (Brunner, 1990). By contrast, abstract analysis is not something that we do naturally. It is something that we have to be trained to do, through many years of schooling. For most of us, it emerges as burdensome work. It may be excellent mental exercise and good for self-improvement. But except for a few unusual people, who like living in an inert world of non-living things, the experience makes us tired and weary, as compared to listening to stories which most of us experience as invigorating and refreshing and energizing. We find the telling of stories inherently pleasurable (Weick, 1995). Stories invite the listener to visualize a different world, and in the imagining, to add value to the activity. The shared imagining of the teller and listener creates a common space. As the storyteller watches the reactions of the listeners, he instinctively builds on and emphasizes the elements that are resonating with the listeners, thereby encouraging the phenomenon of co-creation. The audience senses that the storyteller is interacting with them, and they respond to it with more reactions. The phenomenon is natural, spontaneous and pleasurable.

- *Stories show the connections between things*. A good story holds disparate elements together long enough to energize and guide action, plausibly enough to allow people to make retrospective sense of whatever happens, and engagingly enough that others will contribute their own inputs in the interest of sense-making (Weick, 1995).

- *Stories bypass defense mechanisms*. The story is bypassing defense mechanisms. One of the attractions of the story is that people can not immediately see where this story is going to take. People find it difficult to categorize stories, especially if they are unfamiliar. Therefore, the defense mechanisms are normal in storytelling. The mind is not critiquing it, but following it, and projecting on to it. This enables a more participatory spirit towards understanding what is involved in it, than if listeners are hearing an analytic presentation where they have their critical apparatus at the ready, to dissect, analyze and appraise the proposed change. In the case of a story, the listeners are not analyzing it. They are living it. The mindset is fundamentally different. (Brunner,1990.)

- *Stories help cope with complexity.* The world is a complex place. Despite the impression we have often been given in school, simple linear phenomena are rare in our world. Non-linear phenomena are everywhere. It is only in the last several decades that scientists have been discovering this reality. How then has the human race coped with such complexity for thousands of years? One of the early ways of coping was by personifying complex events, so that we expect the same non-linear behavior that we expect with persons. Stories provide a simple way that has been used since time immemorial to communicate the complexity of the world. Modern corporations, and the changes that are needed in them, are complicated entities. People in them can understand and make sense of what is going on by telling stories to each other (Capra, 1996).

- *Stories engage our feelings:* Stories have the inherent capacity to engage our emotions and get to deep meaning, because stories are in their nature about the irregularities in our lives, things that catch our attention as being different from what is expected, and hence arouse our curiosity, or even fear. The regularities in our lives attract little attention. They are boring. They are the background noise of our lives and do not constitute the subject matter for stories, except when we discover a new regularity, which in itself is unexpected and hence irregular. It is the irregularities that attract our attention: they operate as a potential threat to our capacity to stay in control of our lives, as well as an incentive to understand them so as to be able to have a say in our future. As a result, stories, in addition to their cognitive dimension for understanding the irregularities, tend to engage our emotions to the extent that we perceive our well-being and safety to be at risk. (Brunner, 1990.)

7. AN EXAMPLE

Results of an employee satisfaction survey conducted by Ericsson Australian and New Zealand during the global financial crisis period in 2008 indicated poor results, with: senior leaders' motivation rating 52 per cent; leadership communication capability rating 57 per cent; and, strategy awareness rating 66 per cent (Aplin, 2010). Ericsson launched a three-year strategy with programs addressing business challenges and opportunities, focussing on transforming the organisation's culture to becoming more customer-centric. The goal of the program was to help employees understand the organisation's ambitions and feel motivated to contribute. To achieve this, Ericsson recognised the need to build communication competence with senior leaders. The organisation set objectives to improve leadership communication capability and strategy awareness by three points. The senior leadership group (including the CEO) was required to attend two half-day workshops on storytelling, which had been identified as the way to connect, not just communicate, with the staff.

It was identified from these sessions that although the organisation had a story to share with employees, each team had unique challenges that needed to be addressed by the leaders to gain support for the cultural change. Gaining senior leadership 'buy-in' was an important element to making the storytelling strategy a success. Of the Ericsson leaders, although some scepticism was initially detected, 97 per cent rated the workshops as developing relevant skills for their roles as leaders and 91 per cent saying storytelling improved their influence as a leader (Aplin, 2010). The results from educating leaders in the strategy of storytelling to engage with employees indicated a resounding success rate, with employee surveys at the end of 2009 showing leadership communication competency jumping 18 points to 75 per cent, strategy awareness increased by 11 points to 77 per cent, and senior leaders' motivation increasing by 22 points to 74 per cent. Ericsson's customers rated them five points ahead of their competitors in the Customer Satisfaction Index Survey and the company finished the year in a stronger financial position (Aplin, 2010). The 2009 turn-around was due to a range of initiatives, but equipping leaders with storytelling expertise had a real impact (Aplin, 2010).

Even though just a brief summary of how Ericsson uses storytelling to cope with resistance to change, these results show encouraging effects of corporate storytelling in this domain. Such success stories should encourage other practitioners to deploy this tool, but also researchers to study it more thoroughly.

8. CONCLUSIONS

In this paper I presented the importance of the implementation of corporate storytelling as an internal communication strategy that facilitates the understanding of management decisions. Using the story by the leaders is an interesting way to build loyalty in times of organizational change, and doing so by strengthening the support and communication between employees. References included in this paper strongly support the concept of corporate storytelling as a powerful mean for building stronger engagement and create greater loyalty to employees. The needs of employees include both cognitive and emotional domains, especially during periods of change. Therefore, corporate stories can address these requirements through a deeper and more personal communications medium. A carefully planned narrative delivered through the story, meets employees on a more individual level, strongly enhancing the potential of understanding, memory and commitment to corporate interests. On the basis of the above-mentioned, it can be concluded that the corporate storytelling is an effective medium of communication for the purpose of increasing engagement and building loyalty to employees.

Will the storytelling be more than temporary managerial trend? It is possible, if it is perceived as some kind of drug. But actually, communicative leader who had a positive experience to applying storytelling can choose to keep this as a strong advantage in managing organizational change. The stories represent and shape the organizational culture. They have a role in clarifying ambiguities and provide meaning. The stories also work to change the beliefs and behaviours through cognitive and emotional processes. Once leaders seize the transformational power of language to motivate and inspire, they would undoubtedly conclude that organizational storytelling makes sense. Taking this into consideration, further research should address narratives and corporate storytelling as one of the pillars of the organizational culture. Finally, the development of information-communication technologies has opened a whole new horizon of the possibilities for digital and online storytelling. Examples can already be found both in practice and within the research streams of academics.

Abstract: *Teamwork is a widely recognized form of doing business today. Many organizations implement this form of groups in order to improve their competitive advantage and overall performances. Since performances are affected by inputs, it is important to consider people as the most important input in teamwork and analyze their individual characteristics that might or might not affect the final results. This paper presents a literature review on individual characteristics of team members that contribute to team effectiveness. Most important characteristics are: knowledge, skills and abilities, personality traits, attitudes and diversity.*

Keywords*: team member effectiveness, individual characteristics*

1. INTRODUCTION

Emergence and diffusion of teams – a particular form of groups brought many novelties upon modern organizations. Although a team is a type of group, it has certain distinctions which need to be taken into consideration when analyzing team effectiveness, as no other form of „group work“ matches with it perfectly (Jex & Britt, 2008). Vast number of organizations creates teams for different work assignments and there is a widely popular opinion that teams should be a foundation on which organizations build up and develop in the future (Guzzo & Shea, 1992; Kozlowski & Bell, 2003).

Considering prevalence of teams in business world, it is important to define criteria of successful teamwork. For more than half a century scientists from different disciplines make efforts to understand and measure that success and effectiveness. Dominant approach in literature regarding team effectiveness is explicit or implicit input – process – output sequence, or some sort of modification of this sequence introduces by McGrath 50 years ago (Guzzo & Shea, 1992). Different combination of inputs initiate team processes (interaction) directed at task accomplishment. Researchers considered many inputs of team effectiveness in the past and got to numerous and often contradictory results. Inputs can be described as factors that enable or shape interaction in teams (Mathieu J. , Maynard, Rapp, & Gilson, 2008), and usually include knowledge, status, personality traits, abilities, experience and demographics. Some authors modified definition of input and added certain organizational (rewards, interdependence, task design, etc) (Gladstein, 1984; Guzzo & Shea, 1992) or contextual factors that influence effectiveness directly (Campion, Papper, & Medsker, 1996; Cohen & Bailey, 1997).

Team structure or composition is incorporated element of team effectiveness for more than 50 years (Mann, 1959), and is mostly explored in terms of job related attributes (Webber & Donahue, 2001) and general and specific attributes (Harrison, Price, & Bell, 1998). Research in the field of team structure or individual characteristics of team members are focused on team members' attributes and effects of those attributes on processes, emerging states and outputs. Most common individual characteristics in previous research are: (1) knowledge, skills and abilities; (2) personality traits; (3) attitudes; and (4) diversity. These are explained further in the text based on extensive literature review with the aim to answer the question: “What makes an effective team member?”

2. KNOWLEDGE, SKILLS AND ABILLITIES

Knowledge, skills and abilities necessary for effective performances in teamwork differ from those required for accomplishing individual tasks. (Morgeson, Reider, & Campion, 2005). Interaction in team environment imposes the need for unique set of competencies (Stevens & Campion, 1994) with empirical

confirmation of their influence on performances (Cooke, Kiekel, Salas, Stout, & Bowers, 2003; Hirschfeld, Jordan, Feild, Giles, & Armenakis, 2005; McClough & Rogelberg, 2003). Knowledge of the

task is extremely important for teams working on assignment for a long period of time. Teams with high level of knowledge of the task not only have better performances but go through transition processes much easier (Mathieu & Schulze, 2006).

Average team cognitive ability is a good predictor of performances. Teams with high average cognitive ability acquire new knowledge much easier when there is an equal work overload among members. (Ellis, Hollenbeck, Ilgen, Porter, West, & Moon, 2003). Team performances are influenced by structure with highly interdependent tasks (Tziner & Eden, 1985). In meta analysis of 17 studies considering relationship between cognitive ability and team performances on student population, Devine and Philips (2001) concluded that „functional sum of cognitive abilities in team may affect team performances in different types of teams". According to them, effects are largest in teams working on intellectual tasks or teams involved in decision making process, unlike teams working on tasks with dominant physical component. They also concluded that relationship between cognitive ability and effectiveness is stronger when teams work on unfamiliar task (Devine & Philips, 2001). This conclusion is consistent with literature analyzing individual performances which also proved interdependence between cognitive ability and performances (Jex & Britt, 2008).

Interesting discovery in team effectiveness literature is the fact that team composed of highly skilled individuals is more effective than teams composed of individuals with lower level of absolute skills (Hackman, 1987; Guzzo & Shea, 1992). Although team members' skills and abilities have positive correlation with effectiveness, it doesn't mean organizations only need talented individuals to create effective teams. Another consistent conclusion in literature is although absolute level of individual skills and abilities is necessary in teams; organizations must consider the total sum of skills and abilities in teams (Campion, Papper, & Medsker, 1996). For example, successful basketball team must have pointers to achieve points during game. On the other hand, important players are those who can jump or play defense. It was proven that team member diversity has positive correlation with team performances (Guzzo & Shea, 1992), and teams with diverse knowledge and skills grade their own effectiveness much higher (Magjuka & Baldwin, 1991).

3. PERSONALITY TRAITS

Despite the significance of skills and abilities, in practice situations where teams with high-quality individuals are ineffective are often. Beside cognitive ability, personality traits are a good predictor of performances. Most reliable predictor is team consciousness that reflects as reliability and regularity in performing task related activities (Barrick & Mount, 2005). Van Vianen and De Dreau (2001) found that harmony and consciousness in teams are related to performances. Same conclusions produced meta analysis of other authors (Peeters, Van Tuijl, Rutte, & Reymen, 2006). Interesting conclusion of these authors is that changes in harmony and consciousness have negative impact on team performance.

Researchers analyzed influence of personality traits on team performances in respect with type of task given to team members. LePine, Colquitt i Erez (2000) found negative correlation between consciousness and effective decision making when decision making rules demand the need to adjust (Le Pine, Colquitt, & Erez, 2000). Adjustment to modified conditions is difficult for individuals with need for stability. Other authors came to the conclusion that effect of personality traits varies upon task as well (English, Griffith, & Steelman, 2004). Another argument why personality is important is it's' influence on team climate. George concluded that teams differ on affective tone determined upon individual personalities (George, 1990). The fact that personality influence team climate is not surprising considering the fact that personality traits of all individuals affect organizational climate (Schneider, 1987).

Specific combination of personalities in team has a great influence on team performances. There could be conflicting personalities in team environment, and it is also possible that one individual has a bad influence on team performances just because he/she possesses certain personality trait. Barrick et al.,

(1998) found that teams with emotionally unstable members have lower values in cohesion, flexibility, communication, conflicts and division of labor, in comparison to teams without that type of member. However, one emotionally unstable team member does not influence performances in negative manner (Barrick, Stewart, Neubert, & Mount, 1998).

Bell conducted meta analysis of relationship between personality traits and performances. Her results indicate the fact that average team consciousness, cooperation, extraversion, emotional stability and openness to experience have positive correlation to performances (Bell, 2007). Likewise, teams consisting of highly conscious members who cooperate achieve higher performances (Halfhill, Sundstrom, Lahner, Calderone, & Niels, 2005). At the same time, teams with members who have low need for cooperation are not skilled in acquiring new knowledge (Mathieu, Maynard, Rapp, & Gilson, 2008).

Spectrum of personality traits analyzed in relation to team performances is extremely wide and surpasses the most popular model in the field - Big Five model, that considers neuroticism, extraversion, openness, agreeableness and consciousness (Costa & McCrae, 1995). Many authors include orientation to achievement and dependability (LePine J. A., 2003), assertiveness (Pearsall & Elis, 2006), and locus of control (Boone, Van Olffen, Van Witteloostuijn, & De Brabander, 2004) as significant personality traits in teamwork and team effectiveness.

4. ATTITUDES

Effects of attitudes on team effectiveness can manifest in one of two ways. Campion defined direct effect as „preferences towards teamwork“ that reflect desire of team members to be in team environment (Campion, Medsker, & Higgs, 1993). Irrespective of team presence in organizations, not everyone likes to work in teams and certain employees prefer individual work. Teamwork may bring frustrations due to social loafing, conflicts and other problems. Campion et al., (1993) concluded that teams are less effective in general, looking at several criteria, when members have low preferences towards teamwork (Campion, Medsker, & Higgs, 1993). Other authors came to the same conclusion that preferences towards teamwork increase effectiveness (Bell, 2007; Jung & Sosik, 1999; Watson, Johnson, & Merritt, 1998), quality of teamwork (Eby & Dobbins, 1997; Harris & Barnes-Farrell, 1997) and team sustainability (Harris & Barnes-Farrell, 1997).

Second way of influence attitudes have on effectiveness is through similarities in them. Taking into consideration the findings of social psychologists that people like people similar to themselves (Byrne, Clore, & Smeaton, 1986), teams function better when there is moderate similarity of attitudes on significant matters like team leader effectiveness or organizational support (Bliese & Britt, 2001). Despite potential value of similarities, there are considerable dangers in situations where team members are much alike. When team members agree on every issue, necessary debate in work activities lacks and team members become resilient to changes. Janis (1982) defined such dynamics as group thinking and described it as „model of thinking individuals adopt in cohesive groups in situation when team unity has prevalence over realistic consideration of alternative ways of action... Group thinking is related to deterioration of mental efficiency, reality checks and moral judgment as a result of group pressure“ (Leana, 1985).

5. DIVERSITY

Diversity domain has developed over the last decades and covers a wide range of different phenomena. The term diversity is used in this paper to describe the distribution of different characteristics among interdependent team members that may affect effectiveness, and as a representation of the influence of heterogeneity in teams on processes and outputs.

There is an old dilemma about „homogeneity and heterogeneity“. This a problem of increasing diversity for the purpose of multiplying available set of skills and perspectives necessary for problem solving, but making work and cooperation harder at the same time among significantly different team members (Schermerhorn, Hunt, & Osborn, 2005). Relatively homogenous teams in age, gender, ethnicity, race, experience and culture have quality interpersonal relationships and interact easily during teamwork. On the other hand, homogenous membership may limit the team due to shortage of ideas, creativity, and same views on the problem at hand (Schermerhorn, Hunt, & Osborn, 2005). Certain differences among team members are inevitable, some are even desirable (Mihailović & Ristić, 2005).

Heterogeneous team, with members that vary in demographics, life style, experience and culture, also bring potential advantages to teamwork. Diversity is a rich source of information, talents and different perspectives that can advance problem solving in teams and increase creativity, especially with complex and demanding tasks. Research has shown that team diversity may be the cause of bad

performances, especially in early phases of team development. Problems occur as interpersonal stress or conflict due to diversity. Solving these problems may slow down team development and interfere with interpersonal relations (Schermerhorn, Hunt, & Osborn, 2005), but heterogeneous team have an excellent position for utilizing positive aspects of diversity in achieving high performances after handling difficulties at work. Although it takes more time and effort to create great teamwork based on diversity, long-term benefits in terms of creativity and performances make the investment worthwhile. Full potential of heterogeneous teams is one of great strengths in high performing organizations.

Personal characteristics significant from the diversity aspect can be classified in several ways, as: clearly visible characteristics (e.g. race, gender, age), characteristics evident after introduction (e.g. personality traits, knowledge, values), and characteristics in between two extremes on a transparency continuum (e.g. education, years of employment). Some of them have direct (e.g. education), and others indirect (e.g. age) effect on work results (Jackson, Joshi, & Erhardt, 2003). Jackson et al., (1995) also defined taxonomy of job related attributes and interpersonal related attributes, and grouped them as superficial and essential. Race, age and gender can shape interpersonal relationships, but don't usually affect performances. Differences in knowledge, skills and abilities (e.g. position, education, permanent job), do have a direct impact on performances.

Research shows that diversity is a complex input and findings of different researchers are often conflicting. Some believe that influence of diversity on processes, emerging states and outputs is positive, negative or non-existent (Webber & Donahue, 2001). For example, Campion et al., (1993) looked at heterogeneity in service sector and found no connection with productivity and satisfaction (Campion, Medsker, & Higgs, 1993). Additionally, studies have shown that diversity is in interaction with time (Harrison, Price, & Bell, 1998), task (Pelled, Eisenhardt, & Xin, 1999) and organizational culture (Brickson, 2000; Ely & Thomas, 2001). Though there is a vast literature in the field of diversity and several comprehensive literature reviews (Jackson, Joshi, & Erhardt, 2003; Milliken & Martins, 1996; Williams & O'Reilly, 1998), focus of this paper is on several individual characteristics of team members: demography, functional diversity, personality traits and status.

Demography. Webber and Donahue conducted meta analysis with the aim to find the influence of demographic diversity, and did not manage to prove the relationship with cohesion or team performances (Webber & Donahue, 2001). Several other researchers found diversity in age (Kilduff, Angelmar, & Mehra, 2000) and years of employment (Jehn & Bezrukova, 2004) to have influence on performances. It was shown that ethnicity, gender, age, years of employment and education (Jackson, Joshi, & Erhardt, 2003; Kirkman, Tesluk, & Rosen, 2001; Leonard, Levine, & Joshi, 2004; Li & Hambrick, 2005; Mohammed & Angell, 2003; Simons, Pelled, & Smith, 1999) have negative impact on processes (e.g. managing conflict), emerging states (e.g. empowering employees, commitment to organization) and performances (Townsend & Scott, 2001; Watson, Johnson, & Merritt, 1998). But, if time aspect is taken into consideration, findings change. Harrison et al., (1998) noted that differences in age stop having influence on performance when team members spend significant amount of time working. It can be concluded that effects of diversity vary depending on team task, culture and climate in organization (Jackson, Joshi, & Erhardt, 2003).

Functional diversity. Functional diversity is defined as degree to which team members differ among each other in terms of functional career (Bunderson & Sutcljffe, 2003). This aspect of heterogeneity isn't always

related to increased performances (Carpenter, 2002; Jehn & Bezrukova, 2004; Pelled, Eisenhardt, & Xin, 1999; Pitcher & Smith, 2001) and it was found that it can limit the processes and effectiveness due to numerous appearances of conflict (Knight, et al., 1999; Pelled, Eisenhardt, & Xin, 1999), bad information exchange (Ancona & Caldwell, 1992) and slow response time to set demands (Hambrick, Cho, & Chen, 1996). Despite this fact, different theoretical and practical approaches emerged lately regarding functional diversity. Bunderson and Sutcliffe (2002) found that different conceptualization of functional diversity may influence processes and performance. They introduced the term interpersonal diversity (e.g. degree in which team members posses highly specialized or wide spread of knowledge in certain fields) and concluded that interpersonal functional diversity (among several team members) has a negative impact, while intrapersonal diversity (heterogeneity inside the individual) has a positive impact on data processing inside team and on performances (Bunderson & Sutcljffe, 2003).

Differences in personality traits. Personality traits as individual predispositions to react in a similar manner in different situations (Mihailović, 2010), brought the array of various conclusions in the literature. Authors found that diversity in extraversion (Mohammed & Angell, 2003; Neuman, Wagner, & Christiansen, 1999) and emotional stability (Neuman, Wagner, & Christiansen, 1999) has positive impact on performances. Also, this type of diversity has negative impact on processes (Mohammed & Angell, 2004), while diversity in agreeableness and neuroticism has negative influence on performances (Halfhill, Sundstrom, Lahner, Calderone, & Niels, 2005; Mohammed & Angell, 2003). Besides Big Five personality traits, diversity in perception of urgency has a positive correlation with resolving conflict in teams (Mohammed & Angell, 2004; Landy, Rastegary, Thayer, & Colvin, 1991).

Integration of different personalities is an important aspect of teamwork. FIRO-B theory identifies differences in relationships between individuals in groups upon their needs for love, participation and control. These three groups of needs are the key in work environment and determine behavior of each individual. Schultz, the author FIRO-B theory, believes that groups with compatible members are more successful than groups in which members do not share the same needs. Symptoms of incompatibility may be members' withdrawal, open hostility, fight for control and domination of few. If managers don't pay attention to members' compatibility in times of forming teams, a vase amount of time is lost on resolving interpersonal conflicts (Schultz, 1958).

Status. Another source of diversity is status – rank, prestige or position of team members. Team member's status is influenced by several factors: age, years of employment in organization, profession, education or performances. Status congruence occurs when position of the tem member is equivalent to status outside the team. Problems occur with status inconsistencies, such as if a younger team member takes on leader's role in the team with senior and more experienced workers (Schermerhorn, Hunt, & Osborn, 2005).

6. CONCLUSION

There are many individual characteristics of team members that influence team effectiveness. Most important characteristics, which were in detail explained in this paper, are: knowledge, skills and abilities, personality traits, attitudes and diversity. Looking at knowledge, skills and abilities most important is knowledge of task, average cognitive ability, and absolute level of skill. Personality traits of all individuals affect team climate and specific combination of personalities in team has a great influence on team performances When it comes to attitudes, preferences towards teamwork bring high performances and last, but not least, diversity is a complex input and findings of different researchers are often conflicting. The main dilemma is about „homogeneity and heterogeneity", of team members and the influences of both approaches. Each of individual characteristics may have a positive, neutral or negative impact on overall performances depending on different organizational, situational or contextual factors.

[2]Selaković&Partners marko.selakovic@selakovic.rs

Abstract:*The purpose of this paper is to present the review of the current research conducted in the area of job satisfaction in the university settings, with the specific emphasize on interpersonal and collegial relationships. Job satisfaction is one of the most important variables in the field of the business psychology, sociology of work, and organizational behavior. According to the body of literature, interpersonal relationships have a strong impact on job satisfaction; social support and good interpersonal relationships at the workplace were even found to have a mediating effect on job dissatisfaction rooted in other aspects of the job (Morison, 2004). Interpersonal and collegial relationships within department were found to be the influential factor of the job satisfaction for the faculty members.The relationship with the department head wasfound to influence job satisfaction, with a better relationship with the department head predicting a higher job satisfaction (Drakich et al., 2012).However, all aspects of the impact of the interpersonal relationships on the job satisfaction of the faculty employees have not been that well researched so far as the job satisfaction in the other professions, and literature review indicated that some of the factors that are influential in other professions might not be that influential with the faculty members.*

Keywords*: business psychology, job satisfaction, interpersonal relationships, literature review*

1. INTRODUCTION

The concept of employee job satisfaction has been the topic of interest for the several disciplines –business psychology, sociology of work, and organizational behavior. Employee job satisfaction is a multifaceted construct, influenced by a number of different intertwined external and internal factors. There are several definitions of job satisfaction that can be found in the literature. Locke (1976, as cited in Saari and Judge, 2004) defined job satisfaction as a "pleasurable and positive emotional state, resulting from the appraisal of one's job or job experiences" (page 1304). Brief (1998, as cited in Weiss, 2002) defined job satisfaction from the viewpoint of the positive or negative attitude toward job, and Spector (1997) argued that there are two factors influencing job satisfaction: personal characteristics of an individual and overall job environment.

Why is the study of employee job satisfaction important? According to Landy and Conte (2010) job satisfaction is directly related to productivity level, job performance, job turnover, absenteeism, both organizational citizenship behavior and counterproductive behaviours and a number of other different job related outcomes. The existing body of literature indicates that number of different factors can influence employee job satisfaction.

Job satisfaction has been theoretically explained within several different theoretical conceptual frameworks: process theories, situational theories and content theories. All three groups of theories explain job satisfaction from the different viewpoints. Process theories such as Porter and Lawler model, look at the values and expectations that influence job satisfaction; the greater the disproportion is between some elements of the work that the individual values (e.g. high wages, opportunities for promotion) and the possibility of achieving this goal, the greater will be the dissatisfaction with the work and vice versa.

Situational theories look at the organizational culture and person-organization fit. According to situational theories an individual will adapt his or her behavior to the change in the external environment. Quarstein,McAffee and Glassman (1992) conducted a study in order to test the situational occurrences theory of job satisfaction. The results of the study indicated that a number of situational characteristics and occurrences influenced an individual's job satisfaction. Herzberg's dual factor theory (1957) also looked at the job satisfaction According to this theory satisfaction in the work setting is determined by two separate variables satisfaction and dissatisfaction, which are influenced with the wide range factors. He differentiated

two sets of factors – motivators that directly influence job satisfaction and hygiene factors that do not have a direct influence on job satisfaction but their absence results in increase in job dissatisfaction.

The content theories take a dispositional approach to the job satisfaction, looking at the wide range of personality variables and how they relate to the job satisfaction. Maslow theory of needs with the need for individual growth and self-actualization viewed as the factor influencing job satisfaction, is an example of an dispositional approach to job satisfaction (Landy and Conte, 2010).

A number of different factors influencing job satisfaction in various settings have been researched. All researchers recognized that people and their mutual interaction and synergy are one of the indispensable factors of any institution and organization, strongly influencing the levels of an individual's job satisfaction. Job dissatisfaction has been found to be one of the most important factors influencing employee turnover. However, according to Morison (2004), social support and cohesiveness at the workplace can have a mediating effect on job satisfaction, even when employees are dissatisfied with some other aspects of the job.

2. INTERPERSONAL RELATIONSHIPS

A number of different studies has been undertaken in order to determine influence that interpersonal relationships at the workplace have on overall job satisfaction. Romig, O'Sullivan, and Denmark (2011) and Birx, Lasalla, and Wagstaff, (2011), confirmed interpersonal relationships with coworkers to be one of the main factors influencing job satisfaction of the faculty members. Research has shown that group cohesion and positive interpersonal relationships at the workplace have direct effect on employee job satisfaction and on individual's overall well-being. Inadequate social support and negative interpersonal relationships at the workplace are related to counterproductive work behaviours, negative attitudes toward the job, and a decreased level of overall job satisfaction (Landy& Conte, 2010).

The basic premise of many of these researches was that both interpersonal relationships with coworkers and managers have certain impact on job satisfaction. As mentioned before, collegial relationships are found to be based on two types of relationships: leader-member relationship (exchange) and coworker's interactions (Sherony and Green, 2002). A study conducted by Harmer and Findlay (2005) also indicated that overall job satisfaction of young workers is highly correlated with both the interpersonal relationship with the supervisor /manager and the interpersonal relationships that an individual has with his or her coworkers.

Chiok (2001) explored how job satisfaction is influenced by leadership behaviours. He found significant correlations between five different leadership behaviours and employee job satisfaction; 29% of the overall job satisfaction was explained by leadership behaviours indicating that leadership behaviours are indeed one of the factors that can strongly influence employee job satisfaction.

Birx, Lasalla&Wagstaff (2011) found out that interpersonal relationships at work can be influenced with the intervention programs. In their study they explored influence of a team building retreat on overall job satisfaction and group cohesion. Team building intervention was conducted with a group of participants. The intervention was found to be an effective way to increase faculty cohesion, satisfaction with coworkers and overall job satisfaction. There were statistically significant differences between pretest (before the team building retreat) and posttest (after the team building retreat) on the JDI questionnaire; scores on JDI were higher after the team building intervention indicating that participants' job satisfaction increased after the intervention. However, when the same survey was conducted at the end of semester, several months after the team building retreat, scores on JDI went back to the pretest level, indicating that the positive changes stimulated by the retreat were not maintained over the course of the semester. This indicates that follow up team building activities needs to be conducted on a regular basis in order to preserve positive effects of the team building intervention.

3. FACULTY JOB SATISFACTION

Job satisfaction is one of the most important variables in the field of business psychology, sociology of work, and organizational behavior.As noted before, the number of different factors may influence an individual's level of job satisfaction. The existing body of literature related to the specific factors influencing job satisfaction of the faculty members, and influence of the interpersonal and collegial relationships on job satisfaction will be further reviewed.

Tack and Patitu (1992,as cited in Okpara, Squilace and Erondu, 2005) highlighted the importance of conducting specific research on the faculty job satisfaction. They argued that lower level of job satisfaction of faculty members have a direct impact on quality of both educational and research-related activities that university professors conduct. They also noted that some of the factors that might influence job satisfaction in different environments may not be good predictors of the faculty members' job satisfaction, having in mind the specific characteristics of the university jobs.

Bozeman and Gaughan (2011) wanted to find out if job satisfaction of the university faculty members is determined by the same factors as other workers' job satisfaction, and to explore if there are some specific aspects of the academic faculty job determining job satisfaction. In their research they have found three main determinants of faculty job satisfaction: demographic characteristics, colleague interactions, and pay motivation. However, they have found recognition of the faculty member's research by his or her peers to be the strongest predictor of job satisfaction. Gender was also predictor of job satisfaction; male faculty members were more satisfied with their jobs from their female colleagues. Additionally, perception that they are rewarded accordingly to their qualifications was also a predictor of job satisfaction.

Oshagbemi (1994) conducted the study in order to explore potential differences in the levels of job satisfaction of faculty members and their managers (department heads, deans, etc.). A range of demographic characteristic and differences between faculty members at managerial positions and other academics were explored: age, gender, seniority and rank. Significant differences were found between academic managers and other faculty members on five out of eight explored aspects of the job satisfaction. Faculty members at managerial positions were found to be more satisfied in following aspects: teaching, promotions, supervisor behavior, co-workers behavior, and physical conditions/working facilities. Moreover, some of the demographic characteristics were found to be related to the levels of job satisfaction. Age, seniority and rank were positively related to the job satisfaction; older faculty members, with more years of experience and higher ranks were overall more satisfied with their jobs. Gender was, however, not found to be related to the job satisfaction in this particular study.

In addition to the primary research, the secondary sources have been also analyzed in order to explore the influence that different facets of job have on faculty job satisfaction. For example, Sabharval and Corley (2009) conducted secondary data analysis from the data from the 2003 Survey of Doctorate Recipients funded by the National Science Foundation in USA in order to explore the levels of job satisfaction of faculty members, with special emphasize on how job satisfaction differ by gender and discipline. The main findings were that across all scientific disciplines men were found to have significantly higher levels of overall job satisfaction. Moreover, research productivity was found to be correlated to job satisfaction in a variety of ways in different disciplines. The highest job satisfaction for women was in health, science, social science and, lastly, engineering whereas the highest job satisfaction for men was in the fields of social sciences, engineering, and health and the lowest in the scientific disciplines.

Rosser (2004) analyzed data from the National Study of Postsecondary Faculty. The results of the analysis indicated that quality of faculty work life had a direct impact on both job satisfaction and decision to stay at the particular university. The influence of each component of the quality of faculty work life was explored. Utilization of technologies was found to be the important part of the overall work life of the faculty members. Since all faculty members are expected to quickly adopt and utilize modern technologies; for some faculty members this continuous update of skills related to the use of technologies was found to be a somewhat demanding component of the work life. Committee and service work was found to be the source for dissatisfaction mostly for the junior faculty ranks; some of them perceived those duties as a barrier to earning tenure and promotion. Professional development was another strong contributor to the overall work life of faculty members in this study; travel, conferences, trainings, release time, and sabbatical leave, have been shown to be important factors in the retention of faculty members.

Cultural factors were also found to have impact on faculty job satisfaction. Sabharval (2011) explored the job satisfaction of the foreign-born faculty members in order to find out how their job satisfaction compares with native-born citizens. She analyzed secondary data available from the Survey of Doctorate Recipients funded by the National Science Foundation in USA (2003). Main findings of her study were that all categories of foreign-born university faculty members (naturalized citizens, permanent, and temporary residents) showed significantly lower level of job satisfaction compared with native-born faculty members. Moreover, foreign-born faculty members were found to occupy less leadership positions then native born faculty members did, which according to Sabharval (2011) might also have influenced their level of job satisfaction.

Crothers at al. (2010) explored gender differences in promotion and salary negotiation practices of female and male university faculty members in psychology departments, and its influence on job satisfaction. They have found job satisfaction and salary to be positively correlated for male faculty members, but not for the

female faculty members; for female participants job satisfaction was found to be negatively correlated with the perception of negative repercussions for undertaking promotion and salary negotiations. The results of their study also indicated that the level of job satisfaction for women faculty members is related to the interpersonal relationships and overall departmental climate.

Horton (2006) explored differences and similarities between faculty and staff job satisfaction, looking specifically to look at the relationship between job satisfaction and career aspirations of the university employees. According to the results of this study, faculty members had lower job satisfaction from the university staff. Majority of negative responses of the faculty members were related to issues of workload, work/life balance and university policies. Majority of the faculty members also responded that they would not choose again to work at the same institution. Additionally, faculty members also gave more negative responses related to their satisfaction with supervision, management support and communication than staff members did. This findings relate to the body of literature related to job aspirations, indicating that employee satisfaction also depends on career aspirations (higher aspirations of faculty members is related to lower level of job satisfaction).

Romig (2011) conducted a literature review with an aim of examining the various factors that influence job satisfaction, especially by allied health faculty, in institutions of higher education in the U.S. Compensation, advancement opportunities, the quality of supervision and social and collegial relationships were identified as main factors influencing job satisfaction of the allied faculty members. Literature on work experience and job satisfaction was found to be limited; however, according to the literature presented in the article, years of experience did not have influence on job satisfaction. On the other hand, work experience did influence the faculty turnover with higher turnover being related to fewer years of employment. Additionally, job satisfaction seemed to be related with decision making and locus of control for some of the program directors and department heads and with the specific commitment to the department.

A research conducted at the University of Windsor (Drakich et al, 2012) indicated that the relationship with the department head influenced job satisfaction of the faculty members, with a better relationship with the department head predicting a higher job satisfaction. Gender, rank and faculty positions did not significantly influence quality or satisfaction with collegial relationships in this particular study.

Based on the presented literature review we can conclude that interpersonal and collegial relationships within department are found to be the influential factor of the job satisfaction for the faculty members.

4. CONCLUSION

According to the literature, job satisfaction has been found to be the significant factor for the wide area of other job-related issues such as job performance, productivity, organizational citizenship behavior and a number of counterproductive behaviours and turnover (Landy and Conte, 2010). The influence that job satisfaction may have on all these different aspects of job, explains the importance of the research related to the job satisfaction. Since some studies (Birx, Lasalla&Wagstaff, 2011) have shown that employee job satisfaction can be influenced and improved by the intervention programs, this opens the possibility for other work-related aspects to be influenced through increasing the job satisfaction.

Replication of the presented studiescould be attempted in future studies in order to analyze what are the main factors that influence job satisfaction of the faculty members at Serbian Universities, how interpersonal and collegial relationships influence their overall job satisfaction, and to compare these findings with similar research conducted so far in other countries. Overall, the presented literature review indicated that the specific area of faculty job satisfaction has not been that well researched so far as the job satisfaction in the other professions, and that some of the factors that are influential in other professions might not be that influential with the faculty members.

APPLYING PERSONALITY TESTS IN SELECTION OF EMPLOYEES-THE PROBLEM OF CRITERION VALIDATION

Maja Petrović[1], Dobrivoje Mihailovic[2]

[2]University of Belgrade, Faculty of Organizational Sciences, mihailovic.dobrivoje@fon.bg.ac.rs

Abstract: *For decades, there has been a leading scientific debate on the justification of the personality tests use in the selection of employees. Cognitive tests have found their place in the selection of employees issues, but personality tests are constantly reviewed. Reflections of authors are very different and the analysis of the relation of personality and job performance shows increasing complexity. Personality tests are still used in selection procedures and organizational and industrial psychology continues to deal with the issue - whether and when to use personality tests to enable successful prediction of job success. The research results of personality tests can range from extremely optimistic to extremely pessimistic. The problem can not be easily solved and a solution could be to include the impact of different methodologies and different factors on the relation between personality dimensions and job performance. The job analysis is one of these factors. Summarizing research done by different authors, in fact, creates new problems.*

Key words: *organizational and industrial psychology, selection, personality tests, personality dimensions, job performance, job analysis*

1.INTRODUCTION

At the Conference of the Society for Industrial and Organizational Psychology, held in 2004 in Chicago, the panel discussion on "Usability (utility) of personality tests in the selection situation“ was opened. Participants in the panel discussion were the editors of the journals "Personnel Psychology" and "Journal of Applied Psychology", who are the recognized experts in the field of industrial and organizational psychology.

Although the main focus of these discussions was the problem of counterfeiting (giving false answers) of the personality tests' item, the subject was quickly transformed into the problem of criterion validation. The discussants noted that distortion of responses is to be expected and probably can not be avoided, and that its impact on the criterion validation of personality tests is negligible (Morgeson et al., 2007). Murphy said: "The problem with personality tests is not the falsification of responses, but the validity of the criterion variable which is disappointingly low" (Morgeson et al., 2007). Since the predictive value of personality tests is low in the selection context, they should be avoided and not used in a selection of employees (Morgeson et al., 2007).

This view of the low criterion validation of personality tests has been met with the response of other experts in the field of industrial and organizational psychology. The Ones and Christiansen find that the coefficients of validation can be corrective, and that such corrections suggest that personality tests are significant predictors of job performance (Tett & Christansen, 2007). Likewise, Tett find that compared personality-job success need to respect individual moderators, because, for example, using confirmative study (versus explorative) and application of the personality-oriented job analysis contribute to improving the odds of criterion validation of personality tests (Tett & Christansen, 2007).

Regardless of the criticism of two groups of authors, Morgeson and colleagues maintain their claims and point out that an adequate replacement in the selection should be found for the personality tests.

2. PREDICITVE VALUE OF PERSONALITY TESTS IN SELECTION OF EMPLOYEES

In 1965, Guion and Gottier based on the assessment of criterion validation of personality tests, which was 0.09, concluded that it is difficult to justify the use of the above tests in situations that are the basis for making decisions on hiring candidates (Guion & Gottier, 1965). The conclusion of the mentioned authors prevailed for 25 years in industrial and organizational psychology, until the appearance of two meta-analytic studies have determined that criterion validation of personality tests in the selection context is still significant and meaningful (Barrick & Mount, 1991). The optimistic view of the value of personality tests in predicting job performance, was essentially a phenomenon initiated by a five-factor model of personality and meta-analytic

innovation (Rothstein & Goffin, 2006). In this regard, Barrick and Mount, in their meta-analytic study find that the rights of the correlation dimension of the five-factor model of personality and job performance range from 0.04 for Openness to 0.22 for Conscientiousness [1](Barrick & Mount, 1991; Rothstein & Goffin, 2006).

Mentioned results of meta-analytic studies, although overpriced and under-impressive as it is considered by Murphy (Morgeson et al., 2007), represent a real incentive for the use of personality tests in the selection of employees. In addition to that, research conducted back in 2003 estimated that 30% of U.S. companies use personality tests in the selection of employees (Heller, 2005 by Rothstein & Goffin, 2006).

Despite the "revolution" in the application of personality tests in the areas of organizational and industrial psychology, Schmitt still asks: "Why now all of a sudden we look at personality tests as valid predictors of job performance when the validity over time was not significantly changed and remains equal to zero" (Morgeson et al., 2007)? In support of the aforesaid, Murphy stated that the results of the revolutionary meta-analytic studies are impressive, as the correlation between the Big Five dimensions and job performance is only 0.13 (Morgeson et al., 2007).

Using the median as a measure of central tendency, Campion shows that the middle coefficient of validation, in appraising training, is 0.10 with interquartale range (50% of our core measures) from 0.05 to 0.17 (Morgeson et al., 2007). It is possible to assess that their criterion validity is low, in relation to cognitive tests (Morgeson et al., 2007).

Barrick found a few years ago that the personality test, taking into consideration that it is fully corrected, can explain about 15% of the variance, which is impressive, because simple cognitive tests can assess 25% of the variance (Morgeson et al., 2007). Also, personality tests are not good predictors of success in training, as cognitive ones (Morgeson et al., 2007).However, it is certain that there is a potential for incremental validation of personality tests in relation to the applied cognitive tests, but it should be taken into account that they do not say much about who does work well and who does it badly (Morgenson et al., 2007). On the other hand, Campion considers that incremental validation of personality tests is insignificant if the cognitive battery of tests is applied in selection of employees (Morgeson et al., 2007).

Ones and colleagues agree with the statement that cognitive ability, regardless of the type of job and profession, predict overall job performance well, which is not the case with personality tests (Ones et al., 2007). The predictive power of personality tests is that some of the five-factor model of personality dimensions have predictive value in certain types of jobs, for example, diligence in business sales, conscientiousness, emotional stability, and friendly demeanor in police duties, in management of extraversion and conscientiousness. (Ones et al., 2007).

Also, Ones and colleagues believe that the assessment of criterion validation of personality tests based on observed (unadjusted) meta-analytic data is not reliable (Ones et al., 2007). The observed data on meta-analytic studies are biased because the fact that such data influenced by statistical artifacts (restrictions rank and criterion unreliability) were not taken into consideration. If the correction of data on meta-analytical studies was done, as some scholars have done, data on the criterion variable validation of personality tests would be different and suggested that the predictive value in assessing the performance appraisal was low (Ones et al., 2007). In this regard, Ones and colleagues published corrected data amount of meta-analytic study and determined that the predictive validity of the Big Five was 0.27, as opposed to the non-adjusted, which was 0.13 (Ones et al., 2007).

In the opinion of Morgeson and colleagues, correction data for rank restriction and criterion unreliability is justified, while other adjustments overstate the criterion validation of personality tests (Morgeson et al., 2007). Some meta-analytic studies, in addition to the above corrections, corrected data also because of the predictory unreliability and the constructive invalidity (Morgeson et al., 2007). Correction of predictor of uncertainty and constructive invalidity overestimates validation and it shows in research[2] (Barrick, Mount & Stewart, 1998 by Morgeson et al., 2007).

[1] Five-factor model includes five dimensions of personality: Extraversion, Openness to Experience, Conscientiousness, Emotional Stability and Agreeableness.

[2] Barrick, Mount and Stewart have shown that when the validation corrected only for rank restrictions and criterion unreliability, it was 0.23, and when I make a correction for predictor unreliability, validation is 0.26 (Morgeson et al., 2007).

As in previous meta-analytic studies it is not clear how the data was corrected, the only reliable information is observed (uncorrected) (Morgeson et al., 2007). It should be considered that if the scores are corrected, the correction of the rank restriction is possible only if the data suggest this phenomenon, while correction for criterion unreliability is usually small (Morgeson et al., 2007). Still, regardless of the capabilities of correction, it is well known that organizations in the selection process use personality tests without correcting scores (Morgeson et al., 2007). So, Morgeson and colleagues believe that regardless of the impact of statistical artifacts, the only "real" results are uncorrected scores obtained in the research studies (Morgeson et al., 2007). In addition, they make several claims. Firstly, none of the organizations, which in its selection process used personality tests, adjusted score (Morgeson et al., 2007). Secondly, the correction of the scores, the predictor unreliability and constructive disability, which are in meta-analytic studies used by some authors, usually overestimate the validity coefficients (Morgeson et al., 2007).Thirdly, when the correction is performed due to the rank scores of the restrictions, it is only feasible if the information is available to identify it. Fourthly, correction scores for criterion unreliability, although justified, slightly improve the validity coefficients (Morgeson et al., 2007).

On the basis of these four reasons, Morgeson and colleagues conclude that the usefulness of personality tests can only be judged on the basis of unadjusted data, as previous studies have data corrected, for justified and unjustified reasons, and thus overestimated the power of personality tests in predicting job performance (Morgeson et al., 2007).

But either way, not even corrected data, which are published by Ones and colleagues, are impressive in terms of the assessment of corrected validity, which Schidmt and Hunter gave, and which is for the cognitive tests 0.51, 0.54 for the sample of work and for a structured interview 0.51 (Schidmt & Hunter, 1998 by Morgeson et al., 2007).

Tett and Christiansen believe that the correlation predictor (personality traits) and criterion variables (job performance) is not enough data to make a conclusion on the criterion variable validation test figures (Tett & Christiansen, 2007). In addition to measures of correlation obtained in certain samples, one should not lose sight of the population measures of correlation and standard deviation (Tett & Christiansen, 2007). Specifically, based on the value of correlation obtained by meta-analysis, it is possible to make a conclusion about population measures (parameters) of correlations and standard deviations (Tett & Christiansen, 2007). Confidence intervals, which are defined on the basis of meta-adjusted correlation and the analysis of the population of the standard deviation, indicating that 80% of the population correlation is expected in the range from 0 to 0.54, with an average value of 0.30 (Tett & Christansen, 2007). Even in some cases 10% parametric measure of correlation will be above and below the confidence interval (Tett & Christansen, 2007). The key measure is the population standard deviation, whose variability is not the result of statistical artifacts, but of situational specificity (Tett & Christansen, 2007). Namely, the range of the population correlation indicates bi-directive relation of personality and job performance and the related mean value of the correlation test of personality and job performance, which Morgeson and colleagues presented, understates the potential value of personality tests, ignoring the variability in strength and population directorate validation coefficients (Tett & Christansen, 2007). So, bi-direction of the person-job success relations indicate that the validity of personality tests under certain conditions can reach significant levels (Tett & Christansen, 2007). The attention should be drawn to the conditions that create stronger, more positive relation of personality tests and job performance (Tett & Christansen, 2007).

The relation between personality dimensions and job performance is dependent primarily on a number of moderators and their effects (Tett & Christiansen, 2007). For example, as the personality tests, including the Big Five model, are multi-dimensional, it is necessary to extract the subscales that were positively associated with job success rate. Unlike explorative strategies that take all scales (personality traits) into account, even those that are irrelevant to success in business, confirmative research strategies first identified scales that are associated with the activities and then focus only on them [3] Through his research, Tett pointed to the fact that the validation coefficients are higher by application of confirmative rather than explorative research strategy and he confirmed through his meta-analytic studies that by the application of confirmative strategy the validity coefficient is twice higher (unadjusted data: 0.20 applying confirmative study 0.10 using the explorative strategies; corrected data: 0.30 confirmative application strategies, 0.16 using the explorative strategies) (Tett et al., 1999; Tett & Christiansen, 2007).

In addition to the choice of research strategy, an important factor in relations person-job success is the analysis of person-oriented work. In his research, Tett comes to the conclusion that, by using person-oriented work, validity coefficients are higher (Tett & Christiansen, 2007). Tett has empirically shown that the

[3] 80% confidence interval measures include the adoption of standard meta-analytic studies (Tett & Christiansen, 2007).

study, which included analysis of the work had higher average correlation coefficients (Tett & Christansen, 2007).

Morgeson and colleagues believe that the conclusions of Tett and Christiansen are significant, but still we have little empirical data about it on how (Morgeson et al., 2007). It is clear that the average of the test validation may underestimate validity, but it should be taken into account that the direction of person-job success relations should be defined a priori, and not after data collection (Morgeson et al., 2007). In addition it is not clear which theoretical explanations are the basis of the choice of certain personality traits in predicting job performance (Morgeson et al., 2007). For example, Christiansen in one of his research shows that only four personality dimensions 16PF (Cattell Personality Inventory) can be extracted in predicting job performance in managerial jobs (Morgeson et al., 2007). Although the four personality dimensions showed the highest predictive power, it is not clear which theoretical models explain the relation of the above personality dimensions and job performance (Morgeson et al., 2007).

3.CONCLUSION

The use of personality tests in the selection context has always been and will be a critical issue in the field of industrial and organizational psychology. This eternal question is undoubtedly increasingly more thorough, because the dilemma remains the same as half a century ago when Gottier and Guion noted that the two major problems of personality tests were forging responses to the items and low criterion validation.

Although at first glance it seems that the discussion of speakers and critics has not progressed much since the positions are unchanged, there is an evident consensus on several important dilemmas that can undoubtedly affect the future status of personality tests in the selection context.

In fact, despite the claims of Morgeson and his colleagues that the observed scores are the only real criterion of validation data, there is no doubt that there is consensus that the meta-analytic data can be justified and it is correct in the case of rank restriction and criterion unrealiability. Also, Morgeson and colleagues acknowledge that the relationship personality – job performance is complex and that it is dependant on the situational specificity.

Also, correspondence with the Ones and Tet still led to a partial withdrawal in the stance of Morgeson and colleagues that for the personality tests in the selection context it is neccessary to look for an adequate replacement, although there are firm and steadfast conclusions for such a position, because nothing has changed in the criterion variable validation personality tests since the conclusion of Gottier and Guion (Morgeson et al., 2007). It is worrying that since the appearance of the "revolutionary" meta-analytic studies, personality tests are widely used in a selection of employees that, according to the available empirical data, there is no real basis for (Moregeson et al., 2007).

Regardless of the presented facts and information, Morgeson and colleagues conclude that it is necessary to continue research and examine why the criterion validation is low (Morgeson et al., 2007). Also, they think that the search for an answer to the question "whether personality tests are useful (helpful) in a selection situation", should be disposed of and replaced, and focus should be given to testing all the dilemmas and conflicting attitudes that provoked this question, and there are many (Morgeson et al., 2007).

LOCUS OF CONTROL AND LEVEL OF SELF-CONFIDENCE AS PREDICTORS OF STRIVING FOR POWER AMONG MANAGERS

Tatjana Knežević[1], Ivana Katić[2]
[1]Faculty of Technical Sciences in Novi Sad, tatjana.knezevic@mercator.rs
[2]Faculty of Technical Sciences in Novi Sad, ivana.katic@unc.ac.rs

Abstract: *Power as a skill of imposing influence, capacity to change social behavior of others is a significant tool for managerial population who use their position to empower such influence on their employees. Accordingly, their personal predispositions and key character traits significantly influence managers' behavior. In order to study whether locus of control and level of self-confidence are predictors of strive for power the research was conducted among managers in Mercator Serbia Trade Company. The results show that managers are a population which is dominated by internal locus of control, high level of self-confidence and high level of pursuit for power. We established a predictor connection between levels of self-confidence and levels of pursuit for power but not in the case of locus of control and pursuit for power.*

Keywords*: Managerial population, research, locus of control, level of self-confidence, striving for power, connection predictor...*

1. INTRODUCTION

Management means managing a unique activity in order to achieve targets set by the organization with optimum use of resources. Even though the term management includes managing, planning, organization and control, this paper will focus on managing. Within transactional theory of management (Hollander, 1971), the management is regarded as a two-way, transactional process. A person's manner of managing people is a result of interaction between his/her personality and circumstances defined by hierarchical position within the organizational structure. Based on the theory of roles, a certain management style represents the way a person sees their role in the organization and that role mean strong interaction with other people in the company. The success of entire organization largely depends on management mentality, on their way of thinking about production process issues, on their understanding their own role within the organization, the interpretation of co-workers' behavior...

In this paper, special attention is given to attribution style of managers as a relatively consistent and long lasting way of interpreting causal phenomenon, which plays an important role in the cognitive processing of reality. Within his theory of social study Rotter (1966) defines locus of control as 'personality variable that assigns individuals to the degree to which they accept personal responsibility for what happens to them as opposed to assigning responsibility to forces beyond their control'. Attribution style as a relatively consistent and lasting way of affixing causal phenomenon plays an important role in the cognitive processing of reality and as such, has a great significance in efficient management. Joe (1971) and Lefkart (1976) proved that people with dominant internal locus of control overcome life obstacles more successfully and have better orientation. In accordance with Barnes and Seligman (1991), this research looked at attribution style as a character trait, as a person's relatively permanent tendency to interpret causal phenomenon. Hersch and Scheibe, as stated by Fanelli (1977), find that internally oriented examinees show higher degree of dominance, sociability and intellectual efficiency as opposed to externally oriented ones.

Another important aspect that has been analyzed is self-confidence; a personality trait important to the successful functioning of managers, which Cohen (1968) defines as 'a compatibility degree between the ideal and the actual self perception'. Self-esteem is a significant dimension of a personal integrity.

Position in the organizational structure and the role of the manager necessarily carries a certain degree of latent and manifest power that comes from a given position. Research of power problems within the organization go in several directions. The most common ones are those dealing with problems of efficiency in applying specific types of power in managing people. Based on review of numerous research Podsakoff and associates (Podsakoff, Todor, Grover & Huber,1984) come to conclusion that successful managers base their influence on expert and referent power. There have been only few studies on the topic of connection between need for power and the way of managing. McClelland and Burnham (1976), depending on the function of expressed power on a particular person, differentiate between orientation towards personal power and socialized orientation towards power. People oriented towards personal power have no strong inhibition and self-control, but express their power impulsively. Leaders who use power in order to satisfy personal

needs in the first place (the need for self-confidence and status) try to dominate over their subordinates by creating conditions where those people depend on them. Leaders with socialized orientation towards power are emotionally more mature, less focused on themselves, use power in order to satisfy their personal goals and welfare of others as well. Leaders who exercise their power in a socialized way do so in order to develop and build the success of the organization.

This paper will try to establish whether managers have an increased level of striving for power and if locus of control and level of self-confidence can be observed as predictors of striving for power among managers of different hierarchical level.

2. RESEARCH METHODOLOGY

2.1. Subject and problems of research

This paper analyses one segment of management within a specific type of large groups, such as enterprises, where there is a clear hierarchical structure and formally defined managers' roles. The subject of research is managers' personal traits and their connection as well as different social demographic characteristics. The problem of research will be observed from the points of view of psychology, management psychology, labor psychology and can be determined in the following way: ***What level of self-confidence and locus of control do managers of different hierarchical level have and could these personality aspects be predictors of striving for power?***

2.2. Aims and objectives of research

General theoretical aim of the research is improved by understanding the management process and connection with certain characteristics of managers, and the practical contribution of this paper looked at providing guidelines for improvement of the management of enterprises and for high-quality selection of management. The stated objectives are executed in the following tasks: consider relevant socio-demographic characteristics of managers; determine the managers' level of self-confidence and striving for power, or the domination of locus of control; determine the nature of the relationships between socio-demographic characteristics of managers, or certain aspects of the job and analyzed personality traits, as well as determine the degree of connection predictor between locus of control and level of self-confidence on the one hand and striving for power on the other.

2.3. Hypothesis

The following hypothesis were established during research concept:
H-1. Locus of control of people in managing positions is predominantly internal.
H-2. Managers have a high level of self-confidence.
H-3. Managers strongly strive for power.
H-4. Locus of control and level of self-confidence are predictor connected with strive for power.

2.4. Instruments

In order to collect socio-demographic data an adequate questionnaire was designed. Locus of control (LC) was measured by a scale with 20 items and the results were classified into the following categories: strong external LC, exterior LC, the balance between external and internal LC, internal LC and strong internal LC. Managers' level of self-confidence was measured by a scale created by partially taking over items of S-C inventory, (*Self confidence*) Basavanna, adapted to our population (Djuric, 1980). The instrument has 30 items and responses are given on a six-level Likert scale (reliability– Alpha 0.80). Measuring of striving for power was conducted with the test of directive attitude (DA), by Bastina (1972), which is used for diagnostic evaluation of directivity. The test was adjusted to population in Serbia and has good psychometric properties (reliability –internal consistency coefficient is 0.86).The scale has two poles, with 8 items indicating directive or non-directive attitude of the person, with the answers given on a six-level scale. The total score is obtained by adding the positive and the negative part of the scale. The tendency to direct and control the behavior and attitudes of others in accordance with their own beliefs, managers can manifest in the low, moderate, high and very high level.

2.5. Examinees sample

The research was conducted in April, 2012 in the company Mercator-S, Novi Sad. At that time the company employed 3716 people out of which 700 were managers. The sample is appropriate and it consists of 292

managers of different hierarchical level from the territory of Republic of Serbia, working in operations (in retail and wholesale units of different formats) and administration (sector directors, heads of departments and divisions).

2.6. Method of result analysis

The following was applied on the collected data: descriptive statistics, T-test fo rtesting the significance of differences between arithmetic means of two independent samples; analysis of variance to determine the significance of differences between multiple arithmetic means; correlation analysis to determine the degree and direction of association between variables and regression analysis to determine the predictor connection between locus of control and level of self-esteem, on the one hand and striving for power, on the other hand.

2.7. Results

H -1. Locus of control of people in managing positions is predominantly internal.

The results on a scale of locus of control can be classified into five categories, and the following table lists the frequency of examinees in each category.

Table 1: Frequency of examinees by categories on a scale of locus of control

Locus of control	Results range	Frequency	%
1.strong external	0-19	0	0
2.external	20-39	0	0
3.external and internal (balance)	40-59	36	12.33
4.internal	60-79	143	48.97
5.strong internal	80-100	113	38.70
Total:		292	100

The largest number of respondents (almost 88%) has the internal locus of control dominant, and as many as 38.7% of managers strongly manifested an internal locus of control. In a small number of managers (12.33%) locus of control is in balance. The sample does not have managers who interpret causality phenomenon with external factors.

Table 2: Parameters of normal results distribution

Self-confidence	Kurtosis	Std. error	Skew	Std. error
	- 0.040	**0.284**	**- 0.675**	**0.143**

Since the values of skew (coefficient of curve distribution) and kurtosis (degree of elongation of normal distribution) are less than the limit value of 1.96, at a reliability level of 0.05, it can be concluded that the distribution of the results does not differ significantly from the normal distribution, but it is certainly moved to the right.

Table 3: Test of normality of distribution

	Kolmogorov-Smirnov(a)			Shapiro-Wilk		
	Statistic	Degrees of freedom (df)	Sig.	Statistic	Degrees of freedom (df)	Sig.
Directiv. attitude	0.158	292	0.000	0.945	292	0.000

Test results of Kolmogorov-Smirnov and Shapiro-Wilkinson are statistically significant at all levels of reliability, thus proving that the distribution of the results obtained in the study on a scale of locus of control does not deviate significantly from the normal distribution. Based on the above results, it can be said that the initial assumption was confirmed, at which the locus of control of persons in managerial positions is mostly internal.

H- 2. Managers have a high level of self-confidence.

When initiating the research, the assumption was made that the extent to which managers believe in themselves and their abilities manifests when they make business decisions, communicate with others, in their willingness to provide initiatives, appraisals, interactions to praise and criticism, or in all those situations typical of managers' daily routines.

These results can be divided into five categories, which represent certain levels of self-confidence, so that the distribution of frequencies in each category can be seen in the table below.

Table 4: Distribution of results on a self-confidence scale

Self-confidence levels	Results range	Frequency	%
1. negative self-assessment	30-59	0	0
2. low level of self-confidence	60-89	5	1.71
3. moderate level of self-confidence	90-119	112	38.36
4. high level of self-confidence	120-149	165	56.51
5. very high level of self-confidence	150-180	10	3.42
Total:		292	100

The results show that there are no respondents in the category of negative self-assessment, and a very small number of managers have low self-confidence. Most of the respondents 56.51%) have a high level of confidence, then a moderate 38.36% and 3,42% of managers have a very high level of self-confidence. The values of the mean, standard deviation, and minimum and maximum score of the examinees on a scale of self-confidence are shown in the following table.

Table5: Results distribution characteristics on a scale of self-confidence

Arithmetic mean	Std. Deviation	Minimum score	Maximum score
122.76	15.222	80	171

Comparison with theoretical minimum (30) and maximum (180) results, respectively (mean,105), provides the basis for the conclusion that the distribution of the results obtained in this study is movedt o the right.

Table 6: Test of normality of distribution

	Kolmogorov-Smirnov(a)			Shapiro-Wilk		
	Statistic	Degrees of freedom (df)	Sig.	Statistic	Degrees of freedom (df)	Sig.
Directiv. attitude	0,035	292	0,200(*)	0,995	292	0,450

a Lilliefors Significance Correction

Since the test results are not statistically significant, it is proved that the distribution of the results of the self-confidence scale deviates from the normal distribution. Overall, it can be concluded that the population of managers has a high level of confidence, as it could have been expected. In this way the initial assumption was confirmed according to which managers have a high level of confidence. Gaining a higher-level of the organization is to be successful and somehow above the rest of the employees and that certainly contributes to positive self-image.

H - 3. Managers strongly strive for power.

The values of the mean, standard deviation and minimum and maximum score of the examinees on a scale of directive attitude are shown in the following table.

Table 7: Descriptive parameters of results on a scale of directive attitude

			Statistic	Std. Error
Directive att.	Mean		- 0,86	0,485
	95% Confidence Interval for Mean	Lower Bound	-1,82	
		Upper Bound	0,09	
	5% Trimmed Mean		- 0,63	
	Median		0,00	
	Variance		68,648	
	Std. Deviation		8,285	
	Minimum		-31	
	Maximum		30	
	Range		61	
	Interquartile Range		9	
	Skewness		- 0,434	0,143
	Kurtosis		1,773	0,284

These results can be divided into four categories, which represent certain levels of striving for power, so that low, moderate, high and very high levels of striving for power can be distinguished. Frequency distribution in each category is shown in the following table.

Table 8: Results distribution on a scale of directive attitude

Directivity level or striving for power	Frequency	%
(-33) to (-12) – low level	24	8.22
(-11) to (-4) – moderate level	76	26.03
(-3) to (3) – high level	111	38.01
(4) to (30) – very high level	81	27.74
Total:	292	100

As it can be observed from the table, most of the examinees (38.01%) had a high level of directivity, then the most numerous category is the one with very high levels of striving for power (27.74%). Thus, 65.75% of respondents have high or very high striving for power.

Table 9: Test of normality of distribution

	Kolmogorov-Smirnov(a)			Shapiro-Wilk		
	Statistic	Degrees of freedom (df)	Sig.	Statistic	Degrees of freedom (df)	Sig.
Directive attitude	0,079	292	0,000	0,965	292	0,000

a Lilliefors Significance Correction

Test results of Kolmogorov-Smirnov (0,079) and Shapiro-Wilkinson (0,965) are statistically significant at all levels of reliability, which proves that the distribution of the results on a scale of directive attitude does not differ significantly from the normal distribution. The above results confirm the initial hypothesis that managers have a higher strive for power as it is evidenced by the arithmetic mean of the result which is in the category of high level of striving for power.

H-4.Locus of control and level of self-confidence are predictor connected with strive for power.

Before multiple regression analysis was applied a linear correlation was established between striving for power to each of the predictor variables. Based on the values of the Pearson correlation coefficient (0.185) we see that the positive correlation between striving for power and self-confidence is statistically significant at a reliability level of 0.01.Regarding the locus of control a positive low correlation with striving for power is confirmed but it is not statistically significant at a reliability level of 0.05.

Table 10: Linear correlation between striving for power and locus of control, or self-confidence

		Locus of control	Self-confidence
	N	292	292
Strive for power	Pearson Correlation	0,103	0,185(**)
	Sig. (2-tailed)	0,079	0,002
	N	292	292

** Correlation significant at a level of reliability of 0.01

Multiple regression analysis was used to examine the influence of predictor variables of self-confidence and locus of control on the criterion variable, that is managers' striving for power. The introduction of predictors was conducted in blocks so that the first phase included self-confidence, whose predictor's contribution was to explain the 3.4% variance in striving for power and it is significant at a reliability level of 0.01.

The next step was to introduce the locus of control as a predictor, but since it was found that there is a low correlation with striving for power, which is not statistically significant, it was pointless to continue to measure the predictor correlation.

Table 11: Model Summary

R	R Square	Std. error	Change Statistics				
			R Square Change	F Change	Deg. of freedom (df1)	Deg. of freedom (df2)	Sig. F Change
0,185(a)	0,034	8,157	0,034	10,229	1	290	0,002

a Predictors: (Constant), Self-confidence

Table 12: ANOVA model of hierarchical regression

Model		Sum of Squares	Degrees of freedom (df)	Mean Square	F	Sig.
1	Regression	680,598	1	680,598	10,229	0,002(a)
	Residual	19295,922	290	66,538		
	Total	19976,521	291			

Predictor: (Constant), Self-confidence
Dependant variable: Striving for power

Beta coefficient which confirms partial contribution of predictors of self-confidence is statistically significant at a reliability level of 0.01. Based on all of the above, it can be concluded that self-confidence can be defined as a predictor of striving for power, but not the locus of control.

3. DISCUSSION OF RESULTS

Results of the research regarding the locus of control among managers indicate that they have predominantly internal locus of control. The internalized have a strong need for achievement, high standards of work, challenging goals, control and independence. There are a smaller number of managers where the locus of control is in balance, there is an equal amount of the internal and the external one. The sample did not indicate managers whose interpretation of causality phenomenon gives preference to external factors, as it could have been expected, given the organizational culture of the company in which the study was conducted and where very high expectations of staff in managerial positions are openly communicated. Based on findings of Joe (1971) and Lefkart (1976), people with dominant internal locus of control are more successful in overcoming life problems and are better socially oriented. This manager's characteristic can be a significant predictor of their success as managers. The obtained results confirm findings by Hersch and Scheibe (1977) that internally oriented examinees show higher degree of dominance, sociability and intellectual efficiency as opposed to externally oriented ones.

The findings confirm that managers have a high level of self-confidence. Gaining leadership position in the enterprise means that a person believes in their abilities and their efficiency, and could be viewed as an indicator of the existence of feelings of personal adequacy. Self-confidence plays a very important role in business decision making, problem solving, acceptance of risk, responsibilities, expectations of a positive outcome of his own actions and those of his associates.

The results of the research show that the managers are a population with a characteristic high level of striving for power. These results could have been expected since people with developed striving for power prefer those positions in the organizational structure, which allow them to meet this motivational disposition. On the other hand, striving for power is connected to daily managerial demands when it comes to responsibility to influence their associates, in certain situations managers tell associates what to do, monitor their work in order to achieve better performance, convince them of validity of their opinions etc. Those are all integral activities of a manager which they use to guideline their associates' behavior, organize work activities and maintain necessary work discipline. People who avoid affecting other people, who do not want to impose and who find it difficult to tell others what to do, do not possess the characteristics that are a prerequisite for a manager. Striving for power can be seen as a dimension and managers differ in levels of development of striving for power. The results of the research confirm that managers have a high level of striving for power. People with higher level of self-confidence are less susceptible to the effects of social interaction and they tend to influence attitudes and actions of other people whereas people with lower level

of self-confidence do not exert such tendency. Predictors connection of levels of self-confidence with striving for power is confirmed but not in the case of locus of control and striving for power.

4. CONCLUSION

The employees' personality traits have an important role in predicting different forms of their behavior in the context of the work, and that also applies to the managers. Since the management is a very complex psychological phenomenon, the subject of this research the focus was only on some aspects of this role.

This paper studied leadership within specific types of large groups, such as enterprises, where there is a clear hierarchical structure and formally defined roles for managers. The company where this research was conducted has a very clear and rigid hierarchical structure with the organizational culture in which high demands addressed to managers of all levels are very openly communicated. The subject of the research were some aspects of the managers' personality, locus of control, self-confidence and level of striving for power, their interconnectivity as well as the impact of various socio-demographic characteristics and aspects of work on stated personality traits of managers.

The results of the research showed that basic settings, defined in the starting assumptions, were confirmed in most cases. The results analysis, which are in relation to the interpretation of causality of phenomena, confirmed that people in leadership positions mostly have internal locus of control, and these people successfully overcome life problems and are more socially oriented, which is in accordance with the Rotter (1966) theory. At first glance, the dominance of the internal locus of control is preferable and healthier since it gives a person a sense that they can affect the outcomes in their life, making people more proactive and more oriented toward achievement. However, if the internal locus of control is not accompanied with appropriate competencies, personal efficiency and specific capabilities, it can lead people astray, or cause anxiety, neurosis or depression as evidenced in the research of Kobasa (1979). On the other hand, people with external locus of control, unburdened by high expectations, can lead peaceful and happy life, unless existentially threatened, because they are not expected a higher level of performance. Therefore, rigid and extreme manifestation of internal or external locus of control is not desirable. Simply, some life events can be influenced and some cannot. It is very important to properly distinguish them and accept them adequately.

The main findings of this study about self-confidence confirm that managers have a high level of self-confidence, which helps them in making business decisions, problem solving, risk acceptance, responsibility... Cohen (1968) particularly emphasizes the role of self-confidence in social interaction. People with higher levels of self-esteem are less susceptible to the effects of social interaction and tend to influence the attitudes and actions of others, unlike people with lower levels of self-confidence.

The results confirm that managers at higher hierarchical levels have a higher level of confidence. Education level of managers is a significant factor in self-confidence which means that managers with higher levels of education have higher levels of self-confidence. However, the results did not show that older managers have a higher level of self-confidence than younger ones. This finding is very interesting and is not in line with the initial hypothesis that the total life experience affects self-confidence build-up. Managers who work in administration have a higher level of self-confidence than those who work in operations, which may be associated with the level of their formal education. The number of employees who report to them is not a significant factor in the expression of the level of self-confidence nor is the experience in management.

Striving for power can be observed as dimension and managers can be distinguished by the degree of directivity development. The results of this research confirm the initial assumption that managers strive for power strongly and have a tendency to guide and control behavior and attitude of others. People with higher levels of self-esteem are less susceptible to the effects of social interaction and tend to influence the attitudes and actions of others, unlike people with lower levels of self-confidence. The results are in accordance with those theories which see managing as a role, realized through social interaction between the superiors and subordinates in the group. For managers, subjective experience of social environments the reality within which they choose their own ways of handling the interaction with others, which is consistent with the views represented by Hollander (1971).

This research confirmed the predictors' connection of levels of self-confidence with striving for power but not in the case of locus of control and striving for power.

On the basis of these results, it is recommended that in the management selection process an assessment is conducted which will provide information on the level of self-confidence, the dominance of the internal locus of control and presence of striving for power. All these traits are very important for the successful functioning of managers in their daily activities. It would be very interesting to see what the difference in these respects

between management and non-management population would be through the correlation research model. Striving for power, as a complex variable, can be divided and some of its aspects analyzed as well as its impact on management.

Abstract:*The aim of this research was to examine the habits and appearance of average social network users. With particular behavior on social network, user can provide some basic information about his personality and traits. Therefore, determination of user's profilewas based on examination of their behavioron social network. There were 40 participants involved in this research. Each participant provided answers based on his own experience related to using social network. Four categories of social network users were defined based on their activities on social network, number of friends, photos, etc. Results showed that it is possible to relate behavior on social network with psychological profile of a user.*

Keywords*:social networks, cyber profiling, cyber psychology, behavior on social network*

1. INTRODUCTION

The emergence of social media has resulted in new ways of communication, easier insight into the interests and lifestyles of others, increasing the number of acquaintances, and sometimes false representation. The fact is that more and more young people around the world devote its time to build a certain image on social networks such as Facebook, Twitter, etc. The aim of this paper is to examine what is the impact of social networks to the life of respondents, as well as features that are identifiable regarding their behavior on a social network.

Frequently asked question is what encourages young people to communicate, share interests, photos using social networks. Is it loneliness or some other reason? Social networks like Facebook can provide a sense of importance, belonging and closeness with others (Teppers, Luyckx, Klimstra, & Goossens, 2013). Studies show that the average user usually maintains this "superficial", instead of real "offline" friendships. However, the difference is in the reason for usage of social networks. In fact, if Facebook is used to meeting new people and making new friends, loneliness is decreasesin time.

Popularity on the social network can also affect the emotional condition of the user. The relationship between popularity (status) among coevals and social popularity (likes) was investigated (Stopfer, Egloff, Nestle, & Back, 2013). Their study showed that degree of popularity may be determined based on the profile on the social network and profile picture. The authors divided user's characteristics in the following way: agent (usually in terms of an attractive person with a large number of friends on a social network), utilities (those that have a large number of publications by friends of the opposite sex, and who are members of groups with positive character) and creative (people with innovative profiles and elegant pictures). Research has shown that agents characteristics have influence on the status, while the liking and social popularity is influenced by utility and creative characteristics.

Since social networks make it easier to access and communicate with other people, users often expand circle of friends by accepting / inviting acquaintances, and sometimes even strangers into their virtual life. Not knowing who is behind the profile, an individual can become a victim on the Internet (so-called "fake profiles"). Also, depending on the individual's behavior on the Internet, the type of images and the entire social network look, an average social network user can attract a negative audience which can become so-called "cyber bullying".

By his behavior on the Internet, individual reveals his main character traits and habits. Therefore, it is possible to analyze personality with so-called "profiling".

Some authors have written on the topic of cyber profiling relevant to the determination of the subject's profile based on individual'sbehavior on the Internet (Yu, 2013). The concept itself is derived from crime profiling, which refers to the process of determining the necessary information about the type of criminal, as well as its unknown characteristics based on what is known about him. The cyber profiling was analyzed by(Yu, 2013)using the principles of BPA - Behavioral pattern analysis. In his study he included 100 Facebook users. The conclusion to which he came in his research is that the self-control plays a major role on behavior of individuals on the Internet. Social network user share files, comments, favorite music and choose friends and

according that reveals basic information about them - gender, race, age, while the degree of self-control can be established on the basis of non-verbal behavior, impulsivity, failure to envisage a consequence, inconsistencies, etc.

It is assumed that there is a connection between social networks usage and loneliness and shyness. People who are socially anxious and having difficulty in direct communication with the people, see the Internet as a lighter, alternative type of communication (Papacharissi & Rubin, 2000). By following the comments, photos and videos, shy social network users do not have to reveal their true identity and that is exactly what makes it easy in communication with other users (Aydın, Muyan, & Demir, 2013). When it comes to loneliness (Aydın, Muyan, & Demir, 2013) have come to the conclusion that there is a negative correlation between loneliness and online communications in the sense that when increased levels of loneliness, the frequency of communication with friends decreases, and vice versa. Research shows that although personality characteristics affect the usage of social networks, it is not the only factor that affects the use of the Internet as a means of communication (Ross, Orr, Sisic, Arseneault, Simmering, & Orr, 2009).

On the basis of mentioned above, the question which arise is how the average Facebook user in Serbia is experiencing the opportunities that this social network provides, and which are their habits on the social network that reveal their character. For this purpose, a survey was conducted which will be described in the following sections.

2. RESEARCH METHODOLOGY

Since Facebook has become a trend that is followed by all younger and older people around the world aim of this study was to measure the users' habits, their behavior on Facebook and characteristics of their character.

2.1. Defining the problem

The problem which needs to be examined is importance of social networks like Facebook to the users, and what is the main reason for opening the profile. It is necessary to investigate which personal information users leave on their profiles and how they can assist in determining an individual's lifestyle. Certainly it cannot be ignored the number of friends, number of photos as well as their content. These are all important sources of information requested.

2.2. Designing the research instruments

The research will be conducted on a random basis and will last 3 weeks. It is assumed that respondents spend enough time on the Internet, especially on Facebook and will be able to fill out the online questionnaire. Therefore, for the research instrument it will be used poll. The poll will have seventeen questions that are related to the habits on the social network and three demographic questions.

2.3. Participants

This study involved 40 participants (23 - female, 17 - male). The largest percentage of respondents (45%) are in the age group between 25 and 30 years, 33% had between 20 and 25 years, 3% (i.e. only one respondent) aged between 15 and 20 years. Only 15% of respondents aged between 30 and 40 years and 5% over 40 years. The largest proportion of respondents is from Belgrade, several from Novi Sad, Pirot, Pancevo, Smederevo, Krusevac and Uzice. They are all users of Facebook social network and they accessed online poll through their Facebook accounts.

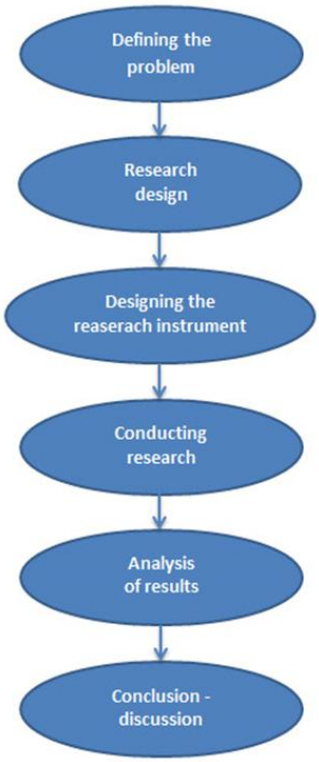

Figure 1: Research methodology

3. ANALYSIS OF RESULTS

Based on the results, the author of this paper has made a classification of participants and divided them into four groups:

- *Facebook addicts* - users whosee Facebook as an important source of information, and way of communicating with even strangers. These are also users who often share their photos, and which every aspect of the "offline" life trying to share with their online friends.
- *Facebook trend followers* - users who access to Facebook because their friends follow this trend. To them Facebook is not very important as a social network, but as aninstrument of following the trend.
- *Curious Facebook users* - these are the most frequent users who are, unlike the previous group, interested in the social network itself, for its functionality, as well as to follow the activities of their Facebook friends.
- *Sociable Facebook users* - these are mostly the users which meet new friends on various places and who are constantly expanding their circle of friends. They have friends abroad and use Facebook as a way to communicate with physically distant friends, sharing photos with them, videos, and so on. They use a check-in option whenever they find themselves in a new, interesting place.

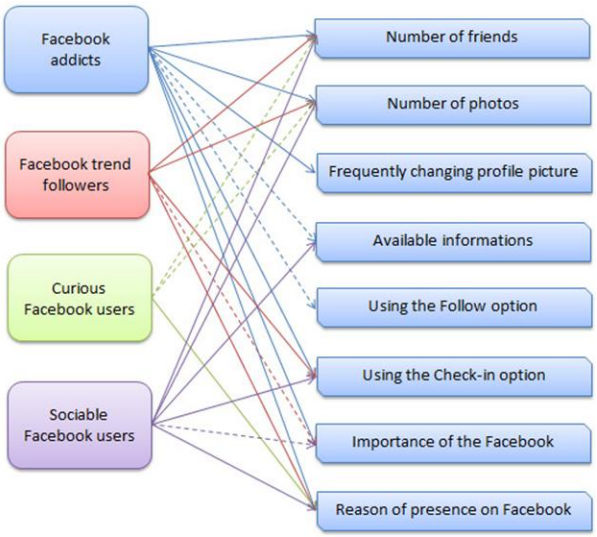

Figure 2: Categories of Facebook users and their habitats

The tables show the answers to the questions in the survey.

Table 1: Results – time spend on Facebook

How much time do you spend on Facebook on a daily basis?	
Half an hour to 1 hour	45%
Between 1 and 2 hours	35%
Between 2 and 3 hours	10%
3 hours and more	10%

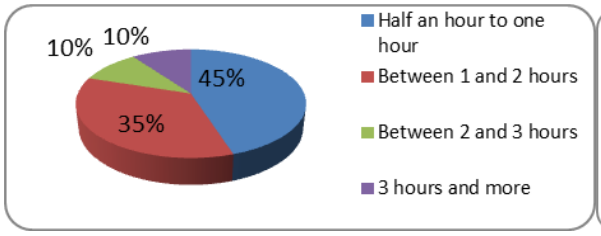

Figure 3: Graphic – time spend on Facebook

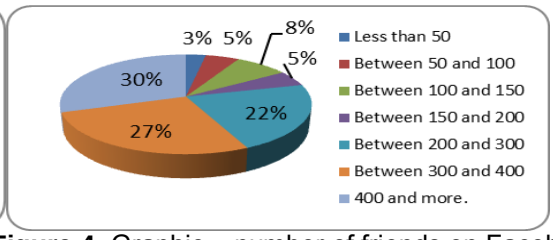

Figure 4: Graphic – number of friends on Facebook

Table 2: Results – number of friends on Facebook

How many friends you have on Facebook?	
Less than 50	3%
Between 50 and 100	5%
Between 100 and 150	8%
Between 150 and 200	5%
Between 200 and 300	22%
Between 300 and 400	27%
400 and more.	30%

The largest proportion of respondents (45%) spends less then hour on Facebook. A slightly smaller percentage (35%) spends mostly two hours. Number of friends varies, but the most (30%) have more than 400 Facebook friends.

Number of photos on profile is one of the indicators of how the subject is active on Facebook, and the results of the survey indicate that the lowest percentage (only 8%) of respondents have over 800 pictures in the profile, and the highest percentage (27%) have less than 50 images on profile.

Table 3: Results – number of photos

How many photos do you have on profile?	
Less than 50	27%
Between 50 and 100	15%
Between 100 and 200	20%
Between 200 and 400	15%
Between 400 and 800	15%
800 and more.	8%

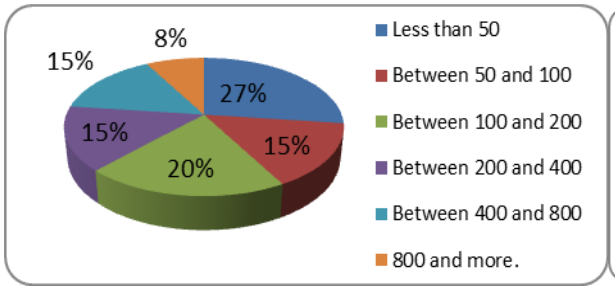

Figure 5: Graphic – number of photos

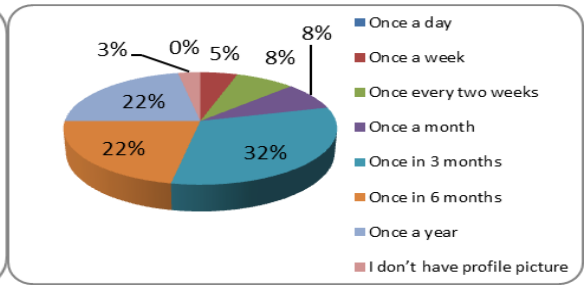

Figure 6: Graphic – Frequency of changing picture

Table 4: Results – Frequency of changing profile picture

How often do you change the profile picture?	
Once a day	0%
Once a week	5%
Once every two weeks	8%
Once a month	8%
Once in 3 months	32%
Once in 6 months	22%
Once a year	22%
I don't have profile picture	3%

The frequency of changingprofile picture also indicates the activity of users on Facebook. 5% of respondents changed the profile picture every week, but the largest percentage of respondents (32%) change their profile picture once in three months. 3% of respondents do not have a profile picture.

Table 5: Results – photos availability

Your photos are available:	
Only me	3%
Only to my friends	70%
Only particular friends	7%
Friends of my friends	13%
Everyone	7%

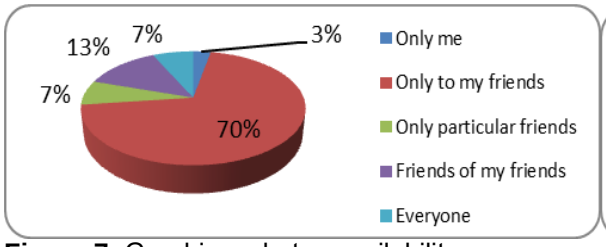

Figure 7: Graphic – photos availability

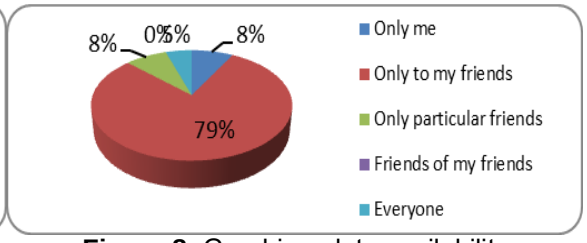

Figure 8: Graphic – data availability

Table 6: Results – photos availability

Your personal information are available:	
Only me	8%
Only to my friends	79%
Only particular friends	8%
Friends of my friends	0%
Everyone	5%

Availability of pictures and basic data is showing how many respondents are open to make new friends and connect with new people. 7% of them leave photos visible to everyone and 13% to friends of their friends. 5% of respondents share personal information with everyone, and 8% of respondents do not share information with anyone. However, the largest proportion of respondents shares photos and information only with friends (70% and 79%).

Of all respondents 73% share music with friends, and even 52% accepted the invitation for friendship from strangers. The largest proportion of respondents (40%) intensively communicates with up to 5 friends. Only 5% of respondents use Facebook as a tool to communicate with more than 15 friends.

Table 7: Results – communication with friends

With how many friends you intensively communicate via Facebook?	
2 at most	10%
Between 2 and 5	40%
Between 5 and 10	28%
Between 10 and 15	17%
More than 15.	5%

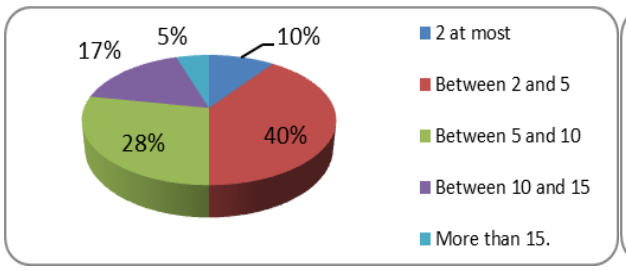

Figure 9: Graphic – communication with friends

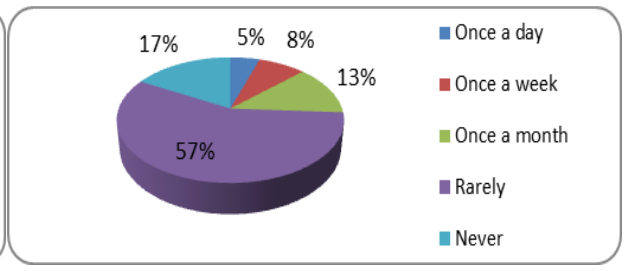

Figure 10: Graphic – posts frequency

Table 8: Results – posts frequency

How often do you post statuses?	
Once a day	5%
Once a week	8%
Once a month	13%
Rarely	57%
Never	17%

According to the survey, 57% of respondents rarely publish status, only 5% of respondents publish once a day. 10% of respondents use the option to follow people who are not their friends. 10% of respondents actively participate in discussions of Facebook groups. The largest proportion of respondents (90%) accesses their Facebook account via mobile phone.

When it comes to the check-in option which Facebook users can use on their mobile devices, the survey shows that 43% of respondents use this option, of which 37% of respondents use it only at interesting places.

During the analysis of poll results it was showed that 10% of respondents said that Facebook is very important to them, 42% believes that access to Facebook has a medium importance, and 15% that it have small importance (see Figure 11). Some respondents indicated that, in addition to connecting with people and sharing photos, Facebook is suitable for easy organization of dates and meetings, as well as the proper place for the collection of new information.

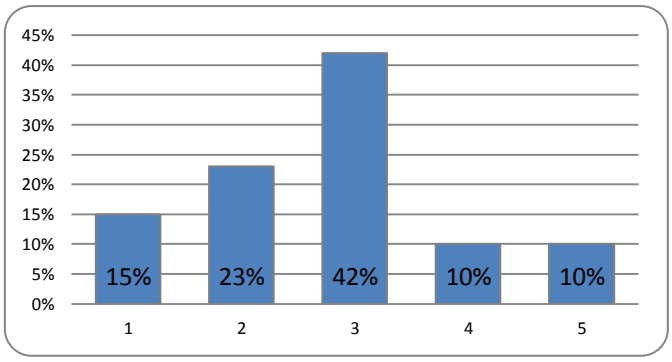

Figure 11: Graphic – Facebook importance for users

The last question concerns the reasons for opening the Facebook profile. This is key question because in most it helps to identify to which category user belongs. The largest proportion of respondents (48%) as the reason for opening the Facebook profile states communication with friends from abroad, which, clearly, indicates that these are *Sociable Facebook users*. 20% of respondents said that they joined to this social network out of curiosity to see how it works and what people share with their friends, and this group of respondents belongs to the *Curious Facebook users*. There are 17% users who belong to the group*Facebook trend followers* because they stated the influence of their friendsas the main reasonfor opening the profiles. 15% of respondents are part of category*Facebook addicts*, because,among other things, they stated that Facebook is extremely important to them, not only for socializing, but also for sharing photos, check-in and connecting with the people in general.

4. CONCLUSION

Taking all the answers of survey participants into consideration, it is possible to determine that among the respondents there are members of all groups represented in Figure 2. Respondents who belong to the first group, *Facebook addicts* have the following characteristics: time spent online (3 hours and more - 10 %), the number of friends on Facebook (between 300 and 400-27%), the number of photos on profile and frequency of changing profile pictures (800 more photos - 8%; once a week - 5%), frequency of publication status (once a day - 5%), network access via mobile phone (yes - 90%), the importance of Facebook (great - 10%). These participants highlighted the importance of Facebook as aninstrumentfor connecting with people and sharing photos and thus they opened their profiles.

On the other hand, among respondents there are those who belong to the group of*Facebook trend followers* with next characteristics: number of friends (which are usually their acquaintances), personal information are available only to friends (79%), intensive communications with up to five friends (40%), rejection the friendship invitation from strangers (48%), rarely publishing status (57%), the importance of Facebook (2-23%). The main reasons for these users to access to Facebook are influence of their friends and a sense of belonging to this trend.

There are also a *Curious Facebook users*, to which is not especially important number of friends (between 100 and 150 - 8%) nor the time spent on Facebook (half an hour to one hour - 45%), but these are the most frequent users who accept the invitation from strangers (52%) out of curiosity and using the option to follow people that are not on their list of friends (10%). The reason for their stay on a social network primarily is curiosity regarding the Facebook functionality as a social network, but also for following the events in the online lives of other users.

For the end, there are *Sociable Facebook users*who open profile to extend the circle of friends they met on their journeys and in different places. These are active users of social networks that leave their photos available to friends and their friends (13%), and for them is extremely important the number of friends (400 or more - 30%). They often use check-in option when they are at the interesting places (37%), but do not attach great importance to Facebook in general (3 - 42%).

From all the above it can be concluded, that based on the respondents' answers and their habits on social networks and Internet in general, can identify some basic characteristics of their personality. The aim of this study was to determine the rough character traits based on the online survey, as well as whether it is possible to determine some of the habits of the participants based on specific questions.

The fact is that social networks have become the basic platform for sharing photos with loved ones, friends, but also the place where you can make new friends. However, the user decides how much and in what way he distributes information about himself. With development of mobile applications, Facebook has opened new doors for spreading among users, and offered users possibility to share favorite moments with friends. Check-in option offers the possibility of capturing the user’s current location.

In order to determine the detailed character traits of Facebook user, this research must be conducted in detailon the contents of customer’s photos, the content of their posts, statuses. Also,the structure of Facebook friends and pages that respondent follows, must be taken into consideration. For the purposes of this paper it was sufficient to collect respondents' opinions about their own habits on the social network.

COMMUNICATION MANAGEMENT AND SOCIAL NETWORKING

MODEL OF CRISIS COMMUNICATION IN MILITARY ORGANISATIONS

Ksenija Djuric-Atanasievski
Military academy, Belgrade; ksenija.djuric@mod.gov.rs

Abstract: *Crisis Communication has become an increasingly important activity of the military organisations. In this study we are considering one of the models of Crisis Communication in the public sector, as well as a special model of responding to crisis, as the most important phase in communication in a crisis case, that may apply in military organization.*

Key words: *crisis communication, crisis communication model, public sector, military organization, crisis management*

1. INTRODUCTION

Crisis communication consists of interlinked processes and activities undertaken by organisations in order to plan for management of unpredictable events. In addition, these activities are parts of continuous research related to public relations and crisis management because inadequate communication, especially in for-profit organisations, can create a perception of crisis; this in turn may affect the reputation, cause financial loss and threaten the existence of the private organisation itself.

Crisis communication has been increasingly perceived as an important activity in the social and public sector. It is due to the fact that the reputation of an organisation relies not only on its ability to manage the crisis, but also in its power to control its public image.

Crisis events in military organisations are always news, because the public is the main stakeholder. The public perceive crisis in military organisations with a lot of scrutiny, as it is the organisation that has a task of protecting the highest values of said society. Crisis communication within military systems creates multiple benefits if it is performed adequately. It lessens the negative effects of the public perception of a crisis, creates trust, and protects the reputation of the military as a socially responsible institution.

Two other elements emphasise the need for preparation and implementation of crisis communication in modern military organisations and these are: the complex roles of the defence forces and the development of information and communications technology (ICT). The tasks of military organisations in many countries worldwide is not only defence but also contribution towards world peace, opposition against asymmetric threats and challenges, and increasingly numerous activities in support of the civic stakeholders of society. At the same time, development of ICT has made mass media an ever-present, accessible, and powerful tool in the information sphere. ICT has reduced the possibility of information control and forced military organisations to be more transparent.

The elements of crisis communication for the Ministry of Defence and the Serbian Army have been included in the existing documents such as *Guidance on Communication Strategy*, as well as instructions on standard operating procedures in the case of unpredictable events. However, there is no policy that would clearly lay out division of jurisdiction and responsibilities related to crisis management; in particular for external stakeholders.

Primary elements of crisis communication in a military organisation that is a part of public sector are not identical with the ones in for-profit organisations or other public sector organisations. Thus it is necessary to examine the model of crisis communication in the public sector and emphasise the specific points of crisis communication in modern military organisations.

2. CRISIS COMMUNICATION MODEL IN THE PUBLIC SECTOR

Various theories of crisis communication, coming mostly from sources within the USA, produced various models. Nevertheless only a few of these are applicable to crisis communication in the public sector. One of these few models was based on analysing the crisis communication in for-profit organisations and then

extrapolated to the public sector. Since these model structures of crisis communication in the for-profit sector have been incorporated into the public sector, it is called a **synthesis model**. (Horley, S., Baker R, 2002).

The synthesis model of crisis communication in public sector organisations has six stages:

1.existing activity related to ongoing public relations;
2.identification of and preparation for potential crises;
3.internal training and rehearsal;
4.a response to the crisis event;
5.evaluation and revision of communication; and
6.Inter-agency and political coordination analysis.

1. In order to create an appropriate public image the organisation must proactively form public relations, be socially responsible, and build a good relationship with journalists. Research in this area has indicated that establishing a good relationship with all stakeholders before the crisis and endorsing social responsibility will increase the organisation's ability to positively influence all interested parties during the crisis event. A proactive stand towards media includes continuous survey of news reports on the organisation, regular contact and visits to news agencies; as well as inviting news agencies to attend important events, take part in training for responses to the crisis event and distributing information that are relevant to organisational crisis management. Equally important is the efficient and positive response to media inquiry, such as requests for interviews or specific information related to defence and security matters.

2. A crisis can be defined as 'a specific, unpredictable and unusual event which creates a high level of uncertainty and (possible) threat to organisational priorities'. (Seeger,M.T and others 2012) In addition to this, another important defining characteristic is the need for change. In the case that change is not needed, the event may be described as (only) a failure. Some organisations define crises as accidents, incidents or conflicts. For this reason it is important that each government entity identify what their perception is of a possible crisis. (Venette, S. J, 2013)

Preparation for a potential crisis starts with identifying and reducing risk that can lead to said crisis. Communication on risk is a two way dialogue between organisation and stakeholders who should be aware of potential risks that the organisation may face and the methods of risk management. Certain government entities and in particular, military organisations often consider risk data to be confidential. This also applies to communication on risk management. The result of such policy is that the public is not sufficiently informed.

The most important activity in the second stage of the model is the preparation of a communication plan. The plan sets out the way in which the organisation will communicate with the public in a certain crisis. Every organisation in the public sector, even those that have not adopted a plan for crisis management, should prepare a plan for effective communication with the public in a case of an unpredictable event. The model for these plans is to contain the following steps: establishment of a special crisis team; selection of the most effective communication methods (communication tools), and assessment of the results. The emphasis in crisis communication plans should be on proactive action in the pre-crisis phase. These plans should be adjusted to each specific potential crisis.

The authors of the synthesis model conducted a study on readiness for crisis communication in 107 state government agencies. The results showed that government agencies do not have proactive communication with the media, although they have developed a good relationship with journalists. Less than half of these agencies had a crises communication plan in place. (Horley, S., Baker R, 2002)

3. The third stage of the model is rehearsal of roles in crisis communication, training and acting out prepared scenarios, and undertaking simulations of crisis communication. A crisis communication team is institutionalised within the preparation for crises with fewer numbers of permanent members. The number of the team members will grow in the moment of crisis with other members joining. These newly joined members would have their role, authority, and expertise defined beforehand.

At this stage the most important thing is selection and training of the spokesperson; one or more of whom will communicate with the public in an instance of crisis. Large organisations, such as an army, should have several spokespersons, i.e. people trained and ready to undertake communication with the public when crisis strikes. In order to gain public trust and support, the most important goals for the organisation are to have enough public exposure, show concern for crisis development, and issue public statements of key personnel. Nevertheless, other member of the military organisation can gain public trust if they are well trained. Well

trained staff are capable enough to prepare and announce appropriate messages, control their statements, and interact well with the media. They also know to provide the right answer that highlights important facts without jeopardising confidential data, prepare succinct answers, and be ready for various requests from the media.

At this stage it is also required to prepare policies on security and quality controls of the measures that organisation employs to prevent a crisis. These policies should be available to media representatives and other stakeholders in the case of a crisis.

The preparation stage of crisis communication relies on three pillars: a crisis plan, a crisis team and a spokesperson that is trained in proper media handling for efficient crisis communication.

4. A response to the crisis event when it actually happens is the key moment for communication. The Synthesis model does not provide specific elements for this phase of crisis communication. The model does not define necessary steps in response to a crisis. However, it would be advisable to identify these steps, which can be outlined as: observation, interpretation, choice and dissemination of crisis messages. (Hale J., Dulek R., Hale D, 2005)

An organisation faces public reaction which is mostly formed by media reports. Crisis produces more intense public emotions which can be influenced by limited access to information, rumours, speculations, and assumptions that may lead to wrong conclusions. Research in crisis communication (Coombs, T, 2005) confirms that a negative reaction by the public to the crisis in any organisation does not always have roots in the crisis itself. It is rather that the organisation refuses to accept responsibility or provide complete and accurate information.

Observation encompasses gathering information on crisis from the place of origin as well as from other sources such as responsible entities outside of the organisation and experts for certain elements of the crisis. The most frequent problems at this stage can be lack of adequate physical indicators of the crisis and inability to use regular channels of communication to collect data due to malfunction of said channels or other various forms of telecommunication network.

Existing information is analysed at the **interpretation** stage. The key task is to establish and identify what is true or half-true, and what is confusing or contradicting information. This is done to address shortcomings such as incomplete and/or contradictory interpretations of the crisis event.

The **choice** of information for dissemination in crisis communication is influenced by the necessity to answer the most important questions and whether the message satisfies public interest. The information must answer questions of interest to the public such as: *What has happened?* What *is the cause?* and *What measures has been undertaken to address the crisis?* At the same time, addressing the public should express behaviour such as empathy and care; competency and credibility, honesty, openness, and commitment. (Djuric-Atanasievski K,Karovic S, 2011)

The message will satisfy public perception if it is well presented which, in other words, means that it has chosen the appropriate aspects of reality. The message should contain the definition of the problem, interpretation of the

cause to it, moral evaluation and/or proposed solutions. Successful presentation of crisis content enables key public stakeholders to assess information, understand implications and, if applicable, undertake action.

Communication done by public sector and private companies differs in legal obligations to provide information. Government institutions and public companies have procedures in place which implement freedom of information and insist on answering the public on any question they may have. Requests for information may be submitted through the media or by individuals requesting access to certain documents. It is common that the public sector would have certain legislative provisions that deal with public access to certain types of information related to military operations, security, investigation and casualties.

Problems that may be present at the choice stage are: lack of time to evaluate and choose alternatives as well as inadequate communication filters. Well prepared communicators in a crisis event need less time to evaluate the significance of all received information and the effectiveness of communication filters. Effective communication filters should give priority to only the information that is relevant to the crisis.

Dissemination or forwarding refers to fast and resolute communication that can help to lessen the effect of rumours and speculations during the time of the crisis; especially in a situation when it produces public fear and uncertainty.

Four steps at the response stage do not represent linear model since one of the activities initiates and completes the other one. These steps represent instead a spiral model. One step would be incorporated into the next one; but at the same time the steps may be repetitive as new information is introduced, interpreted, chosen and addressed to the public (Hale J., Dulek R., Hale D, 2005).

At the response phase, various strategies of crisis communication are implemented. Each one of these strategies may be carried out with different tactics. More than a decade ago, the experience of the US military system offered a list of twelve strategies which represent the stage of proactive response in communication crises (Hunter, D.,2000 as cited in Beyond Maximum Disclosure, Minimum Delay, Military Public Affairs Practitioners on Proactive Crisis Communication Strategies):

1. Openness – all information released immediately;
2. Agenda setting – everything is open to public access, especially at the beginning of the crisis;
3. Relevance – release of information that led to a crisis but without permitting questions on responsive actions
4. Legal privileges – input from a legal team within the organisation that has to be provided at the same time as the media questions are submitted;
5. Legal privileges that are specific to the host country – this is applicable when a crisis is unfolding in a foreign country
6. Coordination of public announcement – this entails that everyone involved in the process of coordination is aware of questions related to the crisis, in order to avoid making any contradictory statements
7. Public opinion – it is necessary to respond to public opinion on said crisis and provide answers to public request for information
8. Response readiness – quick reaction and response to any request for information that the media may have
9. Messages – the appropriate message should be prepared in advance for all scenarios, especially at the initial stages of a crisis;
10. Respect for cultural differences, i.e. awareness of culture, ethnic and language sensitivity;
11. One spokesperson – engagement and training of one person who is ready to answer to all tasks related to the organisation and its role in the crisis;
12. Engagement of a 'fireman', i.e. staff that can analyse all questions that can aggravate the situation during a crisis.

A survey was conducted with professional military personnel of the US army that were engaged in the communication crisis process. The survey results revealed that the most frequently used strategies were messages that were prepared beforehand alongside quick reaction and response to any request for information from journalists and the public media. After that on a list of the most frequently used strategies, comes

'openness' and readiness to provide all relevant information immediately in order to impose their own story. At the bottom of this list are coordination of public announcements, making sure that everybody is on the same page on a crisis and that no contradictory statements are issued. (Beyond Maximum Disclosure, Minimum Delay, Military Public Affairs Practitioners on Proactive Crisis Communication Strategies, 2000).

5. The evaluation is the fifth stage of the crisis communication model which encompasses various activities. As a priority, it includes follow up communication with stakeholders, release of new information on progress and recovery from the crisis, actions that were undertaken to prevent a new crisis, and also, the release of information that have been promised during the crisis but were not presented.(Djuric-Atanasievski K, Karovic S, 2011)

At this stage, proper information will be released to these agencies and services that are in charge of investigating the cause of the crisis. All crises involves investigation that is led by responsible government agency or the organisation itself which is the case with most military organisation. These information must be easy to understand and must be released in due time. During the previous stage of responding to the crisis event, many organisations would initially announce the release of the results of the investigation, but would fail to do that or they would do it after considerable period of time. If an organisation fails to release the outcome of its investigation then the media may do it.

The last component of this stage of crisis communication is an assessment of the 'lessons learnt', that is to say, an evaluation of what was successfully completed and what steps in the process need improvement. This stage is also known as 'post mortem'. The key issue here is an analysis of different aspects of crisis communication. It is related to an analyses of the usefulness of information released as a response to a crisis; and how effective was the dissemination of various messages to numerous stakeholders during the crisis communication.

6. The model of crisis communication for government agencies and public sector differs significantly to crisis communication for independent and for-profit organisations due to the last stage which is inter-agency coordination. Crisis in security sector and especially in military systems, effects the other public sector agencies. Crisis that is of larger proportion and with more casualties can also have impact on other executive and regulative government bodies. It is for this reason that the coordination of crisis communication is very important. It encompasses transparent exchange of information open to public eyes. In addition, this stage includes political analyses that deals with cause and consequences of the crisis effecting not only military organisations but other institutions of public sector as well.

3. CONCLUSION

Crisis communication in a military organisation can be analysed as a specific case of crisis communication within public sector. The synthesis model of crisis communication in public sector organisations sets out six stages; puts emphases on preparation and training for a crisis and clearly defines a response to potential crisis as the most important stage of them all.

In addition to that, it is necessary to be aware of a specific role of military organisations that can greatly influence potential crisis communication. On one side, military organisations are part of public sector and government body that has the task of protecting society and the state. On the other, these specific tasks are influenced by unique nature of military organisations which is characterised by chain of command and decision making process within the limited time-frame.

For these reasons, the synthesis model of crisis communication must be extended to define strategies of proactive response. It is also necessary to choose appropriate policy for relationship with the media. With these additional actions, the syntheses model becomes optimal for military organisations.

Abstract: *The concept of community management in Serbia is spreading in the last few years. Companies became aware of the importance of social networking and their influence on business as well as everyday life. The basics of community management are communication with customers and answering to their needs on the best possible way. Considering the fact this business direction is still in developing process, the most influence on Serbian society have Facebook. The main idea of this study is to approach the concept of community management to people in Serbia, to point out its advantages and development process, but also to point out the differences between social media management and communication management in Serbia and abroad.*

Keywords: *management, communication, customers, social networking, research, development, community*

1. WHAT IS COMMUNITY MANAGEMENT?

Community management can be best described as a complex term, which includes variety of management basics, as well as networking skills. It is a combination of data analysis and strategic inputs for supporting social media strategy, social media campaigns and social reporting, both long-term and short-term engagement. To simplify, it is a mix of skills and knowledge needed for a project, which depends on nature and the purpose of the community. Community management has been treated as a special business direction since the huge expansion of social networks, so today almost every company has its own account on Facebook, Twitter, Google etc. (Gentle, 2012)

Community management is a kind of job direction which is not clearly understandable in Serbia thus is not developed. Still, employers realized that communication with customers is one of the top priorities in their business and that shouldn't be ignored. The most appropriate person for this position is someone who understands the policy of a company, mission and vision, who has information about company itself, but at the same time has marketing skills and creativity. It is important that person is patient and capable to answer to all questions customers have, and to take care about the content of posts which will be posted on some social network.

Considering that on-line communities are really "sensitive", community manager needs to be aware that every mistake can be fatal. It's important that the information we're giving is right and given on time. Besides that, it's of great importance to know when to post something on Facebook, how to reach our target groups and make them trust us.

By defining essential responsibilities of a community manager we can see the complexity of that job. Besides the daily, or better say minute by minute interaction with customers, for that position is important to be “eyes and ears” of a promoting brand as if our own reputation is depending on it. Not only the communication with customers is important, but also interaction with other legal clients and cross corporate agencies. Managing and tracking campaigns, coordinating different spheres of business, creating and updating daily, weekly and monthly reports, translating data into plans for revising the social media campaigns – it’s only a part of job description of community manager. (Bacon, 2009)

In this research focus is on Facebook influence on Serbian society in general and what is the role of community management in business purposes. The goal is to prove what kind of Facebook communication will be the most effective, when we talk about the promotion of a brand or company’s activities. Considering the activities community manager has, which is primarily maintenance of profiles on social networks, here will be focus on the most common ways of communication between companies and customers in Serbia. By companies we mean on international and domestic brands and branches that exists in Serbia.

2. FACEBOOK INFLUENCE ON SERBIAN SOCIETY

Development of community management in Serbia is definitely rising. Community manager, as we said before, could be treated as online PR manager of a company, intermediary between customers and companies, someone who is following situation on market and with online activities is making the brand even better and more successful. Social media marketing as a business direction is trying to get people’s attention, then to make profile visitors to profile followers, followers to buyers, which lead us to sales increase. Only in Serbia there are 3 million Facebook users, which can be treated as a market with a lot of potential clients. Companies, aware of that, are starting to invest in occupation known as “community manager”. However, we can still find a lot of misplaced pages, analytics, market tracking etc. It is of a great importance for companies to realize that the most important thing is following the user’s needs and data updating.

When talking about the specifics of the community manager job on Facebook, it is important to start from the beginning, to give all possible information about the company, business activity, foundation, awards, to leave a contact, pay attention to “about me” part – actually, whatever visitors of Facebook page give the impression of a serious business. Before all of that, it is important to create a strategy for all networks we want to operate on. The Facebook situation is that a people have experienced it as more intimate social network than others, so we need to put an effort to share and post things with positive connotations. We should write simply, understandably, enrich pages with pictures, videos, applications – leave a good visual impression. Often we can unconsciously run negative campaign, so in this situations is important not to argue, but to admit the mistake and to divert attention from the bad to a good thing brand carries. Statistics should be regularly monitored, content changed and adapted according to indicators. (Kirkpatrick, 2010)

2.1. Mistakes and crisis situations on Facebook from the perspective of community manager

As in any business, mistakes are the part of it. Without them we wouldn't be able to have a real insight into what is good and what is bad for us, how to approach to a problem, what to edit, what to delete. When a company has a good community manager or some external collaborator who takes care of company's account on social networks, there is larger possibility errors will be corrected on time and situation will be solved in the best possible way. In every business there are crisis and the reason for their occurrence may be accidental, intentional, products of competition or perhaps expressions of customer's dissatisfaction.

Crisis situations, although they can be very stressful, in the future can reduce the possibility of mistakes in business. In community management there is a "Response Time", which means there is a certain agreed period of time for which community manager needs to respond to an emergency. It suggests that if some undesirable situation happens, community manager will have some time to respond to that situation. The essence of that is to reduce the time as much as possible.

When we talk about those problems in Serbia, crises are usually associated with Facebook, but also with Twitter. Users on these social networks are very different and therefore, there are different approaches for solving problems. As we said before, critical situation can be caused by competitors, dissatisfied clients or some third group of people. People who are loyal to brand usually solve problems directly and they are trying to find a solution. Problems can be made by Facebook status, posting pictures, creating "anti-groups" etc. To reduce and eliminate mistakes and crises, it's very important that community manager react to any kind of people's dissatisfaction and for doing that, it's important to have skills we mentioned before.

Considering that people are the key factor in this type of business, we should try to include them in as many activities, like – asking them for advice, for suggestions about work, brand, actions etc. It is important to build trust with customers, because that will help us to get over crisis.

3. SPECIFICS OF SOCIAL MEDIA MANAGEMENT AND COMMUNITY MANAGEMENT IN SERBIA

It is often a case that, when the job description of a community manager should be given, people think it is a campaign guiding and collaborating with people who are in charge of budget, brand, stores, better say - with anyone who can give us any information about the brand. In Serbia, the practice differs from the theory, so the job of a community manager often identifies with customer service. However, this is far from the truth, although the description of the community manager includes communication with target groups /customers/consumers. People don't pay too much attention to this job, unaware of the fact that it is a job without work time, without holidays and weekends – you always need to be there for your followers. If this work is done within an agency highly specialized for social media marketing, which is rarely the case in Serbia, it can be treated as a desk job, considering you need to participate in activities, starting with creating online campaigns through collaboration with designers, up to posting something on social network.

For this job is important that there is awareness of the individual who is doing this job that he not only represents the brand but also the company. Besides rich vocabulary, creative writing and creativity in general, computer literacy and continuous developing, reading and following trends (or better say, be well informed) is also of a great importance. Another "skill" need is listening to the needs of the target group and indentifying what content will be the most interesting for them. Although this job is still not well defined in Serbia, the competition in this business exists so we need to put an effort to create

something new, unique and something which no one else has the thought of, and in this time of facilities hyper-production, it is very difficult to achieve.

In Serbia is often a situation that clients usually know what they want to achieve by promoting their brands, on which networks they want to promote and how much they want to invest in a particular project. Usually the situation is everyone wants to be represented on Facebook, not realizing the importance of other social networks, so basically the number of clients who want to be promoted on other social networks beside Facebook and Twitter is negligible.

The problem with community management development in Serbia is the fact that a small amount of companies has internal resources (employed persons) who can answer to needs of online communication. In that case, companies often decide either to introduce the business direction under the leadership of their company or to engage the help of an external collaborators (outsourcing). External collaborators in Serbia are usually marketing and PR agencies, which are not focused precisely on online marketing and PR, but they perform those activities as a part of their regular activities, ie. diverted part of the social media campaign on specially created social media accounts for specific campaigns. For social media marketing mostly are engaged companies whose representative offices are outside of Serbia and that's the reason there aren't enough trained experts in the field of community management. In Serbia, situation is that often individuals are conducting various campaigns, instead of separate specialized agencies for social media marketing. Therefore, companies should wait for using social media for business purposes, while they don't "build" a person who will deal only with community manager. (Solis, 2010) Until then, companies operating in Serbia will be forced to hire external resources to communicate on social media, but only at a basic level of communication. As usually happens with most of professions, it's very likely to happen the invasion of this profession of community manager, but it's well know that situation will make clear as to distinguish individuals and companies that have measurable results.

3.1. Difference between community management in Serbia and abroad

Talking about this occupation, the difference in business should be found especially in culture and area we live on. It is difficult to present something which will fully respect the spirit of the Serbian language. This is especially the case when it comes to foreign brands, whose campaigns adapt the area in which the brand is promoted. In addition, our culture is more narrative than visual, grammar is complex and it is difficult for us to seen the message in shorter forms. The opposite example we can find in Western cultures, which can send the message in a short way, without the fear it won't be understood. Besides that, we can see that people more invest in campaigns and contents abroad thus they are getting better and more complete feedback, customers are becoming more interested and they are always waiting for more. Considering all of this, the fact is that creators of campaigns have in mind also the psychological aspect of customers/users. (Evans & McKee, 2010)

People in Serbia are not yet relaxed when it comes to using social networks. Again, culturally speaking, people generally do not debate online, do not express their opinions publicly and usually they don't go beyond some of its narrow interests. However, there is a lot of potential to encourage people to engage and embrace all the benefits social networks have.

3.2. Difference between Community Manager and Social Media Manager

Marketing experts have pretty same opinion about the difference between those two professions. They treat them as separate – community manager is someone whose activities we mentioned before, that

is – they are in charge of placement of the content and social media manager is a person who is in charge of planning network strategies as well as budget part, with experience in that area. In Serbia is case that the entire job is done by one person, but there are certainly chances that result will be better if more than one person is involved in that work and if their activities are divided, instead of dealing with everything in the same time.

Confusion is made because in both cases the person managing the initiative is responsible for being conversational, for making sure that the success of interactions have the desired outcome and they are sometimes using similar tools. (The Community Roundtable, n.d.)

Social Media Manager	**Community Manager**
Responding to conversations about the brand	Moderating conversation and encouraging specific topics
Managing tools - mostly social networks (Facebook, Twitter, etc)	Managing tools – might be a combination of enterprise and social networks
Planning and developing strategies for increasing engagement	Building relationships with key members of the community
Reporting	Welcoming members to the community
Content creation designed to induce conversation	Enforcing guidelines

4. RESEARCH RESULTS

In order to examine the habits and attitudes of Facebook users, with aim to increase effectiveness of Facebook communication between companies and consumers, we conducted an online survey. The main objective of companies which are present on Facebook is to send the right message at the right time, in the right place. In this way, the relationship between companies and consumers becomes stronger and consumers are more engaged to their favorite brands, and therefore to companies that produce these brands.

The survey involved a random sample of 200 respondents – Facebook users, where 60 % are female and 40 % male. 75 % of participants are aged between 21 and 25 years, 16 % are younger than 20, and 10 % are aged between 26 and 30 years. They are all people who live in Serbia, with different household incomes, but the largest group is the one where income is bigger than 100.000 RSD, with 27 % of survey participants.

The question regarding to frequency of use of Facebook indicated that 97 % of survey participants visit their profiles several times a day, with an average stay of 10 minutes per visit. Other 3 % of respondents visit their profiles once a day.

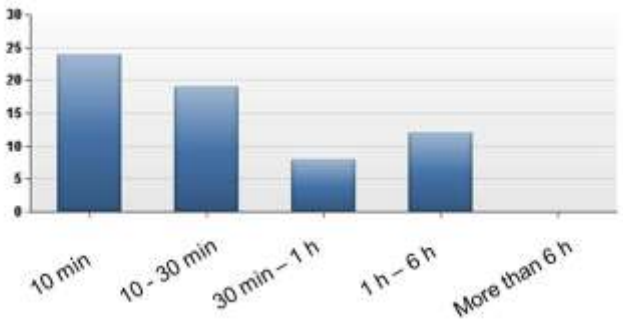

Figure 1: Frequency of Facebook use

We have analyzed the time of the day when our respondents most often visit Facebook. The highest percentage of visits occurs after 9:00 PM (52 %). Possible reason lies in the lifestyle of the majority of Serbs. Working hours in Serbia are until 5:00 PM, but employees often stay longer at work. Students are attending schools and faculties during the day, and unemployed are busy with the house chores. They all have in common the fact that their free time occurs just after 9:00 PM, when they like to socialize through social networks unless they have not done it in person.

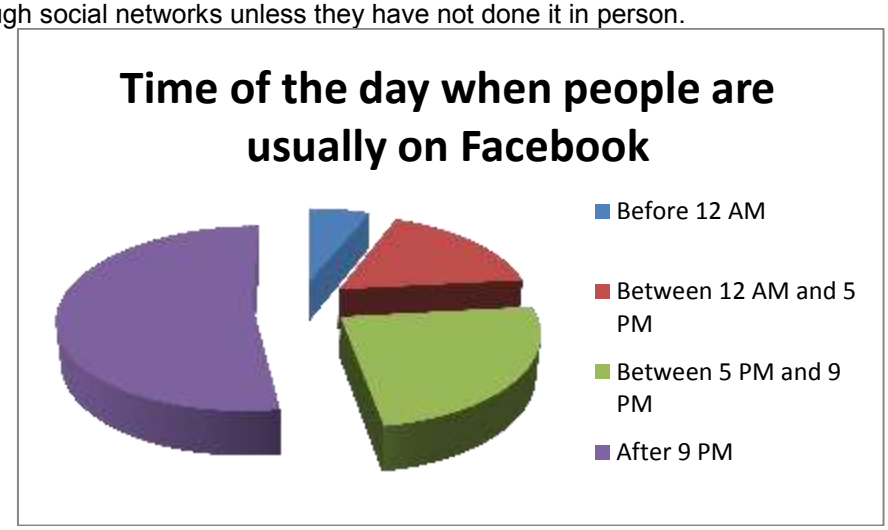

Figure 2: Time of the day when people are usually on Facebook

Taking this into consideration, companies should think about communicating with their fans mostly after 9:00 PM, because it is obvious that then is the greatest opportunity to attract someone's attention.

Examing the attitudes about advertising on Facebook, 41 % of respondents click on the link of an advertisement they are interested in, while 51 % completely ignores it. Only 8 % of respondents said they noticed sponsored advertisements, so companies should otherwise attract the attention of their target audience. 81 % of respondents said they like a Facebook page only when something really interests them. If you offer interesting content to your Facebook page's fans, be sure that they will focus their attention towards you.

Interesting fact is that 78 % of survey respondents are more likely to be informed about company's product or services via company's website, rather than via official Facebook page, while 54 % of respondents are using rather Facebook page for informing about promotional campaigns rather than website. This sets a challenge in front of the companies, where the question is how to interest Facebook users to frequently visit their page. This is where content marketing takes steps.

Furthermore, only 21 % of participants contact the page administrator when something interest them. Contradictory, regarding to 67 % participants who agreed that communication via Facebook company's page is more efficient and easier than via e-mails and telephones, it is possible that people

do not trust the person running the page, or they are suspicious that the page is official, or they are simply indifferent about this type of communication.

5. CONCLUSION

Summing up the impressions from research we made, we came to the conclusion that community management became the necessity of today's business development, when the subject is online marketing and social media management. Therefore, investing in this branch of management could increase the profit of companies and make huge number of satisfied clients in our market. Still, it is necessary to be worked on people's activation and freedom on social networks, not only Facebook, but also on Twitter, Linked in, Google + etc. This is also supported by the fact that our market is suitable for development and on the basis of the above in this study, we can agree that expansion of this profession and business direction generally is expected in the near future.

Abstract: In this paper will be discussed the consideration and the implementation of the elements of mobile applications that are important for internal communication in daily business operations. Regardless of the company size or market position, a good and accurate internal communication provides companies the opportunity to direct their supplies to customers and solve their problems. Internal communication takes place between employees in the organization. Today, it is considered one of the most important tools in the organizational management. Improvement of the internal communication system includes diagnosing the current situation in the organization, identifying difficulties, points of failure and deformation process of communicating with analysis of the key barriers. Improving internal communication can be achieved by changing the organizational structure to combining the existing or establishing new communication channels.

Key words: *Internal communications, internal marketing, Mobile applications*

1. THE CONCEPT OF INTERNAL COMMUNICATIONS AND MOBILE APPLICATIONS

Internal communication significant changes are happening in the organization, it is almost impossible to hide the truth from the employees. In other words, they will create their own version of the truth. In these types of situations, it is necessary to inform employees as much and as quickly as possible, to enable the process of changing. The development and effective performance of internal communication requires:

- establishing the time and the form of communication (meetings, reports, etc)
- utilising all existing and already tested communication channels
- developing efficient channels that are missing
- being familiar with the sources of information
- checking and eliminating rumors
- targeted linking message content to a narrow circle of recipients.

Poor internal communication is considered a key factor to poor employee relations (Proctor&Doukakis, 2003). Therefore, it is necessary for each target group in the organization to develop a separate communication strategy that includes more information about the target group, knowledge of formal channels of communication, informal leaders, and finding more places where the information can be found. Most organizations are in a constant process of change, within which the changing habits of employees and organizational culture are changing as well. Internal communication is almost always a goal and a means of creating a change. This requires openness and a willingness of a holder of internal communication; a message must contain the following: a clear and current substance, call for participation, a broader explanation of why something works. The internal communication receivers know the sender, or have more or less correct information about them. Senders or sources of information must provide feedback and insight into the effects that produced the information. Certain messages or information causes much greater effect if the present context, or the entire process. This avoids the feeling of contempt, and provides behavior that is consistent with the main ideas. People often, consciously or unconsciously, make relevant conclusions and decisions based on impressions from smaller parts of planned and unplanned communication.

Networking through mobile applications is a way of interacting in a virtual environment, where individuals with similar or the same type of interests exchange opinions, views and information, using only their mobile devices. Design and implementation of a specific application is based on the requirements defined by the identified needs and limitations of associates on the interactive mobile systems. Therefore, today there are more organizations that provide formal communication of their employees through mobile applications, while the informal is mainly done through prevalent applications for mobile devices.

The development of the software known by the acronym MoSoSo (Mobile Social Software) was prompted by the fact that users are physically inseparable from their mobile devices, and often wants to use it outside of their homes and offices. This software does not limit the use of mobile phone only to telephone calls between two individuals, and it provides a variety of social networking opportunities (Counts, ter Hoft & Smith, 2006). Authors Biel, Grill and Gruhn (2010) describe the context of use of mobile applications as mobile context

factors (MCF). By using these mobile context factors, we can explain mobile applications with the help of mobile environment and the perspective of the user of mobile devices. Also, the mobile context factors are used to describe mobile applications.

2. COMMUNICATION BETWEEN EMPLOYEES

Communication structure affects the efficiency of operations in the organization. Goldhaber (Berlogar, 1999) defines the communication structure as a system of roads and canals that the messages go through - lines of communication within the organization. In every organization there are both formal and informal communication structures. All organizations communicate with their relevant public inward and outward. Every organization regardless of its size has its own internal public. Relationships with internal public or communication with employees is perhaps the most important communication in the organization, because employees actually represent the organization and achieve the competitive advantage in the marketplace. Employees are not a unified group. They consist of workers, leadership and administration. In order for the organization to be successful, communication between management and the employees must be efficient - and two-way symmetrical. Cutlip (1971) points out that the relationship with the staff is very important for the successful functioning of the organization and he says that: "Nothing is more important for the organization, as much as relationship with employees at all levels." Employees in organizations serve as a means to achieve goals, but they are primarily a group of key stakeholders that affect organizational performance and achieve competitive advantage. For most organizations, this means that good foreign relations are based on the quality of internal relations. Well-informed employees are motivated to be more productive, which certainly helps the organization in its external action. The organizations that communicate with their employees know well what they can expect from them, and vice versa, the employees know what to expect from the organization. Both sides will not always find a common solution, but will achieve an understanding, which is one of the main goals in successful internal communications. The essence of internal communication is to reach a compromise in communication, so that the company will achieve profit without difficulty. Through internal communications, executives 'pilots' the organization, as well as assure and guide employees to follow the mission and goals, encourage loyalty, enhance employees to identify with the organization, increase their motivation and satisfaction with their work, develop mutual positive relationships between employees and the impact on the socialization of employees and organizational culture. Employees receive important information about the work of the organization through internal newsletters, intranet, bulletin boards, mobile applications, meetings, etc. The inside communication takes place in different directions and through different channels, as it depends on the organizational culture.

3. CHARACTERISTICS AND PROBLEMS OF INTERNAL COMMUNICATION

Employee relations are functions of organizational management. Therefore, systematic comunication is necessary, and communication strategies must allow smooth operation in the organization. Employees must be properly informed about the important issues, because it is the only way to get a feedback and create a feeling of being a part of the company. Stone suggests that it is necessary to appoint individuals that will mediate the transfer of information to others (Theaker, 2001). Employees must be provided with the following information: about the organization and everyday activities, the purpose of business, politics, image, reputation, goals, principles, vision, information on the individual department work, information about other companies, of the industry in which the organization operates, about marketing, advertising and sales, information on personnel policy, employees and professional achievements, additional information on education, information on recreational and cultural activities. The diagnosis of the current situation of internal communication include: research awareness and attitudes of employees, the research culture of the company, research the communication channel, to identify delays in the communication of key messages to be transmitted and the way in which communication is performed.

Determining the objectives of internal communication planning involves answering the question: What are the reasons for intensifying the internal communication, and what do we want to improve? Goals in planning internal communication are:

a) Improve internal communication at all levels of the organization
b) Improve clear and accurate expressing of ideas in written and oral form, by mastering communication skills (oral and written communication, managing a business meeting, communication with employees, communication in crisis situations, teamwork, leadership groups, performance in a group...)
c) Removal of information uncertainty, reduce the spread of rumors, raise employee awareness

Practice has shown that middle management is the most responsible for inadequate internal communication - so, when applied to it, these measures give the best result.

There are two opposite extremes which occur as one of the problems of internal communication. These are the lack of information and redundant information. Optimum is somewhere between too little and too much information. Employees will not be satisfied if they do not have enough information that are important for effective job performance. But also, too much unnecessary information leads to confusion and reduces motivation, and employees become dissatisfied with the job. In contrast, the optimum amount of information gives employee maximum satisfaction. The satisfied worker works more and better, and good communication can save time which can be used for work that the employee performs at their workplace. This all leads to increased productivity. (Filipović & Kostic - Stankovic, 2009). An example of a poor internal communication is the fact that many companies fail to link brand strategy with internal communication. People outside the company are traditionally a target group for all the messages about the company's brand. On the other side, employees get a sense of purpose and loyalty through internal branding. The sense of belonging to the company is important because it reduces the departure of the company workers. The departure of skilled workers from the company and hiring new employees is very expensive, and these costs can also affect the productivity of the company.

4. CHANNELS OF INTERNAL COMMUNICATIONS

Communication channels are the media through which messages are sent and received. Today, organizations and their employees have access to many channels of communication. Selection of relevant media for communication is very important for professional communicators who have specific goals and strategies set forth by the relevant public and created posts.

McLuhan (2001) makes a division between "hot" and "cold" media that differ in the degree of participation of the recipient. "Hot" media (eg, print media) require less active participation and involvement, are more segmented and linear than "cold" media (eg TV, FTF), which are more abstract and require participation in understanding the Vedas . Internal communication can be (Wilcox et al, 2005) written, oral, visual and audiovisual.

4.1 Mobile applications in modern communication

Available on almost all phones nowadays, mobile applications represent one segment of the global mobile market which is the largest and fastest-growing. They help a company to easily and efficiently manage and inform its employees of any changes in the market, the stock market and the organization. Their purpose may vary, ranging from basic functionality of mobile phones such as chat and messaging, to play video games, or more advanced services such as search the internet and watching video content. Different types of mobile applications are used in the upgrading of internal communication. Of course, it is possible to combine in a single application and do a number of different categories, all depending on what is the target group of the company. The expansion of mobile telephony in the last year is more expressed. Smartphone or mobile computer is dominant in all business transactions. Smart phones are cheaper and more companies are using packages for their employees. They have a Web browser, PDF reader, DOC, XLS and WiFi.

4.2 The evolution of mobile applications in social networking

The enormous development of mobile / wireless telecommunication networks and the emergence of computers, palmtop and PDA devices have caused the emergence of many new mobile applications and services that enable access to the Internet, corporate intranets and databases, electronic mail, teleconferencing anytime and anywhere. Two main types of mobile applications include: 1) horizontal applications that operate independently of the type of operating system and 2) vertical applications, tailored to specific operating systems. Horizontal mobile applications typically require access to specific local databases depending on the current location of the user , based on which they provide information on local newspapers, information on special offers in supermarkets or films shown in local cinemas. On the other hand, vertical mobile applications are designed for a niche market, ie. segments with specific requirements that make and use mobile devices. For example, technicians who do their work on the ground must have access to the instructions to repair the machine. As a sub-type of mobile applications there are also those that have been developed based on infrared communication, and are used to track employees and divert voice mail and data (Pierre, 2001).

Original mobile applications that are developed for social networking are:
1) MAMJ - a platform for the communication of people who are on the same or relatively near the location via SMS, developed in the UK;

2) Rummble - similar to the previous application also connects people based on their location, ie. their postal code , and for exchanging the same or similar interests and views with friends ; (Terdiman , 2005)
3) Dodgeball functions within twenty two cities in the United States and by advising the networked individuals on the movement of others, their current locations, especially if they are close to the range of ten blocks.
4) Plazes is also an interactive mobile application that connects friends or people who have similar occupations and interests globally.
5) Jumbo Networks connects people with similar interests, which are close to each other, and who want to achieve personal, direct contact. This application requires a stable WiFi connection between laptops, mobile phones and PDAs.
6) ProxyDating is a mobile application that, if it is installed on the mobile phone automatically via Bluetooth technology comes into contact with people with similar interests, provided that the maximum distance of individuals is fifteen meters.

Some of these applications are still operating but under different names. A significant increase in the use of laptop computers, primarily by users who are constantly on the move for accessing Internet services like e - mail and WWW contributed to the increase in demand for mobile applications, which will allow the use of Internet services through other mobile devices (cell phones and PDAs). Internet protocols on mobile devices contribute to the solution of key problems in the development of a mechanism that ensures that IP nodes change their physical location without changing IP addresses, thereby offering Internet users called "nomadism" (Pierre, 2001). This means that you can make telephone calls from their cars or while on the beach, receiving all voice (voice), e- mail or fax messages, and are available all over the world.

In addition to access social networking sites through a desktop computer and a laptop, users can use their smart phones to connect to these services. According to a survey conducted by Ruder Finn (PR agency) showed that 91% of smartphone users in social networks, as opposed to 79 % of the users of traditional desktop computer. This study also showed that 43% of smartphone users use the same communication with other people on social networking sites (Finn, 2012).

4.3. Contemporary mobile applications for social networking

Contemporary mobile applications have become a part of everyday life, as shown by their daily development. They are still developing and are used depending on the mobile device and the operating system on which they operate. Currently present mobile devices that support the installation of mobile applications are mobile smartphones, iPad, iPhone, Tablet, PalmPilot (PDA), etc. Mobile applications are developed in accordance with the operating system (OS) that exists on the mobile device. The latest mobile applications which were developed and caused strong popularity are Viber, Facebook Messenger, Twitter, LinkedIn, WhatsApp, Skype, Hi5, SAPO Messenger, My Space, GoogleTalk, etc.

Viber is a cross-platform application for instant messaging (chat) over the Internet Protocol that was developed for smart phones by Viber Media. Through Viber , users can not only share text messages but also share pictures, video and audio media file. Client software is available for Android, BlackBerry OS, iOS (iPhone Operating System), Series 40, Symbian, Bada and Windows Phone. Viber works over 3G and over Wi - Fi networks, originally launched for iPhone in December 2010, as a direct competitor to Skype. The first release version of Viber for Android is released in May 2011, but was limited to 50,000 users; unlimited version was released on 19 July 2012. Viber application for BlackBerry and Windows Mobile was launched on 8 May 2012. Services group of correspondence and HD Voice have been added on July 24, 2012 for Android and iPhone applications, which has reached 90 million users. Viber includes text, picture and video messages on all platforms, with voice calls (voice calling), which is only available for iPhone, Android and Nokia Windows Phone . The user interface includes an application tab (title) bar on the bottom that provides access to messages, access recent calls, contacts, and keypad and includes a button to access more options. After installation it creates a user account using the personal phone number as the user name. Viber synchronizes contacts from the phone's address book, so that users do not need to add contacts to a separate directory. Since all users are registered with their phone number, the software returns the members of one's contacts.

Facebook Messenger is a service for instant messaging (chat) and a software application that provides text and video communication. Characteristic of Facebook chat is that connects users to Facebook and syncs with the website. Facebook Messenger is developed for mobile devices and desktop computers. This application for mobile devices was released in August 2011 for iOS (iPhone operating system) and Android, and on October 11th was updated in the development of applications available for the BlackBerry OS. In December 2012 Facebook Messenger app for Android added the possibility that in some regions (such as Australia, India, Indonesia, South Africa and Venezuela) use Messenger without Facebook accounts easily

using the name and mobile phone number. These changes are intended to enable Facebook Messenger in order to compete with other similar mobile messaging platforms such as WhatsApp.

LinkedIn is a social networking site for business people, which makes it a unique network to establish business contacts. The site was founded in December 2002 and launched in May 2003 and is mainly used for professional networking. According to the LinkedIn in January 2013, it had registered 200 million users in more than 200 countries. The mobile version of the site was launched in February 2008 which was giving access to reduced operational site via mobile phone. It syncs contacts with selected personal mail and automatically sends request to connect. It also provides an insight into the personal LinkedIn profile, sending messages, reading messages, reading news etc. Mobile service is available in six languages: English, Chinese, French, German, Spanish and Japanese. In January 2011 LinkedIn added a mobile app CardMunch , which scans business cards and converts them into contacts. In August 2011 LinkedIn redid mobile applications for iPhone, Android and HTML 5. The percentage of usage of Linkedin via mobile applications has increased approximately 400% in the last year according to CEO Jef Weiner.

WhatsApp is a cross-platform mobile application for instant messaging (IM) for smart phones. In addition to the text messages users can send each other images, video and audio media files. Client service is available for Android , BlackBerry OS , iOS, Series 40 , Symbian (S60) and Windows Phone . After installation it creates a user account using the personal phone number as the user name, for example: (Jabber ID: [phone number] @ s.whatsapp.net). WhatsApp is facing strong competition Messaging service created in Asia, such as LINE and KakaoTalk. However, WhatsApp recorded about 10 billion messages per day in August 2012, and previously in April 2012 their number amounted to $ 2 billion per day in October 2011 1 billion messages per day. According to the Financial Times "WhatsApp is done for SMS messages to mobile phones what Skype did for international landline calls."

Skype is a software application and service voice (Voice). Skype was first released 2011, written by Estonian developers Ahti Heine Priit Kasesalu and Jaan Tallinn, who originally developed Kazaa application. Skype has evolved into a platform with over 600 million users which was purchased in 2011 by Microsoft for $ 8.5 billion. Skype works on a number of platforms such as Android, BlackBerry 10, iOS, Symbian and Windows Phone. This service enables users to communicate via voice with colleagues and peers using a microphone, allows video calling and instant messaging (chat) over the Internet. Calls can be placed on recipients over the traditional telephone network. Calls to other users within the Skype service are free, while calls to both fixed and mobile networks are charged and collected over debit - based user account system. Skype has also become very popular for its additional features such as file transfer, and video conferencing (group video or just audio call). Its competitors are Linkphone and Google Talk. In October 2007 Skype has launched its own mobile phone under the brand name Skypephone. Skype also offers wireless mobile phone that allows users to make calls within the Skype via wireless (wireless) internet connection. Skype Wi-Fi has a menu screen that allows Skype users to see who is online and available to talk, similar to what is seen on the desktop computer. It can also be used to talk with non - Skype users. SkypeOut minutes can be used to call any mobile phone for a very low price and no monthly fees.

Hi5 is one of the most successful social networks of Web-based assessment with the usage of about 60 million users. This application allows users to create a profile and to present information to their friends and visitors to their profiles, such as interests, age, location, along with a personal photo - album and music preferences. Much like Twitter and Hi5 service allows users to send a message to the network with information about the current activity that the user does. Context information is published via Wi-Fi or GPRS/3G connection and is available at a time.

SAPO Messenger is an instant messaging client (IM - instant messenger client) through which different users can chat via text messages in real time. This allows them to assign each user status message that displays all contacts. In a similar way as the previous scenario, the system announces the context information to update the status messages in the SAPO Messenger.

5. EXAMPLES OF MOBILE APPLICATIONS IN INTERNAL COMMUNICATION

5.1 Example of e-mail application

Communication is the basis of establishing contacts and creates business relationships in the marketing process. Electronic mail is a great communication channel for sending, sharing, receiving information and exchange opinions. For some topics communication via e - mail is more useful than a brief meeting, because

e - mail discussions among the participants give more time to think, to consult and to reflect on all the received information. All participants can easily share documents, images, audio and video recordings. Electronic mail (e - mail) has taken over a large part of business communication, which usage is increasing everyday. All modern mobile units which have e-mail applications that are built-in accelerate the correspondence between the employees themselves as well as internal stakeholder's enables timely information and quick action in emergencies. Suitable means of communication in large organizations, where it is not possible to talk directly. The point of it is to satisfy two factors: the communication needs of employees (information needs and vocational training) and communication goals of management (communication and transfer of the mission and vision of the organization to employees, justification of business decisions that require consensus employees). Increasing the authority (and responsibility) of workers - employees of a company are encouraged to make changes, big and small, every day. Ideas are collected from all employees. All of the information are published via email in need of quick correspondence. Increasing the authority implies that frontline employees are motivated to apply discretion in some sense when providing services. An Innovative hotel chain allows employees expense in the amount of $ 2,000 to correct deficiencies service which were encountered by or to respond to the complaint. E-mail as a mean of internal communication speeds up the flow of information and decisions.

5.2 Example of Instant Messaging applications

Instant messaging has even a full range of benefits of SMS messages. Depending on the tariff or package of traffic that the company uses for the price of one SMS message hundreds of instant messages are sent. Employees of a company use iPhone messaging applications (Beejive), the best known and most reliable application for instant messaging on iPhone. Although the price at which it is sold is relatively high, Beejive offers wide range of options and adjustments to the needs of the company. The application allows you to receive push news and not be active in the background to receive them.

A large number of the studied companies are using horizontal integration in order to achieve the effects of internal marketing , believing that should be addressed each communication with all employees in order to maximize employee participation and commitment. To encourage the commitment of employees, most companies have a shallow hierarchy management processes and provide decision support to employees in many key business decisions. This is done with virtual meetings. Internet and information technology are connecting people who are physically in different locations. By holding virtual meetings temporal and spatial distance is resolved. Also this way of communication helps with addressing important issues. This mode of communication has its advantages and its disadvantages, which will be discussed in the remainder of this paper. Benefits of virtual meetings:

• The main advantage, which is usually put in the first place, is money because they are useful and less expensive than live meetings:
• They eliminate the cost of travel, lodging and meals.
• They minimize the inconvenience of work being constantly interrupted.
• Reduce downtime and increase productivity.

Another great advantage is that it can connect people who are separated by time and space, such as employees who work in different locations and / or in other time zones. It also claims to increase objectivity, because every participant feels the presence of others in the group less than what it would be in person. In famous food company employees in marketing, brand management and communications with other employees have additional applications that the company paid for. By doing so, they ensure meeting the needs of consumers. Some companies implement internal marketing through widely covered steering committee composed of representatives of the departments of human resources, operations, brand management, sales and marketing, among others.

5.3 Example of application news

This type of application is as a periodic reminder to certain contents. Most employees bring about innovations in their field of work, changes in organizational policies, introducing new products and services, specific achievements and awards, and news about specific events, outings, etc. (Wilcox et al, 2005). Their purpose is to make all employees with less cost and more quickly be informed about the overall developments in the organization and to attract them to participate in various activities of the organization. The development of modern technology and IOS systems, especially the Intranet and e-mail makes it easy to quickly and easily perform. That is why they are appropriate for rapid, highly targeted and specific information (Newsom & Carrell, 2001). The practice is to be written in a clear and concise style. With more than 123,000 employees worldwide, the consulting company has put a strong focus on internal communications during the period of reduction of the workforce. Once this trend was set, consulting company continued efforts to improve internal communications. An important lesson drawn from a series of focus groups through internal communications

revealed the desire of employees to communicate with them only the information they need to perform their jobs. The company includes each employee to measure attitudes toward the individual responsibilities of each position in the company, the attitude towards the management, performance and evaluation of corporate programs and initiatives. It was so widespread as to have the applications that they had all the employees in the company.

5.4 Java portals

These portals can help employees in the execution of daily tasks and making everyday decisions, because their primary purpose is primarily informing and educating employees (Newsom & Carrell, 2001). This mean of communication is very important especially for new employees, which helps them in understanding the basic rules, strategies and vision of the organization and contributes to their faster and more successful socialization in the environment (Baskin & Aronoff, 1988). The information which are usually shared are about organizational policies, employment insurance, pensions, information about the broader social issues and standards relevant to the environment that may affect the operation (Baskin & Aronoff, 1988). If the guides include o tips for communicating with the media, tips for resolving conflicts and crises, tips for better relations with subordinates and superiors, they can be more effective. The best guides that are the ones designed modularly and that allow employees the possibility to shape them according to their own measure (Gruban, 2002). A car company has applied this portal mobile application with its employees. Satisfaction increases because of the direct communication and direct interaction between the CEO and other employees.

6. CONCLUSION

The importance of communication and the need for internal communication does not expire, regardless of which period the business is doing. What has certainly changed over time is the intensity of the role of the consumer in communicating with the company, as well as the ways in which communication between them may be performed.

The following conclusions can be pointed out:

- New generation, new technologies and “new" relationships between employees.
- Mobile applications and services are organized around people, not interests.
- Mobile applications support pre-existing social relations and have an impact on employee satisfaction with communication.
- Exclusive use of technology does not contribute to good relations and communication satisfaction of all employees in the organization.
- Employee satisfaction and mobile communication network are critical to the organization.
- Internal communication is not a tactical but a strategic tool.

It is necessary to monitor the behavior of employees in the mobile networks given the ambiguous effect that occurs on the fact that the presence and communications staff on mobile applications and networks can not be managed.
The success and forms of internal communication affects the way managers in the management of the organization. The presence of employees in social networks is a multi-layered and multi-component, which means that the very specific characteristics of social networks have become symbols of communication of employees. This is a very important element, because it is a specific form of informal communication, which can not be caused, but it also can not be controlled within the company

INFOGRAPHIC AS A MARKETING COMMUNICATION TOOL

Dragana Milovanovic[1], Leo Ivanisevic[2]
[1] Student, Faculty of Organizational Sciences, dragana.milovanovic19@gmail.com
[2] Student, Faculty of Organizational Sciences, dreamheart89@hotmail.com

Abstract: *Infographics became powerful and widespread communication tools. Their advantages are related to their design, long history of use and human psychology and behavior on the Web. This paper is taking a special reference on those psychological factors: visual-pictorial primacy, attracting and retaining attention, content organization, shareability and aesthetics. As a marketing tool, infographic has its effectiveness measurement system, its faults and ethical dilemmas, and rules on how to create it and put it to maximum effectiveness. The potential for further research is discovering which industries can profit most with this tool, for its advantages may not be suitable for all target audiences.*

Keywords: *infographic, content marketing, visual communication, Internet, social networks*

1. INTRODUCTION

Communicating with target audiences is one of the functions of marketing. The way that communication is executed determines its success or failure, meaning that marketers are continuously trying to discover more efficient means of distributing their messages. In the age when the quantity of available information overwhelms us, it is challenging to grab our attention. Infographics recently became one of the popular solutions for that. By combining textual and visual elements, they present useful content for consumers and thus attract them to the company.

This analysis will present infographics as a part of content marketing, reasons behind their efficiency, ways they can be created and their advantages and disadvantages.

2. CONTENT MARKETING

Content marketing can be defined as using informative, editorial content in order to direct attention to the company, create impression of it being a leader, with a purpose of attracting present and potential customers (Lankow, Ritchie & Crooks, 2012, p.21). Content launched by the company has a role to empower, engage, educate, inform, entertain, create trust towards the company and connect consumers (The Internet Marketing Academy, 2011, p.11, 15).

As such, content marketing has always existed, but it became more relevant than ever with the increasing number of Internet users and greater availability of information. It is said that this is the age of "information overload", that is, "Big Data" when anyone can publish anything online (Mack, 2011, p.4). These circumstances have forced traditional marketing to change its advertisement-oriented approach and establish new rules (The Internet Marketing Academy, 2011, p.10):

- People are well informed and demand the truth, not "spin";
- Ad-breaks are not tolerated in the age of DVR and e-mail spam filters;
- People are demanding value for their time and are using Internet to get it;
- Marketing and PR strategies are created in a way to target niche audiences, and are using many techniques to achieve that;
- Content stays online forever, thus the campaigns never end.

The general idea behind content marketing is that content consumers will think well of the brand/ company if they find their content useful and if the company creates the image of it being an expert in the industry (Lankow et al., 2012, p.126). For example, technology company Cisco launched the "Internet 2015" infographic based on an internal study about the future of Internet. This showcases the company's reliability and flexibility to changes in the environment, which sells the Cisco brand (Mack, 2011, p.16). Even if the content users do not become consumers, there will still be a non-consumer fan base that can recommend the brand or at least share the content online so potential consumers can see it.

Content marketing is based on five core principles (Lankow et al., 2012, p.11):

- Editorial content which is relevant and valuable to consumers;

- Marketing objectives are a foundation;
- Orientation to changing or maintaining consumer behavior;
- Using different media platforms: print, audio, video, digital media etc;
- Targeting specific consumer segments.

This approach is unique and challenging to marketing professionals because they are not the only ones who create content – consumers can create it and share it online too (The Internet Marketing Academy, 2011, p.11).

It is essential for marketers to understand why consumers share content online. Jason Ho and Melanie Dempsey (2010, p.1004) have identified two key needs which are satisfied by sharing: need to be different and need for altruism. By sharing content, Internet users want to show off their uniqueness in comparison to their group, but they also want to help others. These are the needs campaign creators should have in mind.
Content marketing has several advantages over traditional advertisement: lower expenses and greater interest from consumers who want answers rather than distracting commercials (Houghton, 2013).

3. INFOGRAPHICS – DEFINITION, APPLICATION, HISTORY

An infographic is an image representing an integration of design and visually pictured data helping organizations convey their messages to the audience in a concise fashion. Smiciklas (2012, p.3) defines them as visually presented data or ideas, used to present complex information in a way that makes it easier and faster for audience to understand and adopt it. Infographics can represent (ibid p.5):

- Statistical data;
- Processes;
- Ideas;
- Chronological data;
- Geographical data;
- Anatomy;
- Hierarchy;
- Relations;
- Personality.

It is important to stress that infographics are not only intended for the purpose of communicating with consumers – they are equally used for internal communication (with employees, job candidates, partners, the media and other stakeholders). This way, infographics can be used in a wide range of ways within the framework of a holistic approach to marketing.

The history of the infographic was systematized by Morris and Wocknitz (2013, p.2-8) in the paper they presented at the SAMRA conference.

The visualization of data originated pre-17th century, when it was used to produce maps and geometric diagrams. The beginnings of modern graphics date back to the 19th century, when bar graphs and pie charts came to use, as well as histograms, line charts etc. During this period, graphically represented data were used to analyze military campaigns, meteorological conditions, geology, epidemiological data, social and moral behaviour, economy and trade. In the second half of the 19th century, Florence Nightingale first used the pie chart to show that more British soldiers died during the Crimean war due to poor hygiene conditions in hospitals than in combat. This chart was included in the report of the Royal Commission, and is considered to have been the most significant part of the report, because it quickly relayed important information to the public and thereby instigated public support for reform.
Since 1975 to modern day, the use of computers has been the basis for widespread and speedy development of infographics. The visualization and design of visually presented data are universally available today, and their efficiency and effectiveness have made it so that they are being utilized in nearly all aspects of life.

4. THE EFFECTIVENESS OF INFOGRAPHICS FROM A PSYCHOLOGICAL PERSPECTIVE

There is a sizeable amount of empirical data that attest to advantages of using infographics. In the following section, we shall describe the psychological factors that make the infographic an effective communication tool.

Visual-pictorial primacy

Vision and processing visual information make up a large portion of our brain activity. Around 50% of cerebral structures are in direct or indirect relation to visual function (Sheth, Sharma, Rao, Sur, 1996, p. 2110-2114). Our mind deals mainly with pictorial, not textual data. Reading and writing are skills learned later in life, whereas we deal with pictures from birth. The processing of text, in our minds, takes place in a serial manner, word by word, while a picture is processed as a whole. Accordingly, visual processing of a picture consumes less time and energy than visual processing of textual data (Smiciklas, 2012, p.7).

Initial research of visual representations (Nickerson, 1965; Rock & Englestein, 1959; Shepard, 1967) shows that people are successful in the visual stimuli recognition task, even when a great deal of time has passed since the initial exposure to the stimulus. Later research (Standing, Conezio & Haber, 1970, p.73-74) confirms that even when the number of images that the subject is exposed to is drastically increased, successfulness in delayed recognition does not drop significantly. The fact that such high percentages of correctly recognized stimuli are not achieved in tasks that show verbal (textual) material has lead psychologists to the conclusion that the mechanism of storing and arousing visual representations differs from the mechanism of storing and arousing verbal, symbolic representations. Paivio's research (1969; 1971; Paivio & Csapo, 1969) shows that in the case of recalling and reproducing verbal material, people are better at memorizing concrete terms as opposed to abstract terms. He attributes this phenomenon to the possibility that concrete terms are double-coded. Namely, a concrete term may be memorized verbally, as a written or spoken word, but also visually, as an image of the object it refers to. This theory implies that verbal content is better retained when it can be, or is, accompanied by an image. Infographics provide us with the option of giving visual support of abstract terms (often used in marketing and business) which will result in better memory.

The research of Nelson, Metzler and Reed (1974, p.184-186) showed that superior retention of pictorial material does not depend on the amount of detail contained in the image. This fact contains yet another advantage of infographics: even when reduced and simplified to the extreme, they are still equally successful in improving the retention of material.

One must not forget the VARK model (Fleming & Mills, as cited in Smiciklas, 2012, p.11) which refers to different learning styles. According to this model, people use four primary learning styles by which they process information. An estimated 65% of the population belongs to the group that learns visually (through observing graphs, maps and diagrams), giving infographics an advantage as a form of marketing communication.

Attracting and retaining attention

Today's audience consumes more information than ever by using the Internet. Because of this, it is important to know what separates the process of interacting with digital data as opposed to the process of interacting with printed data. Generally, people have a tendency to read much more slowly from a screen than off of paper. Since we are subjected to an avalanche of data on a daily basis, we have gotten into the habit of skimming online texts without lingering or immersion. During the last two decades, Jakob Nielsen (Weinreich et al, as cited in Smiciklas 2012, p.12) has been conducting research on the ways which users interact with Internet data. He discovered that people do not like to read texts on the Internet almost at all, and that the average person reads a total of 20% of words from a web page. Also, the way we maintain attention when it comes to Internet content has changed. Users are simultaneously connected via multiple channels to maximize their information access. However, Smiciklas (ibid, p.12), despite larger exposure to data, each channel is given attention on a much more superficial level, resulting in fragmented and divided attention. The rapid pace of life prevents us from dedicating too much time to any content. Along with growing time pressures, there is an increasing need for short, clear and concise communication.

Although the world has changed since the first researches of human attention, certain knowledge acquired at the time is useful to us to this day.

Anne Treisman’s research (1960, p.242–248) indicated that even when we devote our undivided attention to a certain content, we are not entirely “blind and deaf” to other stimuli we are exposed to. It is possible to divert attention from one channel to another if some content that differs from the rest, presents news or touches us on a personal level (our own name, emotionally charged content, etc) appears on the other channel.

As an innovation in the world of marketing communication, infographic often stands out from the context in which it is found, so it fulfils all the prerequisites of attracting and keeping the audience’s attention long enough to convey its message in an “online” environment.

Content organization

In 1965 George Miller (as cited in Kostic, 2006, p.115-116) examined the capacity of the human operative memory and got to the conclusion that people can handle a maximum of five to nine elements at a time. In this context, an element does not constitute a piece of information or a fact, but a meaningful unit. One meaningful unit may contain multiple pieces of information. The cognitive system is sensitive to the number of meaningful units, but not to the amount of information derived from the number of elements. Thus, people are capable of simultaneously manipulating a great number of facts if these facts are organized in a meaningful way.

Research conducted by Pressley and McCormick in 1995 (as cited in Vizek-Vidovic, 2003, p.173) shows that, while studying, subjects spontaneously attempt to tie together material that is not meaningfully organized.
An infographic aims to represent data in a clear, concise and organized way, which makes content consumption quicker and easier.

Shareability

One of the core aspects of Internet communication is the possibility of sharing information between people (Smiciklas, 2012, p.15). In addition, people do not like to share links to articles, pages or blogs that they hadn't read. With the aforementioned time pressures in place, less time is dedicated to reading long texts on the Internet. Since an infographic does not take up too much time, it has better odds of being consumed and forwarded to a large number of people.

Aesthetics

A well-designed infographic is an efficient communication tool now when the fight for attention is ruthless. Visual and aesthetic differentiation in organization, brand or idea is critical. The use of attractive colours and shapes, modern design and aesthetic appeal may be the decisive element in winning over audience's attention.

Back in 1933, Nelson Gilbert (1933, p.52) proved that aesthetics play an important role in remembering newspaper ads and advertisements. Respondents were more successful in remembering the products marketed with colour ads than with those printed black and white.

5. MEASURING THE EFFICIENCY OF INFOGRAPHICS

Defining the best way to measure efficiency of infographics can be a futile task. The organization's goals, the way it defines return on an investment – all this affects the decision of how and if at all to measure the business performance of an infographic. Favouring quantitative financial indicators of performance has a long history. In many organizations, it is thought that if the marketing investment is not measurable through a return of the investment, it cannot be considered sustainable or useful.

However, not every marketing initiative can always be directly linked to its results. Understanding the relationship between resource allocation and marketing performances is more important than measuring the direct correlation between marketing initiatives and financial results. To managers justifying the internal and external value of infographics as communication tools is a priority (Smiciklas, 2012, p.159).

This implies the short-term and long-term consideration of tangible indicators and intangible benefits of infographics. Since they are usually distributed via the Internet, we shall focus on indicators in the digital environment, as divided by Smiciklas (ibid, p.161-163).

Tangible indicators include: awareness and engagement of the audience.

Awareness refers to the level of audience exposure to an infographic through various digital channels. It can be measured in several ways:

- Through potential range (using the Google Analytics and Google Webmaster Tools services);
- Through hyperlinks (using the Google Analytics service);
- Data on search keywords;
- By the number of content subscribers.

Engagement refers to how the audience relates and behaves towards infographic content. When measuring engagement, it is important to take into account the level of commitment needed for a content-related action

to take place. Leaving a comment on a blog takes a higher level of engagement than “liking“ content on Facebook or sharing it on Twitter. Engagement may be measured in several ways:

- Through the average amount of time spent on a website monthly (using the Google Analytics service);
- Through the number of comments and their tone;
- Through the number of shares on social networks (using tools such as Hootsuite).

The intangible benefits of infographics can be classified as internal and external.

Intangible external benefits include:

- Establishing relations (through publishing and promoting infographics an organization has the opportunity to establish relations with numerous influential individuals, media and organizations);
- Credibility (publishing relevant and useful infographics and offering first-hand perspectives on an organization builds credibility);
- Connection to the brand (infographics and other content create micro-interactions with their audience thus supporting positive audience experiences related to the organization).

Intangible internal benefits include:

- Ease of communication (infographics facilitate the exchange of problems and ideas among employees, as well as sharing information and relating knowledge, and their viral nature gives them the potential to spread through all parts of an organization and encourage internal debate and dialogue);
- Corporate pride (in the event that an infographic gains popularity and is widely shared through social networks, it may spark employee and organizational pride);
- Easier decision making (infographics expedite the consumption and comprehension of information - quicker decision making follows as a result);
- Better organizational learning (infographics make complex information more understandable, and help employee education).

6. CREATING INFOGRAPHICS

When designing an infographic, the first thing one should have in mind is the end-user, says Natasha Loyd (as cited in Yuk, Diamond, 2014, p.9). According to her, the most important qualities of good visual data presentation are usefulness, because people use them to make decisions, and desirability, because it gives them satisfaction to use data arranged in a pleasant way.

Focusing on the end-user means answering two questions – what the message is and who the receivers are (Smiciklas, 2012, p.77). Smiciklas (ibid, p.78) differentiates the following types of audiences: present and potential consumers, present and potential employees, partners and the media. The type of information that will be launched depends on the audience. For example, employees are interested in the organizational structure, consumers in products and prices, and partners in the value chain. Therefore, an inforgraphic must have a communication goal – to increase awareness of the brand, to entertain, inform, increase web page visibility etc.

One of the key tasks for designers is to use valid data, especially if the goal of the infographic is to educate. Credibility of the company and the brand may be jeopardized if the infographic displays wrong claims, grammatical errors, plagiarism and/or offensive content (Protz, n.d.).

As for the designing process, these are the guidelines we selected:

- Less is more – only one important message should be presented. Less important information should not have a striking size, color and location. The most important part of the story is supposed to be most visible.
- Information should be organized like a story, but there must be a balance between factography and aesthetics – one part should not be emphasized over the other (Suleman, 2012). Having that in mind, the structure *introduction – explanation – conclusion* works best for infographics because it visually and logically guides the reader. Also, all elements of the design should be consistent – typography, colors, shapes, alignments, location etc. (Morris & Wocknitz, 2013, p.17).
- When choosing colors, designer must consider their meanings and associations. Labrecque and Milne (2012, p.712) researched how colors influence the perception of "brand personality" which further influences the customers' relations to the brand, their preferences and trust. For example, when choosing a color for the logo, designer must be careful so that the colors convey values important to the brand, such as trust, honesty, expertise etc. Those associations will then be evoked in consumers who see the

logo for the first time, just because of the colors they connect to certain characteristics. Researchers have discovered that colors influence brand's image and likeability, so they can be used in differentiation strategy; but, marketers have to be aware not only of the general meaning of colors, but also of their meaning in the industry.

Some authors do not consider infographics the best solution for every topic. Shell Harris (2013), the founder of *Bestinfographics.co* website, found seven topics which infographic designers should not use:

- Qualitative data on emotions, preferences and aesthetic choices cannot be measured, which can make them unclear on infographics.
- Simple topics which do not present complex data or comparisons should not be presented with infographics, but with posters or similar visual tools.
- Simple procedures would be further unnecessarily simplified, which would definitely not attract the target audience.
- On the other hand, infographic is not meant to convey complex procedures, especially if they require fast decision making, such as evacuation plan in case of fire.
- Promoting new products and services can be done more efficiently with traditional marketing means. That is primarily because infographics are meant to be shared as useful content, which will not happen if they are advertisements.
- Information already presented as infographics should not be repeated unless it suffered a significant change. For example, searching "social media infographics" on Google displays 124.000.000 results (checked on On March 19th 2014), meaning that users will not be particularly interested in another infographic of this kind.
- Humor should be used carefully, so that it is appropriate for the target audience.

7. ADVANTAGES AND DISADVANTAGES OF USING INFOGRAPHICS

As any marketing tool, infographic is not panacea for every communication. Its unique characteristics make it popular online, but it also has downsides. Both are analyzed in further text.

Advantages

The main qualities of infographics are that they easily get attention and enable further dissemination among potential customers.

Infographics tend to attract more readers than text and distinguish themselves from other online content (Lankow et al., 2012, p.126). As we have already explained, people have access to a lot of media on a daily basis, but they rarely decide to focus on longer texts. They need their answers fast, and well designed infographic provides exactly that (Culberston, 2013). Also, in the section "The effectiveness of infographics from psychological perspective", we explained that visual nature of this communication tool can convey the message faster and more efficiently than words, which enables easier memorization.

From a technical point of view, infographics are easily shared online because of their format (usually PNG or JPEG images) which are displayed as a whole on Internet platforms (Lankow et al., 2012, p.127). Sharing an article on social media, for example, leads to only displaying the URL, title and first few sentences, which will not as easily attract audience.

Disadvantages

Popularity of infographics might be the reason for their downfall. The consumers can become overwhelmed and get used to infographics to the point when they become expected and predictable. That way, they are no longer unique and therefore, unable to attract attention. Brian Eisenberg (2001) believes that marketers rely too much on the idea of people as "visual beings", which results in commercials being easily forgotten because our brain organizes the content in a predictable way. That is why he suggests that marketers focus on sense of hearing and quotes Roy H. Williams, a world-renowned authority and a best-selling author on advertising and marketing: "Describe what you want the listener to see, and she will see it. Cause her to imagine taking the action you'd like her to take, and you've brought her much closer to taking the action".

Different critique deals with the quality of information infographics display. Kendra Mack (2011, p.6) wrote that the most important characteristic of infographic is that it shows the story as a whole, without context or additional content. Since phenomena showcased on infographics are usually more complex than what infographics can convey, there is a distinct possibility for manipulation. That is particularly dangerous in

marketing, because companies are not inclined to show information which can diminish their image, but will probably make them seem less important or not show them at all. Furthermore, most information on infographics are not a result of research, but a pile collected from different sources which then go through companies' and designers' filters. Most infographics do not reveal their sources, not even when they are coming from official institutions such as the White House (ibid, p.11). Also, purchasers and authors of infographics usually do not have experience with quantitative and statistical data which can lead to "style replacing content", that is, valuing design rather than valid information (ibid, p.10).

Finally, infographics are criticized for the same reason as any content on the Internet – that they are encouraging superficial, non-analytical way of thinking. Making facts seem simpler and organizing them so they can be consumed with more ease does not leave much room for thoughtful consideration. Nicholas Carr (2008) in his article "Is Google making us stupid?" analyzes how the Internet as a media influences the way we are thinking. Searching and using data online can be similar to browsing a book – we are trying to get as much information as fast and efficient as we can, while longer texts cannot grab our attention. The reason for that is also in the fact that computers nowadays have functions of different devices – they are a TV, radio, mailbox, alarm clock and book all in one. Different notifications which often pop up at the same time diffuse our attention span, which increases tendency to superficially consume content forced upon us.

8. CONCLUSION

The visual nature in combination with useful information make infographics an important marketing tool in the age of "Big Data" when one of the vital features of content marketing is wide distribution. The infographics' format and likeability provide exactly that. Marketing experts can use this tool to offer valuable information to wide range of consumers and build their company's brand at the same time. On the other hand, because of the potential for deceit, marketers must consider the quality and honesty of information they use. Consumers are not likely to forgive manipulation, not even when it is packed in a colorful and funny infographic.

The potential for further research is discovering how versatile infographics are, that is, which industries can profit most with this tool. Its advantages may not be suitable for all target audiences. Fortunately, since there are ways to measure their effectiveness, companies can decide if infographics can help them achieve their goal image in an online environment.

CORPORATE SOCIAL RESPONSIBILITY

FAIR TRADE BUSINESS MODEL AS A FUNCTION OF SUSTAINABLE DEVELOPMENT

Daniela Nuseva, PhD, Stojanka Dakić, MSc, Ozren Uzelac, MSc
Faculty of Economics Subotica, nusevad@ef.uns.ac.rs

Abstract: *Fair Trade as an innovative trading model strives to achieve greater equality in the international trade, by offering equitably distribution of the gains between marginalized producers, traders and consumers. In this way, it aims to improve producers incomes in some of the poorest countries in the world and help them to actively participate in the development of their communities and societies. Fair Trade contributes to sustainable development by promoting environment-friendly technologies, corporate social responsibility, human rights, elimination of child labour, campaigns to change practices in international trade, raising consumer awareness etc. In this paper are identified the organizations within Fair Trade business model, using the analytical description method. In the proces of analyzing the Fair Trade contribution to sustainable development, the focus is placed on the available data of Fairtrade Labelling Organizations International on benefits of Fair Trade Premium to small producer organizations in the developing countries.*

Keywords*: Fair Trade, supply channel, sustainable development, World Fair Trade Organization, Fairtrade Labelling Organizations International*

1. INTRODUCTION

The following universally accepted definition of Fair Trade was created by FINE in December 2001(World Fair Trade Organization, 2009): „Fair Trade is a trading partnership, based on dialogue, transparency and respect, that seeks greater equity in international trade. It contributes to sustainable development by offering better trading conditions to, and securing the rights of, marginalized producers and workers – especially in the South. Fair Trade organizations have a clear commitment to Fair Trade as the principal core of their mission. They, backed by consumers, are engaged actively in supporting producers, awareness raising and in campaigning for changes in the rules and practice of conventional international trade."

The roots of Fair Trade can be found in the initiatives of North Americа`s and Europe`s churches in the late 1940s. They wanted to assist poor communities in developing countries in a way that will allow them to obtain higher profits through direct tade and fair prices. Fair Trade as a movement pointed to the disadvantaged agricultural and handicrafts producers in the developing countries.

Today, Fair Trade is also a business model, with a number of organizations ensuring compliance to defined Fairtrade standards in every phase of the supply channel from small producers in the South to the consumers in the North.

2. ORGANIZATIONS WITHIN FAIR TRADE SUPPLY CHANNEL

The organizations that make up the structure of Fair Trade movement undertake various activities within the trade chain from producers in the South to consumer in the North. They can be classified into the following groups:

1. Producer organizations in developing countries or countries of the South, which produce and supply the market with Faritrade products;
2. Buyer organizations in developed countries or countries of the North, which appear as importers, wholesalers or retailers of Fairtrade products purchased from producer organizations in a developing country;
3. Network of Fair Trade organizations that sets standards for Fairtrade certification;
4. A large number of primarily conventional organizations involved in some way in the chain of Fair Trade and
5. Lobbying organizations.

2.1. Producer organizations in developing countries or countries of the South

Producer organizations involved in Fair Trade system grow or produce products (food, such as coffee, cocoa, tea, fresh and dried fruit, spices, etc., as well as handicrafts such as balls, glassware, jewelry, musical instruments, toys, etc.) and export them to Fairtrade products consuming countries. Producers are the heart of Fair Trade. Producer organizations differ among regions and depending on product. They include producer associations, cooperatives, family units, workshops for handicrafts, government organizations, private companies and others.

Membership in producer organization is voluntary. There are large differences in the size of the organizations. Although they differ in size, common to all, is that they represent „marginal“ producers. They operate in economies where wages and incomes are low, social benefits almost non-existent and working conditions are extremely difficult. Considering the lack of experience or available resources, without the help of Fair Trade organizations, they are not in position to obtain direct access to the market, neither local nor foreign. Producer organizations face with difficulties which are often associated with issues of racial, ethnic or gender inequality.

Martins (2011) points out that "The participation in the Fair Trade movement implies knowledge of business management, ranging from simple accounting techniques to the sustainable use and conservation of natural resources. Usually, these tasks are far beyond the capabilities of many local communities if they are intending to get involved in exporting their products and becoming part of the international trade. These different capabilities demand efforts in areas that are not directly linked to the production and commercialization of the products, such as education and capacity building" (p. 418).

Any producer organization that wants to support sustainable development, to provide stable income to its members, to encourage democratic participation and respect other criteria, such as women`s equality, human rights, environmental protection, local culture, etc., is a potential partner of Fair Trade. Producer organizations to be accepted as a trade partner in the Fair Trade system, must be able to produce (usually after getting some help) a marketable product. They must be able to provide a range of products at a reasonable price and in sufficient quantity for a specified period of time.

2.2. Buyer organizations in developed countries or countries of the North

To be able to use the Fairtrade mark, organizations which import products with this label, must meet the following requirements:

- They have to buy directly from producer organizations using purchasing agreements that extend beyond one harvest cycle;
- They have to pay a guaranteed minimum price and a social premium above this minimum or pay the world market price when it is higher. For certified organic products they have to pay an additional premium;
- Importers must offer pre-financing equal to 60 percent of the contract upon request.

In addition to these conditions, their role is also, to encourage and assist producer organizations in different ways, such as advising them about the possibilities to develop their production, provide them training and skills in management, provide them with additional support in the difficult economic and social conditions, etc.

Importers initiate or participate in campaigns that aim to increase consumer awareness about the problems in the North-South relations. They promote Fair Trade as an alternative to the „unfair“ foreign trade activities and lobby for change on the policy level. Therefore, they are associated with different organizatios working on similar issues (NGOs, aid agencies, educational centers, etc.).

Organizations which import products with Fairtrade lebel in their countries emerge as wholesalers or retailers (sometimes a combination of both), offering Fairtrade products through various channels, such as specialty shops (Worldshops) and local groups or representatives, as well as many other channels as stores, shops for organic food, gift shops, supermarkets, catalogs and Internet sales. Certainly, an important channels are, also, restaurants, cafes, canteens, etc.

2.3. Network of Fair Trade organizations

Fair Trade organizations work in joint efforts to promote Fair Trade. They have a common vision and principles which direct their operations. A special role and importance in the supply channel have the World

Fair Trade Organization, which has developed Fairtrade standards for the organizations, and Fair Trade Labelling Organizations International, which established standards for the Fairtrade products. Both systems are based on common definitions and principals of Fair Trade.

2.3.1. World Fair Trade Organization – WFTO

The International Federation for Alternative Trade – IFAT was established in 1989. It rebranded and became The World Fair Trade Organization on 15 October 2008. This change is significant and was created to meet the requirements of Fair Trade organizations and the general situation in the modern world. The decision was accepted by the majority of its members (91% of the vote), which are now collectively known as the FT100.

WFTO is one of the most important institutions of Fair Trade and unique in representing Fair Trade members of the North and the South. It represents the Fair Trade organizations at all levels, managing the system of Fair Trade for more than 20 years. It is the only global nework of Fair Trade, in the sense that its members represent the entire range of Fair Trade, from production to sales.

WFTO is the global representative body for over 400 organizations, so we can say that it is the „authentic voice" and „guardian" of the values of Fair Trade. WFTO operates in more than 70 countries, grouped into 5 areas (Africa, Asia, Europe, Latin America and North America and the Pacific), with elected global and regional boards, which create market access through its policies, advocacy, campaigns, marketing and monitoring.

Around 110 million artisans, farmers, growers and producers lead Fair Trade through cooperatives, networks, brands and business and supply around 2.2 billion dollars net sales of Fair Trade throughout the world. One of the goals of WFTO is to enable small producers to improve their lives and communities through sustainble Fair Trade.

In this sense, the agenda of WFTO is very clear: the agreement on the framework and implementation of strategies and tools for change that will affect the poverty reduction, climate change and the financial crisis.

The opportunity to become members of WFTO have only organizations that are fully committed to upholding Fair Trade and its 10 standards. Their specificity is reflected in their 100% commitment to the goals of Fair Trade to eradicate poverty through sustainable economic development, supporting social and environmental policy and continual investment in marginalized artisans, farmers and producer communities in some of the poorest parts of the planet. WFTO members, which are subject to monitoring in relation to the application of these standards are listed on the FT100 index of world`s leading Fairtrade brands, businesses and organizations. FT100 aims to become a powerful instrument of transparency, traceability, social and environmental impact on public opinion.

2.3.2. Fairtrade Labelling Organizations International – FLO

Fairtrade Labelling Organizations International was established in 1997. It represents 24 organizations working to secure better conditions for producers and setting international standards of Fair Trade. FLO members around the world produce and promote products with the Fairtrade mark.

FLO coordinate the processes of identification and standardization of Fair Trade at the international level, through various activities, such as:

- Setting standards of Fair Trade. (The key role of the FLO is reflected in the development and monitoring of standards of Fair Trade. These standards apply to all Fairtrade products.)
- Organizing support for producers around the world. (FLO helps producers to get Fairtrade certified and develop market opportunities through locally established liaison officers to provide training, instruction, certification and to facilitate customer relationship management.)
- Coordinating the global strategy of Fair Trade. (One of the roles of FLO is to determine the feasibility of how members can contribute to progress and become more effective in the future. Changes in the world, climate changes, food insufficiency and global recession are more important issues to the public and stakeholders in Fair Trade. FLO manages the global strategy development on these issues. It is currently implementing a new global strategy for Fair Trade called „Making a Difference".)
- Promoting Fair Trade. (One of the FLO tasks is to create conditions for Fair Trade in debates on trade and development. It does this in cooperation with other international Fair Trade organizations, such as WFTO, NEWS! and EFTA. Together they lead the Fairtrade Advocacy Office in Brussels. This office coordinates the activities of the international Fair Trade movement in Europe and around the world.)

FLO vision is a world in which all producers enjoy security and sustainable development, satisfying their own potential and deciding on their future. FLO believes that trade can be a fundamental leader of poverty reduction and more sustainable development, but only if it is conducted with the aim of creating greater equality and transparency than those that exist today. FLO members believe that producers can overcome inquality and marginalization if they strengthen their position and take more control over their work and their lives, if they are better organized, have better resources and support and can provide acces to markets under Fairtrade conditions.

This FLO vision is based on the fact that citizens, businesses and institutions in developed countries support trade in this way, especially when they understand the needs of producers and the opportunities offered by Fair Trade to change and improve their situation. Informed consumers choices and business desires to meet the expectations of its customers, provide crucial support for FLO broader campaings to reform the rules of international trade and create more just economic system.

FLO vision and mission are reflected in the values and principles by which it works, so it sets itself as an example of the changes required in others. Trust is the most important factor in its operating.

Although the sale of Fairtrade products has grown rapidly last 20 years, many products remain outside the Fair Trade system. Therefore, FLO invited its partners to join it in the development of new strategies.

2.4. A large number of primarily conventional organizations

A large number of primarily conventional organizations, such as supermarkets, are involved in some way in the chain of Fair Trade. Approximately 43,000 supermarkets across Europe and 7,000 in the U.S. and Canada has in its assortment Fairtrade products. Although they are outside Fair Trade movement, they are becoming increasingly important participants in the Fairtrade products retail chain. With the growing Fair Trade market share will increase their importance in the distribution of these products. Many supermarkets are starting to sell Fairtrade products which are purchased directly from the producers with this trademark.

Selling in large supermarkets, national chains or small stores, Fairtrade products are becoming more accessible to consumers. The most important for them is certainly the trust in the Fairtrade label, so the Fair Trade labelling organizations never diminish the criteria that mus be meet. Accordingly, the Fairtrade label on products, no matter where consumers buy them, guarantees that they met the strict social, economic and environmental standards. The same international Fair Trade standards apply to all companies and retailers, regardless of their size or organizational structure.

It is important to point out that the Fairtrade certification model does not include monitoring of other business activities, so the certificate is valid for certain products and not for the company.

2.5. Lobbying organizations

Lobbying organizations contribute Fair Trade development, which is confirmed by the work of Fair Trade Advocacy Office (FTAO). It represents FLO, WFTO and EFTA in Brussels, where successfully lobby for the European Commission contemporary politics to support Fair Trade.

FTAO supports Fair Trade with the aim to improve trading conditions for the benefit of small and marginalized producers and poor workers in developing countries. It:

- Coordinates representation of FLO, WFTO and EFTA;
- Monitors the European and international policies on trade and development;
- Provides a continuous dialogue between the Fair Trade movement and decision makers;
- Develops policy positions in the field of Fair Trade and equity trading;
- Publishes informational publications and brochures.

However, it must be noted that if the lobbying organizations are considered as organizations which are trying to „persuade“ the government to change its views in favor of certain issues, than all Fair Trade organizations have a role in lobbying, either in the traditional way or giving the public its successful story.

3. FAIR TRADE CONTRIBUTION TO SUSTAINABLE DEVELOPMENT

Government support in developing countries is often limited, so communities must take on the role of government structures, providing support, protection and advocacy of individual needs and interests.

Participition in Fair Trade contributes and promotes the survival of communities, and brings many and various benefits to small producers.

One of the most significant is certainly, the guaranteed minimum prices for the products included in it, which increases their income. Jaffee (2010) points out that "The base prices for Fairtrade products (at first only coffee) were initially established by movement NGOs in the late 1980s based on assessments of producers` costs and livelihood needs. Individual buyers may pay higher than the FLO minimums if they choose. The setting of prices became the purview of FLO after its creation in 1997" (p. 276). Greater economic stability, better credit and financing terms, lower interest rates, diversification of income sources, access to markets of developed countries, are important as well.

Beside these obvious benefits of Fair Trade, other are more complexed and less visible. In addition to the minimum prices, producer organizations receive Fairtrade Premium, as a sum of money paid above the guaranteed price of Fair Trade. It is precisely defined for all Fairtrade products and must be invested in a way to contribute sustainable development. Premimum can be invested in projects of social, environmental and economic development, based on democratic decisions at the level of producer organizations. Some forms of using these means are: building pharmacies, hospitals, schools, bakeries, storages and transportation facilities, constraction and reconstruction of houses, promotion of organic industry, effective management of water resources, cooperation with other communities, reducing illiteracy, etc.

Figure 1. shows how producer orgainizations in developing contries distributed Fairtrade Premiums recevied in the period 2010-2011 on the global level (Fairtrade Labelling Organizations Intenational, 2012, p.58). Most of the amount was spent on investment in business or organizational development, production and processing, while there was no expenditure on gender equity during this period.

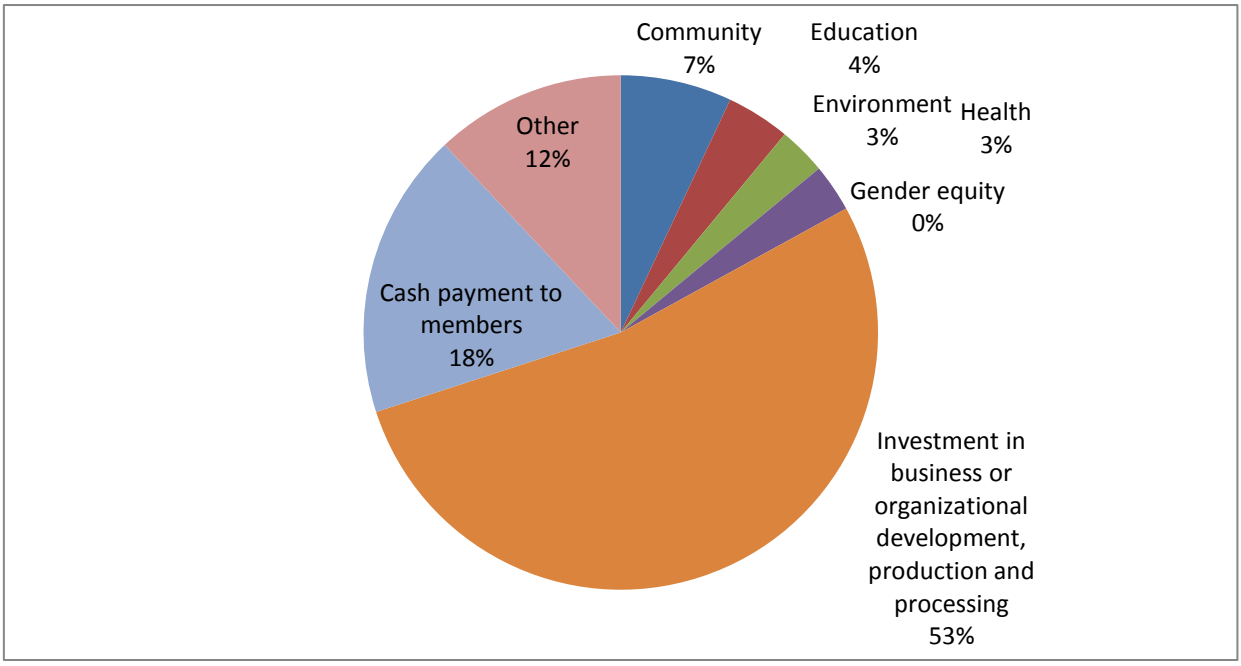

Figure 1: Fairtrade Premium expenditure by category: Small Producer Organizations and Contract Production 2010-11

On the other side, consumers in developed countries show great concern to know not only what quality products they buy, but also, where and how they were produced, and who has benefits of their purchase. They express their concerns through their ethical behaviour and that is why they are willing to pay higher prices for Fairtrade labeled products. Fairtrade label on products packages indicates to consumers that they are produced according to Fairtrade standards whose adoption and implementation is in charge of Fair Trade organizations.

Fair Trade is a part of ethical consumerism, but the profit gained operating through this business model differes from the profit gained by maximizing sales. There are obvious differences in the transparant negotiation, information and Fairtrade premium and prices which receive trading partners within the Fair Trade network.

Kroger and Schafer (2014) point out that "Organic agriculture and Fairtrade have become the most important alternative food production systems worldwide, and both are supported of a broad movement of social actors. They represent important challenges to the ecologically and socially destructive relations that characterize the global agro-food system. Both movements critique conventional agricultural production and consumption patterns and seek to create more sustainable world agro-food system" (p. 45).

4. CONCLUSION

The network of Fair Trade organizations promotes Fair Trade, sharing a common vision and principles which govern their operations. Their work from its foundation until today shows positive sentiments and opinions, emphasizing their contribution to the improvement of living standards and business conditions of marginalized producers, sustainable development, financial and other conditions in local communities, creating a good image in the eyes of consumers and others. The role of Fair Trade organizations as the fundamental „guarantee“ of this concept is unprecedented, even in the future will certainly come to their transformation.

Fair Trade shows that marginalized producers in developing countries can benefit from trade with their partners in developed countries. It is not a charity or donation, but a successful business model including better trading partnership in which each participant achieve profit.

ANALYSIS OF THE LEVEL OF ALIGNMENT OF MARKETING OBJECTIVES WITH SOCIAL RESPONSIBILITY IN THE COUNTRIES IN TRANSITION

Slobodanka Krivokapić[1]
Mediteran University, Montenegro, Faculty of Business Studies, Podgorica,
slobodanka.krivokapic@unimediteran.net

***Abstract**: corporate social responsibility and sustainable development have become a global paradigm. Current conditions and characteristics of the global business point to the necessity of gaining competitive advantage, and achieving goals that do not solely imply an increase in profitability. The companies in the market economy countries follow the strategies that are economically profitable, but at the same time socially responsible and establish a symbiosis between the principles of profitability and social responsibility. Implementation of CSR is based on the full commitment to the principles and processes through the alignment of the objectives of marketing activities. Literature and practice show that profit and social responsibility do not always go together. This is particularly evident in the countries in transition, such as the Western Balkan countries. An undeveloped institutional framework, frequent law amendments, inadequate corporate governance and a lack of strategic approach are conducive to business uncertainty and an exclusive orientation to profit. Doing business in these countries generally carries the risk for the owner, especially when operating in varying conditions where profit is emphasized and social responsibility neglected. Weaknesses in the implementation of corporate social responsibility arise from conflicting objectives, organizational culture, management, strategy and a wider social context. CSR is an important marketing tool in gaining a sustainable competitive advantage that ensures an interaction between different stakeholders and alignment of marketing objectives. The aim of the paper is to point out to the need to reconcile economic with social interests in the countries in transition by analysing the level of alignment of marketing objectives with social responsibility.*

***Key words:** social responsibility, marketing, stakeholders, transition society*

INTRODUCTION

Social responsibility is increasingly growing in importance in the world of business. The organizations that operate at the national and global level, regardless of ownership, are becoming more complex, because the requirements for financial sustainability and integration into the social and economic environment form part of contemporary business premises. Corporate social responsibility (CSR) has become a strategic and integrative element of modern business, which is basically a continuation of business activities. Porter & Kramer (2011) pointed that " CSR programs focus mostly on reputation and have only a limited connection to the business making them hard to justify and maintain over the long run" (p.76) and also emphasize that "the solution lies in the principle of shared value, which involves creating economic value for society by addressing its needs and challenges" (p.64).

An economic approach that perceives business as a basis for making profit is related to the social responsibility of business entities. In modern conditions economic responsibility has a tremendous importance in the competitive game. Harmonization of the interests and demands of stakeholders expressed through an approach for increased social responsibility is not of lesser importance in business, especially in the countries with developed market relations. Today, social responsibility is integrated into the business strategies of companies, particularly regarding the labour standards, environmental sustainability, reporting, transparency and relationships with suppliers and customers which is shown in Reports State of the Profession (2013). Social responsibility has become a necessity of modern business, which includes achieving and maintaining the satisfaction of customers, employees, shareholders, owners and other stakeholders. The companies that establish a symbiosis between the principles of profitability and social responsibility have long-term growth prospects. Development of corporate social responsibility has become a

leading paradigm at the global level. It has originated from the belief that companies are not only economic, but also social entities, which have a responsibility towards the society and are required to do things to improve the situation in the society in general. In addition to knowledge, skills, and process management, modern companies find competitive advantages in social responsibility as well. Social responsibility is seen as a necessity adopted by a growing number of companies with the aim of maintaining their market position.

Corporate social responsibility in the countries in transition is declarative and business entities are faced with numerous problems, including inadequate policies, the practices aimed at profit and maintaining business for profit. The absence of public policies on social responsibility, lack of experience in the application of modern marketing techniques and inadequate strategic management result in a low level of implementation of social responsibility which is reflected in inconsistency and conflicting objectives of business entities with the principles of corporate social responsibility, especially in the Western Balkan countries in the transition process. The aim of the paper is to point to the importance of reconciling marketing objectives with social responsibility in the countries in transition and the need to change the way of doing business in order to strengthen the moral, ethical and business values of modern business in the countries in transition.

1. THE ROLE OF SOCIAL RESPONSIBILITY IN BUSINESS

The role of business is primarily focused on creating the value for the owner or shareholder, in the manner that the value for the society is simultaneously created. When we look at market economies, the primary responsibility of business is the return of invested funds and economic benefit for the society. The fundamental principle of business is the ability of the company to create value for itself and in turn to create value for the society. The differences that arise between the goals of the company and the society cannot be ignored, especially if the societies have developed mechanisms to encourage social responsibility. There are conflicting opinions in the literature over the issue of whether the companies should be focused solely on the financial interests of owners, or the interests of stakeholders. The proponents of the former opinion explain that the business carries a great risk for the owner of the company, and lesser for the public concerned. In corporations, shareholders aim to achieve their interests, according to which they create values. Rappaport (1986) emphasized that business strategies should be aimed at maximizing the shareholder's value. He also pointed out to the fact that corporate missions primarily point to the responsibility of the management for profit maximization in the interest of the owner, and that the research indicates that the majority of employees in industrial complexes have similar views on the issue of profit maximization.

New perspectives have shown the weaknesses of the "shareholders theory" and acceptance of the" stakeholders theory (Freeman and Gilbert 1988) according to which the interested public has the power to seriously affect the corporations and their moral responsibility towards the stakeholders' interests. Hamel & Prahalad (1994) pointed out that the companies join the society due to their interaction in the complex, highly complicated and unstable environment and besides the economic mission they also have social responsibility. The competitive game in a turbulent environment brings to the fore the issue of sustainability which starts from the premise to meet the needs and expectations of customers (Kotler & Armstrong, 2010). .

Corporate social responsibility in the 21st century reflects the core values of the companies and forms part of their business strategies. Under the influence of numerous stakeholders the business is focused on the strategies that include the principles of social responsibility, among which environmental sustainability and resource conservation are very important (EEA 2013). In recent years, a growing number of companies worldwide have some form of corporative social responsibility. The "Sustainability Disclosure Database" Global Reporting Initiative includes 6065 companies with over 17.642 reports. CSR ranks high on the priority list of a growing number of companies and represents their commitment to the society in which they operate and implement their business activities. Requirements for environmental protection and the protection from unethical exploitation of resources have resulted as a response of companies to consumer demands. New technologies, resource conservation, consumer demands and government policies change the objectives of the company towards social responsibility. The companies that wish to maintain their competitive advantage adopt the principles of environmental sustainability and incorporate them into the corporate goals. Nemitz (2013, p 92) points out that "The majority of environmental goals fall into category in which market values are

not available. These goals, termed have two characteristics: non-exclusion-meaning that one person could not prevent another from consuming the resource and joint consumption".

Unlike large corporations, small companies have more freedom to direct their business objectives towards social responsibility, which is due to their financial power, mainly focused on the use of renewable energy sources, efficient use of resources, relationship marketing, as well as philanthropic activities.

The system of social responsibility strengthens the core values of the company, through cohesion of the objectives and tasks focused on the core of the competitiveness and resolving the social and environmental problems of the societies in which they operate.

2. MARKETING OBJECTIVES AND SOCIAL RESPONSIBILITY

The modern market is an "ethical arena" in itself, which reflects the goals of the company and the society, through the application of the principles of social responsibility. Kotler & Armstrong (2010 p. 629) point out that "Good ethic is a cornerstone of sustainable marketing".

Requirements for greater social responsibility are initiated by major social actors, as the need to solve numerous social and ethical issues. Most business organizations are faced with the challenges of reconciling corporative social responsibility (CSR) with strategic goals, and with the problems in their implementation. Modern business conditions require the integration of economic principles and the principles of social responsibility. The marketing objectives must provide the right direction and sufficient flexibility so that the company could adapt to changes. Kotler & Armstrong (2010) point out that „The social marketing concept holds that marketing strategy should deliver value to customers in a way that maintains or improve both the consumer's and society's well-being" (p 35).

Today CSR represents the agenda of all large corporations. The World Economic Forum has particularly stressed the link between corporate governance, corporate responsibility and competition, as the basis for conducting business. The studies show that corporate socially responsibility business is the basis for differentiating companies and consumers choose products of the companies that are recognized for their social responsibility. Most studies confirm a positive correlation between social responsibility and financial performances. Dess, Lumpkin & Eisner (2007) indicated the McKinsey&Company studies (p.332) that have been carried out, point to the relationship between good corporate governance and performance. This study includes the results of 12 analysed developing markets, which indicates that the worst companies, in terms of corporate governance, have lower return on capital than the market average. Moreover, the results show that the activities of the Board of directors were as important as the financial performances. The study showed that effective corporate governance affects the financial viability and social responsibility.

The statements on social responsibility set forth in the missions of companies are reflected on the marketing objectives. The task and purpose of the mission of a business entity is to guide the company towards the execution of its strategies. The power of the mission is reflected in how successfully the objectives of different strategies are harmonized. In practice, it happens that the objectives are intertwined between different business levels. Furthermore, there are conflicting objectives among stakeholders, as well as the question of trust among all stakeholders. Social responsibility rests on trust and voluntariness, and the trust is built through appropriate relations between external and internal stakeholders and managers. The managers are the first strategic players who are responsible for strategic choices, which include the most important predictions about the environment and the need of companies to gain the competitive advantage. The greatest attention of managers is mainly focused on key stakeholders, such as the society and customers, rather than on specific social groups. Their role in the implementation of social responsibility is very important.

The subjects of all marketing efforts that recognize the role and importance of social responsibility are customers. They are the ones who make decisions, put pressure and make purchasing decisions and choices. Customers in developed countries have a high level of awareness of the social corporate responsibility, as a factor that influences their purchases. "Sustainable marketing goes beyond caring for the need and wants of today's customers. It means having concern for tomorrow's customers in assuring the

survival and success of the business, shareholders, employees, and the broader world in which they all live" (Kotler & Armstrong 2010, p 663).The authors point out that the fulfilment of the needs of the target market and consumers is ensured through harmonization of public interests, economic efficiency, and information and consumer protection. The implementation of social responsibility implies harmonization of marketing and strategic goals, as well as the commitment of business entities to their own values and interests, as well as to the society as a whole.

3. SOCIAL RESPONSIBILITY IN THE TRANSITION COUNTRIES

Transition is a challenge for the countries that are building the market economy and which must deal with the issues not only related to business and economy, but to the social responsibility as well. The approach to corporate social responsibility is essentially based on creating a greater quality of life of the societies lagging behind in their development. Addressing this problem cannot be simply a matter of the economy, but the influence of political structures which create the system of values and relationships within individual countries. Numerous problems of the Western Balkan countries are reflected in the high unemployment rates, excessive foreign debt, structural problems and lack of liquidity (EC Progress Report, 2013). The economic objectives have become dominant, so the primary objective of business entities is to make profit, regardless of social consequences. Therefore, the governments in these countries are forced to solve numerous social problems. The uncertainty of economic operations, undeveloped markets and the effects of the economic crisis affect the inconsistency between marketing strategies and social responsibility.

Social responsibility is based on the trust between social actors which has been lost in the transition process. Institutional deficiencies and frequent amendments, or insufficient application of adopted laws, in most of these countries have influenced the level of social trust. There are a lot of regulations and little trust of the companies that do not have adequate strategies for corporate social responsibility and strategic market activities. Social responsibility is generally given very little importance. Improvement of working conditions, the overall social environment and ethical values should be the basis for an increase in profit, with the maintenance of the basic standards of the conservation of natural resources and protection of consumers. Despite this, the fact is that corporate governance is in its infancy. The public owned companies operating in the domain of public interest are an obvious example of this. The mechanisms of management are not aligned with the interests of the owner, or the state. Namely, the boards of directors usually act in an opportunistic manner, while the managers are usually appointed using political connections. The issue of making profit in the companies that are registered as public limited companies is similar. A lack of experience in the application of modern marketing concepts generally reduces the operating results and presents a barrier to business based on social responsibility. Compared with the developed market countries it can be concluded that there is no successful business without the development of the market and social responsibility.

The research on the application of corporate social responsibility in the countries of the Western Balkans is supported by international organizations with the aim of raising awareness, improving the institutional framework and enhancing confidence in social responsibility. The research studies point to the differences in the levels of implementation of social responsibility within the official policies and a declarative public interest for the introduction of corporate social responsibility. The results show that the index of social responsibility is larger in the companies with a large number of employees and that the perception of corporate social responsibility in the public is still low (Project "CSR of MNE Company", 2013).

The analysis of the practice reveals that the companies in the sectors of telecommunications, finance and energy that normally apply CSR in their home countries take advantage of the ambiguities of statutory provisions, the monopoly and underdevelopment of infrastructure for consumer protection by making the extra profit in the markets of these countries. This is particularly reflected in their relations with consumers who still do not have any real protection instruments. Examples of good practice of corporate social responsibility in successful companies are mainly philanthropic activities, rather than a systemic approach that integrates business objectives and social responsibility. The Western Balkan countries that are in the process of accessing the EU are obliged to harmonize the legislation and the policies for the improvement of

business operations and monitoring of social responsibility. The EU policy is focused on maximum transparency and informing consumers about the potential risks in the market (EEA, 2013).

The responsibilities are also aimed at strengthening the institutional mechanisms, developing the market, improving corporate governance and transferring the knowledge of modern business principles so as to create economically viable and socially responsible companies.

CONCLUSIONS

Social responsibility is of special importance in modern business. The theorists suggest that modern business is oriented towards sustainable competitive advantage, superior performances, corporate social responsibility and shared value. The system of social responsibility strengthens the core values of the company, through the cohesion of the objectives and tasks focused on the core of the competitiveness and resolving the social and environmental problems of the societies in which they operate.

The modern business paradigm requires the corporate social responsibility towards the community and developed market relations that create competitive advantage for the socially responsible companies. The business success in the market is achieved through the symbiosis of the business developmental goals and the goals of the society.

Implementation of the goals of the company and the application of social responsibility are ensured through the institutional mechanisms, developed market and the implementation of appropriate stakeholder-oriented strategies. The modern marketing provides the necessary interdependence and harmonization of marketing objectives and social responsibility among all stakeholders. Stakeholders, investors, customers and consumers represent the target points around which it is necessary to integrate the marketing efforts for the acceptance of social responsibility and implementation of the business strategy.

The companies that operate in the markets of transition countries have a low level of harmonization of marketing objectives and social responsibility, which reduces the effects of their operations and is reflected on the society as a whole. Insufficient social responsibility results in the reduction of efficiency and the value created and inadequate exploitation of resources. The companies that operate in the countries with undeveloped social responsibility practices are faced with the problem of sustainability and the slowdown in development.

The Western Balkan countries need to strengthen the institutional framework, develop market mechanisms, and improve corporate governance and the transfer of the knowledge of modern business principles in order to create economically sustainable societies.

EDUCATION MANAGEMENT

STUDENTS' PREFERENCES TOWARDS E-LEARNING ENVIRONMENT

Abstract: *E-learning opportunities are rapidly expanding in higher education. To meet the needs of students enrolled in such courses, universities must rethink how they deliver knowledge and understand the factors that influence students' satisfaction. Such understanding can be used for appropriate design and improvement of e-learning environments based on their preferences, with the aim to enhance student learning experience. The purpose of this study was to identify students' preferences and their levels of satisfaction. Special attention was given to differences between the students in e-learning environment (Moodle and open courses) in comparison to traditional students who experience only face-to-face delivery of knowledge or attend few courses in e-learning environment. Conjoint analysis was used for this purpose. Results indicate that there is a difference both in satisfaction and preferences between two groups of students, and factor that singles out is method of knowledge assessment.*

Keywords*: E-learning, satisfaction factors, student preferences, conjoint analysis.*

1. INTRODUCTION

When learning is mediated with technologies then we can assume that some form of e-learning happened. Advancements in technology have revolutionized the opportunities for educators to teach and the means for students to learn (Tutty & Martin, 2009). Rosenberg (2001) emphasized that e-learning refers to the use of Internet technologies to deliver a broad array of solutions that enhance knowledge and performance. E-learning is networked (instant updating, storage/retrieval, distribution and sharing of instruction or information). It is delivered via computer and goes beyond traditional paradigms of training (Rosenberg, 2001, p. 28). E-learning can be defined as the use of network technology (broadly, the "Internet") to design, deliver, select, administer, and extend learning. Main components of e-learning can include content delivery in multiple formats, management of the learning experience, and a networked community of learners, content developers and experts (Yu et al., 2010).

If e-learning is referred to as part of an educational system then we should explain the term distance education (e-education). E-learning could be viewed as a part of an educational process within educational system. In this sense e-learning is a part of educational process where the teacher and the student are separated from each other and by means of technology they achieve two-way interaction in order to implement the necessary commutation. E-learning also could be seen as content delivery method in distance education that enables synchronous and asynchronous information exchange over the network (Oncu & Cakir, 2011). Today e-learning has become a viable delivery system for both secondary and higher education (Yu et al., 2010).

The central component in e-learning environment is the learner for whose benefit the environment is provided. Understanding the characteristics of learners in respect to how those characteristics may affect the teaching–learning process in the online environment is very important for designing effective instructions for e-learning environment (Roberts, 2010). The manner to achieve that students' perception of the effectiveness of e-learning course and their satisfaction will be evaluated in this paper.

In order to evaluate the effectiveness of e-learning courses researchers examined different components of e-learning. Malik (2009) created a practical model for examining student satisfaction with e-learning and identified five groups of factors: student, instructor, technical, design, course. Matsatsinis et al (2003) selected three criteria of satisfaction with several sub-levels: interface (web design, user-friendliness, personalization, etc), content (structure, extra links, format, etc) and functionality (response time, reliability, security, etc).

Horvat et al. (2014) examined students perception on e-learning courses on Moodle platform at Faculty of Organizational Sciences and concluded that students who use Moodle have a significantly lower satisfaction

only before an exam in comparison to students who use it on daily basis (Horvat et al., 2014). They have suggested that feedback on quality characteristics from students that do not use Moodle regularly should be considered as it is done in this research.

Cavanaugh et al (2004) identified success factor of distance learning programs, and found that most important ones are: abilities and disabilities of the student, quality of the teacher, demands of the content, design of the distance learning system, course, and other assessments. Likewise, Damnjanovic et al. (2013) defined eight factors (behavioral intention to use in the future, communicativeness, format, information quality, performance outcome, perceived usefulness, satisfaction and system quality) in order to measure effectiveness and use of Moodle. Their results showed that system and information quality did not influence satisfaction, while communicativeness had the highest impact on performance outcome. Satisfaction had a significant effect on behavior intention (Damnjanovic et al., 2013).

2. RESEARCH FRAMEWORK

The aim of this study was to acquire a broad view of students' preferences in e-learning in Serbia, and to investigate which learning experiences contribute most to their satisfaction. The assumption behind the study is that students prefer certain online components more than others and that it is possible to identify which of these are most influential on their attitudes. In accordance with this, the study did not examine specific courses but a diverse sample of students that are engaged in: (1) entirely online studying via Moodle learning environment, (2) traditional offline, face-to face studying with some experience with blended courses (combination of face-to-face and e-learning), (3) taking open online courses outside curricula (edX, Coursera, etc). The important element of e-learning is students‘ perception of the effectiveness of e-learning course and their satisfaction with it. Three dimensions of interest were defined in this study as: e-learning technology, teaching method and knowledge assessment. They were chosen by considering previous research (Mosca et al., 2010; Katz, 2002; Ferguson & DeFelice, 2010; Won & Bravo, 2009) and authors‘ own experience in teaching in e-learning environments.

Learning environment, or technology used for delivering knowledge, is important as satisfaction of students from e-learning is based on the student‘s attitude towards ICT (Malik, 2009). Technology is generally not a barrier to the success of participants in e-learning and most students have necessary skills to fully engage in e-learning environments. Drennan et al. (2005) found that student satisfaction is influenced by positive perceptions towards technology, in terms of ease of access.

Teaching method is the most complex dimension as it comprises of several different aspects, mainly related to interaction. According to several authors (Bouhnik & Marcus, 2006; Katz, 2002; Picciano, 2002), interaction is one of the most important factors of e-learning, and can be analyzed on several levels: interaction with content, teacher, other students and the system. Mijatovic et al. (2013) conducted a research on students, who are using Moodle platform for the first time in their studies and they have concluded that active participation in class and interactive usage of the system had strong positive effect on students' achievement. (Mijatovic et al, 2013). Bouhnik & Marcus (2005) found that one of the things students are dissatisfied with is the lack of contact and interaction with their peers. Jung et al. (2002) found that the students who collaborated with each other expressed the highest level of satisfaction. Nummenmaa and Nummenmaa (2010) came to similar conclusion by finding that students who did not interact with others had more negative emotional experiences. The group interactions initiated by teachers are very effective and students enjoy the learning environment. The teacher role is very important and their timely response positively influences student satisfaction (Malik, 2009). Clearly defined objectives, assignments, and deadlines, need to be present in order to increase student satisfaction as well (Stein, 2004).

We found no research results in literature regarding student preferences in knowledge assessment within e-learning environments, but we believe this dimension might have an impact on students‘ satisfaction and therefore have included it in this study. The details on all three dimensions, their attributes and level are presented later in the text.

3. RESEARCH METHOD

3.1. Conjoint analysis

Conjoint analysis (CA) is a multivariate technique that can be used to understand how an individual‘s preferences are developed. It originated in mathematical psychology (Luce & Tukey, 1964), and was first introduced in marketing research to evaluate consumer preferences for hypothetical products and services (Green & Rao, 1971). Today, it is widely used to understand preferences in various markets, including transportation (Hensher, 2001), telecommunication (Kim et al., 2008), labor market (Popovic et al., 2012), etc. Furthermore, conjoint analysis has been successfully applied within the education industry: Soutar and

Turner (2002) used conjoint analysis to reveal what kind of university was most desirable among students; Hur and Pak (2007) attempted to identify what the preferred subjects for an after-school computer education course in elementary schools were by using conjoint analysis; Won and Bravo (2009) applied conjoint model that compares the relative importance of six course attributes that influence students‘ preferences in order to develop courses to satisfy students‘ needs and enhance teaching effectiveness. Sohn and Ju (2010) used conjoint analysis to effectively recruit high quality students for high school; and Kuzmanovic et al. (2012) used conjoint analysis to identify heterogeneity of the students‘ preferences for various aspects of university teaching. Kuzmanovic et al. (2013b) propose a new conjoint-based approach to students‘ evaluations of teaching which takes into account the students' preferences.

However, only a few studies have used conjoint analysis within e-learning environment as of yet. Van Der Rhee et al. (2007) used discrete choice analysis (type of conjoint analysis) to understand student preferences for e-learning technologies. They conducted a large-scale survey to determine whether students who are technology ready would place higher utility on enrolling in mixed classes and/or whether there exists a participation bias such that students with low learning-goal orientation place higher utility on enrolling in mixed classes. Pomales-Garcia et al. (2009) evaluated the relative importance of six design dimensions in order to understand how these dimensions are described by two groups of stakeholders—students versus researchers. To determine the predicted rank of the design dimensions based on participant ranking results, they used conjoint analysis. Dağhan and Akkoyunlu (2012) studied learning styles of students receiving education via online learning environments, and used conjoint analysis to determine students' preferences concerning the online learning environment. Sun and Wang (2013) used conjoint analysis to find out how to choose different e-learning tools for different learning tasks for the design and development of online courses in higher education. The findings yield helpful insights on the best practices concerning the utilization of information technology for the enhancement of student learning outcomes in online course design.

We used conjoint analysis in this study to elicit students' preferences towards e-learning environment for several reasons. First, conjoint analysis has the advantage over conventional satisfaction models in that it can be used to identify and quantify the trade-offs that respondents are prepared to make between conflicting attributes. Second, conjoint analysis transforms respondents‘ subjective attitudes towards estimated parameters into the form of utility functions, thereby making it possible to observe the consequences for the overall preference of a change in the level of an attribute. Third, conjoint analysis allows the utility estimation for any combination of attributes, including combinations that may not currently be available. Fourth, conjoint analysis allows segmentation based on respondents' preferences. In other words, conjoint analysis is a micro-based measurement technique, i.e. preferences are measured at the individual level. Hence, if preference heterogeneity is present, the researcher can find it. Another reason why we chose conjoint analysis in this study is its cost-effectiveness. Conjoint analysis does not require a large sample size. The reason is that the analysis results in a set of utilities for each respondent.

3.2. Survey procedure

Conjoint experiments involve respondents being asked to express their preferences for various experimentally designed, real or hypothetical alternatives. These hypothetical alternatives are descriptions of potential real-world alternatives, in terms of their most relevant features or attributes (both quantitative and qualitative); hence, they are multi-attribute alternatives. Conjoint analysis produces two important results (Levy 1995): utility of attributes and importance of attributes. Utility of attribute also known as part-worth utility, is a numerical expression of the value consumers place in an attribute level. It represents the relative —worth” of the attribute. Low utility indicates less value; high utility indicates more value.

Lists of attributes describing single alternatives are called profiles or concepts. Typically, the set of relevant attributes is generated by expert opinions, reviewing the research literature and performing pilot research with techniques such as focus groups. The list of attributes may include an attribute currently not available (new feature), but its introduction is under consideration. Two or more levels are defined for each attribute, and these are then combined to create different profiles (Kuzmanovic et al., 2013a). In order to measure the relative importance of key attributes of the e-learning environment with reference to student‘ preference, this study followed three key phases.

Phase 1: Specifying attributes and levels. Conjoint analysis starts with the identification of relevant product/service attributes that are believed to influence a customer‘s preference. They should include those more relevant to potential customer (student) and those that can be influenced or manipulated by the seller/service provider (university). Then, levels must be assigned to them. These must be plausible, actionable and capable of being traded-off one against another. Typically, the set of relevant attributes is generated by expert opinions, reviewing the research literature and performing pilot research. In this paper

eight key e-learning attributes based on literature review and opinions both of students and faculty members are selected (see section 2). The list of selected attributes and their levels is given in Table 1.

Table 1: Key e-learning attributes and respected levels

Dimension	Attribute	Level
I E-learning technology	Customize environment based on preferences	Yes
		No
	Simplicity	Simple environment, no training necessary
		Environment requires training or previous experience
II Teaching method	Lectures	Recorded lecture with slides and sound
		Classroom live broadcasting
	Interactive work (discussions, assignments, case studies etc)	Yes
		No
	Cooperation with other students	Individual assignments
		Group assignments
	Flexibility for pre-exam assignments (clear deadlines or flexible deadlines)	Yes
		No
	Communication with teacher	Online (e-mail, chat, forums, etc)
		Online and face-to-face
III Knowledge assessment	Method of assessment of knowledge	100% of pre-exam assignments and exam in e-learning environment
		70% of pre-exam assignments in e-learning environment and 30% offline exam
		30% of pre-exam assignments in e-learning environment, and 70% offline exam

Once attributes and their respective levels have been selected, the number of combinations or profiles can be calculated. In this research, the selection would produce 384 profiles (2^8x3). Conjoint studies tend to focus on just those attributes that have the greatest influence. Unfortunately, this rarely reduces the number of profiles to manageable proportions, so it is common to use an ‚orthogonal array', a subset of all possible concepts that will allow estimation of the part-worths based on a ‚main effects'. Thus, the orthogonal array allows the conjoint analysis to be conducted on a considerably reduced number of product combinations while still retaining statistical reliability. To reduce this number of profiles to a manageable level, in this study a component of the statistical package SPSS 16.0 (Orthoplan) was used. Thus the 384 possible profiles were reduced to 16. Two control profiles (holdout tasks) were added to the given design. These 2 profiles were not used by the conjoint procedure for estimating the utilities. Instead, the conjoint procedure calculates correlations between the observed and predicted rank orders for these profiles, as a check of the validity of the utilities.

Phase 2: Choosing a presentation method. ‚Full-profile' and ‚trade-off' are the two methods of attribute combinations most widely associated with conjoint analysis. This study used the full-profile approach. Each profile was presented visually in the form of a card. Respondents were asked to rate each profile on an ordered scale ranging from 1 (‚least preferred') to 5 (‚most preferred').

Phase 3: Model specification and the estimation technique selection. Having collected the information on individual preference, the responses need to be analyzed. In this survey the linear additive model was used as a composition norm and assumed that overall evaluation is made up of the sum of contributions of the attribute levels. The overall additive model for K attributes, each one with L_k levels, is given by Eq. (1)

$$U_{ij} = \sum_{k=1}^{K} \sum_{l=1}^{L_k} \beta_{ikl} x_{jkl} + \varepsilon_{ij}, \qquad i = 1,...,I, \;\; j = 1,...,J, \quad (1)$$

where U_{ij} is student i's evaluation of a given profile j, β_{ikl} is the part-worth (estimated in the conjoint analysis) associated to the l^{th} level of the k^{th} attribute (with k = 1,2,..., K and l = 1,2,..., L_k) and x_{jkl} is the independent variable (x_{jkl} = 0 or x_{jkl} = 1), which indicates the presence of the l^{th} level of the k^{th} attribute in the j^{th} profile. ε_{ij} is a error.

The parameters β_{ikl} (part-worth utilities) are estimated by Ordinary Least Squares regression analysis. These utilities provide a quantitative measure of the preference for each attribute level, with larger values corresponding to greater preference. Part-worths are expressed in a common unit, allowing them to be added together to give the total utility, or overall preference, for any combination of attribute levels. The part-worths then constitute a model for predicting the preference of any product profile, including profiles, referred to as simulation cases, which were not actually presented in the experiment.

4. RESULTS AND DISCCUSION

4.1. Demographics and students' satisfaction

Data were collected online through a web-based questionnaire in April 2014 in Serbia. Besides conjoint analysis questions, the questionnaire included demographic data, but also questions related to the attitudes toward online courses. The aim was to determine both level of students' satisfaction and whether there is a difference in preferences among students of different modes of studying. Respondents were students of University of Belgrade, Faculty of Organizational Sciences. In total 121 students completed the questionnaire. However, three responses (2.47%) were excluded since those respondents filled in the questionnaire in a monotonous pattern (e.g. marking all profiles as 1 or 2). Another three (2.47%) were eliminated due to inconsistent responses. After this exclusion, the number of valid questionnaires was 115 (95.04 %). The sample consisted of 39 (33.9%) male and 76 (66.1%) female participants, aged 21.5 (SD = 1.789) in average. When it comes to mode of studying, 70 (60.9%) respondents study traditionally and 45 (39.1%) of them are online students.

Table 2: Student satisfaction with online courses

		Number of respondents	Mean	Minimum	Maximum
Mode of studying	Traditional	66	3.96	2	5
	Online	45	2.88	1	4
	Total	111	3.54	1	5
Open online courses outside curricula	Coursera	15	4.56	3	5
	edX	4	4.75	4	5
	Other	5	4.60	3	5
	Total	24	4.60	3	5

In total, 111 (96.50%) students attended at least one course via Moodle during their studies (see table 2). Traditional students are more satisfied with this learning platform (average score of 3.96 out of 5), than online students (with average score of 2.88). Looking at the range of scores, it is obvious that none of traditional students gave grade 1 to Moodle, and none of the online students gave it grade 5. There are 21 (18.26%) students who took one or more open online courses outside curricula (24 graded courses). Average grade for these courses is 4.60, meaning that all those courses are graded much higher in comparison to core studies. None of open online courses were graded with 1 or 2.

4.2. Aggregated student preferences

To estimate conjoint parameters we used the statistical package SPSS 16.0 (conjoint procedure). The parameters are estimated individually for each respondent in the sample (individual preferences), as well as for the total sample (aggregated preferences). Table 3 shows both the averaged part-worth utilities for each level of each attribute and importance scores for each of the attributes. Higher part-worth utility values indicate greater preference.

The internal and predictive validity of the model was estimated by Kendall‘s tau statistic, which provides measures of the correlation between the observed and estimated preferences. Kendall‘s tau statistic (0.924) shows that there is a strong correlation between the observed preferences and those estimated by the model, which suggests a high predictive validity of the model. A high value of the Pearson coefficient, 0.988, confirms the high level of significance of the obtained results. The Kendall coefficient for two holdout profiles has a value of 1.000, which is an additional indicator of the high quality of the obtained data.

Table 3 shows that method of assessment of knowledge was found to have the most significant influence on students‘ preferences in e-learning environment with a relative importance of 23.76%. The importance of other attributes is by far lower. Attribute concerning existing opportunities for interactive work is second most important one (14.20%), whereas flexibility for pre-exam assignments was regarded as the least-valued attribute (7.69%). Looking at the most important attribute (knowledge assessment), students prefer the option to do all of pre-exam assignments and final exam in e-learning environment. Students also have positive but lower preferences towards the option to do 70% of pre-exam assignments in e-learning environment. The last attribute level (30% of pre-exam assignments in e-learning environment, and 70% offline exam) has a negative impact on their preferences.

Table 3: Averaged part-worth utilities and importance of e-learning attributes

Attribute	Attribute level	Part-worths	Std. error	Attributes importance
Customize environment based on preferences	Yes	0.105	0.023	9.31%
	No	-0.105	0.023	
Simplicity	Simple environment, no training necessary	0.172	0.023	12.36%
	Environment requires training or previous experience	-0.172	0.023	
Lectures	Recorded lecture with slides and sound	0.057	0.023	13.24%
	Classroom live broadcasting	-0.057	0.023	
Interactive work (discussions, assignments, case studies etc)	Yes	0.240	0.023	14.20%
	No	-0.240	0.023	
Cooperation with other students	Individual assignments	0.004	0.023	9.48%
	Group assignments	-0.004	0.023	
Flexibility for pre-exam assignments (clear deadlines or flexible deadlines)	Yes	0.021	0.023	7.69%
	No	-0.021	0.023

4.3. Segment level student preferences

In order to identify whether there are differences among the preferences of certain students groups, an analysis was conducted for the a priori defined segments as well. The a priori segmentation was carried out on the basis of the mode of studying: traditional vs. online. Averaged and segment level importance of attributes are given in figure 1. Although there is no significant difference in importance score among two segments and aggregate data, there are differences in preferred attribute levels (see table 4).

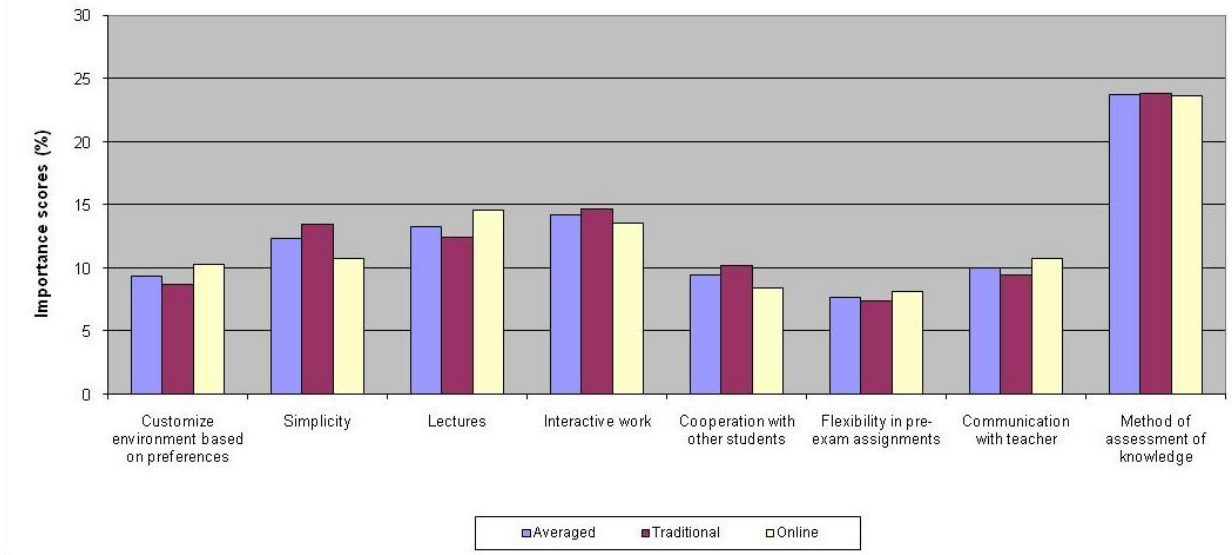

Figure 1: Averaged vs. segment level importance of e-learning attributes

Two segments of students have opposed preferences when it comes to four attributes. Traditional students prefer to listen to recorded lectures with slides and sound, to complete assignments individually, to have flexible deadlines for pre-exam assignments, and to complete the course entirely in e-learning environment. On the other hand, online students want classroom live broadcastings, group assignments, clear deadlines, and as much possible face-to-face tasks. Students have similar preferences towards other four examined e-learning factors.

Table 4: Traditional students‘ vs. online students‘ preferences

Attribute	Attribute level	Part-worths	
		Traditional studying	Online studying
Customize environment based on preferences	Yes	0.101	0.112
	No	-0.101	-0.112
Simplicity	Simple environment, no training necessary	0.203	0.124
	Environment requires training or previous experience	-0.203	-0.124
Lectures	Recorded lecture with slides and sound	0.140	-0.074
	Classroom live broadcasting	-0.140	0.074
Interactive work (discussions, assignments, case studies etc)	Yes	0.251	0.224
	No	-0.251	-0.224
Cooperation with other students	Individual assignments	0.019	-0.018
	Group assignments	-0.019	0.018
Flexibility for pre-exam assignments (clear deadlines or flexible deadlines)	Yes	0.056	-0.035
	No	-0.056	0.035
Communication with teacher	Online (e-mail, chat, forums, etc)	-0.103	-0.146
	Online and face-to-face	0.103	0.146
Method of assessment of knowledge	100% of pre-exam assignments and exam in e-learning environment	0.263	-0.087
	70% of pre-exam assignments in e-learning environment and 30% offline exam	0.013	0.035
	30% of pre-exam assignments in e-learning environment, and 70% offline exam	-0.276	0.052

5. CONCLUSIONS AND FURTHER RESEARCH

The findings in this study represent first empirical insights that examine the preferences of students towards e-learning environment using conjoint analysis in Serbia. Three dimensions of interest were considered in this study: e-learning technology, teaching method and knowledge assessment. The last one was determined to be the most important one for both traditional and online students. At the same time, two groups of students have opposed preferences towards four attributes regarding teaching method and knowledge assessment. E-learning technology produced homogenous preferences. It seems that both groups strive to features of alternative way of studying. The results of our study reveal information that may be useful in directing future research in key factors essential to the adoption and effective implementation of e-learning environment, and provide a guideline for university policy makers in redesigning online mode of studying.

IDENTIFYING POTENTIALS OF INFORMAL E-LEARNING 2.0

Jelena Anđelković Labrović[1], Gordana Milosavljević[2]
[1]University of Belgrade, Faculty of Organizational Sciences, jeca@fon.bg.ac.rs
[2]University of Belgrade, Faculty of Organizational Sciences, gordana@fon.bg.ac.rs

Abstract: *The use of Web 2.0 tools has become common nowadays. The research was conducted in order to investigate to what extent students use web 2.0 tools and its applications in their everyday life, for learning or for entertainment, trough informal process. The results show that the use of Web 2.0 tools for learning and/or entertainment among students of Faculty of organizational sciences is widely spread (in more than 90% cases) and that students use tools 2.0 for entertainment more that for learning. With that conclusion we should take into consideration that their habits in using those tools should be considered and integrated in formal learning processes.*

Keywords*: Web 2.0 tools, e-learning 2.0, informal learning*

1. INTRODUCTION

Contemporary learning and education implies the use of Internet and modern technologies. Web 2.0 (O'Reilly, 2005) represents the second generation of the Web (World Wide Web), in which the users are able to actively participate in the creation of content and where two-way communication between the users, cooperation and exchange of information is applied (Yang & Yuen, 2010). Web 2.0 is otherwise often referred to as the 'social web' (Boulos & Wheeler, 2007) or the 'read/write web' (Hemmi, Bayne, & Land, 2009), which refers to a range of software applications that have been variously described as 'dynamic', 'interactive', 'democratic', 'people centric', 'volatile', 'social' and 'adaptive' (Brown, 2012). In the broadest sense it is possible to state that e-learning is every learning mediated by technology. E-learning, which is implemented using Web 2.0 applications, is called e-learning 2.0 (Downes, 2005). The most common tools used for e-learning 2.0 are: Blogs, Wiki-based sites, Shared media, social networks, social groups, bookmarking and others. In this paper the e-learning 2.0 as a form of informal learning will be analyzed.

From the educational perspective learning could be formal, non-formal and informal, depending on where purposeful learning activity took place (Rubenson, 2011; Anđelković Labrović, Bijelić, & Milosavljević, 2014). Informal learning is learning resulting from daily life activities related to work, family or leisure. It is not structured (in terms of learning objectives, learning time, or learning support) and typically does not lead to certification. It may be intentional, but in most cases it is unintentional, incidental or random (Rubenson, 2011). In relation to the definition as represented in authors' experience in working with students, it appears that whether they are learning retaliated to their modules or anything else that they are interested in many of their learning activities are more similar to informal learning.

Authors believe that a lot of non-formal and informal learning activities are already incorporated in the way of students learning. So we wanted to identify how students informally learn using Web 2.0 tools and applications. The main hypothesis on which it rests is that students use various tools 2.0 in their daily lives and it is important to determine to what extent they are used for learning and how much for entertainment, especially since we cannot claim that thought entertainment informal learning doesn't happen as well.

2. LITERATURE REVIEW

Clark et al. (2009) explored how adolescents use Web 2.0 technologies for formal and informal learning. Students have identified 30 different Web 2.0 sites including the popular MSN (88%), followed by Bebo (67%) and Facebook (59%). All tools are used for various activities during lessons, in their free time as well as to support school activities, except that Bebo is not used for school activities. In fact 45% of students use Web 2.0 technologies to work in schools while 100% of them to work outside of school. 82% of students use social networking sites. Most of the students focused on the free time, entertainment and social networking activities while only 41% of students directly mention schoolwork, homework or research. For school-related activities most mentioned Microsoft Office (52%) and Internet sites such as Google (27%) and Wikipedia (6%) used for research and support for school work (Clark, Logan, Luckin, Mee, & Oliver, 2009). This study showed that Web 2.0 technologies not used to its full potential and that for students to use Web 2.0 technology as a tool for formal learning additional training need to be provided. Similarly, Cigognini et al.

(2011) concluded that students need support, guidance and educational interventions to make the best possible way using social media to support learning objectives (Cigognini, Pettenati, & Edirisingha, 2011).

Hemi et al. (2009) investigated the use of Web 2.0 and social technologies for teaching and learning within the formal educational process of higher education in the three modules, two at the undergraduate and one online graduate studies. In one module a wiki is uses to support teaching and learning, while in the second, blog is used in order to increase participation in discussions in class. At the online postgraduate studies used a wide range of technologies of social media including Facebook, Delicious, blogs, wikis and Second Life (virtual world) to support a variety of learning activities. The results showed that social media caused the pedagogical shift to more common forms of testing, and that their use puts more emphasis on the importance of self-regulation group (Dabbagh & Kitsantas, 2012; Hemmi, Bayne, & Land, 2009).

Vaughan et al. (2011) conducted a research on how students use Web 2.0 technologies to support group work outside of class time. The research results showed that students rather participate in activities that they know that will be assessed by the teacher and that are part of their formal learning process. As opposed to informal learning where researchers were surprised by relatively small number of students that use Blogs, Wikis and other Web 2.0 applications for group work outside of class (Vaughan, Nickle, Silovs, & Zimmer, 2011).

Huang et al. (2013) investigated the role of computer anxiety in influencing female college students' perceptions toward Web 2.0 applications for learning. The research revealed certain significant differences between genders on six Web 2.0 applications (blog, wiki, social networking tool, online video sharing tool, online game and immersive video environment). Overall they have concluded that females felt more anxious while using Web 2.0 applications than males, except for using social networking tools and online video sharing tools (Huang, Hood, & Yoo, 2013).

3. RESEARCH

The research was conducted in order to explain that students use Web 2.0 in their everyday life, for learning or for entertainment, in informal process. Main research objectives were to test students' knowledge of Web 2.0 tools and to identify the extent, to which students informally use Web 2.0 tools to learn and in which they use them for entertainment.

Main research questions are:

- Which Web 2.0 tools are most commonly used among college students for learning?
- Which Web 2.0 tools are most commonly used among college students for entertainment?
- Is there a significant difference in using Web 2.0 tools for learning in relation to the use of Web 2.0 tools for entertainment?

3.1. Overview of participants

The participants were students of the Faculty of Organizational Sciences (FOS), in all fields of study (management and Information systems and technologies) and of all years of study (1-4). Completing the questionnaire was anonymous, and students were informed that the results will be used strictly for research purposes. There were 402 valid questionnaires collected, out of which there were 93 first-year students, 100 second-year students, 94 third year students, 113 fourth year students and 2 graduate students. In further considerations to take into account students of all years except graduate level accounting for a sample of 400 respondents. Analysis of available data was performed using SPSS statistical software version 17.0.

The sample of 400 students is represented by 159 students of men, which was (39.8%) and 241 women (60.3%). Distribution by year of study in relation to gender is shown in the following table (Table 1).

Table 1: Distribution of respondents by year of study in relation to gender

		Gender		
		Male	Female	Total
Year of study	First	40	53	93
	Second	34	66	100
	Third	35	59	94
	Forth	50	63	113
Total		159	241	400

3.2. Research Method

Survey is used to test knowledge of Web 2.0 tools and to analyze how students use these tools for learning and/or entertainment. Analysis of the results of respondents' answers to all research questions was done by groups of tools in relation to their application (for entertainment and/or for learning). Web 2.0 tools and applications were presented in a survey trough following eleven groups of tools: blogs, wikis, shared media, shared workspaces, social networks and micro-blogging, social groups, bookmarking, tagging, web search engines, web aggregators and forums. The 5-point scale was used (never, ones a month, ones a week, few times per week, everyday) to show the frequency of using certain Web 2.0 tools.

To check the reliability of questionnaire the Cronbach's alpha coefficient was used as indicator of internal consistency. Internal reliability is assumed for correlation coefficients greater than 0.7 (Cronbach, 1951) Checking was done for the eleven groups of tools which can be used for entertainment, and eleven groups of tools which can be used for studying (N = 22). Calculated Cronbach's alpha coefficient had a value of 0.839. For data analysis descriptive statistics were used: frequency count to identify percentages in using Web 2.0 tools for learning and/or entertainment and Wilcoxon Signed Ranks Test was used to test potential differences between using Web 2.0 tool for learning and for entertainment.

3.3. Results

Using frequency of certain Web 2.0 tools for learning is observed and the results are presented in the table below (Table 2). Mostly used as a learning tool are Web Search Engines with 97.5%. 69.5% of students are using Web Search Engines every day what could also be connected to the results of daily use of bookmarking of 33.2 %. Then, the students in a very high percentage use forums (93.5%) out of which 77.6% use them on a weekly basis. Likewise, wiki tools are very highly ranked with 92.4% (65.4% on a weekly basis). It is assumed that such a large percentage of using wiki tools exists because most students use Wikipedia. It is particularly interesting to point out that if you ignore the dynamics of the use of certain tools (in the sense that it is used once a month, once a week, several times a week or daily) students use most of the tools in more than 50% of cases when learning is concerned (see details in table 2 row *USES* (2+3+4+5)). It is interesting to point out that most of the students did not use tagging (70.9%) and web aggregators (65%) for learning purposes. A significant number of students pleaded that 47.6% of them have never used blogs to study. Regarding tagging and aggregation it is assumed that the reason for low use could be precisely in the lack of knowledge about how these tools can be used as a learning means, as for the blogs is assumed that the reason could be seen purely as a student's preference for a certain tool. Also, often happens that students do not differentiate Web sites that are blogs from other type of web sites.

Frequency of use of Web 2.0 tools for entertainment is presented in the table below (Table 3). Regarding the group of tools that are used the least a situation is very similar as for the tools that are not used by the students for learning. As in previous case aggregation with 67% and tagging with 54.6% is pointed out. In the domain of using Web 2.0 tools for entertainment purposes Shared work spaces appeared as a group of tools that is not used in 53.5% of cases. Among the tools that are used primarily for entertainment Shared media tools stand out with 96.6%. 95.1% of them are used on a weekly basis, while 76.3% of them every day. The following are Web search engines (96.4%), as was the case among the tools for learning. High position among the tools used for entertainment, as opposed to learning, occupy Social networking and micro-blogging services with 90.2%, of which 87.1% is at weekly level and 69.2% is used on daily basis. It should be noted that most of the tools are used in over 60% of cases for entertainment.

Looking at all groups of Web 2.0 tools that students use for learning and/or entertainment it should be noted that there is no group of tools that is not used at all. Over 90% of students use wikis, shared media, social networking tools, search engines and forums. It is these results that demonstrate that students use above mentioned tools 2.0 on their own initiative in accordance with their wishes, knowledge and potentials. The presented results can be interpreted as another indicator that points to an existing habit for the use of particular tools 2.0 for learning outside the formal learning context, as well as the need for their use for learning at universities (educational institutions).

Table 2: The use of Web 2.0 tools for learning

Frequency of using Web 2.0 tools for learning												
		Blogs (%)	**Wikis (%)**	**Shared media (%)**	**Shared workspaces (%)**	**Social networks and micro-blogging (%)**	**Social groups (%)**	**Bookmarking (%)**	**Tagging (%)**	**Web Search Engines (%)**	**Web aggregators (%)**	**Forums (%)**

5	Everyday	7.0	10.8	76.3	8.6	69.2	21.4	41.4	8.2	82.4	5.2	26.0
TOTAL		100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0
Uses (2+3+4+5)		62.3	81.4	96.6	46.5	90.2	64.9	82.2	45.4	96.4	33.0	81.9
Uses (3+4+5)		39.5	54.6	95.1	26.1	87.1	53.6	71.3	27.7	94.9	19.7	61.2

Based on statistical analysis using Wilcoxon Signed Ranks Test (Table 4) it could be concluded that there is a significant difference in the use of Web 2.0 for learning and for entertainment in all groups of tools except Web aggregators (Z has values ranking from -3.476 to -12.673, $p<0.001$. These results for Web aggregators can be additionally explained because in most cases students do not use aggregator neither for learning nor entertainment (look at table 2 and table 3). Analyzing the other groups of tools 2.0 it is obvious that students are using Wikis, Shared workspaces and Forums more for learning and Blogs, Shared media, Social networks and micro-blogging, Social groups, Bookmarking, Tagging and Web Search Engines for entertainment. With these results, we can emphases once more that students use Web 2.0 tools for entertainment more than for learning (Table 4).

Table 4: Comparative overview of the frequency use of Web 2.0 tools for learning and entertainment

Using frequency		Year of study 1+2+3+4	
		Z	p
Blogs	Entertainment - Learning	-6.667[b]	0.000
Wikis	Entertainment - Learning	-3.476[c]	0.001
Shared media	Entertainment - Learning	-13.166[b]	0.000
Shared workspaces	Entertainment - Learning	-4.245[c]	0.000
Social networks and micro-blogging	Entertainment - Learning	-12.673[b]	0.000
Social groups	Entertainment - Learning	-6.664[b]	0.000
Bookmarking	Entertainment - Learning	-5.340[b]	0.000
Tagging	Entertainment - Learning	-7.186[b]	0.000
Web Search Engines	Entertainment - Learning	-3.913[b]	0.000
Web aggregators	Entertainment - Learning	-.788[b]	0.431
Forums	Entertainment - Learning	-5.815[c]	0.000

b. Based on negative ranks.

c. Based on positive ranks

4. CONCLUSION

Looking at the research results it could be concluded that students use all groups of Web 2.0 tools for learning or for entertainment. Over 90% of students use wikis, shared media, social networking tools, search engines and forums.

Web Search Engines with 97.5% are mostly used for learning, and after that, students use forums (93.5%) and wiki tools (92.4%) in a very high percentage. For entertainment, Shared media tools stand out with 96.6%. The subsequent are Web search engines with 96.4% and Social networking and micro-blogging services with 90.2%.

It is these results that demonstrate that students use above mentioned tools 2.0 on their own initiative in accordance with their wishes, knowledge and potentials. Also it was shown that students use Web 2.0 tools for entertainment more than for learning with what has been proven that these results are precisely indicators that their habits for the use of these tools 2.0 should be considered as pattern for designing formal learning processes within educational systems.

[3]Faculty of Organizational Sciences, adamzp7@gmail.com

Abstract: *This paper investigates the differences in GPA, funding status, alcohol consumption, sport involvement, college experience satisfaction and overall life satisfaction among first, second, third, fourth and postgraduate college students. Research was conducted in the summer semester of 2013 and data was gathered using a questionnaire with the sample of 507 students from the Faculty of Organizational Sciences, including both student courses. The results show that GPA level is higher in fourth-year and postgraduate students groups. Secondly, second-year students displayed far less involvement in sports, while the fourth-year ISAT students displayed significantly lower satisfaction with their college experience than any other group. 85% of students consume alcohol, which is a similar percentage when compared to students from Harvard Business School. Finally, about 80% of students assessed their overall life satisfaction as high and very high, and no significant differences were found between students from different year of study.*
Keywords*: College experience satisfaction, year of study, overall life satisfaction, academic performance, sport involvement, alcohol consumption*

1. INTRODUCTION

Academic predictors such as behavioral experience (behavior at college, grades in college) and social experience (perception of college climate) are the main components of students` college experience and satisfaction (Suld, Shaffer, & Riley, 2008). Higher education is associated with life benefits that students may have, but also with the life satisfaction that occurs as a result of factors such as job security, (household income), health, mental health, happiness, and other results that appear as an output related to educational achievement (Salazar, 2013). Individuals with higher educational level tend to have more developed social networks and contact with the world, which implies an increase in happiness and life satisfaction (Chen, 2011).

In the literature, differences among college students population are usually inspected from demographic aspect, such as gender, race, country of origin, or different psychosocial variables such as life satisfaction or various personality traits. For example, one study from the USA proves that college major choice varies substantially by gender, race, and ethnicity among college graduates and it investigates whether these differences are present at the start of the college career (Dickson, 2010). Another study discusses the influence of personality traits such as the Big Five and the narrow personality traits on certain areas of college experience (Lounsbury, Fisher, Levy, & Welsh, 2009). Similar study also focuses on the relation between emotional intelligence and a number of 'life skills' (academic achievement, life satisfaction, anxiety, problem-solving and coping). Other studies are also focused on differences between students coming from different countries and cultural background in various fields, such as in motivation to study abroad (Salisbury, Paulsen, & Pascarella, 2010) or social network usage (Kim, Sohn, & Choi, 2011).

The decisions that students make in this period of life are very important and have a vast impact on their maturity process and future. The period of emerging adulthood (young people aged 18 to 25 years) is characterized by big transitional changes (like completion of high school, enrollment to university and first employment), which represent a relatively acute stressors and have large impact on their well-being (Gall, Evans, & Bellerose, 2000). Furthermore, Stone et al. suggests that in this particular period of emerging adulthood, people`s wellbeing appear to be the lowest when compared to any other period in the life span (Stone, Schwartz, Broderick, & Deaton, 2010).

Further analysis of literature leads to the conclusion that there are evident distinctions among population of college students, but only few studies are oriented on discovering the differences between students from different year of study (YOS).This also represents the aim of this paper- to discover and analyze the differences between students by grouping them according to YOS in order to get more information about the changes during students' life span. One of the few study using similar approach is the one conducted by Kjeldstadli et al. (2006) which indicates that medical college students from first-year were as satisfied as

students from other universities, but reported less satisfaction in their graduation year. Put in other words, it appears that life satisfaction of students seems to decrease with the increase of years spent in medical school.

Additionally, students who have a positive college experience are more likely to be satisfied with the college or university than students who do not have a positive college experience (DeShields, Kara, & Kaynak, 2005). Therefore the second aim of this study is to provide information for colleges and universities (in this case- Faculty of Organizational Sciences) about the changes in students experience, satisfaction and habits over time, in order to align their organizational structure, processes and procedures to students and to become more customer-oriented. This type of information could enable the educational institutions to establish and to maintain competitive advantage on the higher education marketplace, as well.

The initial hypothesis of this paper is formed on the statement that college students during their studies cope with different challenges that influence their experience and lifestyle, and that it is possible to identify different trends in student's behavior during their college life span. The value of this paper is that it provides the insight about the changes and influences of college experiences on habits, grades, lifestyle and satisfaction of students from different YOS. It could prove particularly useful for educational and organizational staff of FOS, as well as students and other parties with the research focus in the given area.

2. RESEARCH DESIGN AND PROCEDURE

Research was conducted in the period from March to July 2013, during the summer semester with the sample of 507 students from Faculty of Organizational Sciences (FOS). Sample consists of students enrolled to both undergraduate and postgraduate studies, from all 3 study programs (Management, Information Systems and Technology (ISAT) and Information System and Technology- distance learning program although this particular e-learning group has negligible effect because it constitutes for only 2,6% of the respondents). Having in mind that FOS has about 4200 enrolled students in total, sample size of 507 students, can provide adequate information about the observed population.

Original survey was conducted for the purpose of determining relation between 6 life satisfactions components and academic performance, sports involvement and demographic and behavioral characteristics. Data is collected using questionnaire with 31 questions that was published both in paper and online form. Majority of respondents provided their answers through the online survey form which can be found on https://docs.google.com/forms/d/1XDKTVpW8eF6JlBTeT6sWlqStu4ce-EceP1wsWUXR99I/edit?usp=drive_web, in Serbian language, native language of respondents. For the purpose of this particular study, information about student's current grade point average (GPA), funding status, sports involvement, alcohol consumption, college experiences satisfaction and overall life satisfaction are taken from this database and analyzed. College life satisfaction and overall life satisfaction have been measured as integral part of Brief Multi-Dimensional Students' Life Satisfaction Scale (BMSLSS) developed by Züllig et al. (2009). Information about the characteristics of the students involved in the survey is given in the following table:

Table 1: Sample characteristics

Characteristics	N (%)
Year of study	
First	121 (23, 9%)
Second	90 (17, 8%)
Third	127 (25, 0%)
Fourth	117 (23, 1%)
Post-graduate (Masters and PHD studies)	52 (10, 3%)
Sex	
Male	213 (42, 0%)
Female	294 (58, 0%)
Core curriculum	
Management	350 (69, 0%)
Information systems and technologies (ISAT)	144 (28, 4%)
Information systems and technologies- distance learning	13 (2, 6%)
Status	
State scholarship	342 (67, 5%)
Self-financing	165 (32, 5%)

Afterwards, students are categorized according to their year of study into 5 groups- first-year students, second-year students, third-year students, fourth-year students and postgraduate students (includes Masters and PHD students at FOS). Cross sectional analysis is the method used for obtaining the results about the differences among given students groups. Beside Table 1 that contains descriptive statistics and graphical presentations (Figures 1 to 6), Kruskal Wallis nonparametric test is applied to determine if statistically significant differences exist among students from different YOS, using software IBM SPSS Statistics 22. Year of study is the grouping variable (5 groups), while test variables[1] are:

a) Student`s current GPA[2] (4 groups: 1) 6-6.99 2)7-7.99 3) 8-8.99 4) 9-10),
b) Student`s status (2 groups: 1) state scholarship or 2) self-financing),
c) Sport`s involvement (2 groups: 1)yes or 2)no),
d) Alcohol consumption (4 groups : 1) not at all 2) low 3) medium 4) high)
e) College experiences satisfaction (5 groups: 1)very dissatisfied 2) dissatisfied 3)moderately satisfied 4)satisfied 5)very satisfied)
f) Overall life satisfaction (5 groups same as college experiences satisfaction variable)

3. RESULTS

Firstly, the output from IBM SPSS Statistics 22 with the respective values of Kruskal Wallis test statistics is given in the following table:

Table 2: Test Statistics [a,b]:

	Status	GPA	Alcohol consumption	Sport involvement	College experiences satisfaction	Overall life style satisfaction
Chi-Square	36.129	18.806	8.838	12.063	4.314	5.035
df	4	4	4	4	4	4
Asymp. Sig.	.000	.001	.065	.017	.365	.284

a. Kruskal Wallis Test; b. Grouping Variable: Year of study

Secondly, diagrams and tables for every 6 variables (parameters) analyzed, are presented, alongside with brief explanation.

First parameter we analyzed was the grade point average (GPA). Comparing the GPA level throughout the students from different YOS, we found that the highest GPA (in average) is noted within the postgraduate group of students (Master and PhD study program) with 8.73 out of 10. We also noticed a difference between fourth year students compared to the students attending the first three years of Faculty of Organizational Sciences – 8.47 compared to 8.28-8.30.

Table 3: GPA

Year of study/GPA	*6-7*	*7-8*	*8-9*	*9-10*	*Total Responses*	*Average Grade*
First	**3**	**24**	**49**	**25**	**101**	**8.28**
Second	**1**	**29**	**39**	**16**	**85**	**8.3**
Third	**1**	**47**	**52**	**27**	**127**	**8.28**
Fourth	**1**	**35**	**50**	**29**	**115**	**8.47**
Postgraduate		**5**	**29**	**18**	**52**	**8.73**
Total Responses	**6**	**140**	**219**	**115**	**480**	**8.36**

[2] 37 respondents did not entered correct value of GPA and are excluded from respective analysis

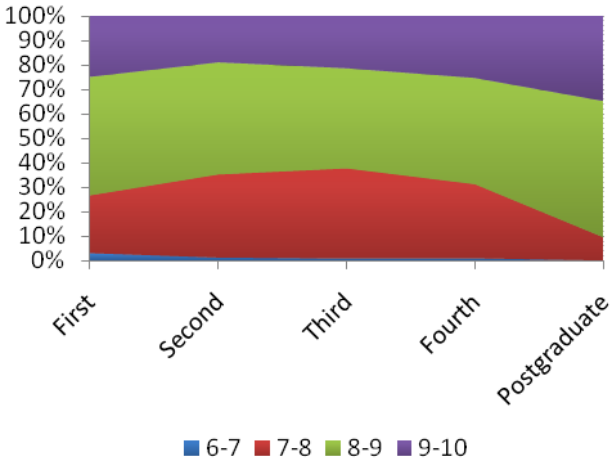

Figure 1: Grade point average (GPA)

Data in the table 3 show student status cross-referenced with the year of study of students. The difference between some of the years was to be expected considering the fact that number of awarded state scholarships increases for 20% in every advancing year of study (with the exception of postgraduate students). It means that for example, second-year students are awarded with 20% more scholarship than first-year students and 20% less than third-year students. This is the actual reason for detected statistically significant difference.

Table 4: Student`s status

Year of study/Status	*State scholarship*	*Self-financing*	*Total Responses*	*Percent of students with scholarships*
First	**59**	**62**	**121**	**48.8%**
Second	**66**	**24**	**90**	**73.3%**
Third	**98**	**29**	**127**	**77.2%**
Forth	**91**	**26**	**117**	**77.8%**
Postgraduate	**28**	**24**	**52**	**53.8%**
Total Responses	**342**	**165**	**507**	**67.4%**

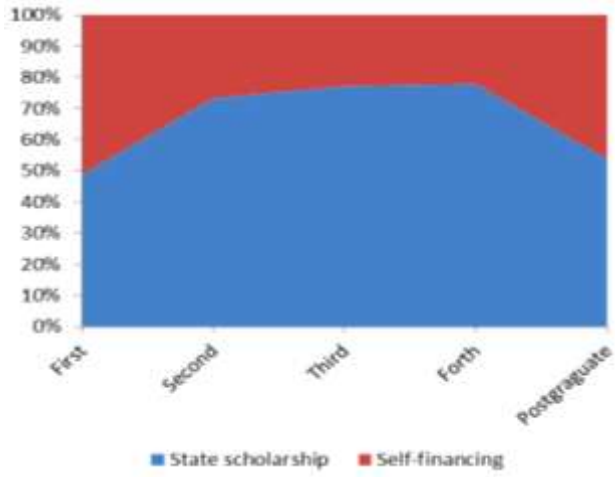

Figure 2: Status

Sport involvement parameter shows a significant drop for second-year students– about 15% fewer students engaged in sports activities, than students from other YOS. We will be discussing about the possible cause of this drop, but it is certain further research is necessary to confirm any assumptions about the potential cause for this drop.

Table 5: Sport involvement

Year of study/ Sport involvement	*Yes*	*No*	*Total Responses*	*Percent of positive answers*
First	**91**	**30**	**121**	**75.2%**
Second	**50**	**40**	**90**	**55.6%**
Third	**89**	**38**	**127**	**70.1%**
Forth	**85**	**32**	**117**	**72.6%**
Postgraduate	**40**	**12**	**52**	**76.9%**
Total Responses	**355**	**152**	**507**	**70.0%**

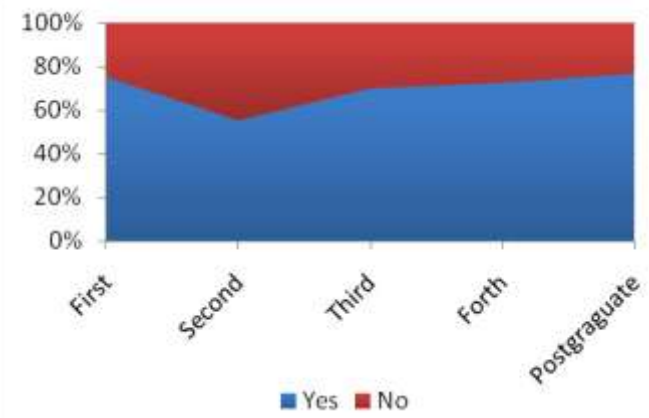

Figure 3: Sport involvement

By analyzing college satisfaction parameter it can be seen that in general, students are happy with their college experience and that they evaluated it as high (with average value of 3.88 out of 5). Third and fourth year students were less satisfied, than the rest of the students involved in the research

Table 6: College experience satisfaction

Year of study/College experience satisfaction	*Very low*	*Low*	*Medium*	*High*	*Very high*	*Total Responses*	*Mean value [1-5]*
First	**2**	**4**	**26**	**57**	**32**	**121**	**3.93**
Second			**20**	**49**	**21**	**90**	**4.01**
Third	**2**	**9**	**37**	**48**	**31**	**127**	**3.76**
Forth	**2**	**8**	**24**	**58**	**25**	**117**	**3.8**
Postgraduate		**1**	**14**	**22**	**15**	**52**	**3.98**
Total Responses	**6**	**22**	**121**	**234**	**124**	**507**	**3.88**

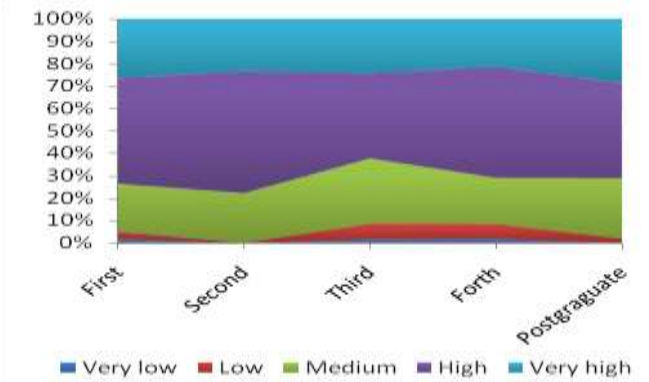

Figure 4: College experience satisfaction

Alcohol consumption parameter displays almost similar percent of students consuming alcohol per YOS. The highest alcohol consumption is noted among third-year students with about 40% rating their consumption of alcohol as high or medium.

Table 7: Alcohol consumption

Year of study/Alcohol consumption	*No*	*Low*	*Medium*	*High*	*Total Responses*	*Mean value [scale 0-3]*	*Percent of students consuming*
First	**20**	**62**	**30**	**9**	**121**	**1.23**	**83.5%**
Second	**16**	**44**	**28**	**2**	**90**	**1.18**	**82.2%**
Third	**15**	**61**	**36**	**15**	**127**	**1.4**	**88.2%**
Fourth	**16**	**65**	**27**	**9**	**117**	**1.25**	**86.3%**
Postgraduate	**12**	**30**	**6**	**4**	**52**	**1.04**	**76.9%**
Total Responses	**79**	**262**	**127**	**39**	**507**	**1.25**	**84.4%**

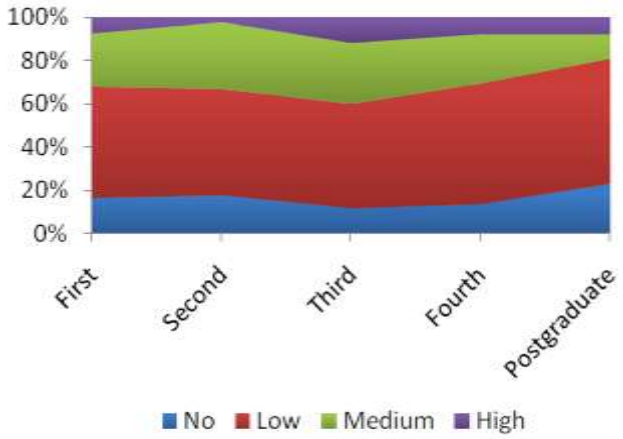

Figure 5: Alcohol consumption

The next set of data represents the parameter of overall life satisfaction. We have noticed that the second-year students have expressed slightly higher satisfaction with life, with the mean value being 0.12 higher than the postgraduate students (who have expressed second highest satisfaction with overall life among sample).

Table 8: Overall life satisfaction

Year of study/Life satisfaction	*Very low*	*Low*	*Medium*	*High*	*Very high*	*Total responses*	*Mean value [scale 1-5]*
First		**5**	**14**	**72**	**30**	**121**	4.05
Second		**1**	**8**	**51**	**30**	**90**	4.22
Third	**1**	**3**	**17**	**77**	**29**	**127**	4.02
Fourth			**20**	**70**	**27**	**117**	4.06
Postgraduate			**7**	**33**	**12**	**52**	4.1
Total responses	**1**	**9**	**66**	**303**	**128**	**507**	4.08

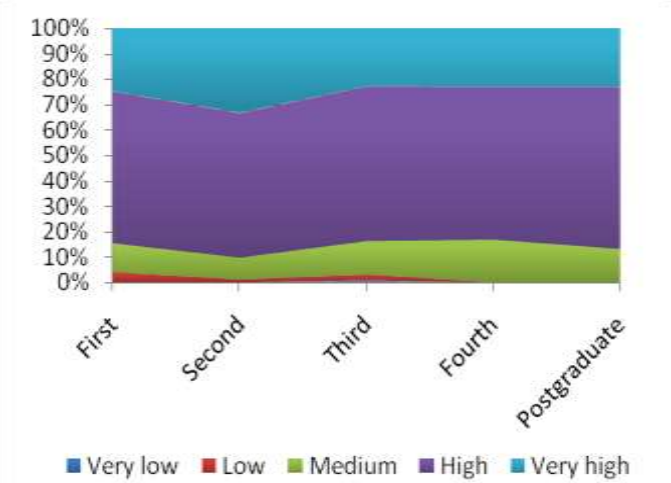

Figure 6: Overall life satisfaction

4. DISCUSSION

From the obtained results it can be concluded that statistically significant differences (with significance level $p<0.05$) are found within status, GPA and sport`s involvement parameters among students from different YOS. No statistically significant differences are found within alcohol consumption, college experiences satisfaction and overall life satisfaction student`s groups (Table 2).

Concerning the ***year of study/GPA*** parameter, there are significant differences in the mean value scores between fourth-year students comparing to all others- 8.47 compared to 8.28 to 8.30 (Table 3, Figure 1). There could be many reasons for this result. Firstly, it may result from the fact that only the most successful students reach the fourth YOS. On the other hand, it can be assumed that students attending higher YOS are more familiar with the materials and syllabuses of the courses and therefore achieve better results. From another point of view, it could be assumed that the fourth year at FOS is less challenging and easier to complete. All these assumptions could represent the future direction of this research and require further analysis in order to determine the actual cause.

Speaking about ***year of study/status*** parameter we can see that there is a much smaller percentage of students with state scholarship in first YOS compared to others (Table 4, Figure 2).. One of the possible reasons for this is that largest number of students drop out or fail at the first year. Still, the actual reason for this is as mentioned previously, that number of awarded state scholarships increases for 20% in every advancing year of study which can be seen from the FOS official documents, too. Also, on postgraduate studies (Master of Science programme) reduced number of state scholarships is awarded.

Physical activity represents one of the factors with positive effects on the quality of physical and mental health (Martin, Church, Thompson, Earnest, & Blair, 2009). Experts in the field of education and health intuitively believe that physically more active students perform better in school (Castelli, Hillman, Buck, & Erwin, 2007). Looking at obtained results and particularly ***year of study/sport involvement parameter***, we can conclude that there is a noteworthy drop considering sport involvement for second-year students– 15% fewer students compared to students from other YOS (Table 5, Figure 3). Still there is no difference in their GPA compared to first and third YOS. With that on mind, a possible explanation could be that after finishing first year, students decide to devote significantly more time to studies and have less time for spare time activities such as sport involvement. Another possible explanation could be that the whole generation of students currently enrolled in second year is not particularly interested for sport activities.

Year of study/college experience satisfaction represents another important parameter included in analysis. No significant differences in college experiences satisfaction are noted among students from different YOS. It should be emphasized that in general, students rated their college experiences satisfaction as high or very high, which is a remarkable result for FOS (Table 6, Figure 4). But by further inspection, it can be noted that third and fourth year students have slightly below average satisfaction. Further analysis of selected parameter according to core curriculum, provides an insight in differences among students from Management and ISAT departments. It is noted that fourth-year students of ISAT have lowest satisfaction with college experiences (mean value at 3.48 out of 5). This can lead to conclusion that decrease of satisfaction with college experiences is more expressed among ISAT students in their final years of study.

Looking at ***year of study/alcohol consumption*** parameter, it is interesting to notice that the percentage of students who consume alcohol is almost the same for all YOS (84.4%), except postgraduate with slight lesser percentage- 76.9% (Table 7, Figure 5). This data can look a bit discouraging, but comparing our results with study from Harvard's College Alcohol Study (Wechsler & Nelson, 2008), it can be seen that alcohol consumption is almost identical for FOS and Harvard students (84% for Harvard Business School). However, we noted that the number of students who declared their consumption of alcohol as high or medium is highest for the third-year students.

By analysing **y*ear of study/life satisfaction*** parameter no significant differences among students from different YOS are noted. In general, students expressed high level of overall life satisfaction. It is important to emphasize that the average student of Faculty of Organizational Sciences is satisfied with his life (Table 8, Figure 6). Second-year students expressed slightly higher level of satisfaction. Already mentioned study from Kjeldstadli et al. (2006), highlights that the life satisfaction of medical students is decreasing during their studies, and that they were as satisfied as other students in the first year of study, but reported less satisfaction in their graduation year. When compared to FOS, overall life satisfaction does not differ significantly among students from different YOS, indicating that this trend is not present in technological and business schools which include FOS, as well.

We encourage further analysis, based on our data, which will further develop each of the segments that were the subject of our research.

5. LIMITATIONS AND CONCLUSION

One of the main limitations of this research is the homogeneity of the sample, because it includes only students from Faculty of Organizational Sciences, as a part of University of Belgrade. Sample that would include other colleges and universities would be far more heterogeneous and would enable us to make comparisons between different educational institutions. On the other hand, this characteristic of sample enables us to make valid conclusions about the student`s population at FOS, such as the inconsistency of second-year students in sport involvement, when compared to other students groups. By further analysis and repeated surveys in future, the actual origin of this inconsistency could be determined. In other words, we could make sure if this inconsistency is the result of trend among every second-year student`s generation at FOS, or just the case with this particular generation enrolled in the year 2011. Secondly, another limitation closely related to previous one is the non-experimental type of research i.e. time-invariant sample. Respondents have filled questionnaire in only one iteration, and certain external events (such as the beginning of exam period, reduced leisure time and increased stress level) could have affected their answers regarding time-variable parameters such as college experiences satisfaction or alcohol consumption level.

Nevertheless, cross-sectional analysis of the data provides useful information about the differences in academic performance (GPA), habits, lifestyles and satisfaction between students from different YOS. Based on the initial statement we can conclude that students' college experiences, overall life satisfaction and alcohol consumption level do not differ significantly among students of first, second, third fourth YOS and postgraduate students. On contrary, these students groups displayed statistically significant differences within average grade (GPA), scholarship status and sport involvement parameters.

Abstract: *In near future, education should take an important place, even in Serbia, in the conditions of "endless" transition. In such context, the area of the education management is of high importance. Professional training in each of the educational segments is particularly significant, especially in the professional college education. The most common remark on the subject of education in Serbia in general is the low level of practical training received by the pupils/students at all levels of education (secondary, higher, academic and master education). This paper shall present the results which show good practice of a college. It is a Medical College of Professional Studies in Belgrade. Today, students of this College have practical training that meets the request of the Bologna process to the largest extent, it being formally and essentially implemented, which is confirmed by the presented results.*

Keywords*: practical training, medical nurses, skills, practical knowledge*

1. INTRODUCTION

It is essential that students work on self-improvement and aim for the development and improvement of their knowledge and skills. Considering the fact that students – medical nurses are entrusted with patient care and the ability to provide such care from day one of their employment, it is important that during their studies, they learn and perfect all of the required activities, theoretically as well as practically, Authors Krasulja and Janjušić (2013) have noted that „global competition, fast and sudden changes, impose the need for continuous improvement so that individuals could ensure the prospect of better employment in an almost unpredictable environment" (Janjušić, 2013, p.45). Employers require practical knowledge and skills, and the higher education institutions should provide to their students precisely that, along with the theoretical knowledge, in order for them to become competitive at the labour market.

If we complement this with the fact, as the authors Vasiljević Blagojević and Perčić state in their research (2010), that students, when choosing their higher education institution, state good practice as one of the best factors of their decisions, we can conclude that practical training is of key importance in the areas of recruiting staff and leading students to a certain educational institution.

Ever since the beginning of the institutionalized education, terms such as practical training and practical work are used in professional training as an irreplaceable method of gaining the required knowledge, know-hows, skills and habits. Ranković Vasiljević (2004) emphasizes that this refers particularly to the education of medical nurses, starting from secondary school, through higher education institutions and later on (Ranković Vasiljević, 2004, p. 69). Practical training has become highly important factor for the connection of theoretical knowledge gained at lectures with their practical application. By using the practical training during the studies, the students have the possibility to gain practical work experience and to apply theoretical knowledge which they gained at theory classes.

In observation of the historical development of medical nurses' education worldwide and domestically, it was noted that practical training actually preceded the theoretical training, although this seems impossible today. Namely, ever since Florence Nightingale and her first school, nurses were taught procedures, activities, techniques, interventions, without previously adopted theoretical knowledge, which are the imperative of any professional education today.

Ranković Vasiljević (2003) emphasizes that, with the development of educational systems, a change occurred in application of didactical principles in the education and teaching process, thus the theory began to precede the practical training (Ranković Vasiljević, 2003, p. 93). Nevertheless, there has always been a need for a special kind of training of future medical nurses in their future career, which differed from the so-called „school-type learning", and which took place in healthcare institutions without teachers' direct supervision. This kind or type of work whose aim is to gain skills is referred to as the practical training.

In analysis historical documents on education of medical nurses, we came across the Rules on summer practical training for students of the School of Medicine and pupils of medical middle schools, dated June 16, 1950, which regulated the need for such practical training and its goal. Within the programme „Basic professional nursing studies“, the Medical College of Professional Studies in Belgrade has foreseen practical training in the duration of 1800 classes in the course of three academic years.

In this paper, we shall show how important the practical training was from students' perspective and whether and to which extent it helped them to gain more specific skills.

2. COMPOSITION

Ranković Vasiljević (2004) state that education represents a process of gaining knowledge, know-hows, development of skills and habits, as well as adoption of the behavioural rules' value system, shaping personalities and making them apt for life in a community (Ranković Vasiljević, 2004, p. 21). Education unifies knowledge and know-hows. Vilotijević (1999) states the following definition of knowledge: „Knowledge is a system of facts and generalization of reality, which the students adopted, permanently preserved in their consciousness and which they can apply in practice“ (Vilotijević, 1999, p. 108). Knowledge represents collected and generalized historical productive-working experience of mankind. Thus, knowledge is the foundation for constructive life and progressive work of a modern man. Working qualifications of any man is dependent on the broadness and depth (extensity and intensity) of knowledge (Vilotijević, 1999, p. 108). A person in possession of a solid knowledge can improve the productiveness of social work in general and contribute to the progress of his/her society. Ranković Vasiljević (2004) concludes that “know-hows are methods of performing certain activities which, unlike skills and habits, do not need to be preceded by certain exercises” (Ranković Vasiljević, 2004, p. 122). One can master a single know-how, without having gained a certain skill yet. Know-hows are in specific relation with the abilities. Gaining know-hows is conditioned by existence of certain abilities. Together with adoption, know-hows assist in the development of abilities.

A skill is psychomotor ability, gained by frequent repetition of selected, rational and successful movements. In the skill-gaining process, the student should learn through insight instead through attempts and mistakes. It enables one to perform a certain activity easier, faster and more accurately. A skill is also one of the stages in the habit-forming process. It precedes habits and is a prerequisite for formation of habits. The authors Djordjevic & Trnavac (2011) state that a habit “through continuous repetition, is an automatic reaction enabling an individual to perform a certain activity with the least required strength, fast and accurately” (Djordjevic & Trnavac, 2011, p. 201). A habit is the last stage, i.e. the final result of practicing. A habit follows the formation of skills and it is an automatic skill. It is difficult to determine where skills end and where habits begin, since habits are skills of a higher quality. Only when a required skill for performance of an activity is formed (e.g. writing skill), such skill can become automatic by further practice and it can turn to a habit.

By a teaching process which accepts didactic requests, gradual gaining of knowledge, know-hows, skills and finally habits, is achieved. Formation of skills and habits, without previous knowledge and know-hows would result in creation of “semi-experts”, which would to work but would not know why are they working, why the exactly like that and with what purpose. During the teaching process, the student gains certain knowledge, know-hows, skills and habits which are predetermined by a certain goal, tasks and contents of the curriculum. Depending of many factors, originating from students, teachers, school, family and social environment, a different level of knowledge is achieved. In healthcare teaching at the Medical College of Professional Studies in Belgrade, contents of the curriculum to be adopted at the levels of knowledge, know-how, skill and habit, are determined through programmes.

The purpose of learning is to have the student change his/her behaviour. The author Woolfolk (1998) concludes that learning is successful if it leads to a permanent change in behaviour. Behaviour and learning should not be equated, although the results of learning are concluded based on the behaviour (Woolfolk, 1998, p. 186). Teaching should be structured as early as in the planning phase, so that it surely leads to the achievement of the learning goal – “resulting behaviour” should differ from the “initial” behaviour, i.e. concordant with the goal set. Teacher selects and prepares the teaching materials with the intention to make understanding and adopting of the new material easier for the students. He/she is the organizer of teaching, which manages the process of the simultaneous upbringing and education of students.

2.1 PRACTICAL TRAINING

Practical training is a form of professional work which, in medical education, dates since the beginning of the institutionalized education. Practical training should make the transfer from academic schooling to the professional work of a medical nurse easier. The goal of the practical training is to make students more familiar with the practical activity through practical work. Thus, students get the opportunity to apply knowledge and abilities gained by learning theory, mainly in separate disciplines. At that, they should gain insight into technical, organizational, commercial and social occurrences and their mutual interconnections in healthcare institutions which are determined as the teaching centres.

Until the last educational reform, known as Bologna process, practical training was conducted for the students from the department of medical nurses / technicians. In the last several years it was conducted as pregraduate training, with the duration of 100 to 200 hours.

The Study programme, accredited on April 29, 2007, practical training with the duration of 1800 hours was determined. Together with the active teaching classes, this programme comes very near to the requests set in terms of education by the European Union, ICN (International Council of Nurses) and other associations. Today, according to the newest accredited 2012 programme, the number of practical training classes at the Department of Professional Medical Nurse has been increased to 2400. In this manner, the European requirements in terms of education of nurses have been fully complied with.

Practical training is attended by students during all three academic years; namely half of these hours are realized in healthcare institutions in Belgrade, and half in institutions the students select themselves. During the sixth semester, the students attend practical training in twice as many hours, in order for them to be able to graduate until June. Practical training is organized in the areas of primary health protection – public health and healthcare in secondary and tertiary health protection.

Students' work, as per fixed weekly schedule, is controlled by professional medical nurses, as a rule by head nurses in institutions which are teaching centres. If a student is employed, he/she can complete the practical training in an appropriate institution, that is, in the institution he/she is employed in – as per the College programme.

3. RESEARCH

The goal of the conducted research is to determine the importance of the practical training within the skill-gaining process in students – future professional medical nurses.

Tasks of the research are as follows:

- Determine the level of mastery in certain nursing interventions, for the students at the third year of studies, as per estimates of the students themselves;
- Determine how do students estimate methods of gaining skills – during regular classes or practical training
- Analyse the students' opinion regarding the practical training;

The following methods were used in this research: descriptive method, which we used to describe all of the relevant procedures for gaining skills in the nursing activities and to discuss the results of the research. For the purpose of preparing this paper, only a part of the obtained results shall be presented; and the scientific research by means of the poll used to learn the subjects' opinions regarding the subject matter of the research.

Specially structured questionnaire was used as an instrument of the research when determining levels of gained skills and manner of their acquiring in the course of school education.

Population consists of students from the Medical Nurse Study group at the Medical College of Professional Studies in Belgrade, academic year 2013/2014, and the analysed sample is 150 third year students.

Research was conducted in November 2013 at the Medical College of Professional Studies in Belgrade. Data are processed by means of simple statistical procedures; they are shown in tables and graphs and expressed in absolute and relative numbers.

4. RESULTS AND DISCUSSION

A part of the questionnaire for the assessment of the level of mastery consists of a list which includes 24 nursing interventions, next to which students were to mark the level of mastery, by marking one of the provided grades (0-5). Next to each intervention, the subjects were to mark the type of classes (active classes – practical training) which enabled better practicing of the given procedure.

Authors Konjihušić and Kocev state that determining the needs for care is the first and very important stage of a healthcare process (Konjikušić & Kocev, 2005, p. 48). It includes organized and systematic collection of data on the reactions of patients to the illness or other life situation, as well as validity assessment of the gathered information and recording of all relevant data. Assessment of conditions and determination of the need for care should provide a solid database for making a nursing diagnosis and implementation of all subsequent process stages. In order to perceive and determine the needs of a patient for care, a nurse should know what the needs are, what the basic human needs are and how are those to be satisfied in circumstances of impaired health or limitations due to illness, inability and/or ignorance.

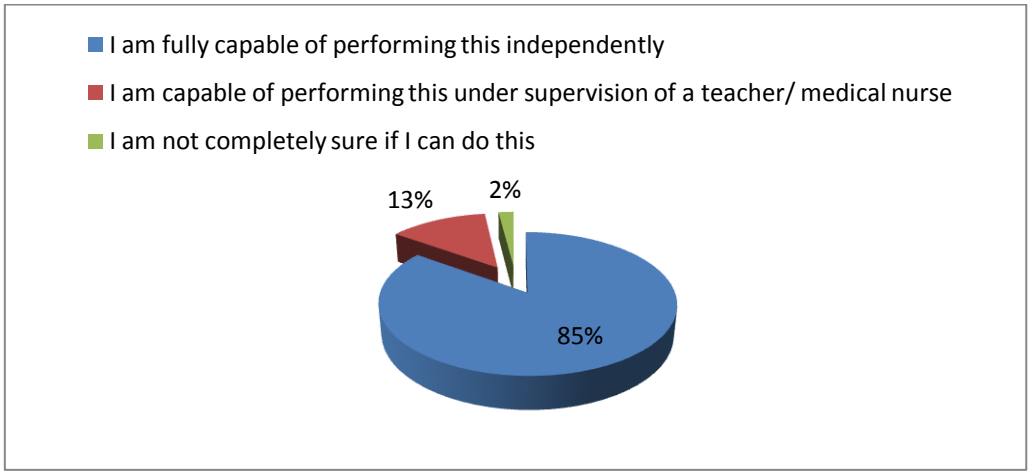

Figure 1: Assessing the patient's condition and determining the need for healthcare

Healthcare process is studied by the students in the second semester of the first year of studies, and they continue to apply it in regular classes and practical training during the whole time of studies. A large percentage of students (85%) deem that they are fully capable of assessing the patient's condition and determining the need for healthcare. More than half of the subjects-students deem that they achieved such result due to regular classes, while one quarter of them deems that active classes and practical training were equally beneficial in mastering of the given skill (15% of the subjects deem that both practical training and classes helped them, while 6% did not answer this question).

The frequency in which a medical nurse should change the patient's position shall depend on the condition assessment, i.e. on the need for care determined at the first stage of the healthcare process. One should also consider that the goal is not to have the medical nurse do everything for the patient, but to teach him/her to help himself/herself in line with his/her abilities, that is, to actively participate. Positioning of a patient appropriately and the regular change of the position are very important for prevention of complications which occur due to lying (thrombosis, thrombophlebitis, pulmonary embolism, joint contractures, muscle atrophy, obstipation, and decubitus). All of these complications put patient's health condition at risk, slow the treatment and rehabilitation processes down and have major impact on the patient's quality of life, and they increase the costs of treatment and rehabilitation for the healthcare service and the society in general.

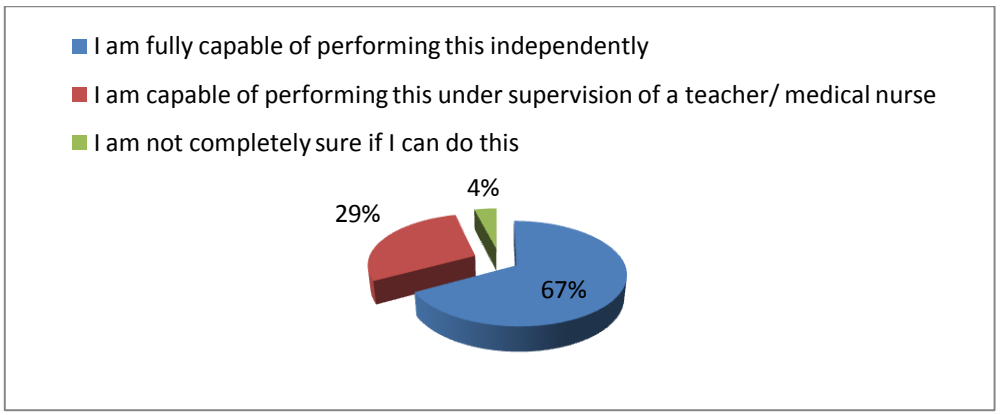

Figure 2: Changing the patient's position in bed

Graph 2 shows that more than two thirds of subjects are able to perform the intervention of changing the patient's position with full independence. Most of the subjects 54% estimate that they acquired this skill at the practical training, although this procedure is learned and exercised in theory classes in schools as well. 31% of subjects deem that regular classes enabled them to independently perform the above intervention (9% of subjects deem that both practical training and classes helped them, while 6% did not answer this question).

Maintaining patient's personal hygiene represents an important part of the treatment and care. It is of the outmost importance to pay special attention to skin and mucous membranes. Numerous functions are performed through skin and while it is unharmed, it represents the best protection against infections. The author Terzić (2006) states that the skin of immobile patients gets dirtier, that is, it is more exposed to the harmful impact of excretions, it endures pressure, humidity, which are good predisposed factors for development of infections and decubitus (Terzić, 2006, p. 29).

Pupils in secondary medical schools are familiarized with patients' personal hygiene as early as during the first grade, while the students, through laboratory classes of healthcare 1 during the first semester repeat and consolidate acquired knowledge, know-hows and skills.

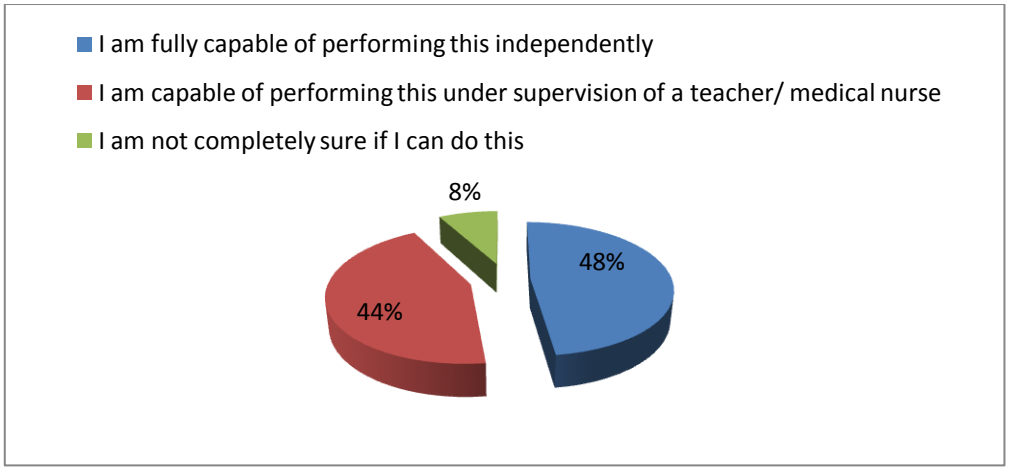

Figure 3: Personal hygiene of immobile patients

Graph No. 3 clearly shows that 48% of students are able to independently, and 44% under supervision, maintain patients' personal hygiene. Subjects also claim that 25% gained the above skill in active classes, while almost 60% claims it occurred at the practical training. Such result could be expected, since the experience of one's own ability for a certain job becomes more realistic in realistic situations, which, in this case, is hospital environment and work with patients.

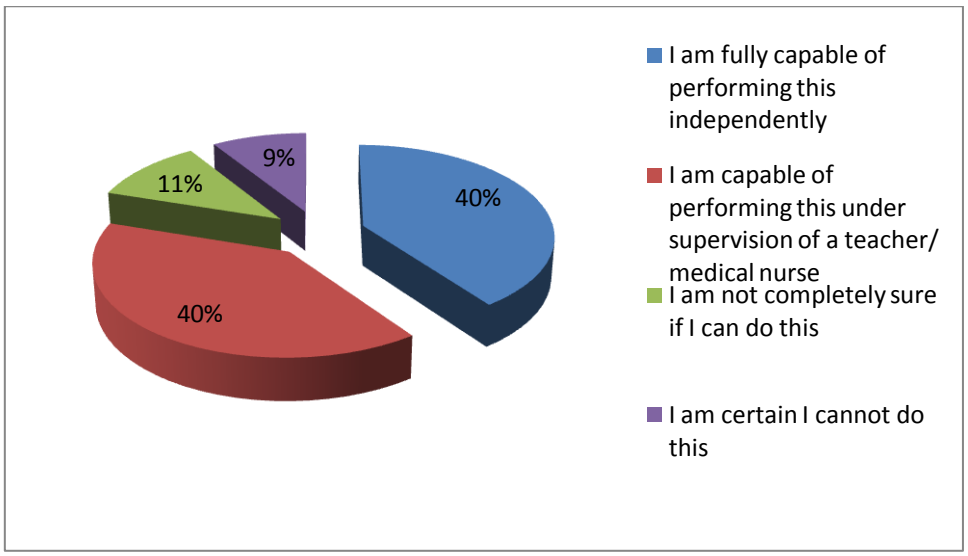

Figure 4: Prevention of decubitus

The author Matic (2001) states that decubitus represents local damage, i.e. necrosis of tissue, which occurs due to pressing of body parts onto the underlying surface, where circulation and insufficient blood flow in these parts of the body, referred to as predilection sites, occur: nape, shoulder blades, lower back, hips, knees, ankles, heels, elbows (Matic, 2001, p. 210). Prevention of decubitus implies monitoring of patient's condition and treatment of the main disease, solving collaborative issues, solving potential problems, patient's activity – active and passive exercises, using auxiliary devices.

The Graph No. 4 shows that 40% of subjects deem that they are able to perform this intervention independently or under supervision. The opinion on their level of mastery is somewhat lower in almost one fifth of the subjects, which certainly tells us about the need to pay more attention to work in relation with decubitus, in active classes as well as in practical training. Regardless of the level of mastery, only one third of subjects deem that they gained their knowledge and skills in active classes, and 40% in practical training, while one fifth of the subjects deems that both forms of teaching are equally beneficial in terms of gaining the aforementioned knowledge and skills.

Vital functions are studied in detail in the second grade of the secondary medical school; monitoring of vital functions is afterwards practiced during the whole secondary school as well as during higher education.
Over 50% of subjects are able to independently monitor vital signs, which is the expected result, while the same percentage of the subjects deems that they acquired this skill in practical training (one can conclude from this that they had not gained this skill during the secondary school education).

Central venous pressure (CVP) is measured in a simple manner. In patients with indicated monitoring of CVP, central venous catheter (CVC) is advanced so that the catheter tip is placed in the right prechamber or near the prechamber inside the proximal inferior vena cava. It is the indicator of the circulating blood volume, state of the vasculature capacity and cardiac function. Values are read directly by means of a transfuse and reader, i.e. on the monitor, expressed in mm of mercury column, or they are read, from a liquid column which is connected by means of a CVC system to the infusion system, and expressed in cm of a water column. Normal values of CVP range from 6 – 12 cm of water column or 2 – 6 mm of Hg column.
Only 6% of subjects deem that they can independently perform this intervention, and as much as one quarter of subjects are only informed about this intervention. Considering that as much as 36% of subjects didn't provide an answer, one can conclude that they don't even know what CVC is, this being the reason they failed to answer this question.

Intramuscular application is application of medicines into the gluteus and thigh muscle tissue. Water solutions, suspensions in water and oil solutions can also be administered in this manner. This is one of the most common nursing interventions in practice and the obtained result was the expected one. Namely, 94% of subjects deem themselves fully capable for independent intramuscular application of medicines, while the remaining 6% of subjects deem that they are able to perform this intervention independently under supervision. During the assessment of this intervention, the high percentage of subjects also recognizes practical training as the type of classes which enabled them to exercise the procedure (above 65%).

5. CONCLUSION

On grounds of the available literature, which was studied for purposes of this paper, analyses of the data obtained from student polls and personal, long-term experience in working with students, and considering the goal and the tasks of the research, we have come to the following conclusions:

- Aside from exercises, practical training is the most important skill-gaining method, especially for the medical nurse profession;
- Practical training completion requires high level of organization, on the end of the higher education institution but equally on the end of the healthcare institution which the practical training is conducted in;
- Practical training organization implies compliance with the existing Programme, which is concordant with the Study programme as a whole;
- Practical training completion requires professional supervision by adequately educated and motivated medical nurses from the teaching centres, which have the support of the institution management for that activity;
- Students understand practical training as a type of classes which enables them additionally to gain the skills for the professional work.

The results reported and commented so far indicate importance of practical training of nurses during the studies. Future studies could extend the group of factors that may influence the skills level. For instance, previous education may also be relevant. Additionally, we would recommend analysis whether knowledge and skills were gained in practical training of a quality level appropriate for future employers. Overcoming the gap between the expectations of institutions/future employers and the quality of gained knowledge and skills of graduates should be emphasized.

The essence of a successful practical training is in the following and complying with the Rules which detail the programme of practical training for each year of studies. Based on the practical training log, records are kept and frequency of the conducted nursing interventions from the practical training programme is controlled. What is imposed as necessary is intensification of communication with the nurses – co-workers for practical trainings, in order to adhere to the process in all stages of work. Regular work assessment by means of student polls is also important, and this is an obligation envisaged in the Quality Standard from the accreditation material.

Considering that practical training of students of the Medical College, Department of Professional Medical Nurses is recognized by this research as well as very significant, work on its modernization and improvement is the primary task. For purposes of appropriate preparation of students for exercises and practical training, demonstration and initial exercise until the basic skill level is reached, should be performed on the model in the school cabinet. We expect that in the future, with the increase of patients' rights, completion of the initial exercises in healthcare institutions, i.e. on patients during practical training, will become much more difficult, which must not lead to a reduced level of knowledge and skills of future generations of professional medical nurses.

1. INTRODUCTION

In order to successfully manage the learning process it is necessary to collect and analyze a large number of data that could potentially affect the students' performance and achievements. An efficient method for analyzing large amounts of data is using data mining. Data mining involves techniques for finding and describing structural patterns in data, as a tool for helping to explain data and make predictions from it (Witten, 2011). It is desirable for discovered patterns to be useful, understandable and to provide new knowledge.The main goal of data mining techniques is to find and describe the structural patterns in the data in order to attempt to explain connections between data and create predictive models based on them (Witten, 2011). Input data for applying data mining techniques are presented in the form of a set of examples, and the output can be expressed in the predictive or descriptive form of the analyzed data structure. Data mining is a multi-disciplinary field involving machine learning, statistics, databases, artificial intelligence, information retrieval, and visualization (Liu, 2007). There are four the most common tasks used in data mining applications: supervised learning (or classification), unsupervised learning (or clustering), association rule mining, and sequential pattern mining. Each of them is characterized by different styles of learning.

Data mining process involves three main steps:

- Pre-processing – the raw data must be cleaned in order to become suitable for mining. Data cleaning includes removing noises and abnormalities, handling too large data, identifying and removing irrelevant attributes, and so on. Data cleaning is procedure that usually consumes a lot of time and it is very labor-intensive but it is absolutely necessary step for successful data mining.
- Data mining – the process of applying data mining algorithm that will produce patterns or knowledge.
- Post–processing – Among all discovered patterns or knowledge, it is necessary to discover ones that are useful for the application. For making the right decision there are many evaluation and visualization techniques that can be used.

Data mining can be applied to explore and analyze data that come from different types of educational environments (Romero, Ventura, 2013). This new developing field, known as Educational Data Mining (EDM), began to develop intensively in recent years. It is engaged in the development of methods for exploring the unique types of data that come from the educational context (Romero, 2008). EDM analyzes data generated by any type of information system supporting learning or education. These data are not restricted to interactions of individual students with an educational system but might also include administrative data (e.g., school, school district, teacher), demographic data (e.g., gender, age, school grades), student affectivity (e.g., motivation, emotional states), etc. (Romero, Ventura, 2013). The main objective is to extract implicit and useful patterns or to obtain useful knowledge about the ways students learn and factors that affect their learning. Applying data mining methods and techniques on data that come from educational systems it is possible to discover new and useful knowledge. That knowledge can help teachers to get proper understanding of student’s performance and to identify different learning capabilities. Different data mining models can be implemented to evaluate student's performance and obtained

knowledge can be used to provide feedback and necessary guidance for teachers in order to improve the teaching process through more quality and easier management.

In recent years a lot of research in the field of educational data mining was performed and various types of mining algorithms applied on educational datasets have been proposed. An overview of the current state and the progress made in the development and implementation of educational data mining is given in (Romero, Ventura, 2013). Comparative analysis of various data mining techniques and algorithms has been shown in (Garg, Sharma, 2013). An investigation of data mining techniques for evaluating quality of a course and analyzing a connection between course learning material and the test for the final exam has been done in (Dimić, Prokin, Kuk, Spalević, 2010). Prediction of the achieved success and the final grade in the exam can be performed applying data mining algorithms. In (Affendey, 2010), the ranking of factors that influence the prediction of academic performance in order to identify students who will need to study harder to pass the exam was performed by the application of data mining methods. An experiment with pattern classification for student performance prediction is performed in (Ai, Laffey, 2007). The obtained results illustrate that recognition for a certain class on a large dataset can be obtained by a classifier built from a small size data set. Applying different data mining classification techniques for predicting the marks in the final exam of the students that use Moodle courses has been shown in (Romero et al, 2010). Using clustering analysis comparing of two algorithms for measuring the potential of students' academic skills has been done in (Dewi, Utomo, Yulianto, 2013). In (Ramesh, 2013), an analysis of the factors that influence students' performance in final examinations and a suitable data mining algorithm for predict the grade of students has been done. The obtained results reveals that type of school does not influence students' performance and parents' occupation plays a major role in predicting grades. The impact of the certain e-learning tools on the achievement of students' objectives is discussed in (Kickul, 2002).

In (Romero, Ventura, 2007) a survey about the application of data mining to web-based electronic courses and learning content management systems was performed. As a result, a general model that represents the whole process of application of data mining techniques in educational systems was created, Figure 1.

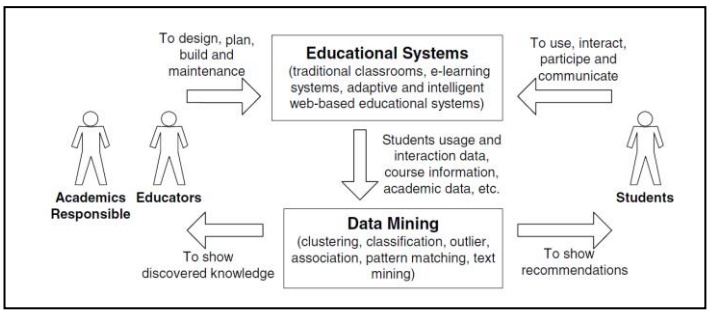

Figure 1: Application of data mining in educational systems

This paper analyzes the impact of specific administrative and demographic data on actual students' performance in the course Introduction to programming that is performed in Faculty of Electrical Engineering in East Sarajevo. Some models for predicting students' performance in the final exam was developed. The models were created using a decision tree and instance based classifiers. Presented experiments were performed using WEKA data mining tool (Weka). The influence of input attributes on the performance of the model was analyzed and higher accuracy of the generated model was achieved by application of appropriate techniques.

The rest of this paper is organized as follows. The process of data collection and preprocessing are described in second section. Classification algorithms implementations is described in the third section, while in the fourth section simulation results of proposed experiments are shown. Finally, fifth section provides conclusion remarks and outlines directions for future work.

2. DATA COLLECTING AND PREPROCESSING

For the purposes of this study, administrative and demographic data of students who have attended the Introduction to Programming course were collected and their impact on students' performance was analyzed. This course is performing during the summer semester of the first year of study at the Faculty of Electrical Engineering in East Sarajevo. Randomly sampling, the data of the two generations of students from all three study programs that are running at the Faculty have been taken into account. Open source data mining tool WEKA (Weka) was used to apply the learning methods to a dataset and analyze their output to extract useful information about the data and their impact on students' performance. The data collected, which represent

the attributes for data mining process performing, include city from where students came (*city*), high school they graduated (*school*), average mark of subject mathematics (*matav*) and informathics (*infav*) in high school, graduated average mark in high school (*hsav*), points obtained on the faculty qualification exam (*test*) and obtained mark in the course Introduction to Programming (*mark*). The last attribute was used as a class attribute.

To be able to apply data mining techniques, it was necessary to preprocess input data. In the initial stage of preprocessing step is identifing and discarding the attributes that have no predictive value (the index number, name, and so on). By manually discretization process (Romero et al., 2013) a numerical values which represented the final grade of class attribute '*mark*' were transformed into nominal values in accordance with the specific needs of the individual experiments performing.

Two experiments were conducted and their results are shown in this paper. First experiment was performed over 6 distinct values of the class attribute: *five, six, seven, eight, nine* and *ten*. In the second experiment class atribute has 3 distinct values (five=*weak*, six, seven and eight=*good*, nine and ten=*excellent*). Excel .csv file is formed of these data and then exported to WEKA data mining tool. Data preprocessing is a procedure that usually consumes a bulk of time and requires a lot of work, but it is an absolutely necessary step for the successful application of data mining techniques and algorithms.

3. CLASSIFICATION ALGORITHMS IMPLEMENTATIONS

One of the most common tasks used in data mining applications is the classification. Classification is type of machine learning analogue to human learning from past experiences to gain new knowledge in order to improve our ability to perform real-world tasks (Liu, 2007). Computers using machine learning learns from data which are collected in the past and represent past experiences. In most cases classification is used for learning a target function that can be used to predict the values of a discrete class attribute, e. g. classification is one type of predictions methods. The goal of prediction is to infer a target attribute, predicted variable, from some combination of other aspects of the data or another attribute. Classification here means the problem of correctly predicting the probability that an example has a predefined class from a set of attributes describing the example. In classification learning, the learning scheme is presented with a set of classified examples from which it is expected to learn a way of classifying unseen examples (Weka).

There are many methods and measures for estimation the strength and the accuracy of a classification/predictive model (Liu, 2007). The main measure is the classification accuracy which is the number of correctly classified instances in the test set divided by the total number of instances in the test set. Some of the common methods for classifier evaluation are holdout set, Multiple Random Sampling and Cross-Validation. One of a number of different evaluation metrics is F-measure. F-measure is used if a single measure to compare different classifiers is needed (Weka). For more detailed analysis of the distribution of instances of the class attribute confusion matrix can be used. It contains information about actual and predicted results given by a classifier for all class attribute' values.

While conducting above mentioned experiments, three different types of classification algorithms provided by Weka were used: two rules-based algorithms – JRip and NNge, and one tree-based algorithm - J48. All these algorithms were executed using their default parameters' values. Every machine learning algorithms have been applied separately on all data set. These algorithms have been selected because they are considered so called „white-box–classification algorithms. These algorithms provide an explanation for the classification result and are preferred to „black-box–data mining models which are usually more accurate but less comprehensible. The classification results obtained by „white-box–classification algorithms can be used directly for decision making. Obtained models can explain their predictions at a higher level of abstraction by IF-THEN rules. These types of rules can be more comprehensible and easily interpreted by non-expert data mining users, such as teacher or course instructor. In this way it is possible for a teacher or course instructor to analyze and use obtained classification output in order to detect certain classes of students and factors that may affect their performance.

For evaluation of classifier 10-fold cross validation testing technique was used. That is a standard method for predicting the error rate of learning techniques performed over a fixed sample of data. During the evaluation process the data set is divided into 10 subsets. Then the classification algorithms are fed with these data subsets. The left-out subsets of the training data are used to evaluate classification accuracy. When seeking an accurate error estimate, it is standard procedure to repeat the cross-validation process 10 times - that is, 10 times tenfold cross-validation and average the results. This involves invoking the learning algorithm 100 times on datasets that are all nine-tenths the size of the original. Getting a good measure of performance is a computation-intensive undertaking (Witten, 2011).

The decision tree is a very popular method for classification and decision making. It is a decision making technique used to solve many problems. It predicts outcomes using a series of questions and rules for data classification. The decision tree branching occurs as a result of meeting the requirements of classification issues. Each question will divide data into subsets that are more homogeneous than the senior set. If the question has two answers, then the response to the question arise two subsets (binary tree). Subsets arise according to number of questions answers. Therefore the classification of certain data are carried out. Predicting the behavior of a particular client can be made on the basis of its belonging to a particular event (which is classified based on a number of issues and conditions), for which we know how it acts. During the construction of decision trees is important to know the right questions. In this paper, J.48 decision tree, which is an implementation of C4.5 algorithm in WEKA data mining tool (Weka), is used.

Instance based classifiers rely on using directly the examples from the training set as concept models without constructing abstractions. They proved to be effective but the absence of an associated compact explicit model limits their —readability. On the other hand, the rule based approaches can provide comprehensible rule sets. The hybrid variants, based on the concept of generalized exemplars, combine the idea of distance based classification with that of best matching rule. The generalized exemplars are sets of instances which can be interpreted as rules and which allow to decrease the model size and to increase the robustness to noise of instance based classifiers. Instance-based classifier Non-Nested Generalized Exemplars (NNGE) is based on algorithm introduced by Brent, 1995. It examines generalized exemplars as a method of improving the classification performance of instance-based learners. It has been shown that generalising exemplars results in improved classification performance over standard nearest neighbor. The only thing that may pose a problem is that the algorithm tends to produce rules that test a large number of attributes. Because of this they are not very intelligible to people.

JRip is Weka's implementation of the RIPPER rule learner. It is a fast algorithm for learning "IF-THEN" rules. RIPPER is an acronym for *repeated incremental pruning to produce error reduction*. Classes are examined in increasing size and an initial set of rules for a class is generated using incremental reduced-error pruning. An extra stopping condition is introduced that depends on the description length of the examples and rule set. The description-length *DL* is a complex formula that takes into account the number of bits needed to send a set of examples with respect to a set of rules, the number of bits required to send a rule with *k* conditions, and the number of bits needed to send the integer *k*—times an arbitrary factor of 50% to compensate for possible redundancy in the attributes. Having produced a rule set for the class, each rule is reconsidered and two variants produced, again using reduced-error pruning—but at this stage, instances covered by other rules for the class are removed from the pruning set, and success rate on the remaining instances is used as the pruning criterion. If one of the two variants yields a better description length, it replaces the rule. Next we reactivate the original building phase to mop up any newly uncovered instances of the class. A final check is made, to ensure that each rule contributes to the reduction of description length, before proceeding to generate rules for the next class. (Witten, 2011)

4. SIMULATION RESULTS

Using above described classification algorithms, results obtained performing the first experiment (six values of class attribute) are shown in Table 1.

Table 1: Classifier evaluation

Algorithm	Correctly Classified Instances - CCI	F-measure	Number of rules
J.48	22.86%	0.20	56
JRip	26.67%	0.16	4
NNge	22.86%	0.23	48

From Table 1 it can be seen that all generated models have very small accuracy and consequently very small F-measure value. Among all classifiers JRip perform the most accurately prediction, 26.67% correctly classified instances (CCI). It also has the smallest number of rules, 4. Generated rules are quite comprehensible, but as it can be seen in Table 2, there are very small number of instances that are correctly predicted (numbers in parentheses indicate the number of totally classified instances of one class / number of incorrectly classified instances of that class).
Detailed distribution of predicted values for every class attribute can be presented in the form of the confusion matrix. Confusion matrix is a two-dimensional matrix with a row and column for each class. Each matrix element shows the number of test examples for which the actual class is the row and the predicted class is the column. Good results correspond to large numbers down the main diagonal and small, ideally

zero, off-diagonal elements (Witten, 2011). Six values of class attributes *mark* are indicated by letters a=five, b=six, c=seven, d=ten, e=eight and f=nine. The results obtained using all three classifiers are shown in Table 3.

Table 2: JRIP rules

JRIP rules:
(test >= 38) => mark=ten (6.0/2.0)
(city = pale) and (test >= 29) => mark=ten (3.0/0.0)
(infav <= 2.5) => mark=six (2.0/0.0)
=> mark=five (94.0/68.0)

Table 3: Confusion matrix

Predicted class																		
J48						***JRip***						***NNge***						
a	***b***	***c***	***d***	***e***	***f***	***a***	***b***	***c***	***d***	***e***	***f***	***a***	***b***	***c***	***d***	***e***	***f***	***Real class***
13	6	3	1	1	2	**24**	0	0	0	*1*	*1*	***9***	*4*	*2*	*2*	*5*	*4*	***a=five***
8	**4**	3	1	0	1	15	**0**	2	0	*0*	*0*	*4*	***5***	*4*	*2*	*1*	*1*	***a=six***
7	5	**3**	2	3	4	17	1	**3**	0	*1*	*2*	*3*	*5*	***4***	*2*	*8*	*2*	***c=seven***
3	1	0	**4**	2	0	9	0	0	**1**	*0*	*0*	*2*	*0*	*1*	***4***	*2*	*1*	***d=ten***
8	2	1	1	**0**	2	11	0	1	2	**0**	0	3	1	3	4	**1**	2	***e=eight***
8	0	3	2	1	**0**	11	0	2	1	0	**0**	2	3	5	1	2	**1**	***f=nine***

From confusion matrix it can be seen that there is an unbalance in the distribution of the value of output classes and the accuracy of small classes is less than the accuracy of the higher class. In the case of unbalanced data sets, examples of small classes are more difficult to train. The problem with unbalanced data arises because learning algorithms tend to overlook less frequent classes (minority classes), paying attention just to the most frequent ones (majority classes). As a result, the classifier obtained is not able to correctly classify data instances corresponding to poorly represented classes. One of the most frequent methods used to learn from unbalanced data consists of re-sampling the data (Romero et al., 2010). To solve this problem, in this paper re-sampling was performed using Resample Weka filter for supervised learning. The result of applying this filter has shown that the difference in the values of attributes decreased. Results obtained by applying above mentioned algorithms on re-sampled data are shown in Table 4.

Table 4: Classifier evaluation (re-sampled data)

Algorithm	**Correctly Classified Instances - CCI**	**F-measure**	**Number of rules**
J.48	56.19%	0.55	54
JRip	54.29%	0.52	12
NNge	70.48%	0.70	33

The generated models performed on re-sampled data enable more precise predictions. Obtained results show that all classifiers applied on re-sampled data have significantly better accuracy compared to results presented in Table 1. NNge classifier in this case obtained the best result, 70.48% correctly classified instances and F-measure of 0.70. It can be concluded that accuracy is significantly increased on resampled data but the number of rules generated by the best classifier in this case is very huge and incomprehensible. The number of rules generated by JRip classifier is 12 and they are shown in Table 5. From Table 5 it can be seen that the most relevant attribute for classification was city. Although the number of correctly classified instance is much higher than in the previous case still there are a significant number of instances whose values are misclassified.

The second experiment again compared the same three classification algorithms using all the available data but now applying pre-processing discretization data task on the class attribute. Discretization divides the numerical data into categorical classes that are easier for the teacher to understand. The manual discretization method (where cut-off points have to be specified) has been applied to the *mark* attribute, where three intervals and labels have been used (*weak*: if value is 5; *good*: if value is 6, 7 and 8 and *excellent*: if value is 9 and 10). Repeating above performed simulation obtained results on unbalanced data set are presented in Table 6.

Table 5: JRIP rules

JRIP rules:
(school = tehnicar racunarstva) and (matav >= 4.8) => mark=nine (4.0/1.0) (city = nevesinje) and (hsav <= 4.6) => mark=nine (2.0/0.0) (school = masinska) => mark=nine (2.0/0.0) (test >= 40) => mark=ten (6.0/0.0) (test >= 25) and (hsav >= 4.8) and (school = gimnazija) => mark=eight (9.0/1.0) (city = zvornik) and (school = tehnicar racunarstva) and (test >= 10) => mark=eight (6.0/0.0) (city = bratunac) => mark=six (9.0/1.0) (city = sokolac) => mark=six (7.0/2.0) (city = cajnice) => mark=six (4.0/1.0) (matav >= 4.75) and (test <= 14) => mark=seven (10.0/0.0) (city = ugljevik) => mark=seven (2.0/0.0) => mark=five (44.0/21.0)

Table 6: Classifier evaluation

Algorithm	**Correctly Classified Instances - CCI**	**F-measure**	**Number of rules**
J.48	53.33%	0.45	2
JRip	57.14%	0.55	3
NNge	46.67%	0.46	36

In this case, the best classification result was obtained using JRip classifier, 57.14% CCI, but J.48 classifier also obtained approximately good result. The rules generated by these two classifiers are shown in Table 7.

Table 7: J48 and JRIP rules

J48 pruned tree:	**JRIP rules:**
test <= 26: good (77.74/33.0) test > 26: excellent (27.26/14.26)	(test >= 26) and (hsav >= 4.7) => mark=excellent (19.0/7.0) (test <= 8) => mark=weak (17.0/6.0) => mark=good (69.0/26.0)

Important conclusion that can be made analyzing the Table 7 is that both the classifier detected the same value of test attribute as a limit for the separation excellent and good class. But still, the number of incorrectly classified instances is relatively huge.

Confusion matrix was used for a more detailed analysis of the class attribute distribution, Table 8.

Table 8: Confusion matrix

Predicted class									
J48			***JRip***			***NNge***			
a	***b***	***c***	***a***	***b***	***c***	***a***	***b***	***c***	***Real class***
0	23	3	**10**	15	1	***7***	*16*	*3*	***a=weak***
1	**47**	7	5	**42**	8	*14*	***34***	*7*	***b=good***
0	15	**9**	1	15	**8**	*6*	*10*	***8***	***c=excellent***

After re-sampling, the generated models enable more precise predictions. Results obtained by applying above mentioned algorithms on re-sampled data are shown in Table 9.

Table 9: Classifier evaluation (re-sampled data)

Algorithm	**Correctly Classified Instances - CCI**	**F-measure**	**Number of rules**
J.48	67.62%	0.66	41
JRip	64.76%	0.64	9
NNge	80%	0.80	22

In this case NNge classifier made a very good prediction, 80% correctly classified instances. The number of generated rules is also significantly reduced. Some rules with the highest coverage (number in parentheses) are shown in Table 10.

Table 10: NNge classifier rules generated

NNge classifier rules generated :
class good IF : city in {cajnice,mostar,trebinje,insarajevo,nevesinje,foca,milici,rudo} ^ school in {gimnazija,tehnicar racunarstva,tehnicar elektronike} ^ 2.0<=matav<=5.0 ^ 2.5<=infav<=5.0 ^ 3.2<=hsav<=4.7 ^ 6.0<=test<=26.0 (28)
class good IF : city in {pale,rogatica,kalinovik} ^ school in {gimnazija} ^ 3.5<=matav<=5.0 ^ 3.5<=infav<=5.0 ^ 3.8<=hsav<=5.0 ^ 11.0<=test<=24.0 (13)
class weak IF : city in {sokolac,visegrad,ilidza,zvornik,gacko} ^ school in {gimnazija} ^ 3.3<=matav<=4.8 ^ 4.5<=infav<=5.0 ^ 3.9<=hsav<=4.9 ^ 7.0<=test<=35.0 (11)
class excellent IF : city in {trebinje,pale,bugojno} ^ school in {gimnazija,tehnicar racunarstva} ^ 3.3<=matav<=5.0 ^ 4.5<=infav<=5.0 ^ 4.1<=hsav<=5.0 ^ 29.0<=test<=49.0 (7)
.
.
.

Although very complex, these rules can be easily interpreted and implemented with the goal of grouping students for better adjustment of teaching materials to their affinities.

NNge confusion matrix is shown in Table 11.

Table 11: Confusion matrix

Predicted class			
NNge			
a	***b***	***c***	***Real class***
16	6	2	*a=weak*
7	**54**	1	*b=good*
2	3	**14**	*c=excellent*

Analyzing confusion matrix of the NNge classifier can be concluded that the largest number of miss predictions was made in the class b. Miss prediction among classes a and c is relatively small. One of the reasons for that may be the fact that class b covers the largest range of obtained marks. This may refer to the future research in which the experiments could be performed with a different redistribution of value within the class.

5. CONCLUSION

The choice of the classifier for generating predictive model is a complex task. The whole data mining process is almost always iterative: it usually takes many rounds to achieve final satisfactory results. The selection of a correct data mining algorithm depends on not only the goal of an application, but also on the compatibility of the data set. Performed experiments have shown that different algorithms obtain the best classification accuracy depending on the different preprocessing tasks like discretization or rebalancing.

This paper describes the analysis of the three white-box classifiers for creating rules and identifying the factors that influence predicting of students' performance in the course Introduction to Programming at Faculty of Electrical Engineering in East Sarajevo. Experiments were performed on two types of the values of class attribute, with and without the applied method of discretization. Several experiments were performed using available administrative and demographic data about students to try to obtain more accuracy and better rules. Rebalance preprocessing techniques have also been used on the original data to test again if better classifier models can be obtained. The two standard measures for evaluation of the accuracy of the predictive model (the number of correctly classified examples and F-measure) were applied. Confusions matrix was used for a more detailed analysis of the class attribute distribution. From the obtained results it can be seen that generated predictive models with re-sampled data enabled more precise predictions.

The aim of future research is to explore the possibility of including the additional parameters in the analysis by which it could be achieved better predictive results and use of other classification algorithms for creating more precise predictive model.

Abstract: *The increasing trend of globalization, international trade and global communication has led to the rise in the need for foreign language learning. Plurilingualism, the command of several languages by an individual is set as a goal for the European environment. Therefore, language policy and planning need to be developed accordingly. This paper gives an overview of relevant European institutions and important documents which have now become an indispensable part of European language policies. The paper also analyzes the situation in Serbia with regards to language policy and planning and the use of these widely-accepted documents.*

Keywords*: language policy and planning, plurilingualism, CEFR, Language Portfolio*

1. INTRODUCTION

The increasing trend of globalization, international trade and global communication has led to the rise in the need for foreign language learning. The need for understanding, communication and cooperation is making it a necessity for people to become proficient in several foreign languages. Nation states are investing resources and staff into implementing curricula which foster language learning and are many themselves multilingual. English has for long established itself as a *ligua franca* in both economic and educational environments. The threat of English-only situation is driving the need to facilitate learning of other languages and promote plurilingualism. In Europe, numerous stakeholders have invested resources and research to meet this aim. This paper will give an overview of language policies in Europe and some of the most important documents regulating and directing them, and attempt to connect it to the situation in Serbia.

2. TERMINOLOGY AND RELEVANT BODIES

According to Filipović (2009), **language policy and planning** are most commonly defined as an organized, targeted and long-term activity of public bodies on different aspects of status, form and domain of the use of a specific language variety. This is an incomplete definition of language policy and planning, since it can be managed outside state institutions, applying different theoretic and methodological activities (p. 54).

As for Europe and its language policy and planning, Bugarski in Filipovic (2009) introduces the term interactive model which means that there is no longer coexistence, but rather interaction or cooperation among speakers of different languages on equal grounds which would provide membership in the European family under a common roof. This interactive model is represented by various documents by the Council of Europe, including the *European Common Framework of Reference.*

Breidbach (2003) perceives “European communicative integration as a political concept which calls for structuring through language education policies” (p. 7).

Concepts important for discussing language policy and planning are multilingualism and plurilingualism and how they should be treated. According to the Council of Europe “**Multilingualism** refers to the presence in a geographical area, large or small, of more than one 'variety of language' i.e. the mode of speaking of a social group whether it is formally recognised as a language or not; in such an area individuals may be monolingual, speaking only their own variety.” Therefore, multilingualism does not include individuals speaking more than one language, which is the aim for the “House of Europe” for the future. On the other hand, “**Plurilingualism** refers to the repertoire of varieties of language which many individuals use, and is therefore the opposite of monolingualism; it includes the language variety referred to as 'mother tongue' or 'first language' and any number of other languages or varieties. Thus in some multilingual areas some individuals are monolingual and some are plurilingual.”

When discussing language policy and planning in Europe, numerous actors are included, but this paper will be limited to three major bodies – Council of Europe, European Commission, and European Centre for Modern Languages which is a Council of Europe institution also supported by the European Commission.

European Commission sees its role in developing language learning policies in Europe by retooling education systems in member States, gathering data to formulate benchmarks in language learning and promoting multilingualism with the aim of improving employability within the EU. Following the change of the labour market and skills necessary, the EU is investing in education system reforms to cater for these changes. They have supported vast analyses of the current state of affairs and provided several instruments to support transparency and recognition of knowledge, skills and competences. As for language skills, the European Commission is working closely with the European Centre for Modern Languages. According to the first European Survey on Language Competences (http://ec.europa.eu/languages/policy/strategic-framework/documents/language-survey-technical-report_en.pdf) "Member States must reform their education systems based on new methodologies for teaching both the first and second foreign languages". The survey included students of lower and upper secondary education and provided an extensive overview of the current state of affairs.

Council of Europe, with headquarters in Strasbourg, aims at promoting linguistic diversity and language learning, and operates under the European Cultural Convention. It currently includes 47 member States; Serbia joined in 2003. The Council promotes policies designed to promote plurilingualism, linguistic diversity, mutual understanding, social cohesion and democratic citizenship in an ever more globalized world. The importance of languages is underlined through the existence of the Language Policy Division in Strasbourg and the European Centre for Modern Languages in Graz, Austria. Policy makers, test designers and teachers have all been influenced by the work of the Council's Language Policy Division, starting from the series of publications between 1975 and 1990 listing the linguistic means necessary to communicate efficiently with speakers in another language, i.e. "the threshold level". The products of several decades of work are two major documents – the Common European Framework of Reference (CEFR) and the European Language Portfolio.

According to data by the European Commission, the data on Educational attainment and outcomes of education – Language skills, show that in the 28 member countries of the European Union in 2011, the self-reported level of foreign language skills on the first and second stage of tertiary education is as shown in Table 1.

Table 1: First and second stage of tertiary education (levels 5 and 6) in 2011

Languages / Countries	No languages	1 language	2 languages	3 languages or more
European Union (28 countries)	11.6%	36.7%	33.7%	17.9%

Eurostat

Table 1 shows that the overall knowledge of foreign languages in the EU is on a satisfactory level. However, it is far from the plurilingual aim. On the other hand, despite not having substantial data on the information in Serbia, the authors are of the opinion that the numbers are far lower (not including speakers of minority languages).

Neuner (2002) indicates that linguistic diversity for a plurilingual individual is the overall guideline for the European language policy so as to be able to interact with other Europeans, thus formulating a threefold objective of such a policy (p. 8):

- pragmatic (facilitate mobility of citizens)
- intercultural (overcome prejudice and develop multicultural interest and tolerance)
- socio-political (protect and support linguistic and cultural diversity)

According to the author, English holds "the first place among foreign languages offered in the curriculum in almost all Member States of the Council of Europe, not only in compulsory education (school level) but also in institutions for adult education and lifelong learning" (p. 10). The author continues to point out that this dominance of the English language represents a danger to the concept of European language policy. Finally, the author proposes limiting the time for learning English and allocating the rest of the time for foreign language learning to other languages.

The following chapter will give an overview of the two main documents aimed at aiding language learning – Common European Framework of Reference and Language portfolio.

3. COMMON EUROPEAN FRAMEWORK OF REFERENCE AND LANGUAGE PORTFOLIO

Common European Framework of Reference (CEFR) is a benchmark document for curriculum design and language policy creation which is the result of over twenty years of research in the field of language planning, learning and assessment done by the Council of Europe. Its aim is to provide a common framework for the design of curricula and syllabi, teaching materials and language testing and assessment. It was officially adopted in 2001 and is now translated into over 39 languages. The primary purpose of the document is to serve as a prescriptive tool and help stakeholders in the field of language learning to describe and compare their teaching options, all with the aim of transparency and comparability. Therefore, according to the Council of Europe's *Tools for Language Teaching*, the document proposes:

- a common methodology for analysing and describing situations and choices in language teaching and learning;
- a common terminology for all languages and educational contexts;
- a common scale of levels of language proficiency to assist with goal-setting and learning outcome assessment.

The CEFR describes foreign language proficiency in six levels (A1, A2, B1, B2, C1, C2). This helps to compare tests and knowledge level across languages, and recognise language qualifications, which helps both educational and occupational mobility. For example, holders of the Cambridge ESOL language certificates of B2 level and higher, are eligible for attending undergraduate, graduate and post graduate courses across Europe and beyond.

The document also gives a detailed overview of "can do" descriptors for all aspects of language competence (Reading, Writing, Listening and Speaking). Table 2 shows a segment of the Global scale (for a proficient user).

Table 2: Common Reference Levels – Global scale

Proficient user	C1	Can understand with ease virtually everything heard or read. Can summarise information from different spoken and written sources, reconstructing arguments and accounts in a coherent presentation. Can express him/herself spontaneously, very fluently and precisely, differentiating finer shades of meaning even in more complex situations
	C2	Can understand a wide range of demanding, longer texts, and recognise implicit meaning. Can express him/herself fluently and spontaneously without much obvious searching for expressions. Can use language flexibly and effectively for social, academic and professional purposes. Can produce clear, well-structured, detailed text on complex subjects, showing controlled use of organisational patterns, connectors and cohesive devices

In addition to principles for teaching and learning which are set out in Chapters 5, 6 and 8 of the CEFR, the Council of Europe has produced several other documents to assist in assessment, such as the Manual for Language Test and Development (2011) and Relating Language Examinations to the Common European Framework for Reference of Languages: Learning, Teaching, Assessment, A Manual (2009).

All of the listed documents do not aim at telling practitioners what to do or how to do it, but rather give guidelines and provide support in line with the specific needs of the users.

Filipovic (2009) lists several reasons for and against the implementation of CEFR. Those against it underline that it is a result of a specific political and ideological position which sees economic power and political influence as an understatement of the explicit aims of this document. Those criticizing the document emphasize that it insists on language equality only formally, while the political reality of the countries it is addressing hinders systematic implementation of its guidelines. Also, many authors within the EU point to a discrepancy between the declarative support to plurilingualism and the support for imperialistic language policies which strengthen the already strong languages. On the other hand, as the author states, those who are for the implementation of the *Framework* actually have an active position in the process of educating the professional and the general public on the importance of plurilingualism and the positive aspects of being competent in a great number of languages. Therefore, if the recommendations of the Framework are responsibly and objectively incorporated in language policy and planning they can help to protect minority languages and promote linguistic and cultural diversity.

European Language Portfolio is a document which helps language learners keep track of their learning process. Its aim is to support plurilingualism and allow users to record their language learning achievements. It consists of three parts – Language Passport, Language Biography and Dossier. The Europass Language

Passport was developed by the Council of Europe and the European Union. Both the standard and the Europass Language Passport contain a record of a learner's progress. The Language Biography helps the learner note down the experience and reflect on the learning of a specific language. Finally, the Dossier serves to keep track of personal work. The Portfolio is the property of an individual learner and it is linked to the CEFR, enabling it to be widely acknowledged. Every Language Portfolio must be accredited by the European Language Portfolio Validation Committee, thus ensuring that the standards and all the necessary criteria are met.

4. SERBIA IN THE CONTEXT

When discussing the pros and cons of the implementation of CEFR, Filipovic (2009) reflects on the language policy and planning in Serbia. The author feels that there is no clear direction or aim of these processes. She proposes an overall analysis of which foreign languages should be taught and for how long, the language content that should be taught, methods in language learning and a strategic and scientific grounds on which language policy and planning should be founded. Only after such an extensive analysis should an overall language policy be designed. This should provide future generations with the possibility to be included in the professional life of a plurilingual Europe.

The authors found vague data on Serbia in the context of the implementation of CEFR. However, in a Survey on the use of CEFR conducted in 2007, Serbia was among the 30 respondents. This survey indicated that CEFR was referred to in a number of official documents at state or regional level, such as primary, secondary or higher education curricula, teacher training, assessment, etc. In addition, CEFR proved to be most useful in curriculum design. In general, the CEFR seems to have a major impact on language education. Countries who responded to the survey indicated that the Framework is well known by the institutions in question and well accepted by teachers. In some countries the CEFR was used in developing both strategic language policy documents and practical teaching materials. In others, it is referred to in curriculum planning. Some respondents stress that the CEFR has made the communicative approach to language teaching more action-oriented.

On the other hand, some respondents state that the CEFR has had a moderate impact. It has contributed to coherence and transparency; however, it does not impact the teaching profession at the school level. These countries feel that the full potential of CEFR is yet to be realised. In addition, they feel that the document needs more clarification.

The survey provided information about the countries' comments on the CEFR:

- there is a need for a concise and reader-friendly summary of the CEFR and of the basic principles of its approach
- national syllabi need to be calibrated to the CEFR
- tests calibrated to the CEFR levels for different age groups need to be developed
- a forum for an exchange of good practice related to the use of the CEFR is necessary.

Since the Survey does not provide specific information on individual respondent countries, it is difficult to say where Serbia stands on these points. However, the feedback gives valuable information on potential problems or suggestions on the implementation of CEFR.

5. CONCLUSION

Without any discussion on whether Serbia should enter the European Union or not, the authors see Serbia as a part of the European academic space since it is a part of the Bologna reform. Therefore, language learning and language policies should be a matter of central interest to all stakeholders in education if students of all levels of education are to be provided with the possibility of participating in this academic space and in the ever growing globalization of economy. The authors suggest further research in the field of language policy implementation, standardization with the adopted European practices and provision of teachers, learners and policy makers with a more in-depth knowledge of both the possibilities and shortcomings of the abovementioned documents and processes, all with the aim of improving cooperation, mutual understanding and development.

Abstract: *Due to non-existing norms and criteria in primary educational system of the Republic of Serbia, each teacher has the right to choose the appropriate textbook on the basis of their own criteria and ratings. That may lead to the selection of a textbook which is not of a high quality. Our objective in this paper is a clear determination of criteria which we have to use when selecting textbooks for primary schools in the educational system of Serbia. In the period between 29th of October and 11th of November, teachers were given an internet questionnaire to rate the most important criteria they rely on when choosing a textbook, using grades 1 to 3. Using the results of the questionnaire, we will try to pinpoint the most important criteria. The latest research has helped us find out that the authors' assumption that the criteria, which help teachers choose a textbook, are actually appropriate for the age of the children who learn from them. They also assume that there are around seven most important criteria which can be applied to any subject. On the basis of previous research on this subject, we expect to conclude that the teachers of the Serbian educational system are mostly guided by the criteria which are oriented on students and that they don't use more than 10 criteria.*

Keywords*: Textbook, Teacher, Entropy, Student, Ranking, Average score, Criteria.*

1. INTRODUCTION

Definition of the importance

Due to non-existing norms and criteria in primary educational system of the Republic of Serbia, each teacher has the right to choose the appropriate textbook on the basis of their own criteria and rating. That may lead to the selection of a textbook which is not of a high quality. Furthermore, we don't know which criterion is the most important when opting for a textbook, therefore, some publishers don't pay attention to important segments when publishing a textbook. It's necessary to focus on the essence – the segment which helps teachers to choose the appropriate textbook for teaching.

Summary

In their study named ''Rhetorical form, selection, and use of textbooks'', the University of Illinois discovered that teachers and administrators, ''tended to perceive the ideal textbook to be well-organized/systematic, informational, appropriate in content to school objectives, and readable on or below grade level'' (Crismore, A., 1989). Another study conducted by Manto Sylvia Ramaligela identified 7 important criteria for textbook evaluation and selection: content, connectedness, language, format, context, activities and teaching strategies (Ramaligela, M. S., 2010). Solomon Olorundare from University of Ilorin also conducted a study named ''Textbook selection: A critical process in the education enterprise''. Professor Olorundare singled out these four criteria: adequacy of the textbook: process, adequacy of the textbook: content, material presentation and teaching ability of the textbook (Olorundare, S. A., 1998).

Study named ''Selecting an E-(text) book: Evaluation criteria'' (2012) by Mariusz Marczak concluded a list of categories of evaluation criteria used when selecting an e-textbook. The categories were: layout and design; content and functionalities (Marczak, M., 2012). These results show us that evaluation criteria regarding textbooks vary depending on their purpose and their form.

Hypothetical paragraph

The latest research has helped us find out that the authors assume that the criteria, which help teachers to choose a textbook, are actually appropriate for the age of the children who learn from them. They also assume that there are about seven most important criteria, which can be used for any subject.

Subject

In the period between 29th of October and 11th of November, teachers were given an internet questionnaire to rate the most important criteria they rely on when choosing a textbook, using grades 1 to 3. Using the results of the questionnaire, we will try to pinpoint the most important criteria in this section. In addition, we will use the methods from the theory of decision making such as entropy, average score, total score and variance to determine values and confirm findings that will be shown in this paper. We will also make a ranking list to see which criteria are the most important for the primary school teachers in the Republic of Serbia.

Objectives

The social objective is a clear determination of criteria which we have to use when opting for primary school textbooks in the educational system of Serbia. That will help us improve their quality.

The scientific objective represents the scientific qualification of the criteria which are used for the selection of textbooks, emphasizing the most significant of them with the aim of enhancing the quality of classes.

Hypothesis

Teachers of the Serbian educational system are mostly guided by the criteria which are oriented on the students, and they don't use more than 10 criteria.

Table 1: The structure of the sample by school administration

School administration	Number of respondents	Percentage of respondents
Sombor	27	3,7%
Novi Sad	142	19,5%
Zrenjanin	73	10%
Belgrade	119	16,3%
Valjevo	47	6,4%
Požarevac	36	4,9%
Kragujevac	30	4,1%
Jagodina	24	3,3%
Zaječar	27	3,7%
Užice	36	4,9%
Čačak	18	2,5%
Novi Pazar	11	1,5%
Kraljevo	16	2,2%
Kruševac	26	3,6%
Niš	67	9,2%
Leskovac	27	3,7%
Kosovska Mitrovica	3	0,4%
Ranilug	1	0,1%
Total:	**730**	**100%**

2. SAMPLE

The study included 770 examinees. The sample consists of 730 of them since the responses of the remaining 40 examinees were not taken into account for failure to fulfill basic conditions. Basic terms that are defined in the questionnaire are: respondents must be class teachers or subject teachers, citizens of the Republic of Serbia, and must fill in certain fields that are marked as required.

- The structure of the sample by years of service

Most of respondents have between 11 to 20 years of service (43%), followed by respondents from 21 to 30 (29%), then respondents with 1 to 10 years of service (23%), and, lastly, the respondents with 31 to 40 years of service (5%).

- The structure of the sample by Level of Education

When it comes to the structure of the sample by Level of Education, the situation is the following: number of those with a bachelor's degree is by far the largest (76.9%), followed by a significantly smaller number of those with a master's degree (13%), and those with a higher level of education (7%), whereas only 4 respondents, or 0.01% have obtained a PhD.

- The structure of the sample by the professional title

The data shows that, by far, the most respondents do not have a professional degree (96%), only 3% have a degree of pedagogical advisor, and 1% are ranked as high pedagogical advisors, three of the respondents hold the title standalone and one respondent holds the title of a higher pedagogical advisor, which makes 0.4% and 0.1% of the total respondents respectively.

- The structure of the sample in relation to whether the respondents are employed in the classroom or subject teaching

In relation to whether respondents work as elementary or subject teachers, it can be seen that there is approximately the same number of respondents who are employed as elementary teachers (49%) and those who are employed as subject teachers (51%).

- The structure of the sample by school administration

The study involved respondents from 210 municipalities of the Republic of Serbia, for easier and more user friendly display, points are classified by school administration. The sample consists of respondents employed in schools in total of 18 school districts. Most of them are those whose schools belong to the school administration Novi Sad (19.5%), followed by Belgrade (16.3%) and Zrenjanin (10%). The least number of respondents are from the school administration Kosovska Mitrovica and Ranilug (0.4, or 0.1%). These results can be seen in Table 1.

3. METHODOLOGY

Textbooks selection criteria

This research includes the evaluation of entropy, as well as the analysis of the variance, average scores and total scores. Method used to rank the criteria in this study is shown below on Chart 1. The method was taken from (Bahraminasab, M., Jahan, A., Mustapha, F., Sapuan, S. M., & Ismail, M. Y. (2012)).

In this paper, parameters of entropy, mean and total values are used for the measurement or quantification criteria.

In order to better understand the responses obtained by questionnaire or teachers' criteria concerning the selection of textbooks, we used the technique of the theory of decision-making called entropy, the measure of dispersion, of order/disorder rate. Entropy provides insight into the actual behavior of the system, meaning, if the survey provides insight into the dissipation of the vote compared to multiple choice. In addition to entropy, respondents have been observed through the average and total scores.

After the application of this method for all the criteria, we can see important criteria in relation with which there is agreement among the respondents, as well as where you can draw the line between very important criteria and those that are less important. This result can be confirmed with an overview of average and total score criteria.

In the process of calculating the entropy for the sake of obtaining these results, we used the following formula:

$$H(x) = -\sum_{i=1}^{n} p(x_i) log_b p(x_i) \qquad (1).$$

The process of calculation is proceeded as follows:

Rating 1 - *Number of votes 7*; **Rating 2** - *Number of votes* 64; **Rating 3** - *Number of votes 659.*

$$H = -\left(\frac{7}{730} * log_3\frac{7}{730} + \frac{64}{730} * log_3\frac{64}{730} + \frac{659}{730} * log_3\frac{659}{730}\right) \qquad (2).$$

The obtained result (for concision criteria) looks like this: Entropy **(H = 0.3188902)**.

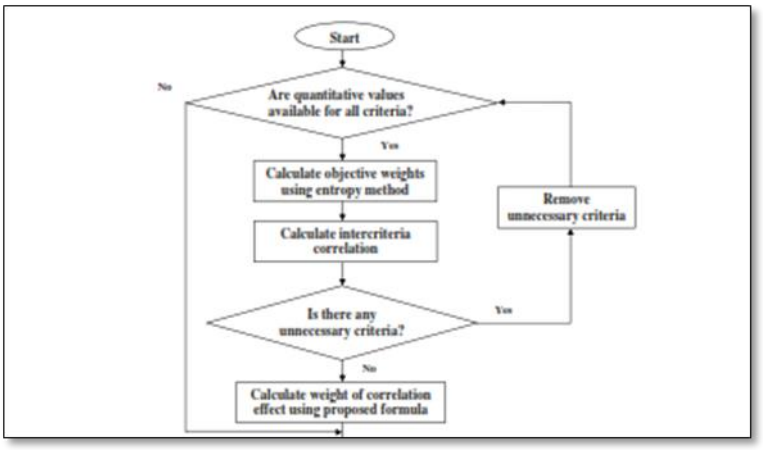

Chart 1: A framework for weighting of criteria in ranking stage of material selection process (Bahraminasab, M., Jahan, A., Mustapha, F., Sapuan, S. M., & Ismail, M. Y. (2012)).

Average score and Entropy

Table 2 shows that there is no difference in the results when taking into account the average score of criteria and obtained values of entropy. It is clearly seen that the results are identical, except that the difference obtained by using entropy convincingly indicates these results.

The results show that criteria named below are, based on the rating of respondents, teachers' most important criteria in the selection of textbooks:

- Language adjustment to the students' age
- Encouraging students to think creatively
- Methodical approach by author
- The opportunity for students to work independently
- Page overview
- Didactic approach by author
- Conciseness in presentation of content

And the least important criteria for teachers in the selection of textbooks:

- Parts of the textbook set are in a blindfold
- Parts of the textbook set are separated
- Price

Table 2: Ordering of criteria in relation to the importance of entropy and average score

	Average score	Entropy
Language adjustment to the students' age	2.971	0.115
Encouraging students to think creatively	2.958	0.160
Methodical approach by the author	2.951	0.177
The opportunity for students to work independently	2.915	0.270
Page overview	2.912	0.277
Didactic approach by the author	2.901	0.301
Conciseness in presentation of content	2.893	0.319
Encourage students' interest in scientific field	2.788	0.494
Additional materials for teachers are available	2.782	0.514
Occupational character of textbooks	2.778	0.521
Multimedia of textbook set	2.711	0.599
Illustrations quality	2.684	0.623
Design quality	2.538	0.725
Price	2.527	0.773
The quality of paper and printing	2.447	0.791
Prolixity in presentation of content	2.356	0.850
Parts of the textbook set are separated	2.110	0.953
Parts of the textbook set are set in a blindfold	1.986	0.994

In order to get the most data from this analysis, the criteria were sorted in groups, depending on their nature. To clarify, selected criteria (Language adjustment to the students' age, Encouraging students to think creatively, Page overview, The opportunity for students to work independently) were sorted in group named Criteria oriented on student. The same sorting method was used to create the remaining three groups:

Criteria oriented on author (Didactic approach by author, Conciseness in presentation of content, Methodical approach by author, Prolixity in exposure of content).

Oriented on the physical quality of textbook (Illustrations quality, Design quality, The quality of paper and printing, Multimedia of textbook set, Parts of the textbook set are in a blindfold, Parts of the textbook set are separated, Price).

Oriented on teacher or scientific field (Encourage students' interest in scientific field, Additional materials for teachers are available, Occupational character of textbooks). The result of this grouping shown with entropy and average score can be seen in Chart 2 and Chart 3.

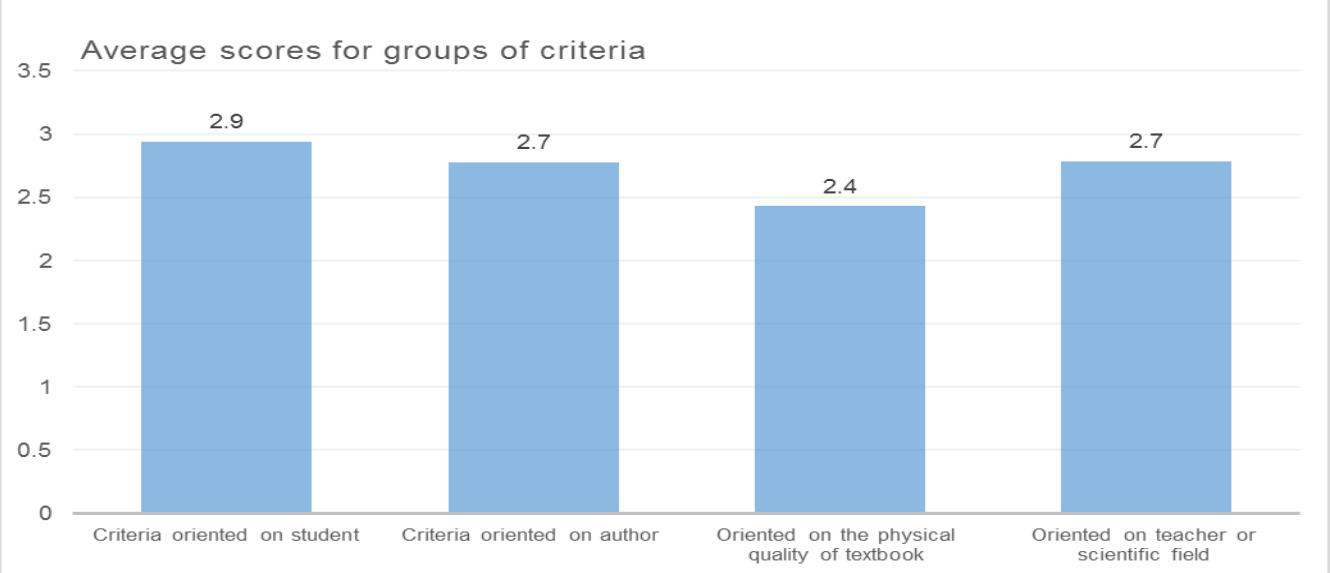

Chart 2: Average scores for groups of criteria

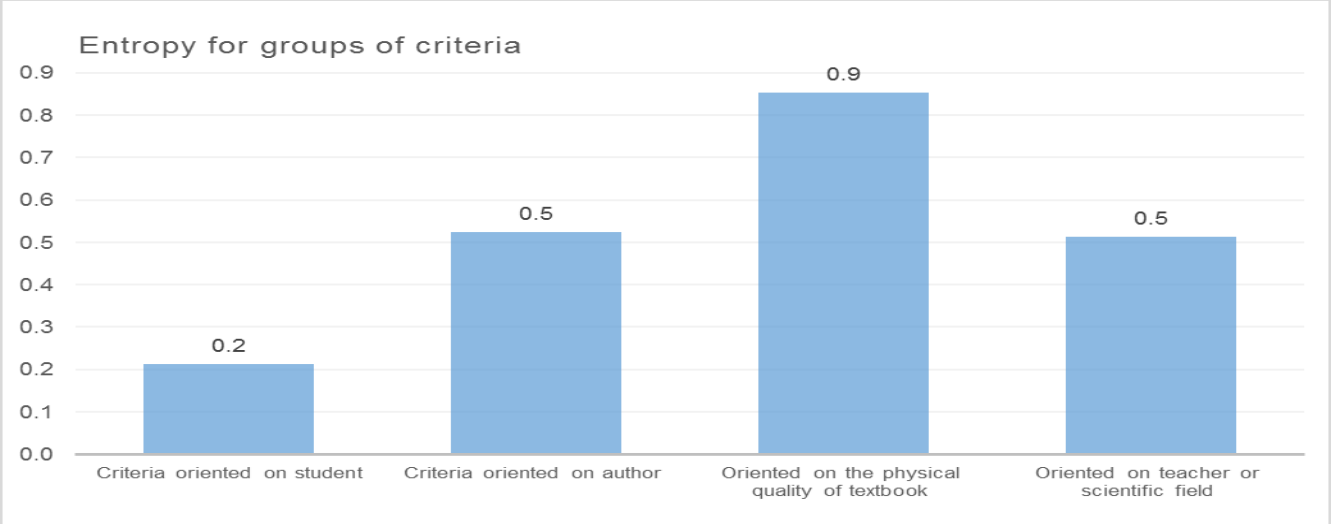

Chart 3: Entropy for groups of criteria

4. CONCLUSION

After using entropy method it became absolutely clear that these seven criteria are, based on the rating of respondents, teachers' most important criteria in the selection of textbooks: Language adjustment to the students' age; Encouraging students to think creatively; Methodical approach by author; The opportunity for students to work independently; Page overview; Didactic approach by author; Conciseness in presentation of content.

And the least important criteria for the teachers in the selection of textbooks: Parts of the textbook set are in a blindfold; Parts of the textbook set are separated; Price.

In order to get the most data from this analysis, the criteria were sorted in groups, depending on their nature. This showed us that teachers tend to use the criteria which are more focused on students and their ability to understand the subject presented in a textbook. This confirms our hypothesis that teachers of the Serbian educational system are mostly guided by the criteria which are oriented on students.

On the basis of the number of the criteria that have been pinpointed as the most important in the selection of textbooks, the other hypothesis, that teachers of the Serbian educational system don't use more than 10 criteria, is also confirmed.

We advise that any research which could follow up on the conclusions made in this study, should involve the application of AHP method for criteria that were offered and were pointed out in this paper as the most important.

LEADERSHIP SKILLS OF A HIGH SCHOOL PRINCIPALS A FIELD STUDY

Mimoza Kasimati, Shyqyri Llaci, Etleva Leskaj
University of Tirana, moza_kasimati@yahoo.com
University of Tirana, shllaci01@yahoo.com
University of Tirana, etlevaleskaj@gmail.com

Abstract: *Completing the mission of pre-university education institutions is of fundamental importance for the evolution of Albanian society and every society in general. One of the important actors in this context is the school principal; his leadership and vision are substantial components that need skill. In the framework of limited resources and relatively rigid structures, management skills of school principals allow for a combination of all factors within and outside the institution to create a value-added service. The complex situation is increasingly presenting social challenges related to individual performance and governing institutions. These individuals must be teachers, principals and leaders of mentally natural processes as well that occur within schools. But how do they actually occur? How many of these individuals are "equipped" with the qualities needed to fulfill their role as leaders? This article gives a description of a research performed on school principals about their leadership skills in Tirana (municipality and district).*

Keywords: *leadership skills, university education, mission, long-term performance, JEL: M19*

1. INTRODUCTION

University education in Albania has been involved in significant changes for several years. New concepts such as school-based management, the school principal being the manager and leader at the same time, the free choice of textbooks from the school itself, etc., have come along with significant changes in curricula. All efforts lead to the decentralization of Albanian education system and assimilation to knowledge for the purpose of creating an open society. These new concepts require significant structural changes and organizational reform and the role of all actors involved in the process, as well.

Time requires new standards and parameters of evaluation. The quality of education depends on how school is managed, as well as on the abundance of resources available. In the context of significant changes, the re-conceptualization of the role of all actors involved in the process is also being considered. In this paper we focus only on the school principal as a very important central figure for coordinating all the actors and factors that determine the school performance.

The perfect role of the school principal is that of an innovative pedagogical leader and a proactive manager all the while. The complex role of the school principal can be played only when creativity is a lifestyle, not a sporadic quality displayed occasionally. Overcoming the individual and collective understanding of the school principal as a midterm operational director should be associated with an individual social investment in developing his management capacity. It certainly requires a coordination of promotion and selective processes for the subtle position of the school principal, and the creation of a long-term training system based on the school and individual level, too. However that may sound absurd, creating a mentoring system for the growth and development of potential leaders, accompanied where appropriate with specific training for concrete capacity building of management, it seems to the authors of this paper as a valuable measure for long-term rewards. But how is the school principal capacity as a leader presented? Due to inability to manage financial incentives, what is his strength level of motivation and inspiration? What qualities of leader are actually presented? Due to inability to study the entire community of 1980 directors of pre-university education system in Albania, the aim of this paper is to identify the leadership capability of school principals in Tirana.

In the academic year 2011-2012 Tirana region had 171 schools of pre-university education system, 86 in the city and 85 in the districts.

2. THEORETICAL BASIS

Since 1950 when researchers at Ohio State University identified the dimensions called "initial structuring" and "consideration" for the first time, the two dimensional model of leadership behavior has influenced on its behavior studies. The researchers aimed at "determining by means of factor analysis procedures of the smallest number of dimensions that describe adequately the behavior of the leader" (Korman, 1966).

Initial Structuring concerns the extent to which a leader tends to define and structure his role and of his followers, with the efforts to achieve their objectives. This includes the morals that attempt to organize work, work relationships and objectives. The leader resulting with a high level in this dimension can be described as a person who "assigns specific tasks to group members", "expects employees reach certain standards of behavior and certain work", "emphasizes the importance of implementing time ".

Consideration is defined as the extent to which an individual has a tendency to build working relations that are characterized by mutual trust, respect for their dependents' ideas and regard to their feelings. The leaders give attention to their followers" contentment, their status and satisfaction. A leader that results in high levels in this dimension is characterized by: helping subordinates for their personal problems, friendship and goodwill, fair and equal treatment to subordinates and predisposition to communicate. These behavior dimensions of leaders have influenced the research in the field of leadership and have been comprised by other theories of school behaviorism and theories of the case. In fact, many researchers continue to use the two dimensional structure to make the leadership measurements functional (Hall, Workman & Marchioro, 1998; Kuntonbutr 1999 SCANDURA, Von Glinow, 1999 Low, B artolo, Furlonger 2000).

Another concept of understanding leadership and its behavior is the *transactional leader* against the *transformative* one. The *transactional* leader directs and motivates his followers towards the realization of their objectives, clarifying roles and task requirements. Besides this type of leader who is based on everyday relationships to achieve the objectives, there is also another type of leader who inspires his followers to overcome their personal interests for the good of the organization and who is likely to have a great and extraordinary impact. This is called the *transformational leader.* This leader changes the way his followers think and feel, by making long-term problems be viewed in a new different perspective; he regards the followers" interests and needs to be developed; is able to inspire, encourage and excite followers to try harder to reach common targets toward a new required state, described from his vision.

Since 1995, when psychologist Goleman stirred the minds of academics and management by publishing "Emotional Intelligence" book, the concept of emotional intelligence (EI) defined as "the ability to motivate yourself and cope with difficulties, to control impulses and restrain pleasure, to self-control humor and prevent disruption from reversing thinking, to have emotional sensitivity to others and hope " has drawn researchers attention as a prerogative that a successful leader should have. Trying to understand more clearly what personal skills generate an uncommon performance, Goleman, Boyatzis and McKee have been encouraged to analyze data from almost 500 models of competences built for various organizations including academic institutions. The list of components that generate altogether an exceptional performance in top level brings attention mostly to initiative, cooperation, empathy, intellect, cognitive skills such as the ability to understand it all and to see beyond the moment, etc. The estimation of technical indicators and cognitive skills (some of which are actually used as a way to show intelligence quotient, IQ) and the comparison to each of the components characterizing the exceptional performance of the case leaders, highlighted that IE-based skills play an increasingly important role the higher the level of hierarchy is, in contrast to technical skills that are playing a less important role. (Goleman, Boyatzis, McKee, 2008).

Therefore, the higher the hierarchy level of leaders with exceptional performance, the more it is noted that IE was the performance explanatory. When compared to average performance leaders at high hierarchy levels, it is noted that approximately 85% of the difference in their profiles attributes to EI factors rather than cognitive skills such as technical expertise, etc. One of the reasons that can explain this is that individuals have strong selection criteria mainly based on IQ until they reach senior management levels. After meeting all criteria and the required post graduate education levels (MBA, etc.) according to some certain levels of IQ standards, almost all those who reach high levels of hierarchy have an approximate comparable intelligence level with each other. On the other hand, the deficiency of emotional intelligence test draws extensive variations between individuals at this hierarchy level. In this context, when it comes to exceptional performance of high-level executives, superiority goes better than intelligence in simple terms.
The IE report of cognition skills of reality depends on how each of them is measured and the unique requirements of each organization. But Goleman, McKee and Boyatzic believe that EI contributes 80 to 90% (sometimes even more) of the competencies that distinguish an exceptional leader from the common one.

3. METHODOLOGY

3.1 The Cluster Study

Thinking about what skills of leader school principals of pre-university education have, the authors collected preliminary data on the number and structural composition of potential subjects under study. Several persons committed to preschool education leadership were interviewed. This preliminary study figured out that the cluster was very big and unattainable beyond the authors‟ possible capacity. Consequently, the group studied was limited within the territorial boundaries of the authors‟ residency (in Tirana). Due to relevant leading authorities‟ approval there were interviewed 62 public school principals in the municipality of Tirana and 63 public school principals in Tirana district. From a particular cluster of 171 schools (86 in the municipality and 85 in the district), 73 per cent of the interviewees represent a big sample. Practically, there were 72% of pre-university education schools interviewed in Tirana municipality and 74% in Tirana district.

The interview‟s questionnaires were carefully outlined to identify the structuring and consideration skills, and the emotional intelligence features. The paper and pencil interviews were conducted concurrently in one day in each subgroup (in the city and district) under the supervision of the respective author. For the sake of preserving the anonymity there was no other data recorded except the interview‟s questionnaires. Considering the data collection method there is a high probability for outspoken answers.

3.2 The research Instrument

The interview was conducted by carefully structured questionnaires. The instrument "How Good Are Your Leadership Skills?" is a certified questionnaire to identify the supervisor‟s individual leadership skills. The questionnaire contains 18 questions according to Likert scale 1-5 (where 1 defines *never,* and 5 *often).* The questionnaire has been arranged and translated as an attachment below:

1. Questions 2.8 both measure *Self confidence*
2. Questions 10.17 both measure *Positive Attitude*
3. Questions 5.15 both measure *Emotional Intelligence*
4. Questions 6.14 both measure *Creating a challenging vision for the future*
5. Questions 9.12 both measure *People Motivation*
6. Questions 4.11 both measure *Being a good model*
7. Questions 3.13 both measure *Effective Management of Performance*
8. Questions 1, 7, 16, 8 suggest *Providing support and incentives* for subordinates.

The questionnaire was applied to both groups of school principals in the city and district.

3.3 Analysis and Findings

There were several types of analysis conducted on the collected data. Each group data was carried separate and it was evaluated once separately and then all together. In the following there are comments for both groups and relevant graphic data in cases of any differences between these two subdivisions.

The questionnaire contains assertions in English and Albanian in order to minimize the differences in translation perception. The questionnaire was applied to a total of 125 school principals of pre-university education level in Tirana. Following there are some of the findings.

3.4 Regression Analysis

In attempt to notice any polarization of these two-dimension characteristics where normally a structuring and consideration leader operates (or in simple terms, the concern to perform a good job and keep helpful relations of your leadership), two statements were arbitrarily considered as dependent variables by the authors and the other assertions were allocated respectively in the role of independent variables. Specifically, question 4 was considered a dependent variable for the *structuring* dimension (task-oriented) and statement 7 as a dependent variable for the *account* dimension (people -oriented). Statements 1, 3,6,11,13,14,18 were related to structuring, statements 5, 9, 12, 16 were related to consideration. According to the overall group calculation, the regression indicators are:

TASKORINTED=1.363+0.158SUBDIVISION-0.029RESULT-
0.179DIFFERENCE+0.069STRUCTURING+0.136IMPLEMENTATION+O.17PLANNING+0.187SPECIALIZATION

The determination coefficient is ($R^{2)}$ 0.079. This shows that 7.9% is explained by the regression variables that we have taken into consideration, which it also means that the model significance level is low and this regression is inadequate to explain the model.

To better prove the interpretation of regression and variables, it is used Durbin-Watson test with the value of about 2. In this case it has the 2:03 value. This indicates that the variables used in the model are important for determining the *task oriented* and there is no autocorrelation between them.

MAINTENANCE = 3969 - 0.416CONSOLATION + 0.222MORALITY - 0.548 ENCOURAGEMENTS - 0:41 INCREASE.

The determination coefficient is ($R^{2)}$ 0.017. This indicates that 1.7% is explained by the regression variables that we have taken into consideration, which it also means that the model significance level is low and this regression is inadequate to explain the model. To better prove the interpretation of regression and variables, it is used Durbin-Watson test with the value of about 2. In this case it has the 1.905 value. This indicates that the variables used in the model are important for determining the *people oriented-consideration* and there is no autocorrelation between them. According to the questionnaire, the regression analysis indicates that the *consideration* dimension (concerning people) is stronger in this group surveyed. Studies have shown that followers prefer *considerate* leaders, but they are much more efficacious when working with *structuring* leaders (Judge, Piccolo, Ilies, 2004). Seeing that the questionnaire does not correspond to the leader two-dimension-analysis, the author developed a simple percentage processing suggested by the authors of test.

4. ANALYSIS OF QUESTIONNAIRE CONTENT

4.1 Personal Characteristics

1. Self-confidence, Self-confidence is one of the characteristics that determine success in any of the individual's activities. Individuals with high self-confidence are usually inspiring; generally people prefer joining sides of people who believe in themselves and in what they do. If a leader is a positive and optimistic person who tries to do his best in every situation, it will be much easier to motivate people to do their best. According to previous studies, self-confidence is so far considered one of the key positive features of a leader (Stogdill 1948, Mann 1959; Zaccaro, 2007; Sternberg, 2007).

Figure 1: Results for self confidence - Tirana District school principals

From questionnaires completed by school principals of Tirana, it is proved that 51% of respondents" self-confidence has been estimated at maximum levels. So they believe in what they do and what they aim to achieve. However, this feature has not proved homogeneous in both groups under study. If we had analyzed this feature focusing on the differences between the two community groups studied, we will note that (Figure 1 and Figure 2): Self-confidence of school principals in the district of Tirana is only 40% at high levels (5 *), while self-confidence of school principals in the city was 63% at high levels. So there is a high percentage of self-confidence at maximum levels of school principals in the municipality of Tirana, given that the number of the respondents in both groups was almost equal (63 questionnaires in the district of
Tirana and 62 questionnaires in the municipality of Tirana).

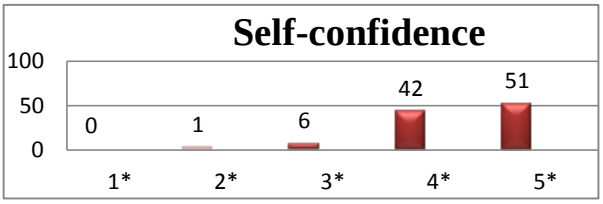

Figure 2: *Results for self confidence - Tirana District and municipality school principals*

2. ***Positive Attitude*** Being positive means much more than wearing a happy face to the world. People with a positive approach can manage a situation realistically and they are prepared to make the necessary changes to overcome any problem. People with a negative approach on the other hand, are often oppressed by stress, the pressure of the situation and the fear of unsolvable situations. This affects on the choice of improper strategies or their improper implementation by engaging in activities that often lead to failure. From the analysis of the questionnaires conducted, we notice that only 9% of the respondents have a low-grade estimation of positive attitude (Chart 3), (or in other words it means that they have no positive attitude at all) and 91% of interviewees have a high or above average estimation. By comparing the two groups (Appendix A) we notice that 13% of school principals in the district of Tirana have a low-grade estimation, whereas only 5% of the respondents in the municipality of Tirana have e low-grade estimation. Generally speaking, district school principals have the highest percentage of low positive estimation.

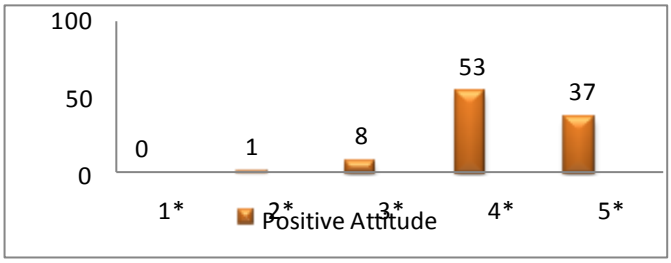

Figure 3: Results for positive attitude for the whole community. Rounded data

4.2 Emotional Intelligence

When someone is upset, I try to understand how this person feels. I feel intimidated when someone criticizes me. According to the authors of the questionnaire, these are two questions that might account for emotional intelligence of those who test. In fact, the authors of this article elaborated the questionnaire considerably by classifying some of the questions under the category of emotional intelligence. A simple percentage processing of answers given to questions 5 and 15 (Figure 4) indicates that 61% of respondents have a maximum self-esteem about the IE feature. Along with the first results between the two groups of respondents, this feature is consistent and there are no significant changes in the results of the two subgroups (city-district).

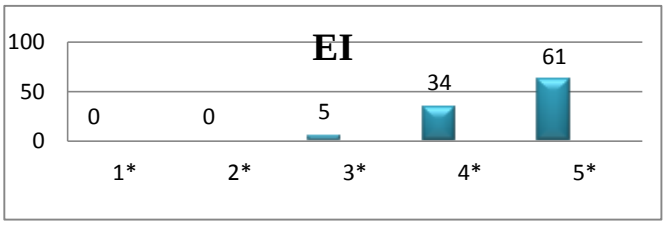

Figure 4: The result of emotional intelligence for the whole community

In regard to the assessment received by school principals in the district of Tirana, it is noted that personal characteristics as confidence, positive attitude and emotional intelligence (according to the authors of the test), are at high estimation levels (according to Likert scale, on level 4 and up), to over 88% of the study sample. These findings on personal features of the study sample are promising and serve as a necessary condition for the school principals to be successful leaders at their schools, despite the limitations public schools confront in meeting their objectives.

4.3 Transformational Leadership

Transformational leadership is that type of leadership which changes goals, values, needs, beliefs and aspirations of followers.

1. Creating a challenging vision for the future. The ability of leaders to create in their mind the image of a desirable future state of their organization and their capacity to convey this image to all the followers is one of the characteristics of a transformational leader.

Referring to the data (Figure 5), we see that 70% of respondents have an average and low-grade assessment of the ability to create a vision for the future.

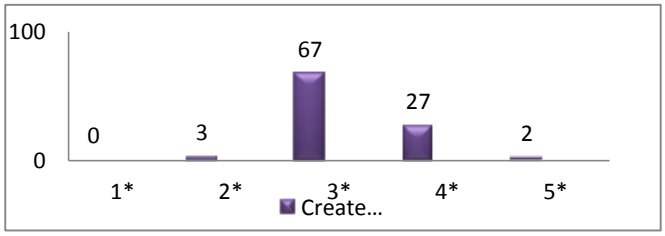

Figure 5: The results for the ability to create a vision for the whole community

The question that naturally arises is: do we want school principals to be transformational leaders? By identifying their role defined within the framework of public service with delineated boundaries and less possible options, the authors" idea was that the school principal should be adapted to the role of a transactional leader. In this context, the above result fits with the logic of the role and can be seen as likeable. Furthermore, other researchers" studies indicate that organizational culture influences the leader"s degree of being transformative (Waldman, Yammarino 1999; Shamir, House, Arthur 1993).

However, school principals are leaders with vision. A vision is a picture of the future of the organization and the results that leaders want to achieve (Grant, 1991). A vision is not a vague desire, dream or hope. Vision comes from the future; it energizes and informs the present.
Vision is important because:

- *The organization inspires action.* A powerful vision attracts on ideas, people and other resources. It creates energy and makes changes happen. It inspires individuals and organizations to continue to give their best.
- *It is a practical guide* for making plans, setting goals and objectives, making decisions, and coordinating and evaluating the work of any project, large or small.
- *And it helps organizations and focused groups stay together*, especially when dealing with complex projects in difficult times.

A director must be a transactional leader, particularly to focus on clarifying roles, the monitoring of progress towards achieving the objectives and giving rewards and penalties as a response to performance (Antonakis, House). Within this framework a leader needs the power that comes from expertise in the relevant field. Using the techniques of strategic analysis for their schools, will help the directors to be not only visionaries, but also realistic about what their schools can achieve. Therefore, the environmental analysis techniques, PESTEL, Porter and SWOT (r Port, M., 1985, Lynch, R. 2006) can help leaders guide their organizations towards the fulfillment of this vision; identify challenges they will have to face and strategic options as well (of course within the framework established by the regional education directors). The authors consider this training course as valid.

2. Motivation of people. A transactional leader must know how to articulate his vision and make the followers want and see the future as described in the vision. Encouraging others to act on achieving the work objectives, motivating followers to achieve individual and institutional performance standards, are areas that define directors leadership capability. The community analysis (Chart 6) indicates that 58% of school principals surveyed consider that they have the maximum ability to motivate followers. As a self-reported indication, (this feature) relies mostly on individual perception and it is more favorable to suggest self-confidence than their leader"s actual behavior.

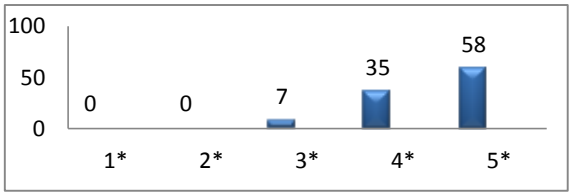

Figure 6: The results of the motivation for the whole community.

3. Setting a good model. Good leaders lead by setting examples. They do what they say and show what they do; they are reliable and highly integrated. They engage in everyday activities if necessary and keep in contact with what happens in the organization. True leaders do not run out of office; they demonstrate actions and values that are expected to be demonstrated by their teams as well. Studies show

that followers expect ever more their leaders to be experts at work and they become willingly subjects of the authority of their expert leaders.

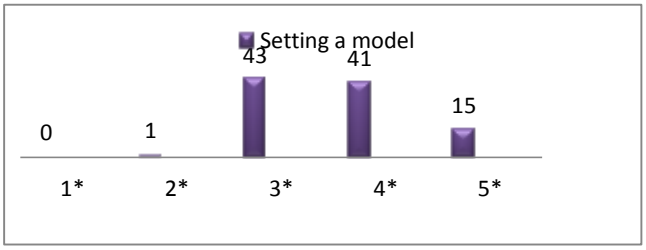

Figure 7: The results on the ability to set a good model for the followers - whole community

In the community research it is noted (chart 7) that only 15% of respondents have a maximum estimation of their ability to set models for their subordinates. On the other hand, this maximum estimation in these two groups relates to respectively 10% of school principals in the district and 20% of school principals in the city. Just as the ability to create inspiring vision and the ability to set a good model for followers, too, indicate that 44% of respondents admit to have an average or below average estimation of their ability. But in contrast to the characteristics of having a vision (not necessarily at high levels) a low-rate perception on personal pattern as a model of behavior is not a good indicator. We can even say that it is an indication that may cancel all the aforesaid values at some perspective.

4. Effective management of performance. Effective leaders tend to define their own role and structure and of their followers", in an effort to achieve the objectives. This includes behavior that attempts to organize work, work relationships and objectives. The leader with high-level-results in this dimension can be described as a person who "assigns specific tasks to group members", "expects employees reach certain standards of behavior and work", "emphasizes the importance of implementing deadlines "," relates performance to rewards ", etc.

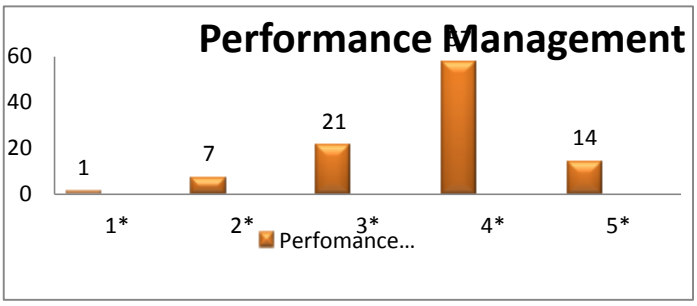

Figure 8: Result s on effective management capability of performance for the whole community

With regard to effective management of performance, 57% of respondents have a satisfactory estimation of this ability, while 14% of the respondents have the highest estimation (Chart 8). Nearly 30% have an average or below average estimation level of this capability.
These results were predictable by the authors of the study. In general, the feeling of being an insignificant factor in the performance management of subordinates, mainly due to not possessing sufficient instruments for material rewards or promotion regarding performance is a phenomenon that occurs frequently in the mindset of public institution directors. Public school principals cannot discount for this stereotype. We believe that directors" training plays an important role in changing the meaning and enhancing their understanding of the different elements of reward and non-material value on their subordinates in the Albanian context (Koli, Dumani, 2000; Kasimati, 2011).

5. Support and promotion of subordinates. To be motivated, men need more than a list of tasks to be performed every day. They need interesting, non monotonous and challenging jobs to develop their skills, have tangible results and deserve gratitude for what they do (Herzberg 1959). Fortunately, teachers" job is one of the most motivating in this context for as much as it has all these features. Teachers „leaders have no obligation of motivation rather than harmonize all factors in order that work motivation comes along with performance satisfaction.

Unfortunately, the analysis of the results observed (Chart 9) indicates that 23% of respondents have a satisfactory estimation of the ability to provide support and encouragement to subordinates, and only 2%

have a maximum estimation level of this ability. Meanwhile, all the rest (75%) of the respondents have an estimation level of their ability to develop average and below average support.

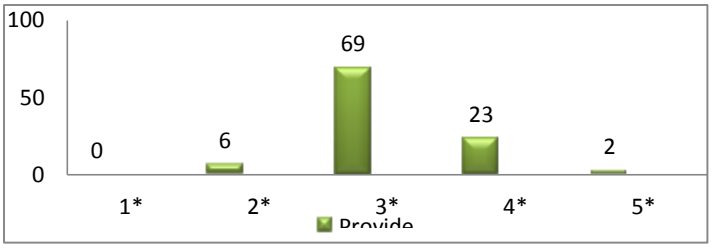

Figure 9: Results on the ability to provide support – whole community

The authors of this study think that low skilled perception in this feature is explained within the context of leaders‟ perceived role in public organizations already interpreted.

5. CONCLUSIONS AND RECOMMENDATIONS

Based on personal perceived and self-reported characteristics, this article aims simply to identify some features of pre-university school principals in Tirana district for the position of potential leaders. The study does not account on personal effectiveness or institution indicators under school principals‟ administration. Neither is described the way their followers (subordinates) perceive their leaders. The concentration of the community surveyed in only one region (the capital) does not necessarily generalize the outcome of data processing.

According to House (1996) effective leaders possess and make use of more than one administration method. Regardless any test results (commented furthermore in the article), school principals are encouraged to adapt to different behavioral categories of the leader and also try to exercise new practices when necessary, in accordance with the characteristics of their followers and institutional objectives. Education directorates can implement on their part developing programs to enhance leadership features of school principals.

PRACTICAL LEARING OUTCOMES OF ADULT EDUCATION INNOVATION IN U3A

Růžena Dvořáčková[1]
[1]Business School Ostrava plc., ruzena.dvorackova@vsp.cz

Abstract: *The paper is based on one decade experience in the management of adult education and training, in particular offered by the university of the third age The paper is an attempt to highlight changing and growing education needs of adults learners and their corresponding changes and trends in education provision. Implementation of the research results of adult learners´ needs and competition analysis is fundamental for the efficiency of the educational process. The most relevant features of the innovated adult learning/teaching methodology incorporating blended learning and exploiting the elements of coaching to achieve expected learning outcomes, are characterized. The desired learning outcomes are the change in individuals, learners and teachers, and the acquisition of practical skills and competences. The author tries to underline the positives and negatives of a new approach to adult education both for the teachers and learners. The Czech population is still getting older and education provided by Universities of the Third Age (U3A) makes their lives active and helps combat ageism.*

Keywords*: Lifelong learning; adult education; motivation; coaching, blended learning, practical outcomes,*

1. INTRODUCTION

Lifelong learning, lifelong teaching, adult education are terms widely used for the education aimed at adults within the European Union education framework, The Czech Republic included. This variety of terms designates the activities leading to widening or deepening the learning process during the life span of a human being. These are carried out in various forms of formal, non formal and in formal education, academic courses, commercial courses, academies, training, preparatory courses, and universities of the third age included. According to Rubenson, European Union, the OECD and the UNESCO proclaimed three fundamental attributes in 1976 that lifelong learning is based on (Rubenson, 2011):

- It is lifelong and therefore concerns everything from cradle to grave
- It is wide-life recognizing that learning occurs in many different settings
- It focuses on learning rather than limit itself to education.

Lifelong learning provided as courses of Universities of the Third Age is an important part of the holistic education, functioning as a corrective to the regular educational system and an innovative mechanism of the educational system.

The objective of this paper is to present ten years experience within the lifelong learning with the provision of the adult education in the University of the Third Age and the application of a new approach to its provision by Business School Ostrava plc. In the first part of the paper the approaches of both the learners and teachers to adult education will be described. In the second part of the paper the results of the research will be presented. The questioning and interviews of 300 respondents took place in 2012 – 2013. The same number of respondents was questioned in Spain and Turkey within the international project of the Grundtvig programme. Though the results show almost identical data in the participating countries, the paper describes findings, and their implications in adult education for the Czech Republic.

The Courses of the University of the Third Age are developed and designed for adult learners, aged 55 and more, which means for experienced mature individuals. Learners of this age had rather limited opportunities for university studies in their young age due to limited access to high education strictly controlled by the government. Minority of adult learners is graduates, but most of the adult learners were quite successful in their careers. Universities of the third age are quite popular within the European Union, and are attractive for and enjoyed by adult learners in the Czech Republic as well. A variety of courses are offered both by public and private high education institutions, while the courses of public high education institution are financially supported by the Ministry of Education, Youth and Sports, the private ones are not eligible for the state subsidy according The Higher Education Act (Ministry of Education, Youth and Sport, 2010). Apart from the educational outcomes the social impact of the education courses is widely promoted and frequently financially supported by municipalities. It is assumed that the person, who is trained, educated on a

permanent long term basis and who maintains active lifestyle has a better chance to live longer, healthier and independent life.
The population of the developed countries within the Europe, the Czech Republic included, is growing older, which is the most charactistic feature of the demographic development. According the Czech statistic institution the inhabitants aged 65 and more will be represented by 22.8 % of the total population in 2030, populace, and by 31.3 % in 2050, which stands for approximately 3 million persons. In 2007 persons aged 65 represented 14.6% of the Czech population. The demographic prognosis expects approximately half a million inhabitants aged 85 and more in 2050 (124.937 in 2007). The National Action Plan for supporting the positive getting older process for 2013 – 2017 was accepted by the Ministry of Labour and Social Affairs., which is in compliance with national priorities and Regional implementation strategy of Madrid international action plan pro the getting older issues (Organisation of United Nations, 2002). Among seven priorities the lifelong learning is included.

The Czech population is getting older. The approximate number of new pensioners is 150 000 each year. These are offered a variety of services: counselling, leisure time activities, palliative care, help lines, health care, special services provided by non-profit organization, in particular. Universities are also very active in this field, offering individual courses, universities of the third age, academies. Though the adult learners may be enrolled in regular studies, they prefer taking the courses without the ambition to be awarded the degree The course content, the affordable price, and the professional, pedagogical and human qualities of teachers are the key criteria for the decision making process of the applicants for the adult learning. High education institutions are appreciated by adult students as the top quality education guaranty.

Generally the contents (curricula), teaching methodology (pedagogy), and the learning outputs of various types of adult education differ. In some learners are guaranteed eligibility for further studies, in others they gain "only" the knowledge and social ties. The knowledge, social networking and especially improvement of the quality of life are considered the crucial issues highly esteemed by adult learners. The courses for adult learners aged 55 and more are typically called the courses for seniors, the courses for the retired, or the University of the Third Age, which is perceived by adult learners and graduates as a very pejorative or even discriminatory labelling and the evidence of ageism.

2. METHODOLOGY

The Courses of the University of the Third Age are particularly developed and designed for adult learners aged 55 and more. Universities of the third age became very popular, they are attractive for and enjoyed by adult learners within the Czech Republic. Restricted opportunities to enter university studies before the Velvet revolution may be one of the significant causes of the unceasing interest in courses offered by universities. The adult education is frequently promoted and financially supported by municipalities within their educational and social initiatives.

Study groups may be organised of large scale, but those of 20 persons at maximum help avoid anonymity and develop positive, warm climate and relaxed atmosphere. All learners are charged fees. Almost 30 per cent of them are graduates, but majority of adult learners gained the experience in managerial positions. Many are still economically active, with full time and part time jobs, most are active in their hobbies, family activities. Although the female learners prevail, the numbers of male learners tend to increase in past two years. The teachers face an extremely highly and permanently motivated group of learners, with fairly high expectations and high demands on the teacher´s expertise and pedagogical skills. The length of studies of adult learners of the University of the Third Age may differ, but four semesters, which means two academic years are customary. Students who complete obligatory courses, usually four core subjects, are invited for the final ceremony similar to graduation ceremony.

This paper presents the results of research that was focused on the approach to adult education aimed at required innovation and development of adult education courses. The paper is based on data gained by the method of questioning, and data collected in interviews. The questionnaire survey was carried out to find out the learners needs and expectations and to gain the feedback by learners for the teachers. The aim was to gather information about learning/teaching process. Questioning was conducted after completing four subjects.

300 respondents, learners of the University of the Third Age executed in different towns took place in questioning; the same numbers participated in the same research done in Spain and Turkey. The research methodology was agreed on by Grundtvig project partners. The core questions, both open and closed, aimed at getting the response to the assumptions that 1. So called traditional approach to education, it means giving the lectures by frontal teaching, is still appropriate for adult learners aged 55 and more, 2. The

adult learners aged 55 and more avoid using new technologies and 3. The adult learners aged 55 and more are neither willing nor are they able to change their approach to learning.

3. ADULT LEARNERS 55+

When designing the courses for adult learners aged 55 and more we strongly believed that so called traditional way of teaching, ex cathedra method, when the focus is on the activity of teachers not on the activity of learners, it means delivering lectures to listeners, would perfectly suit the learners. These could enjoy traditional ex cathedra teaching while listening to the speaker and taking the notes simultaneously. We were convinced that especially graduates appreciated coming back to the environment they were familiar with in their youth. Secondly we assumed that using modern technologies would be not so much popular with adult learners and finally we guessed that adult learners would be not willing to change the attitude towards learning which they got used to.

Surprisingly for us the learners got involved in their studies quite spontaneously and became eager for new and different ways of delivering education they had not experienced during their previous studies. Since the adult learners strongly desired to be actively engaged we understood the must for a dramatic change of our attitude and mindset to adult education.

Three figures are presented.

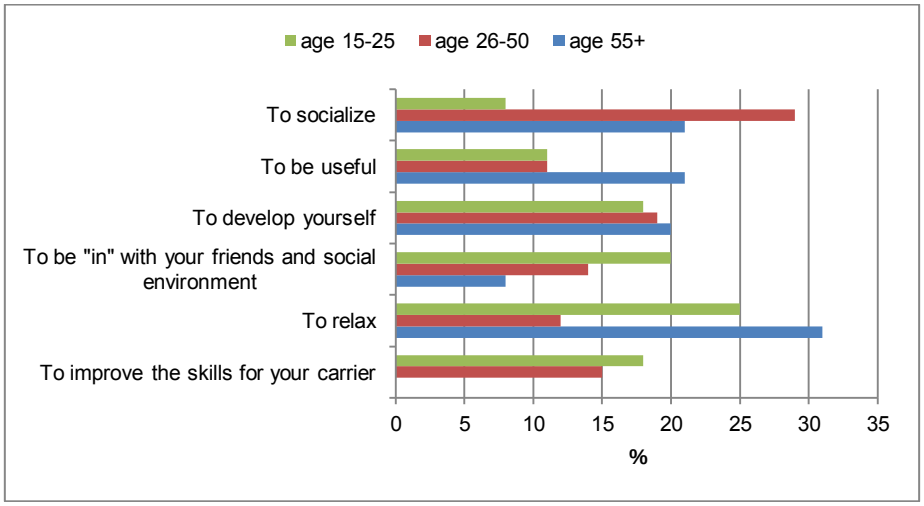

Figure1: The expectations: Why do I attend the courses, 2013, Grundtvig-3G

In Figure 1 the expectations, reasons for attending courses are described. Three age categories were questioned so that expectations, needs could be compared. To relax, socialize, be useful, and develop yourself were the most frequent replies. To develop yourself especially in the field of modern technology was among the priorities. The same questioning took place in Spain and Turkey, with the same number of respondents and almost same results.

Figure 2 describes the experience with previous education university studies or secondary school education. Although theoretical courses were appreciated respondents mentioned that these were so much not enjoyed. The same questioning took place in Spain and Turkey, with the same number of respondents and almost same results.

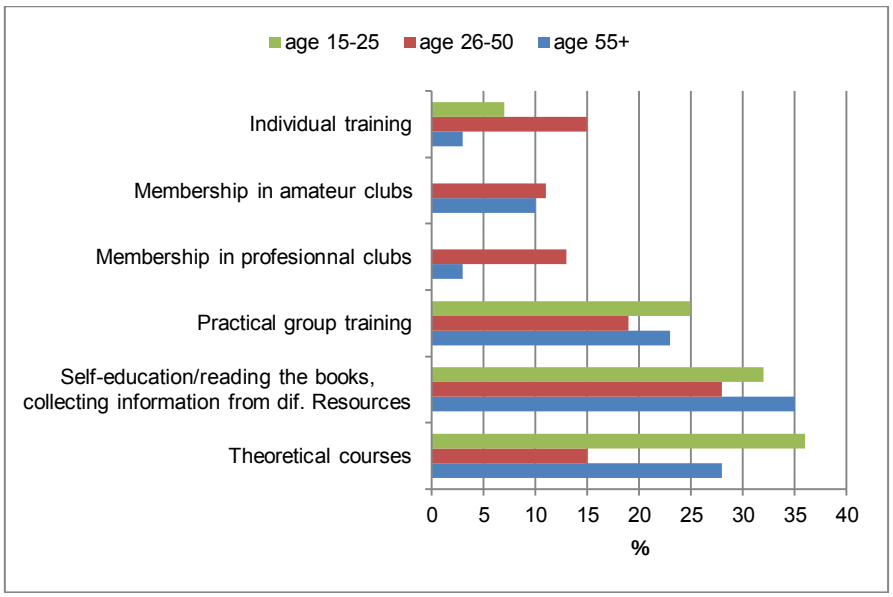

Figure 2: Which type of education I have the experience with, 2013, Grundtvig-3G

Figure 3 expresses the needs and wishes of adult learners. While the theoretical courses took the bottom place, practical group training, self studies, and individual training were preferred by almost the same percentage of replies. The same questioning took place in Spain and Turkey, with the same number of respondents and almost same results.

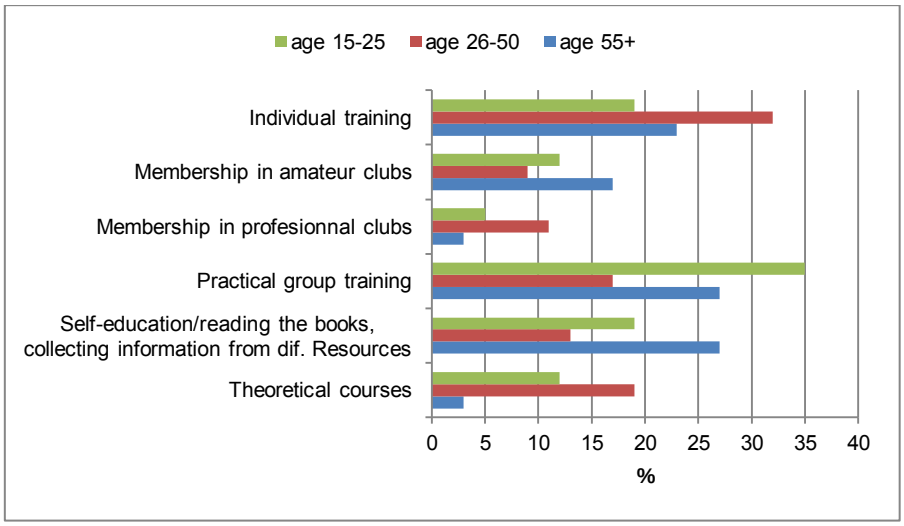

Figure 2: Which type of education do I prefer now, 2013, Grundtvig-3G

Teaching methods

The questionnaire results revealed the following findings: adult students prefer individual form of training in order to deepen and broaden the knowledge in a field that interests them, they prefer individual pace, and although they do appreciate the theoretical courses, their first choice courses are the learning by doing courses, practical group training, the courses with the practical outcomes. Learners do not want to be passive listeners only; being passive consumers of information is not satisfactory for them anymore. They expect being given assignments, being evaluated by the teacher and other learners, being given the feedback. Sharing of ideas and discussions on agreed topics are considered a valuable part of education. Debates, organized discussions were supposed to be strictly controlled by the teacher. Teamwork was described as a new and positive experience, individual projects processed as power point presentations were found enriching challenges.

Meeting on a regular weekly basis brings the adult learners a new quality of life and new challenges. Assignments and project work help connecting generations. Development of verbal skills was considered another benefit.

Subjects
Within the University of the Third Age four compulsory subjects are included. These are aimed at learning and developing computer skills, foreign language skills, and learning the law and legal system issues and fine arts. The subject focused on developing PC skills was appreciated most of all the subjects, especially due to its practical outcomes, while the subject about fine arts was appreciated more than the subjects about a foreign language and law and legal system. Subjects which were offered as voluntary, usually after completing two year course, were appreciated high, because being attended only by those who made the choice (psychology, philosophy, music).

Based on the research results we can say that the offer of the subjects was not the issue to be changed and dealt with dramatically. Three areas to be addressed for the prospective innovation of the course correspond with the assumptions we made at the beginning of developing the adult education courses for the University of the third age and which proved to be our prejudice: traditional ex cathedra teaching complies with the adult learner, adult learners are not excited about using modern technologies, and adult learners are not willing or are not able to change the attitude towards learning which they got used to.

3. NEW MINDSETS

In order to integrate the research results on the demands and wishes by adult learners into innovation of current courses their knowledge and skills, the courses curricula were innovated and new pedagogical approach accepted. Motivation of the learners, their life experience and time at disposal were the positives, while the need to make a change in the attitude to education both by learners and teachers was the only negative. The change of the approach to education, pedagogy, and understanding the need for this change was a little slow and difficult process (but directly associated with the participants´ age). This change occurred during the first course, and was easily adopted in follow up courses. Once understood and accepted, it was appreciated both by the learners and teachers.

New philosophy, new mindset
The initiatives were taken in two areas: the first being to change the attitude, mindset, and the second to change teaching methods. Changes made in one area were immediately reflected in the other.

We did not have to deal with the offered subjects. All the subjects are considered to be needful and attractive.

To improve our teaching methods and the efficiency of education process we decided for a new philosophy of education, which involves changing the focus of education from the process of lecturing to the learning process (Jovanovič et al., 2012). Before implementing different teaching methods the change of the attitude and mindset is necessary. The change in the attitude and mindset is a demanding process. The existing attitudes and mindsets are being developed over a long period of time, and in a way are getting isolated from the society, (Jovanovič et al., 2012). The change of our concept of adult pedagogy was based on incorporating the elements of coaching, a combination of specific attitudes and tools. We looked for a successful model management education in the sense of leadership. We have experienced that success could not be achieved by still increasing effort, more intensive work. I believe that many aspects of coaching were applied intuitively. Initially some approaches seemed to be completely unacceptable, provoking both learners and lecturers. And they do repeatedly provoke new learners every academic year. Our goal was to make a change of thinking, develop action, encourage initiatives and trigger creativity.

The change of the mindset and the attitude towards adult education means the dramatic change of a student's and teacher's roles. The teacher is becoming an advisor, mentor, encouraging learners, but withdrawing from ex cathedra, frontal, teaching. Teachers take much more active role in developing learners speaking skills. Developing reading, writing and listening skills is sufficiently supported by the study material, frequently online resources.

The goal to strengthen student's skills to organize and monitor their performance, control their studies and take responsibility for own learning results was not easily accepted neither by learners nor teachers.

To stimulate the change of traditional roles of learners and teachers our efforts were be directed into five areas:

1. Restriction of the autocratic style of leadership; there is no need for the lecturer to know absolutely everything, to have a solution ready, and to be the first always.
2. Listening. The lecturer learns to listen with no need to make comments; he listens to the opinions and attitudes.
3. To be open, warm: letting the others take the initiative.
4. To help people think more deeply; providing them feeling that the learners are the subjects of the action, developing them in the professional and humanistic ways.
5. To ensure self-reflection, free from stereotypes.

A newly developed and properly accepted attitude to adult learning/teaching process had a very positive impact on the relationship between the learners and teachers. If students perceive the empathy, acceptance and congruence in the teacher´s behaviour, they do not feel threatened, and start be more open to new experiences, which in turn will enhance their confidence and encourage acceptance of responsibility. New and creative solution can be found more easily. (Whitmore,1994)

The teachers training for the adult education included learning the following attitudes and tools:

- Empathy
  The teacher tries to feel the learner´s feelings. He makes no comments. The learner gets the impression: He wants to understand me. This is not: He understood me.
- Acceptance
  Respect is in no relation with the warmth, quality of previous and current experience, feelings, successes, failures. It is the respect with current possibilities, capability and borders of the learner.
- Congruence
  Comprises of sincerity, consistency, authenticity
- Trust
  The teacher brings the learner the confidence, the trust that he is able to develop independently of the starting position and at the individual pace. Each person is fundamentally perfect and has the potential not used previously but being ready to develop. The assumption is that people tend to behave according to the expectations of others.
- Sincere interest
  Interest in the learner´s world, what is his world like, how he perceives it, how he enjoys it.

Our starting point is based on the adult learner's dissatisfaction with the results alongside with his willingness to develop his potential. The tools we used can only support what we had prepared and built by our attitude. The tools not being fully implemented in the pedagogy do not guarantee the success. (Stacke, 2005)

- Creating a relationship
  requires the time investment, ideally in sharing a common experience, as well as the mastery of voice and body language control.
- Asking questions
  asking questions by the teacher is not a sign of uncertainty; questions can stimulate creativity, development of knowledge, skills. Questions generally indicate the respect and interest, primarily because the interviewee is by being asked perceived positively. You can apply a wide range of questions.
- Active listening
  Is related to keeping the eye contact, elimination of disturbing moments, maintaining the interview communication share 50% to 50%, providing sufficient time or the giving the answer, the mastery of keeping and managing the silence.
- Language metamodel
  During our communication, in the dialog, we voice only a part of what we experienced. There are issues of the missing information, reasons why they miss, reasons for applying non-specific verbs, words.
- Expressing and communicating mutual expectations
  Learning to formulate expectations, desires, direction, learning how to define specific goals in individual plans. The conscious and unconscious expectations help develop the educational framework. Communication of mutual expectations is a turning point for learners and teachers. For many participants it is a completely new experience, after which their further development, feelings of satisfaction gradually start evolving.
- Giving and receiving feedback
  Recognition of constructive criticism.
- Reframing
  Finding what is good in a particular situation.

- Dealing with errors and suggested solutions
  Not to avoid mistakes, get rid of perfectionism.
- Using mental techniques
  Applying visualization, relaxation indicates the quality of the relationship between the learner and teacher. Visualization requires to get rid of stereotypes, prejudices, routine. It helps clarify the relationship, develops imagination concerning the future, and removes barriers. (Whitmore, 2007)
-

Mental activities must be maintained, enriched and strengthened though self motivated learning and self education. People can learn about the world by using their common sense and their common sense motivates people to reach the treasuries of knowledge that will enrich their personalities and minds by correcting their own minds and education. (Karavidic et al., 2012)

Teaching methods
Discussions, teamwork, project work, debates accelerate developing verbal skills and help learn the world and its inhabitants and correct the minds and education. High verbal skills are correlated with the decrease in physical aggression by Boone and Montane (Bellon, 2000). Once someone feels capable of responding verbally they fell less inclined to resort to physical force. The learners learn to respect the opposite side. Discussion, debates increase argumentativeness without increasing verbal aggression (Colbert, 1994).

Strengthening the individualization of education and the consequent individualization of learning pace, enhancing practical aspects, practical outcomes, enhancing interaction by involving students in their own learning, based on their learning style, and particularly the sharing of tasks and follow up discussions was partially supported by introducing E- learning.

In the academic circles there is no doubt that E-learning is a significant method of education in the modern world, which backs the modernization and optimization of the educational process in all spheres of modern society. Blended learning, the issue of IT has to be integrated in a very efficient way. Mother tongue, foreign languages and computer languages are ways of communicating and their command creates prerequisites for active participation in a human life, while expertise in the field enriched with the active command of these prerequisites is becoming a must in one´s, not only professional, life nowadays. We strongly believe that e-learning courses will be more theory-led than technology-led in the future; as it is supported by Horton's opinion who claims "E-learning does not change anything about how human beings learn"[1].

The online study material, its structure and learning instructions for use were user friendly. When developing study material close cooperation with IT experts cannot be underestimated at any stage, especially when defining specific needs for the study material, online course structure and the target group of learners.

Learning is a demanding process of acquiring knowledge, abilities and skills. It is the teacher´s approach to learners, which can influence the quality of the educational process, and deal with constrains of online learning process, so the teacher´s role can in no case be neglected. When introducing E-learning the idea was to exploit the online learning as much as possible. Learners were expected to study individually, not only during the lessons in a classroom. The goal was to strengthen student's skills to organize and monitor their performance, control their studies and take responsibility for the results. The opportunity to work at individual pace, and mostly online was considered the benefit by majority of learners while others appreciated more the opportunity to study during the contact lessons. During the lessons in a classroom the learners present their study results, share the experience and discuss.

3. TEACHER´S CONSTRAINS

Even small changes can have a big impact; each activity influences the whole system. If you live in a rather authoritarian environment, both parties are accustomed to issuing and receiving orders. In such an environment, we cannot expect independent personality. For the personal development building a relationship between the learner and teacher and among learners themselves, patience, communicating expectations, consistency, creating a common vision, seeking allies in community, in a family, and friends, networking are needed. When creating the fragile relationship the statements supporting non supportive approach must be excluded from the education process, those of the adult learners exclusively. Statements like I am too busy, Talking is better than asking, They are all the same, I have being doing that for ages have proved to be very contra productive.

[1] Islam, K. (2002) *Is e-learning floundering? Elearning Magazine, 3(5), 22-26*

The need for the change of the attitude towards adult education by teachers was in some cases, dare I say, accepted with more difficulties than by learners. Particularly the teachers with no previous experience with adult education learned a new role more or less that of a tutor, counsellor, or leader with some constrains. If they succeeded they got far beyond their former professional activities and started enjoy new ways of teaching. The emphasis put not only on the education in individual subjects, but also on the personal development of the participants was appreciated by teachers as well. Due to implemented changes, getting the inspiration, motivation, deep insight, taking the corrective measures during the educational process of adult learners became continuous and valuable part of the learning process both for learners and teachers.

The change of a student's and teacher's roles proved to be difficult. The teachers acting as an advisor, mentor motivates and encourages learners. If ex cathedra teaching s abandoned by the teacher takes much more active role in developing learner´s skills. With the aim to strengthen student's skills to organise and monitor their performance, control their studies and take responsibility for learning results the teachers have to adhere to the new role, which cost them a lot of efforts, as they confess. They admit that the need for the change of teaching methods should be brought to the fore with more emphasis.

After the new teaching methods were accepted the teachers noticed a better quality of the relationship between adult learners and teachers, tendencies towards better intergeneration understanding and especially improvement of verbal skills. Though the teachers admit inconvenience, in some cases lower self confidence if letting the more active role to adult learners they notice the increasing level of adult learner motivation and increased level of the assignments quality. The constrains and inconvenience perceived by the teachers during building a different kind of relationship between learners and teacher slowly faded away. The different quality of relationship merged into a more efficient way of education even though the teachers confess that controlling, managing, and leading the teaching process towards changes in individuals based on the new mindset was considered as a very demanding task.

Practical outcomes
Due to the change of the mindset and new philosophy of the adult education the practical outcomes, so needed and expected by the adult learners and expressed in the questionnaires and interviews were achieved. All are considered to be triggered by attending the lifelong courses for adults, the University of the Third Age, by the adult learners. A variety of activities either on a regular basis or unique basis can be regarded the practical, valuable learning outcomes increasing one´s professional or private life. Below you find the listed ones: setting up a nonprofits organization, membership in the international pet club, working with PC: designing web pages for personal use and for business purposes, solving difficult family situation (divorce, marriage), introduction of new family traditions, starting a business (business license), organizing leisure time activities on a regular basis for community members, further studies, solving a difficult situation (illness, finance), charity activities, giving lectures, offering practical training, developing teaching materials, participating in international project, travelling abroad for specific kind of sightseeing, organizing exhibitions.

These effects manifested in the listed areas, include creativity, family planning, care about children, quality of learning, appreciation for arts, culture and learning, health care services, political participation, understanding of social issues, acceptance of social changes, the sense of shared culture and social solidarity. (Karavidic et al., 2012)

5. CONCLUSION

Undoubtedly the primary objective of adult education, the University of the Third Age included, remains the provision of education and increasing knowledge, skills and abilities. Lifelong learning proved to be an integral part of holistic education: a corrective of the regular educational system and an innovative mechanism of the educational system. (Karavidic et al., 2012)
Due to changes in the attitude towards adult education provided for learners over 55 and more, the practical outcomes were reached as being illustrated by a wide variety of activities and events. I do believe the results came into existence due to the efficient interaction of learners and teachers, interconnection of theory and practice. These are the evidence, that education provided to adult learners significantly improves the knowledge levels, intellectual tendencies, influences their self esteem, helps people in finding their own identities and in their individual choice of lifestyles, and to a significant extent increases practical competencies, flexibility and tolerance in their capacities of citizens, workers, family members and consumers, and influences the choice of leisure time activities, their health and their general abilities for coping with problems in life. (Karavidic et al., 2012) Beside the intellectual gains particularly the direction for one´s life are appreciated.

Abstract: This paper introduces software-defined network infrastructure model for e-learning. The goal of this paper is to analyze the potential of software-defined networks in cloud environment of educational institution. This paper provides an overview of current relevant concepts related to software-defined networks. The second part of the paper gives the proposal of a software-defined networks implementation model within the cloud infrastructure for Laboratory for E-business at the Faculty of Organizational Sciences in Belgrade.

Keywords*: software-defined networks, OpenFlow, cloud computing, network infrastructure, e-learning*

1. INTRODUCTION

Educational institutions have high standards that their IT systems must fulfill. Beside high scalability, availability and security, there are specific requests for implementation of various e-learning services. Development and implementation of new e-learning applications and services demand dynamic environment and new network technologies.

With increasing amounts of data in modern computer networks there is a need for a simple and scalable network architecture, which enables efficient use of different e-learning applications. Traditional computer network, based on a hierarchical model, can respond to the requirements regarding the standard client-server communication. However, modern information systems of educational institutions require dynamic architecture, so it is necessary to make some changes when it comes to network infrastructure. Another important requirement is simple network management. In traditional networks there is a need to know a large number of network technologies and to configure large number of devices in order to implement a service. Another issue is the problem of interoperability since today's network environments are mainly multi-vendor.

Cloud computing is the most common solution for educational network infrastructure (Sultan, 2010) (Radhakrishnan, Chelvan, & Ramkumar, 2012). This concept brings many advantages since it provides high degree of network virtualization and scalability. But, there is still a request for very simple network management and possibility to develop different applications and realize various research projects without knowledge of complex underlying network infrastructure.

The above problems can be successfully solved by introducing the concept of programmability of computer networks, which involves the separation of the process of control and forwarding data. Software-defined networks (SDN) operate on this principle, and provide additional functionalities, so they can respond to requirements and challenges simplifying the process of network infrastructure implementation.

This paper is focused on cloud network infrastructure for educational institutions in IT domain and possibility to implement SDN networks in that environment. Conceptual SDN network model is presented for cloud infrastructure for E-business Laboratory at the Faculty of Organizational Sciences in Belgrade.

2. SDN CONCEPTS

Although the concept of programmability in computer networks is present for more than 20 years (Feamster, Rexford, & Zegura, 2013), many believe that the development of a software-defined networks started with Ethan project (Casado, et al., 2007) which defines a new network architecture where a centralized controller manages the process of traffic forwarding. An important factor in the development of the SDN concept is certainly OpenFlow protocol as the first interface for communication between control and traffic forwarding layers (McKeown, et al., 2008).

Centralization of the control process and complete separation from network elements, using open standard interfaces for communication, are the main characteristics of the SDN networks. These features allow simple implementation of new protocols and applications, simplifying the process of virtualization and network management. This is especially important for educational institutions and their research projects. Another request in educational environment is multi-tenancy. This means that many tenants (teachers, students, administrators etc.) can use the same network infrastructure for their applications but with full isolation of their data and resources. Network-as-a-Service (NaaS) (Wolf, Matteo, Peter, & Pietzuch) is a cloud model that supports multi-tenancy and it is implemented using SDN concepts.

Security, scalability and interoperability are the requests that each educational network infrastructure must fulfill, and that is the case with SDN networks, too. The primary requirement is to ensure secure transmission of information in the network, and therefore the issue of security is given a special attention in the process of development and implementation of SDN network. On the one hand, the centralization of the control process brings a number of advantages, such as simple network management and less complex hardware implementation of network devices, but on the other hand leads to the fact that the controller is a single-point-of-failure in network (Kreutz, Ramos, & Verissimo, 2013). In most network environments controller scalability may became an issue, which is why the latest researches are focused on examining possibilities of distributed controller implementation (Dixit, Hao, Mukherjee, Lakshman, & Kompella, 2013). In many network environments, in order to reduce operating costs, SDN network implementation process involves the use of a hybrid approach. The existence of traditional and SDN network infrastructure, raises the question of interoperability and therefore many organizations (IETF, ETSI and ONF) are focused at developing standards for SDN.

2.1. SDN definition and architecture

Software-defined networking is a new concept in computer networks, which allows network and service management abstracting the lower layers of the network infrastructure. There are several definitions of SDN network, the most important are:

- SDN architecture allows direct control and programmability of computer networks by separating the functions of management (control plane) and data forwarding (forwarding plane) (Open Network Foundation).
- SDN is an approach that enables applications to manage networks by interacting and manipulating the control software of network devices and software resources (Nadeau & Pan, 2011).

Figure 1 presents SDN architecture, which defines three layers: infrastructure, management and application (Software-Defined Networking: The New Norm for Networks, ONF White Paper, 2013). Application layer consists of user applications that use SDN communication services. Communication between this layer and the control layer is made via the northbound interface API. The control layer is responsible for the control and monitoring of traffic forwarding in the network. The communication between this layer and the infrastructure layer is realized over the southbound API interface. The infrastructure layer consists of network elements and devices that perform traffic forwarding.

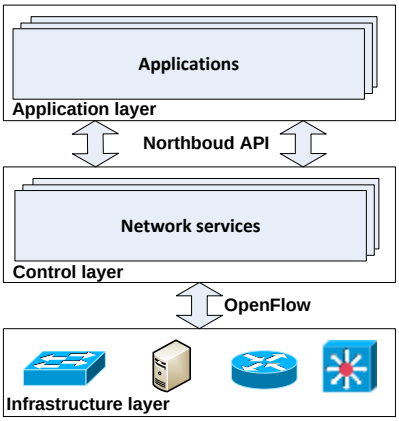

Figure 1: SDN architecture

Basic characteristics of SDN architectures are (SDN in the Campus Environment, ONF Solution Brief, 2013):

- Logical centralization of intelligence - Network management is separated from forwarding traffic, thus the decision making process is simplified and based on the entire network, not just the individual elements, as is the case in traditional computer networks.
- Programmability - Management function in the SDN network is realized by dynamic software programs. The use of open standard API interface allows simple communication between applications and networks.
- Abstraction - In SDN networks are user applications separated from other network elements, and network devices themselves are abstracted from SDN control layer.

In addition to the abstraction of network devices, SDN architecture provides support for different APIs and thus enables the implementation of various network services such as routing, multicast, traffic engineering, QoS and many others.

2.2. OpenFlow protocol

OpenFlow is the first standardized interface between the management and forwarding traffic layers of SDN architecture (McKeown, et al., 2008). This protocol uses the concept of data flow to identify traffic based on predefined rules, which are statically or dynamically defined in the SDN controller software. When it comes to network management, this concept is characterized by high granularity at application, user and session level, which is not feature of the traditional IP networks, in which each data stream must use the same path through the network. OpenFlow can be regarded as a key element of SDN network as it is the only standardized protocol that allows the manipulation of data forwarding plane in network devices. It can be applied to existing physical and virtual networks and due to its flexibility in multi-vendor networks.

OpenFlow logical switch consists of one or more flow table, group table, which performs packet forwarding, and one or more channels to an external OpenFlow controller (Figure 2). Using OpenFlow protocol controller modifies flow entries in flow tables. Packet forwarding is based on set of instructions which are stored in flow entries beside match parameters (OpenFlow Switch Specification, 2013).

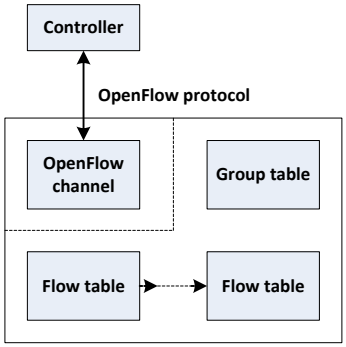

Figure 2: OpenFlow switch

OpenFlow protocol has specific application in scientific research institutions since the possibility of separation of the production and experimental data flows. By defining the route and packet processing rules researchers can control the experimental data flows and thus enable the coexistence of experimental and production data flows in the same network, where production flows are processed in the traditional way. This is particularly important in the case of defining and testing the characteristics of the new routing protocols, address schemes, network models, etc. (McKeown, et al., 2008).

2.3. Application of software defined networking

Thanks to the principles of centralization, abstraction and programmability, SDN architecture can be applied in different network environments, data centers, campuses, and cloud environments, but also in service provider networks.

When it comes to the enterprise environment, the SDN concept can greatly contribute to the businesses since the implementation process of new services is much faster and simplified due to virtualization and configuration automation throughout the network (SDN in the Campus Environment, ONF Solution Brief, 2013). In this way operational costs are reduced too. In addition to the implementation of OpenFlow protocol

this goal can be achieved by a combination of SDN architecture and standard technologies such as VLANs and MPLS protocol (Use Cases and Migration Methods, Open Networking Foundation, 2013).

In data centers SDN concept facilitates the process of virtualization with a high degree of scalability. Migration of virtual machines is implemented automatically, which contributes to better use of server resources and optimum utilization of the available bandwidth in the network (Al-Fares, Loukissas, & Vahdat, 2008).
The complexity of new services, but also complicated process of implementing them, as well as high maintenance costs, impact on service providers to consider the possibility of applying the SDN concept in their networks. Service provider network infrastructure is designed to meet the requirements in terms of scalability, reliability, service quality, and service management (Sezer, et al., 2013).

The traditional approach involves the integration of control and data plane, so the biggest challenge in service provider environments is the separating of these two functions. An important parameter in these environments is also a failure recovery, but without affecting the end-user services. One method is the existence of an additional predefined path in order to protect the data plane. Another way is to incorporate into the OpenFlow support for protocol that already has a mechanism for the failure recovery such as MPLS-TE (Traffic Engineering Multi Protocol) (Das, Sharafat, Parulkar, & McKeown, 2011).

The challenges that face today's networks, such as the efficient management of resources, scalability, flexibility, rapid implementation, and cost reduction can be successfully overcomed by combining cloud computing technology and SDN architecture (Dürr, 2012). SDN concept simplifies the delegation of management functions and makes abstraction of the network, so users beside logical network view, have the ability to configure a small part of the network, which of course raises the question of the safety (Azodolmolky, Wieder, & Yahyapour, 2013).

3. SDN IN OPENSTACK ENVIRONMENT

3.1. OpenStack

OpenStack is a management tool for Infrastructure-as-a-Service (IaaS) cloud computing infrastructure (Bist, Wariya, & Agarwal, 2013). It is an open source project, managed by the OpenStack Foundation, and was released under the Apache license. OpenStack technology makes more related projects, which control a large set of resources (pool) for the calculation, storage and networking resources, which can be controlled via the control panel (dashboard), a command line or a RESTful API (Fifield, et al., 2014). Simple implementation, scalability, and a range of additional features contribute to the popularity of OpenStack project that is used in a number of educational networks.

OpenStack Networking is one of OpenStack projects that have the task to provide the Network-as-a-Service (Neutron's Developer Documentation). The original name of this project is Quantum and in 2013 was changed into a Neutron. The aim of this project is to eliminate the network as a limiting factor in the implementation of cloud solutions and to enable users to easily configure network parameters. In this way, teachers and students can be focused on application development and testing without knowledge about complete underlying network infrastructure. Neutron is an integral part of the OpenStack platform, which should enable network connectivity between device interfaces that are managed by other OpenStack services. The idea is to get users the ability to implement a variety of network technologies in a simple way through the API and all that based on the plug-in principle.

OpenStack Networking provides the ability to manage IP addressing. It supports static addressing and DHCP (Dynamic Host Configuration Protocol) as well. In addition, advanced network services such as IDS (Intrusion Detection System), firewall, VPN (Virtual Private Network), etc. are supported (OpenStack Networking).

3.2. Open vSwitch

Open vSwitch is a multilayer software switch for hypervisors created in order to support standard management interfaces and with the option of programmable control of packet (Open vSwitch, 2013). It represents an open source project and is available under the Apache 2 license. Open vSwitch supports a variety of virtualization technologies such as Xen, KVM and VirtualBox. Main task of the Open vSwitch is to provide communication between virtual machines and physical interfaces. It supports Ethernet technology

and the implementation of VLANs, but also provides the possibility of integration in virtual environments and management by passing data through different interfaces (Pfaff, et al., 2009).

Open vSwitch data forwarding model is similar to OpenFlow. This method allows definition of the traffic forwarding that originates from a virtual interface, one or more virtual machines. Implementation of interfaces for global configuration management and traffic forwarding separates the logical network topology from the physical.

Thanks to the principles of virtualization, it can be said that in modern information systems there is expansion of the network to the host level, where the Open vSwitch is. If it is a completely virtualized environment each network node is in fact a virtual switch. In this way it is possible to make a complete separation of core and edge part of the network infrastructure with the existence of communication between these parts. Virtual switches can implement a large number of network functionality, enabling the very simple design of the core infrastructure which has the main task to provide connectivity between the hosts (Pfaff, et al., 2009).

4. SDN NETWORK INFRASTRUCTURE MODEL FOR E-LEARNING

The network infrastructure of the educational institution has a task to ensure the implementation of a system for e-education and scientific research of high availability, scalability and reliability. In addition to services for teachers and students, the system must support cooperation with external partners in distributed research teams. Flexibility, scalability and high degree of data security are basic requirements that must be met. Cloud computing is a technology that can successfully respond to many requests, such as scalability, availability and security. In order to provide more flexibility and granular network management, it is necessary to implement certain SDN concepts.

4.1. Cloud computing infrastructure of the Laboratory for E-business

Laboratory for E-business at the Faculty of Organizational Sciences organizes courses using the blended learning concept (Despotović-Zrakić, Marković, Bogdanović, Barać, & Krčo, 2012). System for e-learning is based on the Moodle Learning Managemet System, and in addition to this the Laboratory infrastructure provides students with a wide variety of services (Despotović-Zrakić, Simić, Labus, Milić, & Jovanić, 2013), such as web hosting for student projects, CRM services, mobile applications, edutainment services etc.

The network architecture of a laboratory is based on a hierarchical network model where complex network infrastructure is divided into layers, with the definition of certain functions in each layer (Radenković, Despotović-Zrakić, Bogdanović, Vujin, & Barać, 2013). Access layer is the interface to end-users and connects users' devices with the rest of the network. Distribution layer aggregates traffic from access layer and represents interface between the core and access layers. Core layer is the backbone of the network and provides connectivity between distribution layer devices. This layer implements connection to the Internet and the issue of security is of great importance. Firewall/NAT is a software or hardware component of the network infrastructure, which controls incoming and outgoing network traffic.

One part of the network infrastructure is implemented in a traditional manner, while the other part is implemented as a private cloud. Cloud infrastructure includes parts of the distribution and access layers of computer network. This approach allows the further development of educational and research services in the cloud with the flexibility, scalability and high security of data transmission (Vouk, et al., 2008) (Dong, Zheng, Qiao, Shu, & Yang, 2009).

4.2. SDN network infrastructure model of the Laboratory for E-business

Teachers and students of the Laboratory for E-business are constantly working on the development and implementation of new services and applications necessary for the implementation of the educational process in order to improve the quality of teaching. In addition to network services for communication, collaboration and creation of teaching materials, special attention is devoted to applications and services designed for students, such as edutainment services, various quizzes, mobile applications for learning a foreign language, etc. Given the complexity of requests that network infrastructure must fulfill, the concept of software-defined networks are emerging as a natural choice. The following parameters must be taken into account when defining the SDN network model:

- Existing cloud network infrastructure must be used.
- SDN infrastructure must support all existing services.

- Network management should be implemented in a simple way.
- The development and implementation of new services and applications must be enabled without a high degree of knowledge of networking technologies at the infrastructure level.

The conceptual model of the SDN infrastructure is shown in Figure 3. This model is based on a hierarchical model. Interaction between teachers and students and network infrastructure is realized at the application level, which communicates with the SDN controller through the API interface. Business logic is separated from the infrastructure layer and is at the jurisdiction of the SDN controller, which manages OpenFlow infrastructure using OpenFlow protocol. Since there is the request to use the existing network infrastructure, it is not possible to create fully virtualized network as some network devices do not support the OpenFlow protocol. Therefore a hybrid approach is applied, and at the infrastructure layer, there are two sub-layers: the OpenFlow infrastructure and the traditional network infrastructure (non-OpenFlow infrastructure). OpenFlow infrastructure sub-layer can be realized using Open vSwitch and OpenFlow enabled network devices.

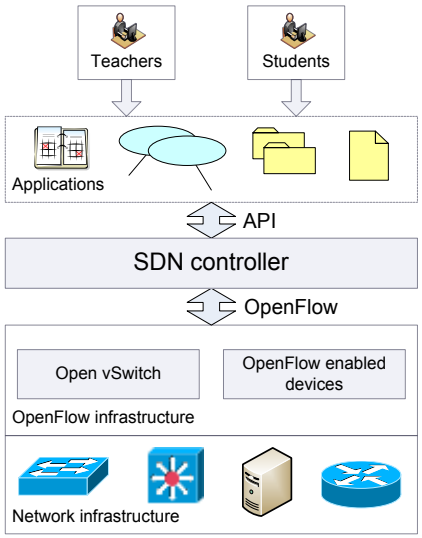

Figure 3: Conceptual model of the SDN network infrastructure

Figure 4 shows the conceptual logic diagram of the OpenFlow infrastructure sub-layer with Open vSwitch. One physical host can have more defined virtual machines that communicate over virtual interface with physical interfaces. This communication takes place via Open vSwitch. Traffic management is performed by SDN controller which defines records in the flow table. Traffic forwarding rules can be defined based on the parameters of the first 4 layers of the OSI network model, such as MAC address, IP address, TCP / UDP port, VLAN ID, etc. Traffic isolation can be performed at the 2 layer using VLANs. Also, implementation of the policies for traffic limiting can affect the quality of service. There are two types of communication: within the private network and via the Internet.

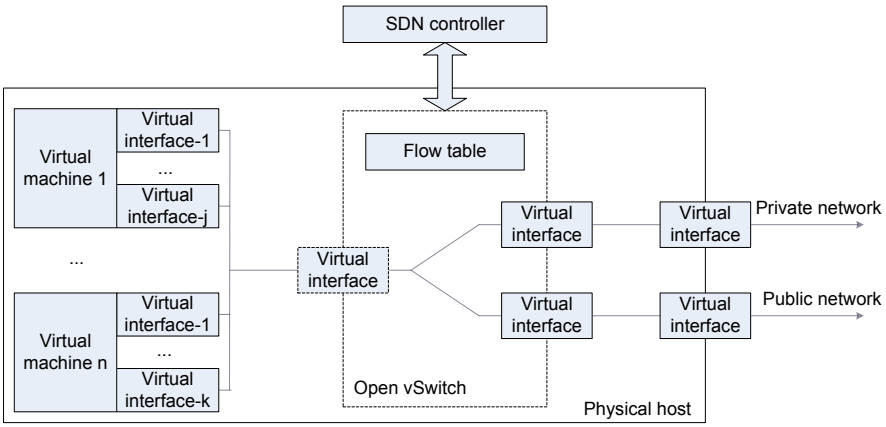

Figure 4: Conceptual logic diagram of the OpenFlow infrastructure sub-layer with Open vSwitch

Neutron OpenStack and Open vSwitch make base for an OpenFlow infrastructure sub-layer. Neutron enables deployment of multiple services on a single or on many physical hosts. The network architecture recognizes the following types of hosts:

- Controller node - manages other hosts

- Network gateway node - provides traffic Layer 3 forwarding and communication with external networks using NAT
- Compute node - performs traffic forwarding

Controller and Network gateway functionalities can be implemented on a single physical host, and it is important to emphasize that the Network node must implement neutron-l3-agent, and if necessary, neutron-dhcp-agent. In the Laboratory network there will be one Network node that has the role of the Controller, as well as more Compute hosts.

Cloud network infrastructure support multi-tenancy concept where the same infrastructure is used by many different users. All tenants can create complete end-to-end network topology based on their specific requirements with complete isolation between their applications. Figure 5 presents multi-tenancy concept in Laboratory network where network topologies for student's projects are created.

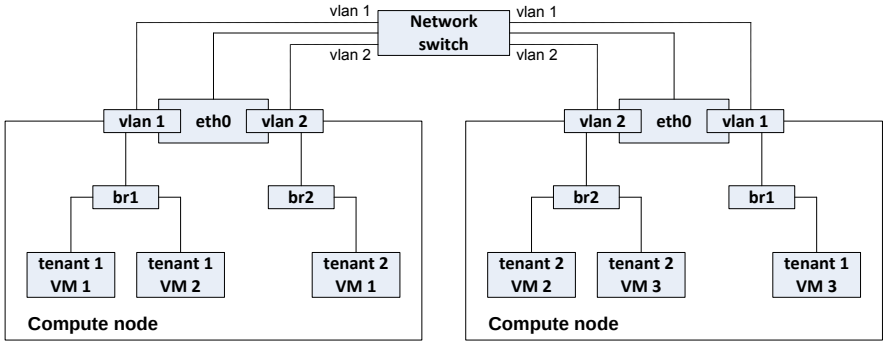

Figure 5: Multi-tenancy concept

Depending on specific needs, tenants can make custom rules for traffic forwarding via SDN controller. Controller manages the OpenFlow infrastructure making changes in Open vSwitch configuration or directly on OpenFlow enabled devices.

There are two types of scenarios based on user groups. Teachers are users who must have full network control and they have possibility to implement their applications and complex projects which demand communication with other networks over the Internet. This means that their environment beside OpenStack Neutron uses external routers for routing and connection to the Internet. Other user group is students and for them is planned different kind of network environment. They also can develop and implement their applications using the same cloud infrastructure and have end-to-end network topology but they do not have possibility to communicate via Internet. Students can create various network topologies and if necessary implement L3 routing between them but only within their projects. That function is realized as NaaS using OpenStack Neutron.

5. CONCLUSION

The new network services and applications place high demands in terms of scalability, availability and flexibility, that traditional computer networks can difficult to meet. A new trend in the design of the network infrastructure is faced to programmability and implementation of software defined networks.

The first part of this paper gives the systematization of knowledge about the basic concepts of SDN networks, with a highlight of OpenFlow protocol as a key component. It then describes a tool for managing cloud computing infrastructure, OpenStack and the Open vSwitch as an example of the virtual switch. The second part of the paper defines and describes the model of cloud network infrastructure of the E-business Laboratory at the Faculty of Organizational Sciences, and then proposes a model of the SDN network infrastructure.

The main contribution of this paper is a definition and a formal description of the network infrastructure model of the research laboratory based on the principles of hierarchy, cloud technology and the concept of a software-defined networks. The presented model can greatly improve the performance of the education processes and contribute to the efficient realization of educational activities. Future research will focus on the implementation of this model, examining the possibilities of Big Data application, and then the quality of service application in order to optimize the processes.

[2]University of Belgrade, Faculty of Organizational Sciences, milovanovicm@elab.rs
[3]University of Belgrade, Faculty of Organizational Sciences, boza@elab.rs

Abstract: *The subject of this paper is Hadoop infrastructure implementation for deploying Big Data technologies. The goal of this paper is to introduce Big Data infrastructure deployed as Hadoop platform in order to improve education process. The platform is convenient for integration with Learning Management System (LMS) Moodle platform. With infrastructure described in this paper, managing large amount of structured and unstructured data from variety of sources is enabled. The platform is deployed within the e-learning infrastructure of Laboratory for E-business at the Faculty of Organizational Sciences - University of Belgrade.*

Keywords*: Hadoop, Big Data, infrastructure, cluster, education, platform*

1. INTRODUCTION

In order to offer high-quality education to their students, education institutions need to have access to relevant information. “Recent advances in educational technology have hinted at a means to measure learning efficiency, in terms of personalization of learner competency and capacity in terms of adaptability of observed practices, using raw data observed from study experiences of learners as individuals and as contributors in social networks (Govindaraja, Somasundaram, Kumar & Kinshuk, 2013).” Information arrive to organizations from variety of sources nowadays, such as databases, sensors, social networks, emails, etc. The flow of this information is rapidly increasing, and it is becoming more complex to manage that information. Another issue to this matter is that nowadays information is represented in variety of types. “The amount of available data increases every day. This huge amount of data is a resource that, if properly exploited, provides useful knowledge. However, to be able to extract useful knowledge from it, efficient and powerful systems are needed. (Garza, Margara, Nepote, Grimaudo & Piccolo, 2014).” A large number of institutions across the world dedicate much of their resources to this matter. “Data driven research has become an important part of scientific discovery in an increasing number of disciplines (Xu, Luo & Woodward, 2012).” A possible approach for exceeding these problems is to introduce Big Data paradigm, “Big data is a term for massive data sets having large, more varied and complex structure with the difficulties of storing, analyzing and visualizing for further processes or results (Sagiroglu and Sinanc, 2013).”

One of the solutions for managing Big Data is Hadoop software framework. It is an open source project developed by Apache Foundation. Reliable, scalable and distributed computing is provided with Hadoop. Laboratory for E-business at the Faculty of Organizational Sciences - University of Belgrade deployed Hadoop infrastructure for dealing with variety of data problems and needs, primarily for Laboratory staff and prominent students to test and deploy Big Data solutions. Two main purposes of this research are devoted to testing different infrastructure approaches and data management functionalities.

2. MODEL DESIGNED IN LABORATORY OF E-BUSINESS FOR IMPLEMENTING HADOOP ECOSYSTEM IN EDUCATIONAL INSTITUTIONS

Hadoop ecosystem can contain various number of tools. These tools are improving performance of Hadoop and help programmers and data analysts to make their work more efficient. Most of the tools come from Apache Foundation and usually work only with Hadoop. The most widely used are Pig, Hive, HCatalog, HBase, Sqoop, Mahout etc. Every tool has its specific functionality, and combining them with Hadoop makes ecosystem very powerful.

These tools can be grouped in few categories. The most common is grouping into tools for importing data in Hadoop file system, data processing, data warehousing and special tools for real time data processing. Another significant Apache projects is Ambari, tool for managing Hadoop cluster which includes all described tools. Some of the companies are offering free or nonfree data platforms that contain already defined ecosystem.

A model for managing Big Data in educational institutions is shown on Figure 1. Laboratory for E-business at the Faculty of Organizational Sciences - University of Belgrade, implemented a modified HDP 2.0 (Hortonworks Data Platform). HDP is a platform that provides a specific Hadoop ecosystem. It is developed by Hortonworks company and it is open source, which allows modification of ecosystem structure.

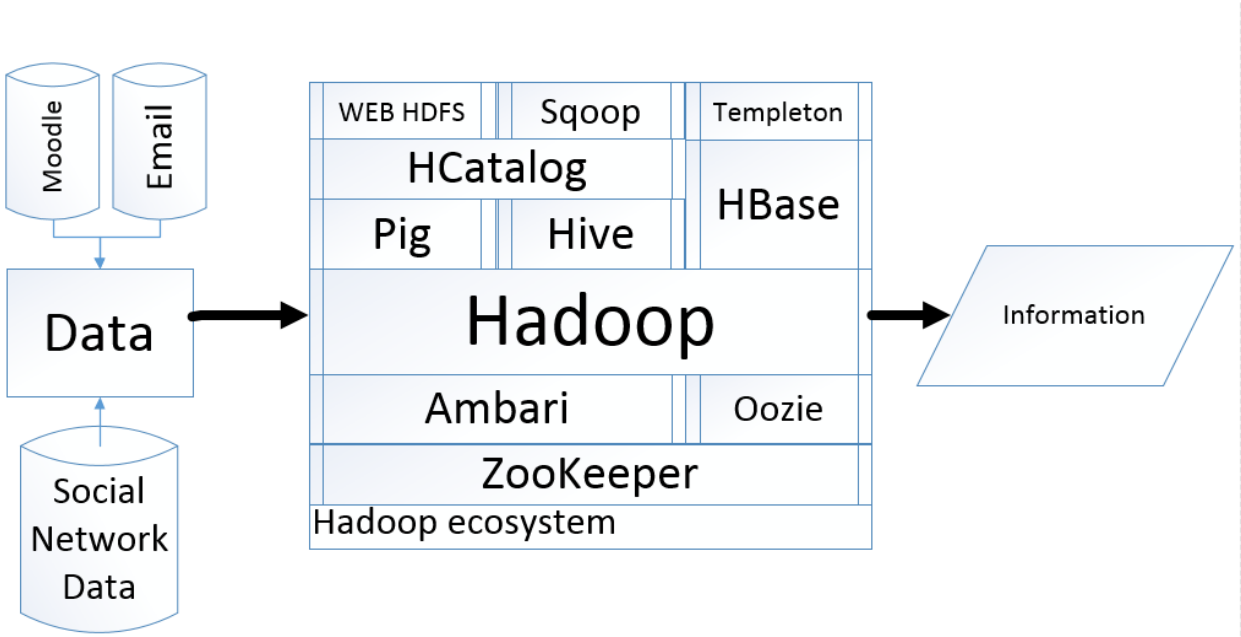

Figure 1: Model for managing Big Data in educational institutions

The Laboratory specifically designed this model for the purposes of educational research and improving quality of education. Principal techniques that are integrated permit working with data from different data sets. The approach that is applied is to collect data generated through the education process, primarily from e-learning processes. Input of the model is represented by structured or unstructured data created from student's activities on their assignments and interaction during process of education. Emails, Moodle logs, student activities on social networks, etc. are collecting in a real time process. Laboratory is focused on finding and resolving student's problems connected to exams and practical assignments, so emails and Moodle logs are chosen as primary input source. Further, the data is transferred to processing.

Whole process of exploiting data into information is happening in Hadoop ecosystem. Core of this ecosystem is Hadoop platform which contains tools needed to process data. Components of Laboratory implementation are elected specifically, based on data generated through main education processes and can be easily reorganized to specific purposes. As a core component of Hadoop ecosystem, Hadoop platform must be applied in every implementation with no exception. Other tools are optional.

Zookeeper, Ambari and Ozzie tools are implemented in this research for cluster management. With this approach it is enabled to easily monitor processes that are performed on a cluster - both processing and management processes.

Pig, Hive, HBase and HCatalog are utilized for data manipulation and WEB HDFS, Sqoop and Templeton which are used for importing data and exporting information. These processes can also be tracked through management tools previously described. Information generated as output of manipulation process contributes to improving the quality of education process at the Laboratory.

The model described in this paper is implemented with a primarily goal for other services of e-learning infrastructure of Laboratory for E-business at the Faculty of Organizational Sciences - University of Belgrade to perform independently of this model.

With this concept, e-learning infrastructure is resistant to failures of Hadoop platform. This provides an environment that is convenient for testing different implementations of the model.
Another characteristic is that the model is flexible and scalable. With these characteristics, the model can be integrated with other e-learning platforms.

3. IMPLEMENTED HADOOP E-LEARNING INFRASTRUCTURE

Hadoop cluster that is designed for the purposes of Laboratory of E-Business at the Faculty of Organizational Sciences is integrated with other e-learning services of the Laboratory.

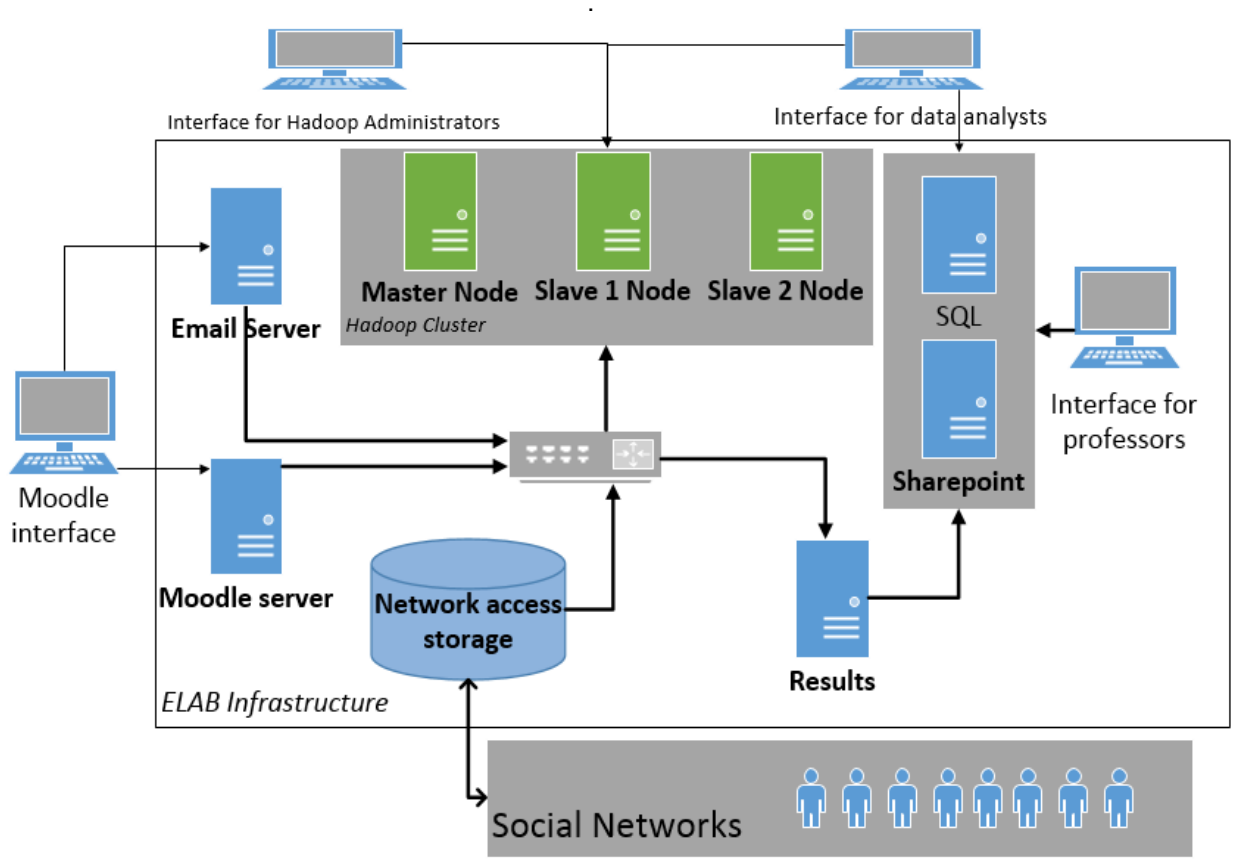

Figure 2: Implemented Hadoop e-learning infrastructure

The implemented solution is based on the model described in chapter 2 of this paper. Cluster communicates with other components using TCP/IP protocol and all data is transferring through Ethernet infrastructure. Hadoop cluster contains three nodes: Master node, Slave 1 node and Slave 2 node. The cluster can be accessed only by Hadoop administrator and Data analysts. Some features are available to students for educational purposes. Important thing to mention is that the cluster can be accessed only through Laboratory for E-business's network. Only Laboratory staff can access the cluster. Hadoop cluster is connected with Email server, Moodle server, Network data storage and Sharepoint cluster through Results server.

Email server collects all mails sent from students to Laboratory staff in text format. Important issue when working with personal information and mails is privacy. In order to overcome this issues, Hadoop cluster is collecting data every day but it uses only mail's body text, omitting student's personal data. It is important for students to be aware that their personal information are not abused.

The primary role of Moodle server is to collect all the data gathered from Moodle LMS, generated in e-learning process. "Learning management systems (LMS) are powerful integrated systems that support a number of activities performed by teachers and students during the e-learning process (Despotović-Zrakić, Marković, Bogdanović, Barać & Krčo, 2012)." In interaction with Hadoop, logs and errors from exams taken by students on Moodle LMS are used as input for manipulation. The primary role here is represented by Sqoop tool, that automatically collects data from Moodle server once a month.

The importance of presence of educational institutions on social networks is inevitable nowadays. The Laboratory of E-business at the Faculty of Organizational Science actively communicates with students via social networks, primarily via Facebook and Twitter. Data that is generated with interaction with students on social networks is accumulated on Network storage. This data is processing in real time since the accumulated data is erased from the storage every week. In that order, the results are stored and can be used as input for further processing. The data from sources other than social networks are imported to Hadoop cluster and stored in Hadoop Distributed File System (HDFS, abbr.) for one year. "For some organizations, the HDFS infrastructure becomes a catch-all for data that has an indeterminate purpose

(Cohen & Acharya, 2013).” Some of data analysis jobs are performed automatically, as a service. Besides this, it is enabled for a data analysts to test new algorithms and perform variety of jobs.

Results of performed jobs are at first stored in Result server. Primary purpose of this server is to store data permanently. With this approach, it is enabled to use variety of tools for visualizing results and applying different Business Intelligence tasks. One possible solution to this matter that is implemented at the Laboratory for E-business is based on Sharepoint cluster. Power BI tools and reporting tools represent the core of this cluster. The data from Result server is transferred to Sharepoint cluster for further manipulation. The Laboratory staff can access the data and perform variety of tasks on it.

The goal in the implementation described in this paper was to make parts of the system independent in work, which enables those parts to be managed in an efficient way. Important issue to notice is that with growth of data, the existing implementation can be too narrow to support it efficiently. Advantage of Hadoop cluster to this issue is it’s linear scalability. New node can be easily implemented to support emerging amount of data. As a principal matter of security, Network storage, Email server and Moodle server are also unreachable outside of the Laboratory facilities.

Three major principles of Big Data are satisfied in the implemented model. Data that accumulates within the network of Laboratory come from variety of sources (Moodle logs, emails, social networks, etc.) - the principle of variety. The speed of data arriving for processing is high, especially in the exam terms - the principle of velocity. The principle of volume is something that comes with time.

Since the implemented platform is still in the testing phase, infrastructure can be easily improved. New devices, tools and even clusters can be easily attached to existing, flexible system. Components of the implemented Hadoop cluster are open source, which allows a whole system to be tailored to specific needs.

Hadoop cluster is implemented on a Laboratory’s hardware infrastructure. In its performance, Hadoop cluster is the biggest consumer of processor power and RAM memory. Principles of optimization are crucial in order to maintain the system upstanding. Hard Disk Drive memory is monitored with cluster management tools previously described. The data that is already explored to its maximum can be erased from the drive. Also, if some raw data is unused for six months, it should be erased from the memory. These principles are implemented to increase the speed of analyzing and to optimize the infrastructure. When it comes to the results of data manipulation, it is up to the Laboratory staff to deal with this matter. Important thing to know is that Hadoop Distributed File System and Result server allocate a significant amount of memory.

Whole Hadoop cluster is deployed on physical servers, but it is tested in parallel on Cloud based infrastructure. Moodle server, email server and Sharepoint cluster are deployed on Cloud. For Cloud software at the Laboratory OpenStack is implemented. With objective of deploying Hadoop cluster on cloud infrastructure variety of testings is performed. “Using a Hadoop cluster in a remote shared infrastructure enables users to avoid the costs of maintaining a physical infrastructure (Xu, Luo & Woodward, 2012).” One direction of research is conducted to implementing Hadoop directly on OpenStack, and the other one is performed via plugins which are still in early phases of development.With this approach infrastructure is gaining flexibility and easier maintenance.

4. CLUSTER ORGANIZATION AND MANAGAMENT OF HADOOP ECOSYSTEM

Hadoop cluster organization currently implemented for the purposes of Laboratory of E-Business is shown in figure 3.

Hadoop components and Apache tools are distributed within three nodes. Central role that is responsible for Hadoop’s performance is represented by Master node. This node contains all clients - Pig, Hive, etc. The main distinction of this node from the others is in Name Node and HBase Master. Main purpose of Name Node is to save meta data for all data stored in Hadoop cluster. HBase Master manages all NoSQL jobs performed on a cluster. These two components are installed only on this node. Component with a purpose of data storing is Data Node. Implementations with more than three nodes usually do not have implemented Data Node on Master Node. Data is stored only on nodes other than Master Node. In order to optimize Hard Disk Drive Memory, in the implementation described here Data Node is installed on the Master Node. With this approach it is enabled to use the Master Node’s unused memory to store data. Ambari Server is a component deployed on a Master Node that is responsible for managing and monitoring the cluster. It provides a web interface convenient for attaching a new node and cluster size management (Figure 4).

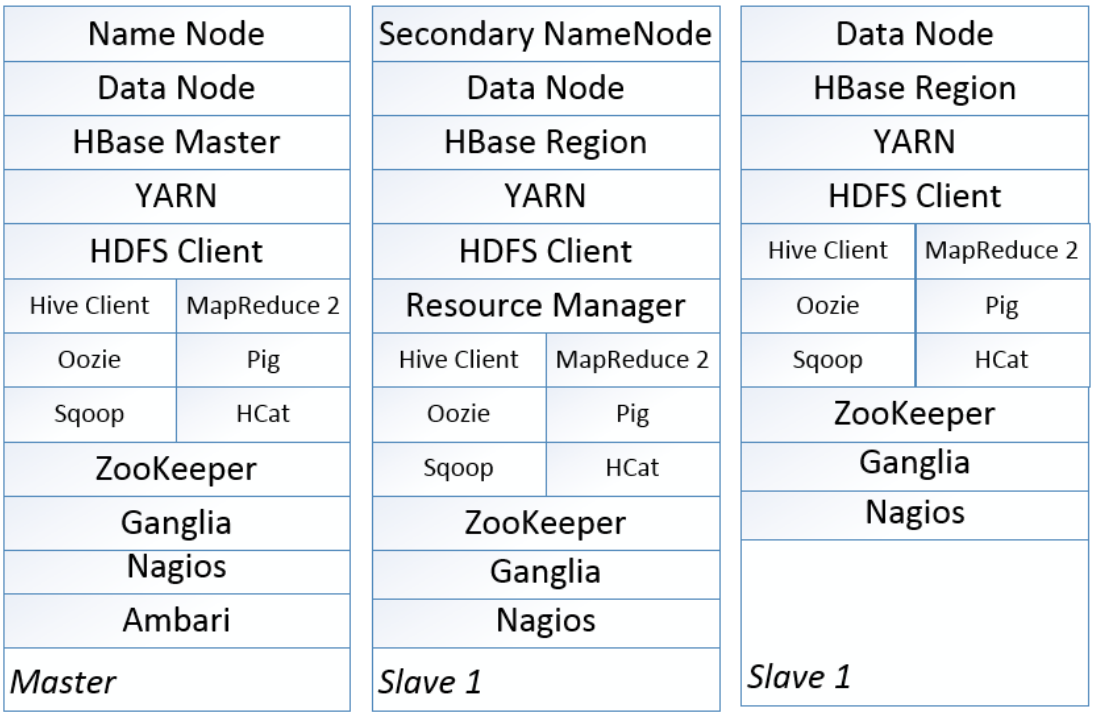

Figure 3: Hadoop cluster organization in Laboratory of E-Business

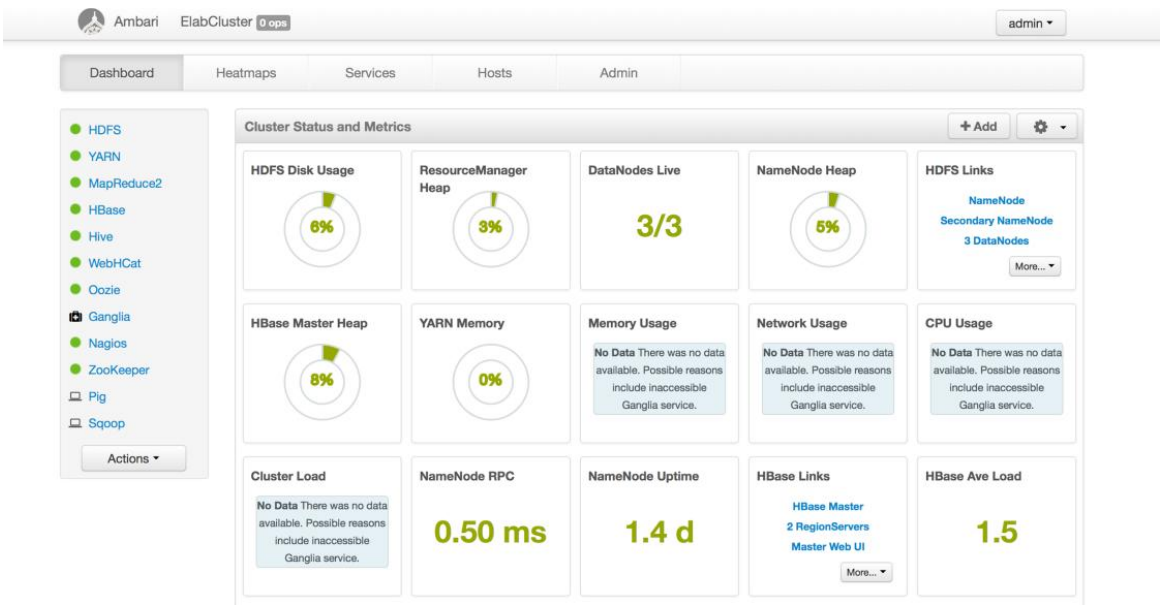

Figure 4: Ambari Web interface

Client components and Data Node are deployed on other two nodes (Node 1 and Node 2). As a mechanism to overcome the issues proceeded from Name Node failure, a Secondary Name Node is deployed on a Node 1 with a purpose to serve as a backup for a Name Node. Node 1 contains Resource Manager component for managing all the resources on the cluster. Node 2 does not contain any extra features besides the storage and processing. With this organizational aspect Node 2 can be used as template for adding new nodes to cluster. This aspect is optional.

Communication that is happening inside the cluster is carried by Ethernet cable supported with TCP/IP protocol. Important issue in distributed systems is performance of the link between components. Problems with the link between nodes may lead to losing of data. Imposed mechanism for overcoming this problem is to constantly monitor network infrastructure. This approach provides possibility to act instantly in these occasions. Data in Hadoop is stored in blocks. Each block is replicated three times, so if one block is lost other two can serve as backup. This means that for storing 1TB (terabyte) of data, 3TB of memory blocks are

required. This replication is distributed on different nodes. Importing and exporting data is automated with Sqoop component. Specific situation requires specific approach to Sqoop processes.

Every Node installation is flexible. New components can be easily added and removed. Client components are elected based on the data to be processed. For structured data such as Moodle logs Hive component is implemented for manipulation. For unstructured data such as emails Pig component is implemented. For real time processing of data from social networks HBase is implemented.

5. CONCLUSION

The paper presented a scalable platform that brings Big Data based on Hadoop to e-learning environment. The infrastructure is integrated with LMS Moodle platform, student's emails and social networks data. Model for managing Big Data in educational institutions enables manipulation of data generated through student's online activities. Output of manipulation process is used to improve the quality of e-learning. Architecture and main mechanisms were described. Described model is implemented in Laboratory for E-Business at Faculty of Organizational Science in Belgrade through unique infrastructure. The model is flexible and allows implementation in other educational institutions as well.

The future research and development are directed to optimizing the model for integration with e-learning services and other existing services at the Laboratory. Primary goal in future research is deploying Hadoop SaaS (Software-as-a-Service) concept based on Cloud infrastructure and migrating entre Hadoop cluster to Cloud environment.

ACKNOWLEDGEMENT

The authors are thankful to Ministry of Education, Science and Technological Development of Republic of Serbia for financial support grant number 174031.

Abstract: *This paper presents various aspects of using Big Data analysis in an educational institution. Hadoop platform for Big Data analysis is used for determining and analyzing scattered data about student's problems. The main goal of this paper is to show that Hadoop can be utilized in e-learningpurposes.In this paper is presented a solution model which works on data analysis. Data used to analyze is mostly from Moodle learning service and other sources of data with various format. Visualization of gathered data can help teachers and course creators to improve existing online courses.*

Keywords: *Big Data,Hadoop, e-learning, visualization, online courses*

1.INTRODUCTION

Using the electronic media and information and communication technologies in the teaching process is broadly inclusive nowadays. A large number of universities all around the world use systems for e-learning. E-learning can take place synchronously or asynchronously. In synchronous systems, participants meet in "real time", and teachers conduct live classes in virtual classrooms. In asynchronous learning, which is sometimes called "self-paced" learning, students' are expected to complete lessons and assignments independently through the e-learning system. Asynchronous courses have deadlines just as synchronous courses do, but each student's is learning at his own pace.

Universities around the world use different LMS systems for e-learning. One of the most used is Moodle LMS (Despotovic-Zrakić, M., Markovic, A., Bogdanovic, Z., Barac, D. & Krco, S. 2012). In this paper is given a preview of Big Data analysis and the LMS Moodle. For Big Data analytics Hadoop platform is used. Student's Moodle logs has been analyzed with a goal to determine student's problems related to overcoming materials of courses which they enrolled. The research was conducted in scope of Laboratory for E-business at the Faculty of Organizational Sciences, University of Belgrade.Collected results are important for teachers because they can help them to improve e-learning services, and for students' to enhance their learning outcomes.

2. TECHNOLOGIES FOR BIG DATA ANALYSIS

The most used technology for Big Data analysis is Hadoop (Wasi-Ur-Rahman, M.; Islam, N.S.; Xiaoyi Lu; Jose, J.; Subramoni, H.; Hao Wang; Panda 2013). For this research apache Hadoop framework is tested as well as their tools: MapReduce, Apache Pig, Apache Hive, HBaseand Apache HCatalog. For data visualization Share Point is used.

MapReduce is framework for programming applications that process large amounts of both structured and unstructured data in parallel across hundreds or thousands of industry-standard servers in a Hadoop cluster, in a reliable and fault-tolerant manner. MapReduce, Hadoop Distributed File System, YARN and Hadoop are usuallycalled in a form the core of Hadoop.
The MapReduce really referes to two distinct tasks that Hadoop program performs.First job is the map, it takes sets of data and converts it in others sets of data where individual elements are broken down into value pairs.The reduce job takes the output from map job as input and combinations of value pairs into a smaller set of value pairs. As the name MapReduce implies, the reduce job is performed after the map job.

MapReduce's benefits:

- Developers can write applications Built-in recovery: MapReduce takes care of failures. Programmers can write map and reduce job codes in their preferred language, such as Java, C++,Python
- MapReduce is scalable, it can process petabytes of data on one cluster.
- Speed: Parallel processing means that Hadoop can take problems that used to take days to solve and solve them in hours or minutes.
- If data is unavailable on one server, and another server has a copy of the same value pair, it can be used to solve the same sub-task. Service called JobTracker keeps track of all jobs and it solves previously mentioned problem.
- MapReduce moves compute processes to the data on HDFS. Processing tasks can occur on the physical node where the data resides. This compellingly reduces the network I/O patterns and keeps the I/O on the local disk or within the rack.
- MapReduce takes care of the prosaicdetails around deployment, resource management, monitoring and scheduling, the users can focus on answering questions about their business (Shengsheng Huang; Jie Huang; Jinquan Dai; Tao Xie; Bo Huang, 2010).

Apache Pig present a platform for MapReduce programming. Apache Pig also referred to as Pig Latin was initially created by Yahoo! to make it easier for researchers and engineers to mine the hugedatasets. It is used in collaboration with Hadoop. This script language is similar to SQL queries for RDBMS systems. Pig Latin can easily be extended using the UDF or (User Defined Functions) which can be written in Java, Python, JavaScript, Ruby or Groovy and then call directly from the language (Yongzhi Wang; Jinpeng Wei; Srivatsa, M.; Yucong Duan; Wencai Du 2013).

Apache Hive is a data warehouse infrastructure. It is a query language used mostly for analyzing structured data. The development of Apache Hive language was done by Facebook to handle the amount of logs and data dimension, but further development of Apache Hive was taken over by Netflix.It supports analysis of large datasets stored in Hadoop's HDFS and compatible file systems such as Amazon S3 filesystem, and provides an SQL-like language called HiveQL while maintaining full support for map/reduce. To accelerate queries, it provides indexes, including bitmap indexes (Im, J.-F.; Villegas, F.G.; McGuffln, M.J., "VisReduce 2013).

HBase is a distributed column-oriented, open source, non-relational, distributed database. HBase is used when real-time read/write random access to a huge datasets is required. It was modeled after Google's BigTable and written in Java, and it is the only tool in Hadoop ecosystem that can process real time data analysis. It is developed as part of Apache Software Foundation's Apache Hadoop project and runs on top of Hadoop Distributed Filesystem, providing BigTable-like capabilities for Hadoop. That is, it provides a fault-tolerant way of storing large quantities of sparse data. HBase features compression, in-memory operation, and Bloom filters on a per-column basis as outlined in the original BigTable paper. Tables in HBase can serve as the input and output for MapReduce jobs run in Hadoop, and may be accessed through the Java API but also through REST, Avro or Thrift gateway APIs. HBase is not a direct replacement for a classic SQL database, although recently its performance has improved, and it is now serving several data-driven websites (Dan Han; Stroulia, E. 2012).

Apache HCatalog can be described asmetadata management tool. Apache HCatalog stores consistent schema information that are important to program languages that implement MapReduce and other third party systems that need to collaborate with Hadoop. It is a table and storage management layer for Hadoop. HCatalog enables users with different data processing tools – Apache Pig, Apache MapReduce, and Apache Hive – to more easily read and write data on the grid. HCatalog's table abstraction presents users with a relational view of data in the Hadoop Distributed File System and ensures that users need not worry about where or in what format their data is stored. HCatalog displays data from RCFile format, text files, or sequence files in a tabular view. It also provides REST APIs so that external systems can access these tables' metadata.

Benefits of using Hadoop to analyze large datasets are: scalability (more nodes can be added if there is a need for more resources), its distributed file system facilitates rapiddata transfer rates among nodes and allows the system to continue operating uninterrupted in case of a node failure.
Hadoopis used for analysis and prediction of behavior throughoutlarge variety of students' demographics, personal backgrounds, learning styles, thinking processes, academic objectives, environmental factors, skills and potentials.

These three points are crucial for enhancing the LMS(Despotovic-Zrakić, M., Markovic, A., Bogdanovic, Z., Barac, D. & Krco, S. 2012):
Volume**:** Benefit from using Big Data is ability to process large amounts of information is the main attraction of big data analytics. Big Data can gather and analyze information from thousands of students taking the

same course. It can also clarify multiple data points, about a single learner. Because of its scalability, Big Data might bring together learning data from hundreds of courses to provide a global perspective on world education.

Velocity**:** The increasing rate at which data flows throughout organization has followed a resembling pattern to that of volume.Big Data enables course creators and students to have instant access to data even in real time. In example if student enters a wrong answer in an online exam.By virtue of velocity he would instantly be provided with remedial and enrichment options based on his historical learning patterns and successful strategies made by thousands of other learners who also failed that question. It would also allow instructors to make adjustments to content delivery, based on rapid analysis of user experience, on a continual basis.

Variety**:** Data is rarely present in a perfectly ordered form and ready for processing. A source data in big data systems is diverse, and it doesn't fall into neat relational structure. It could be text from social networks or emails, image data, a raw feed directly from a sensor. Big Data connects the dots (different case scenarios), connecting together a variety of information from students' with different skills and abilities. It allows us to see the correlations between environment and performance. Without BigData analyses,traveling expenses and limited representation are common and almost always present with people ready to learn something new.

3. MODEL FOR ANALYZING BIG DATA FROM LMS

Model for analyzing Big Data from LMS is developed in scope of Laboratory for E-business at Faculty of Organizational Sciences, University of Belgrade. The model integrates Hadoop platform with Moodle LMS services, Mail services and social networks of the laboratory. This is done in scope of cloud infrastructure. This model is shown in figure 1.

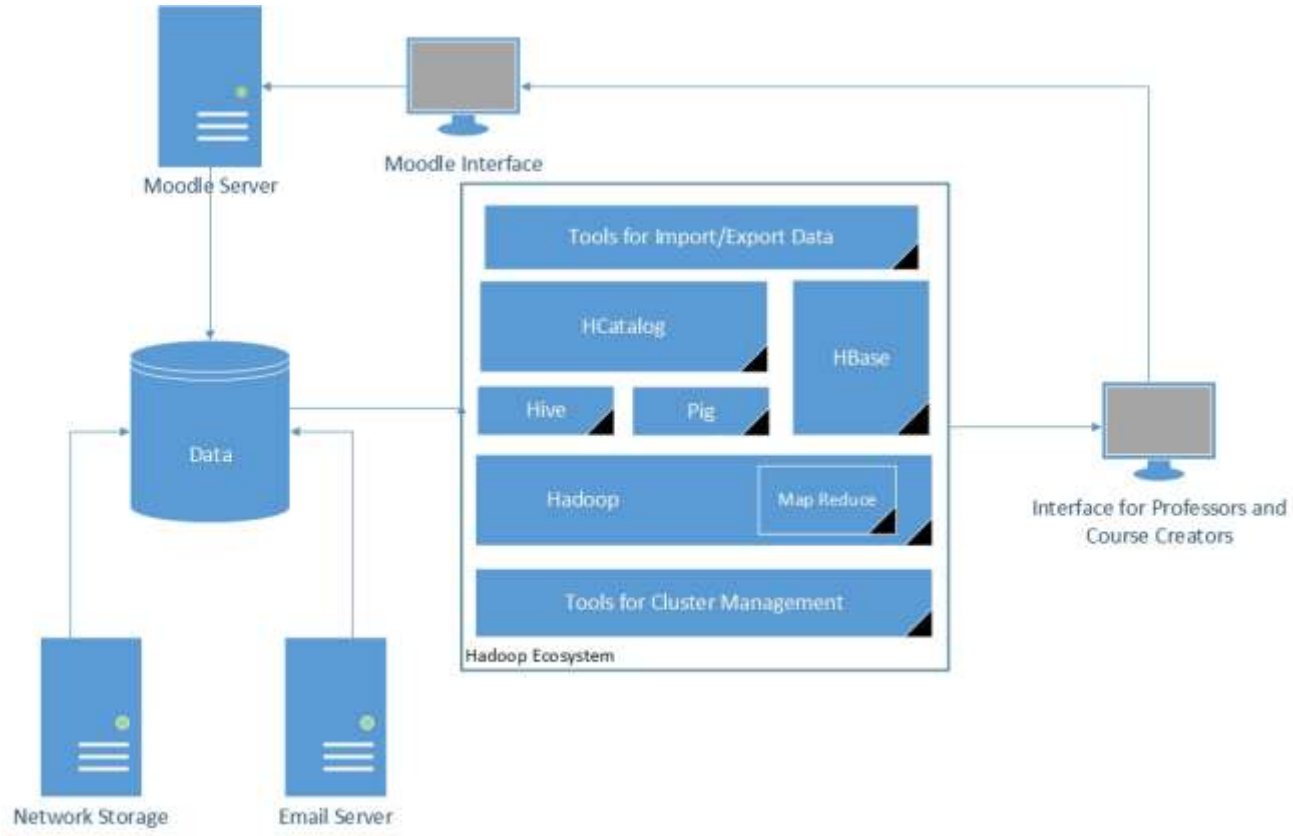

Figure 1: Model for analyzing big data from LMS

Laboratory for E-business at the Faculty of Organizational Sciences in Belgrade organizes a large number of online courses for all level of studies by using Moodle LMS. The most chosen courses by students' are: E-business, Internet Technologies, M-business, Concurrent Programming, Internet Marketing and other courses. Since 2001 the Laboratory has been using e-learning and blended learning concepts (Franzoni, A. & Assar, S. 2009), (Despotovic-Zrakić, M., Markovic, A., Bogdanovic, Z., Barac, D. & Krco, S. 2012). Moodle LMS e-learning system is suitable for mining various data related to e-learning. For student relationship

management (SRM) and collecting relevant data for different kind of analysis Laboratory for E-business uses Facebook and Twitter(Bogdanovic, Z., Barac, D., Labus, A., Simic, K., & Vulic, M. ,2012), (M. Vulić, M. Despotović-Zrakić, D. Barać, A. Labus, Z. Bogdanović, 2011). The main aim of the laboratory appearance on social networks is informing students' about the laboratory activities, providing them with the information related to exams, events and projects in which they can be enrolled in scope of the laboratory. By providing posts from the classes, events, exams, etc. teachers can collect information in which posts students' are interested the most and encouraging students' to interact with each other about the courses and trending topics.
Hadoop ecosystem developed in above mentioned model is convenient for analyzing data provided from Laboratories services to visualize and even predict students' results that can be useful to improve existing and help creating new courses on Moodle LMS. It is possible to visualize results for only one student or groups of students' activities throughout the semester.

4. PERSONALIZATION OF E-LEARNING BY USING HADOOP

The personalization process is focused on providing the students' with the profile on Moodle LMS, and based on their activities and courses they enrolled they get different materials and assignments using Hadoop to analyze Big Data. Big Data is currently used for various purposes, primarily for more productive business results. In the e-learning domain, there are many interesting experiments being carried out around the world, in order to understand the enormous potential of Big Data.

For example, with the help of Big Data, you can watch your students' virtually and track:

- Areas of the program they find hard and spend more time on
- Pages they revisit often
- Areas in which they get stuck
- Sections they recommend to their peers
- Learning styles they prefer
- Time of the day they learn better

Hadoop with Big Data analysis can help teachers understand the real behavior patterns of students' more effectively than traditional beliefs and theories on students' behavior. These patterns could lead us to highly valuable information on what and how they learn; thereby helping us make well-informed decisions about the learning programs and even identify design flaws.However, the real strength of Big Data lies in its power to help forecast or predict scenarios and take preventive action. For example, with the help of Big Data, you could predict:

- How strong your learners are in every concept of the course that they haven't even taken yet!
- Where your learners are likely to struggle or fail

Big Data analysis could help teachersassessaboutstudents' performances and outcomes on their courses before they start a training program. This could even be at the early stages of analyzing the training requirements. It could allow us to forecast trends and draw conclusions about our learning and development initiatives.

By visualizing results from Big Data analysis here at the Laboratory for E-business it can be seen the activities of student's on Moodle LMS via userid. This model does not bind students' personal information and their user id, the model monitors students' userids and the activity of that user on the Moodle LMS.

Figure 2showsvisualized data about activities of all students' on Moodle LMS, this gives the course teacher insight about the time that students' has been most active, so the teacher can try to give the needed materialsand assignments based on this information.

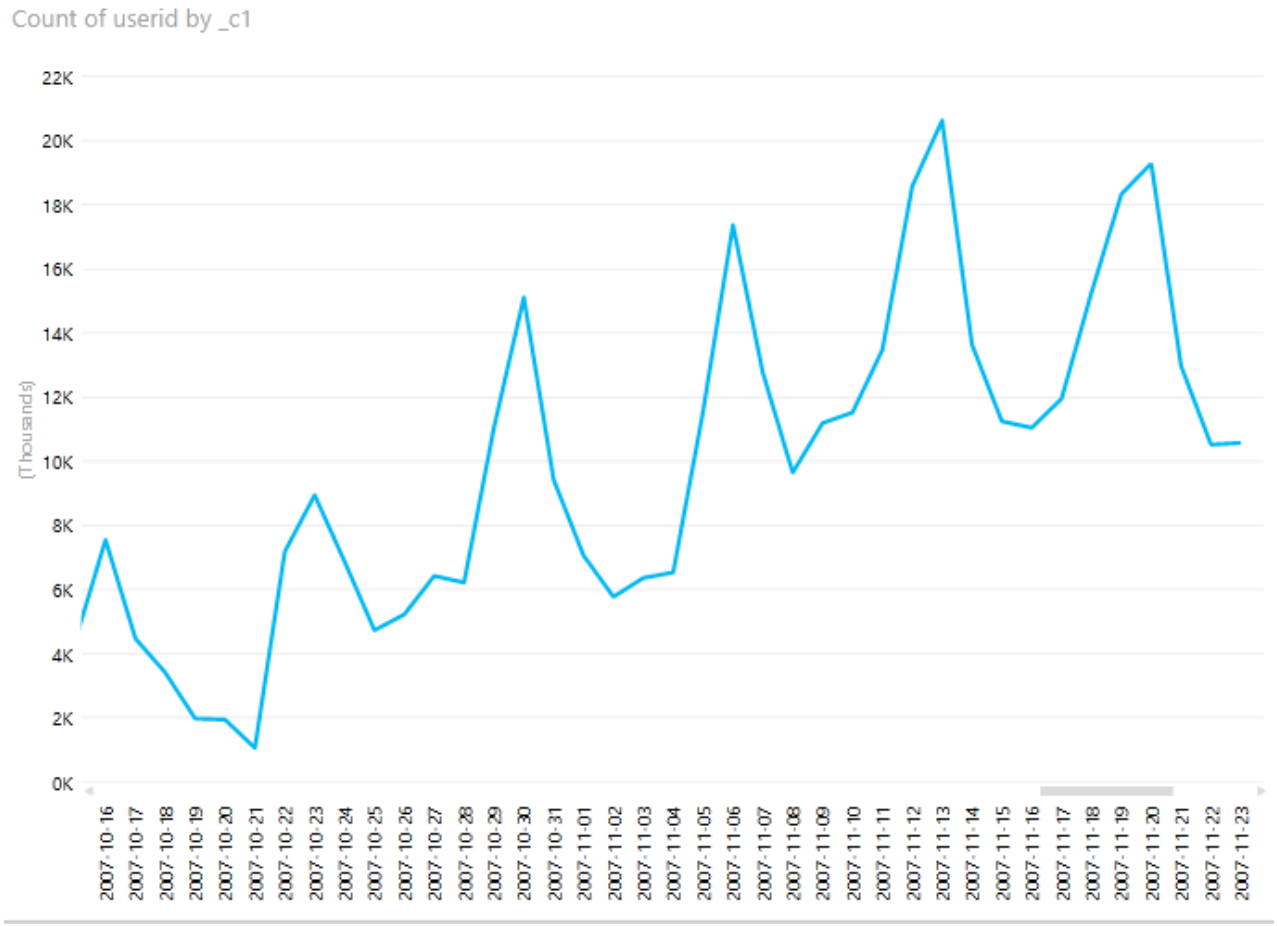

Figure2. Activities of all students' on Moodle LMS

5. FUTURE IMPROVEMENTS OF MODEL

Future improvement of model is to add more information to our analysis for better and more reliable real time information about our students' results. Information that could be added to our analysis would be from different sources like sensors for room temperature where students do their exams or data from VoIP consultations with their mentors. Improvement of our model could provide real time analysis and instant feedback to student behavior on course providing him instantly with needed material.Future researches are directed toward improving adaptation mechanisms and automation of adaptation process for implementation in other online education services, as well as complete integration of all processes in adaptive e-learning system.

6.CONCLUSION

This paper presented how students' learning and efficiency can be improved by analyzing data from Moodle, e-mails with questions and social network to meliorate courses to fit students' characteristics and learning habits and present them with solution for frequent problems. The capability to gather vast amounts of digital data and the computational methodologies to analyze them are changing many aspects of science. The research questions that can be answered using data driven approaches evolve and are multiplied based on the progress of pattern analysis and data mining technology. The adaptation services enable tailoring Moodle courses and features based on data analysis from student's model. Adaptation was performed considering these criteria: common questions from students' via e-mail, students' results on tests, students' social activities, students' learning styles and students' interests. Analytic methods and technologies used for analysis were described.

Evaluation of the system should provide additional information about users experience in using the system, as well as data about system performances and impact on learning process outcome. Integration of social networks and developing services for social interaction should improve students' loyalty and motivation for learning.

ACKNOWLEDGMENT

The authors are thankful to Ministry of Education, Science and Technological Development of Republic of Serbia for financial support grant number 174031.

Abstract: *This paper deals with using Internet of Things and crowdsourcing in education. The main subject of this paper is researching the usage of Internet of Things in e-education. The primary goal of this paper is improving a teaching process at higher education institutions by introducing concepts of Internet of Things and crowdsourcing. Concepts of Internet of Things, e-learning, crowdsourcing and smart environments are described. A model for smart e-learning environment in a higher education institution is proposed.*

Keywords*: Internet of Things, e-learning, crowdsourcing, smart environment, smart classrooms, Cloud Computing*

1. INTRODUCTION

Internet of Things represents a modern research problem nowadays. Internet of Things includes a number of different devices or "things", namely sensors, actuators, tags or mobile devices which can mutually communicate and be used for different purposes. For example, the mentioned devices can be used for building different complex smart environments, such as smart homes, smart classrooms, smart offices, smart factories, smart cities, smart power grids or smart e-government. Smart environments can be customized according to users' needs and preferences which are suitable for automating these environments.

There are few examples in literature of using Internet of Things in education. In this paper, concepts of e-learning, Internet of Things, smart environments and crowdsourcing are defined. Crowdsourcing is a relatively new concept of sharing ideas between "crowds" – large groups of people. Also, we propose a model of smart e-learning environment based on Internet of Things and crowdsourcing.

2. THEORETICAL BACKGROUND

Using information and communication technologies in every part of the modern society has required introducing these technologies in education as well. A lot of universities and other education institutions has been using e-learning systems in addition with traditional learning methods. E-learning represents a complex system which consists of distance learning and teaching as processes separated in space and time and teaching materials available in different forms (Radenković, Despotović, & Bogdanović, 2006). Learning management systems are core components of e-learning systems. They consist of standard learning and teaching tools and components which are usually integrated into information systems of education institutions via portals. Nowadays, e-learning is omnipresent and possible by using a large number of different devices, e.g. mobile phones and tablet computers. This process is known as ubiquitous learning (Casey, 2005; Chen, Chang, & Wang, 2008).

For creating a stable e-learning environment, it is necessary to have a solid and quality, distributed infrastructure which can respond to increasing number of requests. The infrastructure should be highly scalable to accept increasing number of students, reliable and fault-tolerant. Cost-effective solution which can respond to previously mentioned requirements is Cloud Computing (Despotović-Zrakić, Simić, Labus, Milić, & Jovanić, 2013). Many universities around the world have been using their own private clouds for building e-learning environments (Liang & Yang, 2011).

Cloud Computing represents highly scalable and abstracted infrastructure with virtualized resources, hosting various applications for end-users (Sultan, 2010). Depending on the method of delivering the cloud technology to end-users, there are three service models of Cloud Computing: Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS) (De Assunção, Di Costanzo, & Buyya, 2009). According to the ownership of Cloud Computing infrastructure, there are several cloud deployment models: Public Cloud, Hybrid Cloud, Public Cloud and Community Cloud (Mell & Grance, 2011).

Internet of Things can be used for improving the overall learning process. Internet of Things implies connecting different kinds of devices to the Internet (Atzori, Iera, & Morabito, 2010). By using sensors and actuators, it is possible to create smart environments which respond to various automation scenarios. Smart

environments are based on wireless sensor networks, which are distributed networks consisted of sensor areas interconnected by wireless networks. Sensor networks consist of multiple sensor nodes which are spatially placed. The positions of sensor nodes in smart environment are usually random. The main design factors regarding sensor networks are: fault tolerance, scalability, production costs, hardware constrains, sensor network topology, environment, transmission media and power consumption (Akyildiz, Su, Sankarasubramaniam, & Cayirci, 2002a, 2002b).

Wireless sensors networks are highly constrained. Comparing to traditional wireless networks, wireless sensor networks have short range, low bandwidth, limited storage and processing units in each node and limited amount of energy (Yick, Mukherjee, & Ghosal, 2008). The most important components of Wireless Sensor Networks are: sensors which measures physical values of the environment (temperature, pressure, sound, light intensity etc.); actuators which can turn devices on or off and wireless Infrastructure (routers, access points etc.) which makes communication between sensors, actuators and the Internet possible.

Internet of Things is used for creating different types of smart environments, such as smart buildings, smart homes, smart government and smart classrooms. Buildings with some automated elements are known as smart buildings. These buildings are capable of warning their residents and/or employees of fire, flood and other natural disasters. Also, these buildings can “sense” the presence of people and to react adequately (i.e. to turn on the light or to turn the air condition on).

Smart Homes uses home automation systems which integrate several different systems for managing home appliances, such as: Heating System, Air-Conditioning System, Anti Burglar System, Fire Alarming System, Home Lightning Systems, Audio Systems, Video Systems, etc. (Chan, Esteve, Escriba, & Campo, 2008; Ding, Cooper, Pasquina, & Fici-Pasquina, 2011). Smart Government means using information and communication technologies, applications and different contents for improving the process of providing services to citizens/enterprises and for improving the overall processes of public administration (Downs, 2005; Neirotti, De Marco, Cagliano, Mangano, & Scorrano, 2014). The main objective of introducing Smart Government is focusing on structural and fiscal reforms in the public administration for improving the quality of life.

Smart Classrooms represent synthesis of technology, user interface and traditional lecturing methods. New generations of Smart Classrooms are equipped with high technology and they become necessary for performing teaching processes at universities. Smart Classrooms have audio-visual equipment which enables transferring the knowledge by using a wide spectrum of different media (Gligoric, Uzelac, & Krco, 2012; Huang, Hu, Yang, & Xiao, 2012). Some authors propose using of near field communication (NFC) technologies for creating a smart classroom which is able to provide real-time feedback of students, locate them and automate recording of their attendance at classes (Shen, Wu, & Lee, 2014).

With Internet of Things in education, students are able to have teaching process and teaching materials created in accordance to their needs (Yan-lin, 2010). Ubiquitous computing and ambient technologies can be used in synergy with Internet of Things to create a prototype of an environment of smart campus which consists of Touching Note, Touching Cabinet, Touching Campus and NFC Interactive Panel. These elements are used for providing the students with different kinds of useful information related to timetables, teachers’ tutoring classes etc. (Gonzalez, Organero, & Kloos, 2008).

Internet of Things in classrooms can be valuable for collecting different data about students before classes. Teacher can use these data for improving the teaching process (Tissenbaum, Lui, & Slotta, 2012). One example of applying concepts of Internet of Things in education is Open Smart Classroom. This project represents a smart classroom which is able to translate teaching materials (Power Point Presentations) from English to Chinese and Japanese using web services. Also, presentations can be controlled by using smart phones (Suo, Miyata, Morikawa, Ishida, & Shi, 2009).

To personalize teaching and learning experience and to customize these processes according students’ and teachers’ needs, a concept of crowdsourcing can be used. Crowdsourcing involves contribution from a large group of people to a project (Satzger, Psaier, Schall, & Dustdar, 2013). In education, crowdsourcing means active participation of students and different teachers in the learning process. Students are partly involved in creating teaching materials and education environment, according to their needs and affinity (Satzger et al., 2013). Wikis and open source communities are some examples of using crowdsourcing in education (Albors, Ramos, & Hervasa, 2008). Smartphones can be used for crowdsourcing as well (Chatzimilioudis, Konstantinidis, Laoudias, & Zeinalipour-Yazti, 2012).

Poway Unified School District in California used crowdsourcing as a part of the project for improving the safety levels in schools, where all teachers and other employees in education institutions of the District were

involved in proposing their ideas for securing schools. Discussions between staff members were conducted by using different communication channels, such as smart phones, tablets and desktop web browsers. Participants of this crowdsourcing platform generated over than 10000 page views, 500 comments and about a thousand votes on nearly 100 ideas proposed (Davis, 2013).

3. A MODEL FOR E-LEARNING ENVIRONMENT BASED ON INTERNET OF THINGS

Smart building of higher education institution should be constructed according to standards of energy efficiency. New buildings should have energy passports. Energy passports are documents which describe energy efficiency, thermal protection and greenhouse gas emissions (Fehlauer, Winkler, & Braetz, 2009). Concepts of Internet of Things can be deployed in this building. Subjective and objective parameters about students' satisfaction with lecture classes can be measured.

Subjective parameters for quality evaluation of the lecture are measured as students' feedbacks in the real time. During the lesson, students should evaluate the quality of presentation and its contents by filling an electronic survey via their laptops, smart phones or tablet computers. A feedback server collects and processes all data from surveys. Teacher can view statistical results of the survey in the real time.

Objective parameters can be measured by using different sensors. For example, it is possible to measure noise which is relevant to students' satisfaction.

In addition to smart classrooms, a smart building of higher education institution can have a smart corridor with a smart infoboard. Smart infoboard is equipped with Bluetooth and NFC transmiters and it is connected to the main information system of the institution. Students can tap the infoboard with their smart devices to acquire the latest information about the institution. For example, the students can get their latest class timetables or the information about school events.

A model of previously described smart and energy-compliant building of education institution is shown in the Figure 1.

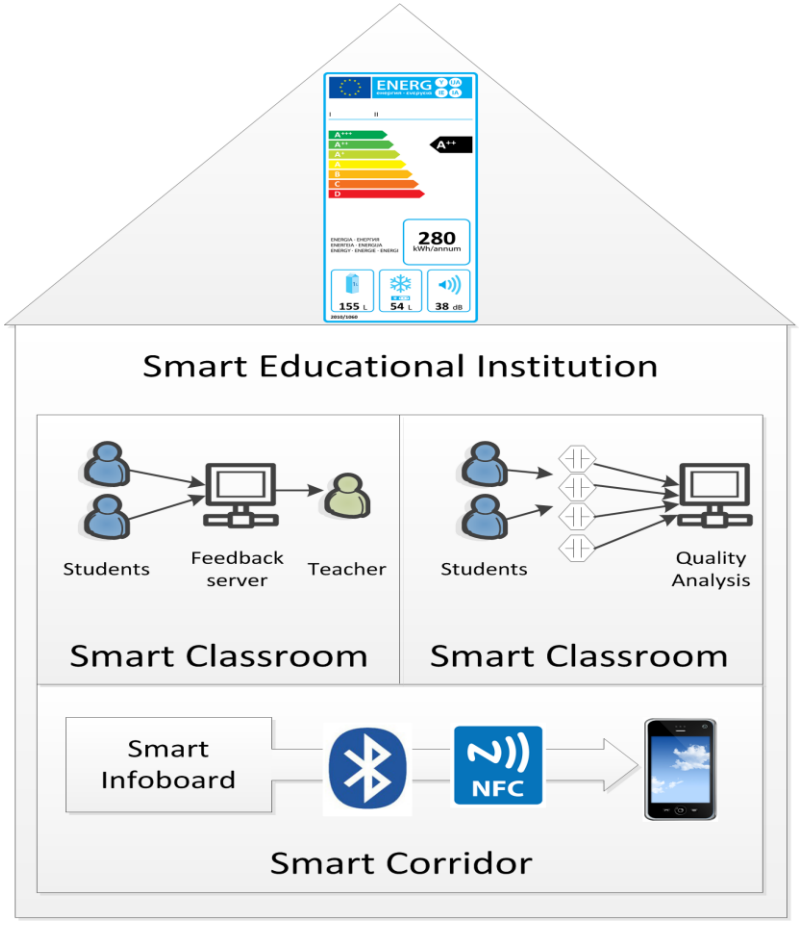

Figure 1: A model of the smart building of higher education institution

A model for e-learning based on Internet of Things and crowdsourcing consists of following main components: Sensors, which gather various data about students, teachers and learning environment; Router, which collects data from sensors wirelessly and stores them into the big data warehouse; Big data warehouse, which is capable to store several terabytes of raw data and Data Analysis Server, which analysis data from the big data warehouse.

The model is shown in the Figure 2.

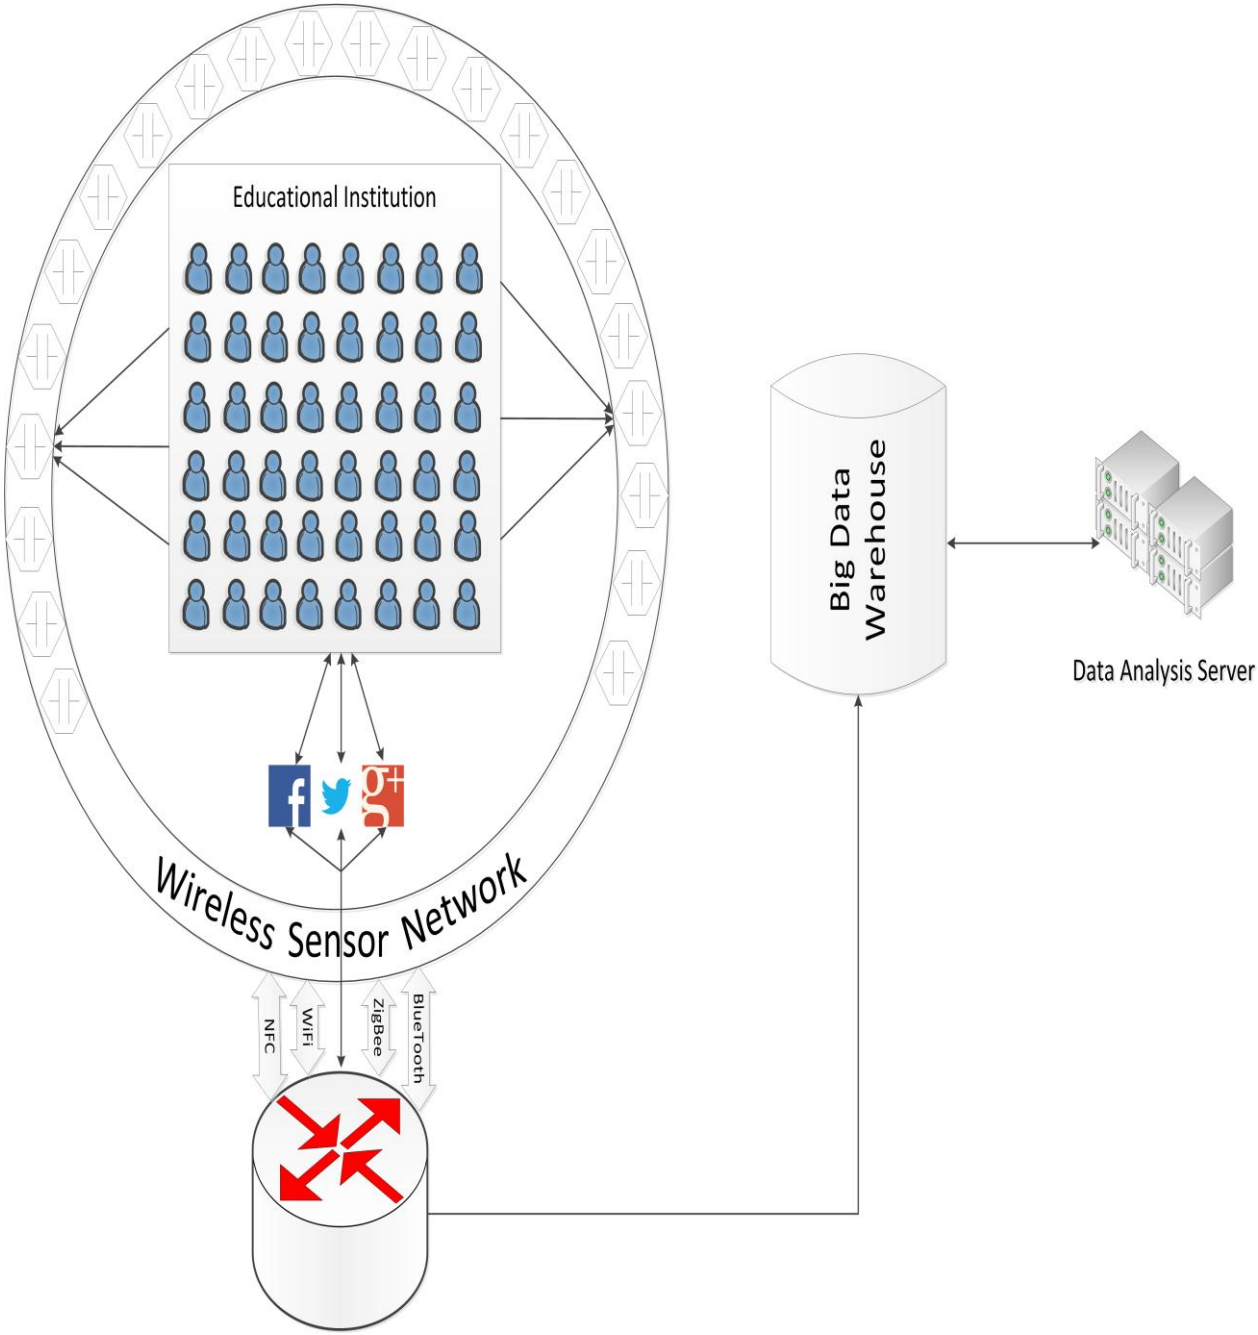

Figure 2: A model for e-learning based on crowdsourcing and Internet of Things

The main purpose of the model is to improve the learning environment according the needs of students.

Students can take surveys and choose their favorite learning styles. These information can be used for creating different teaching materials for each learning style. Data about students can be acquired by using sensors. For example, each chair can be equipped with presence sensor which is useful for creating historical report related to the number of students present on the lecture. Big Data Warehouse and Analytics Server are capable of graphical data visualization. Sensors can also provide participants of the teaching process with the data of teaching environment. It is possible to get values related to temperature, humidity, sound noises, brightness etc. These values can be in correlation with students' motivation and their attention. Different students can prefer entirely different environmental factors, i.e. some students better learn when the

temperature is about 17°C, and others prefer environments with 25°C. Students can vote about their favorite environmental factors. A mean value of the voting results can be used for adjusting environmental factors, such as air conditioning or heating.

Crowdsourcing concept can be used for getting feedback from students about their satisfaction of lecture classes in real time and encouraging students to participate in creating of teaching materials, according their own interests about particular subjects. The proposed model can be integrated with social media. The big data and analysis subsystems can collect data posted on social networks and analyze them. For example, if a student posted a tweet “I am cold” on the day when temperature was 20°C, this information can be used for further analysis of student’s preferences.

4. CONCLUSION

Internet of Things and crowdsourcing in education are not widely used nowadays. The proposed model uses crowdsourcing and Internet of Things concepts for building smart learning environment. Students can provide preferred values of environmental variables or these data can be acquired via social media. In future, the model can be expanded by adding more sensors to the environment according to feedbacks of the students who attended experimental classes in smart environments.

Abstract: *Development, availability and accessibility of information and communication technologies lead to new paradigms in teaching and learning processes. This paper describes a new approach for learning simulation processes. Main goal of the research is to improve process of learning simulation by leveraging platform as a service cloud computing paradigm. The main components of the proposed model are: private cloud of an educational institution, platform as a service delivery model, and platform as a service engine API. The proposed solution is designed to improve scalability, availability, security and modularity of simulation learning processes.*

Keywords*: learning simulation, cloud computing, platform as a service, simulation infrastructure*

1. INTRODUCTION

Modern technologies are used every day for very different purposes: to communicate, collaborate or retrieve information from services, to improve learning process, etc. Many universities in the world organize courses and trainings via distance learning systems. The concept of e-learning can be successfully applied to learning simulations. Simulation tools provide environment for the analysis of various features of system: feasibility, behaviour, stability, performance, etc. (Granlund, Berglund & Eriksson 2000; Banks, Carson, Nelson & Nicol, 2010). However, a majority of simulation tools have limitations such as platform dependence, high costs, maintenance difficulties and limited reusability (Byrne, Heavey & Byrne, (2010); Kuljis & Paul, (2003)). A rapid development and ubiquity of Internet and Internet technologies have had an impact upon the field of simulation, as they provide numerous ideas on how simulation can be improved. One of the methods to overcome these limitations is to develop a cloud computing based model for learning simulation.

The main objective of this paper is to provide a preview of development and realization of model for learning simulation which is based on cloud computing infrastructure in a higher education institution. Proposed model is developed as platform as a service in aim to provide scalability and reliability of educational applications and services. The model can be successfully applied to the study and modelling of processes, applications and real-world objects.

2. KEY CONCEPTS

2.1. Cloud computing

Cloud computing is an area of computing that refers to provide users with highly scalable IT capacities as a service via the Internet. Services and data coexist in a shared and dynamically scaled set of resources (Srinivasa, Nageswara, & Kumar, 2009). Cloud computing is an infrastructure that can bring a new value to an e-learning system, as educational services can be delivered in a reliable and efficient way. It also provides a suitable environment for ubiquitous learning activities (Despotović, Simić, Labus, Milić & Jovanić, 2013).

Talking about application of cloud computing infrastructure in higher education, three basic approaches can be noticed. First approach is complete outsourcing of e-education infrastructure (Sultan, 2010) second approach is cloud within the private infrastructure (Caron, Desprez, Loureiro, & Muresan, 2009) and the third approach represents combination of previous two approaches (Costanzo, Assuncao, & Buyya, 2009). There are three types of model for service delivery: Infrastructure as a Service (IaaS), Platform as a Service (PaaS) and Software as a Service (SaaS) (Peter & Grance, 2011).

The aim of the implementation of the private cloud is to provide users run virtualized infrastructure, environment and service. The system for managing virtual infrastructure will automate, coordinate and integrate the existing solutions for: networking, storage, virtualization, monitoring and management of users. In this way, students and teachers are provided with tools for quick and easy access to the necessary educational and scientific services and resources. (Vujin, Simić, & Kovačević, 2014)

There are several open source packages that take a holistic approach and integrate all of the necessary functionality into a single package (virtualization, management, interfaces, and security). When added to a network of servers and storage, these packages produce flexible cloud computing and storage infrastructures (IaaS). However, in order to fulfill specific requirements, such as providing PaaS on demand, it is necessary to develop a new solution developed to enable integration software for learning simulation and cloud computing infrastructure of educational institution.

Cloud computing can be applied in educational institutions using different deployment and technology models. The problem of modeling infrastructure is specific in terms of resource provisioning and how to deploy virtualized services (Sotomayor, Santiago, Llorente, & Foster, 2009). In (Ercan, 2010) author gives a review on how higher education institutions can benefit from CC infrastructure. Main areas of application include: students and administrative personnel have the opportunity to quickly and economically access various application platforms and resources through the web pages on-demand, cost of organizational expenses are reduced and more powerful functional capabilities can be offered.

Much research has been done in the field of cloud computing in the previous years. However, only a small number of authors deal with the problem of developing and deploying a “platform as a service” model in order to support e-learning. Main research directions relevant to the problems outlined in this paper include supporting simulation learning within cloud computing environments, modelling the cloud computing platform, and resource management in systems for learning simulation.

2.2. The development of simulation approaches

The area of computer simulation has been successfully applied to the study and modelling of processes, applications, and real-world objects. Simulation enables computer-engineering students to analyze various types of systems, investigate relations and interactions between a system‟s components, design a model and an implementation of a system, verify different solutions and environments, and test projected capabilities and technical characteristics.

The main purpose of an educational simulation system is to enable a cheap and easy learning and practising environment, particularly suited for students of engineering (Zikic & Radenkovic, 1992). A Web-based simulation allows simulation to be carried out over the Internet using a standard web browser. A Web-based simulation is defined as the use of resources and technologies offered by the Internet for ensuring an interaction with the client and server modelling and simulation tools (Byrne, Heavey & Byrne, 2010). Downloading simulation software via the Internet and executing simulation on the user‟s computer, independent of browser doesn‟t fall into the category of web simulation: the browser plays an active role in the modelling and simulation process (Byrne, Heavey & Byrne, 2010). The key advantages of the web-based simulation approach are the following: wide availability, controlled access, efficient maintenance, increased integration, availability, interactivity, collaboration, cross platform compatibility and interoperability.

Resource demanding simulation software used to be available to researchers in big scientific centres and big companies which could afford expensive hardware for this purposes. Each researcher needed access to computer with software that is used for modelling and simulation execution and data analysis. Limited resources implied also limited possibilities for performing experiments. Besides that, there were limitations in software infrastructure, especially in simulation experiments which included two or more linked simulations. As we have seen, Cloud computing offers virtually unlimited hardware infrastructure, so companies and researchers who are users of simulation platforms do not need to possess their own servers and other infrastructure. Leasing of simulation software as service (SaaS) offers notable advantages: scalability,

configurability, significantly less time for simulation models and software development (Marinković, Čavoški & Marković,2014).

The reason we propose platform as a service model for learning simulation is that it is beneficial for simulation software to exploit the tremendous resources and huge amount of storage, that cloud computing is able to provide. Another reason to use platform as a service model is the use of composed simulation services. Composed simulation services are constructed by governing multiple individual simulation services and/or composed simulation services within a common temporal factor. Platform as a service model enables user to use and change predefined simulation model or part of the model. This approach enables active planning and monitoring capacities in real time, so that infrastructure can dynamically be scaled to support high loads of users„ requests.

3. PLATFORM AS A SERVICE BASED MODEL FOR LEARNING SIMULATION

Using the concept of cloud computing, educational services and resources can coexist in a shared and dynamically scaled environment. In a higher education institution, IT infrastructure refers to a set of hardware, software, network and other resources meant to provide modern services to support teaching, learning, research, promotion and other processes within the institution. The infrastructure has to be flexible, scalable, reliable and safe, and these requirements can be fulfilled through a private cloud. The architecture of the private cloud is based on flexible federations of servers, storages and networking (Cerbelaud & Huylebroeck, 2009).

Main goal of developing a model of infrastructure for learning simulation is to create a framework, standards and techniques that will lead to higher quality of the overall education process. Key principles in designing the model include:

- Scalability
- Availability
- Security
- Modularity

The model of infrastructure for learning simulation developed as a platform as a service is shown in Figure 1. The model contains: infrastructure (hardware) support, big data database, high-performance, distributed memory object caching system, tasking - asynchronous task queue, servers, controllers, web server solution for proxying TCP and HTTP-based applications, platform as a service engine api and fault tolerance layer. All components are in details described in the text that follows.

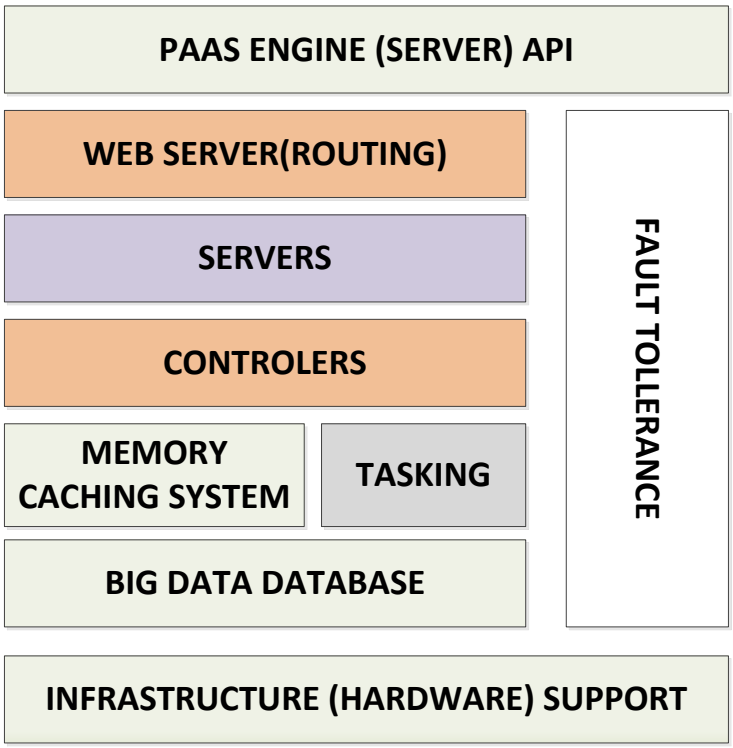

Figure 1. Model of infrastructure for learning simulation developed as a platform as a service

Figure 1. shows the design and implementation of model of infrastructure for learning simulation, an distributed software system that implements a cloud platform as a service (PaaS).

The PAAS engine API includes a module for teachers and a module for students. The module for teachers enables them to create, update, test and manage cases and problems. Teachers can also perform basic system administration tasks such as managing user accounts, resources, etc. Web server should be particularly suited for web sites crawling under very high loads while delivering web assets with unparalleled speed, maximizing performance and efficiency. This solution should support tens of thousands of connections. Its mode of operation makes its integration into existing architectures very easy and riskless, while still offering the possibility not to expose fragile web servers to the Net. Servers are controlled through PAAS Engine SDK. In first phase SDK should provide support for python scripting language. Production of these scripts would be done on some open source 3D graphics and animation software. Memory caching system enables high-performance, distributed memory object caching system and it should be an in-memory key-value store for small chunks of arbitrary data. Tasking system should be focused on real-time operation, and enables support for scheduling as well. The called tasks should be executed concurrently on a single or more worker servers using multiprocessing. Tasks should be preformed asynchronously (in the background) or synchronously (wait until ready). Big data database layer should provide linear scalability and fault-tolerance on cloud computing infrastructure. Leveraging in-memory computing, big data database layer should provide high performance for both reads and writes. Fault tolerance layer should provide resistance to faults within a cluster. It should enable replication support for applications and their data. Processes should be monitored and restored for cases where they have terminated or when they are misusing resources. Using proposed model, system is able to provide fault tolerance and elasticity automatically and in a straightforward manner, since any virtual machine can take on any role on-demand.

A more detailed overview of the proposed model is given in figure 2. The core infrastructure components include:

- A repository of predefined customizable models
- A model transformation service that transforms external models into an internally supported simulation format
- Task management services that manage the entire process and implement fault tolerance
- Task and result queues that accept and store jobs until they are executed by processing nodes
- Interprocess registry that stores all variables shared between the tasks
- Trend analysis and reporting service
- Web interface for creating, editing, and executing jobs.

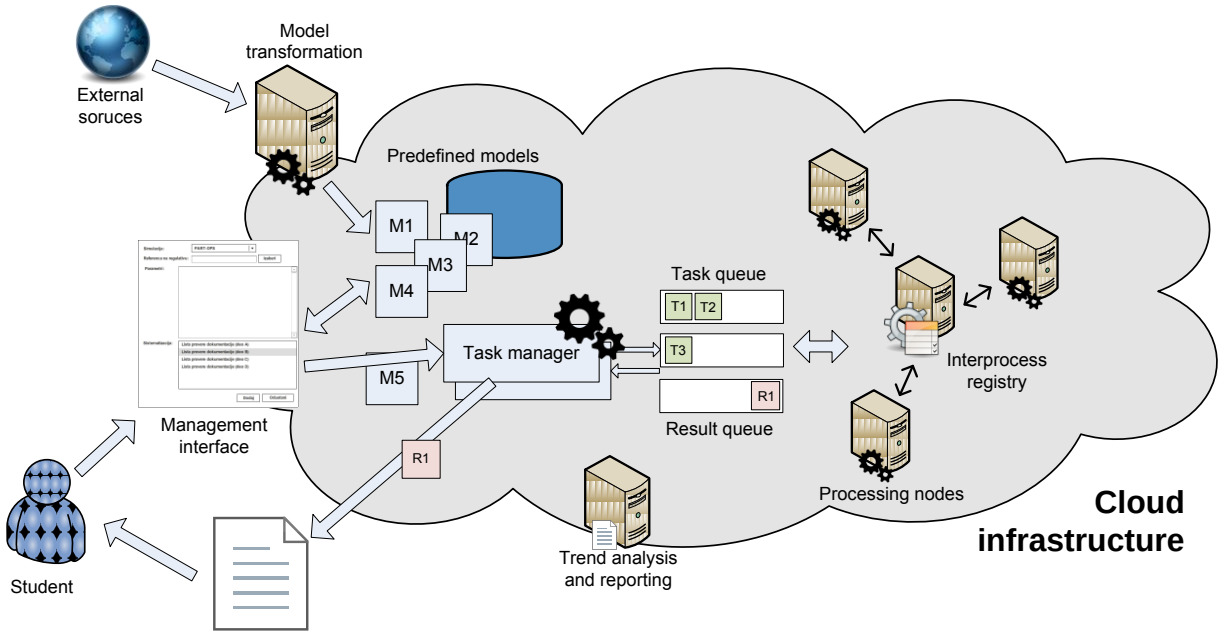

Figure 2 Detailed overview of model for learning simulation developed as a platform as a service

The standard usage scenario for the presented model is based on simulation models defined and stored in an internal model repository. These models describe standard simulation scenarios, and possess modifiable parameters and components. The students can access any of the existing models and modify them to suit

their need, as well as define new models using existing components or external sources. The management and execution of these models is performed through a simple web interface. The backend of the management interface communicates with the task manager, by sending him specific parameters of the simulation model relevant for its execution.

The task manager represents a core component of the system that performs orchestration of all tasks, retrieval of results, and is replicated in order to provide fault tolerance. Using the parameters received from the user, the task manager calculates an estimate of required time and resources for optimal task execution. The calculation is presented to the user. If the student"s privileges are inadequate for execution of submitted simulation (where limitations to maximal CPU/memory allowed are applied), the interface will require the student to modify parameters. When all system conditions are met by the model, the user can submit the model to execution in the system. Upon submitting a simulation model, the task manager decomposes received models into individual tasks/processes. Models are decomposed based on the degree of their mutual independence and processes with the least interdependencies are apportioned directly to the task queue. The processes that are highly interconnected pass another round of analysis in order to ascertain their requirements. This round is performed in order to weigh the potential losses incurred when tightly coupled processes are distributed into separate tasks. If the loss outweighs the gains from parallelization, the processes are bundled into a single task; otherwise, they are distributed into separate tasks.

When execution nodes complete their previous tasks, they poll the queues of corresponding types and grab the tasks. Processing nodes differ in the amount of processing power and memory resources allotted, and are linked to specific queue types, i.e. some queues contain tasks for less powerful nodes, others contain more complex tasks. During the execution, the tasks occasionally need to communicate changes of variables to other tasks. This is done by reporting all such changes to the interprocess registry. The interprocess registry is a quick, memory-based caching system that stores variables shared between processes. Upon completion, the simulation results are forwarded to the result queue. The task manager polls the result queue in order to ascertain whether all of the composing bits of the model are complete. When all processing is completed, the task manager synthesizes all bits into the result, which is then sent to the user. User behavior and executed simulation models are continuously tracked, and all activity is recorded in the logs. These logs can be analyzed later using the trend analysis and reporting service. The results are generated as HTML pages enriched with interactive JavaScript visualizations.

In a platform as a service approach, developers code to standardized APIs. This represents a paradigm shift from infrastructure as a service, where users decide what software needs to be installed, what version of each piece of software are needed to work together, how to configure the software, maintain it, and finally write the software they set out to create. With platform as a service approach students only need to worry about writing their application. Our solution handles how to deploy application to best serve users and provides user with ability to control platform as a service deployment.

4. CONCLUSION

The Internet enables a distributed environment for utilizing simulation tools. The cloud computing concept and its characteristics can help higher education institutions improve productivity and enhance hardware and software resources management that are necessary to provide e-education features, scientific and research activities and students projects (Dong, Zheng, Yang, Li, & Qiao, 2009). By using modern Internet technologies, the transition to platform as a service based model for simulation is simplified. Today, researchers are focused upon finding new approaches and environments that can make learning simulation easier. The potential benefits of designing, developing, and using platform as a service based simulations are huge, and they include improved efficiency and effectiveness in the learning experience.

The objective of this study is to introduce a new platform as a service based environment for learning simulation. The material in this study has provided comprehensive concepts and techniques for embedding specific software tools used in engineering education. The future research is directed toward improving and implementing the model as a proof a concept. Also, the model should be improved with additional features to enable collaborative modelling of systems.

Abstract: *This paper presents a web platform for learning Internet of things in a higher educational institution. The platform enables students to learn about Internet of things and helps them to build applications that can be run on smart devices. The main goal of this paper is to introduce new services and platform to students that will foster e-learning in the Internet of things environment. Paper also presents a model for learning Internet of things that integrates a cloud web application with web services and Moodle Learning Management System. The application uses web services and different smart devices to allow students to build various applications and learn about Internet of things and devices connected with this platform. Model is developed and implemented within Laboratory for e-business at Faculty of Organizational Sciences, University of Belgrade.*

Keywords*: Internet of Things, Raspberry Pi, Arduino, Web Service, Cloud Computing, Moodle.*

1. INTRODUCTION

The Internet of Things (IoT) is the network of physical objects that can be controlled and accessed through Internet and can be used to perform some simple or more complicated tasks. The main devices in IoT paradigm are actuators and sensors. Sensors are objects that receive signals and measure it on some way and actuators are the objects which do some action after receiving some signal.

For example we have temperature sensor which measures temperature. Other example is fire sensor which only shows if there is a flame near the sensor so it returns only true or false (Boolean). Objects which receive some signal and then make some action we call actuators. In other words the devices which are able to perform some actions that will have an impact on the physical realm we call actuators (Miorandi, et al., 2012).

Actuators are objects that react when some signal or smart devices tells them so. For example when temperature is higher than 300 degrees some microcomputer sends a signal to actuator to open the window.

The next era of computing will be outside the traditional desktop approach and devices and their controllers will communicate over the Internet. In the Internet of Things (IoT) paradigm, many of the objects that surround us will be on the network available to communicate on the demand and we will be able to access them even when we are not close to them. Radio Frequency Identification (RFID) and sensor network technologies will be used more in the future to help people and perform some tasks instead of them. It is predictable that, in the future years, the Internet will spread more and more and we will be wrapped all around us with smart devices which will be used for various goals such as education, fun, spraying garden and so on. Content, services and smart devices will be all around us, always available and ready to help us when we need so and enabling new ways of working, interacting, and new ways of living and demanding from programmers new services and applications which will manage with smart devices and tell them when to do some actions. In the future we will be able to rely on sensor which will spray the garden when the earth is dry or order food when our refrigerator is empty.

This paper presents a model based on cloud web applications that could help informatics students to achieve basic knowledge in IoT through process of computer-mediated activities that include presentation of IoT devices, their structure, how they could be connected with other devices and what it could be done with them using the present platform. Platform is integrated with Moodle Learning Management System and developed and implemented at Laboratory for e-business at Faculty of Organizational Scientists. At start, on our platform intelligent devices that will be used are Raspberry Pi microcomputer and Arduino microcontroller. Reason for choosing these two devices is because they are very cheap, easy to use and very easy to connect with web services and actuators which we will also use to perform actions after giving signal over smart devices and Internet web service. A platform for learning IoT is developed in scope of

Laboratory for e-business and deploys Raspberry Pi microcomputer and Arduino microcontroller as intelligent devices.

2. LITERATURE REVIEW

In the last few years, in the area of wireless communications, a new paradigm named the Internet of Things (IoT) which was first familiarized by Kevin Ashton in the year 1998, has gained increasingly more attention in the science and industry and today it is all around us in its various forms ready to help us complete some tasks and jobs. (Santucci, 2009).

Introducing IOT in an environment can be achieved by introducing and linking intelligent devices in various places and giving them various tasks to perform. There is a number of different applications of IoT which can be used in business, education, transportation, logistics, healthcare, public administration, etc, which make life easier and better (Atzori, Lera, & Morabito, 2012).

It is an advanced intelligent devices paradigm that requires technology, knowledge and infrastructure, at the level of which is available, for now only in rich, developed countries. In developing countries IoT solutions can provide more profitable economic development and greater opportunities for outsourcing and really help people to by making their life easier. Cheap micro devices such as Raspberry Pi and Arduino can enable the development of various systems with less investment in infrastructure but with enough power to handle basic applications and requests which are needed to perform tasks (Raihan, 2013)(Kaloxylos, et.al., 2014).

Raspberry Pi and others similar devices provide Application Programming Interfaces(APIs) that abstract his low-level operations , enabling effective use and operation of multiple perspectives .

Depending on the educational context, one can adopt several approaches to learning IOT 's. At the lowest level are individual IoT devices, whose understanding requires knowledge of low level - knowledge of electronics and programming microcontrollers. The middle level is oriented towards computer science and includes communication protocols, systems integration, web services, user interfaces, and so on which will control these devices. Teaching IOT brings a set of problems for students and teachers, particularly at the higher levels of IoT 's. Some of these problems are (Raihan, 2013):

- The need for the use of complex hardware and software tools which are not always available,
- lack of time to create complex IoT projects and always learning about basic applications,
- Lack of implementation of all functionality IoT project .

One approach to teaching IOT is to use simulation tools to simulate the device or the environment in which they will be placed. An example of this approach can be seen in (Callaghan, 2012), where the authors used an electronic board that they have developed themselves. This platform is capable of processing digital and analogue inputs and simulation of home devices. Using this approach teaching can be performed even without the hardware components and the complete course can be more concentrate on the software aspect of the IoT 's even without expensive equipment such are some expensive actuators and complicated sensors. However, the simulation cannot replace the all benefits of working with the real hardware devices and potentially limits the imagination of students, forcing them to work in the framework of simulated scenarios which could not always represent real problems and components so the experience could not be always as the one that can be earned with working with real devices.

Nowadays, new type of service based computing is becoming more and more interesting for programmers. Its name is cloud computing and its main ides is to provide service over Internet on demand. Cloud computing represents extension of virtualization and grid computing. "*Cloud computing makes the computing resource become a kind of professional service, and provides them to users in an informational way*" (Yilmaz, 2011) Cloud Computing represents a highly scalable, and very reliable computer infrastructure that hosts applications for the end-users. Also, Cloud Computing allows efficient usage of resources because having several virtual machines which can operate together so there are a smaller chances of the whole system failrue than there are when an application is running on a single machine (Huang, Li, Yin & Zhao, 2013):

3. MODEL FOR LEARNING INTERNET OF THINGS

The presented model was developed within of Laboratory for e-business at Faculty of Organizational Sciences, University of Belgrade. Present model was designed for students that take a part in subjcects such as "Internet of intelligent devices" on Faculty of Organizational Scientists at all study levels. Within the mentioned subjects students are available to see what are intelligent devices, to learn about them and to

develop smart areas such are smart houses, smart parking, smart classrooms and so on. A generic model for learning IOT should have three layers: Application layer, service layer and the device layer. On the device layer students can use devices such as Raspberry Pi and Arduino because they are very cheap and they have enough power to handle basic instructions and pass them to actuators which will do the specific job. Stronger and more expensive devices can be added if there is need for them. They can be used for some more complicated projects. For the academic purposes, universities don't need to buy expensive actuators. Instead of them some university can use just few led diodes coloured in different colours which could represent different actuators. For example, Red diode could represent fire, yellow presence of magnetic field and white presence of water. On the service layer we have Internet web service that should be able to handle requests from the application layer and also communicate with device layer by sending commands to devices and receiving signals and voltage from devices which will be send to application layer where it will be analysed and, after that, certain action will be performed. Web service should be also available to communicate with the external devices and phone devices which could send some request to application layer that will be processed and send, also over the service layer, to devices to be performed. Application layer and device layer should be inside a cloud ,which will provide us better provide us better and more redundant services so we don't have to worry about system fail true. Platform, through application layer, should be connected with platform for e-learning. Reason for doing this is to integrate theoretical and practical learning which will be described later. In addition, after integration of IoT platform with Moodle Learning and Management System process of grading will be faster and more efficient and some grading could be performed automatically. For example, some applications on application layer can receive signal that certain actuator has been used and, after that, information about well done job can be send to Moodle and students who made actuator move can be graded automatically. Model for learning Internet of things is shown in figure 1.

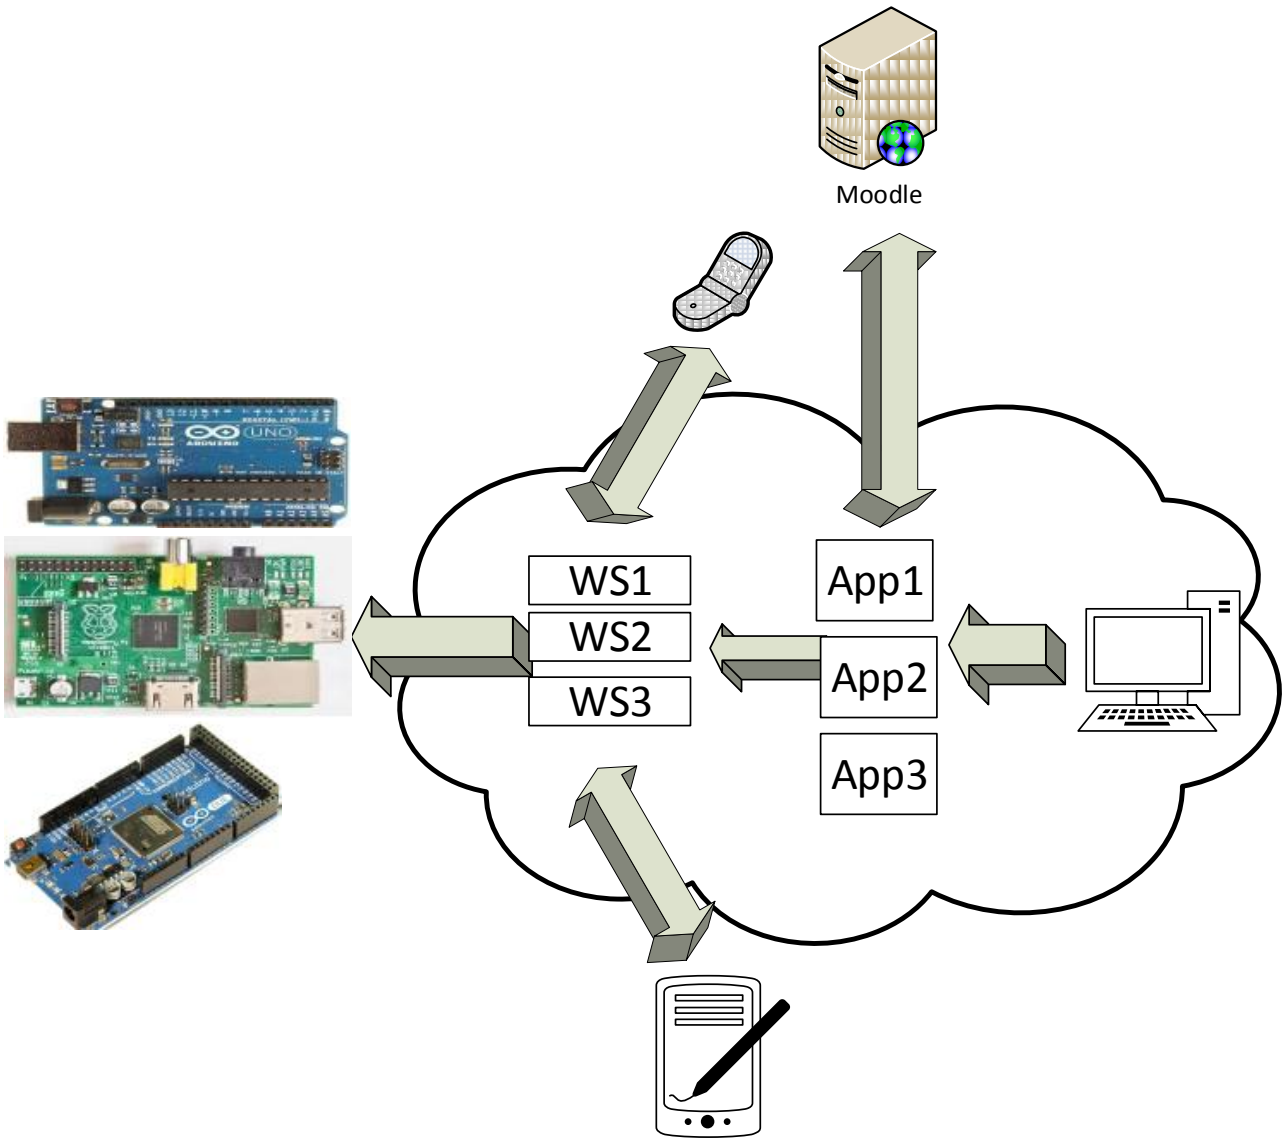

Figure1: Model for learning Internet of thing

When someone adds devices on the device layer, it also should be registered on the application layer so the basic user will be able to use devices through simplified commands. For example, if an university has a Raspberry Pi microcomputer, students can create some generic functions which could be integrated in applications so basic user can drag and drop wanted functionality which he needs it and use it on some pin. Other example can be building application for checking is there a fire in some area, so students can make generic application which sends an e-mail or text message to some address about presence or not present flame in some area. Also, microcontrollers should be registered on web service layer because service layer needs to have a functionality of receiving signals from devices and sending it to application layer or mobile phone or PDA.

Also, some generic functionality on device layer can be integrated in advance. For example students can build functionality of receiving signal from some pin and returning true or false if signal is present. After that, user only needs to set pins for receiving signal. For example, if some university is using Raspberry Pi, they can build generic Python function that returns true if signal is present on some pin and false if signal is not present.

External devices such as mobile phone; PDA devices and so on should have functionality of receiving and sending signals through web service with mobile applications which also should be developed in this course. Also these devices should have a functionality of communicating with application layer and using simplified applications to use smart devices through them. Application layer will contain mobile applications for communicating with devices directly so the user only needs to download the application, install it on the phone and set an ip address after what he can communicate with devices directly. Mobile application should be upgraded every time when some device on device layer is registered and ready to use.

Role of Moodle in this platform is important. Using Moodle and with principle of Blended learning, students will be able to get all literature they need to get theoretical knowledge about IOT and smart devices that we are using on the device layer (Despotovic-Zrakić, et al., 2012) Also, with a help of Moodle teachers are able to track progress of each student. Every student has his own account on Moodle where his activities and grades are stored and which are visible every time when student wants so. Moodle also should contain some tests, quizzes and puzzles which could be solved and by solving those students can earn points and higher grades. Also, on Moodle teachers can create tasks that need to be solved. When teacher creates a task he also needs to create a small application on application layer and new listener on web service layer.
For example one of tasks could be developing Python application for Raspberry Pi which call's fire department if sensor on Raspberry Pi notices smoke in a house. Sensor could be replaced with a led diode. When a certain student makes function which turns on a led diode of noticing a smoke, a web service gets information that a diode is turned on and sends information's on applications layer which sends that information to Moodle. When Moodle gets information about turning on a led diode by a certain student, service writes points for certain task to student who made a function that turns on a led diode.

Application layer should also contain information about devices on the device layer. Information about certain device should have its picture, described performance, ports and some examples connecting devices with sensor and actuators. Description should be implemented in an interactive application which could allow students to click on some of parts of devices after what students will see the description of certain device part and picture of that part. That will help students to get theoretical knowledge about every element of smart device and it will help students understand purpose of every part. Moodle also should have tests based on devices description and parts and students, after seeing the device description and parts can try a Moodle test and see how well they have mastered material about some device. After completing the test, student will get points which will be a part of grade from a subject based on IOT.

On application layer students and teachers also can describe different sensors and actuators. This description will contain performance of sensor or actuator, its price, usability and a small example code which shows how easily students can use certain actuator or sensor in combination with some smart device and how to connect it on smart devices. Also, descriptions should contain an example how students can simulate certain actuator with one or more led diodes and also a small code example how to simulate actuator with led diod. If student chooses to try actuator simulation, code for simulating actuator is being put to one of devices and then started. After this presentation application layer removes code from the device if it's not needed anymore. For sensors, application layer will have example codes how to simulate some signal from sensor with Python or C++ functions and explanation how often signal should be send which will be send to service layer and after that, on application layer processed and utilized. Later, students can run these codes on Raspberry Pi, Arduino and similar smart devices to simulate sensor behaviour and complete tasks even without having a real sensor or actuator.

Application layer would also have a description of devices that university don't have on the device layer and description of their performance and all benefits and faults which can come with a certain device. For some simple microcontrollers, application layer should have a small simulator which allows students to try how it is to use a certain smart device which will allows students to feel the difference between devices. This part will be particularly hard to develop because programmer of this application needs to simulate whole smart device, it's performance, behaviour and weaknesses, it's connection with sensors and actuators and their communication, but, from the other side, virtual smart device will only exist on the application layer and it won't be necessary to register that device on the service layer and on the device layer. Also programmer doesn't need to develop whole virtual smart device and its all possibilities. Instead of that programmer can just make a virtual smart device which will perform basic functions such are connecting with few sensors and actuators and some basic commands in programming language which certain devices uses.

Application layer will also have a videos section which will allow students to see the look of various microcomputers, microcontrollers, sensors, actuators, different smart devices and equipment that is useful for IoT, how to connect microcomputers with microcontrollers, how to attach sensors and actuators to certain smart device and how complex systems of devices, sensors and actuators work. Videos section should also contain videos that show how sensors look and how they can be used, videos section also should contain a section that shows what could be made with smart devices. For example, students or teachers could make a video how smart classroom should look and what smart devices, sensors and actuators we need to have to build a smart classroom. Besides these videos, section will have documentation that describes, step by step, what it takes to build a smart areas such are smart classrooms, smart parkings, smart homes and so on.

Also, platform should have implemented inside itself open-source application called Fritzing which allows students to virtually connect various devices and see what they would get with connecting them because, sometimes, working on real device could damage it if student didn't have earlier experience with smart devices and electricity. Also platform should have some test based on connecting devices like it's done in Fritzing where students can verify that they have a mastered connecting devices smart devices with other smart devices, resistors, actuators and sensors.

Next functionality of this platform is also connected with Moodle. On Moodle, students can choose witch project they want to make and sign up for it. When they sign up, application layer creates project folder for the specified project after what students can start building their application or service. Also project folder will contain documentation about equipment that can be used for specific project such are smart devices and their ip addresses, which sensors, actuators or led diodes students are allowed to use and on which pins specified diodes, sensors and actuators could be found. Student will also get a folder on the device layer where his code should be written. Reason for implementing functionality like this it to allow students to actually work with smart devices from their homes without having their own smart device. Also, if students want so, they can use their own smart devices and connect them with platform's web service or build also and their own service layer and connect their system directly with application layer. After implementing their application on the application layer, students need to make, or, depending of type of specific task, use already build web service that connects smart devices on the device layer and new application on application layer. After completing the project, students will get a grade on Moodle.

Besides this, students will be able to take part of bigger projects for which they can sign up on Moodle. For example, students can sign up for building one of web services or application functionality that is a part of larger application which is being currently developed. After completing some part of application, students will get certain amount of points on Moodle.

Students can also make their own documentation and descriptions of sensors, actuators, microcontrollers and microcomputers or any other part of devices and equipment that they have been using or just suggest what smart device they wish to use and why. After making documentation about specific subject, students can upload it on local server through application layer and, after it passes the checking, documentation will be available for everyone enrolled in this course to see it.

Besides this, students also can make their own presentation of devices which have not been described or mentioned on this platform yet. For example, if students have been using some new microcomputer or microcontroller, student can make a jQuery presentation of device which shows for every device part description and role which certain device part has which will be showed when we place a mouse over it and which shows bigger description and presentation of device when we click on it.

The implementation of the presented model can potentially be very complex, with a large number of interconnected services. Although not necessary, an optimal solution in such conditions is to utilize a cloud platform, providing high scalability and redundancy, with better utilization of available processing resources

(Beaty 2013; Sultan 2010). The suitability of utilizing cloud infrastructure in higher education is presented in a number of research papers (Despotović-Zrakić et al. 2013; Ercan 2010).

4. CONSLUSION

This paper presents a model based on cloud infrastructure that helps students achieve basic and intermediate knowledge in the area of IoT. Advantages of presented model are its way of acting because it uses a specific type of learning which could be very interesting for students and which helps students to start learning about IoT on the way where they can choose which things they like to learn and skip things they already know.

The presented model is simple, cheap and scalable and it wouldn't take long to be implemented. Model like this would allow students to learn about Internet of things on easy and interesting way through tests, quizzes and projects which could be useful in real life and which can be taken from Moodle Learning Management System. Biggest advantage of this platform model is because it allows students to start learning about IoT exactly from their current level. For example, if student already is working with smart devices and really knows what are sensors and actuators, he can take a part of bigger and more complicated projects and extend his knowledge. From the other side, student who doesn't know anything about smart devices can use application layer for developing applications which will allow him to work with smart devices without any earlier knowledge about them. We can conclude that this type of learning would be easy and interesting because very similar approach is already been implemented at Laboratory for e-business at Faculty of Organizational Sciences, University of Belgrade, and it has outstanding results because students are learning very fast and classes are very interesting and with great quality

Abstract: *This paper presents a model for mobile adaptive learning specifically oriented towards the field of language learning. Adaptivity is especially significant in the mobile environment where the learning is performed on the move, in short time intervals, and where the learners' cognitive capacity is often limited. The main goal of this paper is to improve the mobile language learning process using adaptive techniques. Several types of adaptivity applicable to the mobile environment are considered, and an ontological framework supporting aggregation of atomic content units into learning objects and adaptation based on learners' knowledge, interest, behaviour, device, and context is presented. A cloud and web-service based system for adaptation is envisioned on top of the ontological framework and presented, with some implementation suggestions and possibilities discussed.*

Keywords: adaptive learning, mobile learning, ontologies, learning objects, cloud computing

1. INTRODUCTION

E-learning systems support complex learning processes, services, elements and users' roles. Learners are often diverse even if some learning contexts imply the existence of some similarities in their interests and demographic parameters. Various types of e-learning resources are also abundant, each possessing a different structure, and educational and presentational requirements. Accordingly, e-learning systems need to be able to mix and match learning resources in order to accommodate different types of learners.

Mobile learning systems are faced with the same problems, as well as those stemming from the characteristics of the mobile environment. Learning activities and resources must adapt to both the users' and devices' characteristics. Mobile learning is performed on the move, with time constraints and limited cognitive ability of learners, and all aspects of the learning process must adapt in order to keep the interactions with the user simple, effective, and motivating. Language learning also introduces a number of specifics stemming from the high granularity of the learning content, and concepts like learning objects and ontologies can help in describing the learning domain in a way conductive to adaptation algorithms.

The main goal of this paper is to improve the mobile language learning process by designing a model for adaptive learning. The second part of the paper outlines the theoretical background concerning the approaches to adaptivity and mobile language learning. The model for platform-independent adaptive learning, including an ontological framework, adaptation components, and a cloud-based infrastructure is given in third chapter. The final chapter discusses the presented model and possible future improvements.

2. THEORETICAL BACKGROUND

Mobile technologies are a viable solution for learning performed on the move and with heavy time constraints, allowing the learners to control the preferred pace and the location of learning (Wang, Shen, Novak, & Pan, 2009). Such a push towards student-centered learning produces a new problem - increasing the learners' freedom increases the importance of their self-motivation and interest for the area of study. This puts additional importance on understanding the users' needs and interests, and mobile applications should use any means possible to additionally motivate the learners.

Learning resources are easy to access using web-enabled devices, but these resources are usually not very well suited for use in the mobile environment. The designers must adjust the learning environment and the presentation of educational content in order to find an optimum model of interaction with the users. Innovative methods of presenting information, imaginative interaction patterns and edutainment concept make the learning material more accessible to less motivated learners (Arnone, Small, Chauncey, &

McKenna, 2011). The success of such methods inherently depends on two factors - the learner and the device used for learning, and learning activities, lesson structure, extent, and presentation need to adapt to each specific user and device. Additionally, the mobile learning applications can utilize the learning context as a basis for further improvements of the learning process.

The domain of language learning also introduces a number of specifics that need to be considered. Learning vocabulary is the main activity of language learning and requires a high level of repetition from the learners. Language learning can benefit from multimodal learning, while the concept of "learning paths" is of less importance because the highly granulated nature of the core educational content (words) makes it difficult to structure into meaningful units.

Learning systems can be adaptable, allowing the learners to personally change various system parameters and behaviour, and adaptive, possessing some form of logic for automatic adaptation according to learners' behaviour. An e-learning system is considered to be adaptive if it can monitor users' activities, interpret them using domain-specific models, infer user requirements and preferences out of the interpreted activities, represent them appropriately in associated models, and act upon available knowledge about the users and the subject matter in order to dynamically facilitate the learning process (Paramythis & Loidl-reisinger, 2004).

Adaptive e-learning systems come with a number of constraints (Despotović-Zrakić, Marković, Bogdanović, Barać, & Krčo, 2012). Adaptive e-learning systems are complex and expensive to develop and integrate into the educational process. Learning content is often impossible to recreate and use anew, and different learning systems are not interoperable. Course administration, content authoring and other operations are more difficult to carry out in adaptive systems, and teachers/administrators are expected to have some preknowledge about the system. Time is an important factor, and adaptive systems need to know about the students' needs as soon as possible in order to maximize the time a student spend in a personalized environment.

In order to allow matching of appropriate educational content with user/environment characteristics for the purpose of adaptation, the content needs to be annotated at some, preferably smaller level. Learning objects are a concept of e-learning that can serve to this purpose. Learning objects (LOs) denote small, compact educational units focused on achieving a specific educational goal, and most authors put the emphasis on their characteristics – smaller scope, reusability, relative independence, and the possibility of aggregation (McGreal, 2004). These characteristics of learning objects, beneficial for the process of adaptation, are mostly enabled by their heavy reliance on metadata. Metadata can describe both the educational characteristics of learning objects, usable for finding the right content for a specific learner, and the technical characteristics, usable for device adaptation. Different metadata models and standards for learning objects have been developed, IEEE LOM (IEEE Learning Technology Standards Committee, 2002) being among the most prominent. IEEE LOM standard is expandable and can be used to establish advanced semantic relations between educational resources.

Learning objects are usable in a mobile environment, especially when adjusted to a certain extent, especially in the domain of their presentation. A set of recommendations about the design of mobile learning objects is given in (Churchill, 2011), mainly concerning different ways of displaying and repeating the content on a limited surface while avoiding the complexity of the user interface. An example of use of learning objects in a mobile environment for language learning can be found in (Milutinović, Labus, Stojiljković, Bogdanović, & Despotović-Zrakić, 2013).

The educational content model and metamodel need to be rich and flexible enough to support some higher level adaptation logic that could adjust its volume and complexity according to user and device capabilities. Ontologies, defined as formal, explicit specifications of a shared conceptualization (Gruber, 1993) can be used for this purpose. Ontologies represent a linguistic infrastructure that can describe conceptual relations between course materials, and a number of applications exist in the educational domain. Ontologies can assist the automated construction and adaptation of a personalized learning path according to the difficulty level of course materials, learner prior knowledge and abilities, in order to avoid learner cognitive overload or disorientation (Chen, 2009). By describing learning object attributes in an ontology, an appropriate amount of knowledge can be served to learners for consummation on the fly, using their mobile devices. An ontology can then serve as a backbone for the learning domain and support technology at the semantic level by facilitating context acquisition (Basaeed, Berri, Zemerly, & Benlamri, 2007). Multiple ontologies (e.g. user model ontology, domain ontology, learning design ontology, device ontology) can be combined to produce an ontological framework capable of representing context-specific metadata. An example of such framework is given by (Jovanović, Gašević, Knight, & Richards, 2007), where it is utilized to accumulate data about the context of LO usage, by attaching the learners' models to each LO they used. This accumulated data can

then be used for for advanced learning services, such as personalization or adaptation of content in accordance with the students' objectives, preferences, learning styles, and knowledge levels.

Learning objects can be considered as pieces of a puzzle, where ontologies define each piece's connection points to other objects. When combining learning objects, the quality of the result will depend on the size and flexibility of individual units – the smaller they are, the easier it will be to mix them as needed. Although it would require a substantial effort, ideally the learning objects should be the smallest possible, while still retaining a number of semantic links to other objects. Language learning is somewhat specific in this regard, as the smallest learning units are individual words given by a vocabulary. Several machine readable, ontology-like vocabularies, "wordnets," exist, defining concepts, words and their relations in different languages. The original wordnet was developed by Princeton for English language and is described by its authors as a lexical database (Miller, 1995). Other authors often refer to it as an ontology and it has been linked to formal ontologies like SUMO upper ontology (Fellbaum, 2010). Similar projects in different languages have been modeled after the WordNet, one of them being the EuroWordNet that encompasses eight languages. This wordnet is especially interesting for language learning since words in different languages are interconnected with interlingual links stored in a Interlingual Index (ILI) (Vossen, 2002).

A model for ontology based language learning utilizing available wordnets as a starting point for construction of a language learning domain ontology is given in our previous work (Milutinović, Stojiljković, & Lazarević, 2014). However, an implementation of such a system would likely be very complex, and a more general approach can be taken by parsing existing educational materials. The words can be roughly grouped by areas of interest (e.g. sports, cars, economics, politics), by word types (verbs, nouns, adjectives) or by difficulty as defined by existing lists and official learning materials. An example of a system performing adaptation using such parameters to match resources according to learners interests, knowledge and learning style is given in (Li et al., 2010)

Adaptation is usually performed based on a user model. In mobile learning, different devices posses a variety of technical characteristics, and the device model also need to be considered. By using a device based reasoning approach, combined with a standard user model, a technically and educationally appropriate selection of learning objects can be served to learners (Chorfi, Sevkli, & Bousbahi, 2012). In order to facilitate device-based reasoning, device features need to be known for every device using the learning system. Projects like WURFL, OpenDDR, and Apache DeviceMap attempt to maintain databases of all device features for purposes of capability detection (Power, 2012).

Mobile learning is often performed on the move, and mobile devices offer unique opportunities for delivering learning content in authentic learning situations. Modern devices and platforms have built-in GPS, cameras, sensors, accelerometers, and compasses that are valuable sources of context information (Godwin-Jones, 2011). Context information can be used in advanced adaptation scenarios, where content is organized according to some learner context parameter like location (Jong, Specht, & Koper, 2009).

Mobile devices offer unique opportunities to deliver learning content in authentic learning situations. Apart from being able to play various kinds of rich multimedia content, they offer new ways of tailoring information to the learner's situation or context. This paper presents the results of a study of mobile media delivery for language learning, comparing two context filters and four selection methods for language content. Thirty-five

3. MODEL FOR MOBILE ADAPTIVE LANGUAGE LEARNING

In order to design an adaptive language learning system that would fully support mobile learning on different devices, all components must be selected appropriately. In this section we outline a model for adaptive mobile learning (Figure 1) based on the following components:

- An ontological framework, roughly composed out of an educational ontology and a user/device ontology;
- Learning objects for delivery of educational content to learners and institutions;
- Web services as a platform-neutral, developer-friendly interface for accessing system functions;
- Internal services for managing the adaptation process and for processing and correlating user data;
- Cloud computing infrastructure for scalability support.

We base our suggestions on previous experiences in related areas, and especially on our previous work on designing a non-adaptive, ontology-based multimodal language learning system (Milutinović et al., 2014). Unlike some other comparable models available in literature (Basaeed et al., 2007; Jovanović et al., 2007), the model presented in this paper is partially specialized for language learning. Another core concept is the separation of concerns, where the learning objects are used only for the delivery of content and instructions,

while the actual client applications decide how to present content (according to the received instructions). This is in contrast to the popular, standardized Sharable Content Object Reference Model (SCORM) learning objects that mostly contain browser-openable/HTML files, with content being mixed with markup and style data. The separation of concerns generally comes with a trade-off – components tasked with content presentation need to be developed specifically for each platform, but can utilize the device's capabilities much better than generic HTML files. On the other hand, the content is free from variation, can be stored in centralized repositories, and accessed by any number and type of clients.

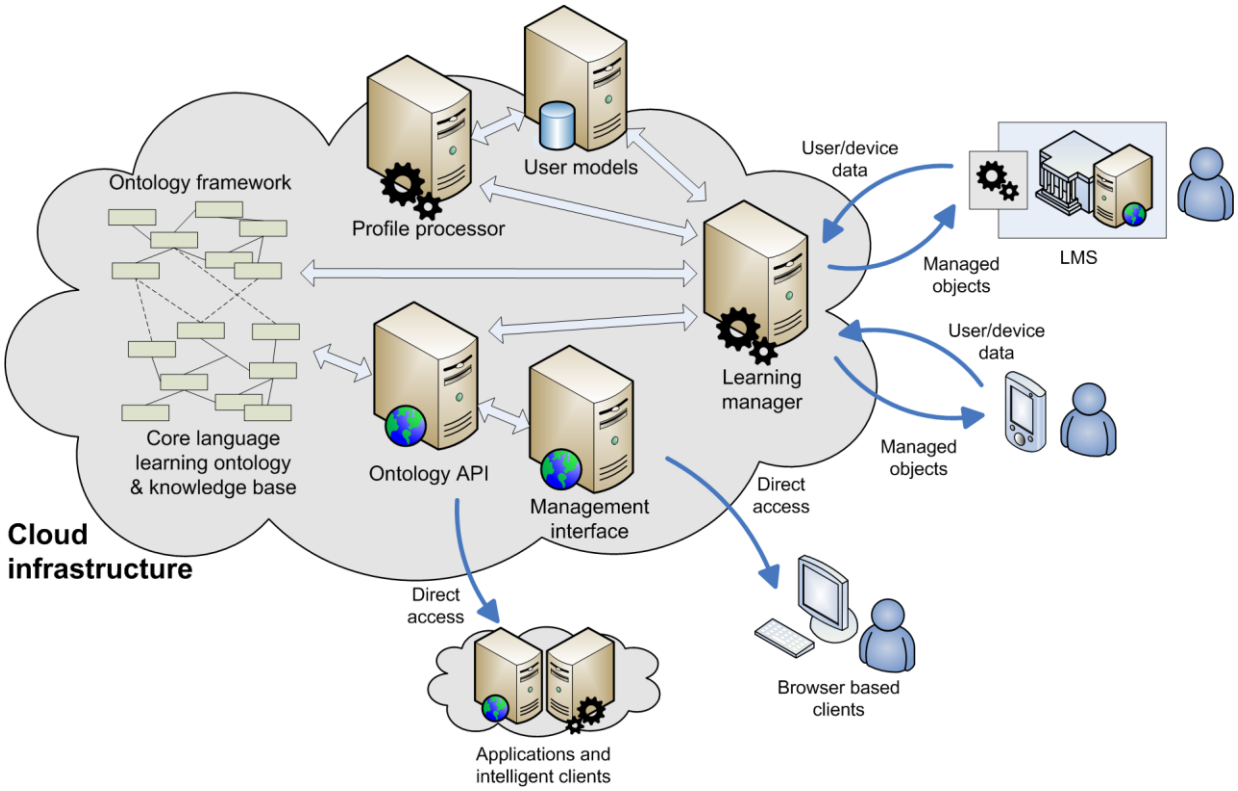

Figure 1: Model for mobile adaptive language learning

Separation of concerns on the account of data storage and presentation also implies a more complex, two-part adaptation process. The core adaptation logic is stored on a centralized location and executed by a learning manager. This manager receives and processes requests for content from various clients. Depending on the input it periodically receives from each client, the learning manager can assemble appropriate learning objects and generic instructions for their adaptation, and return them to clients. The clients then interpret the instructions as well as they can, while gathering further information about the user for the next cycle of communication with the learning manager. In order to allow such a scenario, all communication must be done through standard interfaces and based on a common ontology serving as a common language between the manager and the clients.

Ontology framework

The core component of the presented model is the ontology framework, composed out of following, interconnected and interdependent ontologies: educational content ontology, educational activity/learning design ontology, user knowledge ontology, user interest ontology, user behaviour ontology, device capabilities ontology, and context ontology. Developing all of the aforementioned ontologies in detail is outside of the scope of this chapter, but we give some general remarks and a rough model for future development. When developing a new ontology, existing developments should first be explored and reused, if possible (Noy & McGuinness, 2001).

The language learning ontology must contain concepts like words, grammar rules, typical sentences and other atomic content units. Words can be described using wordnets, with the original, English wordnet, defining several relations, including synonymy, antonymy, hyponymy, meronymy, troponomy, and entailment (Miller, 1995). These relations connect both the concepts (e.g. jet plane is a type of plane, toe is a part of foot), and the words (e.g. interrogate, interrogator, interrogation), providing rich semantics that can be utilized for generation of tailored learning resources. However, the level of detail and complexity of interconnections in a wordnet are likely larger than necessary for language learning, and wordnets do not

describe other relevant concepts (grammar, sentences). Extensive modifications might be required for integration of wordnets with other ontologies, so we suggest developing a simplified ontology by extracting only some of the information from a wordnet or a simple vocabulary – word type, word difficulty (relatable to user knowledge), and a rough domain of use (relatable to user interest). Some guidelines for developing a a content ontology can be found in (Boyce & Pahl, 2007).

The educational activity/learning design ontology should describe different types of activities the learner can take and methods of structuring activities in order to produce a learning session. This ontology should also be connected to the language learning ontology and specify which types and units of content can take part in which activities. The user knowledge ontology should describe concepts needed for construction of the user knowledge model, and for inferring additional information about the user based on his results. The user interest ontology should roughly describe possible areas of interest of the user, and define relations to domains of use from the language learning ontology.

The user behaviour ontology describes possible learners' behaviours. Learners' behaviour implicitly provides information about their knowledge and their interest. For instance, a learner that spends more time learning words in a single, specific domain of use, likely has some interest in that domain. Likewise, if a learner takes more time to answer questions from a specific domain during a quiz, it can be inferred that his knowledge in that area is lacking, even if his actual results do not deviate as much. This ontology needs to be connected to most of the other ontologies. Behaviour will be related to doing specific tasks with specific units of content; it will imply interest and knowledge; and, finally, depending on the device capabilities, some behaviours won't be possible to perform using some clients. Learner behaviour, therefore, needs to be expressed using a generic language that can cover a large number of use scenarios.

The device capabilities ontology can rely on OpenDDR or a similar device capabilities database. However, like in the case of using wordnets for language content, such databases are likely more complicated than necessary for the needs of the language learning domain, and we suggest parsing the capability database and extracting only the minimum necessary information. Domain-specific capabilities should also be defined and associated with the requirements of specific learning activities.

Finally, a context ontology should describe methods of gathering context information (e.g. GPS), related to the device capabilities, and enumerate possible detected contexts for each source of context information (e.g. learner is at the zoo or at the beach). On the other hand, the contexts should be connected to specific activities and domains of use so that the right activity/content can be presented at the right time.

System components and infrastructure

The use of ontologies provides many possibilities, with some added complexity. The designed adaptive system should be completely transparent for the users and they should be shielded from any added complexity. For a Web-centric learning system this can be achieved by providing access to core concepts through Web services (Kreger, 2003) operating with standard interchange formats like XML and JSON.

Components of the presented model that operate upon the ontological framework are: ontology API, ontology management web interface, user model storage, profile processor and learning manager. The ontology API should be implemented as a web service, offering direct access to the ontology framework. This type of access should be used for ontology/content management, and providing direct access to external applications that do not require adaptivity or implement their own mechanisms. A basic management web interface should be developed on top of the ontology API, for use by system administrators and teachers/domain experts.

The user model storage stores all reported information about the users of the system – their knowledge, interests and past behaviour. When a learner starts using the system, he is given an initial test to assess his pre-knowledge, as well as an array of optional questions for assessing his interests. Initial data is stored in the user model, and updated every time the client application sends a report. These reports would ideally be sent periodically, upon completion of any independent content unit, but this must not be relied on. Users in mobile environment might not be able to connect to the Internet at periods, and the system and client must be able to keep functioning even in such cases.

The learning manager is the main component of the system, tasked with receiving client requests and reports, and generating and delivering personalized learning objects. The learning manager contains the adaptation logic, and uses the ontological framework in its decision-making. The learning manager also runs the profile processor after receiving a request from a client and updating the user model. The profile

processor attempts to correlate profiles of different learners and produce groups of similar learners. This information can then be used for predicting learners' needs.

Using all of these inputs available, the learning manager browses the core language learning ontology, selects a number of educational units, and packs them in a learning object. With all of the components at hand, producing a learning object requires only selecting an appropriate syntax for encoding the educational data in a textual format that can be transferred to clients. We suggest using lightweight objects appropriate for the mobile environment (Milutinović et al., 2013), but other formats could be generated, including SCORM. The generated object is then sent to a client, which takes the responsibility for presentation and further information gathering. The clients can run on different devices, and can even be different themselves, e.g. some clients can offer a full learning environment, while others can concentrate on a single aspect of language learning like vocabulary. As long as the clients use the standardized ontology to report the device's and their own capabilities, the centralized adaptation algorithm can select appropriate content and activities. Clients also need not be mobile; a special case of desktop clients can be considered as just another type of device on record. Existing learning management systems like Moodle LMS can also be modified through plugins in order to integrate with the system. Such plugins would take the role of gathering information, reporting, and downloading learning objects, while the presentation would be performed by standard LMS routines.

Learning systems must expand and evolve in order to adapt to changing requirements, and several types of expansion can be envisioned in the presented model: expansion of ontology concepts, expansion of knowledge base with additional educational content, supporting a growing number of users with different use patterns and frequencies, supporting a growing number of types of client systems. In order to support high flexibility and scalability of the entire system, the implementation can be placed on a cloud computing infrastructure (Blakley & Reeves, 2010). Mobile learning can especially benefit from cloud computing since processing, storage, and adaptation of educational resources can be performed using cloud resources instead of those on heavily constrained devices (Ferzli & Khalife, 2011).

5. CONCLUSION

This paper presented a model for mobile adaptive language learning based on an ontological framework and several criteria of adaptation. Used criteria encompassed learner knowledge, interest, behaviour, device capabilities, and context, and all related concepts were defined using ontologies in order to provide a standard, generic vocabulary of terms. This vocabulary was then utilized to enable a separation of concerns between the core system, and mobile and other client applications. Some suggestions were given concerning the development and integration of educational ontologies, with the goal of producing an optimal and efficient ontology. In order to account for possible expansions of ontologies, content, users, and client types, the infrastructure was envisioned as cloud and web-service based, providing needed scalability and generic access.

Future research should be directed towards exploration of existing educational ontologies and development of individual components of the ontological framework. Thanks to the separation of concerns, the minimal implementation of the system can be developed and tested manually, without the existence of actual clients, while individual clients can use a dummy web interface during the development of user tracking and reporting functionalities. A possibility of adapting existing learning applications should also be explored, especially for established learning management systems like Moodle. Other options of gathering information about learners like social networks are also a possible direction of future research.

Abstract: *This paper shows an application of wearable computing in e-education. The main aim of this paper is improving existing e-education infrastructure and e-learning process with current trends in wearable computer-based gadgets. According to actual tendencies in application of wearable devices, a model of wearable computing application in e-learning is developed. The model integrates wearable computer-based gadgets with e-learning services of a higher educational institution. Ethical and social impacts of using this solution are also considered.*

Keywords*: wearable computing, e-education, e-learning, cloud computing, learning management system*

1. INTRODUCTION

The advance of computer technologies had high influence on wide area of human life and it still has. Computer era radically changed ways of communication, business, education or entertainment as well as human perception and socialization.

E-learning concept in Learning management systems (LMS) has been used in higher education for years. Learning services are constantly advancing by application of new information technologies such as multimedia content on the Internet or wireless technologies (Anderson, 2008). The appereance of different devices and gadgets, which are available to improve learning process independently of temporal and spatial constrains, leads to a need of implementing such devices or gadgets in the current e-learning environment.

This paper shows possibilities of wearable computing application in e-learning. A model of wearable computing application in e-learning is developed in a higher educational institution in aim to enhance existing e-learning process.

2. WEARABLE COMPUTING

Considering decrease in scaling, computers forced their way beyond boundaries of isolated appliances. Unlike original idea of machine which occupies space for certain period of time and which is used for alphanumerical calculations, second half of 20th century puts forward different way of thinking. Concept of ubiquitous computers was made in order to describe "computers everywhere" - apparatus which is in wide set of locations, flexible and mobile, small in size and available for communication with other similar devices (Weiser, 1999). Accordingly, this led to the concept of computer devices which are placed not in indoors, but in some sense on human body, to witch these devices are connected and available to communicate.

Terms like wearable computing, wearable devices or wearable technology may be perceived synonymously, in the widest sense. Wearable paradigm generally consists of a device associated with human in sense of interaction. Therefore, the wearable computer device is a gadget that is always connected with its user, while the user is using and wearing it in comfortable and unobtrusive way (Toh, 2013). Wearable computing, as a computing view, may also be understood in sense of having apparatus which is always able for usage, since it is worn in the same way as clothing, and it is also able to perform various kinds of computing (Mann, 2002).

It is difficult to determine exact origin of this idea, since there were some analogue devices associated with human organism, so the conceptual model for wearable computing in today's sense could be even pocket watch. However, first genuine wearable device, which was electrical and based upon digital signal transmission, is Edward Thorp's and Claude Shannon's roulette result simulator (Thorp, 1998). During the second half of the 20th century, there were lots of similar projects and researches, but it was until 1981, when Steve Mann developed wearable battery-operated personal imaging system (Mann, 2002).

Wearable computing in general covers broad range of devices and possible usages. Although it is impossible to highlight a single approach in understanding this idea, there are significant similarities between the main contributors of this area. It is necessarily that wearable computing architecture fulfils the requirements of persistence and constancy in order to be accepted as such, as it is constantly available and being used in concurrent way (Witt, 2008). In addition, wearable devices should also stable in sense of power supply, therefore it is required that they are not connected in a way to restrict their mobility (Mann, 1997). Important characteristic includes context sensitivity in a way of computer device becoming aware of user's surroundings and state whenever it is worn (Billinghurst, & Starner, 1999).

There are three basic operational modes that define wearable computing which have been widely adopted:

- constancy - computer device is ready to accept request from user at any time, unlike the on and off concept of personal computers, so the signal running form device to user and from user to device provides constant user interface

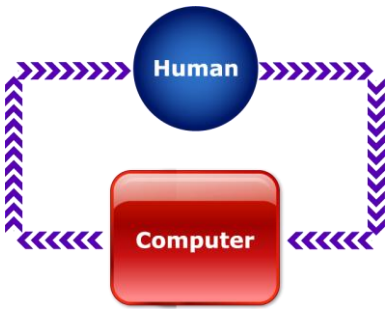

Figure 1: Mode of constancy

- augmentation - in wearable computing, the process of computing is not the primary function of the computer device, since it is combined with augmenting the intellect or senses of the human user

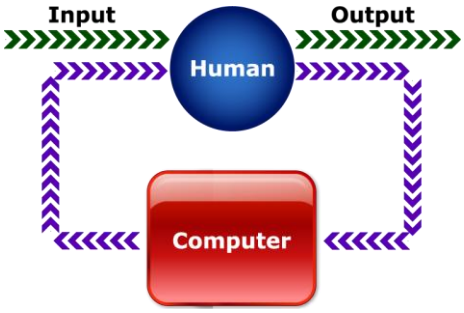

Figure 2: mode of augmentation

- mediation - wearable device is a form of mediator between its human user and the real world since it encapsulates information from the real world and it is possible to be considered as a form of interaction filter

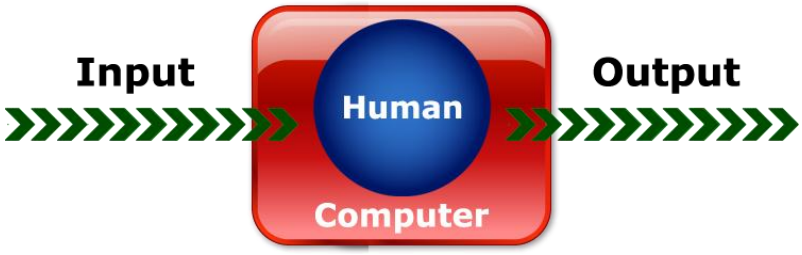

Figure 3: Mode of mediation

In sense of three above mentioned operational modes, the basic idea of wearable computing, wearable devices or wearable technology imposes the concept of framework for enabling various degrees of constancy, augmentation and mediation (Mann, 1998).

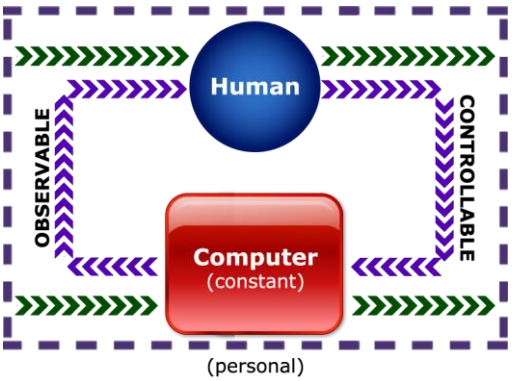

Figure 4: Comprehensive view of wearable computing

Another approach is given by Rhodes (Rhodes, 1997) who defines following characteristics of wearable computing device:

- Device is portable while it is operational
- Usage of such device is hands free
- At least one sensor is part of the device
- Wearable device should be able to convey information even if it is not being actively or directly used
- Wearable device is always in "power on" state, and it is assumed to be shut down only in cases of maintenance

The possible applications of wearable computing are numerous, encompassing various industries, military and modern-day medicine (Randell, 2005). Use of wearable computer devices has been present for two decades in airline industries and manufacturing in general (Caudell, & Mizell, 1992). Present-day implementations of wearable computing are virtually limitless, depending only on developers' creativity and contribution.

Some of currently significant areas for wearable computing implementation:

- Military (aiming optical sights, sensors on soldier's helmet which detects when he is wounded etc.)
- Medicine (sensors inside wearable devices allows continuous monitoring of a patients and decision making)
- Entertainment (smart glasses which provide augmented reality in computer games, for example Oculus Rift)
- Sports and fitness (wearable textiles which provide information on training performance)

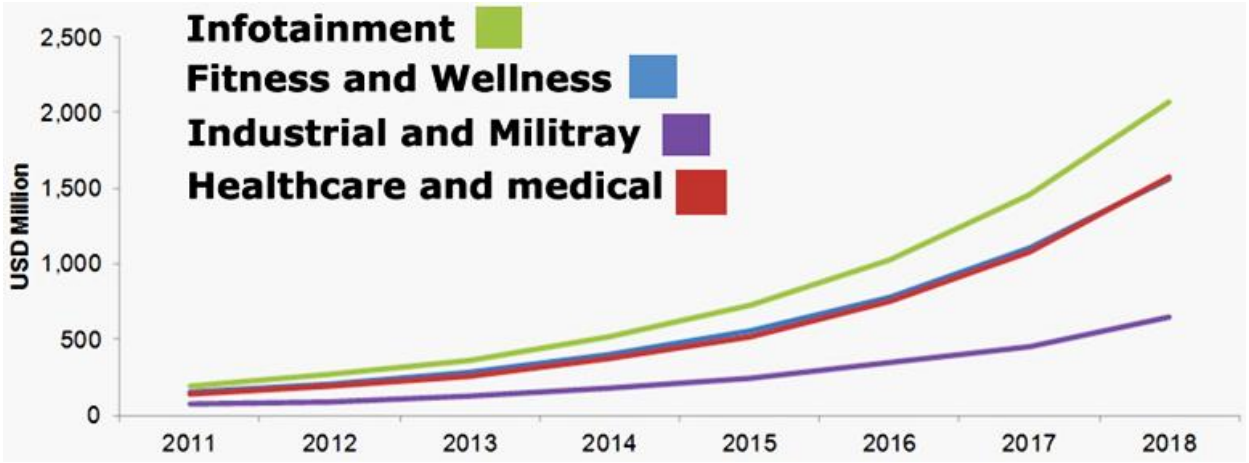

Figure 5: Market growth trends: Wearable technology end use

Contemporary reports (Rizzo, 2013) indicate that it is likely to expect further market growth as well as implementation development of wearable technology.

Recent researches and studies emphatically indicate that wearable computing could become one of emerging technologies considering educational implementations. Wearable and hand-held devices are also mentioned in sense of Web 3.0 trends and e-learning.

3. WEARABLE COMPUTING IN E-LEARNING

In accordance with widespread implementation of computer technologies, the fundamentals of education have also experienced revolutionary modifications. These changes are significantly influenced by new learning theories and the ideas of acquiring knowledge outside the ingrained access, consisting of gaining knowledge only by repetitive process. Ideas of visualization, data availability or interactive learning fundamentally change perspectives of learning and education, and therefore, there are the concepts of e-learning and even e-education, which were formed as effects of cohesion of the mentioned ideas along with the modern technologies. Concept of e-learning (Labus, 2012), for instance, considers electronically mediated process of communication, created for the sake of constructing and confirming knowledge (Garrison, 2011). Such system involves student-lecturer relationship independent from spatial and time constrains with availability of various forms of learning materials (Despotović, & Radenković, 2005). It is difficult to restrict which of the widespread technologies and devices are involved in digital learning, and still it is certain that Internet is the base of modern educational frame. In the broadest sense, there are a lot of technologies which are used in e-learning concept, such as learning management system, various multimedia content and technologies, web white boarding, various wireless technologies (Anderson, 2008).

At this point, there are three dominant Internet-based technologies which are becoming more and more widespread, so that their impact is ensured for future purposes (Garrison, 2011):

- Web 2.0
- Social Media
- Mobile technologies (Labus, Simić, Vulić, Despotović-Zrakić, & Bogdanović, 2012)

The process of e-learning itself is conducted and monitored by the learning management system. The learning management system is a software platform created in order to provide complete management of e-learning course process, as well as performance and talent evaluation (Hirtz, & Kelly, 2011). Both asynchronous and synchronous types of courses are available, depending on the way of leading the lectures. LMS itself is available for use in both primary educational facilities and commercial institutions. Basic functionalities include complete course management, user's management and content management, in a line with multilingual support and support for various devices (Hirtz, & Kelly, 2011).

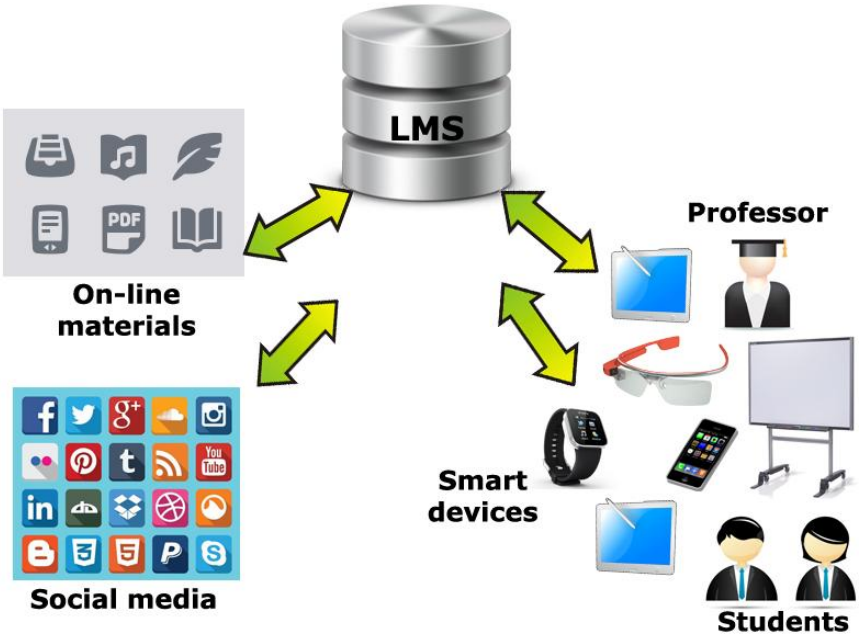

Figure 6: Wearable computing in e-learning

E-learning and especially learning management systems are quite loose-coupled with standard personal or laptop computers. Considering rapid and radical innovations in areas of portable devices, such as smart phones or tablets, LMS itself becomes more flexible in order to meet possibilities of developing services for smart portable devices. In the current learning process, mobile gadgets have an increasing importance, hence their options and possibilities. For instance, one of progressive methods is a so-called "Formative assessment-based mobile learning" (FAML) which provides learning activity together with evaluation, based on wireless networking system (Hwang, & Chang, 2011). Mobile devices are especially convenient because of various platforms and possibilities for developers generally.

Teaching process has become significantly facilitated, both in terms of teaching performance as well as communication and cooperation. Students and lecturers are able to access online materials available through LMS courses by using smart devices like smart glasses and watches or mobile devices and tablets

Wearable devices like glasses or watches rest upon similar principles of application development: development platforms are programmable easily and supported by community. Likewise, considerable part of those applications is free to download from "play stores". For instance, Google with currently most famous wearable gadget, Google Glasses, offers a programmable API for developers (Lardinois, 2013).

4. MODEL OF WEARABLE COMPUTING APPLICATION IN E-LEARNING

Model of wearable computing application in e-learning is developed in scope of Laboratory for E-business (Elab) which exists within the Faculty of Organizational Sciences, University of Belgrade. In this paper, model gives all the information about how it works in real environment and how it should be implemented with existing technologies and infrastructure, as those that are in emerging state. Structure of this model is shown in figure 7.

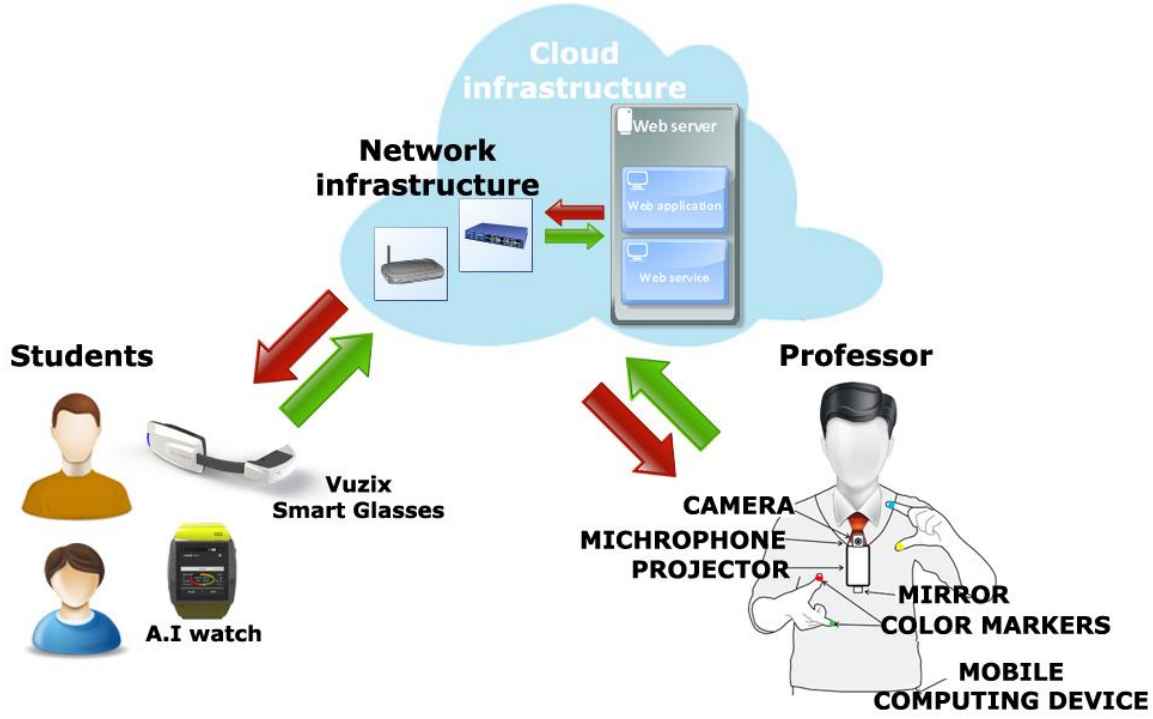

Figure 7: Model of wearable computing application in e-education

Proposed model of wearable computing application in e-education consists of three parts:
- Cloud infrastructure
- Wearable computing devices and software which are used by students
- Wearable computing devices and software which are used by professor.

The most important part in this model is cloud infrastructure, which represents mediator between students and professor in the classroom. On the inside of that infrastructure there are:
- Software system
- Hardware.

Software system is composed of all the applications and services which are located on web server and integrated into the cloud, so their main purpose is to authenticate its users and provide them authorized access to all resources that are intended for education purposes (such as Learning management system, for example open-source Moodle LMS, which implements concept of Blended Learning, a combination of traditional and distance learning, and it is used in Laboratory for E-business for e-learning since 2001).

Hardware, in this case, is represented by a massive server infrastructure which has a lot of processor units, ram memory, data storage and respectable network infrastructure (both wired and wireless network hardware) to provide communication with users from the outside world.

Until now, there were recognized many benefits from cloud computing for education: “centralized computer systems can process large amounts of data (specifically graphics), manage complicated functions and store enormous amounts of keyword searchable data while users can access this information and interact with other users with low-cost simple smart devices (such as smart phones, tablets etc.)” (Sampson, Isaias, Ifenthaler & Spector, 2013).

Wearable computing devices and software which are used by students includes interface which connects students with cloud infrastructure (which can perform or refuse users requests), and further with professor. This type of communication is possible in both directions. In most cases, those devices use wireless or Bluetooth technologies to send user requests and they are controlled by various operating systems and platforms (such as Windows, Android, iOS etc.). In this particular case, the model represents usage of smart watches that provide ability for student to sign in into the class with their digital signature which was automatically recognized (with appropriate application, like “Signature Capture” for Android) as computer text and submitted over the cloud infrastructure to professor so he can access information about list of present and absentee students. Also, there is ability to use some applications that can read textual documents and convert them to speech (for example, Android application “Ivona Text-to-Speech”), and make classes and lectures easy to follow. Smart watches can also be used to notify, so students could be aware of time that is left to complete their tests or other class defined chores.

Next wearable computing device that is intended for usage by students are smart glasses. Their role in this model is to provide visual contact and communication with available resources that are enabled by professor and the system. They can also communicate with other devices in the classroom, such as smart watch which student wears on his hand or with professors Sixth Sense technology wearable computing device, which role in this model and learning process will be explained later. In this moment, on the market various types of glasses can be found for this purpose, such as Vuzix Smart Glasses which can run both on Android and iOS, lately very popular Google Glasses with Android OS or Golden-i headsets which are intended for Windows CE OS.

Wearable computing devices and software which are used by professor for education purposes, in this model, represents interface which connects professor with cloud infrastructure and further with students. It is based on Sixth Sense technology and can be used to take photographs, recognize objects and even bring the information from real to virtual world. With this device, professor in the classroom can easily use resources from cloud infrastructure, communicate with students which are able to participate in demonstrations and activities, get access to their work and administrate its content, provide additional information and have full control of lecture course. In this way, activities can be made and conducted in more interactive way, and there is possibility of constant performance monitoring.

Pranav Mistry, author and pioneer in this technology, defines Sixth Sense (which is open source and in development stage, costs approximate $350 to build) as: “wearable gestural interface that augments the physical world around us with digital information and lets us use natural hand gestures to interact with that information” (Mistry, 2010).

Components of this device (shown on figure 7) are connected to each other, where every part has its function: Projector projects light on object from our environment such as piece of paper, wall, table or anything else, even part of the body like hand which can be used as communication interface between user and this device, shown in figure 8:

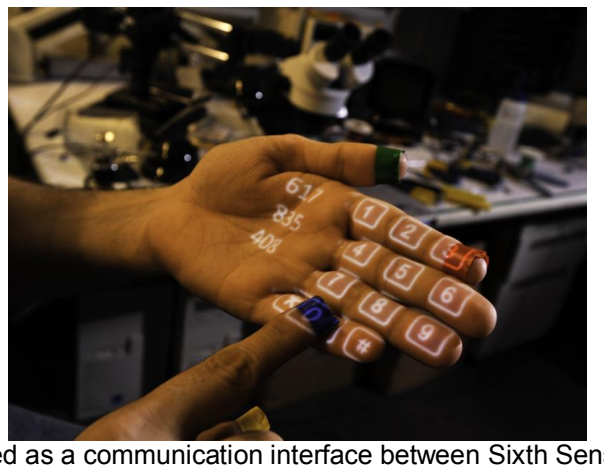

Figure 8: Hand used as a communication interface between Sixth Sense device and user

Camera detects and recognizes user's movements, especially those of colour markers on user's fingers which are later interpreted as actions or commands on mobile computing device (both projector and camera are connected to it) which is located in professor's pocket, so there is no need for usage of devices with multi-touch screens.

5. CONCLUSION

Technologic development has vastly shaped human society and civilization and furthermore continues to form various elements of lifestyle. Taking into consideration the development of computer sciences along with telecommunication improvements, ever since the first telephone was presented, these inventions altered social foundations. This trend is accompanied with advancement of wearable computer devices in the last decades.

The students with disabilities would greatly benefit from wearable computing implementation in education. Along with full inclusion, these students would be able to overcome their disadvantages in various ways, such as motion or vision disabilities.

Described model represents one of potential implementations of wearable computing in existing e-learning environment based upon present software solutions and platforms. Legal and ethical aspects remain opened for discussion of public.

Abstract: *This paper presents an application of social media marketing of a higher educational institution. Performance of higher educational institutions on social media and social media marketing usage, have as a goal improving their business operations, the credibility and implementation of the student relationship management concept. This paper presents student relationship management model of a higher educational institution on social media. It describes social media marketing implementation, specifically for social networks, as well as a model of social media metrics. The main aim of this paper is to improve the process of student relationship management, and emerging brand of the Laboratory for e-business by applying social media marketing.*

Keywords: *Social Media, Social Media Marketing, Internet media plan, Student Relationship Management, Social Media Metrics*

1. SOCIAL MEDIA MARKETING

Social media are presenting as the most commonly used tool for online advertising, as a part of Internet marketing (Kim W., Jeong O.R. & Lee S.W). Internet marketing presents usage of online activities that helps build and manage customer relationships, with a purpose to satisfy the needs of both parties by exchanging products or services (Mohammed, Fisher, Jaworski and Cahill, 2002). Social media is technique of online marketing and a complement to traditional marketing approaches. The idea of 4P in traditional marketing is expanded for social media as 5C: content, collaboration, community, collective intelligence and conversation (Mishra, G., 2012). Social media marketing (hereinafter: SMM) encourages advertisement using social communication channels. An advantage of SMM is to make a larger reach of the target group, where can be easily monitored their needs, reactions to products or services that are promoted through these channels. Before SMM, getting feedback was a process of intersect several channels to collect the opinions of customers; through surveys, guest book, forums etc. Another advantage is achieving this in a short time and at low costs. Using SMM eases to follow the competition, events that they are planning. Flaw of using social media as a tool for Internet marketing is the frequency of the news that has to be maintained. More precisely, those who advertise this way must be constantly active, more often than with traditional marketing channels. If this applies on all who use social media for their advertising, by sending posts for sometimes a few times a day, leads to overcrowding with information. Social media marketing has changed the marketing from only sending the information to customers, to communication process between the company and the consumer where a company can gain the feedback in a second after posting the news. Now users have the opportunity to comment about their satisfaction or dissatisfaction transparent, through social media. For the purpose of SMM different tools can be used, depending on type of the company. There are tools for brand tracking, such as Hootsuite, SocialMention, Klout, Social Media Custom Reports, Bitly, Buffer and many others. Previously listed tools are free and effective, but of course with limited capabilities compared to a complete paid solution. One of the complete paid solutions is the Oracle solution for Social Relationship Management, that can be used for following a brand and managing social pages. Making customers to come back to the company's news source, on their own initiative, can be an indicator that connection is strong with these users. In order to set up strong relationship takes time and high quality content.

2. SOCIAL MEDIA APPLICATION IN HIGH EDUCATIONAL INSTITUTIONS

Analysing the world's top-ranked universities and their performance on social media sites, leads to data that all social networks are included when it comes to communication with students. As the most effective is Facebook, which was created exactly in Harvard University for the purpose of communication between students. In addition to the Facebook appears LinkedIn, for business purposes. LinkedIn works to cut the

age of users, explaining that they want to allow the younger generation, such as future students, to more easily find a college for continuing their education. This shows that universities are highly presented in LinkedIn social network. At the University of North Carolina research showed students prefer discussion over Facebook rather than any other online platforms that are used for learning (Stutzman, 2008). Students said to not wanting their studying to move on social networks, as they can be distracted with the constant notifications about what do their friends. Instead, notification regarding the obligations and time limits for their courses, duties, would be desirable (Kosik A., 2007). Majority of students on social media are the undergraduate ones and use them to wide up a social network, while Master students usually are employed, and use Facebook less because of working hours, and mostly for business purpose. Research conducted at the University of Cape Town, showed that these students also have Facebook profiles, but they do not log on every day and the list of their friends is lower than for undergraduate students. Students on Facebook are divided into three groups, those who enter daily on their profile, the second group are those that are present on a daily basis, but passive and just watching someone else's profile or activities. The third group consists of those who are active on a daily basis, posting statuses, images, and comments (Tanja E Bosch, 2009). Teaching staff should behave as to show that they belong to the same community as students. This reduces the barriers between professors and students that results in better cooperation. Around the world, the practice of universities is to strive better qualification of students and to teach them efficient practical work. They have an interest in a faster and easier way to get closer to students, and inform them about obligations that they have. A study shows that using social networks, each member of the faculty has ability to reach a 75 percent of the target group (Matthews, 2006). It is important having in mind the privacy of students. To make closer contact with them does not have to initiate a friendship on Facebook, just to send a direct message. How important is usage of social media in education is shown by analysing the leaders' behaviour in that field. Analysis of the leaders includes the study of their performance on social media. As the leaders in the field of education were considered the top ranked universities in the Shanghai list (Shanghai list, 2014): Harvard, Stanford, and Oxford, that was taken as a representative in Europe. The following is a summary of all three universities posts on all social media, important to communicate with students:

- Research and studies in progress
- Quotes
- Awards
- Questions on how well are they familiar with University
- Pictures of the atmosphere in lectures or environment of University
- Lectures by experts
- Videos and opinions of students about University
- Alumni achievements
- Student Competition
- Success of students
- Conferences
- Fill in the blank Posts
- Congrats holidays, beginning of the year and successful ending of studies
- Inspirational advice.

Laboratory for e-business (hereinafter: Elab) also uses social media such as social networks and YouTube channel. Choice of using Facebook for a main campaign tool is based on the results of a questionnaire conducted by Elab for students who attempted any of a Moodle LMS courses. The questionnaire showed that 96.43% of students use social networks, but more than half, 55.56% exactly, use Facebook. Other social networks that Elab uses are LinkedIn, Twitter, Google+ and MySpace, and on these go the rest of 44.44%. One of the most important question was why did the students give a Like to some Fan page, 44.64% answered that they want to get notifications about new posts from that specific page. Elab has Fan page and groups for undergraduate and postgraduate studies. In addition, Elab has an edutainment Facebook application that can be used by students who have their enrolment in any Moodle course and have a Facebook account (Labus A., Simic K., Vuluc M., Despotović-Zrakic M., Bogdanovic Z., 2012).

3. SRM MODEL OF A HIGHER EDUCATIONAL INSTITUTION ON SOCIAL MEDIA

Laboratory for e-business exist in scope of Faculty of Organizational Sciences, University of Belgrade. The main motive is improving scientific, researching and educational work of teaching staff and students of the Faculty of Organizational Sciences in the field of e-business, application of the internet and mobile technology in business, as well as teaching at the undergraduate and postgraduate studies. Elab's work is based on the usage of modern technology and permanent innovations. The Elab organizes the following courses: E-business, Internet technology, Simulations and simulation languages, Internet marketing, Mobile business, Risk management in the development of IS, Internet of things, and many other.

Considering the presence of youth on social media, primarily students, occurred the need to have Elab advertise via them. Focus is on free advertising tools, rather than paid advertisement that is just the small part of the Internet media plan (hereinafter: IMP). All the activities that are presented in this paper are designed within the Elab. Goals pursued in this Internet marketing campaign are improvement of Student Relationship Management and emerging brand of Elab. Student Relationship Management (hereinafter: SRM) is a continuous process, which takes a longer period and involves constantly listening to students (Vulić M. Marko, Labus B. Aleksandra, Simić M. Konstanstin). Also means to work on attracting and retaining students, by raising the goals from a level to collect likes, to a level where students are habituated to return to the pages of the Elab on their own initiative. Further, branding the Elab and increasing traffic on its social media, should lead to an increased number of students in Master and PhD studies. Elab performs on social media as it is designed in the IMP. Its main purpose is planning a social media campaign, defining marketing activities, a flow of realisation and defining metrics for following accomplished effects. SRM model of a higher educational institution on social media is developed and applied in scope of Elab (figure 1).

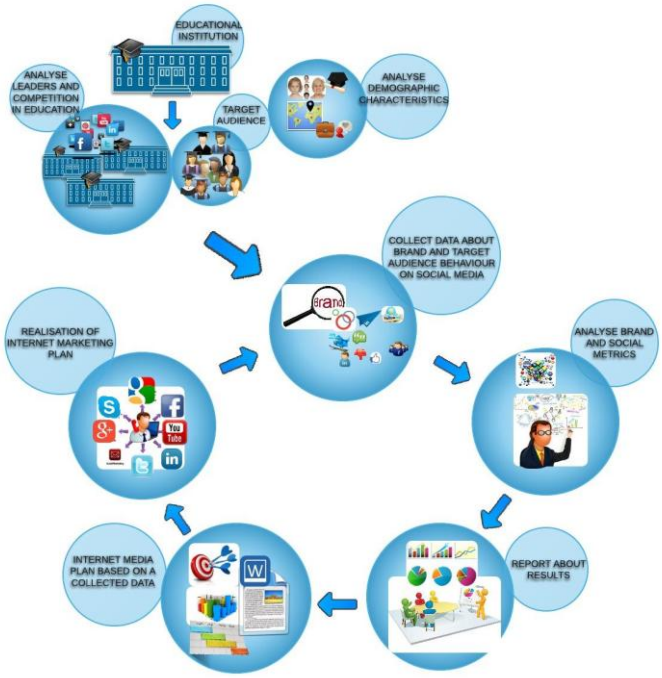

Figure 1: Student relationship management model of a higher educational institution on social media

A model has six phases and after one, full circle it goes to repeat last five phases until the goal is achieved. It is important to target group, what's they like, so in the plan could be designed how to talk to them. First step needed is to do a demographic research of a target group; age, gender, where they live, their interests etc. Competitors have to be well known and analysed, are they better in educational processes; if they are, what parts of education should be improved to reach them. After this, gaining data about leaders, their behaviour on social media, could start. Next phase is exploring how the Internet users see brand and how target group see presentation via social media, until now. Reporting about results includes sharing opinions, observations and having creative ideas about what to do next. That next phase is emerging goals, activities and resources into an IMP as a document that should be a base for conducting the campaign. Sixth phase is an implementation of an IMP on social media as it is planned. Although, it is a last phase of a first cycle, it must not be the last thing to do needed to accomplish SRM. Inasmuch target group and leaders cannot change fast in a short time, it should be continued in the second phase and start analysing data about brand presence on the Internet and opinions of a target group after the campaign is done. After analysing collected data and report meeting, the IMP should be updated with details that reports showing as important. The procedure is further repeated in the same manner in order to eventually get a clear insight into the SRM. In order to create a clearer picture of the model, further is presented model into details.

Target groups for Elab are determined in IMP. It included collecting information about age, gender, job, former or current education, likes, interests, attended groups etc. The target group is between 22 and 45 years, both genders are equally interested in this type of industry for further education, and they belong to:

- Students from following faculties: FON, ETF, PMF (IT Department), FIT, Economics, High school dealing with IT, Megatrend, Singidunum, University of Novi Sad, Kragujevac and Nis.
- All who are interested in e-business: Banks, IT and marketing companies, the National Bank of Serbia, the Ministry of Local Government.

Their interests are everything that Elab could teach them: Computer Programming, PHP, Android, iOS, Mobile Application, Internet marketing, e-Banking, e-Learning, e-Business, Social Networks, Social Media, Cloud Computing etc. Also should be targeting the ones that liked following pages of students' organisations: FONIS, AIESEC, ESTIEM, FON's career Development Centre.

When analysing the leaders, it is necessary to use relevant sources to set up them initially. In this case is used the Shanghai list, considered a recognized and relevant in the field of education. Analysed are Harvard, Stanford and Oxford University. Their activities were shown earlier in this paper so further explanation about leaders is skipped. An overview of the competition in the area of e-business, shows that Elab does not have competitors in this part of Europe. Bearing this in mind, the goal of emerging the brand in national and international level is possible to maintain.

Move forward to analyse brand and placement of Elab can be proceeded with different social media tools. To analyse previous placement in social media in use are insights and analytics tools. When trying to figure out the brand status on the Internet there are many possible tools, as well as a choice to use free or paid tools. For Elab is used free and simple tool SocialMention. In received results, special attention should be on the negative comments and responses (figure 2).

Figure 2: Social media tool - SocialMention

The obtained data analyse professional staff. In case of the Elab all members carried out the work, as they fulfil professional qualifications needed. Report of the results was used for making an IMP. Activities were planned and designed for the following social media: Facebook, LinkedIn, Google+, YouTube channel, Skype, SlideShare. Twitter is not specifically designed for this campaign because it is connected with Facebook and direct pastes the news that posted to Facebook.

Activities for reaching the goals are displayed in IMP with Gantt charts, calendars and schedules on different levels; weekly, for two campaigns (national and international level) and annually. Every activity is presented with the day, social media that should be used, how often and what is the goal of conducted activity. This plan contains activities that relate not only to the period of the campaigns, but the activities conducted independently, every year; such as presentation of elective courses.

Table 1: News on a weekly basis on the social network Facebook

Day	Activity	Time
Monday	Undergraduated studies atmosphere, Master studies promotion	06pm 04pm
Tuesday	Promotion of Monography, Lecture IEEE Chapter Computer Science(CO-16), PhD studies promotion	02pm 11am 02pm
Wednesday	Undergraduated studies atmosphere, Master studies promotion	05pm 04pm
Thursday	PhD studies promotion	02pm
Friday	Promotion of Monography, Master studies promotion	02pm 04pm
Saturday		
Sunday		

Activities of IMP are designed to be educational and entertaining at the same time, which leads to the principle of edutainment that is the core of all activities conducted by Elab. The way Elab is going to get closer to students is by placing them useful materials about e-business, IT and some important notifications about the courses they study.

Facebook is the main channel for campaign conduction. Some of the posts that are going to be used in a campaign are explained in further part.

Activity *The atmosphere in lectures and exercises* is posting pictures with explanations about what have been done that day in courses Internet of things (IoT) or Internet marketing. IoT is one of the areas that grow and it is interesting for future generations to learn about it. It is more interesting because the course conducts in a smart classroom, in the Faculty of Organizational Science. Its aim is to increase the number of students who would choose one of these courses next year in undergraduate, Master or PhD studies. *Alumni reunion* would be conducted annually. Alumni is going to be interviewed, and video materials or posts with pictures, in English and Serbian languages, are promoting about the quality of the studies, as well, how can it help to get a job or to move forward in career after finishing this particular study programme. Activity *Our students about us* is mini Interviews with current students. Students talk about how they improve knowledge in e-business in courses, what is the most interesting to them, and what practical knowledge they gained. *Fill-in-the-blank Post* is posting sentences about some term in e-business with a blank field that gives the student opportunity to answer with the word they think is right. These posts are posting before exercise starts so the students can answer and gain points for participation in social network activities. Each response is free advertising because their friends see the name of the Elab every time the question is answered. *Seminars, conferences and IT events* are conducted throughout the year. At the beginning of each month is important to make review of conferences in IT field and regularly report on it. When there are no other activities, post *Video material, useful tutorials* to help students learn practical things of e-business. Post with *Inspirational advice from experts* or *Quick Tips in IT field* have a purpose to attract students to follow the page on a daily basis because they will receive useful information. Activity *Get to know the Elab Tim,* gives students an opportunity to see who the teaching staffs is, to feel good atmosphere to study and work with them. The activity includes pictures of members in some daily work at the University, interview about their achievements, motivational speech etc. The tone of activity should be friendly. Activity *Summer/New Years Logo of the Elab* is about making mini competition with the task for students to make new logo for the Elab. Student who has the most likes can be released of exam or can get extra points. Conducts open *Workshops* to the target group that may be outside the Faculty of Organizational Sciences. Workshops include short courses lasting from 1 to 5 days, and could be different levels. Use them to gather impressions of participants in e-form. Gallery from the workshop is necessary to be posted. Workshops are organized in collaboration with student organizations, advertised by their sites, which expands the number of people who see the brand of the Elab. In the second half of March Elab starts posting links, on a weekly basis, with *Descriptions of courses* that inform about Master and PhD study programme. Post *Top Jobs* whose list presents some areas that Elab maintains. The goal is to promote that the most popular and highest paid jobs are those included in the courses of the Elab.

Table 2: Schedule of Social Media global activities of Elab for May 2014th

Promotional activities of the Laboratory for e-business, 2014th	May

3. Promotion of lectures and exercises on undergraduate studies																															
1.1 Posting pictures and promotional articles on Facebook social network					06pm		05pm					06pm		05pm					06pm		05pm					06pm		05pm			

Since Facebook Fan Page of Elab is in Serbian language, LinkedIn page is in English, so the international students could find the information about courses they needed. This is necessary due to the lack of bilingual social networking sites. Facebook ads are in Serbian, LinkedIn has an only ability to advertise in English, which perfectly fits the planned.

LinkedIn page contains posts about human resources of the Elab, including students' achievements. Staff of the Elab uses the Recommend option to inform followers and their connections about services of the Elab. In

order to strengthen the brand Elab needs to be found on LinkedIn profiles of its teaching staff. This can be achieved by tagging Elab in the Experience section. To implement this in the part of Company Name find and tag Elab, and mark the checkbox - I currently work here.

YouTube channel is in use for uploading Alumni videos, Webinars and Tutorials related to Elab, in Serbian and English languages. Uploaded materials should be posted with links to Facebook, LinkedIn and Google+ social networks.

4. A MODEL OF SOCIAL MEDIA METRICS

After the Internet media campaign is finished, there is a need to analyse metrics to measure the success of conducted activities. The purpose of social media metrics is to collect data about the performance and to be able to improve activities. Sometimes metrics established at the beginning of the campaign are not entirely relevant at the end; it happens if a campaign is running for a longer time and a fast change in social media. Presented model of social media metrics shows the process of building and improving SRM. It is based on continuous monitoring of the students' behaviour, their activities at the pages of Elab and their opinions - expressed on the outside sites that are not under authority of Elab; forums, groups on Facebook, portals on the study and similar sites.

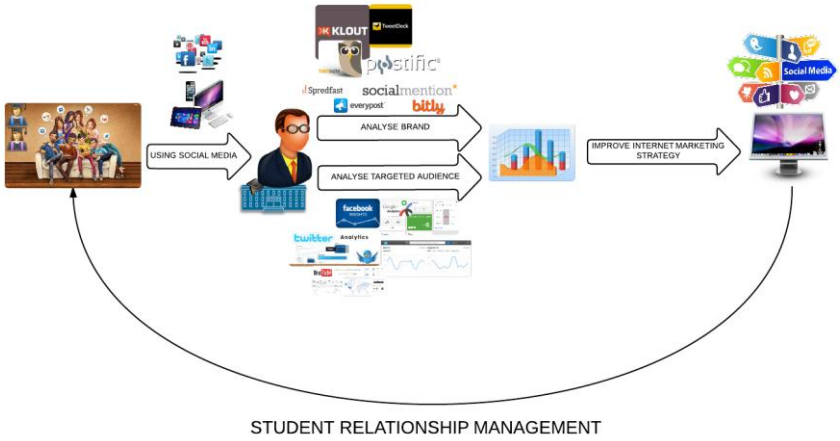

Figure 3: Model of social media metrics

Free tools that offer the possibility of monitoring brand on a global level are: Klout, SocialMention, Everypost, Spredfast, Postific, Bitly, Hootsuite, Tweetcheck etc. As any other free tools, these also have limited capabilities, but with the extra pay, some are able to analyse more detailed.

For tracking the success of social media activities, every social media developed its own tool. It is necessary to summarize the results for conducting campaign, after the first campaign is finished, and later to follow reactions on a monthly basis. The effects of implementation media plans can be seen after three months.

Metrics of a Facebook campaign can be monitored through Facebook Insights tool that provides a complete overview of statistics on a Facebook Fan page. The clearest picture of the fans habits and interests gives an option Posts. Appears that students are equally active on their profiles every day in a week when use their profiles more often in an examination period, for searching materials and communicate with colleagues, and less during the rest of the year, when they are more active on Friday, Saturday and Sunday. The time when most of them are online during one day is a period between 7pm and 11pm, which should be the period for posting. Otherwise, if Elab sends something in the morning, and students are active in the evening, there is a big possibility post is not going to show to them; other newer news sent in the afternoon hours are priority. Because of frequent changes section posts has to be monitored on a monthly basis. Type of post that attracts students the most is picture, which is why they must be high quality. The option People, gives details about Fans, their location and age. In general, the highest number of Fans is from Serbia, Belgrade and age between 18 and 24, which is exactly students' age. It is not important to have as many likes, Fans, on the page, but to interact with students as a sign that they follow the information and topics that appear on the Fan page. When it comes to Likes, optional is Start-End date and can adjust the dates to follow, which is beneficial if needed data is on a campaign level. Here can be kept track of when it was the highest number of likes or, more important, to review the dates when was the lowest number of likes, or even dislikes on a Page. Based on that to see which posts do not cause enough attention. Post Reach shows the number of

people who saw the posts. The result gives an overview of the Organic and Paid. It is necessary to have as much Organic Reach, because it is free. The highest reach Elab had for post thanking about the lecture conducted by one of the alumni of Elab. Post is simple, one picture and brief explanation in one sentence, what was the lecture about. Out of 568 people reached, the post has 292 clicks, which is 51% of the number of people reached. The highest reach is bigger chance to have better engagement. More detailed is part Likes, Comments and Shares, that show sum of 51. That is the most important part to follow, because it shows the actual engagement with Fans (figure 4).

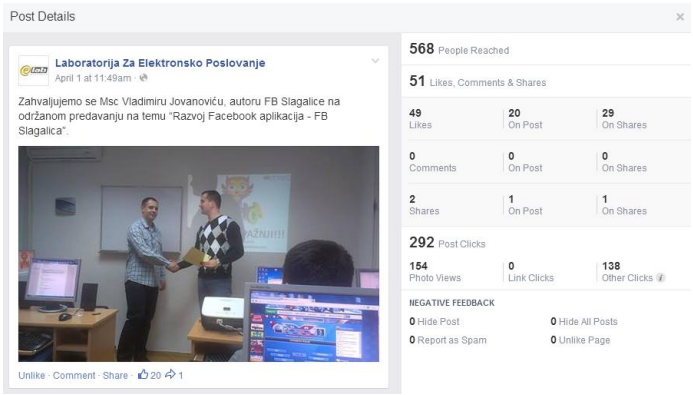

Figure 4: Post details with the highest Reach

The second post is a gallery from the class of Elab's subject IoT where reach is 287 people, post clicks is 4.038, and engagement is 15. The number of Post Clicks is this high because the gallery contains 37 pictures and every click counts as post click. This shows that a high number of post clicks does not mean higher engagement.

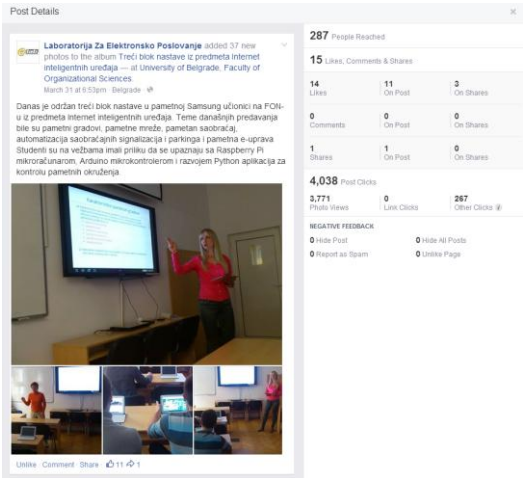

Figure 5: Post details with the highest Post Clicks

Reach has to be high, so chance of someone new can see posts and like a Fan page. This can be achieved if more people like, leave comment, or share the post to others. If the reach is high, it does not mean all the rest metrics are high. Post has to be visually attractive to students to click on. So, if the Reach is high and Clicks are low, means that the post is not enough interesting to students. After the Reach and the Post Clicks are high, if likes, comments or shares are excluded or are close to zero, then the students did not like what they read or saw. In order to achieve high number of metrics, Elab continuously analyses students on a Fan page, and what it is they find interesting in posts.

LinkedIn has its own tools for monitoring the company site. Can be seen Follower; who is and how many, in case of Elab is 63 connections. Reach can be achieved: organic or paid. Engagement is the most important because it gives the overall view of engaging percentage. Demographic characteristics of the Follower in case of the Elab are: Seniority: Entry 45,5%; Industry: Information Technology and Services 33,9%; Company Size: 200-500 25%; Function: Information Technology 17,4%; Employee: Non-Employee 100%.

If some student post a negative comment, or there is a misunderstanding, responds immediately, personally, by name. This is a technique used for conversation with each student, whether it is a positive or negative comment. Elab makes personal communication as much as possible to give the effect of a face-to-face conversation. SRM is based precisely on the fact that students feel close to Elab.

If metrics data stay zero, IMP should be reviewed and improved. Promotion of Master and PhD studies is reflected in activities that promote courses of Elab, with an accent on a practical ability and their usage at work. Activity Top Jobs has a motivating effect on application for further studies in this area. Important activities that may lead to an increase the number of applicants to Master and PhD studies are activities related to direct contact with prospective students. such are workshops. These activities should be carried out as often as possible, because they give the largest space to connect with students through personal contact and answering questions.

After extraction of all metrics, approach to analyse and process obtained results. By analysing all the metrics, IMP updates, activities are replaced and students are let to express their reactions again. Quarterly is necessary to do a detailed analysis, according to plan and the model presented in this paper.

5. CONCLUSION

Social media can be used for entertainment, but equally good as an Internet marketing tool. The paper discusses the concept of social media; how and why educational institutions use this tool for online marketing campaigns. The main advantages of their use are great reach target groups and free usage. This free advertising may be enough in some cases and some period, but it is convenient to pay periodically for advertising on Facebook or LinkedIn to expand the number of fans and connections. In this paper was presented a model that includes a procedure needed to achieve Student Relationship Management. It is necessary to constantly listen and measure the needs and expectations of students, conduct activities accordance the result and continuously improve Internet marketing strategy. The priority for Elab is to provide interesting, reliable and comprehensive information. By fulfilling all these demands, Elab provides a stable and long-term communication with students on social networks. In addition, the Elab maintains course Internet marketing, and consequently must be presented as a leader in this field and to present properly themselves through activities that are tends to be. Some students do not have a social network profile. Reaching them problem can be solved by developing an Android application that sends notification of all activities. This will be further considered as extension of Student Relationship Management.

ACKNOWLEDGEMENT

The authors are thankful to Ministry of Education, Science and Technological Development of Republic of Serbia for financial support grant number 174031.

Abstract: *The abundance of various data which are accumulated and transferred via online social networks and their ability to be extracted and analysed have become the topic which scientific and professional public is becoming more and more intensively interested in. As the activities on online social networks are becoming more and more present sociological phenomenon, online social networks are regarded as reliable indicator of social condition and course of future social development. The objective of this work is to awake the understanding in regard to the overall connection among the students and the position which its members have in the structure through statistical analysis of the structure of friendship relations of the closed Facebook group the members of which are the students of the Vocational College of Technology in Arandjelovac. For the needs of gathering data the created Facebook application was used, which offers the possibility of gathering data on structure and members of any Facebook group whose member is the user of the application. The results that were reached by the research in domain of network density, centralisation and modulation, identified communities and influential individuals, as well as in domain of the identification of the discrepancies in position within a structure depending on member's sex, can be used as the starting point in defining the strategies of managing the relations with the students, viral marketing and generally in managing the flow of information in the Vocational College of Technology in Arandjelovac.*

Keywords: *Online Social Networks, Facebook, Data Mining, graph, analysis, nodes.*

1. INTRODUCTION

The growth of the World Wide Web service led towards the evolution od various types of information sharing systems among which the greatest popularity was achieved by online social networks such as Facebook, MySpace, Flickr, LinkedIn, LiveJournal, Digg, LastFM, Bebo, Twitter, hi5, Orkut and other. Online social networks enable the users to access the network, create connections with other network users, propagate information that represent the users and their preferences, providing an environment for sharing the wanted content with other users. The growing popularity of social networks has been the result of their relevance for various processes within the society, such as the growth of cultural influences, personal beliefs, formation of communities, groups, etc. At the same time, online social networks represent favourable ground for various shapes of research and primarily for sociological one since they provide the access to great quantity of heterogeneous data on individuals, social occurrences, social tendencies and similar. Regarding the growing popularity of online social networks and the availability of great quantity of content which is created by the users themselves, social network analysis has become a burning issue especially in the domain of development and accepting new techniques for social network modelling and analysis in the sphere of Machine Learning and Data Mining.

The subject of the work is research and analysis of friendship relations on Facebook social network among the students of the Vocational College of Technology in Arandjelovac. Nowadays, high-education institutions are facing highly-competitive relations on the market; therefore, they are in such a position that they cannot marginalise the issue of adequate managing the relations with the students. Understanding of the students' position in a society, the ways, and flow of information in a school community, students' affinities, and characteristics are of decisive importance for reaching students' contentment with their studies. As a specific sphere of interest, in the conditions of market economy in an education system, the issue of working out and realisation of promotional activities arises, where familiarity with the students' position in a social community, their connection and degree of influence, can have paramount results regarding the virtual marketing. Under such circumstances the concept of Customer Relationship Management and especially the application of techniques for the analysis of social networks are becoming more and more relevant, in this case, for the users of the education services, that is, the students.

2. ANALYSIS OF SOCIAL NETWORKS

Analysis of social networks is a multidisciplinary sphere targeted at analysing and modelling the connections and diffusion processes among diverse objects in the nature and society with the aim to understand the ways

in which the behaviour of individuals and their interactions are transferred into global sociological phenomena. The analysis of social networks which is according to *Wellman and Berkowitz (1988) also called structural analysis (p.1)* represents, above all, the strategy for exploring the social structures. Traditional individualistic sociological theories and techniques for data analysis have had as their subject research of individual participants who reach decisions, not taking into consideration the behaviour of other individuals, and ignoring the social context of participants. Nevertheless, when analysing social networks, connections among the participants gain the highest priority while the characteristics of the individuals become marginal making the relational data the focus of the research. According to *Wetherell et al.(1994) analysis of social networks (1) conceptualises social structures as networks with connections which link members and resources, (2) focuses on the characteristics of connections instead on the characteristics of individual members and (3) perceives communities as 'personal communities', that is as networks of individual relations developed, maintained and used by people in everyday life (p. 645).*

Two main forms of social network analysis are distinguished depending on the subject of their research: (1) analysis of complete networks which encompass all relations within the defined population and (2) analysis of personal networks (which are also called egocentric networks) which encompass connections that individuals have in the shape of their personal communities. For groups such as enterprises, schools and other communities, analysis should own thorough information about who is on network, and due to this all of the participants are 'egos' and 'alters'. Analysis of personal networks are usually carried out when the 'ego' identities are known but not their 'alters'.

3. REPRESENTATION OF SOCIAL NETWORKS

Aspect and the degree of analysis which can be carried out, as well as the quantity of knowledge which can be obtained through analysis of social networks depend on the technique which is used in their representation. Certain techniques enable mathematical analysis, while others are only dealing with theoretical research and reasoning. The choice of the way of a representation is determined by the nature of the problem and operations that are necessary to carry out on a network as well as the desired degree of network's abstraction. In practice, social networks are most often represented by using graphs, as a cluster of nodes and their connections which are generally called relations. In a social network, a node is usually called a social participant and it can represent a person, a group, a document, an organisation or even an entire nation. Edges between the pairs of nodes represent relations which maintain a friendship, a kinship, mutual interests, financial exchange, physical relations, hyperlinks, etc. In a representation such as this when analysing social networks, depending on the research issue, general indicators of the graph theory are used, such as: degree centrality, betweeness centrality, closeness centrality, average path length, modularity, clustering coefficient, graph density, etc.

Except for the graphic representation, it is also possible to represent social networks by using matrices where adjacency matrix is often used. Adjacency matrix is a matrix A with dimensions $n \times n$, where n represents the number of nodes in a graph. Element a_{ij} is equal to the number of branches which start from a node i, and end at the node j. On weight graphs in the scope *(i, j)* the weight of a edge which connects nodes i and j is located. If types are marked by nodes, and columns by edges of a graph and if element a_{ij} has value 1, and if i node is incidental to the j edge, and if contrary equals 0, in that case a matrix is called incidence matrix. Besides these previous, other matrix representations are used, such as Laplacian matrix of a graph which represents the difference between the degree centrality matrix and its closeness matrix or for example the normalised Laplacian matrix.

Semantic representation of social networks is based on the concept of Semantic Web which, according to *Breslin and Decker (2007), provides mechanisms for representation and navigation by connecting people and objects wit a view to representing heterogeneous relations which connect them (p.88)*. Semantic Web provides representation and exchange of data on social networks by using RDF (eng. Resource Description Framework), query language (SPARQL), and framework for defining schemes (RDFS and OWL). The key concept for semantic representation of data is ontology which *Gruber (1993) defines as: formal, explicit specification of a divided conceptualisation in the form of an explicitly specified vocabulary which describes diverse aspects of a domain being modelled (p.2)*. Among the ontologies used in the representation of social networks, according to *Ereteo et al. (2011) FOAF (Friend-of-a-Friend) is currently used the most (p.5)*, ontology for describing people, their relationships, and activities. A great number of attributes are used in describing the users' profiles (such as surname, user name, interests, etc.), the use of Web (online accounts, weblogs, membership, etc.), relations which connect members (familial, friendly, businesslike, etc.) etc. In addition to the previous ontology, other ontologies are used as well, among which are SIOC (Semantically Interlinked Online Communities), SKOS (Simple Knowledge Organization Systems), RELATIONSHIP ontologies.

4. MAIN RESEARCH TOPICS IN SOCIAL NETWORK ANALYSIS

One of the key research problems in social network analysis is the way to determine the possibility of existence of relations among objects on the basis of their attribute clusters and topology traits of individual objects in a network, for which different social network model variants have been developed, such as: p1 model, which is represented in *Holland and Leinhardt (1981)*, p2 model, Dynamic Preferential Attachment Model which was represented by *Barabasi and Albert (1999),* Watts-Strogats model of a small world represented by *Watts and Strogatz (1998),* model from the domain of the theory of games, adaptive network models, etc.

Analysis of similar nodes is another problem which was noticed by the research community. Usual approach to measuring the similarities between the nodes is the so called structural equivalence, where two nodes are considered to be structurally equivalent if they have a great number of mutual nodes by which they are connected. Jaccard's coefficient which is described in *Han and Kamber (2006) (p. 391)* belongs to this approach group. Alternative approach starts from the concept regular equivalence, where two users are similar if their acquaintances are similar as well. Regular equivalence is self-referential concept: it is primarily obligatory to know the similarity between two neighbouring nodes before the similarity between those two nodes is calculated. Some of the most important algorithms for calculating the regular equivalence are REGE and CATREGE.

Diffusion in networks is a research problem which was the subject of various studies' analysis which studied diverse scenarios of spreading of computer viruses, knowledge, products, etc. Basic mathematical models which can be found in literature for the analysis of information diffusion in social networks are threshold models and cascade models. In threshold model, node *v* in a network can adopt some activity (become active) only if a certain number of nodes within the neighbourhood of the given node are active, that is when the number of active nodes in the neighbourhood of node *v* exceeds the threshold value when node v becomes active. In cascade models of information diffusion each individual in a network which becomes active has a unique probabilistic chance to activate each inactive node within its neighbourhood.

Mesoscopic description of network structures explains the structure of communities within networks. The greatest number of algorithms for the detection of communities is based on the concept of network modularity. A series of diverse techniques and algorithms have been developed for identifying the communities in social networks, such as: Girvan-Newman algorithm, which is described in *Girvan and Newman (2002) (p.7823)*, hierarchical clustering, which is described in Wasserman *and Faust (1994)*, stochastic block of modelling, CPM (Clique Percolation Method) method which is used for detecting communities which overlap (for more see *Palla et all (2005)*), CHRONICLE which is used for discovering communities which change over time (one of the approaches can be found in *Kim and Han (2009)*) and other.

5. EXPERIMENTAL WORK

The objective of the research has been to awake the understanding in regard to the overall connection among the students and the position which its members have in the structure through statistical analysis of the structure of friendship relations of the closed Facebook group, the members of which are the students of the Vocational College of Technology in Arandjelovac. Conclusions which the research has reached can be extended on interpretation of global relationships among the College students and used in defining the strategy for managing the relations with students. The results of data analysis which have been gathered enable: better understanding of the density and relationship character among the group members, community identification within a group, better understanding of the differences in character of connection among the group members who are of male or female sex. In order to test the starting hypothesis in the work, the reached results were compared with average values of referential indicators for the tested group which encompassed ten Facebook network users who submitted needed data which was obtained via application for data gathering as a way to construct ego networks of their friendships on Facebook network. The starting assumption in the analysis was that the network would be considered as centralised, dense, and connected, highly modular, if it has values of relevant indicators which are bigger or equal to values of average indicators for the test group.

The network of Facebook group members is represented by using an unweighted graph, while the derived analysis is static and which refers to data gathered by using the Facebook application which was developed for a specific purpose on April 1st, 2014. Facebook is chosen as a social network from which data on structure of friendship relations was gathered, regarding that this social network provides referential sample

for the Vocational College of Technology in Arandjelovac, who by far uses less other services for social networking.

3.1. GATHERING DATA

Facebook is a robust, documented platform with data organised both in horizontal and vertical sense. Model od friendship relations on Facebook is symmetrical and demands reciprocal consent of users in order to gain access to other user's data and to enable interaction with another user. Facebook provides fine control of privacy, enabling friendships to be organised and maintained as lists with diverse degrees of visibility for users and divers activities. There are three main ways to access the data on Facebook social network. The first one is direct access to data on server which is available only to the intern users or in cooperation between service providers of social networks and a research institution. Another approach is access through sanctioning API[1] which implies that the machine interface is used and which is provided by many Web 2.0 services and especially for programmers so as to stimulate the development of applications and integration with other services in order to provide additional functionality and usefulness for the users. These interfaces ensure structured data, but they are generally limited in scope and the data content as well as in time when data can be gathered. The third approach is browsing the user interface which can be done manually, but most often includes deploying softvare agents which read HTML documents which are used as graphic interface for users, directly through HTTP protocol or through the automatisation of a browser via DOM. These techniques can avoid limits of API, but often disrupt technical or legal authorisation which gives provider platforms. For Facebook platforms mechanisms for detecting bots are used, so suspicious activities often lead to the suspension of the account.

Main restrictions that implements Facebook platform are as follows: each access to data is signed by privileges of a Facebook user whose current status on a platform defines the scope of data which can be accessed; user's settings related to privacy protection influences which information can be gathered; each application has to ask for permission to access various data; there is a restriction regarding the quantity of information which can be obtained from a user's profile that aren't in a mutual friendship relation; there are certain technical limitations such as the one where friend lists are dispatched through asynchronous script. Certain Web servers such as Graph API were introduced in year 2010. However, these services do not abolish previous limitations, but introduce some additional ones. Besides, service providers for online social networks keep the right to modify or close the service interface which can bring about new problems in gathering data from online social networks.

To collect the data about friendship relations between members of the Facebook group in consideration dedicated application had been created using PHP and Facebook SDK for PHP. Facebook SDK for PHP provides a number of server side functionality for accessing Facebook API, including access to functionalities Graph API and FQL's. Graph API is the main way to obtain data from the Facebook Social Graph, a massive data structure that represents social interaction covering nodes and edges between nodes. At issue is the API that is based on HTTP, which can be used for data collection, respect, uploading photos and a host of other functions.

Application for gathering informations about firendship relations, can be found on Facebook platform as Graph Projekat and can be used for any Facebook group of which the user of the application is a member of. Application generates a HTML page with a list of links representing Facebook groups of which the user is a member, whose choice triggers metods for collecting information about group members and their relations. Data collected on members of the group are: Facebook ID, gender, location and friendship relations with other members of the group.The application includes a script that checks if there are repeating nodes and their connections, and as a result generates file with .gdf extension that can be used in Gephi and other similar programs for network analysis and visualization of network graphs.

3.2. DATA ANALYSIS

The overall number of nodes encompassed by graph is 546 with 5680 edges which reciprocally connect nodes. For the purpose of carrying out the analysis and the visualisation of the graph, free open source program Gephi was used. Gephi is an interactive platform for visualisation and study of all types of connections and complex systems, dynamic and hierarchical graphs. It works under Windows, Linux, Mac OS X operating systems.

[1] API- Application Programming Interface

Maximum value of degree for the whole network is 173. Average degree for the whole network is 20.806. The former implies that each node in the network is on average connected with 20.8 other nodes in the network. Twenty nodes aren't connected with any other node in a network. By eliminating these nodes we get the indicator of network's average degree which is 22.188. Since the average degree of the analysed group is greater than the referential value (13.545) it can be concluded that the network has a relatively high average degree.

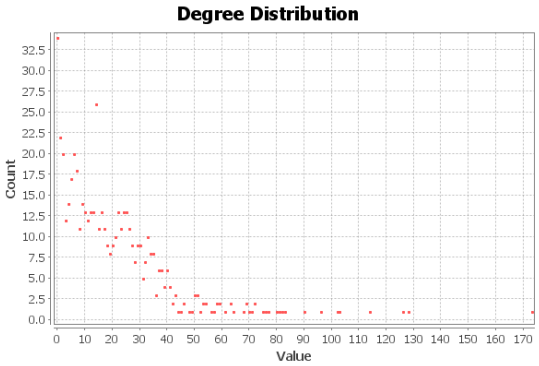

Figure 1: Degree distribution for the whole network

Relatively small number of nodes on the network (7%) has degree in scope from 50 -173. Up to 346 nodes has degree in scope from 1-25 with average degree of 4.2. This implies that a small number of nodes have a significantly higher degree in relation to other nodes.

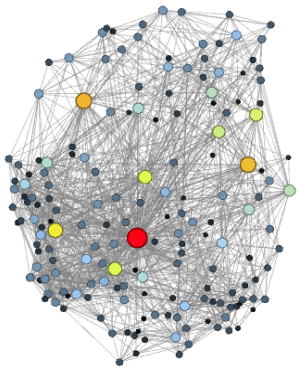

Figure 2: Ego network of the node with the highest degree centrality

The maximum value for betweeness centrality is: 15,724. The former suggests that the node with the highest betweeness centrality is located on 15,724 shortest paths on the network. Extremely high betweeness centrality is the consequence of the fact that it is a closed Facebook group. In Figure 3, nodes with low betweenness centrality are coloured in black, those with betweeness centrality from around 50 are light blue, yellow are those with betweeness centrality around 700, while bright red are those which signify high betweeness centrality (over 3,000).

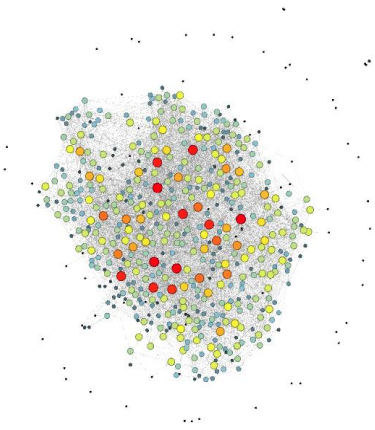

Figure 3: Network graph for the scope of betweeness centrality: 0-15724

It can be said that 11 nodes have a very important betweeness centrality (position) in the network. Thirty three nodes have the betweeness centrality 0. Thirty nine nodes (7%) have got the betweeness centrality higher than 1,000. The node with the highest betweeness centrality (15,724) has a significantly higher betweeness centrality than the second placed one (8,000). The former confirms that there is a small number of nodes which have a significantly higher betweeness centrality when compared to other nodes.

Graph has a diameter 6 and an average path length 2.47 which attests that there is a closely connected group of individuals. The total number of the shortest paths is 256,550. By eliminating the nodes with a low degree and keeping the ones with a degree higher than 3, the graph diameter has the value of 4, radius 2, whereas the average path length value on the graph is 2.35. The maximum value of closeness centrality on the network is 3.97. The former indicates that the average distance for the node with the highest closeness centrality in relation to other nodes on the network amounts to 3.97. Higher values of this indicator suggest greater network distribution. More then 90 nodes of the given network possess five-branch eccentricity, while nearly 400 nodes possess four-branch eccentricity. The average diameter with the test group is 10, whereas the average path length is 3.67. The former emphasises the fact that the distances on the graph are relatively short, meaning to say the graph is compact.

Graph density is 0.038. Eliminating the nodes not connected to the other nodes on the network one gets the graph density value 0.043, while the graph density average value in the test group is 0.30.

The average clustering coefficient is 0.299 for the entire network. The total number of registered triangles is 15,106. Nine users have the clustering coefficient with the value 1. The former indicates that 9 nodes on the network are neighbours with each given node connected with all other neighbours of the given nodes which says a lot about the high network connectivity. The clustering coefficient average value for a test group is 0.438, whereas the average triangle number is 7,481.

The existence of 37 weak components for all the nodes on the graph has been identified. Such a high value is the result of the fact that as many as 33 nodes in the given group have no connection towards the other members of the network. For those nodes which possess a degree higher than 8 (389 nodes), the existence of one component has been identified.

In order to detect communities within the network, Gephi program uses a special algorithm for examining the modularity. This algorithm enables the randomisation which improves decomposition, but requires greater processing time and resolution defining, whereby the resolution value is less than one which facilitates the production of a greater number of smaller communities, whereas values higher than 1 enable the production of smaller number of greater communities. For the resolution value 1, and the graph which consists of nodes with the average degree higher than 8, there is a modularity degree 0.365 and the number of the detected communities is 6. The greatest community comprises 110 nodes, and the next one comprises of 100 nodes.The modularity indicator average value in the test group is 0.595, for resolution 1 and the number of registered communities is 41. The modularity of the group is lower when compared to the test group average modularity which implies that the members of the observed group are more closely related according to the average test data.

For the resolution value 0.5 the existence of 14 communities for the same nodes has been registered (average degree > 8, modularity 0.322), whereas for the resolution value 2 (modularity 0.2198) the existence of 2 communities has been identified. The former group has 270 members and the latter 110 members. A great number of connections which represent local bridges among the communities and high discrepancy in the number of communities for different resolution values are indicators that the communities of the group members are mutually closely connected.

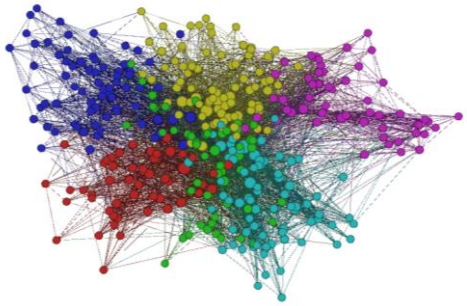

Figure 4. Six discovered communities for the resolution 1 and the network with nodes whose average degree is higher than 8.

The average degree for female group members is 10.557 (291 nodes), whereas for the male ones (253 nodes) the average degree is 8.933. Lower average degree values are the consequence of the fact that the exclusion of the opposite sex the entire network becomes reduced. Network diameter for the females is 6, whereas the average shortest length path is 2.68. Network diameter for the males is 7, whereas the average shortest length path is 2.73. Based on this it can be concluded that females are slightly more connected within the network than males.

In the aspect of analysis on the community forming tendencies which depend on sexes of the group, for the resolution value 1 and nodes with a higher degree than 0, the existence of 8 communities for the males has been identified, whereas the clustering coefficient is 0.258 (the total number of triangles is 1.224). For same parameters for the females there has been identified the existence of 9 communities and clustering coefficient average value of 0.343 (the total number of triangles 2,365). Based on the former, it can be concluded that there is a greater tendency toward clustering when it comes to females when compared with males.

4. CONCLUSION

The premises regarding the network structure of the analysed closed Facebook group have been confirmed by conducting analysis of friend relationships by using standard indicators from the Graph theory area. It has been proven that the network has a relatively high connection among the elements.

Group members with the highest values of centrality measures have been identified, which can be generally interpreted as the influence degree which these members achieve in the group. The data gained in this way can be used in the domain of promoting relationships with the students of the College, that is to say the realisation of the CRM concept, through directing more attention to demands and opinions of students with a higher degree of influence.

Through the identification of the communities, the correlation can be made between students' year of studies/study program and the community within the Facebook group they belong to. In this way, the interaction quantity between students of different years of study and study programs could be ascertained and we could come up with activities with a view to promoting the relations between the existent structures at College**.** When it comes to position of nodes on the network in relation to criteria half member, the results have shown that females are more prone to clustering, meaning to say that they are connected in strongly connected groups with a high number of relations among group members and they are stricter within specific limits among communities when compared to male communities. In addition, possessing information on community membership can be useful in the domain of figuring out methods for transferring relevant information to students.

With this study it has been confirmed that the analysis of the online social network structure is a powerful tool which can provide relevant information for promoting the quality of regulating the relationships with service users/product buyers and directing the information diffusion in an organisation. From the point of view of higher education, the information on students which can be acquired in this way offers endless possibilities for promoting the quality of relationships with students and enhancing the education process.

Abstract: *This paper describes application of the Internet of Things (IoT) in hydrology. The aim of this paper is to investigate possibilities of harnessing Internet of things in business systems, particularly hydrology. Main characteristics and applications of IoT are discussed. Using IoT increases business efficiency, reduce costs and increase safety. Specific context of the research is related to the application of the IoT on dams in Serbia. Several recommendations and approaches are discussed in order to improve the system functionality of dams.*

Keywords*: Internet of Things, M2M, IoT, Dam, Safety of Dams, Dam Prvonek.*

1. INTRODUCTION

The appearance of wireless technology has raised the world of communication to a higher level, making it possible to interact with the Internet at any place and at any time. Lately, term "ubiquitous" is frequently used. The ubiquitous term describes a situation in which the previous constraints of time and space have been overcome and the boundaries between the real and digital worlds become blurred, and the computer becomes fully integrated into the environment of the individual.

The implementation of intelligent devices within the communication-controlling network created Internet of Things (IoT), with sensors and actuators seamlessly blend with our surroundings, and the information is used across different platforms in order to create a unified whole (Gubbi, Buyya, Marusic, & Palaniswami, 2013). In the literature the term "Internet of Things" refers also as the M2M (machine-to-machine), The Web of Things and the Industrial Internet. By the recent upgrade of devices with numerous wireless technologies, such as radio-frequency identification tags (RFID tags), built-in sensors and nodes drivers, IoT has gone one step further in the development, and become a new breakthrough technology that transforms the classic Internet in a brand new all-integrated Internet. The essence of M2M is based on the idea of small sensors that collect data and automatically transfer them to the server or the cloud, where the data can be easily analyzed. The implementation of RFID tags has influenced in the way of using intelligent devices and allows users to have access to all necessary information at any time. The reason for the implementation of IoT technology is fast feedback. Information obtained in real time and detailed insight into them, allows more efficient decision making. All received information is linked to big data, which will be in the near future very important for the areas such as manufacturing, healthcare, construction, public utilities, and so on. Due to the global warming of the Earth, which resulted in the occurrence of extreme climate change and frequent natural disasters, the need for surveillance and dams security control increase.

This paper describes how IoT can help in more accurate measurement of critical points, better management tools, and providing timely notification to the population of the flood wave.

The first heading gives short introduction to the Internet of Things. The second heading describes related literature. Third heading gives different definition, structure pros and cons of using IoT and application of the IoT. Application of the IoT on dams and possible improvement functionality dam using IoT are described in forth heading. The last two headings are conclusion and literature.

2. LITERATURE REVIEW

In (Gubbi, Buyya, Marusic, & Palaniswami, 2013), the authors state that the ubiquity, which was enabled by wireless sensor networks, has been implemented in all areas of life. With the implementation of new wireless technology such as RFID, IoT have improved the use of the Internet. This paper illustrates the idea of a global realization IoT using the central cloud. Authors described the implementation of the cloud application

Aneka (.NET platform based on a cloud), which is based on the interaction between private and public clouds.

In (Sun, Zhang, & Li, 2011), the authors write about the importance of dam safety. In this paper authors specifically deal with tailings dam issues. Tailings disposal is very important in mining. In recent years there has been a number of accidents on the tailings dams as well as in mines with such dams, what leaded to catastrophic consequences for people's lives. In order to improve dam safety, dam monitoring and alarms for alert are modernized with IoT and cloud, which can in real time 24/7 monitor the water level and deformities that occur in the dams. In this paper, the authors explain the system TDMPAS (The Tailings Dam Monitoring and Pre-alarm System) and its implementation. In (Castillejo, Martinez, Rodriguez-Molina, & Cuerva, 2013), the authors described the applications based on wireless sensor networks. The application is developed to implement the collected data in the smart spaces in order to obtain a better athletic performance. The system has been tested in high school to the real nodes and devices, and graphical interface gives possibility to the athletes, who use them, to improve their physical qualities with minimal changes in their training regime. Users can use a variety of devices (such as smart phones, smart watches or tablet) to allow easier monitoring of the whole body. In (Alcaraz, Roman, Najera, & Lopez, 2013), the authors state that the main task of remote substations to the central system is to provide sensitive information about the critical infrastructure such as power systems for power generation and transmission. Thanks to its features, such as simplicity, reliability and cost savings, wireless sensor networks have recently been applied in this area. Number of control and data acquisition systems, which use the Internet infrastructure to be hooked up to the sub-station in the function of time has been increased. It is very important to make a decision of use between complete isolation from the Internet or full integration with the Internet. Full integration with the Internet involves the use of IoT. This paper describes both options whereby analyzed security and infrastructure requirements that are appropriate for all TCP / IP protocols.

Many algorithms and positioning systems have been developed by using wireless sensor networks in indoor and outdoor environments. In order to achieve higher positioning accuracy, in most cases there is need for more equipment. Primary IoT services are based on positioning, so the precise location is a key problem. In (Chen, Xia, Huang, Bu, & Wang, 2013), the authors propose a specific scheme which can meet the needs of different devices for precise locating. The proposed solution consists of two phases:

- Phase dividing, in which a certain region is divided into smaller units with the help of the network grid.
- Phase detail, in which it is possible to implement an algorithm for better positioning, as described in this paper.

Test system is set up to verify the accuracy of the proposed schemes and to illustrate its capabilities and availability. In conclusion of this work can be seen that this scheme improves the retrieval facilities.

3. INTERNET OF THINGS. TERMS AND DEFINITIONS.

According to analysts and visionaries in technology, Internet of Things (IoT) is a network of physical objects connected via Internet. These objects embedded technology that allows interaction with the internal state of the object or the outside environment. If subject can perceive and communicate, then the way how decisions are made, where and who makes them change (IoT Overview, n.d.). IoT is part of the future Internet that includes billions of intelligent communication "things" or objects connected to the Internet (Internet Connected Objects or ICOs), which will have the ability to perceive, initiate and processing capabilities (Perera, et al., 2014). IoT is massive electronic equipment with interconnected large virtual networks, including RFID, sensors and actuators devices based on Internet connections (Lin, Hu, & Qui, 2013).

IoT is ubiquitous connections between things that everyday interest people, which provides connectivity anytime, anywhere and with anything (Barthwal, Misra, & Obaidat, 2013). In the past one-dimension bar code had a significant role in the supply chain and other business models. It was quickly overcome because it was a general identifier without specifications. Unlike the one-dimensional, two-dimensional bar code provides a larger set of data, but the problem is that a printed bar code is not possible to change. IoT is a concept that has a huge impact on business and society. The whole concept is still based on the capabilities and limitations of the technology identified as RFID. RFID is the successor to bar codes.

ARCHITECTURE OF IOT SYSTEM

The word "thing" in the concept of Internet of Things or the word "machine" in the M2M represents a physical object which identification or condition may be transmitted to the infrastructure that is connected to the

Internet. Almost everything what can be connected with sensor (cows in a field, a container on a cargo ship, air conditioning in the office, street lighting...) can become part of the Internet of Things.

The sensors are part of the things that collect or distribute information whether it is on location, altitude, speed, temperatures, brightness, motion, force, humidity, sugar levels, air quality, humidity, country, etc. Regardless of whether is it a communication device on a local or wide area, all IoT sensors need technology for transferring data to the outside world. There are number of available local short-range wireless technology. Such include RFID, NFC, Wi-Fi, Bluetooth, XBee, ZigBee, Z-Wave. In addition to wireless links also cable connections can be used, such as Home Plug, Home PNA, HomeGrid/G.hn and Lon Works. When it is necessary to use worldwide connection, it is possible to use mobile network (e.g. GSM, GPRS, 3G, LTE or WiMAX) and satellite links. New wireless networks such as ultra-narrowband (using the channel that almost have a flat signal) and the TV white-space (used for broadcasting services outside the local area) are specifically adapted and used for M2M. The architecture of IoT with all necessary elements is shown in next Figure.

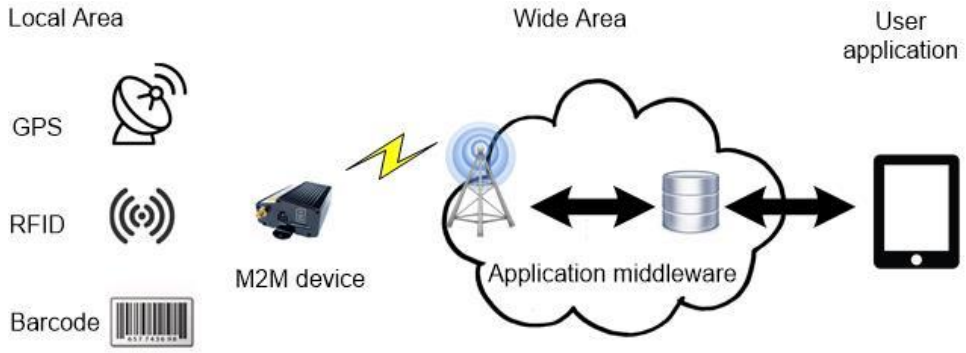

Figure 1 Structure of IoT

It is important to place the storage of all collected data. In the case of a large number of data, IoT will require massive, variable data warehouses which are mainly located in the cloud, unless it is not about some sensitive data which will be processed locally. Some types of M2M settings, such as a smart house or office, use a server that physical is on the same location as the devices and serve to collect and analyze data in real time or periodically.

Figure below presents a flow of data in the modern systems such as IoT.

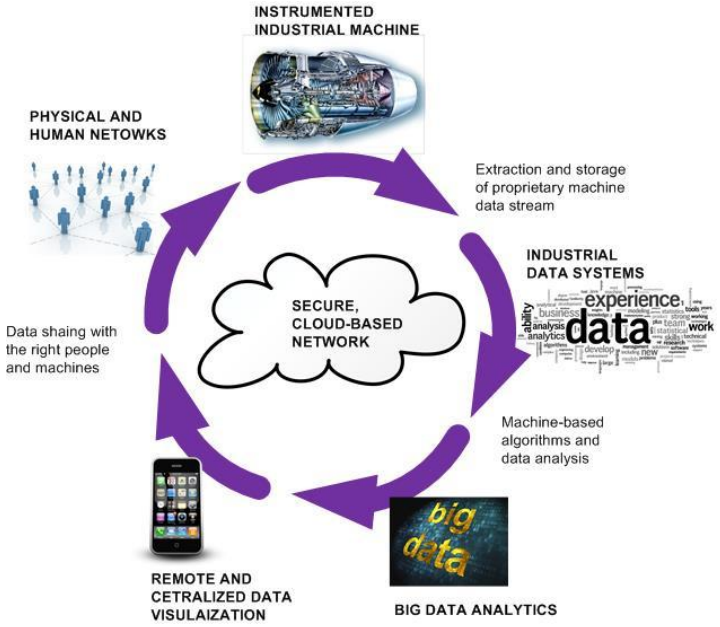

Figure 2 Secure network based on the cloud

BENEFITS OF USING IOT

Internet of Things is still in the early, developmental stage. In the coming period, it is expected that people will become more creative and will appear the new ideas of implementation new sensors. With the rise of creativity, Internet of Things industry will be faster developing. Experts predict that the implementation billions of connected devices, change the world where we live into the better world, so it will be less sick people who will be in life-threatening situations, because doctors will be on the time informed. Less aircraft failures and less fall down of planes, because planes will be electronic followed by the condition of the parts. Quality of wine will be better because they winemakers will be able to monitor the percentage of sugar in the grapes and know when is the ideal time for harvesting, etc. (Johnson, 2014)

Water, electricity and natural gas are among the most important resources. As population and standard of living growth, in the situation that was mentioned people need to use resources more efficiently.

Devices used in a household can be improved with the IOT, which would change the living environment and lifestyle. Improving devices, people will make smarter decisions that will enhance safety in the home, improve health conditions and make better use of resources.

Company Belkin has introduced a pilot program, which uses sensors in houses and with the help of various algorithms make scheme of using water, power and gas, and provide recommendations on how to use them rationally (The Internet of Things, n.d.). The technology provides a graphical display of accurate consumption of each device, enabling more rational consumption.

PROBLEMS IN USING IOT

The biggest observed problem using IoT is in the area of data protection (theft and abuse), and the other problem is identified in assigning IPv4 address to devices.

Application of Internet of Things is divided into two broad areas: Critical infrastructure (energy production and distribution, manufacturing, transport…) and identity infrastructure (personal medical devices, auto industry, home entertainment and control devices and retailing) (Internet of things summit, 2013). Possession of devices connected to the Internet opens the possibility hackers to remotely take control of the device. Critical infrastructure is an attractive target for national and industrial espionage. Things are connected to the Internet and in contact with highly sensitive personal data are interesting target for cyber criminals (identity theft, electronic fraud...). Every day, developing new methods that can be extremely effective in providing data: secure operating systems, applications that are installed in devices, flexible and simple monitoring system, new forms discovers and blocks active threats. With the development of IoT, more devices will be connected to the Internet, which would pose a greater risk of attack by hackers, and all devices will have to be monitored.

Robert Le Busque said that all things which have IP address should have specific security protocol and the policy of protection should be identical to policy which the company uses. Rawlson King said, today there are various versions of the OS for mobiles, for desktop computers, a large number of different devices and so on. He also said that similar thing for all these devices is the network, where all devices are connected. Network, which is a bottleneck, should be the most important thing where companies should implement theirs security (Lee, 2013).

A key part of the business is to protect communications. So far the security of communication was based on encryption methods. Using certificates in IoT encountering problems because certificates have limited validity period, after which they must be renewed. Another problem that arises the implementation of IoT is assigning IPv4 address to the devices. The network won't have enough number of free addresses to allocate all devices, unless move to IPv6 addresses. IPv4 is using modern equipment and modern operating system and has adequate security, opposed to IPv6, which still have to go through certain stages in the elimination of failure.

There is another side of the problem which is not related to the technology, and concerns of people. The implementation of automation will make people losing the habit of thinking and their brains will slowly dye. People will less move, because it won't have the urge to get up and everything will be customizable thanks to sensors. Reducing activities will lead to various health problems. The problem of privacy is possible to solve if legislatures write rules, that clearly define what the company can do with the data and what are the sanctions for violators.

APPLICATION OF IOT

Next figure shows the taxonomy of IoT, areas wherein is applied IoT.

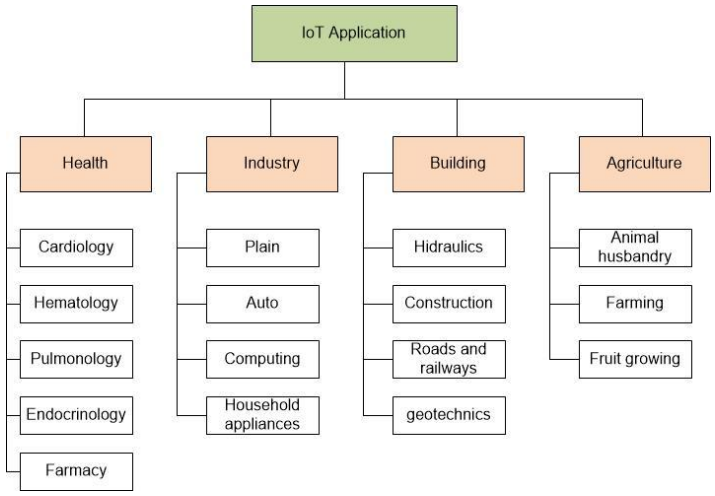

Figure 3 IoT taxonomy

A very important application of the IoT is in healthcare. Sensors are installed on the packages of pills that resemble one that should bring or take the pills at a certain time. The sensors are installed in artificial organs and keep statistics on the state of the organism. For instance, in England, cows are connected to the Internet in order to monitor their movements. In San Diego trash cans are connected to the Internet, so when the trash is fully loaded, the container sends the message to sanitation that should be emptied garbage (Johnson, 2014).

Interesting application of IoT may be seen in San Francisco and Los Angeles where the sensors are placed in the parking lots, and with the help of the application can be seen in the street where is a free parking place or the price of parking in the garage is formed based on the availability of parking and at any time there is 80% free space.

4. APPLICATION OF IOT IN DAMS

Area where IoT is already implemented is construction, hydrology - dams. In recent years there have been several failures of dams. Most of these unfortunate events led to enormous damage in terms of human life, property, environment and economic losses (Sun, Zhang, & Li, 2011).

The problems of instability of large dams and the possibility of failure can menace the safety of people and industrial property, and can leave consequences on the environment. Therefore, in recent years, great attention is paid to control the functioning of the measuring instruments on the dam and the dam itself. Special attention is paid to the protection of possible floods and flood waves.

DAM "PRVONEK"

Dam "Prvonek" is on the Banjska river, right tributary of the South Morava river. Partition space is located about 9 km from the mouth of the South Morava, at the site of the village Prvonek.

Dam "Prvonek" is a regional multi-purpose water management facility, which main purposes are: water supply, flood protection, improvement of low flows during periods of unfavorable hydrological conditions in the basin, as well as the production of electricity.

On dam Prvonek, meteorological observations are used to measure: precipitation, air temperature, humidity, solar, radiation, wind (speed and direction), depth and atmospheric pressure.

Hydrological observations are used to measure: water level in the reservoir, the level of ground water, discharge at the entrance to the reservoir, discharge at the outlet of the reservoir (measuring profile downstream from the dam) and water quality.

Equipment for monitoring water quality follow next parameters: temperature, pH value, electrical conductivity, redox potential, depth, turbidity and dissolved oxygen.

Hydrogeological observations: groundwater level in the field and groundwater level in the dam.

Observations in the body of the dam: pore pressures in the clay core, total pressures in the clay core and adverse effects of water in an injection gallery.

Flow in the outlet valve chambers foundation drain. Real-time (20 minutes) is secured by performing measurements of the flow: water supply, to waterfalls, towards the chute, to small aggregate shp (small hydro-power plant) and to a large aggregate shp (Divac, Milivojević, Pavić, & Jovičić, 2013).

IMPROVING THE DAM "PRVONEK" USING THE IOT

In the dams design and functionality important segment is related to dam safety, particularly in flood control and flood wave. The most important devices which are responsible for monitoring are probes for measuring the water level in the reservoir and piezometers for measuring groundwater levels. At all dams exists boreholes, in which devices measure water level. The devices can be configured in two ways: in graphical user interface or directly in the developer's code.

For implementation of sensor it is necessary to: measure the depth of the borehole, determine the range of measurement devices (0-10, 0-20, 0-40...), set the device into the borehole, measure the height of water column (the water level above the unit), the formula to calculate the elevation of the device and with the aid of the cable which is fixed to the device, the device connected to the data logger (which is connected to the data acquisition server). There are two types of sensors: ceramic and with vibrating wire. Ceramic sensors are the new generation and used for measuring the water level in the reservoir and it is done in the intake tower. In the instruction manual ceramic sensors receive basic parameters that are needed during installation. Devices with vibrating wire used calibration list. Calibration list is a set of parameters provided by the factory and each unit is different. In addition to the calibration data obtained from the list, it is necessary to read data (frequency) by means of the device. By using both types of data in the appropriate formula, formula gives the height of the water column.

Figure below shows the current structure of the data on dam "Prvonek".

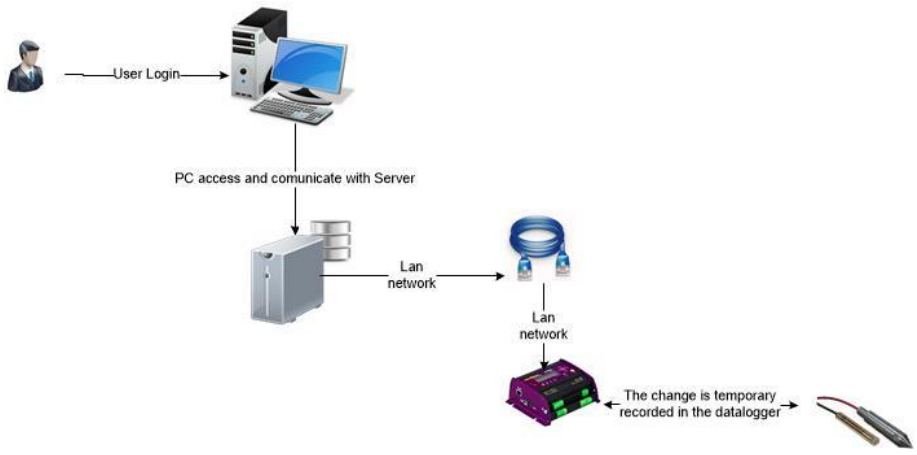

Figure 4 The structure of the data transfer from the probe to the end user

The present way of controlling the dams could be improved in several ways. The use of RFID sensors in devices would provide better evidence and better tracking of the device. It is necessary to mark each device with RFID tag where will be written device ID, year of manufacture, year of installation, calibration list that is data with calibration certificates, service and breakdowns.

It is an essential to install RFID readers in the borehole. The reader can read the ID of the device that is placed in the borehole and send signal to the operator, which is monitoring functionality of the device. This is

very important, because if there is a malfunction of a sensor, in his place may be moved other similar device that is already in use (if the company doesn't have a new device to change), but less important for the functioning of the whole system. The implementation of RFID tags allows employees fewer errors during operation, because the employee will be able easily to read the required data and can rarely replace calibration certificate. If RFID reader is installed in a workshop for repairing the device, it is possible to automatically record the date, length of service and type of failure that occurred. In holes can be installed sensors, which provide information - the depth of the probe or metal rings that register while placing the probe in the borehole. Incorporating RFID sensors in the borehole can be obtained from the specification of each borehole. The specification can include ID hole, deep hole, its location, date of last measurement and the measured value.

By placing sensors on the devices that need to be read manually, such as vertical, horizontal displacements or relative subsidence, allows worker easier reading. If technology is used to transfer data such as NFC, the employee can read data touching your computer at a specific measuring instrument.

In the body of the dam, which is located in the ground, it is impossible to receive a GPS signal, and also there isn't Internet connection. To have the device located (without the use of paper maps) and to allow direct data transfer from the device to the base it is necessary implementation of wireless Internet. By setting more wireless router to work in "repeat" mode (the mode that allows the expansion of the scope of coverage of a wireless network) the entire dam will have possibility to be covered by the Internet. The spread of the Internet on the dam allows direct transmission, processing and storage, and full implementation of the Internet of Things. By placing additional sensors at various locations in the dam, would allow the employee at any time to obtain a map with locations of all devices.

To end-user or operator is possible to implement smart ID cards. The cards can be used when entering the office to monitor the state of the system and logging software. In the body of the dam can be installed RFID sensors that were read smart cards of employees. The implementation of smart cards would allow automation of recording employees who read the data and the device on which the data is read. Automation of the process of reading and data transmission, and additional software development would allow the operator the current (real-time) overview of the changes at the dam. The software would show a graphic in a variety of colors and blinking functionality of the device and the changes that occur.

Figure below shows improved reading and structure data.

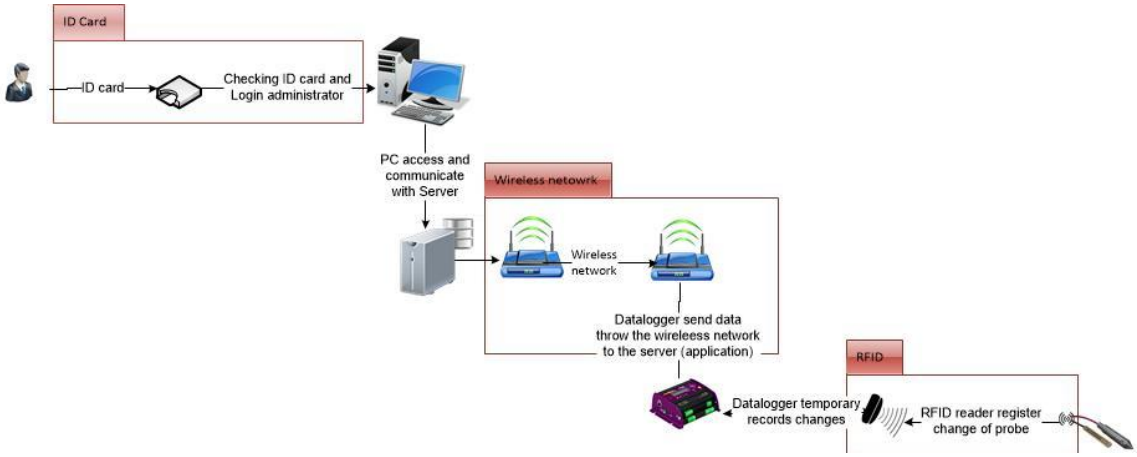

Figure 5 Improved structure reading and data transfer

5. CONCLUSION

Benefits and risks related to IoT will have a huge impact on individuals, organizations and governments in many countries. The use of smart devices is simplified, but the risk of use is high. Users have become aware of the opportunity provided by the Internet of Things, and their expectations for Internet services will change over time. Criteria for the purchase will be developed, and users will achieve greater power over providers of service and goods. M2M technology is growing rapidly and becoming part of a global economy, especially in areas such as auto industry, transports, logistics, energy, construction, health care and so on. Internet with the help of sensors allows each device in the environment to become smart. Soon the human environment will become an eco-system where the devices will use the OS and will be able to automatically connect to other devices and extend their knowledge and intelligence. The implementation of IoT brings better protect,

improves instrumentation, makes easier tracking of the history of instrument failures, improves operations and increases the safety of dams.

The next huge step is to connect the development of IoT data smart devices, services based on the Internet and existing databases. In the future, the field of application of the Internet of Things will continue to expand. People should pay more attention to the safety and protection from abuse of the collected data, and not just on the tags we use for marking. While RFID has a very important role in the IoT, RFID technology is only one kind of technology that is used to transmit data and for a short time will be overcome.

This paper describes term Internet of Things, architecture of IoT, benefits and problem of using IoT. It describes application IoT on dams in Serbia and given proposal of improving dam functionality and flood alarming.

In the future it will be taken further improvements in dams functionality and in better flood and flood wave control, and will be developed new IoT applications for other measuring devices.

Abstract: *This document presents potential technologies for implementing security requirements of services that use Near Field Communication (NFC) technology. Depending on application design and its security requirements there are three possible alternatives for storing sensitive data and application code within NFC enabled mobile phone: secure element (SE), Trusted Execution Environment (TEE) and device's operating system memory - using Host Card Emulation (HCE) service. Paper provides comparative analysis of mentioned alternatives in terms of technical issues as well as business ones.*

Keywords*: NFC, Secure Element (SE), Trusted Execution Environment (TEE), Host Card Emulation (HCE)*

1. INTRODUCTION

Until recently, we had ID cards, driving licence, healthcare card, loyalty cards and all other cards in the form of paper documents. In time, all those paper cards transformed into plastic cards – some of those called "smart" (the ones with chip). Today we have new trend coming up – transforming those plastic cards into applications – "virtual smart cards"- residing on our mobile phone. That mobile phone has the ability to interact with its surrounding using Near Field Communication (NFC) technology – wireless standard based on the same principles as RFID, that allows communication between two devices within maximum distance of 10 cm. NFC allows user to exchange the data from "virtual smart card" on the phone with reader (e.g. POS terminal) in contactless fashion. All he has to do is to "tap".

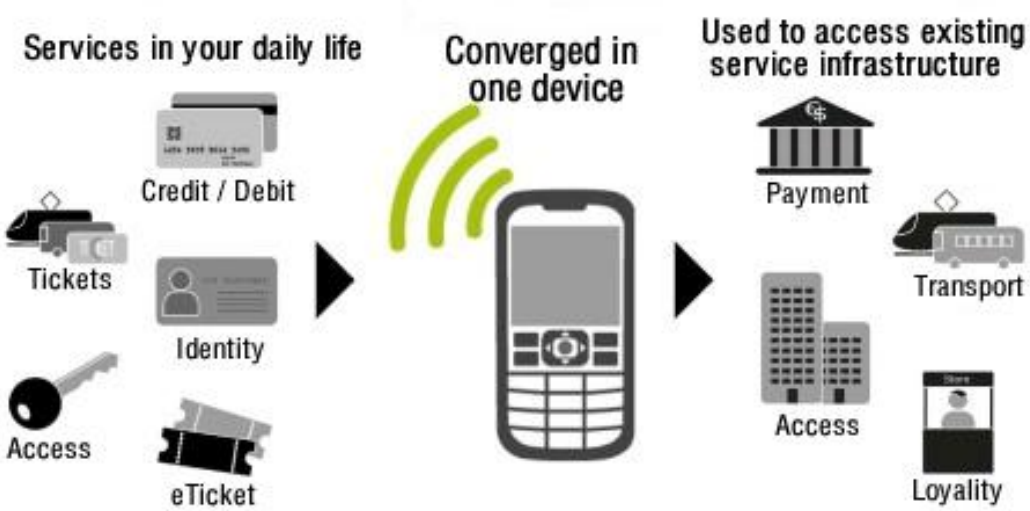

Figure 1: Usage of NFC enabled smart phone (Giesecke & Devrient, 2014)

By using NFC mobile phone, one could tap his phone to pay the bill, open the door of his home or office, use public transportation or send parking ticket. Use cases are numerous. However, in order to achieve that, many open questions must be resolved. Many of those questions are related to security. For an example, if NFC payment service should be implemented, where those sensitive personalized data and applications could be stored, in order to achieve the same security level as with classic payment smart-card (such as Visa or MasterCard)? Could it be in memory of operating system or in some dedicated hardware that will provide tamper-resistant environment? How any of these solutions should be implemented and what are the pros & cons of each? Following aims to give preview of possible answers to this security related questions.

2. SECURE ELEMENT (SE)

A secure element (SE) is a tamper-resistant platform (typically a one chip secure microcontroller) capable of securely hosting applications and their confidential and cryptographic data (e.g. key management) in accordance with the rules and security requirements set forth by a set of well-identified trusted authorities (GlobalPlatform, 2014). To put it more simple – SE is a smart cart in mobile phone (Lepojevic, 2012). As such, SE provides the highest level of security for applications residing on it (SE level of security is the same as security level of classic smart cards).

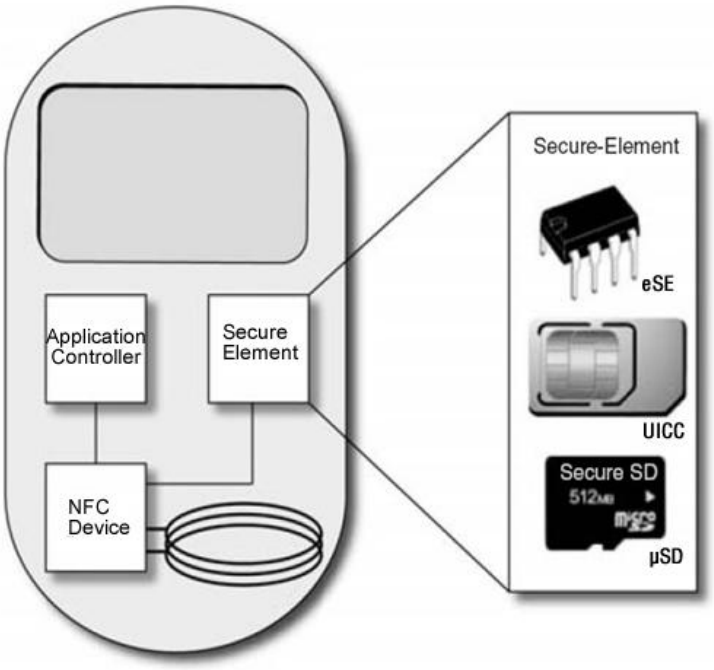

Figure 2: Secure element form factors (Finkenzeller, 2010)

There are three different form factors of SE: Universal Integrated Circuit Card (UICC), embedded SE (eSE) and microSD. UICC is advanced type of SIM card. eSE is smart card soldered to device's main board. Third is also smart card chip in form factor of microSD. While the UICC and microSD are removable, eSE is not (part of mobile phone hardware). All SE form factors are complying to the GlobalPlatform and EMV standards (Lepojevic, 2012).

Each form factor links to a different business implementation and satisfies a different market need. While UICC, as advanced version of SIM card, is controlled by the Mobile Network Operator (MNO), eSE, as a part of mobile phone, is being controlled by mobile phone manufacturer. In order for service provider (SP) to use UICC to host its application, SP must make business agreement with MNO. In the case of eSE, agreement must be made with mobile phone manufacturer. On the other hand, when microSD is about, SPs need to make arrangements with each other (to share the space on microSD) in order not to force user to have multiple microSD cards - for each NFC service. To reach acceptable agreement between any of these parties happened to be not so easy in practise, because each party wanted to hold favourable business position. That is why these agreements weren't achievable easy and, despite high security and standardization of the SE, it hasn't reached mass market so far.

3. TRUSTED EXECUTION ENVIRONMENT (TEE)

The TEE is a separate execution environment that runs alongside the mobile device's OS (Rich OS[1]) and provides security services to that rich environment. The TEE offers an execution space that provides a higher level of security than a Rich OS; though not as secure as a secure element, the security offered by the TEE is sufficient for most applications. In this way, the TEE delivers a balance allowing for greater security than a Rich OS environment with considerably lower cost than an SE (Global Platform, 2011).

TEE is secure area that resides in the main device processor (CPU), running its own operating system separated from device Rich OS, ensuring that data is stored, processed and protected in a trusted environment. As shown in the Figure 3, TEE provides safe execution of authorized security software - "trusted applications". It also enforces protection, confidentiality, integrity and access rights of the resources and data belonging to those trusted applications (Global Platform, 2014). Inside TEE, each trusted applications is independent from the others and one trusted application can not access trusted resources from another trusted application – which enables secure storing of applications of many different service providers.

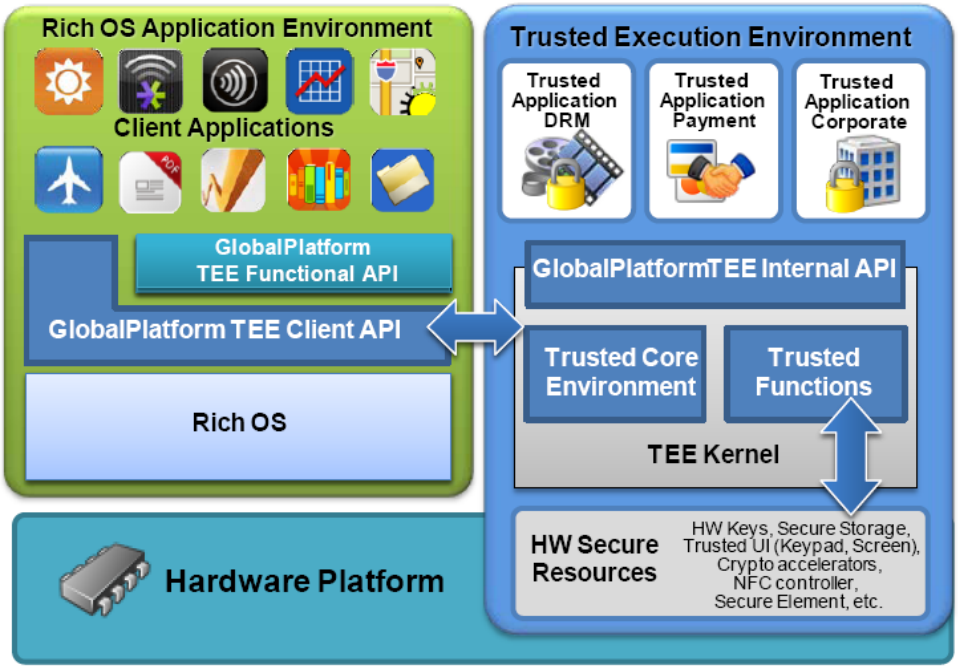

Figure 3: Trusted Execution Environment (Global Platform, 2011*)*

TEE provides layer of security between device OS (low security level) and SE (high security level). Although some NFC services such as payment or identification require high level of security (only provided by SE), there are applications that do not need to fulfil highest security standards, requiring, at the same time, better user experience and performance that resource-limited SE can't provide. That is the peace of puzzle where TEE fits in, as a compromise between Rich OS performance and SE security (Global Platform, 2011).

It is important to note that TEE standardization is still in progress.

4. HOST CARD EMULATION (HCE)

Android's release 4.4., so-called "KitKat", brought to life Host Card Emulation concept[2]. What is HCE? NFC device can operate in 3 modes: reader/writer mode, peer-to-peer mode and card emulation mode (CE). In first two modes NFC controller routes data to the host CPU (device OS), while when in card emulation mode data is routed towards SE. Android KitKat changed this – allowing commands in card emulation mode to be routed towards HCE service in CPU (Janssen & Zandstra, 2014). HCE service emulates contactless smart card or SE, allowing user's device to act as smart card from the contactless reader perspective, without presence of actual smart card or SE (Consult Hyperion, 2013).

[1] Rich OS refers (in Global Platform terminology) to operating system of mobile device, which is considered to be untrusted and vulnerable to attacks.

[2] HCE was already implemented by RIM's Blackberry in 2011. But HCE is often referred as Android 4.4 feature, because Android dominates smart-phone market.

Although Android 4.4 changes the default routing behaviour in CE mode, it doesn't prevent routing to SE in CE mode (Figure 3). Routing is based on application identifier (AID). When user taps his device to contactless terminal, terminal needs to "say" which application it wants to "talk to" – that is AID (Janssen & Zandstra, 2014; Android Developer, 2014). When this information reaches device's NFC controller, it looks for that AID in its routing table. If AID is found in NFC controller routing table communication shell be routed to the SE – if not, communication flows by default to the appropriate HCE service in the device's OS.

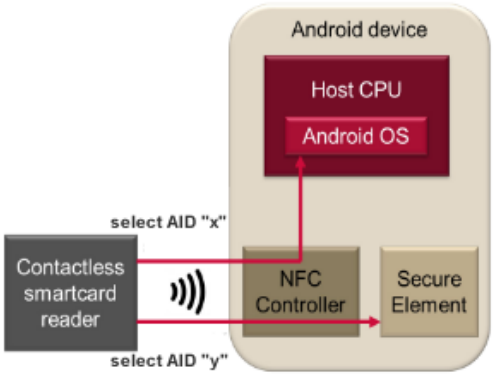

Figure 4: Android 4.4 routing based on AID
and NFC controller routing table (Janssen & Zandstra, 2014)

From the point of view of service provider – HCE looks quite good. No need for exhausting negotiation with MNO or mobile phone manufacturer, aimed at finding appropriate business model for using SE. No profit sharing. On the other hand, HCE has many functional drawbacks compared to SE (SimAlliance, 2014):

- Low power mode (no function when battery runs out)
- Roaming and "no data connectivity" scenario (no access to cloud)
- Depending on connection speed

When it comes down to HCE security – many issues arise. Most of those regarding the case of Android "rooting"[3]. If Android is routed, attacker could access all the informations stored in the applications, including sensitive informations such as payment credentials. When "pure" HCE is about, there is no secure area for storing sensitive data, that could not be affected by rooting. Mitigating HCE related risks can be done in two different ways (Janssen & Zandstra, 2014):

- Provide more secure location for storing sensitive data
- Apply security mechanisms to make existing location more secure

In order to provide more secure location for sensitive data, storage and processing of sensitive data could be done in the "cloud". Fundamental issue, when it comes to the "cloud security services", is how to enable handset to securely identify itself to the cloud. This could be resolved by requiring user interaction for accessing the cloud, which would in turn negatively impact the user experience. Also, accessing the cloud poses functional question regarding need for constant and quick connection (e.g. according to the MasterCard standards mobile payment transaction must be completed within narrow time limit – up to 400ms for MasterCard PayPass M/Chip or 170ms for PayPass magstripe (MasterCard, 2013)), something that can not be guaranteed.

Second way to mitigate HCE risks is about applying security mechanisms. Tokenisation is one of those. Each time HCE service access the cloud, a number of tokens is issued to that HCE service. Token is "limited version of security information" (Consult Hyperion, 2013) that is valid for specific period of time (one hour, one day) or limited to specific number of transactions. Tokenisation partly solves problem with constant need for connection to the cloud. Besides tokenization, mechanisms that can mitigate HCE risks are user and hardware verification - based on "what user knows" (e.g. PIN code) , "what user has" (e.g. sticker) and "what user is" (biometrics like fingerprint scan) – as well as Android checks prior transaction (check if user has root privileges).

[3] Android "rooting" is the process of allowing users of smart phones, tablets, and other devices running the Android mobile operating system to attain privileged control (known as "root access") within Android's sub-system.

5. CONCLUSION

Each of presented security solutions alternatives, when NFC services are about, has it's pros & cons. Which security implementation to use for specific NFC service, depends on that service design and requirements. How secure should it be? Does it contain very sensitive data which, if compromised, can produce severe damage for the user? How important is user-experience and service performance? What is the estimation of extra costs, and is it affordable? Can we (as a service provider) do this on our own, or we need to form strategic partnership with other stakeholders (MNOs, smart card or mobile device manufacturers, security solution providers, etc)? These are just some of many question that must be taken into account in order to make appropriate choice when it comes to NFC service security.

Table 1: Comparative analysis of NFC service security alternatives (based on GlobalPlatform, 2011)

	SE	TEE	HCE
Rich resources	*no (limited)*	*yes*	*yes*
Level of security	*high*	*middle*	*low*
Performance	*low*	*high*	*high*
Need (number of apps that need it)	*small*	*high*	*high*
User Interface	*none or very limited*	*middle rich*	*very rich*
Processing speed	*low*	*high*	*high*
Extra costs	*high*	*low*	*low or none*

From the technical point of view SE as an alternative has many advantages. It is mature technology, that provides high level of security. It is fully standardised and supported by the industry. Only technical drawback is it's limited resources and low performance. From the business point of view, SE is complicated, because service providers need to make agreements with other actors in order to use and share space on the SE. It always comes down to question of ownership of the SE. The one who owns it has monopoly role in that business case.

HCE is solution for business drawbacks of SE alternative. It is "no secure element" – NoSE (Consult Hyperion, 2013) solution. Although it has great added value for SPs that can accept a reduced level of security in exchange for an improvement of other factors such as time to market, development costs and the need to cooperate with other parties, HCE has serious lacks when security is about. HCE can not be used for NFC services that require high level of security (such as open-loop payments, identification, access control). It should be perceived as more-simple-but-less-secure solution, intended to accelerate adoption of NFC services (Janssen & Zandstra, 2014; SimAlliance, 2014).

TEE is alternative "in the middle" on security scale. It provides much better security environment than HCE, with much lower cost than SE. Besides, it provides much better user experience and performance than SE. Main drawback of TEE is it's not yet accomplished standardization process. However, TEE must be taken into account as a promising security solution alternative.

It is important to note that SE, TEE and HCE are not mutually exclusive. On the contrary. These security solutions can and should be used to complement each other.

APPLICATION OF RFID TECHNOLOGY IN WAREHOUSE MANAGEMENT

Ivana Tomanović[1], Iva Vojinović[2]
[1] Faculty of Organizational Sciences, Information systems and management, study field E - business, ivana.tubic@gmail.com
[2] Faculty of Organizational Sciences, Information systems and management, study field E - business, ivavojinovic@hotmail.com

Abstract: *In recent years, RFID technology achieves expansion of commercial use in logistics, primarily because of the possibility of use in all areas - transport, transshipment, warehousing, and distribution. The implementation of RFID technology allows companies to achieve efficient warehousing, with immediate access to all of its details. RFID technology (Radio Frequency Identification) has become an important "means of labor" that not only captures the data in real time, but also directs the business, establishing full control over the warehouse. This paper presents examples of successfully completed implementation of RFID technology in logistics activities in retail companies. The basic operation principles of this technology are presented. The key segment of this paper is dedicated to creation of a model of RFID technology application, based on improving warehousing in analyzed company. Along with the description of integration process, in the above mentioned model is also presented integration with existing corporate information system. Last segment of paper sublimates advantages of RFID technologies and potential limitations.*

Keywords*: RFID technology, warehousing, logistics in trade, retail, supply chains.*

1. INTRODUCTION

The development of logistics processes is conditioned by the development of technology. In constant striving for faster and easier flow of information and the product distribution, logistics is an area of business that has recognized the possibility of using RFID technology. RFID is not just about to promote business and increase productivity, but also significantly reduces the cost, creating space for strategic investments and focus on the primary goals of the company.

Changes in the global economy significantly redefined the way business enterprises. One of the major changes is that the main activity of warehousing in the supply chain is no longer limited to the storage of large amounts of stock. Supply chains have become more dynamic, customers ordered more frequently and in smaller quantities than before. All of these require smaller warehouse and greater rotation of stock *(Ramírez D., Ramírez L., Jimenez, Miguel, Castro and Maldonado, 2013, June).*

After a concise description of the RFID technology, the main components and system characteristics, paper presents examples of the successful implementation of RFID technology in logistics activities of trading companies. Application model presented in this paper is based on the improvement of warehousing in selected business entities. In the model, the emphasis is on the integration of RFID technology with existing customer information system. Increase efficiency, automation and optimization of warehousing are some of the most important benefits that are expected by adoption of the proposed model. Also, the paper specified potential limitations and disadvantages of the RFID technology applications.

2. RFID TECHNOLOGY

RFID is an automatic identification technology, which means a system for wireless reading and data transmission via radio waves *(Aysegul, Nabil and Stéphane, 2010).* RFID enables identification from a distance unlike earlier bar-code technology, it does so without the need for direct line of sight *(Kaur, Sandhu M, Mohan and Sandhu P, 2011).* RFID is an effective wireless technology for managing and monitoring of goods in the supply chain.

In addition to RFID tags and RFID readers, in each RFID system must be RFID central computer-host (Figure 1).

Figure 1: Basic components of RFID system

RFID tags are placed on objects that need to be identified. RFID readers are devices with an antenna, which one of the roles is scanning of tags. They verify the tag, read and convert the radio waves emitted from the tag into a form suitable for further processing. The central computer - host and software (which collects data and connects tags and readers into a single system) is a very important component of RFID systems.

In RFID system, it is necessary to establish a connection between the RFID reader and the computer system in which collected informations are stored and updated. This connection can be made through Middleware and Edgeware platform. Middleware is a software platform that connects the RFID reader to the computer system, enabling the exchange of data between the RFID reader and business information systems, such as WMS Warehouse Management System and ERP - Enterprise Resource Planning. Middleware filter, format, and translates the data registered by the RFID reader, forwards them to the computer, combining the work of a number of different applications that monitor objects. Edgeware platform, which includes software and hardware enables business systems to provide the necessary control and management for interface devices such as RFID readers, sensors and hand-held terminals, but also allows the collection, processing and cooperation with other applications and systems.

According to the type of power supply, RFID tags are classified into the following groups: active, passive and semi-passive *(El Khadar, Boulmalf, Harroud and Elkoutbi, 2011).* Active have their own power, a battery with a limited lifespan, which powers the microchip and broadcast the signal to the reader. They are more expensive and bigger, but have a greater range of signal transmission. Passive do not have their own power, the energy is obtained through the RF emissions from the readers. The main drawback is the lower range of signal processing, data storage capacity and lower resistance to electromagnetic noise in the environment. Their advantage is low cost and durability, which allows large-scale use. Semi-passive has a battery that powers the chip, but to communicate use energy of reader. These tags have a good performance in terms of capacity, range and service life.

3. ANALYSIS USING RFID TECHNOLOGY IN BUSINESS

Survey indicates the possibility of using RFID technology in nearly all aspects of life and business, ranging from traffic through commodity flows, medicine, pharmacology, military, aerospace industry to electronic documents and labeling of living beings.

Successful implementation of RFID technology, or pilot project implementation, is seen through the examples of the most dominant U.S. and European retailers, which are considered to be the pioneers of the RFID technology application in their operations. Wal-Mart (the leading retail chain in the world), in mid-2003 asked its 100 largest suppliers to place RFID tags on pallets, which were delivered in order to improve operational efficiency, giving them a deadline for implementation, in the beginning of year 2005. According to power on market and representation, the number of people it employs in stores worldwide, market share which it has realized and the number of suppliers with whom it work with, claimed request was attainable. The use of bar-code technology expanded greatly as a technique for labeling products on the world market, only when the Wal-Mart asked its suppliers that all shipments are marked with bar-code passwords. History repeated itself, and in 2003, when Wal-Mart sent a request, but this time related to RFID technology, which once again proved its supremacy and visionary role. Full effect of RFID Technology Company Wal-Mart considered to achieve by highlighting individual products with RFID tags, however suppliers were not ready for this step from the start, and the RFID technology primarily used for marking of containers and packages. In the period from mid-February to mid-September 2005, 24 stores (12 RFID test stores and 12 control stores) representing all Wal-Mart format, followed by the OOS (Out of Stock) on daily level. Results, observed from several perspectives, showed that RFID makes the difference between test and control stores. In test stores, which were RFID-oriented, OOS reduction of 26% was realized compared to those who were not oriented RFID *(Hardgrave, Waller, Walton and Miller, 2007, June).* Just one year later, Wal-Mart has announced that from January, 2006 this request will be extended to 200 more suppliers.

The largest retailer in the UK, the company Tesco, has announced that in early 2004 will mark non-food products with RFID tags in its distribution centers and that will follow up them to retail stores. Tesco expects

that the deadline for the implementation of RFID technology for all suppliers will be in 2007 *(Bob, 2003, November).*

Marks&Spencer, the famous retail company in the UK, firstly applied in 2004 labeling of certain products with RFID tags in a number of shops (120 shops) in its supply chain. Afterwards, the company has spread application of RFID technology on about 10.000 items in 550 stores, to about a year and a half ago, the company management decided to extend the application of RFID technologies to an assortment of household equipment. Also, Marks&Spencer is planning further improvements in terms of replacing the system with a newer RFID technology, which includes EPC Gen 2 Read-Write tags and readers *(Bob, 2013, March).* By applying the mentioned technologies, the company's management expects to record even more impressive results in terms of a faster return on investment. The company started the implementation of Gen 2 tags in the spring of 2012. Full implementation is expected by the spring of 2014. Many trade organizations in the UK, including House of Fraser, Selfridges and Woolworths have also recently participated in the experiments with RFID technology.

Retail chain Metro went further than any other company with the implementation of RFID technology in Europe. In order to fully utilize the potential of RFID logistics, Metro Group has decided to implement in the retail and wholesale establishments, of which almost all major formats in Germany are equipped with RFID portals. In addition, in 2003, after years of research in collaboration with IT companies like SAP, Intel, IBM and others, German Metro (member of Metro Group) in April 2003, in Rheinberg, opened the first Extra Future Store *(Bob, 2004, April)*, a hypermarket designed for testing over 20 advanced technologies, and most of all the possibilities and advantages of RFID technology, both for the company and for the end customer.

A large number of authors who are engaged in the study of RFID technology are interested in eliminating the problem of supply chain which RFID technology has the ability to resolve, such as inaccurate inventories *(Kang and Gershwin, 2005; Atali, Lee and Özer, 2006; Fleisch and Tellkamp, 2005).* In order to assess the impact of RFID technology in the supply chain system, four approaches were investigated: analytical *(Lee and Özer, 2007; Rekik, Sahin and Dallery, 2008),* simulation, case studies and experiments *(Lefebvre L., Lefebvre E., Bendavid, Wamba and Boeck, 2006, January; Wamba, Lefebvre L. and Lefebvre E., 2007).*

Some carried out studies considered the sustainability of logistics systems through the use of knowledge based systems (KBS - Knowledge Based Systems). For this reason, in many logistic facilities, particularly in warehouses, intelligent systems are integrated with RFID technology. *Chow, Choy and Lee (2007*) presented aknowledge based system applications in real time, incorporating RFID and mobile technologies to collect information in a dynamic way through the multi-agent approach. *Chow, Choy, Lee and Lau (2006)* presented a RFID-based system resource management using RFID technology and artificial intelligence for the collection of dynamic and static logistic data.

4. MODEL FOR THE APPLICATION OF RFID TECHNOLOGY IN WAREHOUSE MANAGEMENT

4.1. Description of the business entity

Business entity that was analyzed is the company Centro Stampa Holding Ltd., one of the five largest private companies in Serbia, with over 3.500 employees. Within a holding exist three business companies:

- Retail company - a chain of retail outlets (Stampa sistem, Futura plus, Moj kiosk), with over 1.100 retail outlets.
- Wholesale Company (Centrosinergija) - distribution of top ups, newspaper category management.
- Logistic Company (Centrologistika) - the provision of logistics services to network of retail outlets within the retail companies, as well as external customers (3rd part logistics provider).

A wide range of activities within the Holding company requires the existence of a large number of complex processes in which there is space for integration and implementation of new technologies in order to achieve business improvement.

Very important part in the business of retail stores is the timely and accurate delivery of goods. Considering that timely and accurate delivery is directly determined by optimizing processes within the warehousing, which are under the jurisdiction of the said logistics company, the company pays a lot of attention to their analysis in order to find and implement possible improvements. In this paper, the focus is on process improvement warehousing, through the use of RFID technology.

4.2. Description of the warehouse operations process with the applied RFID technology

Logistics is a business function that requires constant technological innovation and improvement. One of the reasons for the application of RFID technology is realised cost saving (RFID technology achieves the greatest savings in logistics costs).

It is important to note that the introduction of RFID technology in the retail SCM (Supply Chain Management), recognize three phases:

- Pallet Tagging - labelling of containers and/or pallets,
- Case Tagging - labelling of boxes (or smaller packages that are on pallets), and
- Item Tagging - labelling of individual products.

In the described model, the introduction of RFID technology in warehouse management is envisaged, through marking and identification of transport packaging (boxes) and pallets. Use of RFID technology in warehouse management provides control of the goods from the entrance to the exit from the warehouse. Description of all processes of warehousing with the use of RFID technology is shown below.

Receipt of goods
Based on the input documents (invoices/receipts), the goods receipt is created in RFID technology. Each transport package and pallet is assigned with a unique mark, printed in the form of label with the help of RFID printers, which encode RFID tags on the label. Information comes to the RFID printer through software or wireless network. RFID labels that are positioned on the surface of transport package (palett), contains a unique ID number, and other necessary information (name, date of receipt, quantity, expiry date, etc.). When warehouseman using handheld RFID reader scans the labels affixed to the pallet, the pallet gets its own unique identification number in the system.

Palletizing goods
Pallet positions where the goods will be stored are designated by RFID tags as well. RFID application determines the position where the certain pallet will be stored. By reading the label on a pallet, RFID application assigns appropriate storage place (optimal position), conditioned by the article type.

Warehousing and storage
Storekeeper stored goods placing it at a defined location. Upon completion of the above mentioned activity, storekeeper confirms the end of receiving process with the help of a handheld RFID reader. In this way, it is confirmed to the system that goods are received and stored in the appropriate place.

Commissioning/picking goods
Upon receiving and confirmation of the Purchase Orders, entering in the RFID application is done, based on which orders are generated for picking up the goods. An employee responsible for the receipts carries out the distribution of receipts that needs to be implemented by warehousemen. Created orders are displayed on the handheld RFID reader that uses warehousemen.

Shipping goods
Warehousemen drags goods in the dispatch area, according to the direction of macro-or micro-distribution lines. Upon completion of the above mentioned activity, warehouse confirms the end of the order by the handheld RFID reader.

Inventory Tracking
Tracking and managing of inventory levels is done with the help of RFID technology. When the minimum of predefined values is reached, RFID application automatically creates an account for the transfer of the optimal quantity of goods with the necessary commission.

RFID enables the development of partnerships between retailers and suppliers on the highest level. The advantages that this form of partnership achieves are at the same time imperative for its conclusion. High level of mutual trust is required in order to be able to implement inventory management by suppliers - Vendor Managed Inventory. It is expected that the high level of development of relations in which the supplier decides on the appropriate level of stock in the retail store, to an even higher level when tagging of individual products RFID tags is carried out.

4.3. Integration of RFID technology with information system of monitored company

The scheme given below (Figure 2) shows the existing Holding information system, upgraded with segment related to the integration of RFID technology.

Description of Information system:

- ASW - integrated information system (ERP - Enterprise Resource Planning System) which is a comprehensive solution for business process management and enterprise resource management. It is structured in a modular way thereby achieving flexibility and adaptation to different needs of users.
- WMS (Warehouse Management System) - enables the management of all processes in the warehouse (receiving, storage, picking, shipping of goods). Storage is organized based on FIFO (First In - First Out) or FEFO (First Expired - First Out) principle, respecting all the standards for monitoring traceability of goods and fulfillment of existing standards. It is designed for logistics and distribution companies and retail chains.
- Pantheon Professional - business information system for fast growing companies. In the present IS the company, is designed for carrying business segment.
- Jitex - a software solution designed for business operations related to the commodity group of newspapers.
- Oracle iAS (Oracle Application Server) - application server, which allows the integration of WMS with RFID reader.

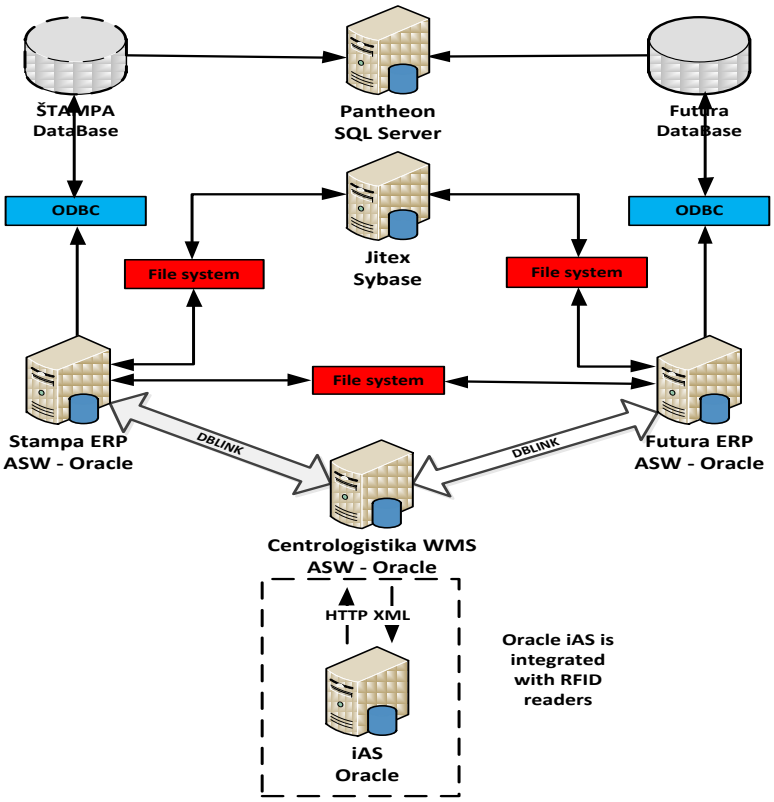

Figure 2: Holding Information System

Integration model of RFID technology in the IS observed Holding (Figure 3), is shown below:

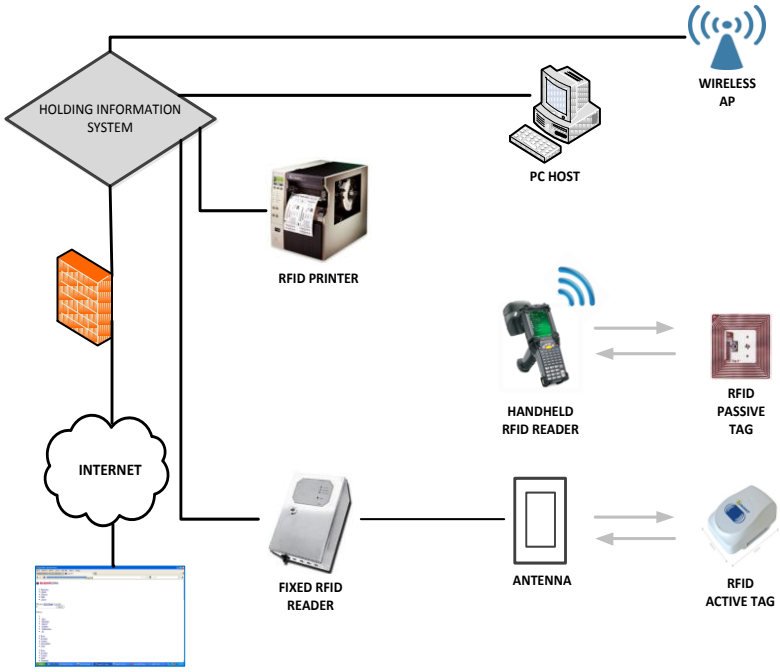

Figure 3: Integration Model

5. ADVANTAGES AND DISADVANTAGES OF RFID TECHNOLOGY APPLICATION

The advantages of using RFID technology are the main reason why organizations are examining the potential of RFID technology and considering its adoption *(Waters, 2013)*. Literature describes the direct benefits, including cost savings and the progress in time needed for the delivery and indirect benefits, such as the establishment of new business processes *(Bhattacharya, Chu and Mullen, 2007, November).* The advantages of using RFID technology are conditioned by the ability to provide timely information, where the data exchange between the object and the system is realized automatically.

The primary advantages of RFID technology are: process automation, which leads to a reduction in labor costs, creating new process in which products have greater visibility, providing innovative services and improving the quality of the information obtained, and thus ability to make better decisions *(Sellitto, Burgess and Hawking, 2007).* Optimization of the process supported by RFID technology is also important *(Wamba, 2012).* Additional advantages of RFID technology include increasing accuracy, reducing inventory levels and OOS *(Lee and Özer, 2007),* the establishment of closer relations with business partners, the ability to track goods throughout the supply chain and efficient shipping and receiving of goods *(Vijayaraman, Osyk and Chavada, 2008).*

Using RFID technology, the described model is expected to increase efficiency, as well as the automation and optimization of warehousing. Facilitated quantity and quality control during receipt and dispatch of goods provides constant access to inventory in real time. By introducing optimal storage and automatic respect of FIFO or FEFO principles, better planning of availability and stock is achieved. Better layout organization of warehouse and better analysis of return are provided. Contact bearer of the RFID system is made from tough and durable material suitable for prolonged use in different environmental conditions. The time required for the implementation of processes within the warehouse is reduced, and the level of human error is minimized. The identity of the RFID tag is not suitable for copying, therefore it is expected to contribute in raising the level of protection against counterfeiting and to prevent possible abuses.

Besides many advantages, the literature recognizes the disadvantages that can negatively affect the adoption of RFID technology in business systems. These includes high costs, problems related to compatibility, reliability, difficulty in upgrading existing systems for the introduction of RFID technology *(Wamba, 2012).*

The high cost of the necessary hardware equipment adversely affect, especially the smaller companies that are often unable to invest in RFID technology. The high costs of introducing RFID technology may adversely affect, or reduce ROI - Return on investment *(Lin, 2009).* Compatibility with ERP (or other customer information system), is also a challenge that is set before RFID technology. Reliability and accuracy of reading tags is still not consistently high *(Soon and Gutierrez, 2008)*. Functioning and capabilities of RFID technology is largely dependent on the standard of electronic labels and readers, as well as the capabilities

of the software for business integration, to cheaply record and store data obtained by the RFID technology. Even with the generally accepted standard Gen 2 for RFID labels, there are still limited interoperability problems when it comes to the different available browsers or different custom integrative software. When introducing RFID technology it is important to consider that the probability of the resulting data may not be in a standard format, which requires the implementation of customized software to enable the integration of RFID data from corporate databases. Also, the proximity of metal or magnetic fields can adversely affect the operation of RFID systems. The restrictions that are less noticeable, but may also be present in some form, are the difficulty in finding qualified staff as well as the resistance of employees due to the changes brought by the new technology.

6. CONCLUSION

Despite certain imperfections and limitations that accompanies RFID technology, the growing number of companies worldwide decides to integrate RFID technology in business, because RFID is the future of monitoring the flows of information, goods and resources.

Entity that carries out the implementation of RFID technology in business system must be very careful not to jeopardize the functioning of the process in transitional period. In the described model, the use of RFID technology in logistics company, in the area of warehouse operations, implementation of RFID technologies needs to be implemented gradually over several stages that are crucial for success, and include: defining the project plan, the understanding of the technology that is used, the procurement of appropriate hardware and software equipment, system integration with existing equipment and existing information systems, system testing before moving to full implementation and the inevitable training and education of employees.

Also, for the company that decides to implement RFID technology in their business system, the tendency to form partnerships with all stakeholders in the supply chain is of strategic importance, through the introduction of RFID technology in the entire chain, from manufacturers to retailers. The above method allows the application of RFID technology to achieve the maximum positive effect.

[2]PE Post of Serbia, drdjokic@fon.bg.ac.rs
[3] University of Belgrade, Faculty of Organizational Sciences, aleksandra@elab.rs

Abstract: *This paper shows an e-business model of footwear industry. For managing production process an Information system is used as a support. The main goal of the paper is improving existing e-business process in footwear industry by applying concept of supply chain management and contemporary information technologies. A model for supply chain management in e-business of footwear industry is shown, as well as an application for supply chain management.*

Keywords*: E-business, Supply Chain Management, Logistics, Information System, Application for Supply Chain Management, RFID*

1. INTRODUCTION

With rapid growth and continual changes in industrial footwear production, companies are facing with problems related to competition on market, management of supplier relationships and logistics. Dynamic of industrial footwear production affects on shaping of footwear, activities and goals in supply chain system according to following requirements:

- improving quality of product and services,
- shorter time of delivery,
- reducing logistics and other costs,
- integrating information technologies with flowcharts,
- planning and directing the flow of movement of raw materials and finished products in the supply chain,
- products and services flexibility for consumers satisfaction.

The supply chain includes all activities related with the flow and transformation of goods, from raw materials stage through to the end user (Handfield and Nichols, 1999). Supply chain management (hereinafter: SCM) is process of planning, implementation and control of supply chain with aim to satisfy customers' needs (Seuring and Mueller, 2008). Represents term related to optimizing the delivery of product, services and information from supplier to customer (Bertolini, Bottani, Rizzi and Bevilacqua, 2007). A supply chain usually includes manufacturer and its suppliers, various wholesalers and distributors, to the owner of a retail store.

In manufacturing, the supply chain is an integrated set of business functions, which directs all activities of procurement of raw materials to delivery of finished products to the end user. Basic goals of effective and efficient supply chain are related to "Just in time" concept that implies delivery of specific product in real time, place and quantity. For the realization of these requires certain measures must be taken in order to insure of efficient functionality of all operative components of a supply chain. Main components are supply, storage and distribution. Sometimes variance of orders may affect on sales and produce stocks surpluses, cost increase, errors in production activities due to overload and other. This is so called bullwhip effect (Lee, Padmanabhan and Whang, 1997).

Information technologies have significant role in tracking of raw materials, semi-finished and finished products from the origin place to the point where they will be spent. This paper presents a model for supply chain management in e-business of footwear industry. Model is developed and applied in footwear industry Falc East d.o.o., Ruma in aim to enhance existing e-business and supply chain management process. Model also proposes application of RFID technologies in production and warehousing process. Furthermore, an application for supply chain management in footwear industry is shown.

2. E-BUSINESS IN FOOTWEAR INDUSTRY

This paper presents an e-business process of footwear industry Falc East d.o.o., Ruma. The main business of Falc East is production and distribution of Italian footwear to a number of countries around the world. All footwear models are design and technically prepared for the production process in subsidiary Falc from Italy.

For the realization of e-business Falc East uses modern technologies. For accounting records and records of workers Falc East uses software package and Italian AS400 database that allows access to all customers orders from the date of delivery, access to state of the material both in Italy and in Serbia, to the state of development of the model and all other processes that are carried out in Italy. E-business model of Falc East is shown in figure 1 (Milinović, 2009).

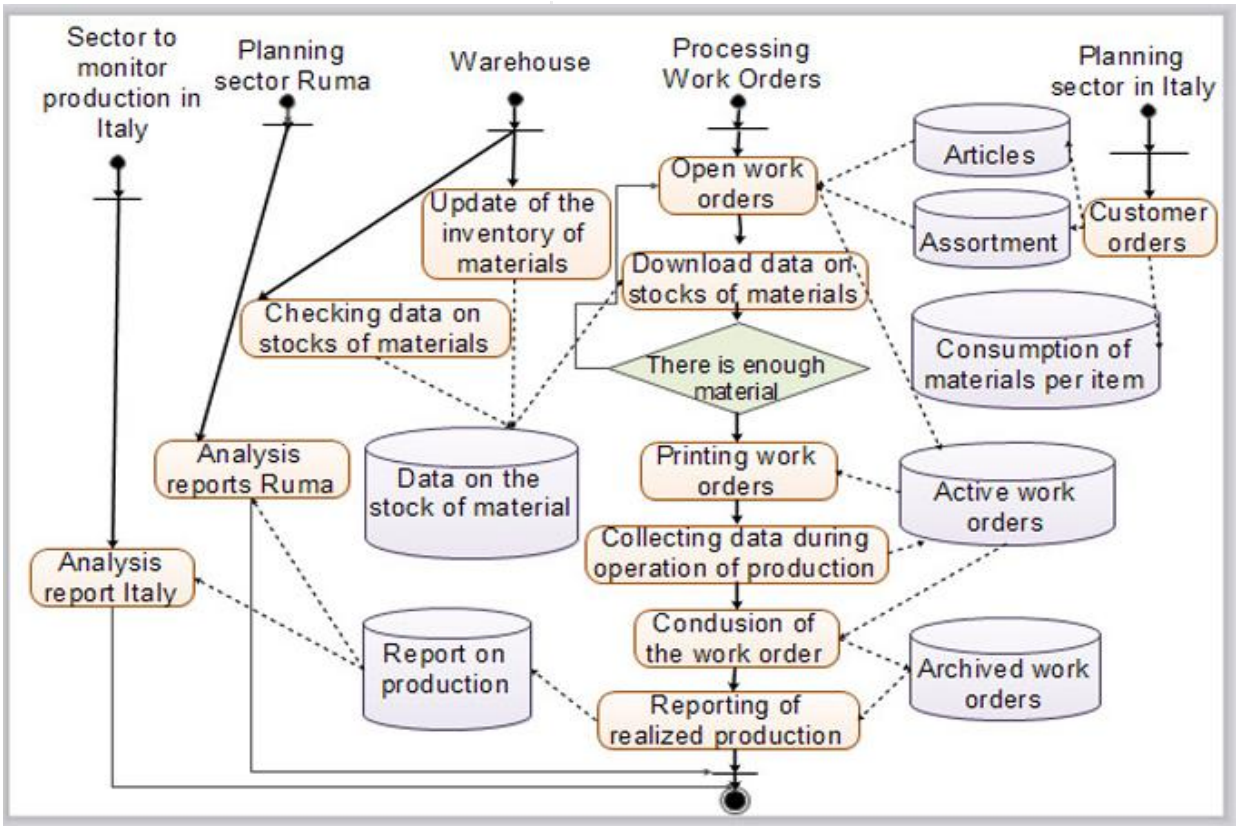

Figure 1: E-business model of Falc East

Footwear industry Falc East uses e-business application that enables management of working orders, code lists, and data protection. Management of working orders implies entry of new and update of existing working orders, archive and reports. Code lists enables updating of articles, assortment and consumption. Data protection enables user administration and password management.

In the realization of all processes Falc East uses two software tools. Software tool AS400 is used for managing orders from all production facilities and complete accounting in Italy and the second one is deployed in Serbia and adjusted for managing the production process and the details about clients, production and materials. Customers make orders through authorized agents which they forwards, over Internet, to planning sector. All orders are stored in AS400 database in Italy. Planning sector in Serbia has approach to these data and uses them in their software. Software in Serbia is adjust to production process and is used for data analysis, issuing work orders, analysis of material on stocks and tracking production process. Sector in Italy can track production process trough the same software.

3. MODEL FOR SUPPLY CHAIN MANAGEMENT IN E-BUSINESS OF FOOTWEAR INDUSTRY

Model for supply chain management in e-business of footwear industry is developed in scope of Falc East industry and it is shown in figure 2. Planning sector in Italy sends customers' orders which contain products, assortment and consumption of materials per item. After opening new working order and taking data about materials on stocks, the planning sector in Serbia creates and processing working orders. Information system of Falc East enables analysis of these materials on stocks. Upon confirmation that there are enough materials, a working order can be sent to press and given into production. Working order and analysis is made on the basis of the date of delivery to customers. Collecting data about the finished production and closed working orders is on daily basis. Creation of reports about finished production is important for analysis in planning sector in Ruma and for sector for monitoring production in Italy. Warehouse checking and updates data about material on stocks.

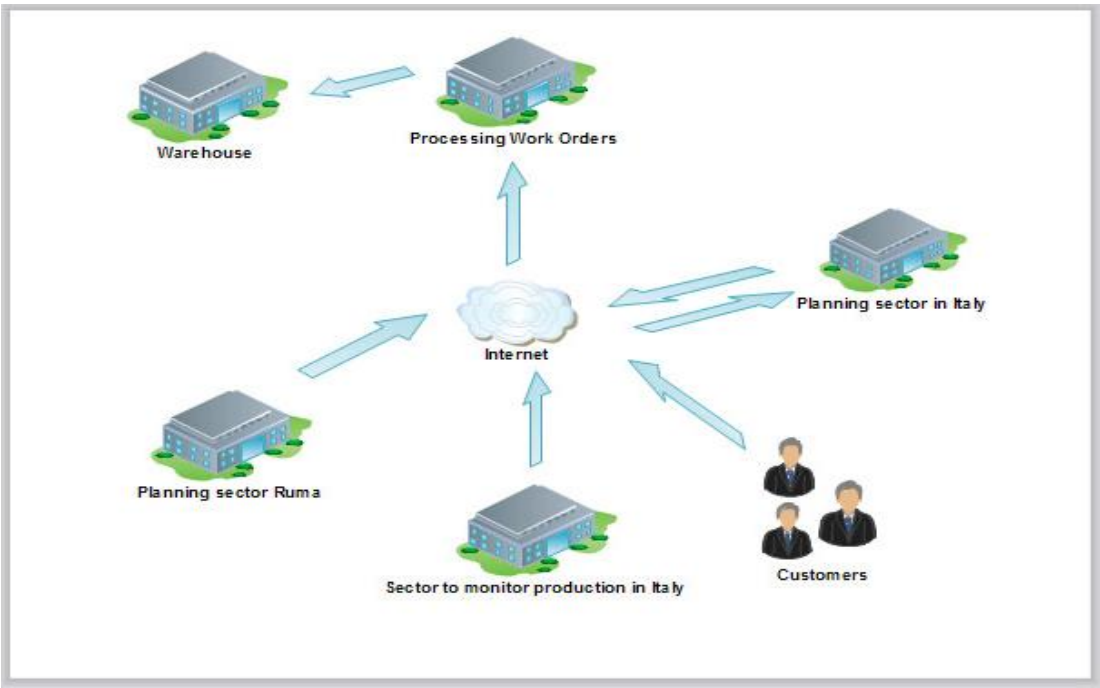

Figure 2: Model for supply chain management in e-business of footwear industry

In aim to enhance existing supply chain management system in footwear industry Falc East, model also proposes introduction of new technologies and adding new functionalities in existing software that for referent should enable tracking and monitoring of production process according to customers' orders and materials on stocks. These procedure should be conducted by referent by following steps:

- making a purchase invoice with all materials and quantities in a software system
- openning a new working order (automatic assignment of new working order number)
- selecting the item from the active items and entering the number of bolle
- entering assortment by bolla on the order
- the total number of pairs per item and the total number of pairs per order is assigning automatically
- the date of the opening of the working order should be automatically
- analysing the stock material
- referent printing order for production for bolle for wich have materials on stocks and gives further to manager, merchants and production workers
- printing of materials that are missing and sends order for them in Italy.

Received materials are chacked by a warehouse clerk and if they are matched with invoice, referent is making a report. After the end of the working day a manager is delivering referent daily report in which defines the number bollas that are finished and:

- calls the number of bolla and enters what was done by updating working orders
- concludes the working orders.

Model for supply chain management in e-business of footwear industry also proposes applying RFID technology for sorting and tracking materials in production and warehousing processes. Material are marks with appropriate RFID taggs. With the implementation of RFID technology in the industry, the production and wearhouse processes can be faster and more precisely conducted. Application of RFID in the production process can be described with following procedure:

1. In production factory hall, materials are passing through a fixed portal with the RFID reader which can read unique EPC number and other details about the delivery;
2. Received materials must pass control and then distributed to the warehouse, production or return if not fulfill the requirements;
3. Materials for returning are RFID marked and returned to the supplier;
4. Listing materials is done by reader located on the forklift which then sends data of the exact place of storage in the system;
5. Materials in the production are read at a specified levels from where the system sends information about the necessary materials for production;
6. How grouped products are moving through the production line, the data about them are loaded into the system by using a fixed reader along the production line;
7. When product is finished, the worker puts product label with a RFID chip;

8. EPC number and product data are stored in the database in every workplace. This provides the relevant documentation on the quality before the product enters further into the chain of commerce;
9. The product then goes to the packaging. A label with the chip is created to contain new information about the product.

In production process RFID technologies bring following advantages (Michael and McCathie, 2005; Ferrer, Dew and Apte, 2010):

- Automatic collection of data in real time
- Time reduction
- A large amount of various types of data
- Insight in materials and products on stocks
- High accuracy of data collection.

Automatic collection of data in real time provides current information about the state of stocks, the execution of the production process and the real demand. In this way, RFID technology provides continuity in production process and eliminates possibility of excess inventory.

4. APPLICATION FOR SUPPLY CHAIN MANAGEMENT IN FOOTWEAR INDUSTRY

For the production process footwear industry Falc East uses an application for supply chain management. The application is based on supply chain management process described in section three of this paper.

Italy sends order of customers and bolle for printing. Bolle includes all fabrics (materials) which are required for the production.

Beside of the customer's order, bolle are printed too, and given into production. At first, they are placed in warehouse, in order to prepare materials. Warehouse manager prepare only that bolle which referent of planning and monitoring gave him through working order but based on previously performed analysis. Then he gives printed bolle in the tailor who designs the shoes. They forward those parts at the preparation sector, where the parts be numbered and prepare for sew and from that place it send to sewing workshops. When the upper parts are finished, products were packaged and sent to Italy. There, in Italy, the footwear will be compiled and send to the final customer.

Referent of production monitoring from the database in Italy AS400 takes orders and bolle with delivery dates and sends itself to mail (shown in figure 3).

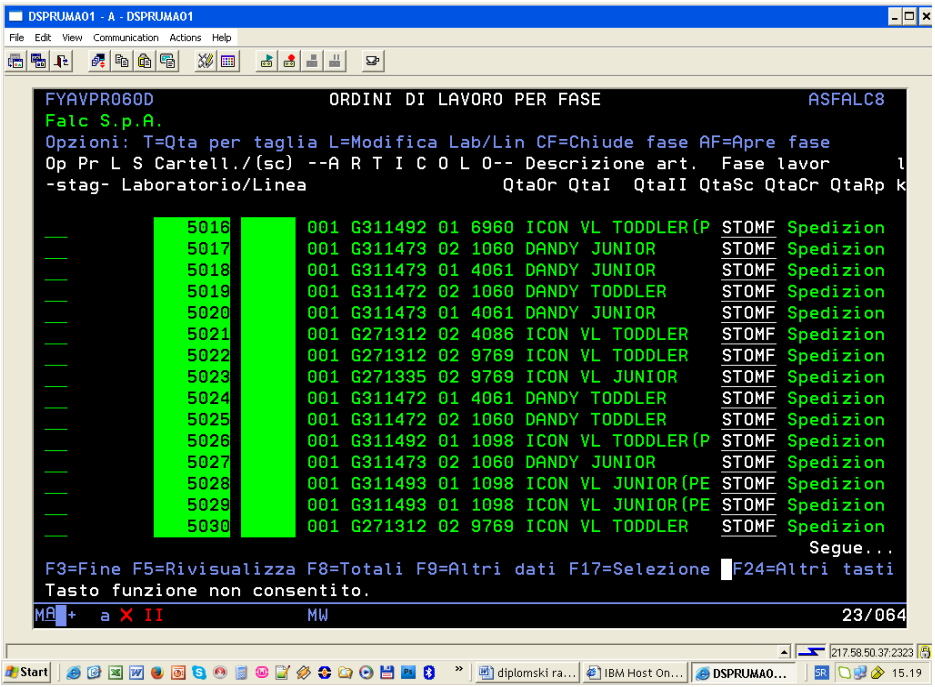

Figure 3: Bolle

Based on these, referent of production monitoring enters data into program and begins with the analysis. When finished the analysis, announcing working order for production and gives it to the manager, the warehouse clerks and the tailors. First, input invoice inserts with fabrics which sent by Italy to work. Then, after that, they create a new work order in which put in items, color, number and selection of bolle. Afterwards, they do analysis in order to organize work according to fabrics stocks, while the lack of fabrics will be ordered from Italy.

Monitoring of production is based on daily reports written by each of tailors in their workshop. Every day they must to put in the program what they from products were designed, were prepared, sewn and delivered. Each phase enters separately. These Web interface called Ambari is shown in figure 5.

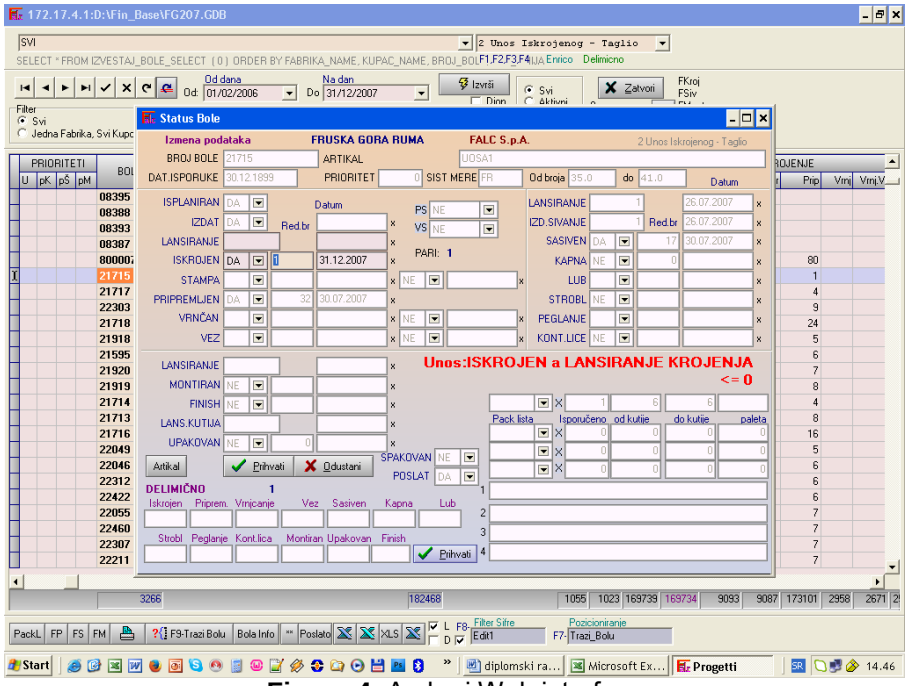

Figure 4: Ambari Web interface

The program gives the possibility of different overviews, where can be ask various parameters and may to print reports. Each review can be printed or to be export to excel.

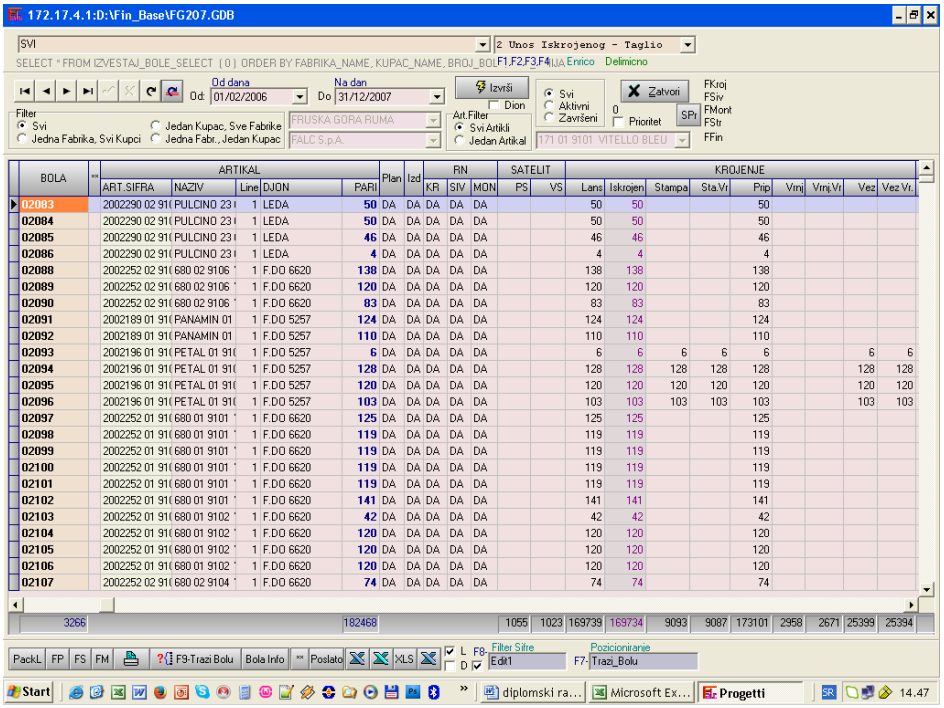

Figure 5: Complete overview

Application, also enables searching by different criteria (figure 6).

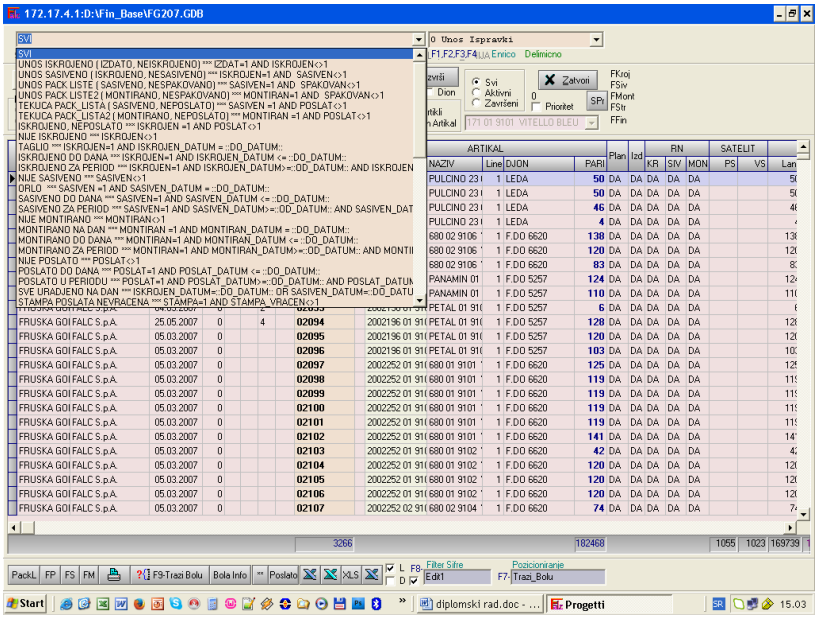

Figure 6: Searching by different criteria

When the process of production is finished, the pack list is sending to import / export service which makes documents for clearance of goods and send it to Italy.

For different users approach to this application is limited. Manager has access to:

- archived working orders
- printing and searching working orders.

Referent every week has possibility to:

- open and close the working orders
- update articles
- view consumption
- delete working orders.

Director of organizational unit is an administrator of the system and can create system users with different rolles and level powers.

At the beginning of the season Falc East receives from Italy catalog of all articles that should be produced, as well as drawing of items with the instructions. According to this instructions, Falc East makes prepration and realization of production process, as well as the delivery. Example is shown is figure 7.

5. CONCLUSION

The paper presents an application of supply chain management in footwear industry based on model for supply chain management in e-business of footwear industry. Model is developed and applied in scope of the footwear industry Falc East d.o.o, Ruma. Model also suggests application of RFID technology in aim of improving existing e-business and production process. RFID in production process brings many advantages such as time and cost reduction, simpler manipulation with various type and amount of data. This can be very important for Just in time decision making related to the production process in footwear industry. Existing supply chain performance can be also improved in the future with point-of-sale scanners that allow industry to capture the customer's voice. In this way electronic data interchange can enable hearing that voice in supply chain and faster reaction by using flexible manufacturing, automated warehousing and rapid logistics (Fisher, 1997).

Abstract: *The article provides an overview of the possibilities of application virtual logistic concept in supply management and storage of materials field in Serbian Armed Forces. The development of modern information and telecommunication technology increases the importance of the concept of virtual logistics. The appearance of virtual logistics has brought great benefits, by changing the borders of efficiency and effectiveness and setting up the new criteria that organization need to satisfy and adopt, if they want to remain competitive and profitable in the local as well as in the global market.*

Keywords*: logistics, virtual logistics, trends, concept, virtual supply management, virtual material storage.*

1. INTRODUCTION

As well as in the business world in which tends to meet customer requirements while reducing costs, the armed forces all over the world are faced with necessity to establish the optimal balance between the needs for the greater availability of military equipment and better support for maneuver forces, and reducing costs and decreasing logistical resources.

The traditional form of military forces support, based on collecting large amount of resources in the zone of operation, is being abandoned. That is affected by unacceptable costs and lack of ability to support dynamic changes in the zone of operations.

The new concept of force projection requires the rapid deployment of combat forces, accepting the initial combat action and at the same time autonomous support, which is directly reflected at the establishment of new logistics processes and procedures that have to be effective, flexible, and appropriate, according to specific combat forces requests that have to be supported.

In order to ensure desirable characteristics of combat forces, such as agility, mobility and flexibility or speed of response, it is necessary to provide adequate logistical support, which also has to be fast, accurate and in proper time.

For that reason, logistics management tends during planning, creating, developing, launching, maintenance, and ongoing support of efficient and effective fighting forces "provide maneuver, precision effects (fire), comprehensive protection, and rational and focused support to defense forces. That provide based on model "top-down", when, where is that necessary and in required manners , as close to the place of issuing logistics requirements, but all that in accordance with an appropriate price "(Andrejić and Milenkov, 2012).

None of combat forces will not maintain own speed if run out of fuel, ammunition, food, spare parts, medicines or other needs which are provided by the logistic units. Those are the reasons why the organization and management of logistic support are very important for performing tasks of logistic support, as well as well planned and organized use of logistic resources and units, and finally, for rational consumption of logistic resources. On the other hand, the introduction of automated information systems gives strong influence on decreasing cost in system of logistic support. Rapid information transmission, efficient processing of customer requirements and continuous availability of reserves data is affected on significantly lower levels of inventories, and in same time on increasing the level of operational availability of weapon system and military equipment. That is the reason why information is so important and why the progress in information technology provides numerous opportunities for the logisticians, in support issues forces in the zone of operations, like never before. In the era of information technology victory applies a force that has the right information at the right time. The right information gives to decision makers, knowledge of the situation on the battlefield, which they need to make right decisions to achieve the goal. However, the information and the real situation on the battlefield is not complete without proper logistic information. (Pavlović, 2006)

Proper and timely logistics information, provides timely logistic support and making the right decisions that lead to raising the quality of logistic services, shortening the response time of the logistic system, increasing the efficiency and effectiveness of logistic support, as well as increased confidence of combat forces in their logistics units.

Applying modern IT tools in the logistics support, it is possible to achieve development, processing and exchange of relevant data, information and knowledge, based on real-time and global connections between maintenance systems, supply and transportation with logistic support of units to their peacetime location as well as in the area of operations. If information system is integrated and if it provide the collection, processing, exchange and display of all the necessary information, in each logistic element vertically and horizontally, logistics management can timely and accurately to meet the requirements of users of logistics services.

Such logistical support today has accomplished by information system based on Web technology, an environment that contains a virtual data warehouse and logistics management support tools.

Sophisticated information management and dynamics of development of software applications provides sharing and information management in nearly real-time. The system allows access from each level to all data as well as supplements of the information directly from the individual locations, at low cost.

2. LOGISTIC AND MODERN TRENDS

Logistics is a key factor in the development of the armed forces, successful companies, national and international associations. Logistic is present in all areas of human endeavor encompassing all the systems and processes that allow the movement of material and immaterial flows in the physical, information and organizational terms. In the last thirty years, logistics has developed and established itself more than in the previous three centuries Logistics has become a system of skills and disciplines that are grounded in fundamental and applied scientific knowledge of each system. It is an interdisciplinary and multidisciplinary branch of science related to the operation of a variety of support systems, where operations can be in the domain of the armed forces, production, customer service, etc.

In economically developed countries, logistics and logistic processes are subject to continuous improvement, as more and more manifest the problem of using time and space to achieve effectiveness and efficiency in achieving various goals. Logistics, now days, addressing the problems of providing all the conditions, necessary for the successful operation of the business, military or technical systems and organizations, and to study all the elements of integrated logistics support necessary to keep the system carrying out their functions properly, and the way you want. This means that integrated logistic support includes elements of a technical character (development, production, transportation, supply, maintenance, etc.), and the elements of general or of the social (availability of personnel, training, environmental conditions, consumer services, etc...) and economic character (costs, working capital, profitability, profit, etc.) (Andrejić and Milenkov, 2012).

Intensive development of logistics is characterized by new concepts and technology in all areas of logistics. Some trends that were present in the past will continue with some modifications, but they appear and a new vision of technical, organizational and educational components of logistics. Identifying the need and trying to meet user requirements are the new approaches to logistics. The aim of all logistic activities is: meeting the needs of users with different products and different services in different places of origin, reducing the cost of logistics processes; improving the quality of logistic processes and services (speed, reliability, and offer to service users), protection of the environment (air, water, humanization of logistics operations, packaging material for recycling, etc…). Developed business systems increasingly used different approaches to solving the problem of logistics on various decision-making levels that allow increasing business efficiency and improve the quality of logistic services. On the one hand, users of logistic services are increasing demands for better quality products and services, on the other hand, operating systems increasing tendency to reduce logistics costs and reducing harmful impact on the environment, leading to permanent changes in all components of the logistics system, as well as the implementation of new logistics strategies and concepts.

Today's stage of development of logistic is characterized by the following trends (Zečevic and Gojković, 2010):

- introduction of new logistics strategies and concepts;
- unification and integration of smaller and more frequent logistic flows in order to reduce inventory;
- the creation of a logistics system of profit through the process of outsourcing, specialization and extension services;
- design of new logistics centers, networks and supply chain networks with a wider set of activities and participants;

- development and implementation of automation and advanced information technology;
- establishment of logistics companies and associations;
- the creating of alliances by geographic principles, principles of technology, interest and other preferences;
- the creation of supply chains with strong performance flexibility, visibility, security, economy and sustainable development;
- training new profile experts and the general specific knowledge of the multidisciplinary, interdisciplinary field.

The armed forces of the developed countries great attention is paid to the development of automated information systems to enable timely delivery of information at various levels of command. As a special type of information system within the armed forces, there is a logistics information system Adequate logistics information system provides automatic data processing, distribution and presentation of relevant information in real time, according to user requirements logistic support, logistic units (command, administrative and executive), commanders and other units, resulting in timely fulfillment logistics requires supported units. In such an information system, there are standardized relationships and information flow between elements within the logistical support system and between the system of logistical support system and its environment, which is the purpose of existing. In addition, emphasis is placed on a modular approach in projecting, which has to allow its robustness and the ability of continuous development and improvement (Dronjak and Milenkov 2012).

In modern armed forces, approaches and concepts of logistics aim to achieve:

- full integration of logistic support to make the system capable of quickly distributing goods, people and information, thus increasing the response speed of logistics;
- a general overview of logistic resources allowing decision makers quick connection of operational requirements and available logistic capabilities;
- timely supply in order to reduce the need for storage and to increase the speed of funds flow in the supply system;
- reduce cost and increase efficiency.

Changes in logistics, which have recently become noticeable, caused profound changes in the operation of the new (virtual) economy. The main driver of these changes is the development of information and telecommunication technologies that are at same time drivers of globalization at the world market. Logistic play a key role in the development of this new view of the functioning of business systems, which include the logistics system of the armed forces. Classic logistics systems, which are strictly limited flexibility and resource utilization, are beyond the development of virtual logistics where logistics facilities treat by availability, not by identity or physical form. This allows greater flexibility in the construction of the logistics system, the availability, and utilization of all resources.

Great progress in information and communication technology has allowed information to replace inventory. As information becomes cheap and stocks more expensive, the trend will surely continue, with the goal of optimizing inventory. Electronic data interchange allows optimization of compromise between stocks and information across the entire supply chain. The appearance of expert systems and artificial intelligence, suggests that the logistics optimization become increasingly sophisticated and will cover the wider area of business.

3. VIRTUAL LOGISTIC

Virtualization of logistics business comes as a result of the use of new information and telecommunication technologies knowledge. This mode of operation allows the creation of an effective logistics network increases the efficiency of logistics resource through flexible allocation of the resources and reduces logistical support time, which improves efficiency and effectiveness of logistic support.

Virtualization of business generally brings fundamental changes that Skyrme (1998) manifests most through three business dimensions: space, time and structure. The general perception of logistics resources in virtual logistics system is that it does not matter where they are or which they are forming, than availability of the specific logistical resources in sufficient time. On that way, the location of the materials and capacity of logistic units are the secondary importance. Their availability at the time when they are needed is priority.

Virtual Logistics treat logistical resources as a means of exchange. If the logistical resources treated strictly physical, it would limit their flexibility and limited the efficiency of their. Viewed in the past, in practice it is not possible to treat the logistic resources in this way because of the tendency to be accurate location spaced. Information about them was available locally, and their capacity utilization only locally available. With the

development of information and communication systems, in particular the Internet, the local barrier is overcome and opens the possibility of obtaining information on the availability of logistical resources, and then the degree of availability and efficiency regardless of their location (Protrka, 2009). Virtual logistic handle the physical and logical aspects of information activities. Management and control of resources is done via the internet (intranet) applications. This kind of management allows efficient construction logistics systems. The great advantage of virtual logistics is achieved by increasing the availability of operational information that can be used when setting deadlines, traffic monitoring, accounting, material management, and so on. Concepts of virtual logistics are: logistics virtual organizations, virtual storage, virtual inventory management, virtual supply chain, the virtual control of the goods, virtual trading, virtual delivery, virtual manufacturing, virtual logistics services, virtual markets, virtual development, and so on. (Protrka, 2009).

From the above concepts, practical applications in the Serbian Armed Forces may have virtual storage concepts and virtual inventory management.

4. VIRTUAL WAREHOUSE CONCEPT AND VIRTUAL INVENTORY MANAGEMENT

Supply system in the Serbian Armed Forces, as designed, has staff structure. The system is clearly identified:

- material flows are expressed with material flow through the warehouse - linear structure,
- collection and processing of information and system management through desk officers - staff structure.

Basic features of this organizational structure of the system are low vertical level of decentralization, although it exists, on the other hand, a very high level of horizontal decentralization. The tack of horizontal linkages affects that any cooperation between adjacent elements of the same level can be organized only by the superior level, which causes time loss and the apparent lack of occurrence of certain assets, although the system has.

Time losses and the apparent lack of resources prevent the timely achievement of logistic objectives, which represents an imperative of every logistics system that wants to be competitive in the market.

The problem could be overcome by applying the concept of virtual inventory management and concept of a virtual warehouse of the Serbian Army.

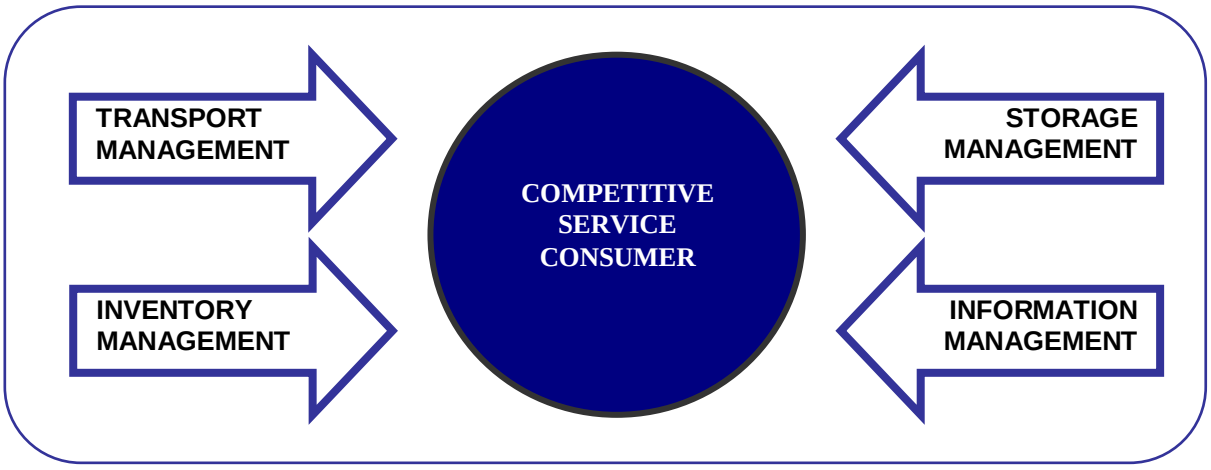

Figure 1: The four subsystems of logistics management and the ultimate goal (Božić and Aćimović, 2010)

4.1. Virtual warehouse concept in the Serbian Army

In the Serbian Armed Forces, material is stored at the logistic unit's warehouses that are not mutually linked. The advantage of introducing the concept of a virtual warehouse in SAF has simplified access to information about the materials that are stored in the warehouses and storages of logistics units, which would be easier to manage and control inventory levels.

Information about warehouses, storages and materials stored in them, would be accessed on local level and the Serbian Army catalog of material would provide organized access to remote information about the materials in a virtual warehouse of the Army of Serbia.

The physical location of stored materials would be in multiple places. The advantages of keeping the material in this way are:

- Greater flexibility and increased storage utilization and storage.
- Storage capacity become a potential which not only locally available.
- The geographical spread storage of materials contributes to finding stores and warehouses that most closely meets our requirements.
- It reduces the risk of keeping the material in one place.

The catalog of virtual Army storage would look the same as the catalog of conventional storage. The only difference would be in a physical location of material. The materials in virtual storage can be in different locations (Figure 2). Virtual stores and warehouses can therefore abolish spatial constraints, the size of the catalog and sort of materials, so it leads an increase in the efficiency of storage.

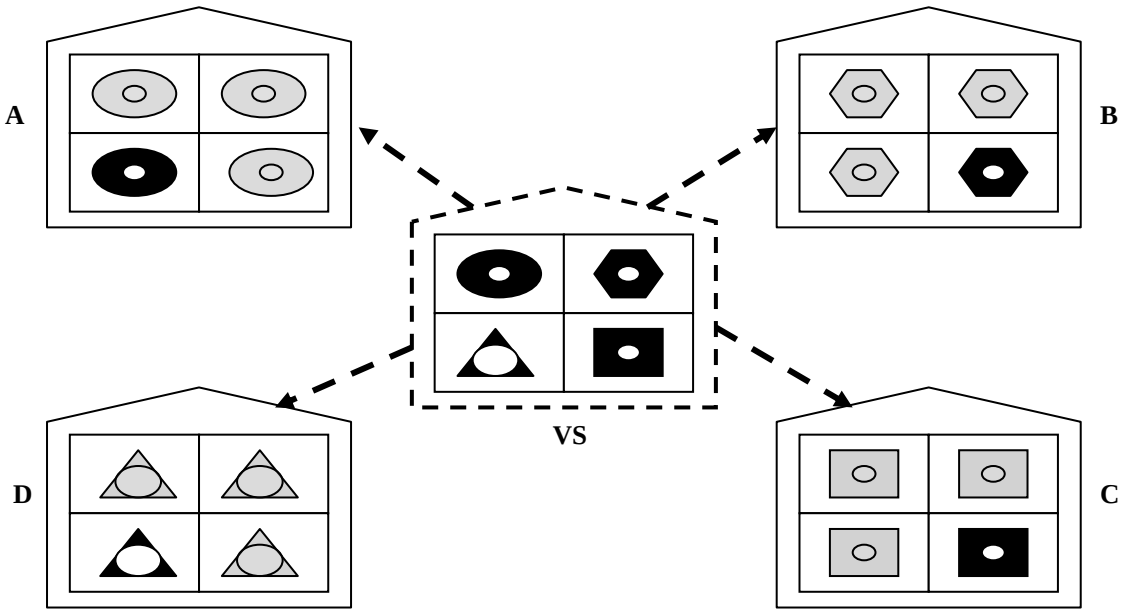

Figure 2: Virtual storage (Clarke, 1998)

Facilitated communication, application of information technology and creation a virtual warehouse would create a good basis for the introduction of the internal market of the material within the Serbian Army as an innovative business concept. Internal market within an organization can help her to realize significant benefits in: efficiency, freedom, flexibility and motivation (Malone, 2004).

4.2. Virtual inventory concept

Inventory management represents finding the optimal balance between requests for material and the amount of stock material (material management costs). The analysis of the previous problems, we see that, in addition to being on its own technical (material requirements), and economic in nature (material obtained in the optimal time to avoid delays logistic support which relates to hold the material). Its effective resolution requires respect for both aspects, as well as the application of modern methods for management of technical systems and materials.

By virtual management can be stored and utilized materials such as spare parts, fuel, lubricants, and food items, reproductive and other materials. In some cases, it would greatly change the purpose of storage. The material in them would not be such a far spent, but also developed. It is possible to owe more than you own. It is still enough material to fulfill short-term demand.

Conventional logistic considered that material is available if it is on stock (Figure 3 a). It is kept for a certain period, a critical reserve materials are used only in special cases. There are visible gaps of this storage method. It is obvious that some critical reserves will not be used, and the cost of storage of such inventory can be very large. The alternative of keeping reserves of critical materials is keeping the virtual stock. Virtual stock may physically exist in another location and material can be assured through a virtual supply chain (Figure 3 b). In this way, the cost of storage could be reduced.

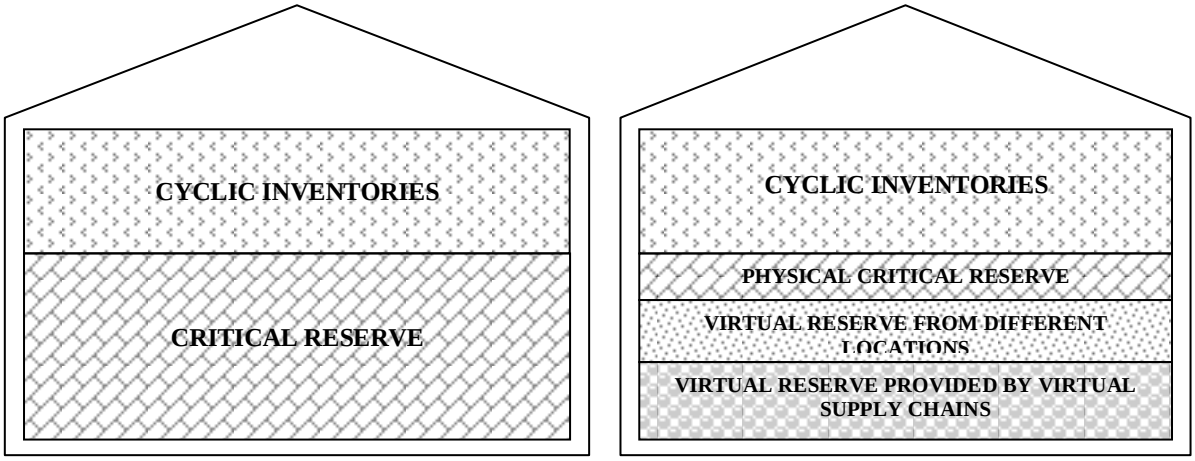

Figure 3: Comparative review of conventional storage and virtual storage (Clarke, 1998)

They ideally, the savings gained control in this way would result in reduced total cost of storage material. Virtual inventory management brings storage to a new level.

5. CONCLUSION

The development of information and communication technologies, as well as the globalization of business, makes strong influence on change in the perception on the models of organization logistic systems.

The endeavors to keep up with the high quality standards required to change the way of business thinking at all levels of logistic system in the Serbian Armed forces. As it is necessary to change the interaction with the environment, it is necessary to change the relationships within the logistics system. In addition, it is necessary the implementation of modern technologies and software models that allow precise monitoring logistic units capacities and faster and more sophisticated planning processes and logistic support in SAF.

Timely logistic information provides timely logistic support, which leads to raising the quality of logistics services, shortening the response time of the logistics system, increasing the efficiency and effectiveness of logistics support. Now, virtual logistics change the role of logisticians. Instead, to manage the physical resources, now they manage the information.

In the long run, the implementation of the concept of virtual logistics in the Army of Serbia would allow increased efficiency of logistics operations, minimize response time, and the operation would eventually become more equivalent with user needs. As a result, it is possible to get more sophisticated, less expensive products and services.

The ultimate effects of the application of the proposed system are getting in time, money and quality of the information.

Abstract: *The number of computer and Internet users in Serbia, as well as the number of companies that use computers and electronic communications in their daily operations is certain from the surveying point of view and there are also time series accessible that represent the grounds for drawing conclusions on the degree of growth and the user structure over time. Even the 2012 Census included questions on computer ownership by households as a core demographic factor for the age in which we live. During the Internet expansion in Serbia, an online population was created and it reaches the level of approximately 60% of the total population (aged between 16 and 74) and includes almost all companies. It is to be expected that the online market segment will have a powerful impact on the overall socio-economic trends in the country. The main goal of this study is the determination of the percentage share of economic entities on the Internet in Serbia by sectors and regions and explore communication channels, primarily e-mail and web, in order to determine their status. The research was conducted by CATI (Computer Assisted Telephone Interviewing) method using a representative sample of 3197 companies.*

Keywords*: Analysis, communications, domain, e-mail, research, website.*

1. INTRODUCTION

Internet domains represent one of the strategically important issues, both for the functioning of the systems within the online sphere and for the homogenization of the national online community – individuals, companies and institutions. There are no records or reliable estimations for Serbia on the prevalence of the Internet domains, so that this paper is dedicated to a statistical survey on the Internet domains used by companies and institutions.

The information and communications technologies (hereinafter: ICT) have been recognized within the European Union (hereinafter: EU) as the main factor influencing economic growth and innovations, and among seven leading initiatives of the Europe 2020 economic strategy there is “Digital Agenda for Europe,” highlighting the significance of ICT in the modern economy. The goal of the strategy is to focus the development of the information society on the utilization of the ICT potentials for the benefits of increasing work efficiency, fostering economic growth, higher employment and improvement of life quality of all citizens of the Republic of Serbia. Moreover, it is expected that by the year 2020 the Republic of Serbia reaches the EU average by the information society development indicators.

The STRATEGY FOR THE DEVELOPMENT OF THE INFORMATION SOCIETY IN THE REPUBLIC OF SERBIA BY 2020 was adopted in 2010 (“The Official Gazette of the RS,” no. 51/2010). The implementation of the Strategy is monitored by the Ministry in charge of the information society affairs. Together with the strategy in the sphere of telecommunications, this strategy compiles the Digital Agenda for the Republic of Serbia.

One of the basic preconditions for the functioning of the Internet, in terms of the assigning of domains in Serbia, was met by founding of the Register of the National Internet Domains of Serbia (hereinafter: the RNIDS) through the enactment of the decision ICANN (hereinafter: international organization Internet Corporation for Assigned Names and Numbers) no 07.76 of 11.09.2007 which gave consent to the RNIDS to manage the register of the national internet domains for the Republic of Serbia (Document of the Ministry of Science and Environmental Protection no. 451-01-01600/2007-01 of 10/05/2007). In the same year, there was an exchange of the Letters of Intention between the RNIDS and the ICANN managing the global system of textual and numeric Internet addresses and prescribing the rules for the introduction of the national Internet domains, which the Serbian delegation signed in October 2007.

The Ministry of Foreign and Internal Trade and Telecommunications was founded as of the date when the new Law on Ministries (“The Official Gazette of the RS,” no. 72/12 and 76/2013) entered into force on

26.07.2012. Under the Article 36 of this law, in addition to other affairs, it also took over from the Ministry of Culture, Information and Information society, as the legal successor of the Ministry for Telecommunications and Information Society, the execution of the competencies in the sphere of information society and the managing of the Directorate for Digital Agenda which is in charge of the information society affairs. In this way the legal continuity of the agreements signed by the RNIDS with the authorized Ministry of the Republic of Serbia (hereinafter: the Ministry) has been preserved both in the material and formal sense.
With regards to the regional backdrop, the RNIDS has a more favourable position as an autonomous and independent organization in comparison to the registers in the region. Namely, most of the regional registers are parts of an organization originating in state universities, such as the case with Bosnia and Herzegovina (link: http://www.nic.ba/); Slovenia (link: http://www.arnes.si/en/about-arnes.html) where the academic network is the administrator of the national domains, somewhat independent but under the control of the state university; Croatia (link: http://www.dns.hr/ and http://www.carnet.hr/) where the work of the national register is regulated by a special rulebook within the public organization of the university; Macedonia (link: http://marnet.mk/); with individual cases of Montenegro (link: http://domen.me/) that ceded the administration of the national internet domain to the international company „Godady" and Bulgaria (link: https://www.register.bg/user/index_en.html) where the management of the national Internet domain is owned by a private company.

2. METHODOLOGICAL FRAMEWORK

In Serbia, there are no reliable estimates regarding the prevalence of Internet domains. The authorized Internet providers have records on their users, but not only do these records not have complete coverage, they are also not joined together and cannot be generalized to the population at large. In other words, they cannot be used as the grounds for drawing any conclusions. This chapter shows the basic methodological references of the survey using a representative sample that is a basis for making statistically reliable assessments on the degree of prevalence of the Internet domains used by companies and institutions.
The survey was conducted in the period 10 – 28 March 2014 using the telephone survey method that takes approximately 15 minutes. The collocutors were the owners and general managers of companies or IT managers. The survey was conducted using a representative sample of 3197 companies. The SORS also applied the post-stratification by the size of company, industries and regional distribution.

3. MAIN RESEARCH RESULTS

All statistical series and assessments go to confirm that in Serbia today computers and Internet are used in almost all companies. At the same time, the data show that there are rare companies where computers and e-operations have completely replaced the classic ways of handling administrative operations. In those terms, the subject of this survey is primarily the prevalence of e-mail and web communication in the daily operations of companies.

As regards the question on whether they use e-mail communication with clients and business partners, in 79.9% of the companies the response was affirmative. There are significant differences in the prevalence of e-mail use depending on the size of the company, the size of the municipality in which the company is located and region. The prevalence of e-mail business communication increases with the size of the company, so that it is least used by the companies with one to two employees (69%), a little more by the companies with three to five employees (73%), and mostly used by the companies with more than six (80%) and more than 30 employees (83%). Moreover, there are significant differences in the use of e-mail communication depending on whether the settlement in which the company headquarters is located is urban or not.

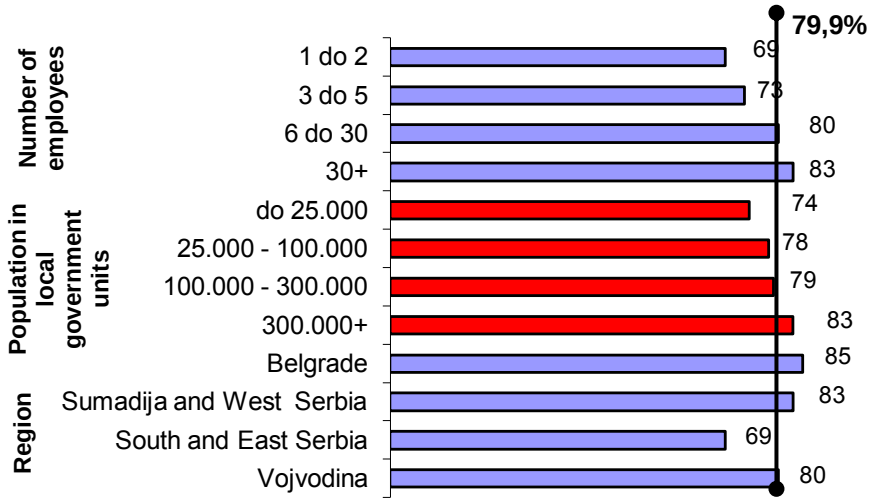

Figure 1: Prevalence of e-mail business communication use by companies

The prevalence of e-mail communication is directly proportionate to the size of the town/municipality by the number of residents. Thus, in smaller settlements (up to 25,000 residents), there is a significantly smaller number of companies (74%) that use e-mail in comparison to bigger towns of up to 100,000 residents (78%), up to 300,000 residents (79%) and over 300,000 residents (83%). Regionally observed, e-mail is most prevalent in companies based in Belgrade (85%), followed by Sumadija and West Serbia (83%), Vojvodina (80%), and South and East Serbia (69%).

It is common practice for Serbian business people and companies to use informally registered (with foreign or domestic providers) e-mail addresses for business communication, which is frequently not in line with the corporate e-identity of the company. One of the objectives of this survey was also the assessment of the degree of prevalence of Internet domains for e-mail communication in our companies.

Most frequent are the companies where the e-mail addresses of the employees are a part of the company"s e-identity (45%). Figure 2. This approach is particularly common for companies with more than 30 employees (62%), significantly less common for the companies with 6 to 30 employees (39%) and least prevalent in the companies with up to 5 employees (31%). 28.5% of the companies use the e-mail for business communications that is registered with some of the domestic providers, such as EuNet, Sbb, Ptt, SezamPro, etc., while approximately every fourth company (26.5%) uses e-mail registered with some of the global providers, such as Gmail, Hotmail, yahoo, etc. These types of e-mail addresses are most frequently used by small companies with up to five employees (39%), significantly less by larger companies with six and more employees (28%) and least by companies with 30 and more employees (16%). Also, the prevalence of the companies using these e-mail addresses is almost twice as high in smaller settlements with up to 25,000 residents (38%) than in bigger towns with over 300,000 residents (20%). If observed regionally, they are least prevalent in Belgrade (20%) and Vojvodina (25%), and significantly more in Sumadija and West Serbia (29%) and in South and East Serbia (36%) where almost every third company uses for their business communications e-mail addresses registered with global providers, such as Gmail, Hotmail, yahoo, etc.

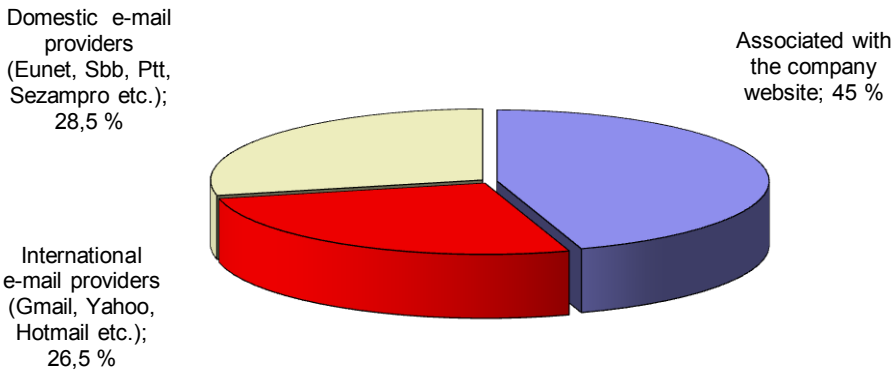

Figure 2: Internet domains companies use for e-mail business communication

According to the results of this survey, a little over half the companies (54.9%) in Serbia have a website (Figure 3). There is a statistically significant difference (Sig. 0.000) by the number of employees =27) a website. Thus, the average number of employees in the companies that have a website is approximately three times as high in comparison to the companies that do not have a website. Also, there is a statistically significant difference (Sig. 0.000) by the number of residents in the municipality/town – headquarters =378436) a website. Thus, the average number of residents in the municipality/town –headquarters of the company is approximately 58% higher for the group of companies that have a website in comparison to the group of companies that do not have one. If regionally observed, most of the companies that have a website are located in Belgrade (65%), significantly less in Vojvodina (56%), Sumadija and West Serbia (51%), and South and East Serbia (44%).

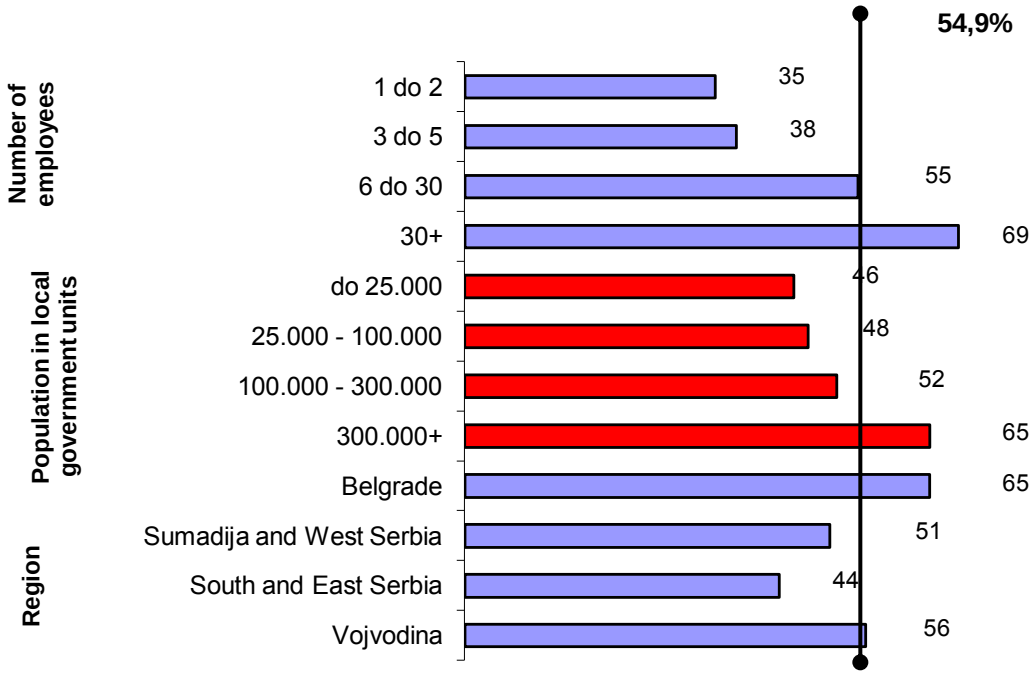

Figure 3: Prevalence of websites in companies

Out of the total number of companies that have a website (54.9%), a little over two thirds (67.9%) use national domains .rs and .co.rs. The .com domain is significantly less prevalent and it is used in 27.9% of the companies. All other domains (including .org and .net) are present in only 4.2% of the companies (Figure 4). Regionally speaking, the national domains .rs and .co.rs are most prevalent in the Belgrade companies (73%), followed by the region of Sumadija and West Serbia (66%), South and East Serbia (65%) and Vojvodina (65%).

There are no statistically significant differences in the prevalence of the national Internet domains when it comes to the websites of our companies with respect to the number of employees and number of residents in the municipality/town – headquarters of the company.

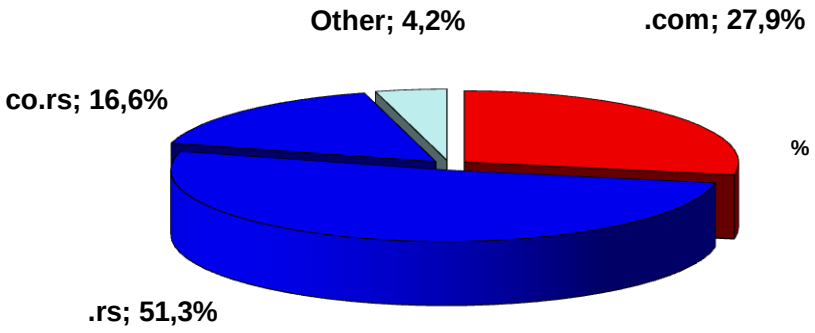

Figure 4: Prevalence of web domains

Through the analysis of the prevalence of the .com domain, it is possible to observe regional differences and thus the .com domain is most prevalent in Vojvodina (31%), a little less in the region of South and East Serbia (30%), and Sumadija and West Serbia (29%), and it is least prevalent when it comes to the sites of the Belgrade companies (23%).

4. CONCLUSION

The topic of this paper is an analysis of the role and importance of the Internet (e-mail and web) services with a special view at the Internet domains used by Serbian companies.
According to the data of the Statistical Office of the Republic of Serbia from 2013, 59.9% of the households in Serbia own a computer, while 55.8% of the households have an Internet access. 63.4% of the observed population (16 – 74) use a computer and 58.5% use internet. There is a continuous growth of the on-line population, with the annual growth rates of 7.5% (2012/2013), 4.6% (2011/2012), 1.1% (2010/2011) and 2.9% (2009/2010), which on average amounts to ~4% annually for the period from 2009 to 2013. Statistical data show that the growth of the on-line community in a demographic sense has reached a certain level of "saturation." Since population ageing and low level of education are the factors that to the greatest degree limit the growth of the number of Internet users, it is not to be expected that the number and structure of the on-line community will significantly change in the following period. Out of the Internet activities, the most prevalent are still e-mail (70.4%), surfing – browsing and downloading of web contents (69.5%), although the on-line user habits have significantly changed over the past few years with a larger share now being taken by the "social networks."

Out of the total number of Internet users, 68% are active on social networks, and as much as 93.4% of the online population between 16 and 24 years of age have a Facebook and/or a Twitter profile. The survey shows that 44.2% of the total Internet population use Internet for access to public institutions and administration. When it comes to e-commerce, during 2013 more than 900,000 people bought/paid something using Internet (increase by 300,000 in comparison to 2012). The results of this survey show that today in Serbia almost all companies and institutions use computers and Internet.

The survey has revealed the results shown in this study that can, in the briefest form, be brought down to the following:
Out of the total number of companies that have a website (54.9%), a little over two thirds (67.9%) use national domains .rs and .co.rs.
Out of the companies that have a company"s website, only in 45% of the cases the e-mail addresses of the employees are a part of the company"s e-identity.
For their business communications, 28.5% of the companies use e-mail that is registered with some of the domestic providers, such as EuNet, Sbb, Ptt, SezamPro, etc., while approximately every fourth company (26.5%) uses e-mail registered with some of the global providers, such as gmail, hotmail, yahoo, etc. This phenomenon is directly correlated with the size of the company measured by the number of employees and inversely correlated with the degree of urbanization. This demonstrates insufficient marketing literacy.
All of this goes to show that there is ample space in Serbia for further development of ICT, primarily in the sphere of education.
The global trends show a dominant impact of information technologies, Internet in particular, on contemporary business operations and it can be expected to see an even faster growth of this sector in the future.

The field of ICT has been recognized as the key factor for the economic development of Serbia and particularly for strengthening exports.

The (national) Internet domain is an important factor in the market approach of the businesses.
The national Internet domains provide a higher degree of reliability and security, thus ensuring a higher degree of clients" trust, since the domains cannot be registered by unidentified companies or individuals, which are very important in preventing misuses of domains (fraudulent misinterpretation, cyber crime...). For instance, the .com domain can be registered by anyone, without any real identification, even with completely fabricated data. Contrary to this, the users of the national .rs and .срб domains must provide accurate, complete and valid data when registering the domain, and these data are checked from time to time. This brings the possibility of frauds during on-line purchases, E-banking and other transactions on the Internet to the least possible degree.

The growing trend in Serbia of buying via Internet and the growing trend of using e-administration services

The growing use of computer applications: applications in large companies (airline companies, insurance, internet banking); applications in public organizations (e-voting, tax return); applications in health care sector (patient data, diagnostic tools and instruments, special surgical equipment); applications in education (learning through computer – CBT, distance learning, homework through Internet): adaptable learning time, adaptable place of learning, experience in multimedia learning, and reduced costs. Positive trends of applying distance working (teleworking):

The growing awareness among the citizens of Serbia of the need for environmental protection: use of electronic documents reduced the need for printed materials; recycling of printed materials; use of monitors with reduced energy consumption; recycling of used or broken computer components – all of this together leads to the broadening of the scope of electronic business operations.

INVESTIGATING WEB-BASED DECISION SUPPORT SYSTEMS SUCCESS IN ONLINE SHOPPING CONTEXT

Mohammed A. I. Ayoub

Limkokwing University of Creative Technology, Cyberjaya, Selangor, Malaysia
ayoub22265@hotmail.com

Abstract: *The web-based DSS success in online shopping field lead to increase the purchase level and attracting new customers. The objective behind various online shopping systems initiatives has shifted in recent years towards establishing services and demands that cater more to citizens' needs and offer greater accessibility. As a result, it is necessary to develop a theoretical framework to measure the success of web-based DSS in online shopping context. The purpose of this study is to identify the success factors influencing web-based DSS in online shopping field from the internet users' viewpoint. A theoretical framework was developed to evaluate online shopping systems success. Initially, DeLone and McLean's IS success model (1992; 2003) was used as the base model for this research. Additional variable was incorporated into the model from web-based DSS literature, and re-specifications and extensions were made to develop a proposed success model for web-based DSS in online shopping context. Consumer decision making satisfaction and perceived net benefit was proposed as a measure of web-based DSS success in online shopping field, and its relationships were hypothesized with online shopping system quality, data quality, and knowledge management. Five hypotheses were formulated to test the proposed research model.*

Keywords**:***Success factors;Web-based DSS Success; Decision making satisfaction; Perceived net benefit; Online shopping; Knowledge management.*

1. INTRODUCTION

The usage of Internet has grown rapidly over the past years and it has become a common means for delivering and trading information, services and goods (Delafrooz, 2009). The web in particular and the Internet as a mother network, vital area to manage and develop the technical capabilities of decision support systems. There are different types of decision support systems that are based on the Web (Web-Based DSS) are directed to support management and decision-making and decision support systems geared to the customer. Also, online shopping has become very popular in the last few years. There are many of online shops available all around the Internet, where customers can purchase any commodity that they want as cars, books, electronics, jewellery, clothing and many other products while sitting comfortably at their home (Janik, 2007). Recently, the web has now become the platform of choice for building consumer Decision Support Systems (DSS). According to Bharati & Chaudhury, (2004) DSS on the web has precipitated three major changes to the environment where DSS is being employed: a change in the user community, a change in problem domains, and a change in the underlying technology architecture. In the past, DSS applications have generally been implemented in commercial environments where users are employees of the firm. With the advent of web-based DSS, the user community is no longer limited to the managers and experts working on business-related problems, but beyond that to the ordinary users and customers. These changes in DSS have made it incumbent on the DSS researchers to reexamine the factors that influence efficacy and success of DSS in this new environment. An example of a web-based DSS for customers is found at www.amazon.com, www.dell.com, www.overstock.com, www.myidaman.com, www.shopping.com, and www.tabo.ps and others, as online shopping systems, where customers can choose the kind of Commodity or service. These and other self-service information technologies that aid in decision-making are becoming quite prevalent. These web-based DSS are being used, but there is little research that has evaluated these systems from the perspective of users. Thus, more studies are needed that focuses on evaluating web-based DSS in online shopping context and exploring the success factors influencing web-based DSS success in this field.

This study investigated the factors that affect consumer decision making satisfaction and in turn, perceived net benefit, that is to say measuring the success of web-based DSS through decision making satisfaction and perceived net benefit, where the research model developed based on the Delone & McLean, (1992; 2033)IS success models.

2. BACKGROUND

Web-based DSS in Online shopping context is relatively a new phenomenon but expanding very rapidly worldwide. In comparison to in-store shopping, online shopping is far too much efficient in reaching the targeted customers that can provide substantial time and cost saving (Anwaar, 2008). During the last 30 years the access of personal computers has increased all over the world. Along with the development of new technology and computers, the ability to connect computers all over the world emerged in the 1970s. This worldwide computer network was called the Internet. Along with the Internet an opportunity has emerged; the possibility to make purchases online which is called Electronic commerce (E-commerce) (Eliasson, et al., 2009). As said by Brown & Jayakody (2008), the e-commerce is more narrowly defined in terms of the purchasing and selling products or services through the medium of the Internet, and Companies are making large investments in e-commerce applications but are hard pressed to evaluate the success of their e-commerce systems (DeLone & McLean, 2003). This growth in e-commerce is the reason behind recent attempts to measure the success of online shopping systems. The advent of E-Commerce, from the Business to Consumer (B2C) perspective, has opened new opportunities for sales, as well as new issues to address in the design of web-based DSS in online shopping field. In online shopping systems, buyers benefit from convenient access to information and commerce while sellers benefit from selling to consumers anytime and anywhere with low bricks-and-mortar and intermediary costs. Despite these benefits for both buyers and sellers, the current conversion rates are still very low (2%-6%) (Eisenberg, 2004).Furthermore, the proliferation of online products provides a wide variety of choices for the consumer in selecting a product that meets his/her preferences. However, the large number of choices available on the web, Difficult to use, and inadequate information and non-obvious and perhaps other reasons, consumers often find it difficult to make a final choice of a product. Therefore, one crucial task for online shopping systems is to help buyers select products with a minimal amount of effort and time, to attract consumer to choose his demand (Pu, & Kumar, 2004). Since online shopping sites are accessed by diverse types of consumers with different backgrounds, preferences and expertise, their usability should satisfy different consumer needs and preferences in the process of product search and choice. As a result, it is an essential task to provide decision assistance for the end user to determine the target product both accurately and efficiently. Understanding the factors influencing consumer decision-making satisfaction could guide designers and researchers to build more effective online shopping systems that provide the necessary support for consumers. So, many researchers have argued that consumers with DSS will perceive better information quality, faster decision, more satisfaction and higher intention to use the system in the future than without such support. To summarize, several researchers have studied the effect of consumer decision support systems on the online shopping environment and its importance in providing an effective support to in raising the level of sales and then the success of online shopping systems. As result, purchase decision-making process and the availability of such DSS in online environments will enhance the ability of individuals to identify the products that best match their preferences.

2.1. Decision Support System (DSS)

As known, the DSS technology has been rising and flourishing since 1970s. By the 1980s, dramatic improvements in technology resulted in information systems that were less expensive but more powerful than earlier systems. People at all levels of organizations began using personal computers to do variety of tasks; they were no longer solely dependent on the IS department for all their information needs. So, people quickly recognized that computer systems could support additional decision-making activities. A DSS is an organized collection of people, procedures, software, databases, and devices used to support problem-specific decision making. The focus of a DSS is on decision-making effectiveness. Where a management information system helps an organization" do thing right," a DSS helps a manager "do the right thing" (Ralph & George, 2006). DSS's components are: base models and database management systems models MBMS, and database management systems and databases DBMS, with an interface provides ease of use, and flexibility to deal with the system software (Al-Takreety, 2004). In short, the Essential idea based decision support systems is to build systems give the ultimate beneficiary useful tools for data analysis using models and databases, and provide possible solutions to the problems presented. Recently, DSS have become a significant domain of Information Systems research. According to Newman et al., (2000), Decision support systems are computer systems assist the user in complex problem solving or decision-making. Cited in Holley, (2011) Burstein & Holsapple (2008) define the term of DSS as systems which represent and process information for the purpose of improving decision making. In turn, Holley, (2011) said that DSS can range in

level of sophistication from a simple spreadsheet to sophisticated data warehousing and mining applications, knowledge management systems, or modeling systems. According to Kwakkel, (2006) the field has evolved from two research areas: the study of organizational decision making and technical studies into applications for computers. According to Keen, (1980); Huber, (1983) & Schroff, (1998), it is impossible to give a definition of DSS that covers all the aspects. Holsapple (2008) presents Figure (1) as the framework most commonly cited in literature to illustrate a typical DSS architecture.

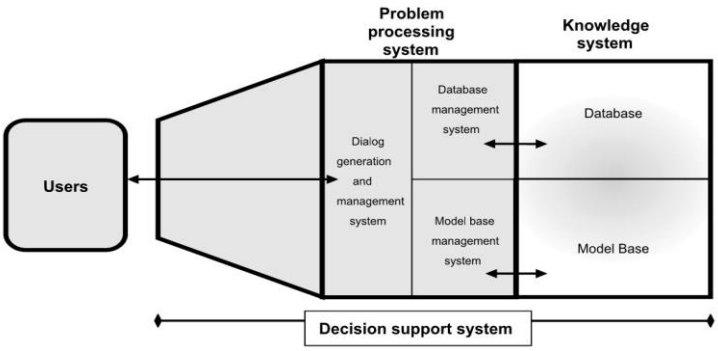

Figure 1: Popular DSS architecture framework. Holsapple (2008) p.183

To summarize, based on previous definitions of DSS and through a comprehensive survey of many of the definitions of DSS in the literature, the researcher concluded that there is no one single definition, Full, inclusive, generalizable, and agreed on by all researchers of DSS, but it is clear that there is consensus about the fact that DSS are computer-based systems that support management decision making. This broad definition can encompass many systems as web-based DSS. Pattern offers a way to characterize these systems and differentiate between them. The current research focusing on web-based DSS directed to consumer in online shopping context.

2.2. Web-Based Decision Support Systems

With the enormous development in the techniques of the Internet and the vast amount of information, data, and alternatives of various goods and services provided by Web sites, the concept of decision support systems In the development of a permanent, so, became one of the most important types of decision support systems is web-based DSS, therefore, the web-based DSS is chosen as the DSS architecture. And as mentioned by Aldhmour & Eleyan, (2012) that many types of Computer-Based Information Systems have been developed to support decision making. According to Wang & Yeh, (2009) a web-based DSS refers to a computerized system that delivers decision support information through a web browser to someone who needs it. According to Friedman, (2005) the importance of using web based DSS originates from the growing amount of available information that should be identified, controlled and accessed remotely using web based tools to support reusability of integrated decision modules. According to Gasmelseid, (2006) web-based systems are regarded as "platforms of choice" for delivering decision support while taking into account many technical, economic and social considerations. With the advent of web-based DSS, the user community expands to include, in addition to the managers and experts working on business-related problems, customers, suppliers and financers who shape the firm's policies and decisions (Gasmelseid, 2006). According to Velmurugan & Narayanasamy, (2008), the term is usually used to describe a computer based system designed to help decision makers use data, knowledge and communications technology to identify problems and make decisions to solve those problems.

2.3. Online Shopping Decision Making

Online shopping are interactions between individual recipients and consumers rather than being directed from marketing to masses of consumers (budi, 2010).The most common types of information systems used in business organizations are electronic and mobile commerce systems, transaction processing systems, management information systems, and decision support systems. In addition, some organizations employ special-purpose systems such as artificial intelligence systems, expert systems, and virtual reality systems. Together, these systems help employees in organizations accomplish both routine and special task-rom recording sales, to processing payrolls, to supporting decisions in various departments, to providing alternatives for large-scale projects and opportunities (Ralph & George, 2006).E-commerce involves any business transaction executed electronically between parties such as companies (business to business, B2B), companies and consumers (business to consumer, B2C), consumers and other consumers (consumer

to consumer, C2C), business and the public sector (administration), and consumers and the public sector. As known, web shopping is a part of the e-commerce picture. Figure (2) shows the different sectors of E-Commerce, as Merz describes them (Sebastian, 2008).

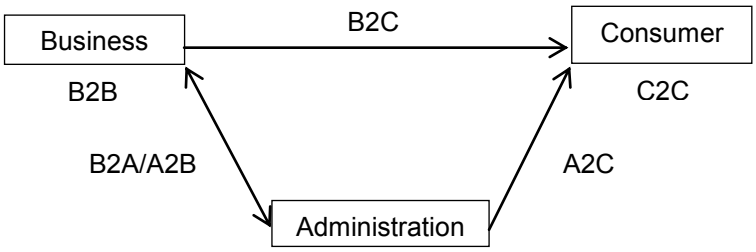

Figure 2: E-Commerce Sectors

E-commerce offers opportunities for small businesses, too, by enabling them to market and sell at a low cost worldwide, thus allowing them to center the global market right from start-up.Consumers who have tried online shopping appreciate the case of e-commerce. They can avoid fighting crowds in the malls, shop online at any time from the comfort of their home, and have goods delivered to them directly.The online Shopping Decision Making is act of purchasing products or services over the Internet, Where online shopping has grown in popularity over the years, mainly because people find it convenient and easy to bargain shop from the comfort of their home or office. Since the Internet provides quick and easy comparison of many different types ofProducts, searching for product information and buying goods online are becoming increasingly popular activities. According to Park, (2007) online shopping is an activity in which consumers make a transaction to purchase products or services offered by online stores.According to Zhang, (2011) consumer decision making process consists five stages: problem recognition, search, alternatives evaluation, choice and outcome.

According to Sharkey et al., (2009) selecting a product alternative is a multi-attribute decision process. Based on Waterfall diagram of decision process, the super-set, which contains all existing product alternatives, is the Universal Set, of course, the consumer may not be interested in all the alternatives in the set that sub-set of alternatives of which the consumer is aware, is the Awareness Set. All of the alternatives which the consumer proceeds to collect information about is called the Evoked Set and the set which the consumer evaluates further from the Evoked Set is called the Consideration Set, in turn, the choice is made from this final Consideration Set, see figure (4)

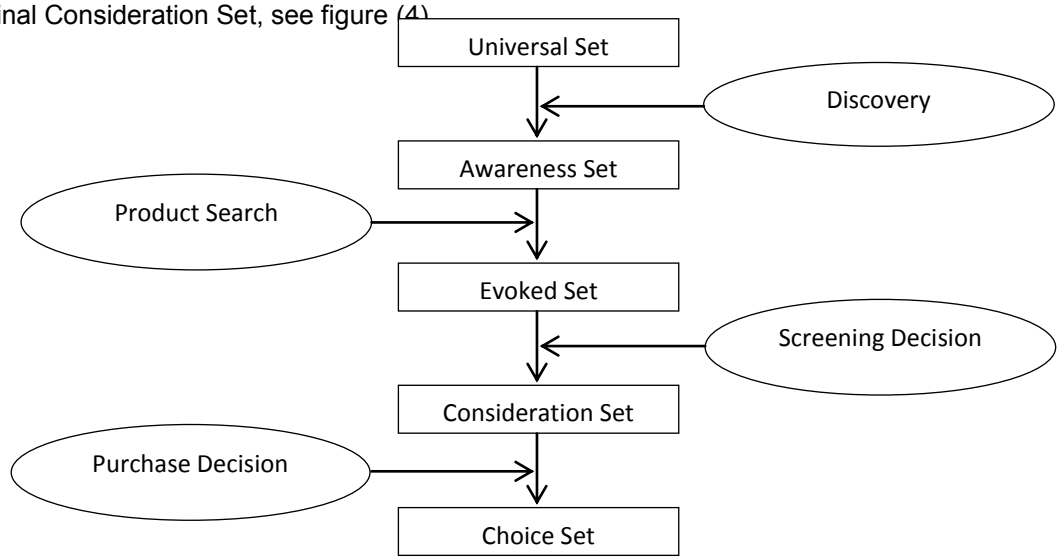

Figure 4: Waterfall diagram of decision process (Sharkey et al., 2009)

3. PROBLEM DEFINITION

A lot of active online stores do not provide enough motivations to the customers to get attracted to online shopping. Also, many of companies in the world rushing to open their online shopping systems which led to fail to support consumer's decision making, and loss of sale and the customer's repeat business.

The current study attempts to investigate and explore the success factors that influence consumer decision making satisfaction in online shopping context. Also, this research will use existing models that explain and predict information systems (IS) success as Delone & McLean, (1992; 2003). However, these success models need to be updated to recurrent industry developments. Where the researcher believes that the E-commerce environment and specifically the online shopping field is a unique setting to study and develop the DeLone and McLean's model of IS Success. Where the online shopping system is different from other types of systems implemented because its use is volitional instead of mandatory. Also, the system is not internal to the organization; in its primary use, it faces the customer, not organizational employees (Perez-Mira, 2010).

4. THEORETICAL ADVANCEMENT

IS researchers within the field of DSS have been attempting to identify more up-to-date and modern factors that affect web-based DSS success in field of online shopping. Based on this, we set out to find the opportunity factors that could suit the suggested research model by complementing it, where it today lack coverage (Johansson & Gustafsson, 2009).

Previous research on DSS has been mainly focused on factors for successful implementations of DSS for different scopes. Park (2007) identified aspects such as project factors, organizational factors and infrastructure factors have had significant impact on successful implementation. Further, he also found indications of that the external environment and prototyping were critical for successful implementation. Hence, the factors that were suitable and relevant for this investigation were accordingly those that relate to the web-based DSS success part of the previous models and concentrates on what factors affects the consumer decision making satisfaction, in turn perceived net benefit within an end-user perspective in online shopping context (Johansson & Gustafsson, 2009).

4.1.Perceived Net Benefit

According to Marafie, (2008) the perceived net benefits of online shopping in relation to traditional store shopping are one of the driving forces in the adoption. Convenience factors such as ease in purchase and time saving could be considered as perceive benefits of online shopping.

As known, Net benefits added as new construct to the updated DeLone & McLean (2003) model. The construct includes and replaces two variables previously found in the DeLone & McLean (1992) model: individual impact and organizational impact. These are defined as the system impact on an individual (user) and organizational performance, respectively. According to Holley, (2011) Critics of the model point out the Restriction of these two variables, arguing that the impacts of a system can span a wide range of stakeholders - consumers, work groups (e.g. Ishman (1998)), industries (e.g. Clemons et al. (1993)), even society (e.g. Seddon (1997)). Accordingly, the DeLone & McLean (2003) replace the two "impact constructs" with the more generic construct net benefits.

According to Delone & McLean, (2003) the impacts of IS have evolved beyond the immediate user, where some of researchers have suggested additional IS impact measures, such as work group impacts, Inter-organizational and industry impacts, consumer impacts, and societal impacts. Clearly, there is a continuum of ever-increasing entities, from individuals to national economic accounts, which could be affected by IS activity. The choice of where the impacts should be measured will depend on the system or systems being evaluated and their purposes. Rather than complicate the model with more success measures, Delone & McLean Preferred to move in the opposite direction and group all the "impact" measures into a single impact or benefit category called "net benefits." We can study net benefits at the individual level, where the customer can benefit from the system in terms of increased information, lower prices, ease of purchase, etc. Accordingly, in present research, we will adopt the net benefits as measurement Factor for web-based DSS success in online shopping context (dependent variable).

4.2.Consumer Decision Making Satisfaction

User Satisfaction is the most general perceptual measure of information systems success (Seddon, 1997). In the e-commerce environment it is an important means of measuring customers' opinions of the e-commerce system (DeLone & McLean, 2003). Customers in this study refer to only those who are familiarity with online shopping systems.Many of studies that emphasized decision performance typically downplayed or ignored the level satisfaction of the Web-based DSS users. With the growth of competitive Web retailing, however, understanding how to satisfy customers who obtain their information or services from web sites will be critical for establishing long-term client relationships, which consequently increases profitability. Therefore, understanding how online shopping users formulate satisfaction when obtaining information and services is

of great importance to Internet business. However, based on literature review, there are very few studies that systematically examined antecedents variables to satisfaction of users obtaining their information and services from Web-based DSS in online shopping context (Gudigantala, et al., 2011).
According to Saha, (2008) User satisfaction is the most common measure of success determination, and many researchers have developed and tested several standardized instruments to measure satisfaction as (DeLone & McLean, 1992, 2004).Although several authors have defined satisfaction, there is no single universally accepted definition. DeLone & McLean (1992) defined satisfaction as "Recipient Response to the Use of the Output of an Information System." A researcher must define the concept according to the context when multiple definitions exist for the construct; and also define the measurement criteria for the construct according to the chosen definition and the scope of research. In the present study, satisfaction was considered as a citizen's evaluative judgment of overall use of the online shopping service.According to Saha, (2008) in information system success and e-commerce success, different scholars developed antecedents of satisfaction, such as system quality, information quality, service quality, perceived usefulness, perceived ease of use, and trust (DeLone & McLean, 1992, 2004; Seddon & Kiew, 1996; Seddon, 1997).
In this current research we explore critical success factors influencing decision making satisfaction with web-based DSS which refers to the contentment of the consumer with the particular DSS application used.
It is noted that decision making satisfaction significantly correlated with perceived net benefit where the most important reasons for decision making satisfaction are to achieve some or all of the benefits that expected from the decision making. Also, Achievement of benefits and satisfy the desires will have the effect on decision making satisfaction. In other words, there is a mutual effect between decision making satisfaction and perceived net benefit. Accordingly, we will adopt decision making satisfaction as other measuring factor for web-based DSS success in online shopping context (dependent variable).

4.3.Online shopping System quality

There are different types of e-Commerce websites that focus on different areas of business activities. The most common type of e-Commerce website is business web portal (Wei, 2012).A great number of new websites have been launched every day. Ones with similar content will not have the same degree of quality. If the quality is poor, the user will simply leave the website and go elsewhere. Generally, there is no second chance to get a user back to the website especially in online shopping context. Therefore, in order to improve the quality of a website. The quality of a website makes a website profitable, user friendly and accessible, and it also offers useful and reliable information, providing good design and visual appearance to meet the users' needs and expectations (Zhou, 2009). In the Internet environment, System Quality measures the desire characteristics of an e-commerce system (DeLone & McLean, 2003, 2004). It is important to evaluate Web site functionality that focuses on the online service functions it provides.In the context of the present study, we changed system quality by online shopping system quality and defined it as follows: "online shopping system quality measures the desired functionality and performance characteristics of online shopping system".According to Stevens, (2008) many studies reported, a company's website is the key tool for the user's communication and it is the primary interface when searching forInformation and/or products online. If an organization's website is difficult to use, it will project a poor image on the Internet and will weaken the organizations position.Therefore, it is important that an online shopping system possesses a qualitative good website.

Online systems are measured in many studies. Measuring goes from online system interface up to the entire purchase experience. In this study, online shopping system quality will be approached from a more technical view and the objective is to know what consumers expect of the online shopping system they use and their experience; which attributes are important if a consumer makes his judgment about the quality? For measuring online shopping system quality many academic researches exist, but the outcomes are mostly fragmented and only discussing the meaning of some aspects of online system quality, but no scales to measure users' perceived online shopping system quality are available.

In summary, the dimensions of the researchers are quite wide. These differences arise mostly because they all did a survey with a somewhat different focus and their methodological approaches are varied. In this research, online shopping system quality is defined as the users' evaluation of the online shopping system features meeting users' needs. This definition is important to detain the domain of online shopping system quality.Therefore not all the existing literature is mentioned, but only the relevant literature from which sample items for the web quality construct can be taken.

4.4. Data Quality

Information Quality is concerned with issues such as the relevance, timeliness, and accuracy of the information generated by an information system (DeLone & McLean, 2003; 2004). In the e-commerce

context, as we mentioned earlier, we replaced information by data, and data delivery is an important role of online shopping systems, and quality is considered a critical issue. In addition, Cowie & Burstei, (2007) also addressed the issue of quality of data that was considered as an important factor influencing the quality of the decision by implement of the DSS.
Several quality evaluation aspects are essential, including the correctness of the output information or data, the availability of the output information at a time suitable for its use, and the comprehensiveness of the output information content.
In the context of the present study, we defined Data quality as follows: Data quality measures the characteristics of Data provided by a online shopping system. (Saha, 2008).

4.5.Knowledge Management

As known, today the usage of information and knowledge has increased in all types of organizations in order to simplify all the activities and enhance the decisions making process. Knowledge Management (KM) is an organization strategic effort that used to capture information and experience of employees and customers which is stored in database, paper or in peoples' intellect then distributes this knowledge to gain more benefit. KM is a value-added technique that aims to maximize profits, innovation, and decision making by share better information and knowledge between every member working within the organization (Mohsen et al., 2011).
On the other hand, one factor influencing customer purchasing habits is customer knowledge. Some people are not interested in online shopping because they lack knowledge of the Internet, computers and modern technology. They also do not want to take the time to learn about those areas. They would like to go to retail shops to ask staff for the information that they want and to choose products by physically seeing and touching the products. different groups of people with different knowledge backgrounds regarding any product may choose different ways to buy the products: for example, many customers may prefer shopping online for products because they have more prior knowledge of products on which to base their research, while older people may choose to buy products in the retail shops because they require more information and assistance from a salesperson and they may not be comfortable with online shopping forms" (Li, 2010).
The emergence of the Internet has also created a dynamic, electronic marketplace, where a new species of e-commerce organization is being established (Singh & Kundu, 2002). At the heart of the e-commerce organization is the website through which all the transactions take place. Besides supporting online transactions, a website can also give customers a means to obtain information about products and services (Kohavi, 2001) and companies the means to obtain information about their customers.
With the growing importance of knowledge in e-commerce, one of the main purposes of a website is the ability to acquire knowledge by the both the customers and the organizations (Fang & Holsapple 2003).

5. CONCEPTUAL RESEARCH MODEL

Based on the discussion above, the factors that are important in the context of online shopping systems include the core IS success measures of system quality (referred to Online Shopping System Quality), information quality (also referred as data quality in Online Shopping environments), Knowledge Management (referred as knowledge in Online Shopping systems)user satisfaction (also referred as Consumer Decision Making Satisfaction in Online Shopping field)and Perceived Net Benefit in the same field.
Based on the theoretical perspectives, the following conceptual model is proposed, which incorporates concepts from earlier models to be applied to testing in the area of online shopping and other fields. This model is conceptually based on the DeLone & McLean(1992; 2003) IS success model which explains the impact of IS at the individual and organizational levels.
From previous studies and from the discussions concluded so far, it becomes evident that the dependent constructs in the model are "consumer decision making satisfaction and Perceived Net Benefit" and the independent constructs are: online shopping system quality, data quality, and Knowledge Management, as shown in Figure (5).
The researcher Expect that online shopping system quality, data quality and knowledge management have an impact on consumer decision making satisfaction. Consumer decision making satisfaction have an impact on perceived net benefit, and perceived net benefit have an impact on consumer decision making satisfaction. This means there is mutual effect between consumer decision making satisfaction and perceived net benefit.

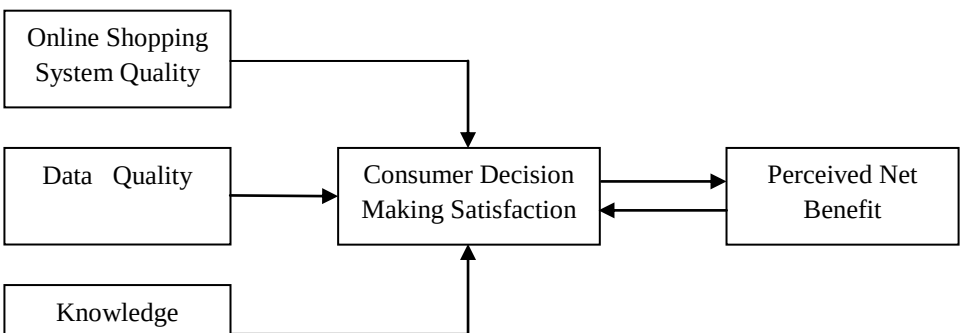

Figure 5: Proposed model for web-based DSS Success in online shopping context

In this study, Web-based DSS success in online shopping field is defined through consumer decision-making satisfaction and perceived net benefit. Consumer decision-making satisfaction is proposed to be determined by online shopping system quality, data quality, and knowledge management, in turn, consumer decision-making satisfaction and perceived net benefit have mutual effect. Therefore, the hypotheses can be generated as follows:

H1: Online Shopping System Quality positively affects Consumer Decision Making Satisfaction.
H2: Data Quality positively affects Consumer Decision Making Satisfaction.
H3: Knowledge Management positively affects Consumer Decision Making Satisfaction.
H4: A high level of Consumer Decision Making Satisfaction is associated with a high level of Perceived Net Benefit.
H5: A high level of Perceived Net Benefit is associated with a high level of Consumer Decision Making Satisfaction.

6. CONCLUSIONS AND FUTURE RESEARCH

The propositions presented in this paper an opportunity for further investigation in the web-based DSS evaluation with focus on success factors influencing Web-Based DSS in Online Shopping Context.

The proposed model should be of interest to IS practitioners in general and DSS practitioners in particular and academic community. For the practitioner community, the model will enhance their understanding on the factors that contribute of DSS success and enlighten DSS-vendors about what parts of the post-implementation phase they should concentrate on to increase the success of the system and end users decision making satisfaction. For the academic community, the proposed model provides ample research opportunity to validate in order to support or refute the proposed propositions.

We recommend other researchers for the work of empirical study on the proposed model in communities that have a weakness in the field of online shopping to measure the success of web-based DSS in the field of online shopping. Also, to know and anticipate the factors that affect the acceptance of online shopping idea by citizen's especially in countries that in initiative stage of construction and implementation of online shopping systems.

USING BIG DATA FOR CUSTOMER LOYALTY IN ONLINE BUSINESS

Natasa Djurdjevic[1]
[1]Faculty of Organizational Sciences, ndjurdjevic@coca-cola.com

Abstract: *Concept of Big Data is one of the key trends in recent years which significantly affects all players in the marketplace and which will be one of key sources of competitive advantage in the future. Nowadays, many start-up companies base their entire business model on big data while established old corporations seek ways and build infrastructure to enable efficient use of big data in management processes for achieving their business objectives.*

Big data can have many applications in a company – this paper focuses on online sales and rewarding loyal customers. Paper reviews internal corporate capabilities and processes, online solutions as well as how to engage and reward customers. Upon review of theory, existing solutions and good practices from various business fields, paper provides customer loyalty program management model which aims at integrating internal capabilities and process with internet and technology necessary for big data deployment for loyalty management and customer as critical determinant of business success. Ultimate benefit of the approach is in optimal resources allocation and maximization of profit.

Keywords*: big data, loyalty program, cloud, personalization, customer satisfaction, customer management*

1. INTRODUCTION

As Bo Li (2013) states “big data is the term for data sets so large and complicated that it becomes difficult to process using traditional data management tools or processing applications” (p.2). Difficulties occur in all phases of the process: collection, sorting, storage, search, distribution, transfer, analysis and visualization. Based on data sets so huge it is possible to better observe connections and generate new insights in various fields (from business management to fighting crime or preventing diseases).

Big data brings revolutionary step forward compared to traditional data analysis and it is characterized by three main factors: variation, volume and velocity – three Vs (Minelli et al, 2013). Referring to Lee (2013) variation refers to today’s mainly unstructured data collected by social networks, online retail, search engines… Volume of data is enormous. Such amount of data cannot be processed by standard analytics tools because it flows in at great speed. That is why it becomes necessary to provide new way to access this data and have analytics output in real time.

2. BIG DATA TECHNOLOGY

Specific technology is needed to manipulate with big data. As Bo Li (2013) summarizes, this refers to (p3):

- Classic big data technologies
  Classic big data networking technologies are Hadoop, MapReduce and NoSQL. In recent years significant progress has been made in the areas of data storage and warehousing, transfer, software defined networking and analytics.
- Cloud computing technologies
  Referring to Furth (2010) (p18) cloud computing can be defined as new style of computing which provides flexible, on demand and scalable computing infrastructure. This is a new computing practice which provides virtual and dynamically scalable resources as a service via internet. Some of the big data related topics are opportunities and challenges related to big data networks in cloud, big data resource management in cloud, big data performance optimization in cloud. There are several cloud services: SaaS (software as service), IaaS (infrastructure as service), PaaS (platform as service) and dSaaS (data storage as service).
- Benchmarking

Benchmarking is relevant for big data analytics and methodologies verification. As big data systems and architectures evolve, there is a need for comparison, evaluation and measurement of these systems and architectures. In the benchmarking work by Wang, Zhan, Luo et al (2014), several aspects of this problem are stated. Class of big data can be different: search engine, social network or online retail. Software solutions can be different, with Hadoop being the most frequently used. For comparison validity, different data sets analytics should be evaluated – text, tables, charts, multimedia). Finally, analytics requirements may be online, offline or in real time. All of this combined allows valid comparison of big data architectures and systems and comparison of their performance metrics, energy efficiency and cost.

- Mobile networking technologies
  Mobile technologies are becoming more and more relevant with fast expansion of smart phones and tablets – device is constantly connected to the internet and that connection needs to be reliable and fast. In 2013 for the first time sales of smart phones exceeded the sales of regular mobile phones, as tracked by Gartner. Mobile technologies can be considered for the role they have in data collection, management, analytics and application.

3. BIG DATA IN BUSINESS

Big data is a concept relevant for any company and is not exclusively linked with new online businesses (Google, Amazon, Facebook and others that base their business on big data) nor only for big companies (which have been having and using huge amounts of data due to their size and scope). In today's world enabled by today's technology and cloud computing big data becomes accessible to all and at the same time necessary to create and maintain competitive advantage. Devenport and Dyche (2013) argue that big companies for years have had lots of data from various sources but it is not the bigness of data that is impressive, but the lack of structure, opportunities that arise and low cost of technology.

Objectives of big data application in a company can be different: cost reduction, processing time reduction, offering new products and services or decision making system support. Using big data must result in financial gain – management should invest in big data capabilities with the purpose of creating long term sustainable competitive advantage.

Large companies have had some systems how to organize, store and manipulate the data. Applying big data requires significant changes and investments: abandoning existing proprietary systems and adopting open source solutions (like Apache Hadoop, for example); replacing expensive hardware with cheaper solutions; replacing proprietary and customized applications with packaged solutions; replacing decades old business intelligence tools with data visualization (Devenport and Dyche, 2013).

In terms of organization, big companies need to evolve their organization structure and people's skills and capabilities as well as to consider integration with existing solutions before introducing completely new systems. It has been most effective if there is close relationship between big data users and IT sector. In terms of skills, it is necessary to balance the scientific knowledge required for big data with understanding of business needs – having mixed teams has been proven to be the most efficient solution.

With big data there is the evolution of new analytics, so called analytics 3.0 (Devenport and Dyche 2013), when big companies combine traditional analytics with big data to generate insights fast and at scale. Such approach allows any company, regardless of its size, to be part of the data based economy. New models based on prediction and prescription are generated.

4. APPLYING BIG DATA FOR CUSTOMER LOYALTY IN ONLINE BUSINESS

4.1 Customer loyalty

As stated by Paharia (2013) purpose of loyalty is "to give customers a compelling reason to continue to patronize the business and to resist competitive offers". Loyalty exists when people decide to use one particular store (real or virtual) or to buy one particular product rather than to use different stores and products and when such behaviour is consistent over time.

In business, term loyalty can be used to describe the readiness of a customer to patronize a firm, preferably as exclusive choice and to recommend products of that firm to friends and acquaintances, referring to Lovelock and Wirtz (2011).

Loyalty can be behavioural or attitudinal, referring to Richard in FT article. Behavioural loyalty can be measured by share-of-wallet or how much of the total spend goes for a specific product/service/store. Attitudinal loyalty refers to emotional connection to the brand and is measured as share-of-heart. One is not prerequisite for the other. Here big data helps to establish whether it is financially viable and how to convert emotional loyalty into desired behaviour of regular purchase.

As customers nowadays on average participate in 6-8 different loyalty programs, it is crucial to understand what loyalty really means. Paharia (2013) provides interesting concept of Loyalty 3.0. According to Paharia Loyalty 1.0 is transactional level relationship: application to the program and reward redemption can create some engagement but there is no interaction in the meantime. Loyalty 2.0 starts using data for segmentation and personalization (direct mail, email). Loyalty 3.0 combines understanding of motivations, big data analytics and gamification i.e. applying elements of games to create engagement, excitement, satisfaction, accomplishment. And only at this level true loyalty is created.

4.2 Loyalty programs

With such high level of proliferation and multiple participation in loyalty programs, using data and big data analytics helps to identify which 30% of customers generate 70% of total turnover, as well as to reduce activities and wasting resources on those who are in the program for discount only. In their 14 year study on retail loyalty in Great Britain Werner, Reinartz and V Kumar have identified 4 customer segments based on level of loyalty: real friends (long term loyal and highly profitable), butterflies (changing behaviour but still profitable), strangers (lowest profit generating potential) and barnacles (only create hassle and should be got rid of). In retail most customers are butterflies, as the result of continuous competitive struggle and discounting of retailers. Referring to Kantar Worldpanel Hill (2013) states that largest retailer in GB Tesco has highest share of real friends and it is just under 30%. Next retailer in size Sainsbury has only 16% share of this segment. Objective of efficient customer loyalty program management is maintaining and developing profitable relationship with customers. Advantages of using data and targeting offer appropriately are following:

- Reducing investment in unnecessary mass promotions,
- Defining most valuable customer segment,
- Segmenting and targeted approach,
- Tracking efficiency and pay back of activities.

There are two basic loyalty models in retail, by Cox (2012): deal loyalty (discounts and other offers created using big data algorithms) and relationship loyalty (connecting the customer to the brand, building relationship via exclusive offers like trying new products before they reach the stores for example). Working on both at the same time is the approach that enables long term sustainable business result.

Loyalty programs are expensive and it is important to have right metrics to determine their efficacy. One aspect of loyalty program measurement is related to (Isson and Harriotti, 2013):

- Customer acquisition (getting customers to join the program),
- Customer retention (keeping customers in the program and engaging them),
- Share of customer's wallet (influencing behaviour in terms of order size, frequency and value).

Also, loyalty program can be measured by following key performance indicators (PWC, 2013):

- Participation rate,
- Activity rate,
- Tenure,
- Attrition rate,
- Cost per redeemed point,
- Total revenue,
- Revenue per transaction,
- Loyalty program percentage cost etc.

Summary metric is customer lifetime value (CLTV) – projecting net profit generated during entire relationship a customer has with a firm. This is the present value of future revenue of one customer during his/her entire relationship with the firm, as defined by Farris, Bendle, Pfeifer and David (2010). Harvard Business School has developed the formula and the model to calculate CLTV as a useful tool that helps marketing managers determine the value of customer relationship considering the cost of attaining and servicing the customer.

4.3 Role of Big Data in loyalty programs

Introducing a loyalty program which would generate valuable data from huge number of interactions with customers and then use the program only to allow discounts to all members under same conditions is almost equally inefficient as running standard mass promotions (this is still the situation with most of loyalty programs in the country today). Contemporary possibilities for manipulating the data in large databases should enable running the business more efficiently and providing better customer service.

One of probably most important applications of big data analytics is customer segmentation by specific characteristics. Segmentation is the first step towards personalization – having focused and relevant communication even towards groups of users (before one to one stage) is a precondition for targeted offers, content and services to users. Of course, that assumes appropriate infrastructure and process that would enable real time response in line with predefined criteria.

Customer satisfaction is critical for keeping users in the program as well as to drive desired behaviour. Big data framework for customer relationship management assumes possibilities for creating the feeling of satisfaction. In online environment, people expect immediate response as well as that this response would meet their expectations. Without big data as base, right infrastructure and management process it becomes more difficult to have the real time contact and give impression of good customer service. Research results from Maritz-Loyalty Marketing in US show that communication within loyalty program increases overall program satisfaction by factor of 3. This further drives desired customer behaviour.

Combining data from different sources and their interpretation while the user is online is a precondition to allow appropriate reaction along the path to purchase: before, during and post shop. Figure 1 is one of the illustrations of a path to purchase model (used by Metro in Canada) and in online environment big data allows appropriate communication and interaction at every stage.

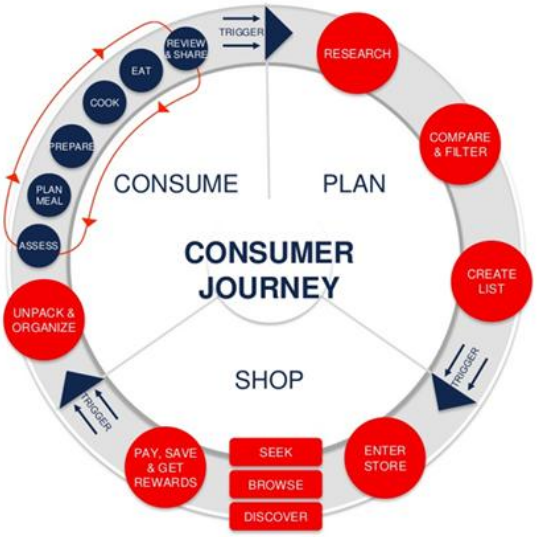

Figure 1: Metro's (Canadian retailer) path to purchase model

Another way to look at this is illustrated in Figure 2 – how to develop efficient marketing strategy and offer according to users' needs or possibilities, how to efficiently track and mix media contact points and maximize the use of owned and earned channels (mainly possible because of big data analytics and real time reaction) and finally customize the offer either as discounts, cross purchases, additional information or services – all with the objective to minimize wasting resources on non-differentiated initiatives.

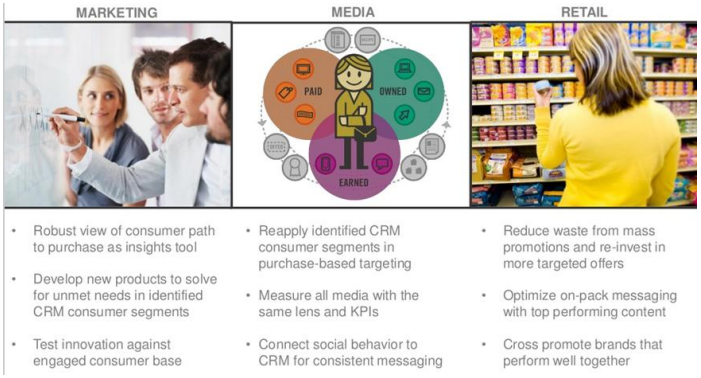

Figure 2: How to influence the customer along the path to purchase by dunnhumby

Personalization should ultimately lead to increased transaction value, providing relevant service, additional offers, solving customer's problem, all but giving only the lowest price.

Big data availability and right implementation in reporting, management and control should result in more efficient resources deployment and maximizing business result.

4.3 Customer loyalty program management

Running a loyalty program is a complex and expensive initiative. In order to ensure it achieves desired financial result it needs to be carefully thought through, planned and managed. Some of the questions that should be answered before launching a loyalty program are:

- Level of profitability,
- Cost efficiency level,
- Sustainability,
- Exit strategy,
- Speed and level of benefits redemption,
- Communication and building awareness with potential users,
- Success criteria and time frame to reach success.

Considering everything reviewed until now, customer loyalty management model which summarizes relevant aspects of setting up and managing a loyalty program has been proposed and illustrated in Figure 3.

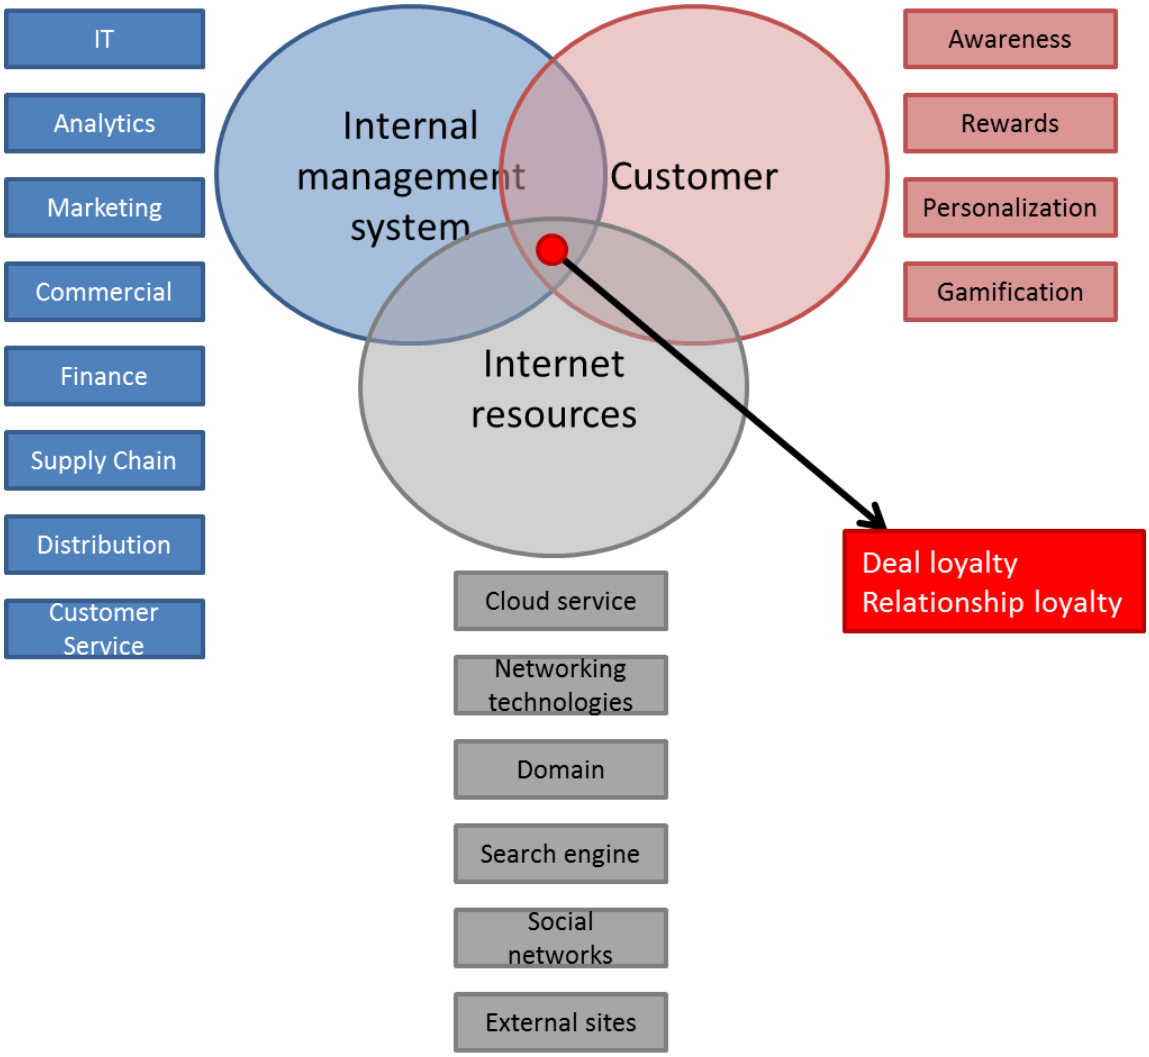

Figure 3: Customer loyalty management model

The program should lead to deal loyalty – loyalty to what the program offers to the user in terms of special offers, solutions, personalization i.e. purchase according to program scheme; and relationship loyalty – long term commitment to the brand or firm, establishing positive attitude and behaviour that would favour the brand or firm.

4.3.1 Internal management system

Internal management system deals with organizational solution that will allow for decision making and management process and running the program efficiently. Loyalty program by its nature, importance and scope assumes multifunctional approach. In the context of big data as key success factor for the program, big focus is on IT sector and analytics. Appropriate technology solutions and skills and knowledge of analytics teams are at the base. In some cases it makes sense to outsource the analytics to highly specialized suppliers in this field.

Next important topic is reporting and communication between sectors to secure that: there are sufficient stocks, delivery is made within committed timeframe, payment is easy and accurate, offers are provided timely, communication with users is relevant and timely.

An excellent example of big data analytics application for efficient functioning and cooperation of multiple sectors (analytics, distribution, logistics, finance) is the recent Amazon example with “anticipatory shipping”. This innovation is based on an algorithm which forecasts future orders and according to those forecasts products are shipped to distribution centres even before customers place the orders. Ultimate goal is to achieve same day delivery. Data quality is key in this case to enable more efficient stocks management and to avoid increased cost to the business due to higher costs for managing unsold stocks and returns. Another reference is Walmart which is fully integrating big data into management processes between functions, to

avoid “analysis-paralysis” i.e. enable fast and fact based decision making. Recently they have changed their shipping policy based on big data analytics, lowering order size and expanding product offering.

Customer service is something that can be critical for success and longevity of the loyalty program. Jao (2014) stated that 68% of users leave the site because of bad customer service. Utilizing big data can help coordinate communication with the user via different channels (mobile, email, chat) as well as to recognize which service is the most frequently requested in order to optimize own resources accordingly and reduce customer conflict resolution to minimum time needed.

4.3.1 Internet resources

In online business, internet is naturally key part of the system. Some of the tasks that need to be solved in setting up the loyalty program are: enable easy and fast purchase, be accessible always and everywhere, maximize users’ data and track their behaviour within own domain as well as outside to direct them more efficiently to our program and offer them solutions which stand the highest probability for purchase.

Advantages of cloud based solutions, primarily for data storage dSaaS, can help to set up and utilize the system. Classic networking technology solutions like Hadoop, MapReduce or NoSQL are standard for big data access. Loyalty program needs to be based in a domain. How to get to the site and what is the communication flow with other content and platforms needs to be optimized. According to recent research by Shopify, Facebook is the number one social platform from which 85% of buyers come from. Big data analytics is key to select external links and communication with the loyalty program users in order to customize the offers, communication and call to action i.e. purchase.

4.3.1 Customer

Final element of the system – the customer. All is created for the customer and customer’s action is the end goal.

First step that needs to be completed is to build awareness with potential customers about the loyalty program and its benefits. Classic advertising in offline media, online advertising as well as big data analytics can be used to effectively target most promising customer segments according to their profile and behaviour.

Probably most important area for big data analytics application is reward system and personalization. Dynamic pricing and promotions i.e. optimizing the price and additional features and service offer to secure desired transaction without giving too big of a discount or giving it to the wrong recipient is where big data plays key role. Combining loyalty program database, internet search and previous behaviour enables creation of customized optimal offer for each customer which should be supported with personalized communication. Personalization drives loyalty which leads to repeated purchase.

Recent trend and opportunity for better interaction with the customer and driving relationship loyalty is application of concepts and principles that successful games apply – i.e. gamification.

In terms of its scope, this model can be relevant both for companies that directly or via third party engage in online commerce and for retailers either those purely based in online or those combining multiple online and offline channels. Functions may be differently called but the responsibilities and work flows are equally relevant. Level of interaction and connection between online and offline business may be different, but the functions and process still apply.

5. CONCLUSION

Concept of big data and firm’s capability to master it is one of the key factors of creating and maintaining competitive advantage. Big data analytics enable customer communication which can lead to purchase in shortest, most efficient and cheapest way while creating long term customer loyalty in terms of both deal and relationship loyalty. Big data management in the context of loyalty programs should enable optimal resources allocation and revenue and profit maximization.

Further builds to the model should deal with integration of mobility – in developed markets already today more than 50% of shoppers use mobile devices to plan and make their purchases.

Abstract: *This paper will show the status of the postal services and the reasons for the introduction of services that are based on IT technologies. The Internet and the digital revolution are changing the world of communications, and postal sector must adapt to the digital age. Postal digital platform was created with the aim of integrating three dimensions - physical, electronic and financial. This creates a postal network dedicated to electronic services. In order to led this project in the right direction, at the 25th Congress of the Universal Postal Union in the Doha the strategy oriented towards electronic services was set forth. In line with this strategy, actual state of the postal system in Serbia will be analysed and given suggestions of new services which could be provided to users as well as the future of the postal sector in a smart city.*

Keywords*: IT, digital revolution, postal digital platform, smart city,*

1. INTRODUCTION

Postal sector has to adapt to modern business conditions, continuously improve and develop its range of services. Postal operators shouldn‟t rely on conventional transfer of letters and packages and have to indroduce new services that are based on information technologies.

The second chapter will give more details about the reforms in the postal services and the need to develop new services based on ICT.

The third part of the paper shows the connection between the postal service and the digital space .

The fourth section will give some more information about the electronic future of the postal sector , postal digital platform and the Italian post. For an example Italian post is taken as one of the most advanced in this area and their web portal with post domain is given.

The fifth chapter deals with the implementation of e-services in Serbia . It also describes which goals from defined strategy and the Doha Proposals has Serbia fulfilled and new services that could be provided in the future by the existing infrastructure and would fit into the concept of a smart city.

In conclusion the results of our research and suggestions for further research in this area are presented.

2. POSTAL REFORM

The Internet and the digital revolution are fundamentally changing the worlds of communications and commerce. The digital economy continues to grow at a rapid rate. Electronic substitution of traditional mail is accelerating as both consumers and businesses adopt electronic processes across multiple domains. Mail users are shifting from traditional hard copy distribution models to a variety of new ways to digitally communicate, advertise, or transact. They are attracted by greater convenience, faster service, and lower cost. The digital revolution has become the “disruptive innovation” to the traditional business of the Postal Service. With several different communications channels competing for consumers, the Postal Service needs to modernize its role to accommodate for the digital age.

The transition to a new digital landscape is already under way. The Postal Service should consider new products and services that reflect the evolving mandate to “bind the nation together” in a new world where people are increasingly communicating digitally. Using a foundation that links a physical address to an

* This paper is derived from research within the project funded by the Ministry of Education and Science of the Republic Serbia, under the name of „Reengineering the operator network of the universal postal service, with the organisational synergy of govermental and economic resources“ (TR 36040)

electronic mail box for every citizen and business, the Postal Service can build a digital platform that facilitates communications and commerce for postal, governmental, and commercial applications that are available to all (U.S Postal Sevice Office of Inspector General (2011, April)) .

3. THE POSTAL SERVICE AND DIGITAL SPACE

With more than 660,000 post offices throughout the world, the postal network is the biggest phyical network in the world . Post offices are everywhere, from capitals of bigger industrialized countries to small rural towns of least-developed countries. In outlying areas, they are often the only public service available and in many cases, they constitute vital channel to communicate and exchange goods between communities. Bilions of people visit post offices every year for a reason or another (Universal Postal Union (2010)).

Market liberalization, globalization, and the rapidly advancing digital technologies that challenge the Post today should be viewed as an excellent opportunities. At the same time, today"s advances in technology also provide the greatest opportunities for tomorrow"s Posts. By combining the traditional strengths and "reach" of postal services with the flexibility and speed of electronic media, a whole new range of products can be developed to meet emerging customer needs for value added communications products. Some of these applications, such as electronic bill presentation and payment, trusted third-party certification, electronic stamps, directory services, and secure e-mail already exist.

The synergistic merging of the Post"s unrivalled retail and delivery networks with electronic media and the Internet is still in its very earliest stages. Vast possibilities in areas such as financial services, eBusiness applications, and the conversion of post offices into "Communications Centers" which provide universal Internet access are only now being researched and implemented. Postal services are also continually seeking out ways of incorporating modern information technologies into their operations to raise productivity and lower costs. In order to maximize its contribution to economic development, the postal service of the future will need to provide hard copy communications and hybrid digital/mail products while simultaneously providing general access to the Internet and eCommerce.

The Digital Age has arrived and is the motor for a New Economy based on instant communications and universally accessible information. Each day, the "e-World" spawns a new e-concept or e-technological advance based on making the interfaces between people, businesses, and information faster, cheaper, and more reliable. One side effect of this growing wave of technological progress has been to forget, or at the very least diminish, how much these advances depend on sound physical distribution systems for their success. The information available through cyberspace can be digitized, compressed, and transmitted instantly, but the goods and merchandise this information describes must travel through physical transportation systems and be delivered to actual, not virtual addresses. Furthermore, the future growth of the New Economy will be directly related to the capacity of physical distribution networks to efficiently process the increased traffic being generated by new technologies (Universal Postal Uninon and World Bank, joint publication (2001, April)).

The Postal Service can develop and maintain a secure digital postal platform, accessible to all citizens through a website. Private industry would be invited to provide commercial solutions and work with the Postal Service on developing effective postal and governmental applications on the platform to serve all. The Postal Service can fill its established role of providing a trusted communications infrastructure. This represents a modern manifestation and a natural extension of its traditional mandate in the physical space to meet the new requirements of the digital age. Apple"s strategy of encouraging independent development of applications or "apps" for its iPhone® and iPad® platforms would serve as a relevant model for independent development of digital products on the postal platform. Apple invites all developers to bring their applications to its online App Store, until they meet the required technical and content standards. The Postal Service identifies the standards to allow innovation and allows market forces to determine success and failure (U.S Postal Sevice Office of Inspector General (2011, April)).

4. ELECTRONIC FUTURE OF THE POSTAL SECTOR

Post is the UPU"s sponsored top-level domain for the postal sector. The domain"s technical infrastructure became a reality in 2012, and member countries and their designated operators can now register for their domains and explore the possibilities of .post. Some Posts, for example, have plans to use .post to stimulate cross-border e-commerce and hybrid mail.

More than 70 per cent of the world's Posts say that electronic services are strategically important to their business, according to UPU research. This finding provides impetus to the goal of developing the .post (dotpost) platform, and the 2012 Universal Postal Congress decided that work should continue in this direction.

The platform‟s goal is to interconnect current and future electronic postal services and make them interoperable in a secure and trusted environment. It will authenticate postal service providers and strengthen the postal brand globally. post intends to link the physical and digital worlds, creating a secure platform that enables postal e-services to be delivered to all citizens and businesses.

Applications, such as identity management, e-shops, e-payments, e-forms, secure postal mailboxes, address management, hybrid mail and advertising mail, would have a home on this future platform.
In 2009, the Universal Postal Union became the first United Nations agency to be granted a sponsored top-level domain for the postal sector.

What the UPU is trying to achieve through .post is not different to what happened when the organization was created in 1874. At that time, 22 countries with their own postal infrastructure, services and bilateral agreements came together to create the UPU and a single physical postal territory that interconnected them.
Poste Italiane has already set up its .post site (www.posteitaliane.post-figure 2) and has plans for future services branded with the .post suffix. The Italian operator is teaming up with the Netherlands‟ PostNL to look at developing cross-border e-commerce on the platform. Poste Italiane is also trialing a postal registered electronic mail service with China and Macau Posts. The .post platform extends the physical postal network into cyberspace, enabling the community to offer trusted and secure postal e-services.

In order to show the possibilities of .post, the Postal Technology Centre (PTC), the UPU‟s technical arm, has created a global track and trace application which, eventually will enable customers to track the items they have ordered until final delivery. Using the electronic data that the world‟s Posts exchange on the UPU‟s Post*Net network and other interconnected networks managed by external partners, participating Posts could benefit from a comprehensive end-to-end track and trace system.
Malaysia has also pledged 100,000 USD to the project. Earlier this year, Poste Italiane has donated 500,000 EUR to get .post off the ground.

A post user-group is expected to be set up at the next Postal Operations Council in April 2013 to oversee the future development and management of the top-level domain. Member countries will be able to join the group for a fee and help to shape the future of .post. This will bring the funding of .post in line with other user-funded groups, such as the EMS and Telematics Cooperatives. In the interim, a committee headed by Italy is ensuring work continues. In 2009, the UPU became the first United Nations agency to be granted a sponsored top-level domain (www.upu.com).

5. THE IMPLEMENTATION OF E-SERVICES IN SERBIAN POST

Universal Postal Union has conducted a study related to the determination of the level of development of e-services offered by the postal administrations around the world (Abdallah, F., Shakurova, Y. (2012)). Services are divided into four groups: e-post services, e-financial services, e-commerce services and e-government services. Total has identified 55 e-services. This paper will describe the services offered by Serbian post.

Traditionally, postal services have been used to facilitate communication between citizens and businesses via physical means, such as letters. E-post services are communication services delivered to customers via ICT means. Serbian post offers following e-post services:

- Public Internet access point in post offices (Customers can access Internet services in post offices)
- Hybrid mail (Enables customers to send an original message, which is then processed electronically and converted into a letter-post item for physical delivery to the addressee)
- Post office location lookup (Enables customers to search for the address of a post office online by entering information such as the street, the city or the postcode. Customers can also obtain additional information about the different products and services provided at the post office as well as its business hours)
- Track and trace (Enables customers to electronically track and trace a postal item)
- Electronic notification to an addressee that letter is to be delivered to (The Post notifies an addressee electronically (e.g. by SMS or e-mail) about a letter item to be delivered to a specific address)
- Electronic notification to a sender that letter has been delivered (The Post notifies a sender electronically (e.g. by SMS or e-mail) that a letter item has been delivered to a specific address)
- Web-based customer service and contact (Allow customers to contact the Post electronically for a service or information, via a website, e-mail or telephone)

E-finance services are financial services provided by postal operators to end customers using ICTs. The UPU has developed regulations for postal payment services provided among Posts. Serbian post offers following e-financial services:

- Electronic money transfer (A service allowing account-to-account fund transfers from a sender to a payee through the Posts)

E-commerce services consist of buying and selling products and services using ICTs. It involves processing and delivering purchased items physically or electronically. Serbian post offers following e-commerce services:

- SSL web certificates (The Post issues SSL certificates for securing websites)

E-government services are driven by government and provided through ICT means, using Posts as a trusted third party. Serbian post offers following e-government services:

- Digital identity (The Post issues a digital identity legally identifying its customers. The digital identity can be secured with a simple electronic authentication using a password or with more secure authentication technologies using cryptography and public key infrastructure)

Doha strategy (Universal Postal Union (2012, September)) defines regional development for countries with four goals: 1. Improve the interoperability of the international postal network, 2. Provide technical knowledge and expertise related to the postal sector, 3. Promote innovative products and services (develop the 3-D network), 4. Foster sustainable development of the postal sector. Serbia must adhere to this strategy. Improvement of quality of the service and efficiency of the postal network and development of e-commerce are the top goals. Serbian post improves quality of the service and efficiency of the postal network, but e-commerce must be improved in accordance with the development of e-commerce in leading postal administrations. Serbian post does not join global monitoring system, but there is tendency to modernize and reform postal sector, and provide staff training in the application of new technologies to master operational, technical innovation in key areas of postal activity. 3 D network involves the integration of physical and financial dimensions of post. Serbian post must orient its development in this direction. Improvement of marketing activities is evident in the Serbian post, which has the status of trusted third parties and recognizable brand.

Table 1: Strategy for regional development-Europe

Improve the interoperability of the international postal networks	**Provide technical knowledge and expertise related to the postal sector**	**Promote innovative products and services (develop the 3-D network)_**	**Foster sustainable development of the postal sector**
Improve quality of service and efficiency of the postal network	Modernize and reform the postal sector	Develop e-commerce	Carry out marketing and advertising activities to promote electronic, financial, business and e-government services
Join the Global Monitoring System	Provide staff training in application of new technologies to master operational, technical and technological innovations in key areas of postal activity	Further develop and improve electronic payment services	Improve marketing and sales potential

Information and communications technology (ICT) is a key enabler for cities to address challenges in a „smart" manner. Smart City is one with at least one initiative addressing one or more of the following six characteristics: Smart Governance, Smart People, Smart Living, Smart Mobility, Smart Economy and Smart Environment. ICT links and strengthens networks of people, businesses, infrastructures, resources, energy and spaces (Manville, C., Cochrane, G., Cave, G., Millard, J., Kevin, J., Thaarup, R., Liebe, A., Wiesner, M., Massink, R. (2014, January)).

The convergence of information and communication technologies is producing urban environments that are quite different from anything that we have experienced hitherto. Cities are becoming smart not only in terms of the way we can automate routine functions serving individual persons, buildings, traffic systems but in ways that enable us to monitor, understand, analyse and plan the city to improve the efficiency, equity and quality of life for its citizens in real time.

Having this in mind, the postal sector needs to focus its development towards smart cities

Post has a strong telecommunication infrastructure and brand, and can provide good and reliable services in the field of security and teleservices. Post is faced with the failling of profits from classic delivery of items and health services could bring a new profit. This primarily relies to the delivery of various health"s reports. Services in the field of education could be further strengthen the brand, and they should be offered free of charge as well as services that are related to entertaintment. Post could use for delivery electrical vehicles and that electrical vehicles could be rented for tourism purposes and could offer to citizens delivery of formal documents through its infrastructure.

Based on the experience of foreign countries, taking into account the existing capacities of Serbian post, we can expect the appearance of the different services. These services are given below and are divided by areas.

Security:

- Integrated traffic control management
- Telesurveillance

Health:

- Online diagnostic reports
- Drugs home delivery
- Health information management
- Individual Health Record
- Online management prescriptions and recipes for drugs

Education:

- Circuit discounts for students
- Parents Online: access system to pupil data

Entertainment :

- E-ticketing
- Multimedia tourist guide

Sustainability:

- Use of electric vehicles

Citizenship:

- Dematerialization of administrative document
- E-democracy (televoting)
- Improvement of administrative process

6. CONCLUSION

The postal digital platform is created with the aim of integrating postal administrations, in order to overcome many limitations and obstacles, by facilitating the international exchange of information and goods. Post platform presents new special space on Internet that interconnects current and future electronic postal services and make them interoperable in a secure and trusted environment.

In some countries, a post office provides valuable social services, and they are poised to become an even more important business centers. Postal sector in Serbia also plays a role in the interconnection of other public utilities, administrative and social networks, which is necessary for the development of the country and a better life for the population. For development of e- services in Serbian post there is a lot of space. The most common e- services is e-post services, but must be developed and other e-services, especially e-commerce and e-government services. Integration of public administration and post will provide a new opportunity for post and place for the creation of new services.

Post Serbia can follow model of the Italian post, which is very good or to apply the strategy as implemented by Apple. Postal sector, with its physical, electronic and financial capabilities can provide many opportunities for e-commerce. Italian postal e-commerce services meet all online business needs, offering important facilities, such as websites realisation, catalogue configuration and the integration of dispaches and payments.

Future research in this area should be directed towards the development of new services based on IT technologies, increasing profit and in meeting the rapidly changing needs of users.

USING MOBILE TECHNOLOGIES IN FOSTERING THE DEVELOPMENT POSTAL SERVICES

Slavica Štrbac[1], Biljana Grgurović2,Jelena Milutinović[3]
[1]ICT College slavica.strbac@ict.edu.rs
[2]ICT College biljana.grgurovic@ict.edu.rs
[3]ICT Collage jelena.milutinovic@ict.edu.rs

Abstract:*Aside from being an everyday phenomenon when it comes to communication, mobile technologies today create a way of doing business and provide support during execution of services, selling of goods, and, of course, payment. Development of new services, as well as the already existing ones, in all areas, calls for precise predicting of possibilities and efficient placement of information, especially when it comes to a segment of a potential market. Newest trends emphasize that mobile technologies are becoming an important (if not crucial) line of communication with potential clients. Postal services, especially newly developed ones, are not an exception, so this work will present the importance of using mobile technologies as a way of generating the development of postal services.*

Keywords*:postal services, electronic services, mobile technologies, clients*

1. INTRODUCTION

Postal traffic is a very important infrastructural unity. Using this kind of service is defined as citizens' right, so that developing new, as well as already existing services represents an imperative for postal operators in the country, as well as internationally. According to the latest statistics of Universal Postal Union (UPU), over the 60 % of the market for this sector in Europe and central Asia implies financial services and transfer of regular post items (UPU, 2014).

Liberalizing the postal service market, which means the appearing of new players in the field is defined by The Strategy of Postal Service Development in Serbia 2013-2016. and it relies on the recommendations of the Universal Postal Union (UPU) and the directive of the European Union (Strategy, 2013).

Postal sector in region SI Europe represents a huge mechanism and support for development of small and medium-sized businesses. Service time, which is time required for receipt of the consignment, time required for automatizing the process of adaptation and time required for delivery can vary significantly for a certain number of items with registered acceptance number (no matter if it is recommended mail or valuable shipment), as well as for a certain number with incorrectly paid postages depending on the speed of sensing data and the way the customer choses to pay for the services. In order to do business more efficiently, it is important to reduce business charges, since they are a great part of the overall costs, even in countries far more developed than ours. (Okholm, Winiarczyk, Moller, Nielsen, 2010.).

Using mobile technologies enables faster and more efficient communication, gathering and processing important information, based on which it is possible to manage further.

The goal of this text is viewing the possibilities of using mobile technologies in processes connected to realizing postal sevice offering. The solution to integrating mobile technologies is introduced for each process: reception, processing and delivering consignments. Forming a geo-network can be used for segmenting the market while placing an accent on the physical location where a customer can receive required service (Location Based Services – LBSs). Also, social networks built based on this form and GPS technology can be used for geomarketing postal services. Mobile payment points, such as mPOS (mobile Point Of Sale) devices can be used for counting postages for consignments which are being delivered in specific circumstances, such as unexpectid increasing number of parcels. NFC (Near Field Communication) technology, combined with QR codes, can increase the speed of scanning and charging postages for consignments which would be handed over on self-service counters or other places meant for automatized receiving. In fact, given the option of creating a free QR code based on different information about dimensions, weight and sending destination, the sender could simply equip the consignment with a QR code. Informing the customer via a mobile device about the reception, manner and time of delivery, while delivering a consignment introduces great savings. Electronical platform *.post* is different when it comes to transactions

being realized by customers all around the world. Physical and electronical customer's address can be integrated within the *.post identificator* app, which means that the risk of delivery failing is minimal.

2. TRANSFORMING THE POSTAL SERVICE MARKET

Traditional limits of postal services sector are becoming broader, so its economical function is defined by the content of basic activities of this branch, which are reduced to communications, logistics and advertising (Grgurović, 2013).

Postal services market, just like most of other markets, is going through a transformation, transgressing into a virtual space. Supply, price and demand remain basic elements of this kind of market. Components of the market which stay the same as the ones of a traditional market are existence in certain time intervals, objects of exchange (product/service), participants, ways of forming prices and regulations, while space, i.e. the place of the exchange transgresses from physical to virtual. The speed of emerging (and disappearing) in this type of market, the influence on potential and old clients, the speed of reacting to changes in the items being offered, user comfort during the process of service realization… These are just some examples of the potential of the new way of doing business which could be viewed as additional values which influence the increase of availability of management as well as the efficiency of management.

The need to establish stronger connections with business partners, no matter if they are clients or collaborators, cannot be pictured without mobile technologies which no longer serve as just a line of communication or application support, but as a business platform.

2.1. Space for mobile technology: physical,virtual or hybrid?

Over the last couple of years, a tendency to merge digital information with physical space has been noticed, which introduces a brand new space dimension: hybrid space (Frith, 2012.). Digital information is becoming a part of physical space. There is almost no physical place of any type (shop, stadium, restaurant etc.) that isn't minutely filled with digital information in the virtual world (social networks, browsers, web pages). Spreading of digital media when it comes to multimedia contents certainly leads to an increase in the use of mobile devices. World statistics show that the digital media are extending to the field of mobile devices and of accessing content through mobile devices (Comscore, February 2013). Despite the existence of a vast number of electronic shops, clients still go to physical shops, browse and buy products. Certain economic areas, including postal service, cannot provide all their services through the virtual world, but they can use it to get closer to their clients.

Hybrid spaces in postal services could enable a faster and more efficient finding of closest units of postal network using an application on mobile devices. This sort of application uses the client's geographical location to find the shortest possible way to a postal unit which provides a certain service. Canadian and American postal services have a similar offer. They enable smart phone users to use a free application which can find the closest facility which administers receiving shipments and packages. An application which provides information about the location and time of submitting shipments using postal vehicles is designed for rural and less populated areas. Synchronization of the time of the physical encounter, through the digital information about the location and the time of the encounter optimizes the expenditure of the client and of the operator (provider). Changing the address of the delivery after the receipt of the shipment, in terms of redirection, in this kind of environment has minimal effect on the efficiency of the process. By the way, this is one of the crucial problems in the area of the delivery of consignments, not only because the shipment has to me set back to the delivery terminal (and often to the sender), but because of the expenses of taking up space during storage and re-sending. The efficiency of the last stage of the technological process in postal services is a constant problem, conditioned by harmonizing different parameters, among which the time of the delivery and the time when the recipient is ready to pick up the consignment are the most sensitive ones(Toime, E. 2013.)..

2.2. Location based services (LBS) and Location based social networks (LBSN)

To every physical location we can add a pile of digital information which changes and enriches the initial information. E.g. using contemporary mobile phones with GPS and internet connection we can get information about a client's location, as well as all the characteristics of the given location. Physical location is being enriched by information from virtual world. Aside from basic location information, e.g. a chain the shop belongs to, different information about management, forums with other customers' experiences, ongoing and future actions etc. can also be found there. Physical location is enriched with valid information, while the mobile device interface becomes a representative of a corporation with a goal to entertain users.

Information offered through mobile devices can easily be changed, adjusted, followed and used to establish and strengthen relationships with clients. That is, personalizing services through individual offers to every potential and old client according to their needs through mobile devices reaches full potential, which enables a long-lasting relationship with a client – from satisfaction, through loyalty to the fact that the client becomes a supporter of new services.

Offering a big number of useful information in the hybrid space through mobile devices develops a new dimension of experience, use and realization of services, at an exactly defined location.

Positioning business points depending on the density of potential clients is a particularly sensitive category. This problem can be solved by GIS (Geographical Information System) technology, which can help analyze market, rationalize charges of the distance travelled, defining optimal routes etc. (Marković, Grgurović,Štrbac, 2011.).GIS applications on mobile devices are completed by coordinates of objects, which enables viewing digital maps in order to develop a social network based on certain locations (LBSNs – Location Based Social Networks). This kind of geographical networks ensure that the information about the benefits currently offered in objects on certain locations be delivered, so that clients can stay informed about products, services, business hours, actions etc. These networks are adaptable when it comes to already existing networks such as Twitter, WhatsApp, My Space etc. which makes an available information possible to multiplex. Simple modulation, in terms of adjusting information based on statuses, interests or some other characteristics of users is a reality.

Making a list of potential clients who would have information delivered via mobile devices in postal sector is a relatively achievable task. Survey is a possibility when it comes to already existing clients. Potential clients can be informed based on information from database about PAC (Postal Address Code). Every address can be delivered a consignment with information about accessing mobile service. Free access to the mobile service is already being practiced by companies which value their clients even in our region. Location based service could offer to clients in postal units information about new or hardly known services which, based on marketing activity, at least when it comes to domestic public operators, aren't accessible enough.

Users' social networks based on location can offer information about business of resources in near-by locations, sharing experiences with other users on the network about services and products, information about possible waiting queues and business hours, as well as prolongation of business hours if the number of potential requests is higher than expected (holiday jam while paying bills or turning in consignments etc.).

3. MOBILE TECHNOLOGIES IN PROCESSING CONSIGNMENTS

3.1. An app for following consignments until the moment of delivery

The processing of consignments is a series of operations between the reception phase and the delivery phase. Since this is about manipulating physical objects, following all operations in processing is important for multiple reasons: from safety, to exactly locating consignments at any given moment, to the possibility of managing routes in case of changing delivery location. Using postal model of EPC RFID (Electronic Product Code Radio Frequency Identification) It is possible to follow consignments trough all phases with a high information safety level (Melia-Segui, Garcia-Alfaro, Herrera-Joancomarti, 2010.). Communicating with the final customer (the sender or the receiver) contributes to the faster and more efficient manner of doing business.

Big postal operators, such as UPS (United Parcel Service Inc.) have noticed that the communication with clients is of mutual interest and have decided to adjust to clients' needs using a new application through which they get information about clients' basic preferences – whether they live in a rural or an urban area, how much time do they daily spend at home, how they feel when they see a report about a shipment which had been delivered during their absence and how often they receive various consignments. Depending on their responds, clients are offered a free or a yearly paid membership as well as some other utilities. The day before the delivery, clients are being notified by a text message, e-mail or by telephone. The application enables tracing the path of a consignment, as well as a calendar of all deliveries during the past period of time, defining the approximate time of arrival of the consignment, the possibility to give permission to the operator to deliver a shipment without demanding a signature (if the consignment isn't being received personally), the possibility to define a place of delivery (front yard, a neighbor's house, in an operator's facility), the possibility of redirection or the possibility to change the date of the delivery (e.g. if the recipient is on vacation) etc. (fig. 1) (UPSP, 2014.).

Fig 1. The design of the app used for informing about the time and the location of consignment delivery

4. M-PAYING – THE INCREASINGLY PRESENT FUTURE

Minor payments via mobile phones, such as paying for parking, mobile payments to online accounts, etc. are becoming more and more common. Mistrust and fear when using new technology, especially when it comes to money transactions are being overpowered by the speed of the realization and the comfort for clients, especially in situations related to the moment out of regular business hours.

Most mobile payments currently offered are being refused by clients for solely one reason – user safety. This is because realization of money transactions required providing clients' bank card numbers.

4.1. NFC Technology and QR code as an option for more efficient mail logistics

Mobile devices have stopped being just a symbol of communication a long time ago. Aside from other devices (which we will not discuss and which are related to fashion or status accessories) it also includes an informational device (whether it uses online or offline connections), as well as recording and updating devices (photos, videos). According to the latest trends, paying via mobile devices as becoming a regular part of financial transactions. There are more and more department stores which have a serious approach to this question and offer their customers a solution in the form of buying and paying via their mobile devices. These two terms are separated by intention, because buying includes the phase of choosing a product or a form of service, while paying can be separated from it both in time and space.

Increasingly popular QR code opens new possibilities of using mobile devices. Source QR code is designed to enable additional information to mobile device users. The camera on a mobile device is supposed to scan a two-dimensional code, after which the client is redirected to a specific URL page which contains required information using a special software.

NFC (Near Field Communication) completes the story of mobile payments. After scanning information required for paying for a certain product or service, by activating NFC device, the financial transaction of a the appropriate amount of money is performed, which transfers a certain amount of money from a customer's account to the seller's account. Customers can choose products or services at any physical place, even via interactive boards, which have a certain offer for customers to choose from. These boards exist in big retail chains, such as Tesco or Casino. The question of safety of these money transactions leads us to new solutions, which offer information in form of a code, time-limited, which do not require providing any information regarding clients' accounts (card number or expiration date).

Latest UPU statistics show that over 6.5 billion packages and 346.5 billion letters have been sent during the year 2012, which points out the extremely large potential of the market, both globally and locally. Internal (domestic) traffic is especially interesting, given that, according to these statistics, it takes up around 99 per cent of this sum (UPU, 2014).

NFC technology, combined with QR codes, can increase the speed of scanning and charging postages for consignments which would be handed over on self-service counters or other places meant for automatized receiving. In fact, given the option of creating a free QR code based on different information about dimensions, weight and sending destination, the sender could simply equip the consignment with a QR code. Once the information on the consignment has been scanned, the postage would be calculated automatically,

which the client could pay using the NFC technology and a mobile device. The receipt for the transaction with details regarding the consignment would either be printed immediately if the client requires so, or it would be sent to the client's e-mail address, to be printed if needed.

4.2. Mobile selling point as a support for hybrid space

Charging postage on consignment acceptance, especially when it comes to non-standard consignments which must be brought to a counter of a postal unit, means a client would have to wait in a queue if the number of present clients is bigger than service capacity. Physical places of consignment receipt are reduced down to counters with required equipment for receiving, such as electronic scales and POS (Point of Sale) device. Increasing the number of available counters in case of queuing can be done easily by turning client queues into mobile points of reception, using a modified mPOS (mobile Point of Sale) device.

Mobile device for charging postages, mPOS, is a system of transmission equipment for scanning, postage counting and receipt (receiving confirmation) printing. This device can read franked consignments, re-print postages and count postages which the client shall pay through credit card reading, just like at any other POS terminal.

4.3. Electronic platform: .post

The spotted problem and the care for clients caused the making of a trusted international electronic platform regulated by The UPU which integrates physical, financial and electronic postal dimensions: .post. This platform integrates e-post, e-market and e-management. The idea of developing .post platform is making an innovative business model by postal operators and their partners aiming to bring a new value to buyers.

Some of the management problems which .post should solve are: How can physical postal network be converted into the digital world? As a postal service provider, how can we guarantee to our clients safety and confidence in electronic communication and ensure they can receive their consignments in every part of the world, even during holidays or short business trips? How can the problem of undelivered shipments be reduced, which would also reduce expenses?

New .post domain differs from other domains, such as .com, .int or .org, mainly by its restrictive access, which is meant only for legitimate members of postal sector.

This domain enables governments and postal operators to define the internet space which can be used for safe realization of business transactions of any kind. This opens the possibility of development of electronic postal services outside the borders of postal administration. Also, this platform brings the idea of transmitting the trust in physical network into the digital world, especially on international level, when it comes to transference of official documents or legal contracts where the distrust in digital communication is especially present.

The problem of updating data about changing the address of clients who change their place of residence often, influences the possibility of regular consignment delivery. This platform offers to connect the physical and electronic address into a unique identifier. A client can simply update .post identifier from any place and by doing so, he/she provides a new address for consignment delivery. By updating addresses, the number of undeliverable shipments is in rapid decrease. Another role of the identifier is filtering direct mail by the hand of a client, which significantly reduces the amount of unwanted mail, and senders get a chance to adjust to clients. Access to .post is available from mobile phones from any place at any time, which is of great importance when it comes to integrating continuality of business processes and time differences.

The .post platform, among other things, enables both sides which participate in a transaction to know exact customs and tax charges before the transaction is over, simply by developing a systematic customs declaration, which hasn't existed up until now. Transparent use of the platform with tracking system (track and trace) integrated in it enables users to follow the trip of their order. Following orders via mobile phones makes even more sense, especially if the shipment is expected in a non-standard regime.

E-management services are developed so as to be available anywhere and at any given moment. One of the challenges which is being set for the countries' governments is enabling a universal service for their mobile citizens according to the defined international rules. Using .post domain can reduce charges of a universal service by combining traditional and new electronic services via mobile phones through hybrid communicational service.

4. CONCLUSION

Mobile applications were initially designed to make communication easier. The development of social activities sets new requirements, new challenges for new applications and new functions. Mobile devices surely belong to not only private, but also business environment. Communicating does no longer mean only transferring information, but also a corresponding (and fast) reaction in means of verification of the value of the transferred information.

Using mobile devices in business represents a great challenge for postal sector. Developing new applications requires improving, upgrading and coming up with specially designed solutions in order to provide postal service to clients.

Various use of mobile devices is present in all areas and most commonly means locating, following, gathering information, realizing and confirming activities. All these functions can be used in the field of postal service, in order to achieve a market advantage, good relationship with clients and optimal solutions for using existing capacities.

According to NSA (National Statistics Association) statistics for the year 2013, 87 percent of population in Republic Serbia uses mobile phones, the number of internet users has risen for 6.9 per cent compared to the year before, over 900 thousand people have bought or ordered products/service via internet during that year, and 30.3 percent of the internet population have used mobile phones to access internet when outside their house or office (NSA, 2013). That said, integrating the traditional and the new, electronic service, as well as using positive experiences of big postal managements and private operators can be of help in making a good starting position in the upcoming market competition and the fight for new service users.

WARRANTY MANAGEMENT MODEL IN E- COMMERCE

[3] Belgrade Business School, Serbia, vaskovic@bvcom.net

Abstract: *Virtual market is a place with a significant number of retailers offering their products or services. In addition, buyers have a wide selection of goods and services to choose from and their decision to purchase something is based on the offer and impression that sellers make on potential customers. Such conditions require traders to treat every customer with due care and not let him/her be unhappy with the purchase, even if they must complain about the purchased product. The system of automated management of warranty claim process is very important, because it allows the buyers to exercise their rights acquired by purchase, and the vendors to make a good impression without harming their reputation. Moreover, customer feedback obtained via warranty claim processes can be of great importance for improving products or services. The paper presents a system of production management, while special attention is given to one of its segments - warranty management system.*

Keywords: *Warranty, Warranty management, eBusiness, Escrows, e-commerce.*

1. INTRODUCTION

The increased availability of online products and the modern lifestyle, with average users having less and less time for shopping in retail shops, have both made the consumers turn to online shopping. This phenomenon resulted in the increased number of online purchases, even in our country.

According to the data provided by the Statistics Office of the Republic of Serbia in October 2013, over 900,000 persons have purchased or ordered goods via the Internet in the last year, which is an increase of slightly over 300,000 than in 2012. In terms of timeframe, 19.3% of users have made a purchase or ordered goods or services over the Internet in the last three months, 9.2% more than three months ago, and 7% over a year ago, from the time of the issuance of reports. A significant number of customers, 64.5% in total, have never purchased or ordered the goods online.

These data suggest that an increasing number of users have been opting to purchase or order goods and services over the Internet. With an increased number of customers, the problem of dealing with customer warranty claims and possible refunds is becoming increasingly important, especially if we take into account the fact that buying over the Internet is somewhat unreliable, because customers do not have an opportunity to take a product they intend to buy in their own hands and examine it for quality, but have to rely on the description and characteristics of the product given by the vendor. There is a possibility that the ordered product is not in conformity with its description and characteristics, or that it may be damaged during transport. Such conditions of purchase require a system that will enable warranty management, as well as the vendors, to provide a good quality post-sale support. According to Jim Ericson [Ericson, J. (2002)], "Warranty management today is about faster cycles for engineering design and redesign, better consumer response, recovering costs, improving channel relationships, and building a service business with much higher margins than traditional manufacturing. Today, the customer demands the warranty, but the manufacturer needs it as well."

The use of specialized websites that serve as intermediaries and safeguard the entire process of purchasing and delivery of goods is one of possible modes of online customer protection. These websites are called Internet Escrows and their role is mediation of payment. The user orders goods on the vendor's site and chooses an escrow website as a mode of payment. In the next step, the buyer pays the money to the escrow provider's account, after which the vendor sends the goods to the customer. When the buyer receives the product and checks its quality, he/she updates the transaction, after which the money is paid to the vendor. This method of securing purchases eliminates the possibility of fraud, because the buyers cannot get the goods until they pay for them, and the vendors cannot send the goods without previously getting paid for them, provided the goods conform to their description. While trading by using escrows reduces the possibility

of customer warranty claims, it does not reduce the possibility of complaints for goods that are non-functional or defective. Escrow network does not cover such defects and these products are returned to vendors (manufacturers). Servicing of this type of warranty claims requires background business operations that will accept and process them.

2. ANALYSIS OF THE EXISTING SYSTEMS

Companies all around the world are being faced with great costs incurred by customer warranty claims. According to the statistics, the losses comprise approximately 7% of revenue, while US companies alone spend more than 22 billion dolars each year on resolving warranty claim issues. Poor warranty management may leave a company at mercy of its competitors and can further entail:

- Increased costs
- Loss of customer-vendor trust
- Decreased revenue
- Lack of trust in the product or service reliability.

Warranty claim processes can be improved by applying the knowledge of new technologies and their integration into the business system. There is a significant number of organizations on the market that offer their platforms for warranty management, and the best include: Oracle, Tavant, Optimum-us, Entigo, Product& Service Advantage (PTC).

The analysis of the existing warranty management systems has shown that their essence lies in a constant monitoring of products and services. The analysis makes possible the prediction of unwanted consequences, as well as a timely response to them. All examined systems have some common characteristics, including:

- Centralization and automatization – involve the creation of a central database where all relevant data will be stored. When the data are organized in this way, forms and questionnaires can be created and specific conclusions reached - automatically.
- Personalization and optimization – by using automatic data processing, all warranty questionnaires can be dynamically optimized, adjusted to specific situations and customized for each individual client. This method helps remove the obstacles in terms of language, device, location or any other charatcteristic.
- Analysis and adaptation – adaptation to organizational change requires the use of tools that will help data analysis provide accurate, timely and measurable results.

The integration of the warranty management system can help reduce administrative costs, as well as time spent on warranty claim processing. It can also reduce errors, prevent their recurrence and increase productivity. The possibility of automation is one of the biggest advantages, because it can improve business operations in terms of eliminating customer dissatisfaction and providing confidence in the product.

3. WARRANTY MANAGEMENT IN E-COMMERCE

Warranty is defined as a guarantee that a product will perform as stipulated, and as a commitment to correct problems if the product fails during the warranty period. There are various levels of product warranties, as well as differing implications for buyers and manufacturers.

Electronic commerce has increased in recent years and the number of users who opt to shop online has been on the rise, which has led to an increased number of websites for this type of sales. Greater competition requires that the providers improve the quality of goods and services if they wish to retain the existing customers and attract new ones. This entails the need for an adequate warranty management which would reduce the level of dissatisfaction among customers who had to complain about the purchased products. In order to place a product on the market, the manufacturer must guarantee for its correctness, and provide a written guarantee that the product is correct and usable within a specified period. As products are mostly made up of components that manufacturers purchase from their suppliers, the warranty that the manufacturers obtain from the suppliers is further transferred onto the finished product and its warranty. The warranty does not always imply refund, but the repair of the product instead, in which case the warranty system includes service network. Warranty claims can be organized in such manner that the goods are returned to the manufacturer, or the warranty claims can be dealt with through the service network.

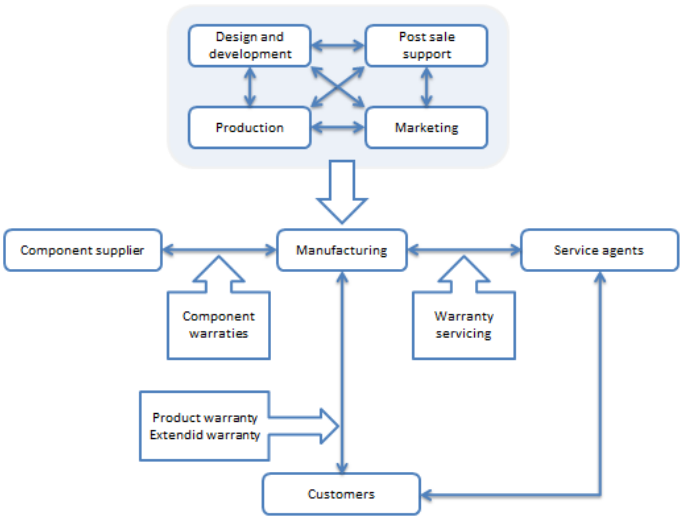

Figure 1. Key elements of warranty management [Shriti, and Meraj,2008]

Whenever an item is returned under warranty, the manufacturer incurs various costs (handling, material, labor, facilities, etc.). These costs are random (unpredictable) quantities. The following three costs are of importance to both consumers and manufacturers:

- Warranty cost per unit sale
- Life cycle cost per unit sale
- Life cycle cost over repeat purchases.

4. WARRANTY MANAGEMENT MODEL

Warranty management model can be divided into two separate segments. The first segment is the information model for production management that constitutes the internal part of the warranty management model, while the second one is external and it includes processes such as receiving warranty claims and their processing. Receiving warranty claims can be organized on the website, via the Call Centre, directly through the outlet network, or through the service network. At this point it is also important to check the agreed terms and the ones defined in the contract.

Warranty claims are a segment of the trading process both in real-time and virtual environments. The Image 2 shows their place and role in the process which includes a set of activities that must be carried out for the successful placement of products on the market.

The process of product advertising includes a number of activities which have a direct impact on other processes that occur in the production. First of all, technical service must identify and analyze the product defect or flaw, as well as its effect on the functionality of the product. Also, this service has to determine whether the error occurred in the production process or whether it was made by the subcontractor-supplier of the parts and assemblies that were built into the product. Given that the supply of parts for the majority of products involves multiple suppliers (sub-manufacturers), the analysis of the resulting error must encompass the entire process in order to determine where it was made or not and who the claim should be forwarded to. These data can be found in the part of the database where the supply side is processed (SCM). The cycle of product replacement begins with the identification of the causes of the product malfunction or failure. This means that the number of newly manufactured parts that will replace the returned products will increase. Well-established production lines know in advance the percentage of products that are usually returned, and the number of products to be released is also increased in advance for that percentage.

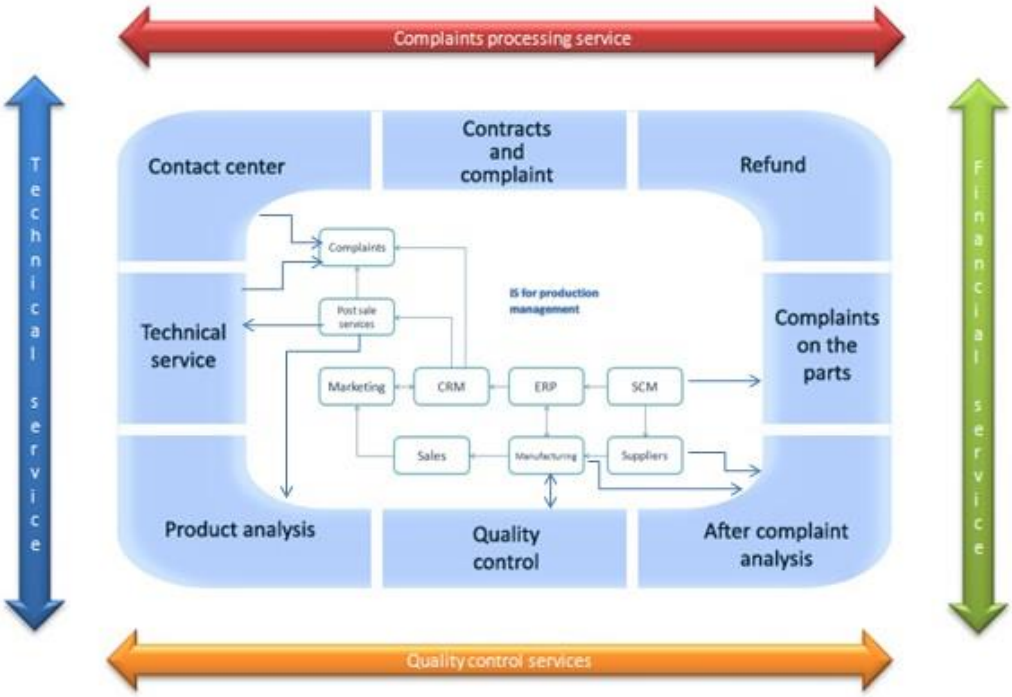

Figure *2 – Warranty management information system*

Warranty management model should encompass the entire process which includes a range of activities, from communication with customers and analyzing warranty claims, through acceptance or rejection of their request, to the analysis of the causes of errors, refunds, etc. A model of warranty claims coordination process which, apart from a standard procedure for warranty processing, includes the activities carried out by the technical service, is described in the further text. Management of the quality of products and their parts, as well as the financial aspect of the entire process, has also been covered.

Elements of the model:

- Contact center deals with customer information, receives warranty claims and determines their validity. Detection of false claims is an important segment in this phase of the process. Here the focus of warranty management is on the administration of warranty claims. It involves the following steps:
    - Receiving claims from service agents
    - Processing claims to check for the validity of claim (so as to prevent fraud)
    - Arranging for reimbursement
    - Part management (to update the part inventory of service agents).

The aim is to control warranty servicing costs through detection of fraud (by customers and/or service agents) and to ensure a certain level of customer satisfaction through efficient servicing of valid claims by service agents. The approach to warranty is reactive and warranty is viewed mainly as a cost element with an accounting emphasis [Shriti, and Meraj,2008].

- The part of the model related to contracts and warranty claims serves to analyze the conditions of the sales transaction. It registers returned products, checks for any specific terms or if the goods were sold as part of a campaign, etc. Legal department is in charge of this type of activities because the above-mentioned elements must be viewed in light of customer rights and vendor obligations.
- Reimbursement is valid if the analysis of the warranty terms shows that the customer has a right to claim refund. Reimbursement is a duty of the Finance Department. In this process there is a part of funds that cannot be reimbursed and which always represents a loss – fees to payment processors.
- Technical service is tasked with warranty claim processing and determining of the product repair or replacement costs.
- The potential error is detected in the process of product analysis**.** Parts and assemblies are checked, etc.
- Quality control involves finding possibilities for improvement of products, servicing or operations with the aim of reducing the number of warranty claims and improving the products.

- Post-warranty claim analysis and quality research involve a process where the quantity of the needed parts is estimated, based on the research and analysis of the percentage of returned or replaced products. An overall product quality analysis.
- Component warranty claims are an important segment of warranty claim process, as the manufacturer is not solely responsible for the poor quality of the product. A part of the responsibility lies with the component manufacturers, in terms of the warranty they give for the components installed in the final product and which can be returned as a part of the warranty claim.

A specific problem occurs when payment was made by credit card or by using any of the electronic forms of payment. In this case, the payment includes the sum paid by a customer, but the bank transaction fee is then deducted from this sum. This means that the reimbursed amount is smaller than the actual refund, and the customer is entitled to total refund under warranty terms. The difference must be compensated from the vendor's own assets.

5. CONCLUSION

The tendency of the customers to buy online is constantly on the rise, and so is the competition. Therefore, the need for adequate service is becoming increasingly important. Customers whose expectations are not adequately met and who had to complain about the purchased product could harm the reputation of the vendor. The warranty claim system is very important for traditional retailers, but it is even more important for those who primarily do business on the Internet, because this is the environment which customers do not trust enough and they generally seek traders with good reputation who they can trust. As the information in the virtual world is widely available and customers can easily read various comments about the vendors, it is important to pay attention to each customer, especially the ones whose expectations have not been met and who complain about it.

An adequate system of warranty management is very important. It allows traders to check the validity of claims easily and to respond appropriately. It also makes possible the collection of information important for determining the quality of the product, as well as of its components. In this way, the warranty management system is the means for getting customer feedback that can be used for product improvement.

[2] Faculty for Strategic and Operational management, e-mail: sava.smiljic@fpsp.edu.rs

Abstract: *In this paper, we applied the techniques of descriptive statistics to analyze the use of credit cards at ATMs and points of sale in the country and outside the country, issued by the commercial banks that operate within the banking system of the Republic of Serbia and issued by commercial banks outside the Republic of Serbia in the period from 2009 to 2013. Payment cards as an instrument of cashless payments are becoming an important part of our daily lives, whether we use them as an instrument of payment transactions (payment transactions made over the Internet), for the payment of goods and services, for cash withdrawals or as an instrument of identification.*

Keywords: *payment cards, electronic banking, cashless payment, ATM, POS systems.*

1. INTRODUCTION

Credit cards appeared in the United States during the 1920s, when individual firms, such as oil companies and hotel chains, began issuing them to their customers. The first card for deferred payment for privileged users was issued by Western Union Telegraph Company in 1914. These credit cards had a restricted use, ie. could only be used in the sales/service facilities of the company that issued them. The first bank card named "Charg-It" was introduced in 1946 by John Biggins, a banker from Brooklyn, which allowed bank customers to purchase consumer goods in local stores that entered into an agreement with the Bank.

The first universal credit card made of cardboard, which could be used in a variety of sales / service facilities, was issued by the Diners' Club International on 8/02/1950. By the end of 1951, 20.000 Diners Club cardboard cards were issued and a decade later they were replaced with plastic. The other significant cardboard credit card of this type was launched by American Express Company in 1958 and in early 1959, it issued a plastic credit card. The first banking system of national importance was "BankAmericard", launched by the Bank of America in California in 1959. This system was licensed in other states in the beginning of 1966 and since 1976-77 was renamed Visa. Other major bank cards are MasterCard (formerly Master Charge, 1966) and Barclay's. Discover is the American organization that launched the Discover card in 1985. In our country, the first cards appeared in 1969, issued by Diners Club, and the first national bank card is DinaCard, established in 2003 by the National Bank of Serbia and commercial banks.

2. ELECTRONIC PAYMENT CARDS

In traditional retail payment systems, electronic payments credit have been functioning for many years, and today they represent the dominant payment system in e-business. Electronic payment cards are used in most business transactions carried out over the Internet. Payment cards can be defined as the standardized (ISO 7810 standard and physical characteristics [9]) of non-cash payment instrument emitted by the banking system, commercial or specialized systems with which the cardholder may purchase goods or services (POS systems) and withdraw cash (ATM) charged to his bank account. According to the generally accepted definition, the debit card is a small piece of plastic that contains a means of identification (signature or photo), which allows the cardholder to purchase goods or services charged to his/her account.

Payment cards can be divided into several groups [2], [4], [12]:
- According to the use:

a) horizontal cards: credit cards, debit cards, prepaid cards (single-purpose/multi-purpose and specialized), corporate cards, Internet cards and loyalty cards;
b) vertical cards: platinum card, gold card, business cards, classic cards and virtual cards.
- By technological drafting:

a) standard embossed payment cards, engraved cards defined by ISO standard 7811, as follows: form, size, height and position of the bulge;

b) electronic magnetic stripe cards, today represents the most popular instrument of payment, defined by ISO 7811 (chapters 1, 2 and 3), where are specified characteristics of magnetic stripes, coding techniques and positions;
c) smart card, these are physical cards with embedded chips that allow the storage of significant amounts of data [1]. It is widely used in: financial transactions (e-banking, e-commerce, e-governance), hardware-software protection of business systems that require a higher level of security for their business data on computer networks and computer systems (authentication, authorization, privacy, integrity, inability of rejection), and in the user identity identification, defined by ISO7816 series of standards and EMV standards (global standard for smart card-based payments) [8].
Smart cards can be divided into three groups:
- smart card with the possibility of an internal microprocessor data processing, capable of remembering and protecting the data and making decisions within certain limits,
- only memory cards, the cards with direct access to memory, where static data is stored, and consist of ROM and EEPROM memory, and
- hybrid smart cards, cards with contact chip (providing logical access control – access to computer and other resources) and contactless chip (providing physical access control).
Today, for greater security, there are cards with built-in LCD display and touch keypad that allow generating One Time Passwords (OTP), as an authentication security measure.

- According to the application location:

a) domestic (national) credit cards: DinaCard and YUBA in Serbia;

b) international credit cards: VISA, MasterCard/Maestro, American Express, Diners Club Card, Discovery, JCB, are all international credit card organizations, card schemes or networks that are globally interoperable. Visa, MasterCard/Maestro, Dina and YUBA are bank payment cards, where banks appear as a credit card issuer. American Express, Diners Club Card, JCB and Discovery are non-bank cards issued by other entities, and banks may emerge as mediators in issuing cards.

2.1. The electronic cards payment process

Modern information and communication technologies have initiated many technological innovations in the financial services industry, particularly in the area of new models of electronic banking (online banking, Internet banking, SMS banking and mobile banking) as well as payment systems (electronic accounting systems of large value payment and distribution retail systems). In the further text, we will briefly explaine the traditional distribution retail payment systems, which include: Automated Teller Machine-ATM, Point of Sale/Electronic Funds Transfer at Point of Sale-POS/EFTPOS and Home Banking-HB, which use electronic payment cards and today increasingly mobile phones (Near-Field Communication - NFC) as an alternative to paper payment systems.

2.1.1. Automatic bank tellers-ATM

Automatic bank teller or ATM, according to the NBS, is "The device usually installed in a crowded area or the branch of the bank and enables the cardholder to withdraw cash from his account 24 hours a day. To withdraw cash from an ATM, the cardholder must, as identification, type a PIN number, obtained from the bank in a sealed envelope, known only to him."
The first traditional distribution retail payment system was an automatic bank teller/ATM Machine (ATM-Automated Teller Machine) that worked in the off-line mode. It was invented and installed by John Shepherd-Barron at Barclays Bank in London in 1967 and was able to pay a voucher worth 10 pounds. Vouchers were later replaced by plastic cards, kept in the ATM after the transaction. The bank would return them later by mail to clients for further use.
Automatic bank tellers (ATMs) are self-service devices placed in crowded areas (airports, railway stations, bus stations, subway stations, factories, universities, convention centers, sports facilities ...) and connected to a distributed network (ATM networks) within the electronic banking system. They are now divided into two groups according to their functionality:
1. Monofunctional automatic bank tellers-ATM (older versions) that provide 24 hours a day, 356 days a year, the bank customers and other users with: cash withdrawal and account balance inquiry;
2. Multifunctional automated teller-bank ATM, the modern ATMs that provide bank customers and others users, 24 hours a day, 356 days a year, with the following functions: cash payment and withdrawal, account balance inquiry, taking deposits, transfer funds to other accounts within the bank, payment of various bills, querying and obtaining information, a list of recent transactions, printing transactions, change of PIN, mobile impulse purchasing... [5].
The best-known manufacturers of ATM terminals are: NCR (world's number one ATM manufacturer, NCR SelfServ™ 26, NCR SelfServ™ 31…), Diebold-Incorporated (Diebold 429 Lobby, Opteva® 923 In-Lobby Teller…), Wincor Nixdorf (CINEO C2040, CINEO C2550…), Hitachi-Omron (HT-2845-SR, ATM SR7500…)… Figure 1 shows the diagram of transaction processes of an ATM.

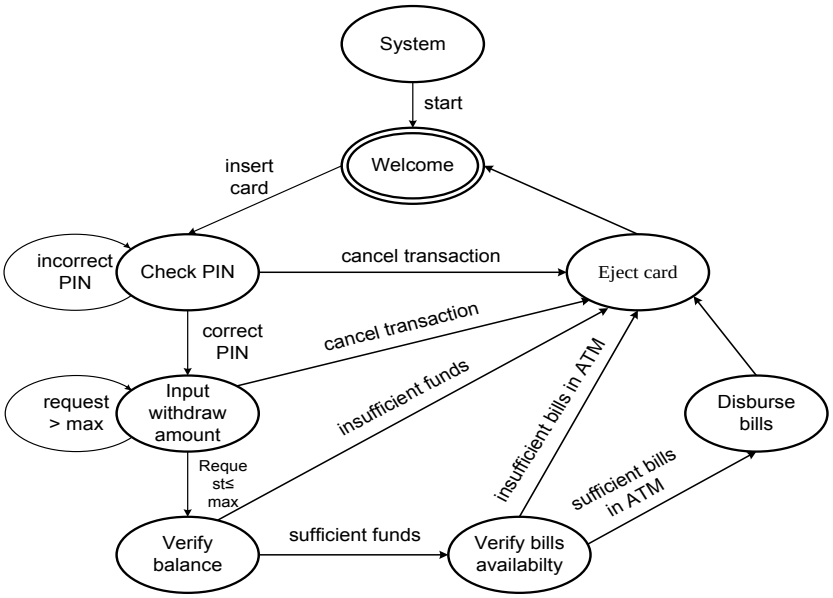

Figure 1: Diagram of the ATM transaction processes [13]

2.1.2. Point of sale devices – EFTPOS

According to the NBS, EFTPOS is the electronic terminal, placed at the point of sale, which allows payment for goods and services. It is equipped with software for processing payment card transactions (reading data from the card, forwarding to the recepient bank and the issuing bank acceptance of the response, based on which the money is withdrown for the purchase of goods). EFTPOS devices or systems work in off-line processing mode (accumulating all clients' transactions carried out during the day and later withdrawing certain amount of money from the customer's account) and on-line processing mode (processing is performed at the time of card activation through the EFTPOS terminal), which is now the dominant mode.
There are "four participants" in the process of payment for goods and services at the EFTPOS device/ terminal, as follows:

- Customer-cardholder;
- The card issuing bank;
- Merchant;
- Merchant's bank - card recipient .

Lately, in the credit cards payment transactions, there is the fifth participant (credit card networks-Visa, MasterCard), which checks the security functions, coordinates the transfer of funds and the transfer of necessary information between the card issuer bank and the card recepient bank. When paying with credit cards, there is a model where the transaction involves three actors: the customer, the merchant and the card network (American Express, Diners Club and Discover Card). This model recently also includes the bank as the card issuer. Figure 2 shows the graphical model of on-line business transactions using payment cards and EFTPOS terminals.

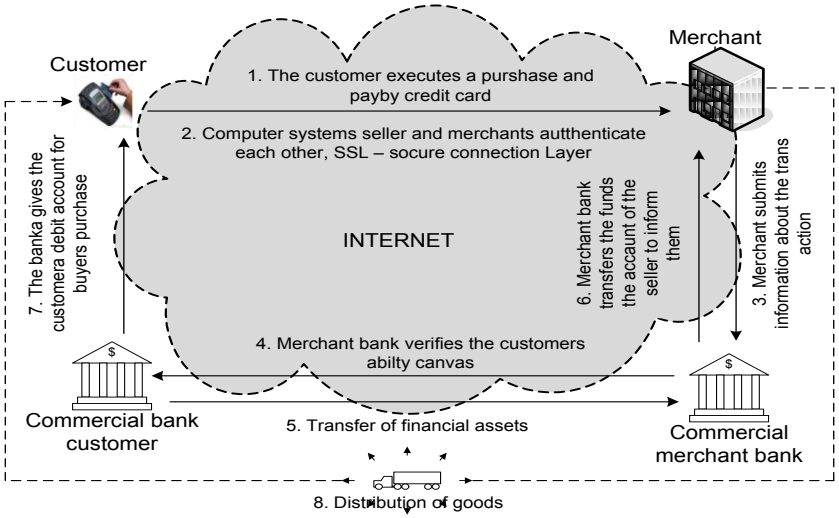

Figure 2: Business transactions using payment cards and EFTPOS terminals [4]

Introduction of EFTPOS devices decreases: circulation of cash, the use of checks by customers, the cost of treatment, time needed for financial transactions, and increases the overall safety of both payment card users and payment.

3. ANALYSIS OF THE USE OF DISTRIBUTION RETAIL PAYMENT SYSTEMS IN SERBIA IN THE PERIOD 2009-2013

In the analysis of the use of distribution retail payment systems in Serbia for the observed period, we will use the statistical analysis descriptive methods [6]. The analysis will include: Number of installed ATMs and POS terminals in Republic of Serbia; Number and value of transactions with cards issued in the Republic of Serbia at ATMs in the country; number and activity of cards issued in the Republic of Serbia.

Number of installed ATMs and POS terminals in Republic of Serbia

Table 1 and Figure 3 shows the official statistical data of the National Bank of Serbia on the total number of installed ATMs and POS terminals, the number of transactions and the total turnover in the Republic of Serbia [11].

Table 1: The number of installed ATMs and POS terminals in Republic of Serbia

Year	Number of ATMs	Index	Number of retail stores with POS t.	Index
2009.	2.723	100	59.058	100
2010.	2.857	104	57.459	97
2011.	2.830	104	58.012	98
2012.	2.785	102	62.656	106
2013.	2.613	96	59.822	101

Source: bank reports

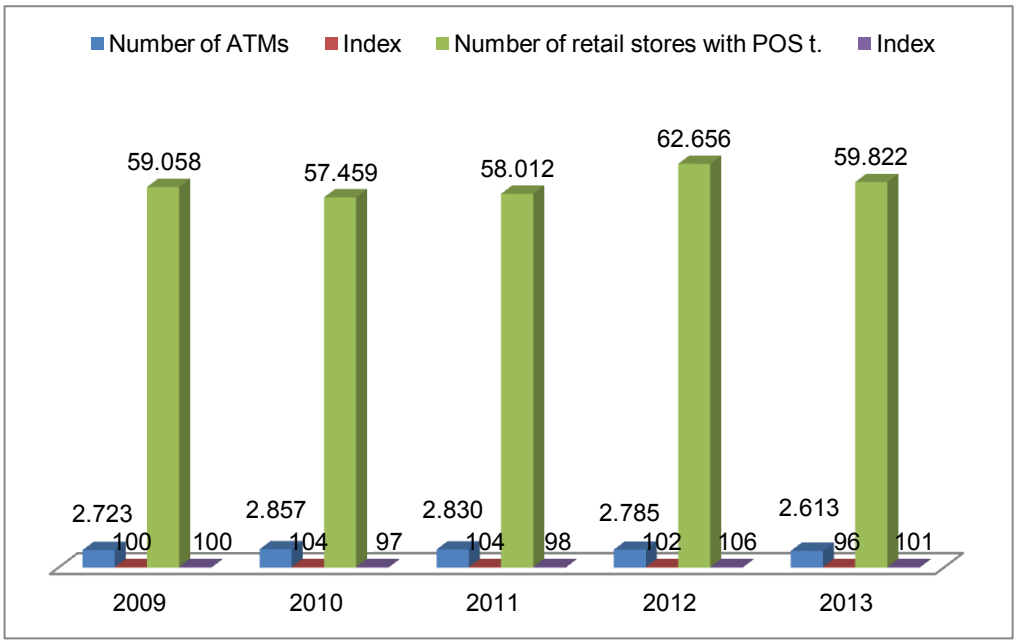

Figure 3: Number of installed ATMs and POS terminals and total turnover in the Republic of Serbia

Based on Table 1 and Figure 3, we can conclude that the number of installed ATMs in 2009 was 2.723, and 59.058 EFTPOS terminals. In the next two years, the number of ATMs increased by 241 which is 8.9% (2010: 4,9%-134 and 2011: 3,9%-107). In 2012 and 2013, there was a reduction in the number of ATMs by 217 (revoked license: Poljoprivredna banka Agrobanka a.d. Belgrade-25.05.2012, Nova Agrobanka a.d. Belgrade-27.10.2012, Development Bank of Vojvodina a.d. Novi Sad-06.04.2013. and Privredna Banka a.d. Belgrade-26.10.2013), as follows: 2012: 2,3%-62 and 2013: 4,0%-110. The number of EFTPOS terminals but in 2010 and 2011 there was a reduction in the number: 2,7% (1599) and 1,7% (1046) compared to 2009 (due to the economic crisis, many shops closed). In 2012 the number of EFTPOS terminals increased by 6,1% (3589) and 2013 by 1,3% (764) compared to 2009 year.

Number and value of transactions performed with cards issued in the Republic of Serbia at ATMs and POS terminals in the country

Table 2 and Figure 4 show number and value of transactions performed with cards issued in the Republic of Serbia at ATMs and POS terminals in the country.

Table 2: Number and value of transactions performed with cards issued in the Republic of Serbia at ATMs and POS terminals in the country

Year	Number of ATM transactions	TOTAL turnover of * ATMs	Number of retail stores with POS t.	TOTAL turnover at * POS t.
2009.	48.123.180	263.782.000	57.457.802	124.832.000
2010.	51.986.007	312.659.000	64.210.478	141.573.000
2011.	57.490.112	372.483.000	74.729.116	161.486.000
2012.	62.833.608	430.000.000	86.826.191	194.262.000

* Value of transactions performed with cards issued in Serbia at ATMs and POS terminals in RSD

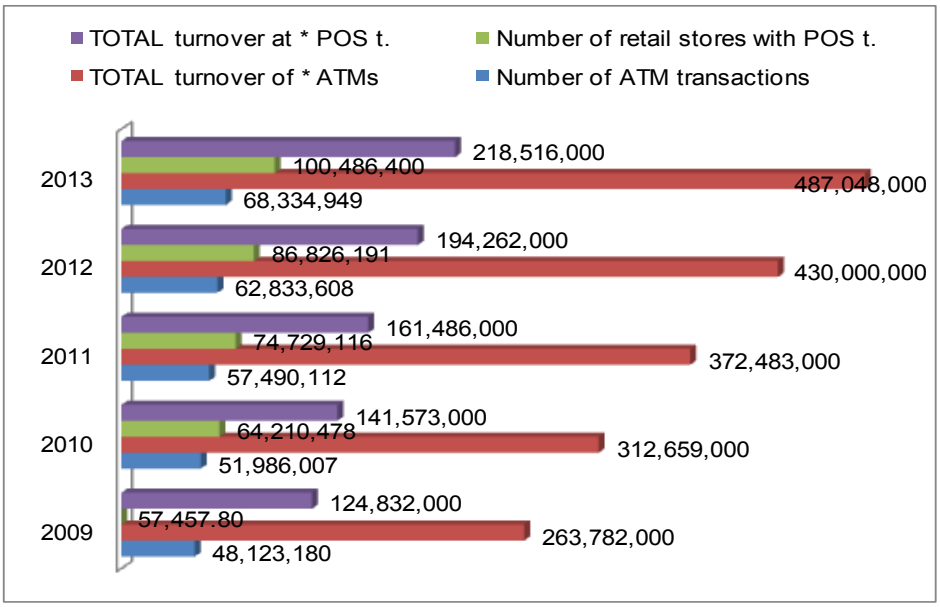

Figure 4: Number and value of transactions performed with cards issued in the Republic of Serbia at ATMs and POS terminals in the country

In the observed period, from the data in Table 2 and Figure 4, we can conclude that the number of transactions and the turnover using cards at automated banking counters-ATM and POS terminals in the country continues to increase. The number of transactions at ATMs in 2009 was 48.123.180,00 in the year 2013 was 68.334.949,00 which was an increase of 20.211.769,00 (70,4%), and in point of sale terminals in 2009 there were 57.457.802, in 2013, it was 86,826,191, which was an increase of 35,093,920 (40.4%). The total turnover at the ATMs in 2009 was 263.782.000,00 RSD, which is a decrease of 223.266.000,00 (84,6%) compared to 2013, and in point of sale terminals total turnover in the year 2009 was124.832.000,00 RSD which was a 93.684.000,00 RSD (42,8%).

Number and value of transactions performed with cards issued in the Republic of Serbia

According to the official statistics from the National Bank of Serbia, Table 3 and Figure 5 show the data on the number of transactions and turnover in the country, using the cards issued in the Republic of Serbia.

Table 3: Number and value of transactions performed with cards issued in the Republic of Serbia

Year	Number of transactions			Turnover*		
	debit	credit	business	debit	credit	business
2009.	84.658.239	12.948.369	3.441.739	300.853.196	38.546.530	15.739.154
2010.	93.760.724	12.648.839	4.083.366	354033.741	38.290.743	20.762.245
2011.	107.497.491	12.844.824	4.836.075	418.847.126	39.556.433	26.462.510
2012.	121.926.831	14.074.197	5.621.490	485.635.250	44.895.663	34.129.391
2013.	139.500.639	13.179.107	6.578.497	552.219.873	42.552.204	42.942.087

Source: NBS reports
* Value of transactions with debit, credit and business cards in RSD

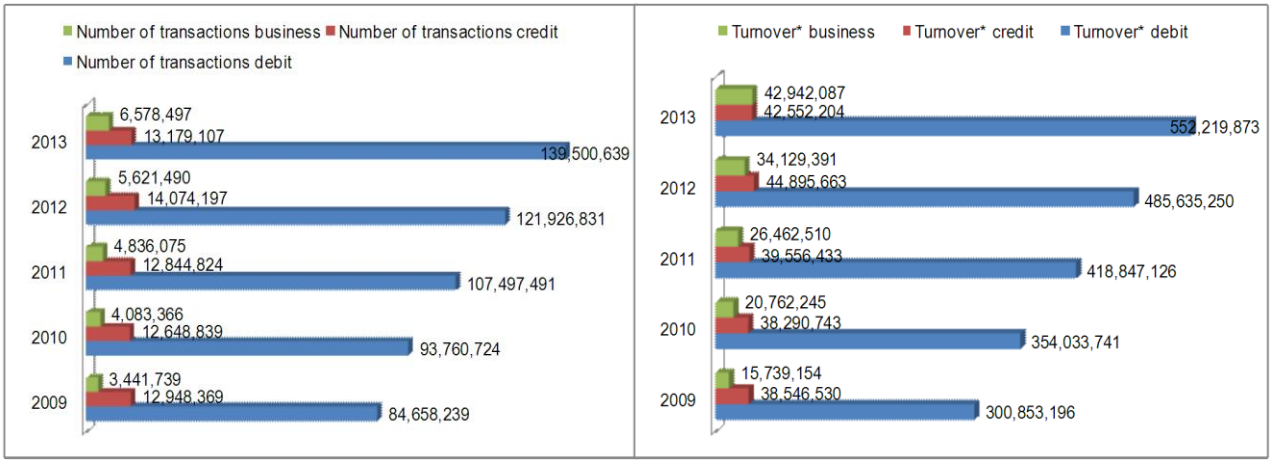

Figure 5: Number and value of transactions performed with cards issued in the Republic of Serbia

From Table 3 and Figure 5 we can conclude that the number of transactions and turnover in the country, using cards issued in the Republic of Serbia, in the observed period, continuously increases. Most transactions were achieved by debit cards in the 2013 is 139.500.639, credit cards 13.179.107, and the least transactions by using business cards 6.578.497, with the turnover of 552.219.873,00 RSD for debit cards, 42.552.204,00 RSD, credit cards and 42.942.087,00 RSD for business cards. In comparison to the year 2009 (84.658.239 transactions), the number of transactions with debit cards has increased by 64.8% (54.842.400), and turnover by 83,6% (251.366,134,00 RSD). Concerning credit cards, the number of transactions increased by 1,8% (233.738), and the turnover by 10.4% (4.005.674), business cards, the number of transactions increased by 9,9% (3.136.758), and the turnover by 172.8% (27.202.933). The economic crisis and unfavorable interest rates have influenced the decrease in the number of transactions and turnover using credit cards 2010 and 2011.

Number of transactions and turnover in the Republic of Serbia of cards issued abroad

With the increase in the number of tourists, sporting and cultural events in the country, the number of transactions and turnover using payment cards issued by banks outside of the Republic of Serbia has also increased, Table 4 and Figure 6.

Table 4: Number of transactions and turnover in the Republic of Serbia of cards issued abroad

Year	Number of transactions				Turnover*			
	ATM	POS	Counters	Total	ATM	POS	Counters	Total
2009	2.258.461	2.548.700	42.512.000	4.849.673	20.887.000	14.330.000	963.000	36.180.000
2010	2.420.087	3.553.606	39.941.000	6.013.634	24.618.000	18.246.000	1.130.000	43.995.000
2011	2.636.487	4.668.949	41.449.000	7.346.885	29.224.000	21.604.000	1.135.000	51.963.000
2012	2.943.814	5.343.233	47.957.000	8.335.004	34.042.000	27.112.000	1.178.000	62.332.000
2013	3.193.444	6.672.340	55.985.000	9.921.769	38.444.000	31.255.000	1.295.000	70.994.000

Source: bank reports

* Turnover in the country using cards issued by banks outside of the Republic of Serbia, stated in RSD

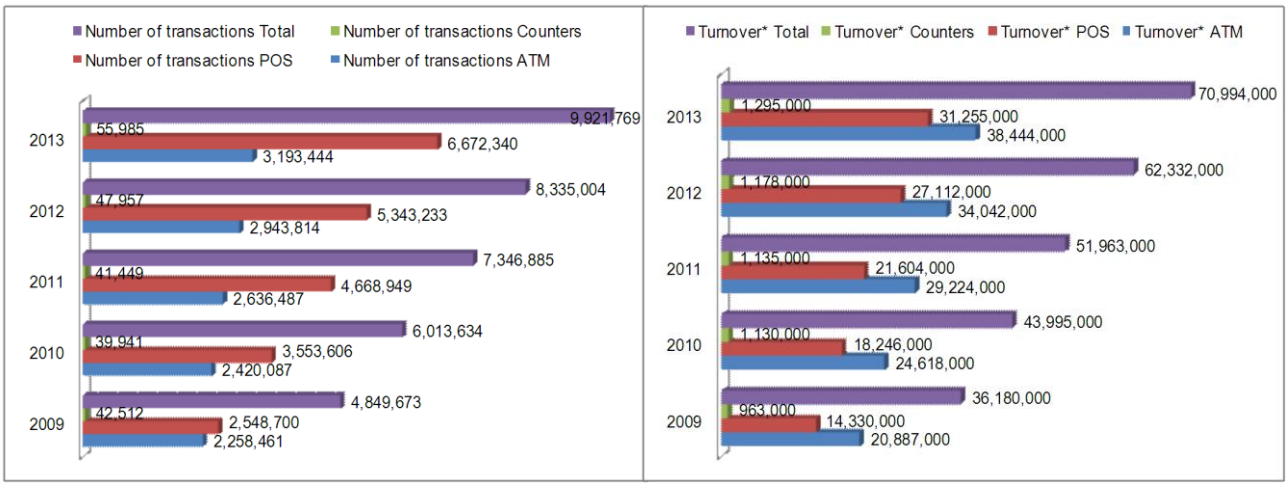

Figure 6: Number of transactions and turnover in the Republic of Serbia of cards issued abroad

In the observed period, based on the data given in Table 4 and Graph 4, we can conclude that the majority of transactions using cards issued by the banks outside of the Republic of Serbia were carried out in 2013: 3.193.444 ATM transactions and the turnover of 38.444.000,00 RSD. The lowest number of transactions took place in 2009: 2.258.461, as well as the lowest turnover 20.887.000,00 RSD. POS terminals have achieved the highest number of transactions 20.887.000 (2013), the lowest being 2,169,416 (2009). The highest recorded turnover was: 27,112,000 RSD (2013) and the lowest 14,330,000,00 RSD (2009). The traditional banking model (counters), or face-to-face interactions have made much less transactions compared to ATMs and POS terminals, the highest number of transactions 9.921.769 (2013), the lowest number of transactions 4.849.673 (2009). The highest recorded turnover was: 1.295.000,00 RSD and the lowest 1.500.000,00 RSD (2009). The total number of transactions and turnover (ATMs, POS terminals and counters) increased by 104,6% (5.072.096) and 96.2% (34.814.000,00€) in the 2013 compared to 2009.

Number and value of transactions with cards issued in Serbian foreign acceptance networks

Table 5 and Figure 7 shows number and value of transactions with cards issued in Serbian foreign acceptance networks

Table 5: Number and value of transactions with cards issued in Serbian foreign acceptance networks

Year	Number of transactions				Turnover*			
	ATM	POS	Counters	Total	ATM	POS	Counters	Total
2009.	324.088	1.547.973	7.275	1.879.366	42.900.000	115.400.000	1.500.000	159.800.000
2010.	337.958	1.967.284	7.242	2.312.484	43.900.000	142.600.000	1.600.000	188.100.000
2011.	382.162	2.479.524	7.800	2.869.486	50.500.000	182.300.000	1.500.000	234.300.000

* Turnover in the country using cards issued in cards issued in the country in EUR

From Table 5 and Figure 7, we can conclude that the number of transactions and the turnover in euro at the Automatic Teller Machines-ATMs, POS terminals and counters outside the Republic of Serbia using cards issued in the country in the observed period have continually increased. The largest number of ATM transactions is achieved in the year 2013 (506.402), which is by 56.3% higher compared to 2009 (324.088). The number of transactions at POS terminals was much higher compared to 2009 (1.547.973) and amounted to 158.4% in favor of the 2013 (4.001.323), and lowest number of transactions was carried out through the counter (2009: 7.275 and 2013: 11.022). The total turnover of ATM in the year 2009 was 42.900.000,00€ which was an increase of 43.2% (18.600.000,00€) compared to the 2013. In the observed period, turnover at the counter was in most cases even. The total turnover of POS terminals in the year 2009 was 115.400.000€ which was an increase of 100,6% (116.200.000,00€). The total number of transactions and turnover (ATMs, POS terminals and counters) increased by 140% (2.639.381) and 84.5% (135.100.000,00€) in the 2013 compared to 2009.

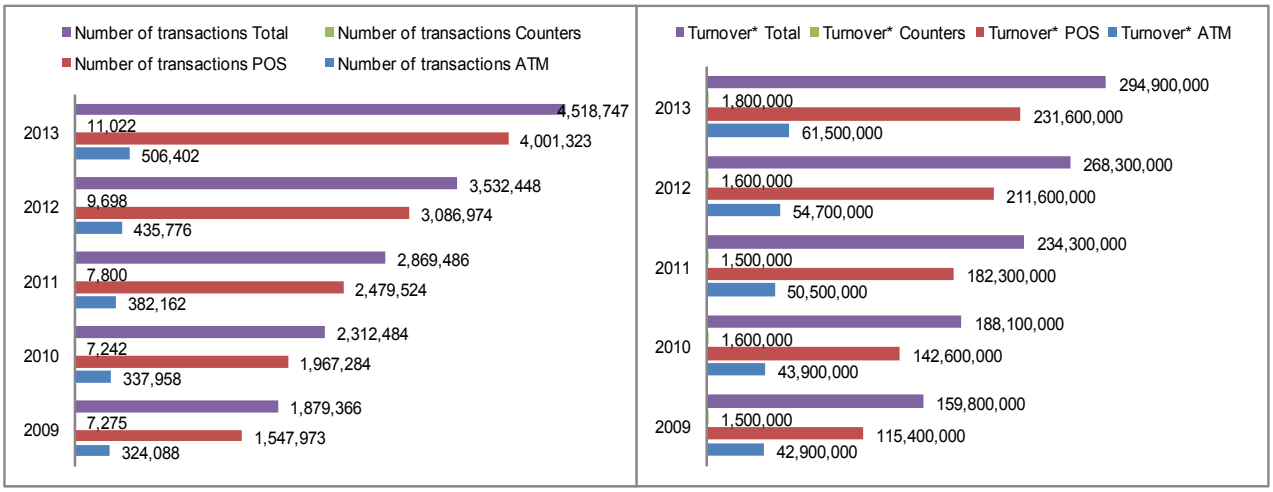

Figure 7: Number and value of transactions with cards issued in Serbian foreign acceptance networks

4. CONCLUSION

The traditional distribution retail payment systems will continue to play an important role in the future period in the financial transactions of modern banking systems. Based on the results of descriptive statistical analysis, we can conclude that the use of automatic bank tellers-ATMs, point of sale terminals-POS and

payment card system as payment instruments have an upward trend in our country. The increasing interoperability of ATMs and POS networks, the prices of payment instruments, innovations in payment instruments and the legislation have all initiated the upward trend in applying the traditional distribution retail payments systems. In spite of this upward trend in the use of payment cards as a payment instrument on POS terminals or cash withdrawal at an ATM, these transactions are far less used in our country compared to the global scale.

Abstract: *This paper describes an approach for providing CRM services within B2B business of electronic media. Main goal of the paper is to foster CRM processes, particularly marketing activities oriented toward business partners of a TV station. The main component of the solution proposed in the paper is based on web portal that provide plethora of services in the context of CRM. B2B web portal enable access all relevant services, resources and information related to the electronic media business. The approach is adapted to the specific conditions of business within electronic media in Serbia. The web portal is implemented within business system of Radio Television of Serbia. Further, electronic media B2B business framework is proposed. Model of CRM metrics in electronic media business is described, too.*

Keywords*: CRM services, B2B portal, Electronic media.*

1. INTRODUCTION

In modern environments success in business of an electronic media primarily depends on its ability to maximize outcome of relations with all stakeholders: audience, citizens, marketers, content providers, customers, business partners, etc. New business models are based on connected and integrated processes, collaborative decision-making, transparency of information, integrated metrics and lower barriers for expanding business partnerships. Medias are forced to develop new methods and services, to harmonize appropriate business processes and implement newest concepts in communication and collaboration with all partners.

Customer Relationship Management in electronic media is a set of methods, techniques and best practices implemented within a business system of an electronic media so as to enhance communication and cooperation with all customers, promote activities and services of electronic media and maximize business profits. In the context of e-business of media following CRM services are the most important: management of specific channels of distribution, analytics, customer services, sales, marketing, social CRM and internal CRM. Development and ubiquity of ICT enables application of advanced tools and services for customer relationship management. Nowadays, users of electronic media are increasingly oriented toward the use of mobile technologies, social networks and other modern media for transferring information. Compared to previous methods of communication with customers, which were implemented exclusively through TV or radio devices, today, media companies can easily manage customer relationships and establish a direct connection.

Main goal of the paper is to foster CRM processes, particularly marketing activities oriented toward business partners of a TV station. The main component of the solution proposed in the paper is based on web portal that provide plethora of services in the context of CRM. The approach is adapted to the specific conditions of business within electronic media in Serbia. The web portal is implemented within business system of Radio Television of Serbia.

2. LITERATURE REVIEW

In business of an electronic media it is necessary to implement modern concepts in business, especially in dealing with customers: personalized approach, adaptability, accessibility, user-generated content, use of social media, information timeliness, uniqueness, and comprehensiveness. Electronic media are forced to transform infrastructure and business model to ensure provision of facilities at any time, any place and on any device. Defining customers' profiles that include characteristics, expectations, and habits is an important task.

Complexity of the design and implementation of CRM systems increases with the number of services provided, as well as with number of users. It is necessary to define a method for modelling and development

of customer relationship management in e-business media. The model should include modern standards, concepts and services related to various business segments of an electronic media. A framework consists of set of tools and methods that enable integration of various components. Main problem in implementation of CRM strategy is a heterogenity of components and clients.

The significant role of CRM in business of electronic media has been recognized in a number of studies. In (LaRose, 2004; 2010) authors emphasize importance of analyzing certain characteristics of audience, especially their habit. TV media should analyse way of establishing and changing habits of audience in order to realize a high quality program that meets needs of the audience. Further, Adams (2000) discusses the ways and habits of watching TV by certain target groups. Impact of large quantity of information on modern world and importance of this issue in the context of electronic media business is discussed in (Diddy & LaRose, 2006; Kishi, 2008).

Importance of determining patterns of clients' behaviour in digital environment is discussed in (Webster, 2011). The authors discuss structure and ways of providing content to customers, but also point out that convergence and integration of media is best solution. Role of TV as a medium and relationship with other media types is discussed in (Cooper & Tang, 2009). In (Napoli, 2010), author discusses the modern trends in electronic media with a focus on the transformation of behaviour and expectations of those who are provided with services and media services. Connection between TV and Internet as a medium, is discussed in (Cha, 2013), with particular focus on videos.

Methods of research and audience measurement are explained in (Webster, 2008). Integration of a large number of methods is required, as well as use of modern technology such as business intelligence, semantic web etc. Applying the concept of big data and importance of electronic media is analyzed in (Mahrt & Scharkow, 2013). The role of social media in business TV stations are discussed in details in (Kishi, 2008; Baym & Boyd, 2012; Greer & Ferguson, 2011). Social media can be defined as a set of web applications, platforms and media which aim to facilitate collaboration between users and content sharing (Deandrea et al., 2012). The author points out great potential of application and integration of standard content and services on the TV with the capabilities of social networks. Particularly noteworthy is importance of information that can be collected on the social networks and used to improve customer relationships management.

Main idea of using social CRM in media is to engage customers and build loyalty and trust. Social media include: social networks (Facebook, Twitter, Google +, Pinterest, etc.), blogs, wikis, forums, etc. Medias can use social CRM in following contexts:

- Using social media tools for promoting TV media's services and products, collaboration and communication with business partners and customers.
- Tracking activities of competition and public opinion about the particular TV media
- Fostering the medias 's proactive communications via social media tools
- Mapping business partners' social profiles with internal and external CRM applications

Types of CRM applications

Most used classification of CRM applications includes four groups (Seybold, 2008):

- Customer-facing applications – in this category TV media provides customers and business partners with call centres, automated responders, field service automation, applications that help medias' employees, etc.
- Customer-touching applications – these include personalized web pages for customers, web self-service systems, FAQs, etc.
- Customer-centric applications – purpose of these applications is to analyze all data gathered within CRM process. Numerous tools and techniques are used: reporting services, business intelligence, data warehousing, etc. Based on these analyses CRM plans are created and implemented.
- Online networking and other applications – idea is to establish direct relationship with customers and partners. Main tools are: social media, web sites, advertisements, forum, blog, chat, etc.

Electronic media B2B business framework

Figure 1. presents a framework of B2B business of electronic media.

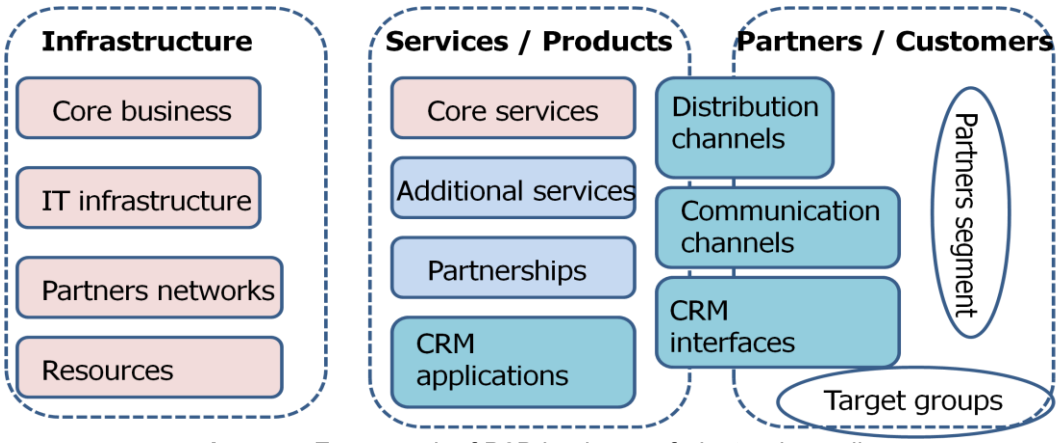

Figure 1: Framework of B2B business of electronic media

Infrastructure for B2B business includes:

- Core business processes – such as finance, HR, marketing, CRM, sales management
- IT infrastructure – hardware and software infrastructure, web portal that integrates internal processes and provide content and services to extranet. In this research, web portal is implemented and described as one of the main infrastructure component and CRM channels.
- Partner networks
- Business resources - such as buildings, equipment, studios, etc.

Core services that a TV media provide to business partners are:

- Place for advertisement
- Broadcasting
- Recording events and programs
- RSS
- Podcasting
- Web site services
- Digital TV

Model of CRM metrics in media

Metrics that are used in order to measure effects of the CRM activities and applications within a TV media are presented in table 1 (Kellen, 2014).

Table 1: CRM metrics in business of TV media

Metrics	Attrbibute
Marketing	Response rate
	RFM
	Conversion rate
	Churn
	Product category involvement
	Average order size
Sales	Customer score
	Cross-sell rate
	Number of calls
	Number of new customers
	Sales quota
Service	Call counts and duration
	Service level
Social	Business partner engagement
	Conversion rate
	Audience Growth Rate
	Total Followers

3. DEVELOPING B2B PORTAL OF TV STATION

3.1. Requirements

Main idea was to develop portal that would integrate a number of services for business partners, with particular focus on informing potential partners about possibilities to advertise on RTS. The portal is electronic point of sale for all partners of RTS, with up-to-date information about prices and availability. Business partners are provided with information about prices for advertizing on RTS's emissions, programs, broadcasts, RTS' web site and information about additional service as well. Business partners can see detailed schedules, make reservations, queries for broadcasting commercials and order a number of services. At the same time, the portal is connected with internal CRM processes and enables RTS employees to implement abovementioned CRM activities.

3.2. Architecture of the proposed solution

There are three main roles among users of the portal:

- Employees – they are enabled to perform CRM activities, for instance: create and implement email campaign, do CRM analytics, write articles, etc.
- Administrators – manage portal content and services, role management, news management
- Business partners – they posses their own profiles and can view various contents on the portal, make order, view their orders, apply for several services, ask for help, make query for collaboration, etc.

Data layer include data from various sources, such as: internal databases and files, social networks, web portal database, knowledge database, etc.

Central component is part of the web portal responsible for executing business logic. This layer communicates with different components in background and provides adequate content for users.

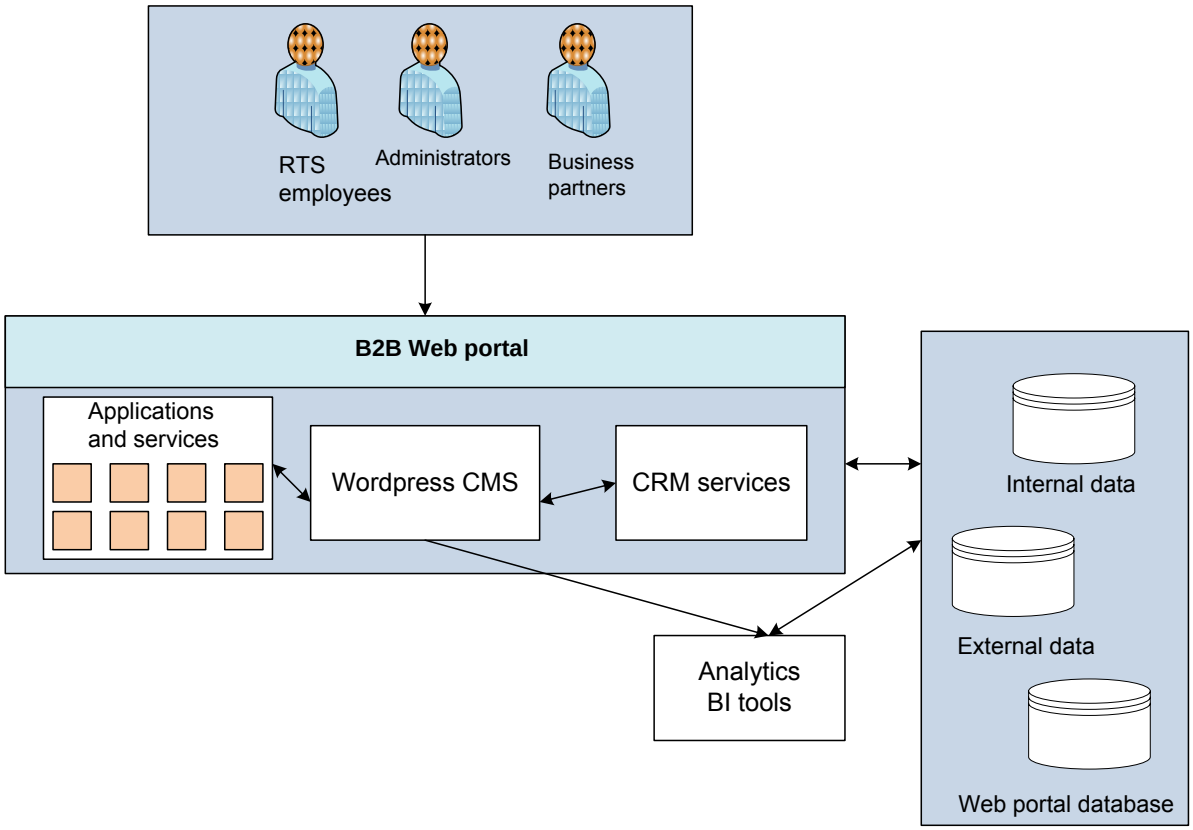

Figure 2: Architecture of the portal

3.3 Description of the implemented portal

Wordpress CMS solution was used for developing the portal. Further, several Wordpress plugins were used and developed in order to fulfill all the requirements and integrate services. Figure 3 shows the portal home page.

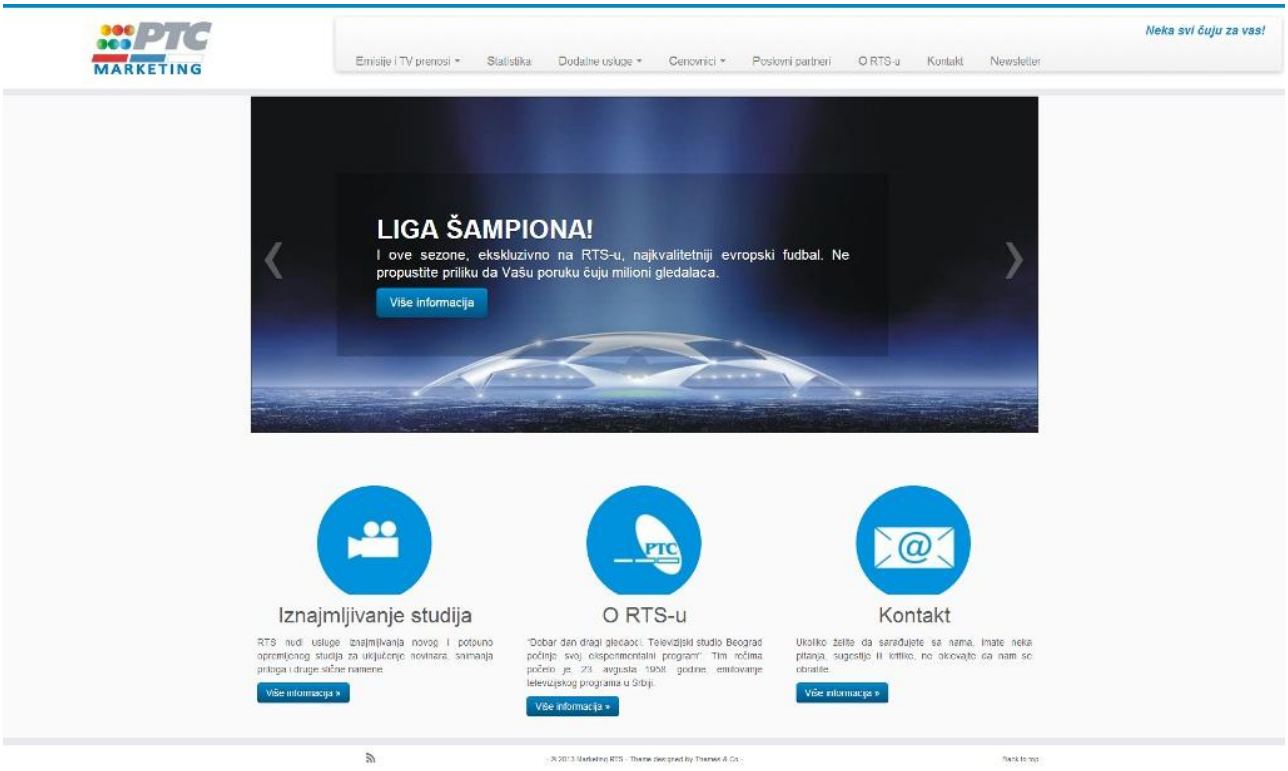

Figure 3: Home page of the portal

Slider is positioned in the central part of the home page. The slider presents selected news. Below the slider are three columns with links to description of the services and information about RTS.

Links toward main features are situated in the main menu:

- Emissions and broadcasts – each emission has its own page with title, description of content, schedule, information about host, photos and price of commercials during the emission (Figure 4.).

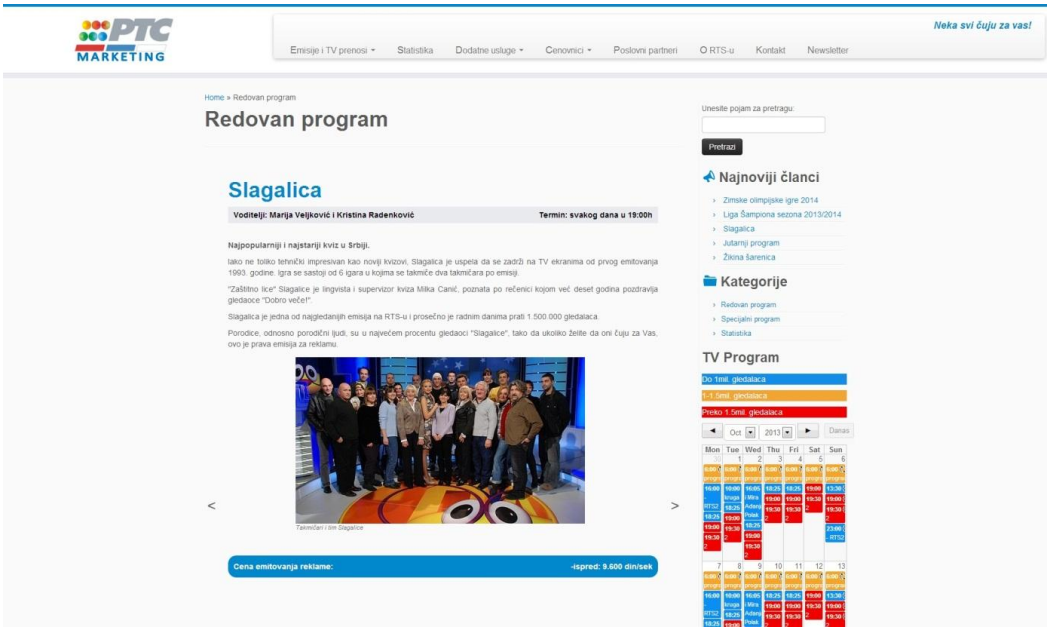

Figure 4: Page of TV emission “Slagalica”

- Reports – detailed statistics about ratings, advanced reports, advices for advertisement on RTS
- Additional services – description of services, such as studio for recording, direct broadcast, etc.
- Pricelist – detailed pricelist of RTS's services and products
- Business partners – List of RTS's business partners, partner networks, partnerships, etc
- About RTS
- Contact – form that enable business partners to contact RTS marketing department
- Newsletters – business partners have possibility to apply for newsletters

Adapted calendar, i.e. schedule of the emissions on RTS is provided in right column. All the programs are classified in three categories, based on number of viewers (red, orange and blue colour in Figure 4).

Variety of CRM services are integrated within the portal (table 2.)

Table 2: List of CRM services available via web portal (internal and external services)

Name of CRM process	Service
Marketing	• Campaign management • E-mail marketing campaign • Loyalty programs • Budget management • Campaigns analysis • User analysis
Sales	• Sales strategy • Business partners management • Analytics
Customer service	• Lead and contact management • Tickets management • Integration with external services for compliances
Social module	• Communication and collaboration service • Integration with enterprise social networking services

4. CONCLUSION

We proposed an approach for providing electronic media services for business partners via web portal. The portal integrated a number of services for business partners, with particular focus on informing potential partners about possibilities to advertise on RTS. The portal usage in real system and evaluation will provide additional information about users' experience in using the services, as well as data about web portal's performance and impact on business process outcome. Harnessing proposed model of CRM metrics will give an insight and clear picture of CRM performances. Future researches are directed toward improving CRM results and automation of CRM processes, as well as complete integration of all B2B processes in the web portal.

ENTREPRENEURSHIP AND MANAGEMENT OF SMALL AND MEDIUM ENTERPRISES

THE BANKING FOR SMALL AND MEDIUM ENTERPRISES

Abstract: *The development of banking which provides services to small and medium-sized enterprises (SME) represents one of the key economic objectives in developing countries. Small and medium-sized enterprises are focused on the banking sector due to limited financing opportunities through alternative channels, especially in the countries where financial markets are insufficiently developed. The main reasons for the difficulty in financing the SME segment in developing countries are: complicated procedures, insufficiently defined laws, negative macroeconomic factors and lack of financing opportunities. However, there are a number of ways to overcome the problem, and it is in this process that the banks have found their place. This paper aims to better understand the potential of the SME market. The first part of this paper relates to the definition of key features of SME segment, and the literature review. The challenges which banks face are described further on, as well as the approaches used by banks in the value chain. A special emphasis is placed on risk management activities, due to the fact that it occurs in all phases of the business cycle. Finally, the paper provides a brief description of the economic importance of small and medium-sized enterprises.*

Keywords*: Small and medium-sized enterprises, the SME value banking chain, risk management, economic development*

1. KEY FEATURES OF SMALL AND MEDIUM-SIZED ENTERPRISES

Although it is widely accepted that the market of small and medium-sized enterprises is an important part of any economy, the definition of small and medium-sized enterprises is often different from country to country. However, they are most often defined as business entities that employ less than 250 people. It is estimated that over 95% of the companies worldwide are small and medium, while in Europe, their importance is even more prominent since they make up 99% of the total number of enterprises. In addition to small, medium and large enterprises, another segment has been classified as micro-enterprises. They are very similar in their characteristics to small and medium-sized enterprises, with the difference that they generally have fewer than 5 employees. Alternative criteria for the classification of companies include the volume of annual revenues, the value of assets on the balance sheet, as well as the ratio of borrowed and own funds. It is clear that defining the types of companies on the basis of quantitative criteria is not enough to describe the market of small and medium-sized enterprises.

Small and medium-sized enterprises and entrepreneurs are the most efficient segment of the economy in almost all countries of the world. Individually, these enterprises make the largest contribution to the increase in employment, gross added value and turnover, and are, therefore, considered to be the backbone of growth and development of a national economy. Their role is particularly important in countries in transition which are faced with problems of high unemployment, low level of economic activity, insufficient competition and lack of investment, and where large inefficient state-owned enterprises are still present. As a reliable source of employment, small and medium-sized enterprises have an important social role in absorbing surplus labour generated in the processes of transition and ownership transformation of state-owned and socially-owned enterprises.

Basic characteristics of small and medium-sized enterprises and entrepreneurs, primarily referring to their size, flexibility, propensity for innovative and risky ventures, and greater opportunity for specialization, enable these companies to adapt much easier than large business systems to continuous changes in consumer demand and business conditions in the global market. In this way, SMEs encourage the strengthening of competition, which results in the improvement of the quality of products and services and lower prices, innovations and development of new technologies, and the growth of the national economy in general.

Survival, growth and development of small and medium-sized enterprises are primarily determined by funding opportunities from favourable sources. Limited access to the sources of finance, both on the money market and the capital market, especially in terms of prices and conditions of use, is perhaps the most important feature and the biggest problem of these companies. In an effort to provide the necessary funding

from the most favourable sources, companies face, throughout their existence, the following dilemmas: should the investments and business development be financed from own resources or borrowed; how much capital should be obtained from loans; should the capital be provided by banks and other financial institutions, on the securities market, or by attracting formal or informal investors; and what is the desired capital structure. Depending on the objectives of growth and development, stage in the life cycle, financial status, nature of business activity and investment structure, the stability of cash flows, the relationship to risk management and the availability of certain resources, companies decide to obtain capital from one or a combination of funding sources, while aiming for the optimal capital structure. The number of available sources of financing SMEs is small and they meet their needs for capital much harder than large business systems.

2. LITERATURE REVIEW

In academic circles, it is widely believed that large and foreign banks are generally not interested in investing in SMEs, while on the other hand, small banks which are focused on a specific niche are more motivated to overcome the problems which arise within SMEs. A research conducted by Torre et al. (2010) showed that there are no sufficient arguments for this claim, and that banks believe that small and medium-sized enterprises are highly profitable clients. In addition, regardless of the size of the bank, the practice has shown that they will always strive to maintain long-term relationships with the SME segment, especially when it comes to developing countries where the number of financial sources is limited. Through new technologies, business models and management systems, the banking sector is giving their best to meet the requirements of small and medium-sized enterprises. Financial experts argue that the limits of small and medium-sized enterprises in financial terms are very large and that this represents the main potential of credit institutions. Bankers, through continuous, personalized and direct contacts with SMEs, gather information relevant to the decision to grant loans.

Large banks, as well as foreign universal banks are leaders in the banking industry, as they are operating under the laws of economy of scale. In addition to having developed mechanisms for analysis and control of the clients, the large banks are capable of developing products and services for the specific needs of small and medium-sized enterprises. However, in recent years there has been an increase in number of specialized banks which do business with only one market segment. Torre et al. (2010) state that it appears that, despite the strengthening of relations between banks and companies, there are still limited opportunities in developing countries for key products, such as loans secured by adequate collateral, and loans that have long-term fixed interest rates indexed in the local currency.

Hanedar, Broccard and Bazzana (2013) have conducted a research on the characteristics of the collateral of small and medium-sized enterprises in developing countries. Regarding the type of collaterals, the results show that the specific features of a loan applicant are much more important than the characteristics of the country they come from. These authors emphasize the importance of credit risk which a specific loan applicant brings, as well as the level of transaction costs compared with the characteristics of the underlying collateral. Menkhoff et al. (2012) state that, in developing countries, companies are less interested in loans that require collateral. The reason for this lies in the fact that they do not have enough high-quality collateral, and that they have access to relatively expensive sources of funding and insufficiently attractive credit terms.

The World Bank has conducted a research on the business environment and the performance of small and medium-sized enterprises in Eastern Europe and Central Asia. The results show that high demands for collateral are the third factor influencing the decision of the company not to apply for loan financing. The first two reasons are related to high interest rates and complicated procedures, which are also very time consuming. The results of this study can be found in the Niinimaki (2009) paper. In addition, Berger et al. (2011) emphasize that, in developing countries, it is very difficult to obtain relevant quality assessment of the collateral, and that a high risk occurs due to information asymmetry.

In their research, Bartoli et al. (2013) classify the information that banks use as "hard" and "soft". Hard information includes various quantitative data that banks obtain from the data in the financial reports or collateral offered by the loan applicant as security. Soft information relates to qualitative data, and their main source is the personalized relationship between banks and clients. It goes without saying that the soft information is more difficult to collect and there is a higher probability of errors, but the aforementioned group of authors believes that it is this information that presents a competitive advantage of the small banks relative to the large. They explain this attitude with the fact that small banks are more focused on their clients, that they meet specific requirements better, and that, in this process, they obtain valuable data of insufficiently transparent companies more easily.

3. THE SME BANKING OPPORTUNITY

Even though banks have recognized the need to provide services to small and medium-sized enterprises, studies have shown that, underdeveloped bank services and products are becoming a critical factor for growth and development of SMEs. Bank fees make the business transactions more difficult and, according to the research of the World Bank, even in the developed financial markets, one third of the enterprises define limited financial sources as one of the main problems. As a result, more than half of the companies in the developing countries cannot reach their goals due to financial difficulties. This research has also shown that SMEs, in comparison to large enterprises, use external financial sources less, which increases the costs of their liabilities. SMEs usually use bank loans as the only available financial source. It is much easier for large corporations to decide and finance investment projects through loans.

SMEs are more focused on banks and their services due to the limited options they have to borrow money through alternative channels. They do not have enough capital to finance big projects and cannot participate in the financial market in a way large corporations can. The reason for this is very often the lack of qualified financial experts who would define an adequate financial source structure. Bank loans contribute to the long-term strategies of SME and thus enable the ownership structure to remain unchanged. Another advantage of banking development in the SME section is related to the banking consulting services. SMEs can have benefits such as adequate financial reports, business plan development, as well as the selection of optimal financial sources. Banking consulting services enable SMEs to follow the bank loan contract terms.

It is a fact that banks have greater concerns regarding risk when it comes to investing in the developing countries. The basic reasons for this include: complicated procedures, undefined laws and negative macroeconomic factors. These restraints lead to situations where banks require good quality collaterals, are less interested in financing investment ventures, and are defining high interest rates. All of the above mentioned directly reduce the profitability of SMEs and lead to a great number of uncollectible debts. Governmental interference very often creates competition misbalance and price instability. If regulatory organs and the government of a country recognized the importance of SMEs, they could support them through redefining the legal limits and through export inducement. Although there is no unique solution to boost SME segment, any intervention to improve the market conditions is welcomed.

4. THE BANKING VALUE CHAIN

To frame the discussion of how banks approach the challenge of serving SMEs, we adopt a standard banking value chain framework consisting of five discrete stages and one cross-cutting task. The five stages of this banking value chain are (1) understanding the market, (2) developing products and services, (3) acquiring and screening clients, (4) serving clients, and (5) managing information and knowledge. Cutting across each of these five stages is the ongoing and critical task of risk management. At each stage of the value chain, there are actions and considerations particularly relevant to the SME sector. Each part of further discussed challenges banks face, describes how banks are approaching this stage, and provides examples of leading banks moving toward excellence in SME banking. Table 1 provides a condensed overview of the key activities within each stage of the banking value chain in the context of serving SMEs.

Table 1. SME banking value chain

Risk management →

Understand the SME market →	**Develop products & services** →	**Acquire & screen SME clients** →	**Serve SME clients** →	**Manage Information & knowledge** →
• Define the SME sector • Research SME needs & preferences • Sub-segment the market	• Design & bundle lending and non-lending products • Ensure profitability of product offering • Develop SME-specific lending technologies	• Market product & service offering to clients • Build a growing & diversified portfolio • Distinguish profitable from unprofitable prospective clients	• Meet the needs of existing clients • Cultivate new business through cross-selling •Use teams organized for front & back-end servicing • Monitor loans	• Model & manage risks using portfolio data • Use current customer data to adapt service approaches • Analyze & respond to profitability data at segment, product & client level

(Source: World Bank group, 2010)

According to World Bank group (2010), highlighted observations from the five value chain stages are: understanding the market is critical and serves as a foundation to being able to address the unique needs of SMEs, nonlending products should not be overlooked, as they may generate more revenues than SME loans, a bank's current portfolio is a critical potential source of new business, segmenting service approaches (i.e., the level of relationship management by client value) can help banks balance customer service and operating cost concerns, and effective information management means knowing how to maximize the use of IT systems.

5. CHALLENGES AND APPROACHES ALONG THE BANKING VALUE CHAIN

Risk management is always one of the most difficult tasks in the banking industry, especially when you take into account the existence of all the informational asymmetries in the SMEs banking sector. Although a bank is faced with credit, market, strategic and operational risks, the most important ones to mention here are the credit risk and the risk of high costs of providing services. The credit risk is related to the bank`s inability to collect the debt and the interest within the agreed time. Due to the limited information sources, banks require additional insurance such as different collaterals whose value depends on the assessed risk and the amount of the wanted resources. In the emerging markets more than 80% of the loans for the SMEs are insured (Beck et al., 2008). A bank encounters costs inefficiency because there is no unique model of financing identical for every SME. Corporations are clients whose transactions have great value for the banks. On the other hand, SMEs demand more transactions of a lower value. If you add consulting services, assessments, specific requests of a SME, it is clear why banks often have high costs and lower profits when investing in SME segment. There is, however, a great number of ways to overcome these problems. In the table 2 some of the key steps and approaches for managing the above mentioned risks are given.

When considering risk management strategies more attention should be paid to the occurrence and the role of uncollectible debts. It is crucial to recognize the loans which are very likely to become bad debts. Proactive solutions reduce the costs and ensure a better bank portfolio.
These proactive strategies include:

- quick reactions,
- timely and frequent communication with clients and
- minimizing the credit risk.

The steps bank will take depend on the informational system the bank is using, as well as on recognizing the first indicators of credit risk appearance. Some of the basic indicators of the credit risks are irregular payments, frequent changes of the loan terms, unusually high interest rates, incomplete documentation collected by a client, poor quality collaterals, lack of reports and cash flow forecasts, as well as the client`s reliance on non-renewable sources. Taking all these into consideration, banks are required to control the situation and thus prevent the losses.

The first stage of the banking value chain is the adequate understanding of the market needs. In order to diversify their portfolios, banks need to analyze the market and client`s preferences constantly. SMEs on the Eastern European territory do not use bank loans as a way to finance their business as much as they are able. The strategy to be used on this territory should be significantly different from the one used on the developed financial markets. Even when they choose the market segment to invest in, banks should define the annual range of services they will provide and their conditions. The segmentation of the SME market is very demanding and important because, among other things, every firm has its own specific needs. Techniques banks are using in order to research the SME market include the surveys, direct insight into company's business transactions and the interaction with the employees of the particular firm. If the owner of the firm which is in the SME market segment is already the bank`s client, the bank can have the insight into their business transactions and responsibilities. SME can also be a part of a larger corporate chain that a bank cooperated with in the past or still cooperates with at present.

The products and services a bank offers are usually related to the loans and deposit collection as traditional ways of conducting business. In order to expand its market share and strengthen its position on the SME market, a bank has to update its offer and attract new clients.

- The first challenge to face on this market is related to defining the range of products suitable for one particular client. In this process the key role lies in the appropriate communication with the client, which means investing into a loyal and long-standing relationship.
- The second challenge is related to the overall profitability that a bank realizes through its services, since the bank`s politics regarding the costs influences the SME segments.
- The third challenge is about balancing the market offer increase and recognizing bank`s limits. The experience in banking has shown that some banks would take high risks when financing SMEs

without having adequate collateral on the other side. If this kind of contract is made with several clients, diversification is achieved, but in case when the number of unsecured loans is getting disproportionately higher, especially during the expansion period, the bank loses control and this can lead to losses. Price, contract terms and monitoring mechanism have to be aligned in order to have a good estimate of the costs and the risk level. Banks will have exceptional results in the process of designing and selecting the products they offer only if they are certain that their offer is cost-efficient and if they can recognize the moment when providing their services is no longer profitable.

Table 2. Common approaches to risk management

	Risk management →				
	Understand the SME market →	**Develop products & services** →	**Acquire & screen SME clients** →	**Serve SME clients** →	**Manage Information & knowledge** →
Approaches to managing credit risk	• Quantify risks in target market by leveraging existing research & other bank data • Sub-segment the SME market by risk profile • Enhance predictive capabilities by gathering information on local SME success factors	• Develop loan pricing models that match client risk profile • Incorporate innovative forms of collateral, such as accounts receivable • Prioritize role of non-lending products in establishing customer relationship & providing predictive data	• Lend to current clients first, learning from portfolio information • Use internal rating & scoring methods to assess loans • Separate sales from credit approval for more rigorous underwriting	• Dedicate staff to spot signs of SME default early • Provide advisory services to assist SMEs in cash flow management	• Establish centralized teams to monitor loan data for risks & early warning signs & to incorporate data into improved credit policies • Use portfolio data to customize models for statistical credit scoring
Approaches to managing risk of excessive cost to serve	• Inform pricing & operational approach by understanding level of unmet SME demand • Segment the market in order to identify & limit effects of cost drivers linked to SME characteristics	• Use sophisticated but standardized products to minimize transaction costs • Increase the overall value of each SME client by offering & building a wide variety of products & services	• Focus customer acquisition on clients “close to” the current portfolio • Separate business development from relationship management for efficiency • Use automated screening processes to reduce underwriting costs	• Dedicate processes & staff to SME segment to streamline operations • Use direct channels like branches & call centers to reduce relationship management cost • Adjust level of personal service to SME size or value	• Enhance profitability analysis capabilities to disaggregate revenue & costs by key units (branch, product, client) • Apply cost-saving innovations discovered at branches and learn from it

(Source: World Bank group, 2010)

The main challenges a bank faces when attracting new clients include cost efficiency of the marketing strategy the bank is conducting, as well as the credit risk management which is done through an effective analysis and through recognizing the profitable clients in spite of insufficient information. Majority of SMEs cannot recognize the benefits of using bank services due to the lack of knowledge and information, and because of this the firms are reluctant to cooperate with bank sector, especially in the developing countries. This problem can become more complicated if the credit bureau cannot find any relevant historical data on the business transactions of the particular firm. Successful banks overcome these problems through

benchmarking process and through conducting proactive strategies and developing a great number of communication channels through which they try to gain insight into the client`s real state. Banks will profit if they can recognize the needs of the current clients and adjust their offer accordingly. In order to diversify their portfolio, developed banks adopt the concept of “one stop shop”, which implies having a wide range of different services in one financial institution.

Long-term cooperation with clients from the SME sector provides a stable income with the tendency to increase and is an excellent source of desired information. However, banks are faced with the risk when an individual approach to a different company leads to high operational costs and this can put the investment in question. Bank has priorities when choosing clients for approving the loan. This very often leads to loss of client`s trust, higher interest rates and lower sale possibilities. Clients very often do not want to accept the loan conditions which are barely profitable for the banks. The process of collecting all the necessary documents is not easy for both the bank and the clients and many of them are not ready to wait patiently for the loan to be approved. Banks serving SMEs have found ways to cost-effectively meet and even capitalize on the unique demands of SMEs. They do this by using direct delivery channels, segmenting and redefining relationship management, and turning demands into opportunities through cross selling.

The fifth stage of the banking value chain is related to the information and knowledge management in banks. SME banking is a relatively young and dynamic industry and it is clear why experience has the crucial role. Banks that invest into information technology have better chances to have a profitable and safe business, as well as to maintain long-standing relationships with clients. This effective information and knowledge management is the key to improving relations with clients. Two main challenges to managing information and knowledge include developing the infrastructure (tools and systems) to collect and analyze information, and developing the capacity (skills and processes) to turn information into knowledge and adjust operations accordingly. In order to use the knowledge potential, a bank should have a portfolio check and risk analysis. Client relations management and profitability analyses are crucial steps for running a good business.

6. BANK APPROACHES IN SME MARKETS

Each bank has different possibilities and capacities for achieving strategic goals. Bank performances primarily depend on the way that income is generated (the profit rate), required quality of assets (the risk level), and defined level of management efficiency.

In order to make an adequate profit with the cost-efficiency and risk minimization banks should, in the first place, define a strategy that suits their capacities and the chosen market segment. Successful banks focus on the business structure, human resources and software support. At the same time, the bank management is in charge of the implementation of the essential procedures and processes, as well as their constant control and coordination. The ordering of above-mentioned activities is significant for the banks that enter the SME market for the first time. The SME banking requires the realization of scale economy and greater selling power of employees in comparison to the corporate banking. On the other hand, it means even more detailed processing of claims and risk analysis when defining the offer that refers to consumer banking. The process of corporate governance and organization is a crucial element, especially when positioning the bank on the global market.

One of the crucial economic goals of the developing countries is the development of banking that provides services to small and medium-sized enterprises. Small and medium-sized enterprises provide a healthy economic system, contribute to creating new business opportunities, employ a large number of people and are responsible for the increase in gross national product. Due to their contribution to the economic diversification and social stability, their role in the market is rather significant. Limited market and capital access increase financial expenses and has a negative influence on the productivity and competitiveness of enterprises.

7. CLOSING REMARKS

In recent years, financing of small and medium-sized enterprises has attracted a lot of attention and has become one of the main topics for economists and regulators who are working on economic and financial development strategies. One of the reasons for the great interest in this segment is the fact that most businesses are small and medium-sized, and they employ a significant number of people. In addition, practice has shown that it often happens that small employers eventually become large. Furthermore, they are necessary for further economic prosperity. The majority of banks have organized a special department for cooperation with the SME segment, not only in the field of credit, but in light of the various advisory roles which banks can offer as one of their services. Since Serbia is extremely bank-centered country, it is clear that products and services offered by banks should be constantly innovated and thus contribute to the development of small and medium-sized enterprises which have limited possibilities for borrowing through

alternative channels. The aim of this paper is to stimulate discussion and further research in the field of small and medium-sized enterprises, particularly in the context of improving their performance through external financing in the form of bank loans.

Abstract: *If one takes into account consequences of excessive use of natural resource, the need for its sustainable use is understandable. Bearing in mind increasing importance of non-wood forest products (NWFPs) for sustainable use of natural resources, and for revenue generating, the role of entrepreneurs and small and medium enterprises (SMEs) in this sector also increases. The aim of this research is to gain knowledge on the organization of the process of NWFPs selling in SMEs in Central Serbia. Research was conducted in two phases. In the first phase, 91 representatives of SMEs (ΣSME) were surveyed and in the second, survey was conducted with representatives of 19 leading enterprises (LEs). The results are showing that process of NWFPs selling is present in most of ΣSME and all LEs. Wholesale is present in most ΣSME and LEs, which is opposite to retail. The most present form of wholesale is to "foreign buyers", although in the most ΣSME is also present selling to "other processors". The most common export destinations (ΣSME and LEs) are countries of EU, mainly Italy and Germany. The analysis indicated specific problems in organization of selling in these SME. Hence, recommendations for improvement are given.*

Keywords*: organization, selling, small and medium enterprises, non-wood forest products, forestry*

1. INTRODUCTION

The role of **small and medium-sized enterprises** (SMEs) in the economic development is of increasing importance and particularly challenging in rural areas, which are less attractive for the development of entrepreneurial activities than urban and semi-urban (Niskanen et al., 2007). Forest products (wood and non-wood) have a particularly important role in the development of rural areas (López-Feldman, 2014). In this paper, as non-wood forest products (NWFPs) are considered: mushrooms, medicinal and aromatic plants (MAP), wild berries and other forest fruits (WBFF), i.e., products that can be quite quickly and successfully collected in nature, processed and sold. These characteristics, and increasing demand for NWFPs[1] in recent years (Booker, Johnston, & Heinrich, 2012; Pettenella, Secco, & Maso, 2007), make these products extremely attractive to private entrepreneurs.

Collection, purchase, processing and **selling of NWFPs in Serbia** have a long tradition. In the period after Second World War until the 1990s, revenues from NWFPs were significant (USAID, 2008; Donnelly, Helberg, 2003). Serbia was, until 1992 "*...one of the largest exporters of medicinal plants in South Eastern Europe ...*" with "*... about 6000 t of raw materials and sales of about 11 million $*" (Turudija-Ţivanović, 2010, p 68). However, collection and trade in NWFPs were centralized at that time, because the sector was dominated by a small number of state enterprises. Attempt of privatization of these enterprises was mostly unsuccessful. This, in combination with all the economic events during the 1990s, has led to fact that, today, this sector is largely unorganized. As a consequence, NWFPs are marketed mainly as unprocessed raw materials or semi-finished product (Donnelly & Helberg, 2003; USAID, 2008).

However, after 2000 activities in MAP market gradually were revitalized i.e. "*…new enterprises are being established, contacts with old customers are renewed and new ones gained, which have resulted in increasing export of herbal raw material*" (Turudija-Ţivanović, 2010, p. 68).

In accordance with the increasing importance of NWFPs for achieving the objectives of multifunctional forest management (Wang & Wilson, 2007), as well as for revenue generating, the role of SMEs engaged in the procurement, processing and selling of NWFPs (NWFP-SMEs)[2] increases.

[1] According to data of World Health Organization (WHO), "*…the demand for medicinal plants is approximately $14 billion per annum, and growing at the rate of 15–25% annually. The WHO estimates that by 2050 the trade will be up to US$ 5 trillion*" (Booker et al., 2012, p. 625).
[2] In support of this goes the fact that, e.g. "*…MAP market is often dominated by SMEs*" (Booker et al., 2012, p. 632).

Results of previous studies indicated several types of NWFPs selling: directly marketed products[3], selling of fresh and semi-products, and selling of final products (USAID, 2008). This research also shows that "...*only one-third of fresh and semi-products goes to final processing, while the majority is sold via wholesalers and retailers to consumers (domestic or foreign) and to foreign processors*" (USAID, 2008 p. 19).

Studies conducted in Central Serbia showed that "...*the most common way of selling is wholesale, i.e. it is only exports*" (Nonić, Rankovic, & Nedeljkovic, 2013, p. 151). The reason for that is, primarily, unorganized NWFP sector, but also underdevelopment of the domestic market (Nedeljković, Nonić, Ranković, & Mandić, 2012; Nonić et al., 2013; Turudija-Ţivanović, 2010).

The need for this research comes from the lack of comprehensive knowledge on the characteristics of selling and its organization in NWFP-SMEs. In previous studies were primarily analysed:

- indicators related to the selling of only one type of NWFPs (but not from an organizational perspective);
- all business entities that operate in this sector (not only SMEs);
- only one of the sub-processes within the process of selling.

In this paper are presented and analyzed results related to all NWFP-SMEs (ΣSME), and selected leading enterprises (LEs) in Central Serbia, whose representatives participated in the study.

In accordance with the previous, the **aim** of this research is to gain knowledge on the organization of NWFPs selling in SMEs in Central Serbia[4]. The **objects** of research are sub-processes in NWFPs selling (retail and wholesale). The **purpose** is to provide recommendations for improvement of NWFPs selling in SMEs.

2. METHODS

Methods of analysis and synthesis, comparative, and statistical method are applied. Partial structural analysis (Nonić et al., 2013), was used in order to study organization of selling within NWFP-SMEs. Method of synthesis was used for drawing conclusions and giving recommendations for improvement of organization of NWFP selling. The comparative method was applied to determine similarities and differences in the organization of selling in ΣSME and LEs.

"Door to door" survey (Aker, Kumar, & Daj, 2008) was used as a research **technique**. The survey was conducted during 2011 and 2012, within 17 forest areas (FAs)[5] in Central Serbia. Distribution of the analyzed enterprises in forest areas is shown in Figure 1.

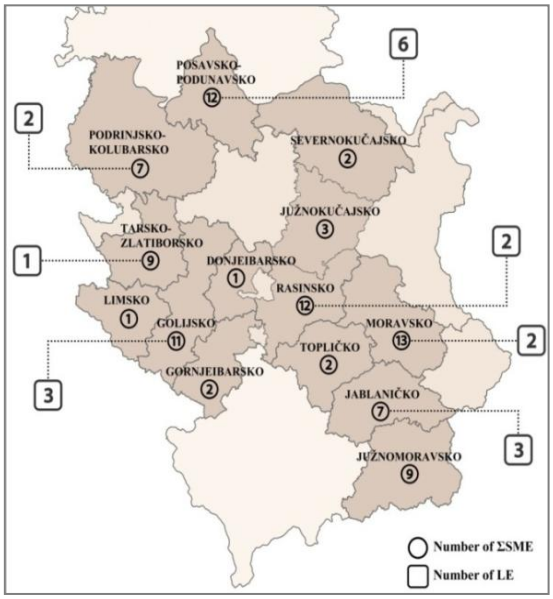

Figure 1. Distribution of ΣSME and LEs in forest areas

[3] Research has shown that about 2% of NWFP collectors sell products directly to consumers, mainly at local green markets and road stalls (USAID, 2008).

[4] The term "central" Serbia refers to the territory of Serbia, without AP Vojvodina and Kosovo and Metohija.

[5] Detail information about forest areas in Serbia can be found in Law on forests (2010) and professional literature (see Aleksić, Stingić, & Milić, 2007). On FAs which were included in the research, state forests are managed by the State Enterprise "Srbijašume", which also performs extension service in private forests.

Data were **collected** in two phases. In the first phase, representatives of 91 NWFP-SMEs in Central Serbia were surveyed. Representatives of 19 LEs were surveyed in the second phase. LEs were selected on the basis of pre-established criteria[6], as "best practice" examples in: i) the organization of all NWFPs-related business activities and ii) business management.

In the first phase of data collection, the questionnaire consisted of 65 questions, and in the second, there were 40 questions. In both questionnaires, there were open- and close-ended questions, where close-ended were with multiple-answer (one or more choices), and Likert scale. For the purposes of this paper, only questions related the organization of selling in ΣSME and LEs were selected from both questionnaires.

Data processing was performed in the statistical program SPSS ver. 20. Bearing in mind that all variables in questions selected for this paper were categorical (discontinuous), frequency analysis was used.

3. RESULTS

Within the results are presented and analyzed data related to the organization of selling in ΣSME and selected LEs:

- share of selling (retail and wholesale);
- organizational forms of selling (retail and wholesale);
- organizational forms of NWFP transport (to customers);
- exports destinations;
- attitudes of respondents toward NWFP market;
- attitudes of LEs representatives toward the improvement of NWFP selling.

3.1. Analysis of organization in the selling of NWFPs in ΣSME/LEs

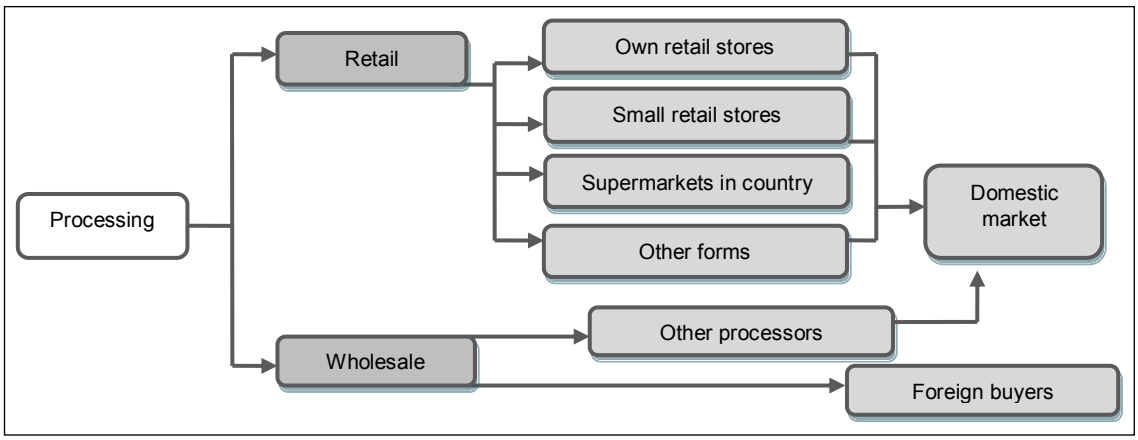
Share of selling, retail and wholesale in ΣSME and LEs is shown in Table 1.

Table 1. Share of NWFP selling in ΣSME/LEs on the territory of Central Serbia

Process / sub-process	ΣSME	LEs
Selling	68.1%	100%
Retail	8.8%	15.8%
Wholesale	96.7%	100%

Selling is present in more than ⅔ of ΣSME (69.2%), as well as in all LEs. Also, NWFPs wholesale is present in dominant share of ΣSME (96.7%) and all LEs. Retail is present in lesser extent (only 8.8% in ΣSME and 15.8% in LEs), which indicates that selling strategies of NWFP-SMEs are not focused on retail, but on other business subjects.

In Central Serbia are present different forms of **organizing of NWFP selling** in SMEs (Figure).



[6] The criteria were: 1) criteria prescribed by the *Law on accounting and auditing* from 2006 (number of employees, total income and value of assets); 2) characteristics of the company (all NWFPs-related business activities, quantity of purchased products, etc.; 3) general impression of researcher (method of observation) on advanced business activities (Nonić, Nedeljković, & Jovanović, 2012).

Figure 2. Forms of organizing of NWFP selling in ΣSME/LEs

Retail can be organized through:
- own retail stores;
- small retail stores;
- supermarkets in country;
- other forms.

Wholesale is done in two ways:
- foreign buyers;
- other processors.

Share of specific forms of NWFPs selling in ΣSME/LEs is given in Table 2.

Table 2. Share of specific forms of NWFP selling in ΣSME/LEs in Central Serbia

Form of selling		ΣSME	LEs
Retail	Own retail stores	4.4%	5.3%
	Small retail stores	3.3%	5.3%
	Supermarkets in country	4.4%	5.3%
	Other	11%	5.3%
Wholesale	Foreign buyers	**61.5%**	**100%**
	Other processors	**53.8%**	31.6%

In **NWFPs retail** are, mostly present "other forms" (11% in ΣSME primarily, through sale to labour unions, while 5.3% in LEs and mostly, catering enterprises). A small number of analyzed enterprises have own retail stores (4.4% in ΣSME and 5.3% in LEs), or they sell products to supermarkets in the country (3.3% in ΣSME and 5.3% in LEs).

The most common form of **NWFPs wholesale** is selling to foreign buyers (dominant in ΣSME-61.5% and in all LEs). The reason for this is mostly, huge demand and quality of these products from Serbia. In terms of selling to foreign buyers, 29.7% ΣSME and 47.4% LEs, only exports, with no selling on the domestic market.

Selling on foreign markets can be organized differently (sale agents, offices abroad, etc.). Representatives of all LEs noted that sale on foreign markets is organized in cooperation with regular customers, with whom they have direct contact and long-term cooperation.

In more than ½ ΣSME (53.8%) and about ⅓ LEs (31.6%), wholesale is also done to other processors, which, after additional processing, sell NWFPs.

In all LEs selling is arranged from headquarters, and products are sold from processing facilities[7]. Also, most of these enterprises sell to known customers, with whom they have long-term cooperation.

As part of organizing of NWFPs selling, **transportation** to the place of delivery, or customers, can be:
- own;
- organized by customers;
- engagement of transport enterprises.

Share of specific forms of NWFPs transport in ΣSME/LEs in Central Serbia is given in Table 3.

Table 3. Share of transport forms in ΣSME/LEs in Central Serbia

Form of transport	ΣSME	LEs
Own	45.6%	57.9%
Organized by customers	**66.7%**	52.6%
Engagement of transport enterprises	23.3%	47.4%

In most ΣSME (66.7%), NWFPs transport is organized by customers. On the other hand, in LEs are present all three forms, to approximately same extent, but organization of own transport (57.9%) stands out. This

[7] Only representative of one LE, located at Rasinsko FA, stated that, if "*...no processing is done, then goods are directly sold from purchasing stations*".

especially relates to the transportation to buyers on the domestic market, which is, mainly, performed by their own means of transport.

3.2. Analysis of export destinations

Export destinations of NWFPs are shown in Figure .

	Italy	Austria	Germany	Switzerland	France	Western Balkans countries	Canada	USA	Australia
ΣSMEs	64,3%	30,4%	69,6%	26,8%	42,9%	21,4%	5,4%	5,4%	5,4%
LE	63,2%	21,1%	68,4%	15,8%	31,6%	21,1%	10,5%	10,5%	5,3%

Figure 3. Share of ΣSME/LEs in export destinations of NWFPs

NWFPs are usually exported to Germany (69.6% in ΣSME and 68.4% in LEs) and Italy (64.3% in ΣSME and 63.2% in LEs). Important export destinations are also France (42.9% in ΣSME and 31.6% in LEs), Austria (30.4% ΣSME and 21.1% for LEs), and Switzerland (26.8% in ΣSME and 15.8% in LEs).

In addition, NWFPs are exported in some countries of the Western Balkan region (WBR)[8] (21.4% in ΣSME and 21.1% in LEs), in Canada and USA (each 5.4% in ΣSME and 10.5% in LEs), and Australia[9] (5.4% in ΣSME and 5.3% in LEs).

There are differences in relation to the export destinations of **certain types of NWFPs** (Table 4). Only data for enterprises (ΣSME/LEs) which business activities relate to one type of NWFPs[10] (mushrooms, MAP or WBFF) were taken into account during this analysis.

It was found that the most important export destinations of certain types of NWFPs are:
- mushrooms: Italy (81.3% in ΣSME and 100% in LEs) and Germany (68.8% in ΣSME and 100% in LEs);
- MAP: WBR (85.7% in ΣSME and 100% in LEs) and France (57.1% in ΣSME);
- WBFF: Germany (80% in ΣSME and 100% in LEs).

Table 4. Share of ΣSME/LEs to export destinations for specific types of NWFPs

Product / State	Mushrooms		MAP		WBFF	
	ΣSME	LEs	ΣSME	LEs	ΣSME	LEs
Italy	**81.3%**	**100%**	28.6%	–	40%	50%
Germany	**68.8%**	**100%**	42.9%	33.3%	**80%**	**100%**
Austria	31.3%	–	14.3%	–	20%	50%
France	43.8%	–	**57.1%**	–	40%	–
Switzerland	37.5%	50%	–	33.3%	–	–
USA	6.3%	–	14.3%	–	–	50%
Canada	–	–	–	–	–	50%
Australia	–	–	14.3%	–	–	–
WBR	6.3%	–	**85.7%**	**100%**	20%	–

[8] Term WBR here refers to some former Yugoslavian republics (BiH, Croatia, Macedonia, and Montenegro).
[9] It is interesting to emphasize that one enterprise from Posavsko-podunavsko FA, beside export to countries of west and north Europe, sell products in Japan.
[10] 23 ΣSME and 2 LEs are engaged only in mushrooms, 10 ΣSME and 3 LEs only in MAP, and 12 ΣSME and 2 LEs only in WBFF business.

For ΣSME, other countries are not quite important export destination, while for LEs, as significant export destinations, in terms of the share of the enterprises, stands out Switzerland (with 50% for mushrooms) and Italy, Austria, Canada and the United States (all with 50% for WBFF).

3.3. Analysis of attitudes of representatives of ΣSME/LEs

Despite the smooth sale of products, most of representatives of ΣSME (70.3%) and LEs (63.2%), believe that **NWFPs market**, in this moment, is not stable enough.

As reasons for the instability of the market, representatives of ΣSME, stated: "*impact of the global economic crisis*", "*dependence on weather conditions*" and "*insufficient number of collectors*". These reasons influence, on the one hand, decrease in the purchasing power ("*impact of global economic crisis*"), and, on the other hand, the amount of available NWFPs, i.e., market of raw materials ("*dependence of weather conditions*" and "*insufficient number of collectors*"), despite the high demand for final products for the end-consumer.

According to the attitudes of representatives of LEs, beside above mention facts, reasons for the instability of the market are: "*lack of organization of NWFPs sector",* "*problems with payments*", "*existence of a grey market*", "*unfair competition*", "*price fluctuations*" (often on a daily basis), etc.

In terms of **improvement of selling**, approximately ⅓ representatives of LEs (31.6%) are satisfied with existing organization and did not indicate need for its improvement. Their attitudes are claimed with fact that they "...*can respond to all customer requirements, if there are enough NWFPs in nature*", and that they have "...*permanent customers abroad, with whom successfully cooperate*".

However, most representatives of LEs (68.4%) believe that the organization of NWFPs selling can be improved through:

- "…*opening offices (branches) in some EU country*…";
- "…*engaging permanent representatives abroad*…", through which they "…*will always be up to date with prices, type of goods that are required, etc.*…";
- increase in the number of employees, so, they could quickly respond to customer demands;
- expansion of the distribution network, "…*visiting customers*…", i.e. making direct contact with them;
- associating, which would allow "…*to act with unit price from Serbia on foreign market*…".

Representative of one LE from Posavsko-podunavsko FA believe that possible solution could be "...*establishment of one more enterprise, which will deal with transport*". This is because "...*it is absolutely not profitable that vehicles which transport the goods to a foreign buyer return 'empty' to Serbia*". A similar proposal comes from representative of the other LE from the same FA, who stated that they should "...*get their own transport vehicle (truck), with which they would drive the goods alone*", because "...*this is the best way for foreign buyer to be satisfied*". Purchase of new vehicles, as believes representative of one LE from Rasinsko FA, can support improvement of organization of selling, because, in this way, they "...*would not depend on third parties*," as they do now.

4. DISCUSSION

When it comes to **forms of organization** of retail, most ΣSME and LEs do not have their own retail stores, nor do they sell products to small retail stores and/or supermarkets in the country. Following causes of the lack of direct selling to consumers are distinguished: low finalization of products (primarily mushrooms and WBFF), insufficient consumption of NWFPs in Serbia and underdevelopment of the domestic market (Nedeljkovic et al., 2012). Also, the cause may be the lack of sufficient human and technical capacities. In addition, when products are not sold directly to end consumers, but through third parties (retail chains), business success also depends on the acceptance of business partners, their support and quality of mutual cooperation (Chris Lin & Chang, 2012).

In terms of wholesale organization, usually it is selling to foreign buyers, i.e. exports, which is understandable if one bears in mind, that in our case, e.g. "...*market of MAP is not sufficiently developed*" (Turudija-Ţivanović, 2010, p. 78). However, it is evident that export opportunities are not fully exploited[11]. In order to achieve competitive advantage in selling on foreign markets, especially to EU, less successful enterprises

[11] Results of previous studies indicate that, in terms of MAP "…*Serbia is the marginal supplier to the EU, because Serbian exports accounts for less than two percent to the EU imports of this product group*" (Zarić, Deljanin, Petković, & Beatović, 2012, p. 477).

need to implement business strategies of leaders in the markets of the „old" EU member states, which are aimed at highlighting the product quality, and not on the price (Glob & Podnar, 2007).

Bearing in mind the fact that exports is risky business activity (D'Angelo, Majocchi, Zucchella, & Buck, 2013), it is understandable that all analyzed LEs organize selling on foreign markets in cooperation with long-time customers. This type of exports organization, with presence of adequate resources, provides LEs opportunity to "...*successfully overcome obstacles to foreign development and to manage a process of international growth*" (D'Angelo et al., 2013, p. 82).

Results of previous research show positive relationship between the use of business networks that consist of business partners and customers, and reduce the uncertainty on foreign markets. Those networks provide necessary information and knowledge, understanding of customer needs and reduce the risk of failure (Helm & Gritsch, 2014).

In Serbia, the most ΣSME sell products to other processors, which, after additional processing, sell NWFPs to wholesalers or retailers. On the other hand, this type of selling is not present in most of LEs. Selling to other processors indicates lack of product finalization. This was confirmed by previous studies, which emphasize that NWFPs from Serbia are, on foreign market, mostly sold as a raw material or semi-finished products (Nonić et al., 2013; USAID, 2008).

Transportation of NWFPs to the delivery point, in ΣSME, is usually, organized by customers, while in most LEs is present own transport. Optimal organisation of transport activities is of special importance for enterprises engaged in food business (Bosona & Gebresenbet, 2011). Because of this, it is needed, within each enterprise, to well consider which type of transport is mostly suitable to particular situation.
