The most important **export destinations** are countries of central, west and south Europe (Austria, France, Germany, Switzerland, Italy, etc.), between which particularly stand out Germany and Italy. Similar results occurred in previous studies, which indicated that the most common export destinations are EU countries, as well as Switzerland, but also United States (Nonić et al., 2013; Sitta & Floriani, 2008; Zarić et al., 2012).

Most representatives of ΣSME and LEs believe that NWFPs **market** is not stable. Market instability is caused by various factors: economic (e.g. the global economic crisis, price fluctuations[12], insufficient development of the domestic market), ecological (e.g. dependence of yield on the weather conditions, the vulnerability of biodiversity) and social (e.g., decreasing purchasing power, insufficient number of collectors). Instability of the market has been marked in previous studies as one of the challenges for performing successful selling (Chris Lin & Chang, 2012). However, it is emphasized that "...*addressing market needs leads to increased acceptance by consumers and retailers*" (Chris Lin, & Chang 2012, p. 91), regardless of its stability.

5. CONCLUSIONS

Conducted analysis of organization of NWFPs selling in SME has led to following **conclusions:**

- selling is present in most studied enterprises, where:
  - retail is not performed in the biggest number of ΣSME and LEs;
  - wholesale is present in most of ΣSME and LEs;
- in relations to forms of retail organization, it can be concluded that:
  - most of ΣSME and LEs do not have their own retails nor do they perform selling through small retail stores/supermarkets in the country;
  - most common form of organizing of this activity in ΣSME is "other forms", primary selling to labour unions;
- in relations to forms of wholesale organization, it was concluded that:
  - in ΣSME, two forms are the most common: "foreign buyers" and "other processors";
  - in LEs is mostly present selling to "foreign buyers", while small number of these enterprises conduct selling to "other processors";
- transport of products to customers can be organized in three ways ("own", "organized by customer" and "engagement of transport enterprises"), where:
  - in ΣSME, the most common form is "organized by customer";
  - in most LEs is organized "own" transport;
- the most common export destinations, in both ΣSME and LEs are Germany and Italy:

[12] For example, MAP prices on domestic and international market "…*are subject to constant corrections*….", i.e. "…*respecting exchange rate of euro and growth of fuel prices and other inputs*" (Turudija-Ţivanović, 2010, p. 72). But it should be noted that "…*higher price fluctuations are due to the deficit of specific raw material, when seller can achieve much higher price*" (Turudija-Ţivanović, 2010, p. 72).

    - mushrooms are, mostly, exported to Italy and Germany, MAP in WBC and WBFF in Germany;
- most representatives of ΣSME and LEs, believe that market of NWFPs is not stable;
- most representatives of LEs believe that there is a need for improvement of organization of selling.

Based on the analysis of results, following specific **problems** in organization of NWFPs selling in SMEs are noticed:

- in relation to organization of retail:
  - insufficient representation of this form of selling, and insufficient cooperation of SMEs;
- in relation to organization of wholesale:
  - high share of selling to "other processors".

According to this, as well as to the attitudes of LEs representatives, following **recommendations** are defined for improving the process of selling:

- networking of SMEs, though creation of "business networks" in selling and joint cooperation with customers, within the supply chain of NWFPs;
- reduction of presence of selling to "other processors".

If enterprises do not organize own selling, their business success is partly dependent on third parties, entrusted with these activities. For this reason, SMEs could establish business networks in supply chains for joint cooperation in the selling, and for entering into certain markets. Risk to enter into the domestic market is connected with its insufficient development. On the other hand, foreign markets of NWFPs have specific requirements in relation to quantity and quality, which NWFP-SMEs from Central Serbia can hardly meet. In addition, there is competition from other EU countries (Romania, Bulgaria, Poland, etc.), which, because of EU membership, have easier access to the major markets for NWFPs.

Recommendation that relates to the reduction of presence of selling to "other processors" means greater product finalization, which will also have positive impact on increasing income of the enterprises.

Abstract: *In order to increase the contribution of forestry sector to economic and social development, it is necessary to support the establishment and development of small and medium-sized enterprises (SMEs) which business is based on wood and non-wood forest products (NWFPs). To properly plan development of the private forestry sector, it is also necessary to establish the basic structure and forms of SMEs for procurement, processing and sale of NWFPs (NWFP-SMEs) and their business. In this context, the aim of the research was to determine the characteristics and types of NWFP-SMEs. The study included 91 representatives of NWFP-SMEs in Central Serbia. Analysis of the results showed that, based on the characteristics and activities they perform, there are three types of NWFP-SMEs. Based on the characteristics and attitudes towards additional training, four types of NWFP-SMEs representatives can be distinguished. The results can serve as a basis for further study on types of SMEs and improving the entrepreneurship in NWFP sector.*

Keywords*: small and medium enterprises, entrepreneurship, types, non-wood forest products, forestry*

1. INTRODUCTION

Small and medium enterprises (SMEs) have an important role in every economic sector, primarily due to "*...contribution to social stability and significant fiscal revenues generation*" (Premović, Boljević, & Arsić, 2011). In order to increase the contribution of forestry sector to the economic and social development, it is necessary to support the establishment and development of forest-based SMEs (Ranković, Nonić, Nedeljković, Marinković, & Glavonjić, 2012). To properly plan development of the private forestry sector and ensure the development of SMEs in forestry, it is necessary, in addition to wood products, to pay special attention to non-wood forest products[1] (NWFPs).

Previous research show that entrepreneurs in forestry sector should take into account NWFPs, when exploring new development strategies, as these products provide significant opportunities for additional revenues (Niskanen et al., 2007). In this paper, as NWFPs are considered mushrooms, medicinal and aromatic plants (MAP), wild berries and other forest fruits (WBFF).

Research on SMEs for procurement, processing and selling of NWFPs (NWFP-SMEs) in Serbia argue that structure of these enterprises is very heterogeneous, and production capacities are underutilized and often inadequate. One of the reasons for this may be the lack of adequate support, as it was determined that most of these enterprises do not have sufficient financial resources, nor do they have access to favourable bank loans (Nonić, Nedeljković, & Jovanović, 2012; Nonić, Ranković, & Nedeljković, 2013a).

Results of research conducted in different countries indicate that SMEs need more support in order to enlarge and improve production capacities, obtain necessary technical knowledge and increase profitability (Pettenella, Secco, & Maso, 2007; Uddin et al., 2008). However, in many countries is noticeable lack of support for development of SMEs in forestry and, if support exists, it is often inadequate or poorly targeted (Macqueen, 2007). Therefore, policy-makers may need "*...policies that support the varying needs of different types of entrepreneur, rather than provide broad 'blanket' policies to all types of entrepreneur, irrespective of need or ability*" (Westhead, Ucbasaran, Wright, & Binks 2005, p. 110). For these reasons, it is essential that decision-makers have necessary information about the types of enterprises in the private forestry sector, or in this case, NWFP-SMEs.

In literature, there are several typologies of entrepreneurs (Dowell, Dawson, Fuller-Love, & Hopkins, 2012; Schwienbacher, 2007; Westhead et al., 2005), and SMEs (Andersén, 2012; Franco & Haase, 2013; Swoboda & Olejnik, 2013). Also, some authors have studied types of business strategies, which are not

[1] NWFPs are "*…goods of biological origin other than wood, derived from forests, other wooded land and trees outside forests*" (FAO, 1999).

directly related to SMEs, but can be applied to them (Grant, Cadden, McIvor, & Humphreys, 2013; Löfving, Säfsten, & Winroth, 2014; Miller & Roth, 1994).

Previous studies in private forestry sector in Serbia, have determined several types of classification, in relation to: private forest owners (Nonić, Ranković, Glavonjić, & Nedeljković, 2013); SMEs and entrepreneurs operating with wood products (Ranković et al., 2012); supply chains of NWFPs (Nonić, Ranković, & Nedeljković, 2013b), and the attitudes of representatives of NWFP-SMEs towards the documentation needed for NWFPs collection (Nedeljković et al., 2013).

However, there is a lack of knowledge about the types of NWFP-SMEs and their representatives. For these reasons, the **aim** of the research was to determine the characteristics and types of NWFP-SMEs in Central Serbia[2]. The **purpose** of the research is to create a basis for further research and improvement of the entrepreneurship in NWFP sector. The **subjects** are attitudes of the representatives of NWFP-SMEs.

2. METHODS

Different scientific methods are applied in the paper: statistical, comparative, analysis and synthesis. As research techniques for data collection, “door-to-door" survey was used (Malhotra, 2007). The questionnaire was created as a combination of 65 open- and close-ended questions, divided into six groups. Only those questions that relate to the basic characteristics of NWFP-SMEs and their business, and basic (socio-demographic) characteristics of the respondents, were selected for the purposes of this paper.

During the statistical processing of answers to questions that were continuous variables, descriptive statistics was used, while in the case of categorical variables, frequency analysis was applied. Cluster analysis was used as statistical analysis, which is mainly applied in determining the specific typology in socio-economic studies (Grant et al., 2013; Swoboda & Olejnik, 2013).

For grouping objects into relatively homogeneous groups (so-called clusters), i.e. to determine the types of SMEs and theirs representatives, two-step cluster analysis (Malhotra, 2007) was applied. The criterion for clustering was Schwarz’s Bayesian Criterion (BIC). Two-step cluster analysis allows grouping of categorical, and categorical and non-categorical variables, and does not require prior knowledge on number and characteristics of clusters. Those are determined by the value of BIC and Ratio of distance measures (RDM). The quality of the grouping is determined on the basis of Silhouette coefficient[3]. To test the differences in the obtained (empiric) and expected frequencies[4], χ^2 test for goodness-of-fit was used.

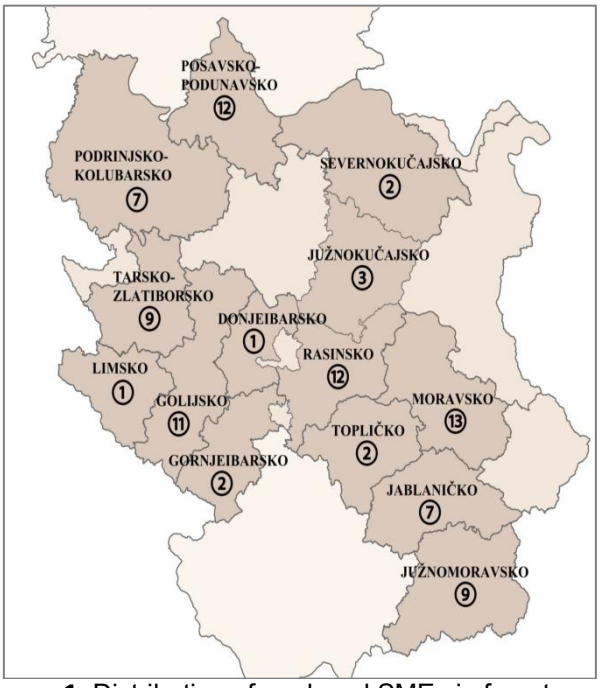

Figure 1. Distribution of analyzed SMEs in forest areas

[2] Term “Central Serbia” refers to the territory of Serbia without AP Vojvodina and Kosovo and Metohija.
[3] If the average value of Silhouette is 0.70-1, quality of data grouping is strong, if >0.50 and ≤0.70, quality is reasonable, if >0.25 and ≤0.50, quality is week, and if ≤0.25, grouping is not statistically significant (Pearson et al., 2004).
[4] In all cases it was assumed that expected (hypothetical) frequency distribution was 50%:50%, i.e. null hypothesis was that all proportions were equal.

Basic information (name, registered office, contact) on NWFP-SMEs, were obtained from internal reports of the Ministry of Environment, Mining and Spatial Planning[5], which was, in the research period (2011-2012), responsible for these tasks. Data collection was conducted with representatives of 91 enterprises (from the total number of 127 SMEs active in the moment of research)[6]. Distribution of these SMEs in forest areas[7] is shown in Figure 1. Sampling was not used in research, i.e. census was conducted because of the small population (Malhotra, 2007).

3. RESULTS

In results are presented and analysed data related to characteristics and types of NWFP-SMEs and its representatives.

3.1. Characteristics and types of NWFP-SMEs

As basic **characteristics of NWFP-SMEs**, in this research are considered (Table 1):

- location;
- number of employees and seasonal workers;
- type of NWFPs;
- transportation equipment and mechanization.

Table 1. Share of NWFP-SMEs in regard to basic characteristic

NWFP-SMEs basic characteristics		**Frequencies** (%)
Location	Rural	**70,3**
	Urban	**57,1**
Number of employees	Up to 10	31,9
	11-50	**49,5**
	51-250	18,7
Type of NWFPs	Mushrooms	**62,6**
	MAP	35,2
	WBFF	**62,6**
Transportation equipment and mechanization	Van with refrigerator	42,9
	Van without refrigerator	**60,4**
	Weighing machine	**95,6**
	Drying machine	**65,9**
	Machine for processing	**75,8**
	Machine for packaging	22.0
	Cold-store	**56.0**

In relation to the location, most NWFP-SMEs are located in urban, but also in rural areas, i.e. there is certain number (27.5%) that is performing business activities in both locations.

Around ½ of NWFP-SMEs (49.5%) has 11-50 employees. Results of χ^2 test for goodness-of-fit show statistically significant difference between these groups (χ^2=13.01, df=2, p=0.00). Most enterprises, in regard to the number of employees, belong to the group of small enterprises[8].

Most NWFP-SMEs (84.6%) hire seasonal workers, whose average number is 10 and maximal 250. NWFP-SMEs have need for hiring seasonal workers because collection, purchase and processing of NWFPs are seasonal activities, mainly preformed during summer and autumn.

When it comes to type of NWFPs, most SMEs (62.2%) are engaged in mushrooms and WBFF business and 35.2% in MAP.

[5] In accordance to Decree on putting under control the use of and trade in wild flora and fauna, all legal entities, engaged in collection of NWFPs for commercial purposes, are obliged to have the permit. The register of these legal entities is kept, based on the data from the permits.

[6] After determining the final number of SMEs that asked for the permit for commercial collection of NWFPs in the period 2007-2010, their liquidity was verified (telephone contact and checking databases of Serbian Business Register Agency and National Bank of Serbia).

[7] Detail information about forest areas are given in Law on forests (2010).

[8] If only number of employees is taken as a criterion, these enterprises, in accordance with the current Law on accounting (from 2013), belong to the category of small enterprises.

Regarding transportation equipment and mechanization, most NWFP-SMEs have van without refrigerator (60.4%) and other equipment, necessary for secondary processing of NWFPs (weighing machine, drying machine, machine for processing and cold-stores).

The oldest equipment, which enterprises purchased at the time of establishment, are drying machines, vans, machines for processing (10 yrs.) and packaging (8 yrs.), and cold (7 yrs.). The average age of weighing machine is smaller (5 yrs.), because they need to be renewed frequently.

Analysed **major characteristic of NWFP-SMEs**[9] business are (Table 2):

- business activities;
- average use of technological capacity;
- working conditions;
- problems in business;
- relationship to investments.

Table 2. Share of NWFP-SMEs in regard to basic characteristic of business

Basic characteristics of NWFP-SMEs business		**Frequencies** (%)
Business activity	Procurement	98.9
	Processing	95.6
	Selling	68.1
	NWFPs main/sole activity	**73.6**
Average utilization of technological capacity	Coldstore	57.6
	Drying machine	74.8
	Equipment for other processing	70.8
Working conditions	Old equipment and mechanization	14.6
	Dependence of weather conditions	**78.7**
	Inadequate legal framework	**70.8**
Problems in business	Unqualified labour	22.0
	Insufficient labour	39.6
	Lack of trainings	14.3
	Unfair competition	**60.4**
	Lack of export	16.5
	Undeveloped national market	39.6
	Insufficient utilization of capacities	27.5
	Payments	39.6
	Clients	9.9
	Cooperation with other enterprises	11.0
	Other	14.3
Investments	Fixed assets of expanded reproduction	**74.1**
	Product finalization	17.6
	Introduction of additional activities	7.1
	Marketing instruments	7.1
	Working assets	9.4

Business activities of most NWFP-SMEs include procurement (98.9%), processing (95.6%) and selling (68.1%). Also, NWFP-related business activities are main or sole activity for around ¾ (73.6%) SMEs.

In analysed enterprises, there is high degree of utilization of drying machine (74.8%) and equipment used for other processing (70.8%), while degree of utilization of cold-stores is slightly less (57.6%).

Respondents believe that working conditions are mostly defined by weather (78.7%), which is understandable bearing in mind that NWFPs yield depends solely on nature and weather conditions. Also, majority of respondents (70.8%) claim that legal framework is inadequate.

Unfair competition is the most important problem in business (60.4% of SMEs representatives). Representatives also think that insufficient labour, undeveloped national market, and payments (each

[9] In relation to legal form, most enterprises are registered as business companies (74.7% as Limited Liability Company and 1.1% as Joint Stock Company). In addition, there are entrepreneurs (22.0%) and cooperatives (2.2%).

39.6%) cause problems in business. On the other hand, the smallest number of respondents believes that problems are caused by clients (9.9%) and cooperation with other enterprises (11.0%)[10].

Most SMEs representatives (74.1%) believe that financial resources should be invested in new equipment, i.e. fixed assets.

Types of NWFP-SMEs were determined based on two groups of variables:
1) basic characteristics (location, number of employees and seasonal workers);
2) SMEs activities.

Three types[11] of enterprises are distinguished based on the characteristics (Table 3):
- "small rural" (50.6%);
- "small urban" (29.9%);
- "medium urban" (19.5%).

Table 3. Types of enterprises in relation to the characteristics

Type of enterprise	Location	Number of employees	Number of seasonal workers
Small rural	Rural	11-50	16
Small urban	Urban	11-50	17
Medium urban	Urban	51-250	133

Most SMEs belong to the type "small rural enterprises", which is understandable, bearing in mind that the activities related to NWFPs, particularly procurement of raw materials, belong to rural areas. This is because NWFPs collection and purchase are performed in villages and their surroundings, which are closer to the forest resources than urban areas.

Results of χ^2 test goodness-of-fit show a statistically significant difference between these types (χ^2=11.64, df=2, p=0.003).

"Small rural" and "small urban" types are very similar (differ only in location). On the other hand, "medium urban" type clearly differs, both in terms of the number of employees and seasonal workers.

Three types of enterprises are determined, based on SMEs business activities[12]:
- SMEs engaged in procurement, processing and selling of NWFPs (64.8%);
- SMEs engaged in procurement, and processing of NWFPs (30.8%);
- SMEs engaged in procurement, and selling of NWFPs (4.4%).

Results of χ^2 test goodness-of-fit show a statistically significant difference between these types (χ^2=50.13, df=2, p=0.0).

The majority of enterprises belong to the type engaged in all three activities. This is understandable if one takes into account the above results, which indicate that procurement and processing are present in almost all studied SMEs and selling in the majority.

3.2. Characteristics and types of representatives of NWFP-SMEs

Following **characteristics of representatives of NWFP-SMEs** were analysed (Table 4):
- position;
- age;
- gender;
- education.

In terms of positions in the enterprise, 69.2% of all representatives NWFP-SMEs are owners and/or managers (27.5% owners, 22.0% owner-managers and 19.8% managers). Presented results indicate that no position prevails. However, results of the χ^2 test goodness-of-fit show a statistically significant difference between observed variables (χ^2=40.31, df=6, p=0.0).

[10] Most respondents believe that unfair competition represents „*...problem in NWFP purchase*", while on the other hand majority emphasize that "*...with other enterprises usually cooperate in selling*".
[11] Silhouette=0.5, BIC=253.87, RDM=1.86
[12] Silhouette=1.0, BIC=55.23, RDM=3.01

Table 4. Share of NWFP-SMEs representatives' in regard to the characteristic

Characteristics		Owner	Manager	Owner-manager	All respondents
		Frequencies (%)			
Position	Owner	100	-	-	27.5
	Manager	-	100	-	19.8
	Owner-manager	-	-	100	22.0
	Employee	-	-	-	17.6
	PR	-	-	-	1.1
	Consultant	-	-	-	1.1
	Other	-	-	-	11.0
Age	18-25	-	-	-	2.2
	26-45	**52.0**	27.8	**55.0**	49.5
	46-65	48.0	**72.5**	40.0	47.3
	More than 65	-	-	5.0	1.1
Gender	Male	**84.0**	**83.3**	**75.0**	**74.7**
	Female	16.0	16.7	25.0	25.3
Education	Secondary school	40.0	22.2	**55.0**	41.8
	High school	28.0	33.3	20.0	22.0
	Faculty	32.0	44.4	25.0	36.3

Regarding gender, representatives of SMEs are mostly males (74.7%). The majority of owners and owner-managers belong to age group 26-45 years.

In relation to education, results of χ^2 test goodness-of-fit indicated no statistically significant difference between education categories[13], i.e. none of them can be described as prevailing.

Following **attitudes of NWFP-SMEs representatives**, towards additional trainings were analysed (Table 5):

- importance of additional trainings;
- previous trainings;
- type of training;
- interest in future trainings;
- type of training required in future.

Table 5. Share of NWFP-SMEs representatives' in regard to attitudes toward training

Attitudes		Owner	Manager	Owner-manager	All respondents
		Frequencies (%)			
Importance of additional trainings[14]	Negative	8.0	11.1	5.0	7.7
	Indifferent	28.0	11.1	15.0	16.5
	Positive	**64.0**	**77.8**	**80.0**	**75.8**
Previous trainings	Yes	**56.0**	44.4	**60.0**	**52.7**
	No	44.0	**55.6**	40.0	47.3
Type of training	Informal	7.1	28.6	25.0	15.2
	Formal	**92.9**	**71.4**	**75.0**	**84.8**
Interest in future trainings	Yes	**80.0**	**72.2**	**80.0**	**79.1**
	No	20.0	27.8	20.0	20.9
Type of training required in future	Entrepreneurship	42.9	30.8	37.5	35.6
	Business administration	42.9	46.2	43.8	43.8
	Management	**57.1**	**61.5**	37.5	**53.4**
	Supply chain management	42.9	38.5	31.3	35.6
	Legislation	42.9	38.5	37.5	35.6
	Professional knowledge on NWFPs	**66.7**	**61.5**	**75.0**	**68.5**
	Other	9.5	23.1	12.5	16.7

[13] Values of χ^2 test goodness-of-fit are: owners-χ^2=0.56, df=2, p=0.76; managers-χ^2=1.33, df=2, p=0.51, owner-managers-χ^2=4.3, df=2, p=0.12.

[14] 5-degree Likert scale was applied for evaluation of additional training importance. In this paper, points 1 (very unimportant) and 2 (unimportant) are shown as negative, 3 (neither important nor unimportant) as indifferent, and 4 (important) and 5 (very important) as positive attitude.

Most respondents have a positive attitude toward the importance of additional training. Also, most of them, except those in the position of managers, have attended some training, mostly formal. The majority of respondents, regardless of the position, showed interest in attending trainings in the future.

In relation to the type of training, 68.5% of respondents believe that they need professional knowledge on NWFP and 53.4% require training in management.

Types of NWFP-SMEs representatives (owner, manager and owner- manager), were distinguished on the basis of two groups of variables: basic characteristics, and attitudes toward type of training.

In regard to characteristics (**Error! Not a valid bookmark self-reference.**), majority of owners (52.0%) and the highest number of owner-managers (45.0%) are "younger secondary school graduates", and 44.4% of managers are "older secondary school graduates". Common characteristics of these types are male sex and secondary education.

Table 6. Share of types of NWFP-SMEs representatives in regard to the basic characteristics

Type[15] of NWFP-SMEs representatives	Owner	Manager	Owner-manager
	Frequencies (%)		
Younger secondary school graduates	**52.0**	-	45.0
Older secondary school graduates	-	44.4	-
Older high school graduates[16]	-	16.7	20.0
Older with faculty	48.0	38.9	35.0

However, results of χ^2 test goodness-of-fit indicated no statistically significant difference between these types (none can be described as prevailing), because:
- for owners, χ^2=0.04, df=1, p=0.84;
- for managers, χ^2=2.33, df=2, p=0.31;
- for owner-managers, χ^2=1.90, df=2, p=0.39.

In regard to attitudes toward type of training (**Error! Not a valid bookmark self-reference.**), following types of NWFP-SMEs representatives are distinguished:
- "professional knowledge on NWFPs" – only professional knowledge of NWFPs, related to the type of product, methods of collection, processing, etc. (75% owner-managers);
- "broad managerial & professional knowledge" – knowledge from the field of management and related disciplines (entrepreneurship, business administration, etc.), and professional knowledge on NWFPs;
- "narrow managerial & professional knowledge" – knowledge from the field of management, and professional knowledge on NWFPs (61.5% of managers);
- "lack of interest in additional training in proposed fields" – no need for additional training from management and related disciplines, nor professional knowledge on NWFPs, but still show interest in additional education (61.9% of owners).

Table 7. Share of types of NWFP-SMEs representatives in regard to the type of training

Type[17] of NWFP-SMEs representatives	Owner	Manager	Owner-manager
	Frequencies (%)		
Professional knowledge on NWFPs	-	-	**75.0**
Broad managerial & professional knowledge	38.1	38.5	25.0
Narrow managerial & professional knowledge	-	**61.5**	-
Lack of interest in additional training in proposed fields	**61.9**	-	-

However, results of χ^2 test goodness-of-fit show that there is no statistically significant difference between these types (none can be described as prevailing, except in case of owner-managers), because:
- for owners, χ^2=1.19, df=1, p=0.28;
- for managers, χ^2=0.69, df=1, p=0.41;
- for owner-managers, χ^2=4.0, df=1, p=0.046.

[15] Owners: Silhouette=0.5, BIC=99.85, RDM=1.81; managers: Silhouette=0.6, BIC=64.50, RDM=1.66; owner-managers: Silhouette=0.5, BIC=87.01, RDM=1.53.
[16] Types of managers and owner-managers "older high school graduates" are 46-65 years old, with high school. The difference is in gender: managers are females and owner-managers are males.
[17] Owners: Silhouette=0.7, BIC=108.87, RDM=4.28; managers: Silhouette=0.5, BIC=93.01, RDM=2.56; owner-managers: Silhouette=0.7, BIC=101.37, RDM=2.32.

Common characteristic for owners, managers and owner-managers is that few of them show interest in acquiring "broad managerial & professional knowledge".

4. DISCUSSION

In relation to **basic characteristics of NWFP-SMEs**, it can be seen that their location is both in urban and rural areas, and that they are small enterprises, in regard to the number of employees. The most common NWFPs are mushrooms and WBFF. Most NWFP-SMEs belong to the type "small rural enterprises".

Previous studies on forest-based enterprises indicate that small family enterprises (FAO, 2005; USAID, 2008), located in rural areas (FAO, 2005; Niskanen et al., 2007; Pettenella et al., 2007), are mainly engaged in these activities.

Regarding **characteristics of NWFP-SMEs business**, it is noticeable that selling is present in most enterprises, while almost all of them are engaged in procurement and processing. The prevailing type of NWFP-SMEs, distinguished on the basis of their activities, is the one that integrates procurement, processing and selling. Previous studies in the region of Šumadija and Western Serbia showed similar results (Nonić, Ranković, & Nedeljković, 2013b).

Most NWFP-SMEs representatives believe that working conditions are defined by weather. Considering that NWFPs are seasonal products, whose yields depend on nature and weather "*...their supply cannot be regular and fully reliable*" (FAO, 2005, p. 6). This is the reason why SMEs in this sector "*...seldom rely on one product*" (FAO, 2005, p. 6). In this way, they are trying to minimize potential losses.

Unfair competition, insufficient labour, underdevelopment of national market, and payments are important problems in business. Although there are certain differences in attitudes, these problems are to some extent similar to those reported in the literature. Research conducted abroad show that the main problems are: "…*lack of capital investment and shortage of raw materials, skilled manpower and up-to-date information*" (Uddin et al., 2008, p. 147). Also, problem can be caused by "…*financial and technical limitations, (…), market insecurity (with large price fluctuations) and lack of research*" (Uddin et al., 2008, p. 148).

Despite appropriate technological equipment, most respondents believe that additional funds should be invested in fixed assets (cold-stores, drying machines, etc.). According to the results of previous research in Serbia, representatives of NWFP-SMEs emphasize the need for additional financial support measures, which would be used for purchase of new equipment and machinery (Nonić, Ranković, & Nedeljković, 2013a).

In regard to the basic **characteristics of NWFP-SMEs representatives**, most respondents are owners and/or managers. The biggest (but not prevailing) number of owners and owner-managers belong to the type "younger secondary school graduates". This means that all of them are males, 26-45 years old, with secondary school. These results are in line with previous studies that indicate entrepreneurs are mainly males, 20-50 years old, and have secondary school education (Ayala & Manzano, 2014).

Most respondents have positive attitude towards additional education and have attended some kind of formal training. In terms of types of NWFP-SMEs representatives, most owner-managers belong to the type being interested in professional knowledge on NWFPs. On the other hand, most owners show lack of interest in additional training in proposed fields. Reason for this may be the fact that "owner-managers" in forestry "…*see their businesses primarily as a source of revenue and a way to provide for their own employment*" (St-Jean, LeBel, & Audet, 2010, p. 212). The importance of additional education is emphasized in previous studies showing that "…*certain factors such as human capital and characteristics (education, training, manager experience) have a direct influence on rural business growth*" (St-Jean et al., 2010, p. 213).

5. CONCLUSION

In regard to **characteristics of NWFP-SMEs**, following conclusion can be drawn:

- most enterprises have 11-50 employees and operate with mushrooms and/or WBFF;
- most enterprises have van without refrigerator, weighing and drying machines, machine for processing and cold-stores.

In regard to **characteristics of NWFP-SMEs business**, following can be concluded:

- most enterprises are engaged in all three activities (procurement, processing, selling), and NWFPs are predominant/sole activity;
- there is high degree of utilization of drying machine and equipment for other processing;
- working conditions are defined by dependence on weather and inadequate legal framework;

- the most important problem in business is “unfair competition”;
- financial resources should be invested in fixed assets.

Research results showed following **types of NWFP-SMEs**:
- in regard to basic characteristics of SMEs:
  1) “small rural” (prevailing);
  2) “small urban”;
  3) “medium urban”;
- in regard to business activities:
  1) “procurement, processing, selling” (prevailing);
  2) “procurement, processing”;
  3) “procurement, selling”.

Following can be concluded in relation to **characteristics of NWFP-SMEs representatives**:
- most are at the position of the owner and/or manager, are 26-45 years old, male with secondary school education;
- most have positive attitude towards the importance of additional training, have attended formal trainings and show interests in additional education, mainly in the field of management and professional knowledge on NWFPs.

Following **types of NWFP-SMEs representatives** are distinguished:
- in regard to some basic characteristics (none is prevailing):
  1) “younger secondary school graduates”;
  2) “older secondary school graduates”;
  3) “older high school graduates”;
  4) “older with faculty”;
- in regard to attitudes toward the type of additional training:
  1) “professional knowledge on NWFPs” (prevailing within owner-managers);
  2) “broad managerial & professional knowledge”
  3) “narrow managerial & professional knowledge”
  4) “lack of interest in additional training in proposed fields”.

These results can serve as a basis for further research on types of SMEs and possibilities of improvement of entrepreneurship in NWFPs sector. Also, in the coming period should be studied the need for specific support measures in relation to different types of entrepreneurs.

Acknowledgment: *This study was conducted within the project “Sustainable management of the overall potential of forests in the Republic of Serbia” (no. 37008-TR) and project “Research on climate changes and its impact on the environment - monitoring of impacts, adaptation and mitigation” (no. 43007), subproject “Socio-economic development, mitigation and adaptation to climate changes” (no. 43007/16-III), funded by the Ministry of Education, Science and Technological development.*

THE IMPORTANCE OF HUMAN RESOURCES DEVELOPMENT AS NON-FINANCIAL SUPPORT TO SMES IN SEE AND SERBIA

Sanja Popovic-Pantic[1]
[1]**Institute Mihajlo Pupin, sanjap.pantic@pupin.rs**

Abstract: *Having in mind that systematic approach to developing human capital requires the identification of training needs of SMEs, this paper will present the main results of the comparative analysis on the main challenges in HR of SMEs in South- East Europe, including Serbia which was done by SEECEL[1]. The key challenges of SMEs in choosing the relevant training program will be presented as well. The paper will also highlight the specific needs of SMEs in Serbia regarding the non-financial services. This part of analysis is based on the Report which is regularly published by National Agency for regional development so that the progress achieved in 2013. could be measured and presented as well.*

Keywords*: training, SME, HR, needs, challenges, non-financial service*

1. INTRODUCTION

Human capital development is considered as one of the key areas for fostering the competitiveness of SMEs as the basis for sustainable growth. Since economic crisis affected SMEs considerably, EU countries prepared the appropriate response in many relevant development aspects, including the human capital. Training needs analysis is one of the backbone for the systematic approach to developing human capital. Although the financial support prevailed among the priorities for SMEs growth, non-financial support which refers to the training needs mainly, is becoming more and more important.

It is widely promoted over the Europe that key successes factor for growth is smart, sustainable and inclusive development. In order to take advantage of this opportunity, steps were outlined in the EU 2020 Strategy which set the targets and key priorities and initiatives. Recognizing that Europe can "count on the talent and creativity of [its] people"[2], the EU 2020 strategy places a great focus on the development of Europe's human capital. In particular, it stipulates that promoting smart growth driven by knowledge and innovation necessitates reforms which should improve the quality of education and training, and reforms should contribute to "ensuring that innovative ideas can be turned into new products and services that create growth, quality jobs and help address European and global societal challenges. But, to succeed, this must be combined with entrepreneurship, finance, and a focus on user needs and market opportunities."[3]

The development of the SME sector has consistently been highlighted in national SME strategies, programs and action plans as one of the economic priorities of South East European countries. To achieve this economic priority, the focus has been placed on fostering the competitiveness of SMEs by improving the competences of SME's human capital. The education and training system, which plays a crucial role in strengthening the competences of SME's human capital, should remain flexible and respond accurately to the demands of the labor market. The discrepancy between the expressed needs for training and the training provision offered in the market and the lack of data on SME's training needs should be addressed through systematic Training Needs Analysis (TNA) (SEECEL, 2013). All pre-accession countries which belong to SEE region are committed to the performing of TNA as this is a milestone for the evidence-based policy making. The SEECEL developed instrument and associated methodology as well as the first implementation of an SEE-wide TNA provides the platform for future Training Needs Analysis System (TNAS). The results

[1] South East European Center for Entrepreneurial Learning (SEECEL) is regional institution with the mission to promote the development of the lifelong entrepreneurial learning system and entrepreneurship as key competence in eight pre-accession countries of South East Europe (SEE). SEECEL is funded by EU, under the IPA and from the state budget of the Government of the Republic of Croatia.
[2] Europe 2020: A strategy for smart, sustainable and inclusive growth" (COM(2010)), p.7
[3] Europe 2020: A strategy for smart, sustainable and inclusive growth" (COM(2010)), p.11-12

which will be presented in this paper on the main challenges that SMEs are facing in human capital development, will be based on the recently published SEECEL comparative analysis in SEE[4].

EU 2020 Strategy and other relevant documents recognize the impact that entrepreneurship has on economy and society and consequently support human capital development in the SME sector as a key driver of competitiveness. This message was further reinforced with the Entrepreneurship 2020 Action Plan (2012). Another important policy document which highlight the importance of human capital development is Small Business Act (SBA). SBA is a key instrument of the policy of promotion of entrepreneurship and small enterprises, which replaced European Charter for Small Enterprises**.** The SBA builds on Commission and Member States policy achievements and creates a new policy framework that integrates the existing enterprise policy instruments. SBA also promotes SMEs to grow by helping them tackle the remaining problems which hamper their development. Similar to the European Charter, this document also contains 10 key areas for the development of SME and is, basically, conceived as a shift from guidelines to real, targeted activities. SBA is a part of *acquis communautaire*, which makes it even more important for candidate countries and potential candidate for EU membership.
Progress in entrepreneurship learning according to SBA, in Serbia was slow. Except the establishment of the Council of Partnership for Entrepreneurial Learning by the end 2012., there was not other significant signs of progress in this particular area. The main responsibilities of the Council are to coordinate policy action in order to develop a lifelong entrepreneurial learning system (LLEL) (2012). There are also some training programs for start ups and growing companies available through the network of the regional agencies for SME development and National agency for regional development.

2. KEY CHALLENGES IN HUMAN CAPITAL DEVELOPMENT SMEs ARE FACING

Human resources are the most valuable asset of each enterprise, as a key driver of individual, organizational, civic, and national integrated, inclusive, smart and sustainable growth. Improving human resources is essential as improved competences, higher motivation and greater activation of employees are crucial preconditions for increasing productivity, innovation and high performance-competitiveness of SMEs. However, SMEs are facing both external and internal barriers in improving their key business competence base. In addition to this there are also practical financial and organizational barriers (Buschfeld, D. and all, 2011). Organization of training programs is time and money consuming, therefore small companies can hardly afford them. On the other hand, existing training offers and programs are normally designed and organized from the point of view of larger companies and they simply don't fit into the organizational needs of smaller companies EC, (Directorate-General for Employment, Social Affairs and Equal Opportunities, 2009). This is particularly evident in terms of financing of training where SMEs cannot match the learning and training investments of larger companies. There appear to be a number of misconceptions about SMEs and their capacity to provide timely, practical and effective learning and training activities (Watt, D., Kitagawa, K. 2009). This is largely due to unfavorable comparisons with larger companies in terms of organization, financing and training and learning activities. One of the biggest challenges that SMEs are facing is the organization and funding of human resources and training in South East countries.

The share of enterprises that prepare financial and budgeting plans for learning and training investments and human resources development increases with the size of the enterprise, which is an expected result. The stated share is generally higher in medium-sized enterprises, in comparison with micro and small. Consequently, in micro and small enterprises a slightly higher percentage of interviewees stated that HR development is financed mostly by employees themselves (SEECEL,2013). Governmental subsidies in the form of total financing are extremely rarely used. According to the research conducted by SEECEL in 2013[5]. the highest share of enterprises that use such subsidies is recorded in Turkey and amounts to only 11%, while in Former Yugoslav Republic of Macedonia (FYROM) there are no such enterprises in the sample. Governmental subsidies in the form of co-financing are also rarely used, but slightly more often than subsidies in the form of total financing. Governmental subsidies in the form of tax incentives are generally the least used subsidy form.

Although in the last three years many enterprises were strongly affected by the impact of the crisis, investments made in development of human resources generally stayed on the same level or even slightly

[4] The overall sample used in the analysis contains 2.335 enterprises in eight SEE countries, which of 51% are micro, 34% are small and 15% are medium-sized enterprises.

[5] The overall sample used in the analysis contains 2.335 enterprises in eight SEE countries, which of 51% are micro, 34% are small and 15% are medium-sized enterprises.

increased. This is undoubtedly an important finding, particularly as most enterprises had to reduce their operating costs, which usually leads to a restriction of the available budget for training and HR development (SEECEL, 2013). The findings from the SEECEL study confirms that enterprises in SEE region are still very aware of the need for constant employee competence development. Furthermore, they recognize the quality and expertise of employees as a necessary precondition for the maintenance and development of business entities in difficult market and economic conditions.

Second challenge that SMEs are usually facing in SEE refers to the availability of the information on learning and training programs. The most of interviewed SMEs claimed that media is the most important source for information on the training opportunities. On the other hand, in Albania only 8.4% of enterprises acquire information from media, but over 70% of Albania SMEs obtain information from other sources. Mouth to mouth advertisement is the most pronounced in Croatia and holds the same place of importance as media (36.6%). In Serbia, this percentage accounts for 25.2%. Finding information about available training from other enterprises is also relatively important in countries where approximately one third of enterprises from the survey stressed its relevance (Serbia 33.3%) (SEECEL, 2013).

The training needs analysis in SEE also has shown that training programs providers are not fully adjusted to the needs of SMEs and that policy makers should base future development of programs and policies on concrete feedback provided by the SMEs themselves. The relative usefulness of training areas, can be, therefore the next challenge for SMEs and for training providers as well. Taking into account the entire regional sample, it may be concluded that financial management, information technologies and accounting were the most useful training areas performed within the company, while intellectual and industrial property rights and innovation management were the least useful training areas performed within the company, although they may be considered as partially useful (SEECEL, 2013). The highest usefulness of the training areas is associated with market trends and regulations, and financial management in case of FYROM and accounting in case of Albania, where every enterprise that responded to the questionnaire found these training areas useful. Bosnia and Herzegovina and Croatia also set accounting as the most useful one while Serbia put the highest usefulness score on market trends and regulations.

Export/import related knowledge and skills have the lowest average usefulness score amongst the five observed training areas, as well as the highest standard deviation among countries.
The overall highest usefulness score is associated with product development and the lowest one with intellectual and industrial property rights.

Other challenges that influence decision –making process for the selection of training and learning programs could be proper timing, duration, applicable competencies in work environment, location, methodology applied, certificates, price, quality and so on. The highest importance is recorded in Serbia where in average 96% of these decision factors are considered important.

All SMEs (100%) that responded to the question from Serbia specify that the duration of the program, the development of relevant competencies applicable in work environment and the applied methodology, the price and the trainers' quality and eligibility are important to make the decision.

There are significant differences amongst the observed countries related to the most suitable timing for conducting the training, education and skill improvement programmes. Enterprises from FYROM and Serbia think that the most suitable timing for training of the employees is during work hours, while on the other hand the majority of enterprises from Albania (54%) think that the timing during work hours is not appropriate.

The enterprises differs also in the attitude on the most appropriate method of training. Practical on-the-job training and a mix of lecturing and interactive approach are generally the most appropriate methods used for conducting the learning and training programmes, with quite a similar level of appropriateness in all countries. Technology and ICT oriented methods like using simulation, distant learning, video conference and similar, as well as different kinds of study tours may also be considered as appropriate methods in the majority of the observed countries, although showing a generally lower level of appropriateness than the first two. Albania and Serbia prefer practical on-the-job training, a mix of lecturing and interactive approach and technology and ICT oriented methods (SEECEL, 2013).

3. NEEDS FOR NON-FINANCIAL SUPPORT OF SMEs IN SERBIA

3.1 The use of non-financial support among SMEs

Non-financial support of SMEs like training, advising and consulting service are focusing to human resource development in the SMEs. However, this support is usually considered as a second the most important service to SMEs after enabling better access to finance. Human resources for competitive SMEs and entrepreneurs (SMEE) has been identified as one among 5 pillars within the Development Strategy of Innovative and Competitive SME for the period of 2008-2013. in Serbia (Report on SMEE, 2011). National Agency for Regional Development is the key stakeholder in providing the training to SMEs with the aim to make them more successful and competitive at the market. The main target group to which NARD provided training was start up companies. The topic of the training which prevailed was business plan writing but also mentoring .

The findings from the recently conducted research on the conditions, needs and problems of SMEs in Serbia, in 2013. (NARD, 2013) also indicates that the need for financial support is much more significant in relation to non-financial types of support. Majority of enterprises (80%) express the need for financial support, whereas non-financial support is needed in only one out of two enterprises. Actually 43 % of enterprises claimed that non-financial support mostly is not needed and is not needed at all. On the other hand, some 52% is positive toward the non-financial services, as 35% think that non-financial support is needed, but not necessary while 15% claimed that they are very much needed. Enterprises who underlined the need for non -financial support belong mostly to South Serbia and are medium-sized (NARD, 2013).

As to gender structure, one out of two women entrepreneurs believe that non-financial support services (advice, trainings and consulting services) are needed, of which 36% consider them needed, but not necessary.

Table 1: Need for non-financial types of support-by type of business entity

Need for non-financial types of support – by type of business entity					
	Micro	Small	Medium	Sole trader	**Total SMEs**
Very much needed	18.4%	17.7%	24.7%	13.4%	**16.7%**
Needed, but not necessary	33.3%	39.0%	44.7%	33.3%	**35.4%**
Mostly not needed	26.0%	25.5%	18.7%	23.5%	**24.5%**
Not needed at all	19.4%	12.7%	4.7%	23.1%	**18.3%**
Don't know/no answer	2.9%	5.0%	7.3%	6.7%	**5.1%**
Total	100.0%	100.0%	100.0%	100.0%	**100.0%**

Source: Research on conditions, needs and problems of small and medium-sized enterprises and entrepreneurs (SMEs) in Serbia in 2013., National Agency for Regional Development, 2013.

Table 2. Need for non-financial types of support-by region

Need for non-financial types of support – by region					
	Belgrade Region	Vojvodina Region	Šumadija and West Serbia	South and East Serbia	**Total SMEs**
Very much needed	20.5%	18.2%	12.5%	12.6%	**16.7%**
Needed, but not necessary	31.8%	35.9%	32.4%	45.5%	**35.4%**
Mostly not needed	22.9%	28.4%	24.2%	22.4%	**24.5%**
Not needed at all	21.1%	11.6%	23.7%	15.3%	**18.3%**
Don't know/no answer	3.7%	5.9%	7.1%	4.1%	**5.1%**
Total	100.0%	100.0%	100.0%	100.0%	**100.0%**

Source: Research on conditions, needs and problems of small and medium-sized enterprises and entrepreneurs (SMEs) in Serbia in 2013., National Agency for Regional Development, 2013.

3.2 Services used

While start ups are mostly focused to the training as a type of non-financial support, developed companies are more using advisory service. Actually, more than half of surveyed enterprises have previously used advisory services, whereas around two fifths have not used them. In relation to the previous year, there was a growth in the use of advisory services (NARD research,2013). This type of support has so far mostly been used by medium-sized enterprises, as well as enterprises from Belgrade.

More than half of women entrepreneurs (56%) have so far used some sort of non-financial support.

Among free services which rise the capacity of human resources in-house, there is a growth in relation to the previous year in the field of marketing / promotion / sales, whereas a drop was recorded in the following services: human resources management, accounting, audit and taxes, financial management and preparation of documents to apply for funds.

As for paid service, in relation to the previous year, there is a growth in used services in the field of legal support, quality control/certification and participation in research and development projects. This services are usually outsourced and not necessarily rise the capacity of in-house human resources. The drop in used services was recorded in the following services: work safety and protection, environmental protection, financial management, production and technology operations, IT, technical testing / maintenance / supervision and PC training.

Of the free of charge programmes, women entrepreneurs most often used consulting for start-ups (38%), then marketing services (26%), business development strategies (24%) and legal services (24%). In case of paid non-financial services, the leading services are accounting, audit and taxes (39%), legal services (31%), and marketing/promotion/sales (39%).

3.3 Interest in non-financial services in the future in Serbia

Entrepreneurs in Serbia show most interest in free use of marketing services (36%) and business development strategy (29%). Women entrepreneurs significantly more than men see the need for PC training (29%) and foreign language courses (28%). Entrepreneurs in Serbia consider accounting, audit and tax assistance the most needed paid services in the future (NARD 2013).
Entrepreneurs were asked also about the importance of the sources of business information relevant for company development. Business entities consider Internet, business partners and colleagues to be the most important sources of information needed for business. In Vojvodina region, enterprises are significantly more informed from accountants / bookkeepers, whereas in Southeast Serbia they use significantly more the information from local self-government / local economic development office. Women entrepreneurs are significantly more than men informed by their friends and family (30%), as well as from TV (24%). Agencies for support to small and medium-sized enterprises are a source for only a fifth of SMEs (19%).

4. CONCLUSION

Serbian entrepreneurs are divided in almost two equal groups according to the attitudes about the importance, sort and usage of non-financial services which refers to training, advisory and consulting as a part of human resources development. While 43% of entrepreneurs claimed that non-financial support mostly is not needed and is not needed at all, more than half is positive toward the usage of non-financial services . Mostly used non-financial services refer to the advisory services and training programs in marketing/sales/promotion, whereas a drop was recorded in the following services: human resources management, accounting, audit and taxes, financial management and preparation of documents to apply for funds. It can be concluded that Serbian enterprises have a developed awareness on the need for non – financial support including the need for constant employee competence development but still the need for financial support prevailed. The lack of financial resources is the most important reason for the insufficient usage of non-financial services. The economic crisis is still affecting the budgets for non-financial services in the region including Serbia, which resulted in the still limited scope of the non-financial services used by enterprises in the region. It especially stands for micro companies which stated that i.e HR development is financed mostly by employees themselves while the share of enterprises that prepare financial and budgeting plans for learning and training investments is more practiced among the medium sized companies. Maybe launch of the voucher system for micro, small and medium sized companies in Serbia could increase

the number of entrepreneurs users of non-financial services since it had good results in other countries in the region and EU, where it was applied. It seems to be the win-win situation as it represents good solution for the government as provider of voucher, as voucher system enables subsides available only for the purpose of training, advisory or some other non-financial support which will contribute to the human resources development in the SMEs and raise their competitiveness.

Abstract: *This paper presents a study on the entrepreneurial readiness of 113 students from several faculties in Serbia. Research data were collected through the scientifically verified questionnaire. Authors examined the opinions of the students related to the five dimensions of Entrepreneurial readiness (Entrepreneurial intention, Perceived ability, Perceived attractiveness, Learning Orientation, Passion for work). The aim of the study was to determine whether the following characteristics of students have an impact on their entrepreneurial intentions: a) Education (manager, engineer); b) Education in entrepreneurship – through classes at the faculty; c) Entrepreneurial experience in the environment (family) and d) Different socio-demographic characteristics of the students. According to this, authors define nine research questions that are analyzed on a sample of students using statistical analysis (correlation coefficient, T - test and multivariate analysis). The most interesting research question refers to the comparison of two groups of students (1. management education and 2. engineering education) according to their tendency towards entrepreneurship and starting their own business. Based on the analyzed sample of students, the difference between these two groups is statistically proven and shown in this paper, together with all other research results. The presented results can be useful for: a) Educational institutions – in order to create educational programs for youth entrepreneurship support; b) The state – to stimulate entrepreneurial economy among youth, and c) Individuals who would like to examine their entrepreneurial readiness and intentions.*

Keywords*: Entrepreneurship, Entrepreneurial readiness, Entrepreneurial intention, University students in Serbia.*

1. INTRODUCTION

Each entrepreneurial venture which is launched presents the result of the entrepreneurial intentions of individuals or groups. The future success of a business largely depends on the individual's entrepreneurial intentions (future entrepreneurs) and his willingness to "sacrifice" for achieving business objectives. Entrepreneurial intention refers to the intention of setting up the business in the future.

Different authors examine the entrepreneurial intentions and its relation with other factors: De Clercq et al. (2013) examined the effects of learning orientation and passion for work on the entrepreneurial intentions of students; Dinis et al. (2013) and Zampetakis et al. (2011) explored the impact of psychological characteristics of students (creativity and emotional intelligence); Farashah (2013) and Souitaris (2013) examined the impact of entrepreneurship education and training; Lee et al. (2011) showed the influence of work environment and job satisfaction; Nabi et al. (2010) and Zhang et al. (2013) explored the influence of high education. Domestic research on the students' entrepreneurial intentions is conducted by Markov & Mirkov (2006), Markov & Stankovic (2008) and Đorđević et al. (2010).

This paper examines the entrepreneurial intention of students from several faculties in Serbia, through questioning their entrepreneurial readiness. The data were collected by using a questionnaire that is scientifically verified by De Clercq et al. (2013). This questionnaire contains questions about the entrepreneurial intention, perceived ability and attractiveness for entrepreneurship, learning orientation, passion for work and students' characteristics. According to that, we define the following research questions (RQ1-RQ9):

RQ1: Do the students' age predetermine their entrepreneurial readiness?
RQ2: Is there a relationship between the students' grade point average at studies and their entrepreneurial readiness?
RQ3: Does the students' gender predetermine their entrepreneurial readiness?
RQ4: Do the students from the capital city (Belgrade) differ from those who don't live in it, regarding the level of their entrepreneurial readiness?
RQ5: Are the final-year students more prepared for entrepreneurship than the students at the lower years of studies?

RQ6: Do the engineering and management students differ regarding their entrepreneurial readiness?
RQ7: Do the students who have entrepreneurs in their family, or a close environment, have higher level of the entrepreneurial readiness, than those students who do not have family entrepreneurs?
RQ8: Do the students who attended the entrepreneurship course at faculty have higher level of readiness for entrepreneurship?
RQ9: Do the students who have shown a real interest in entrepreneurship (by attending the seminars about entrepreneurship) have a higher level of entrepreneurial readiness?

For answering the previously defined research questions, we use the techniques of statistical inference based on the analysis of the correlation coefficient, t-test and multivariate analysis.

The paper consists of the following sections. After the introduction, Section 2 discusses the topic of entrepreneurship. Section 3 describes the concept of entrepreneurial readiness and presents the factors which, according to various authors, affect the entrepreneurial readiness. Section 4 presents the conducted research on the entrepreneurial readiness of university students in Serbia. Section 5 discusses the results of the research and gives the answers to the posed research questions. Section 6 concludes the paper.

2. ENTREPRENEURSHIP

Entrepreneurship is defined as the process by which individuals follow opportunities without regard to resources they currently control, and as "art of turning an idea into a business" (Beringer & Ireland, 2010, p. 30). Entrepreneurs recognize opportunities (i.e. discover market needs) and turn them into successful businesses (launch new firms to meet those needs) (Hsieh et al., 2007; Moore et al., 2008, p. 6). According to Omerbegović-Bijelović (2010, p. 234), entrepreneurship can be defined as "a social function of creating new values through the creative combination of business resources". Zampetakis et al. (2013) claim that entrepreneurship is linked with the value creation, and has a significant impact on economic growth and employment.

There are two types of entrepreneurship activities (Tang & Koveos, 2004): 1) Venture entrepreneurship, which deals with new venture creation, and 2) Innovation entrepreneurship, which involves innovations within existing enterprises. List of personal characteristics that make some people better at recognizing business opportunities than others are (Beringer & Ireland, 2010, p. 77-79): 1) Prior experience in an industry (which helps entrepreneurs to recognize business opportunities); 2) Cognitive factors (opportunity recognition may be an innate skill or a cognitive process); 3) Social networks (the extent and depth of an individual's social network affects opportunity recognition); 4) Creativity (encourages the process of generating novel or useful ideas).

3. ENTREPRENEURIAL READINESS

One of the most common questions about entrepreneurs is whether entrepreneurs are born or created. This question is based on a myth that some people are genetically predisposed to be entrepreneurs. Two main factors that may affect the initiation of successful business venture are entrepreneurial opportunity and person's tendency towards entrepreneurship. Entrepreneurship opportunity is an auspicious set of circumstances that creates a need for new product, service or business (Beringer & Ireland, 2010, p 66). Souitaris et al. (2007) believe that inspiration for entrepreneurship comes from the emotional chemistry between an individual and particular opportunity (Zampetakis et al., 2013). Person's tendency towards entrepreneurship is defined as an entrepreneurial intention (De Clercq et al., 2013). Entrepreneurial intention refers to the intention of setting up business in the future. In the entrepreneurial context, Thompson (2009, p. 676) defines intention as the "self-acknowledged conviction by a person that they intend to set up a new business venture and consciously plan to do so at some point in the future". Ajzen (1991) states a generic definition of intention as "a person's readiness to perform a given behaviour". This means that the intention and readiness can be considered as synonyms.

In this paper we observe entrepreneurial readiness as a broader concept than entrepreneurial intention. Entrepreneurial readiness is defined as a personal competence and potential for entrepreneurship, which includes entrepreneurial intention as a part. Entrepreneurial intention is considered as existence of personal decision to start a new business at some point of time.

Different types of relationship between entrepreneurial intention and personal and environmental factors are explored in the literature:

- **Entrepreneurial environment**: People with self-employed parents are more likely to become entrepreneurs (Solesvik et al., 2013). The same relationship is proven for those who have entrepreneur acquaintances (Beringer & Ireland, 2010, p. 40).

- **High Education**: According to Nabi et al. (2010), higher education reduces the likelihood of entrepreneurship. Opposite to this, Zhang et al. (2013) state that relationship between high education and entrepreneurship is positive.
- **Entrepreneurial education**: This type of education in childhood and adolescence was confirmed as important for later entrepreneurial intentions (Dinis et al., 2013). Farashah (2013), Solesvik et al. (2013) and Souitaris et al. (2007) showed that there is positive relation between entrepreneurship education and entrepreneurial intention. Farashah (2013) differ tree types of entrepreneurial education: learn to understand entrepreneurship, learn to act in an entrepreneurial way and learn to become an entrepreneur.
- **Personality and psychological factors**: Those are the factors that attract the greatest research attention. The main psychological characteristics associated with entrepreneurial intention, according to Dinis et al. (2013) are: propensity to take risks (has a negative influence on entrepreneurial intentions), self-confidence (has a positive influence on entrepreneurial intentions) and need for achievement (has a positive influence on entrepreneurial intentions). Zampetakis et al. (2013) showed the link between emotional intelligence and students' entrepreneurship attitudes and intentions. In another paper Zampetakis et al. (2011) established the links between individual creativity and entrepreneurial intention of students.
- **Gender**: Lee et al. (2011) and Zhang et al. (2013) showed that women have less desire to start a new business than men.
- **Economic environment:** Entrepreneurial intentions can also depend on external factors such as the existence of an unfavourable economic environment or a lack of regular employment options (De Clercq et al., 2013).
- **Work environment:** Lee et al. (2011) suggest that work environments, with an unfavourable innovation climate and/or lack of technical excellence incentives influence entrepreneurial intentions, through low job satisfaction.
- **Learning orientation and passion for work:** De Clercq et al. (2013) claim that learning orientation and passion for work are not relevant only for formation of entrepreneurial intention, but they support translation of every entrepreneurial feasibility and desirability into entrepreneurial intentions.

In this paper, for collecting data on students' entrepreneurial readiness, we use De Clercq et al.'s (2013) questionnaire. We define Entrepreneurial readiness as a vector which contains five different dimensions: *Entrepreneurial intention* – individual intention to set up business in the future; *Perceived ability* – potential with which people see them capable of becoming successful entrepreneurs; *Perceived attractiveness* – perception of the attractiveness for becoming an entrepreneur*; Learning orientation* – people's tendency to update and expand their knowledge continuously; *Passion for work* - the degree to which people love work-related activities. All questions about these five dimensions of entrepreneurial readiness are given in Table 3.

4. SURVEY ON ENTREPRENEURIAL READINESS OF STUDENTS IN SERBIA

Survey about entrepreneurial readiness was conducted between December 2013 and February 2014. It included 113 students from state and private universities in Serbia. Students responded to two sets of questions. The first set of questions consists of general information about students: gender, age, faculty, year of studies, grade point average at studies, student's living place, information about entrepreneurs in the family, information about having lectures in entrepreneurship and attending entrepreneurship seminars. Table 1 presents general information about the survey sample, while Table 2 presents the categorical variables and frequencies of their values obtained from the survey sample.

Table 1: Structure of the sample

Sampling units	Students from faculties in Serbia
Sample	115 students
Response rate	98% (113 students)
Research technique	Self-administered questionnaire

The second part of the questionnaire included five groups of questions about entrepreneurial readiness, defined through the five dimensions: *Entrepreneurial intention, Perceived ability, Perceived attractiveness, Learning Orientation,* and *Passion for work* (Table 3). All these questions are formulated as statements with five-point Likert-scale answers, from 1 – "completely disagree" to 5 – "completely agree". These questions were interspersed throughout the questionnaire in order to avoid bias in responses. Based on the collected data, we defined nine research questions (RQ1-RQ9) which are presented on Figure 1. Survey results and discussion, and answers to the posed research questions and presented in the next section.

Table 2: Categorical variables and frequencies

Categorical variables (for N = 113) *		Number	Percentage
Gender	Male	46	40,7%
	Female	67	59,3%
Faculty	**State**	**104**	**92%**
	Faculty of Organizational Sciences, University of Belgrade	74	65,5%
	Faculty of Mechanical Engineering, University of Belgrade	8	7,1%
	Faculty of Economics, University of Belgrade	3	2,7%
	Faculty of Electrical Engineering, University of Belgrade	3	2,7%
	Faculty of Technology and Metallurgy, University of Belgrade	3	2,7%
	Faculty of Architecture, University of Belgrade	2	1,8%
	Faculty of Dramatic Arts, University of Belgrade	2	1,8%

5. SURVEY RESULTS AND DISCUSSION

Survey data were statistically analysed using the "PASW Statistics - SPSS 18" statistical software. Table 3 shows the descriptive statistics of scale variables (five dimensions of entrepreneurial readiness) from the second part of the questionnaire.

Table 3: Scale variables and descriptive statistics

Variables	Mean	Std. deviation
Age (N=113)	21,98	1,685
Grade point average (GPA) (N=109)	8,524	0,806
Entrepreneurial readiness:	**3,73**	**0,632**
Entrepreneurial intention (Likert scale 1-5):	**3,23**	**1,099**
I am likely to start my own business soon.	3,32	1,054
I have been preparing to start my own business.	3,14	1,238
Perceived ability (Likert scale 1-5):	**3,34**	**0,917**
It is highly feasible that I could start my own business.	3,03	1,022
I feel certain that I would be able to start my own business if I wished to do so.	3,65	1,024
Perceived attractiveness (Likert scale 1-5):	**3,80**	**1,114**
I have a strong desire to start my own business.	3,80	1,189
I feel a strong urge to become self-employed. My overall wish is to have my own business.	3,81	1,151
Learning orientation (Likert scale 1-5):	**4,41**	**0,476**
I often read materials (articles, internet, books, etc.) to improve my abilities.	4,42	0,729
I often look for opportunities to develop new skills and knowledge.	4,50	0,709
For me, developing my abilities is important enough to take risks.	4,25	0,829
I enjoy challenging and difficult tasks through which I can learn new skills.	4,41	0,650
I prefer to work in situations that require a high level of ability and talent.	4,42	0,624
I like to take on a challenging task from which I can learn a lot.	4,50	0,614
Passion for work (Likert scale 1-5):	**3,90**	**0,546**
I derive most of my life satisfaction from working hard. I love to work hard.	4,15	0,759
I accomplish a lot because I love to work hard.	4,19	0,739
Sometimes I wish that I could be working harder when I am not.	3,86	1,068
I look forward to returning to work when I am away from it.	3,41	1,023

From the table 3, it can be seen that Entrepreneurial readiness mean is 3.73. Within that, the mean values of the five dimensions are as follows: Entrepreneurial intention (3.23); Perceived ability (3.34); Perceived attractiveness (3.80); Learning orientation (4.41); Passion for work (3.90). Total value of Entrepreneurial readiness is calculated as average value of previously listed five dimensions, i.e. all dimensions have equal weights. Consideration of different weights among dimensions can be the subject of the future work.

Before comparing different groups of students (which is defined in research questions), we need to verify the reliability of measurement scale, which we use for measuring the vector Entrepreneurial readiness. For this purpose, we use *Cronbah's Alpha coefficient* and average inter-correlation between five dimensions of entrepreneurial readiness. These results are obtained using reliability analysis in the SPSS. For five dimensions, *Cronbah's Alpha* = 0.78. The reliability criterion is satisfied, because *Cronbah's Alpha*, according to DeVellis (2011), needs to be higher than 0.7. Another way to measure reliability of measurement scale is with inter-item correlation. According to Briggs & Cheek (1986), this value needs to be between 0.2 and 0.4 as an optimal range between the items-correlation on the measurement scale. In our case this condition is also satisfied, because inter-item correlation equals 0.39.

Also, before answering the research questions, it is necessary to present the correlation table (Table 4) which shows the correlations between dimensions of entrepreneurial readiness. Table 4 shows that, compared with entrepreneurial readiness, entrepreneurial intention, perceived attractiveness and perceived ability have large correlation coefficients (0.896; 0.880 and 0.795, respectively), learning orientation has medium correlation (0.577), while passion for work has small correlation (0.378). All correlation coefficients are statistically significant at the level 0.01 or 0.05.

Table 4: Pearson's correlation coefficient among variables

Variables:	**(ER)**	**(1)**	**(2)**	**(3)**	**(4)**	**(5)**
(ER) Entrepreneurial readiness	1	0.896**	0.795**	0.880**	0.577**	0.378**
(1) Entrepreneurial intention	0.896**	1	0.619**	0.804**	0.449**	0.146
(2) Perceived ability	0.795**	0.619**	1	0.611**	0.327**	0.191*
(3) Perceived attractiveness	0.880**	0.804**	0.611**	1	0.349**	0.124
(4) Learning orientation	0.577**	0.449**	0.327**	0.349**	1	0.338**
(5) Passion for work	0.378**	0.146	0.191*	0.124	0.338**	1
**Correlation is significant at the 0.01 level (2-tailed). *Correlation is significant at the 0.05 level (2-tailed).						

Next analysis (Tables 5-7) provides the answers to the research questions (RQ1-RQ9). First two research questions are analyzed using the Pearson's correlation coefficient.

RQ1: *Do the students' age predetermine their entrepreneurial readiness?*
Regarding the value of correlation coefficients from Table 5, it is not possible to prove the existence of this relation (students' age and their entrepreneurial readiness), because correlation coefficients are not statistically significant and are very close to zero.

RQ2: *Is there a relationship between the students' grade point average at studies (GPA) and their entrepreneurial readiness?*
Based on the results presented in Table 5, statistically significant correlation between the grade point average and the entrepreneurial readiness is not obtained. Therefore, the relation is not proven. It is very interesting to notice that GPA is not in correlation with learning orientation (correlation coefficient equals 0.067).

Table 5: Correlation coefficient and t-test: Entrepreneurial readiness and students' age, GPA and gender

Variables:	**Correlation Coefficient**		**Mean values (T-test)**	
			Gender	
	Age	**GPA**	**Male** N = 46	**Female** N = 67
(ER) Entrepreneurial readiness	- 0.007	- 0.120	3,86	3,64
(1) Entrepreneurial intention	0.053	- 0.110	3,59* ~	2,98* ~
(2) Perceived ability	- 0.057	- 0.202*	3,53	3,21
(3) Perceived attractiveness	- 0.094	- 0.168	4,01	3,66
(4) Learning orientation	0.078	0.067	4,42	4,41
(5) Passion for work	0.037	0.036	3,83	3,95
Correlation coefficient and stat. significance	** 0.01 level (2-tailed); * 0.05 level (2-tailed).			
T-test stat. significance and eta square value	* p<0,05 (T - test); ~ 0,06-0,07 (middle effect size);			

Next group of research questions (RQ3-RQ9) are analysed using the T-test.

RQ3: *Does the students' gender predetermine their entrepreneurial readiness?*
Based on the results in Table 5, there is statistically significant difference (p<0.05) between male and female students, regarding their attitudes towards entrepreneurial intention. This difference has the middle effect size (eta square: 0.06-0.07). However, the existence of relation between students' gender and their entrepreneurial readiness is not proven, since the mean values of two groups (male, female) do not differ significantly.

RQ4: *Do the students from the capital city (Belgrade) differ from those who don't live there (non-Belgrade students), regarding the level of their entrepreneurial readiness?*
We ask this research question because Belgrade, as the capital city and the most developed part of Serbia, gives more challenges for setting up business. According to the results presented in Table 6, there is no statistically significant difference between these two groups (Belgrade, Non-Belgrade students), regarding their entrepreneurial readiness.

Table 6: Mean values of students' ER by categorical variables: living place, study year, education

Variables and mean value	**Living place**		**Study year**		**Education**	
	Bgd N = 68	**Non-Bgd** N = 45	**F** N = 60	**Non F** N = 53	**Managers** N = 43	**Engineers** N = 67
(ER) Entrepreneurial readiness	3.77	3.67	3,63	3,85	3,98**°	3,53**°
(1) Entrepreneurial intention	3.37	3.01	3,13	3,35	3,56**~	2,98**~
(2) Perceived ability	3.43	3.20	3,18* ¬	3,53* ¬	3,58*~	3,15*~
(3) Perceived attractiveness	3.85	3.72	3,54** ~	4,10** ~	4,21**•	3,50**•
(4) Learning orientation	4.38	4.46	4,40	4,43	4,53*~	4,32*~
(5) Passion for work	3.88	3.93	3,90	3,89	4,02*¬	3,79*¬
Stat. significance:	* p<0,05 (T - test); ** p<0,01 (T - test)					
Eta square:	° 0,12-0,13 (large effect size); • 0,09-0,10 (medium-large effect size); ~ 0,05-0,07 (medium effect size); ¬ 0,03-0,04 (small effect size).					

RQ5: *Are the final-year students more prepared for entrepreneurship than the students at the lower years of studies?*
We ask this question based on the assumption that final-year students, who passed more exams, think more about their future employment, so they could have higher level of readiness for self-employment, i.e.

entrepreneurship. Unlike them, students at earlier years of studies are more oriented towards passing exams. Two groups of students were analysed (Table 6). The first group (F) consists of students that are close to finishing studies (4th year of studies or master studies). Second group (Non-F) consists of students that are not close to finishing studies (3rd, 2nd or 1st year of studies). These two groups are compared in terms of their entrepreneurial readiness. Regarding the results in Table 6, it is noticed that there isn't a statistically significant difference between two groups (F, Non-F), in terms of entrepreneurial readiness. If we consider all five dimensions, there is a difference in perceived ability ($p<0.05$) and perceived attractiveness ($p<0.01$) of entrepreneurship.

RQ6: *Do the engineering and management students differ regarding their entrepreneurial readiness?*

In the survey sample there are two large groups of students (Table 2): students with management education (Faculty of Organizational Sciences – management department, Faculty of Economics, Faculty of Business, etc.) and students with engineering education (Faculty of Organizational Sciences – department for information technology, Faculty of Mechanical Engineering, Faculty of Electrical Engineering, Faculty of Technology and Metallurgy, School of computing, etc.). These two groups are compared in terms of their entrepreneurial readiness for all five dimensions. The results of t-test (Table 7) show a statistically significant difference between the students of management and students of engineering, regarding the readiness for entrepreneurship. Actually, students from management faculties have higher entrepreneurial readiness than students from engineering faculties (difference between mean values is $\Delta 0.45$; $p<0.01$). If we compare these groups through all five dimensions, the differences in favour of management students are: entrepreneurial intention ($\Delta 0.58$); perceived ability ($\Delta 0.43$); perceived attractiveness ($\Delta 0.71$); learning orientation ($\Delta 0.21$); passion for work ($\Delta 0.23$). Large difference is present regarding perceived attractiveness and entrepreneurial intention, while small difference regarding the learning orientation and passion for work.

Table 7: Mean values of students' ER by categorical variables: entrepreneurs in family, subject entrepreneurship and seminar in entrepreneurship

Variables and mean value	Entrepreneurs in Family		Subject Entrepreneurship		Entrepreneurship seminar	
	Yes N = 36	**No** N = 77	**Yes** N = 20	**No** N = 90	**Yes** N = 52	**No** N = 21
(ER) Entrepreneurial readiness	3,88	3,66	3,80	3,71	4,07** °	3,45** °
(1) Entrepreneurial intention	3,50♦¬	3,10♦¬	3,55	3,15	3,78** °	2,76** °
(2) Perceived ability	3,67**~	3,19**~	3,32	3,35	3,69** °	3,04** °
(3) Perceived attractiveness	4,00	3,71	4,03	3,74	4,29** °	3,38** °
(4) Learning orientation	4,43	4,40	4,47	4,39	4,59** °	4,26** °
(5) Passion for work	3,87	3,92	3,84	3,93	4,02* ¬	3,80* ¬
Stat. significance:	** p<0,01 (T - test); * p<0,05 (T - test); ♦ p<0,08 (T - test).					
Eta square:	° 0,12-0,13 (large effect size); • 0,09-0,10 (medium-large effect size); ~ 0,05-0,07 (medium effect size); ¬ 0,03-0,04 (small effect size).					

RQ7: *Do the students who have entrepreneurs in their family, or a close environment, have higher level of the entrepreneurial readiness, than those students who do not have family entrepreneurs?*

Students in the survey were asked whether they have entrepreneurs in their family or close environment. Based on the response, students are divided into two groups and analysed. Results in Table 7 show that there is no statistically significant difference in readiness for entrepreneurship. The only difference ($p<0.01$) is noticed in perceived ability for entrepreneurship.

RQ8: *Do the students who attended the entrepreneurship course at faculty have higher level of readiness for entrepreneurship?*

In our survey, students were asked if they attended entrepreneurship course at faculty within their studies. Based on the answers, two groups were generated (students who had lectures in entrepreneurship and those who did not). The comparison of the groups (Table 7) did not show statistically significant result. There was a difference in terms of entrepreneurial intention ($\Delta 0.40$) and perceived attractiveness ($\Delta 0.29$), but not statistically significant because of unequal size of groups. This result may indicate to the existence of effect of the entrepreneurship education on entrepreneurial intentions and attractiveness towards entrepreneurship as a profession. However, existence of this relation could not be proven with our survey sample.

RQ9: *Do the students who have shown a real interest in entrepreneurship (by attending the seminars about entrepreneurship) have a higher level of entrepreneurial readiness?*

In our survey we questioned students during the seminar: "Academy of Modern Management – Entrepreneurship and Start-up" that was organized by student's organization ESTIEM LG Belgrade. The students, who attended this seminar, expressed real interest in entrepreneurship, so we wanted to examine and compare this group of students with students who didn't attend the seminar. The results are presented in

Table 7. Students who attended entrepreneurship seminar have higher level of entrepreneurial readiness (difference between mean values is ∆0.62; p<0.01). The difference between groups regarding five dimensions are: entrepreneurial intention (∆1.02), perceived ability (∆0.65), perceived attractiveness (∆0.91), learning orientation (∆0.33) and passion for work (∆0.22). These results show that students who express interest in entrepreneurship and attended entrepreneurship seminar differ from other students, regarding their entrepreneurial readiness.

The most interesting research question - RQ6 was also analysed using multivariate analysis (MANOVA) in order to further explore the statistically significant differences between entrepreneurial readiness between students of management and engineering, through the linear combinations of the five dimensions (entrepreneurial intention, perceived ability, perceived attractiveness, learning orientation, passion for work). The necessary conditions for the implementation of the MANOVA, at the sample size of 113 respondents are:
1) Multivariate normality: The essence of this analysis is to check the extreme points in respondents' answers (answers which mostly differ from the average answers) using Mahalanobis distance (the distance of a particular case – respondent's answer – from the centroid of other cases). Centroid is the point in n-dimensional space, whose dimensions are the mean values of all variables in considered cases, i.e. respondent's answers. In our case, this is a point whose dimensions are average values of the five variables, i.e. dimensions that form the vector entrepreneurial readiness. Mahalanobis distance value is 12.788 (generated by the SPSS), which is not higher than the critical value for the model of five variables (which equals 20.52). This means that the assumption of the multivariate normality is proven.
2) Homogeneity of variance and covariance: This assumption is proven because the values of statistical significance obtained in *Box's test of equality of covariance matrices* and *Levene's test of equality of error variances* is greater than 0.05 (which means that variances of five dimensions don't differ in the survey sample; the same is with the covariances).

After applying the MANOVA, statistically significant difference between the students of management and engineering is determined, regarding combinations of the five dimensions of the vector entrepreneurial readiness*: F (5,103) = 3.24, p = 0.009, Wilks' lambda = 0.87, partial eta squared = 0.136 (representing large effect size).* When these two groups of students are compared using the considered dimensions separately (entrepreneurial intention, perceived ability, perceived attractiveness, learning orientation and passion for work), statistically significant differences ($p < 0.01$) are determined only for the following three dimensions: Entrepreneurial intention: *F(1,107) = 8.425, p = 0.004, partial eta squared = 0.073 (representing medium effect size)*; Perceived ability: *F(1,107) = 7.421, p = 0.008, partial eta squared = 0.065 (representing medium effect size)*; and Perceived attractiveness: *F(1,107) = 11.431, p = 0.001, Partial eta squared = 0.097 (representing medium-large effect size)*. Dimension with the greatest impact on the observed groups of students is perceived attractiveness. Statistically significant difference between the students of management and engineering is not obtained for the dimensions learning orientation and passion for work.

6. CONCLUSION

In this paper the authors analyse entrepreneurial readiness of university students in Serbia. The survey was inspired with the study conducted by De Clercq et al. (2013). The idea was to compare different groups of students in order to make relationship between entrepreneurial readiness and different characteristics of students. The questioned characteristics of students were: gender, age, year of studies, living place, grade point average at studies, educational profile (management or engineering), entrepreneurial environment (in terms of having entrepreneurs in the family), entrepreneurial education (in terms of entrepreneurship lectures at studies and attending entrepreneurship seminars). All these variables are considered in the research questions (RQ1-RQ9), which were analyzed using different statistical methods (correlation coefficients, T-test, Multivariate analysis). The most interesting research question was: *Do the engineering and management students differ regarding their entrepreneurial readiness?* It is shown that students of management have grater entrepreneurial readiness than students of engineering. This result can help as an evidence for promoting Entrepreneurship among students at technical and engineering faculties, because it is well-know that the greatest innovations in industry come from engineers. Therefore, it is particularly important to stimulate youth entrepreneurship and teach creative and innovative engineering students how to venture new businesses based on their ideas. This can lead to the economic development of every country. The limitation of this paper is reflected in the small sample of students from several faculties who participated in this survey. In the future, the authors intend to spread the survey by increasing the sample of students (through questioning students from more universities in the country and abroad). The authors also desire to create and apply other interesting research methods and techniques (questionnaires) which can be used for measuring students' entrepreneurial readiness, intention and mindset.

[2] Teaching Assistant, Higher School of Professional Business Studies, Novi Sad,
milica.stankovic.vps@gmail.com

Abstract: *In contemporary conditions franchising experiences expansion and continued growth as a business model. The paper explains the entrepreneurial model of franchising, according to the coherence of the concepts of entrepreneurship and franchising. Based on the definitions of entrepreneurship and its applicability to the franchise concept, it is pointed out that the concept of franchising is almost fully compatible with the concept of entrepreneurship. The aim of this paper is to stress the relationship between the concept of entrepreneurship and concept of franchising, and to explain the theoretical model of entrepreneurial behavior in the franchising system. The theoretical model of entrepreneurial behavior that is exhibited in the paper shows that the maximization of franchisee entrepreneurial behavior can be achieved through the use of the franchisee networks. Through networks and entrepreneurial behavior, franchisees create new value in terms of business growth and entrepreneurial initiatives adaptation, achieve market leadership and solve business problems.*

Key words*: franchising, entrepreneurship, franchisor, franchisee, entrepreneurial behavior*

1. INTRODUCTION

Modern trends indicate the growing importance of the entrepreneurial model of franchising. As an organizational form, franchising is widely recognized as an important growth driver of entrepreneurship, mainly through customization of products to the needs of geographically dispersed customers. The essence of franchising are standardization and uniformity. However, under conditions of more intense generation of new ideas and innovations, participants in franchise systems are increasingly turning to entrepreneurial behavior. In the past, studies about franchising were based on the franchisor's attitudes and interests, while recent studies emphasize the importance of integration of both sides of the franchise system. The aim of this paper is to highlight the importance of connection between entrepreneurship and franchising and to explain the theoretical model for maximizing franchisee entrepreneurial behavior. In the first part of the paper, the relationship between entrepreneurship and franchising is explained, giving the definition of entrepreneurship and identifying ways to apply these definitions to the franchising concept. The second part refers to the analysis of franchisors and franchisees as entrepreneurs and their franchise relationship as entrepreneurial partnership in which franchisor's innovative concept is distributed to the market through a network of franchised units. The third part presents a theoretical model of entrepreneurial behavior that indicates the possibility of maximizing the enterpreneurial behavior through the use of formal franchisee networks. These networks primarily include mutual learning and exchange of information between members of a franchise system. Based on a comprehensive analysis of available literature, relevant conclusions will be presented.

2. RELATIONSHIP BETWEEN ENTREPRENEURSHIP AND FRANCHISING

Franchising is an area that is still insufficiently researched by scholars and business professionals. In fact, franchising surveys have fairly short history, considering that the oldest known and most widely cited studies dating back to the late 1960s. Over the past two decades, franchising experienced expansion and continuous growth which is largely stimulated by the emergence of new forms of franchising in new areas, ranging from hotels, restaurants, real estate, to the education of children, beauty salons etc. (Grunhagen & Mittelstaedt, 2005). Franchising can be seen as a commercial relationship in which one party (franchisor) allows the another (franchisee) to clone a proven business system with payment of fee, which varies depending on the sector (Stefanović & Stanković, 2013). In fact, it can be said that franchising offers a combination of franchisor's economies of scale and franchisee's flexibility to exploit local market opportunities (Watson & Kirby, 2004). A successful franchising system entails the benefits for both franchisors and franchisees. Franchisor benefits from some franchisee's resources such as specific local knowledge, while franchisees benefit from franchisor's assets including brand, organizational routines, managerial inputs etc. Therefore, franchising can be seen as a form of intercompany cooperation in which two types of entrepreneurs share the tangible and intangible resources in order to increase performances (Chirico, Ireland & Sirmon, 2011).

In business studies, franchising is mainly viewed from the standpoint of marketing and trade as a form of international business and from the standpoint of management as a form of organization, strategy and cooperation between enterprises. Earlier studies on the franchising were largely isolated, insufficiently integrated and too relied on one side, the franchisor (Elango & Fried, 1997). In modern researches, it is emphasized that franchising creates entrepreneurial opportunities for both sides of the franchise relationship (Combs, Ketchen, Shook & Short, 2011). Correlation between franchising and entrepreneurship can be justified by the fact that franchising research is, in fact, research on entrepreneurial cooperation between the two different types of entrepreneurs, franchisors and franchisees. In addition, franchising can be defined as a type of entrepreneurial organization (Hoy & Shane, 1998). Franchisor's operations (for example, establishing a franchise system), as well as franchisee's operations (for example, implementation of entrepreneurship model within a franchise chain) are entrepreneurial activities. It is necessary to point out the significant overlaps of entrepreneurship and franchising into 7 main approaches dominant in entrepreneurship researches (Hoy & Shane, 1998):

1) Incubator organization. Franchising systems act as incubators for new ventures and franchising operations.
2) Business plans. The franchisor requires from franchisees to have a business plan. In the United States, franchisors are required to prepare a "public business plan" to ensure access to information for potential franchisees.
3) Investment criteria. Franchising is a source of capital necessary for growth when other sources of funding are not available to the franchisor.
4) Success factors. Failure and survival of franchisors and franchisees are subjects of continuous researches. The objective is to compare the results on the causes of failure and survival of franchise company with respect to the independent company.
5) Corridor principle. Franchisors recruit potential franchisees among active entrepreneurs. In addition, franchisors often have worked as entrepreneurs or business managers before starting the franchise.
6) Corporate culture. In franchising, the franchisor must be able to establish and maintain conditions in which new franchisees have units and manage them independently (franchise units), or together with the franchisor (units owned by the company, double-distribution).
7) Life cycle models. In franchising, the key issue is to understand the birth of a business organization and its subsequent evolution in the franchising system.

When analyzing the relationship between franchising and entrepreneurship and their research domain, we begin by categorizing the focus of various representative definitions of entrepreneurship. These definitions can be classified into 3 groups: definitions which emphasize personal characteristics or qualities of entrepreneurs, definitions that emphasize the entrepreneurial process and definitions focused on entrepreneurial activities. Examples of these definitions are given below and are summarized in Table 1 (Kaufmann & Dant, 1999). Definitions that emphasize the personal perspective of personal characteristics are as follows:

- Entrepreneur is an individual who possesses qualities of risk-taking, leadership, motivation, and the ability to resolve crises (Leibenstein, 1968).
- Entrepreneurs are leaders and major contributors to the process of creative destruction (Schumpeter, 1942).
- Entrepreneur is an individual who undertakes uncertain investments and possesses an unusually low level of uncertainty aversion (Knight, 1921).

Successful entrepreneurs are characterized by qualities such as creativity, adaptability, vision, leadership, managerial and organizational skills, quick decision making, rapid response to changing and uncertain environment, personal integrity and education. Taking into account the perspective of the entrepreneurial process, the concept of entrepreneurship can be defined as follows:

- Entrepreneurship is the creation of new organizations (Gartner, 1985).
- Entrepreneurship is the process of extracting profits from new, unique, and valuable combinations of resources (ambiguous in an uncertain and ambiguous environment (Amit, Glosten & Muller, 1993).

From the perspective of entrepreneurial activity, some of the definitions of entrepreneurship are as follows:

- Entrepreneurship is the purposeful activity to initiate, maintain, and develop a profit-oriented business (Cole, 1968).
- Entrepreneurs perceive profit opportunities and initiate actions to fill currently unsatisfied needs or to do more efficiently what is already being done (Kirzner, 1985).

Table 1. gives an overview of definitions of entrepreneurship and their applicability to the franchise concept. Based on the conducted comparisons it can be concluded that the concept of franchising is almost fully compatible with the concept of entrepreneurship.

Table 1: Definitions of entrepreneurship and their applicability to the franchising context

Definitions of entrepreneurship	Application to franchisors	Application to franchisees
Entrepreneur is an individual who possesses qualities of risk-taking, leadership, motivation, and the ability to resolve crises (Liebenstein 1968)	Yes	Yes
Entrepreneurs are leaders and major contributors to the process of creative destruction (Schumpeter 1942)	Yes	No
Entrepreneur is an individual who undertakes uncertain investments and possesses an unusually low level of uncertainty aversion (Knight 1921)	Yes	Yes
Entrepreneurship is the creation of new organizations (Gartner 1985)	Yes	Yes
Entrepreneurship is the process of extracting profits from new, unique, and valuable combinations of resources (ambiguous in an uncertain and ambiguous environment (Amit Glosten and Muller 1993)	Yes	Yes
Entrepreneurship is the purposeful activity to initiate, maintain, and develop a profit-oriented business (Cole 1968)	Yes	Yes
Entrepreneurs perceive profit opportunities and initiate actions to fill currently unsatisfied needs or to do more efficiently what is already being done (Kirzner 1985)	Yes	Yes

3. FRANCHISOR AND FRANCHISEES AS ENTREPRENEURS

Through the reproduction of successful business concept in new market areas, franchising contributes to the efficient dissemination of innovation. Franchising offers a unique and fertile environment for future studies in entrepreneurship: the franchisor as an entrepreneur, franchisee as an entrepreneur, and franchise relationship as an entrepreneurial partnership. In fact, franchising is based on entrepreneurial partnership, where franchisor's innovative concept is distributed to the market through a network of franchised units operated by local franchisees. In the economic literature, there are two unique models that offer an explanation of the entrepreneurial model of franchising. The first model is the model of capital acquisition that suggests that franchisees are efficient source of financial capital for companies that want to expand on new markets (Dant, 1995). While franchisor's risk relates to the risk of brand development, franchisee's risk refers to the development of local markets. Very often, franchisee is more familiar with the local markets and their potential than franchisor. Also, since franchisors often depend on franchisees' local expertise and contacts, franchisees are encouraged to make appropriate marketing programs for specific markets. Another model is based on the agency theory. Franchising solves the problem that occurs because the franchisor can not monitor very widespread network of franchise units directly and effectively. Therefore, franchisees can generate profit in exchange for an appropriate fee, which provide incentives for both contractual parties. In this case, it is a quasi-independence which allows franchisees to qualify as entrepreneurs. Franchisees have to be proactive in exploiting local opportunities. Franchising literature suggests that franchisors and franchisees may have a lot in common, although they are partners with very different roles (Kaufmann & Stanworth, 1995).

Entrepreneurs can be divided into two groups based on the nature of the business idea: innovative and imitative entrepreneurs (Aldrich & Martinez, 2007). In the franchise system, franchisor can be seen as an innovative and franchisees are specified as imitative entrepreneurs. Thus, the role of the entrepreneur is primarily related to the franchisor, while franchisees generally work under the disciplined system of contractual obligations (Clarkin & Rosa, 2005). Individual roles and responsibilities in the franchise system are explicitly defined in the detailed contract documents. Providers, owners and creators of franchise concepts are widely accepted as entrepreneurs in accordance with the risk they take and innovative profile that is similar to individual entrepreneurs. It is pointed out that the franchisor may be considered as entrepreneur only if he/she enter the market with an innovative idea. Creating a franchise system can be viewed as an entrepreneurial growth strategy (Fillion, 1998).

In contrast, franchisees are often seen as the opposite of the entrepreneurs, since they only follow the model developed by the franchisor and lose the independence that is associated with entrepreneurship (Hoy, 2008). In fact, it is considered that franchisees have little or no role in the creation of innovative business

processes. They operate within the uniformed organizations focused on efficent production (Morgan, 1997). Franchisees only purchase the right to implement a franchise concept, often in a predetermined area in a very proper manner and only for a certain period of time. This role is traditionally associated with the manager, rather than the entrepreneur. Franchise agreements, made by the franchisor, include prescribed and restrictive provisions, leaving little or no room for franchisee's entrepreneurial creativity. These contracts are often unchangeable and they are usually offered to franchisees on a "take it or leave it" basis (Clarkin & Rosa, 2005). Replication and standardization, as a symbols of success within the franchise system, are in the sharp contrast to the creativity and innovation that are associated with entrepreneurship. Franchisor can prevent franchisees to deviate too much from the prescribed business formula through proper control systems (Phan, Butler & Lee, 1996). For this and many other reasons, the relationship between franchisor and franchisee is often seen as the relationship between innovators/entrepreneurs and implementers/managers. From the organizational perspective, franchising companies are generally understood as hybrid organizational form (Shane, 1996).

However, a systematic review of opportunities for entrepreneurship in the context of franchising is reasonable, primarily because franchisees take risks in their business ventures. While franchisors risk their resources during the development of the brand, franchisees risk their resources when developing local markets. In addition, franchisees can be considered as entrepreneurs because they invest their own capital in the business through fees paid to the franchisor (Ketchen, Short & Combs, 2011). Franchisees are also often seen as entrepreneurs because they have entrepreneurial profile and they are innovators in the franchising system, as they can provide the initiative for the improvement and introduction of new products with franchisor's agreement (Grunhagen & Mettelstaedt, 2005). For example, McDonald's has a number of new products developed by franchisees, including the Big Mac, Filet-O-Fish and Egg McMuffin (Morrison & Lashley, 2003). Franchisees transform existing and develop new market offers and create solutions to problems in the whole system by their efforts for local adaptation (Kaufmann & Eroglu, 1998). In many systems, franchisees stimulate innovative ideas and their proximity to clients provides better opportunities to recognize customer's needs (Burkle & Posselt, 2008). Despite evidence that franchisees can take an entrepreneurial role, it is necessary to point out how to maximize entrepreneurial behavior without compromising standardization and uniformity of franchising system.

4. THEORETICAL MODEL OF ENTREPRENEURIAL BEHAVIOR

Franchising is designed in the manner that it refers to equally replication of standardized business format throughout the entire system, which leads to many controversies about how entrepreneurial behavior can prosper in this organizational form. Standardization involves development of working patterns which are constantly applied and participants in franchising concept consistently adhere to them to minimize the difference in business (Gilson, Mathieu, Shalley & Ruddy, 2005). Franchising business model improves efficiency and enables economies of scale that allows both the franchisor and franchisees to minimize costs. In addition, franchise units share a common identity and operate under the common trade mark (Bradach, 1997). If franchisees deviate from the system's standard model in search of self-interest, it can lead to erosion and deterioration of the quality of trade mark. Franchisee's compliance with standardized framework is essential for maintenance and development of the desired image of franchise system (Pizanti & Lerner, 2003). However, the majority of franchisees operate within areas that differ in terms of market conditions, income levels, consumer tastes, competition level and demand nature. Company's ability to adapt to different market conditions is part of identity of an entrepreneurial oriented organization (Muzyka, De Koning & Churchill, 1995). Healthy franchise system should be developed over time according to changes in the external environment (Hoy, 2008).

Entrepreneurial behavior at the firm level is widely accepted as a tool for revitalization of the company and achievement of sustainable competitive advantage and superior performances in organizations of all types and sizes (Antoncic & Hisrich, 2004). In the context of franchising, encouraging entrepreneurial behavior in franchise units can be considered as contrast to the requirements of standardization and uniformity, which are the cornerstone of franchising (Cox & Mason, 2007). Franchising involves a set of established procedures and proven methods. It can be said that franchising refers to cloning successful business model. Although franchising relations are mainly regulated by strict contract, they often exceed formal interactions, so that franchisees still have a partial strategic flexibility as entrepreneurs. In addition, numerous studies showed that franchisees actually play an important role in innovative and entrepreneurial behavior, which is necessary in franchising system (Clarkin & Rosa, 2005). Franchisors should provide an appropriate structure that will allow franchisees to contribute to business development. Those who do not develop such an approach will risk that franchisees form their own association to raise a collective voice (Cochet & Ehrmann, 2007).

Entrepreneurial behavior among franchisees is certainly maximized through the use of formal franchisee network. Networks are forms of voluntary cooperation that involves mutual learning and exchange of information between members of the franchise system (Johannisson, Ramirez-Pasillas & Karlsson, 2002). Franchisee networks include using forums, working groups and regional and national meetings which

provides interaction between franchisees. Franchisees are allowed to work in a cluster for the dissemination of knowledge, which in turn maximizes entrepreneurial behavior in three ways: through acquisition of relational and informational capital, promotion of competition within the system and facilitation of franchisee learning through the generation of new knowledge. These processes produce significant organizational outcomes for both the franchisee and the whole system in terms of business growth, system adaptation, market leadership and solution of business problems (Dada, Watson & Kirby, 2010). The model of maximization the entrepreneurial behavior among franchisees is shown in Figure 1.

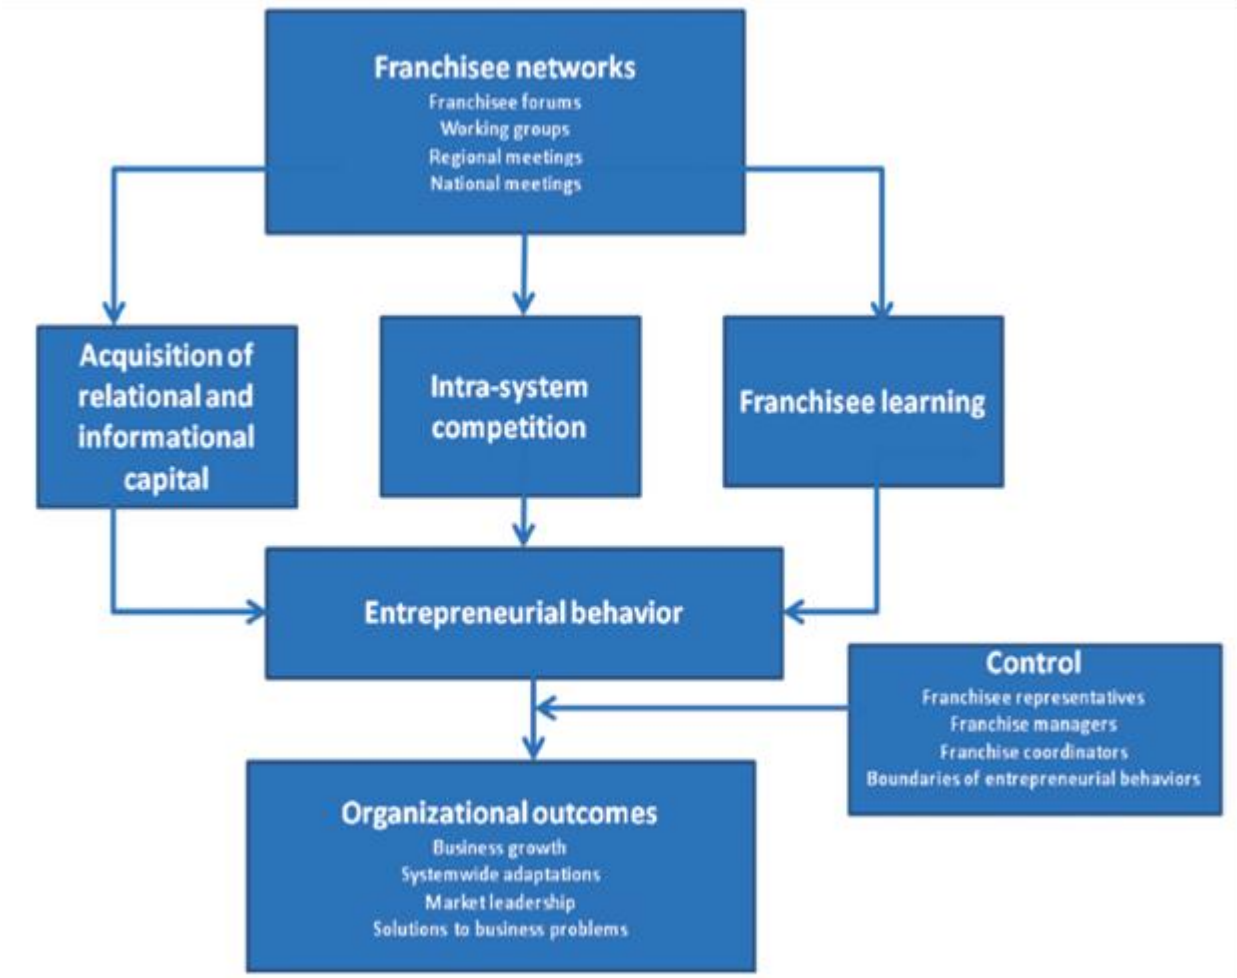

Figure 1: Model of maximization of entrepreneurial behavior amongst franchisees
Source: Dada, O., Watson, A., Kirby, D. (2010), „Toward a model of franchisee entrepreneurship“, International Small Business Journal, 30(5), pp. 559–583.

- Acquisition of relational and informational capital. Relational capital can be perceived as a set of business relationships between members of the organization. Information capital includes information about company's products or services, customers and competition (Griffith & Lusch, 2007). Franchisees particularly emphasize the importance of franchising forums within which they discuss issues related to entrepreneurship, exchange ideas, receive additional information about the business etc. A large number of franchisees provide their ideas in order to facilitate functioning of the entire franchising system. Depending on the system, forums are held a few times a year or a couple times a month and present formal way to exchange ideas. In this way, much more interaction between franchisors and franchisees can be realized. National forum is of great importance, since franchisors have ability to monitor operations of each of franchisees on a daily basis. A large number of ideas that arise on these forums can be implemented in practice, since in this way franchisees improve business operations of the entire franchising system. It can be concluded that franchisee networks affect the increase of information and relational capital which has a positive impact on franchisee's entrepreneurial behavior (Dada, Watson & Kirby, 2010).
- Competition within the system. The high level of competition has been observed between franchisees, as they try to be the best within franchising system through entrepreneurial behavior. Franchisee's competitive aggressiveness is attributed to networks that are designed by the franchisor, so that franchisees are informed about activities of other franchisees which leads to

intensified competition. So, franchisees often want to prove themselves in front of the franchisor and to make progress on the list of the best franchisees. "Club of high achievements" consists of the top 12 franchisees and they receive awards such as "Franchisee of the year". In order to win this award, franchisee must be more than just a franchisee, he/she should strive to improve himself/herself and to be better than others. A large number of franchisors organize competitions for franchisees to generate new ideas. Entrepreneurial minded franchisees have closer and better relations with the franchisor (Michael & Combs, 2008). Franchisees who have a more entrepreneurial initiatives often pay lower fee compared to other franchisees. Franchisees do not only compete within the system with other franchisees, but they are expected to win in the local market. This means that they are not expected to follow the market conditions, but to be market leaders. In order to become a market leader, franchisees try to do something different in relation to their competitors, which will make them entrepreneurs. They tend to achieve USP (Unique Selling Point). Franchisee network have positive impact on competition within the system and on franchisee's entrepreneurial behavior (Dada, Watson & Kirby, 2010).

- Franchisee's learning. Learning is process by which knowledge is generated (Harrison & Leitch, 2005). Networks facilitate the essential learning process through franchisee's experience that is exchanged via forums. Forums give a chance to franchisees to see errors of other franchisees, and to work together in order to solve problems. Franchisors emphasize the importance of using franchise network as learning medium, because there is a possibility that franchisees participate in entrepreneurial activities and thus contribute to the development of franchising system. In this regard, if a franchisee creates a successful innovation, he should forwards it to other members in order to contribute to a better functioning of franchising system as a whole. Some of franchisors hire a franchise coordinator to coordinate franchisees, so that they function simultaneously. Networks have a positive impact on the learning that encourages franchisee's entrepreneurial behavior. Organizations oriented on learning have a positive relationship with corporate entrepreneurship (Holt, Rutherford & Clohessy, 2007).

Franchisee network is a form of formalized and institutionalized management support for corporate entrepreneurship, which allows franchisees to discuss and exchange ideas (Kelley, Peters & O'Connor, 2009). Franchisors allow franchisees a degree of freedom, but do not allow them to go beyond the scope of franchising system too much. However, if franchisees do something completely different from what was established by franchise agreement, franchisors will be prepared to sanction such behavior. Entrepreneurial behavior leads to different outcomes at the individual and organizational level (Ireland, Covin & Kuratko, 2009). Franchisees create new value through entrepreneurial behavior. This refers to business growth, adjusting entrepreneurial initiatives throughout the system, solution of operational problems and market leadership. It rarely happens that franchisor comes to the franchisees with a new idea. More often happens the reverse. Then the product is marketed as a pilot in a specific area, and if it is successful, it will be applyed by other franchisees. So, franchisees are the source of new ideas and innovation for new product/ service development (Cox & Mason, 2007). The motivation for franchisee's entrepreneurial behavior is to generate more business which leads to generation of more revenue. Therefore, franchisee's entrepreneurial behavior has a positive impact on the business performance of franchising system (Dada, Watson & Kirby, 2010).

5. CONCLUSION

Franchising concepts were originally referred to the replication of standardized business concepts. In conditions of more intense competition, the importance of entrepreneurial behavior of participants in franchise systems is emphasized. Surveys on franchising are actually surveys on entrepreneurial cooperation between the two different types of entrepreneurs: franchisors and franchisees. Entrepreneurship and franchising overlap in a number of segments, so definitions of these two terms are related. Based on the review of definitions of entrepreneurship and its application to franchising it can be concluded that they are almost compatible concepts. We have identified two different approaches that can cause a dilemma: franchising as the antithesis of entrepreneurship and franchising as an entrepreneurial model. The first approach is explained by the fact that the stimulation of entrepreneurial behavior in franchise units is inconsistent with the requirements for the uniformity of the franchise system. The second approach is supported by the fact that franchisees play an important role in innovative and entrepreneurial behavior that is necessary for the functioning of the franchise system in modern conditions. The solution to the dilemma is "controlled entrepreneurship", which should provide control of franchisees' behavior in order to maintain uniformity of the system, while providing entrepreneurial autonomy. This can be achieved by using formal networks that enable interaction between franchisees (forums, working groups and regional and national meetings). Franchisee networks contribute to the maximization of entrepreneurial behavior through: acquisition of relational and informational capital, promotion of competition within the system and facilitation franchisee learning through the generation of new knowledge. The culmination of franchisee entrepreneurial behavior is reflected in business growth, adaptability of the franchise system, market leadership, innovation

and solving business problems. Future research can be focused on the analysis the impact of franchise system's size on the entrepreneurial model of franchising. Also, global trends indicate growing importance of research of franchising systems involved in social entrepreneurship. Human resource management in entrepreneurial oriented franchising concepts is another topic which should be researched in the future.

FINANCIAL MANAGEMENT

ALTERNATIVE SOURCES OF FINANCING OF THE SMALL AND MEDIUM SIZE ENTERPRISES IN THE REPUBLIC OF MACEDONIA

Meri Boskoska[1], Violeta Panovska-Boskoska[2]
[1]University "St.Kliment Ohridski" - Bitola, meribb@yahoo.com
[2] University "St.Kliment Ohridski" - Bitola, vpanoska@yahoo.com

Abstract: *The effective managing with a company, to a large extent, depends on the sources of financing of its business activities. The decisions that the entrepreneurs make for financing of the business activities are rather complex and are related to the planning, providing and using of the finances. The establishment and the continuity of the work of the small and/or medium sized enterprises, mainly depends on approachability to the finances that can be obtained from different sources and under different financing conditions.*

The main goal of this paper is to point out the alternative sources of financing that can help the Macedonian small and medium sized enterprises to provide enough capital for improving and enlarging the scale of their productivity, competence, as well as the development of new products and innovations.

In this paper, a theoretical research is presented concerned with the financing of the small and/or medium sized enterprises through analytic description and a synthesis method that will be applied after the content analysis.

The expected results of the research are actually the answers to the following questions:

- *How important are the small and/or medium sized enterprises in the development and the stability of the Macedonian economy?*
- *Which are the additional sources of financing available for the Macedonian small and medium sized enterprises?*

Key words: *small and medium enterprise, alternative financial sources, commercial banks, economic development, economic stability.*

1. INTRODUCTION

Many analysts and policymakers (Albert Berry, 2007, OECD, USAID) recognize the importance of SMEs in economic development, especially for the developing countries. According to USAID (2009) small and medium enterprises (SMEs) are critical because they account for large shares of the total output and employment and are thus a key to the strategic objective of overcoming the poverty.

Risteska (2012) concludes that SMEs have by far big part in the development of the national economy, because of which the governments take different measures, using different instruments and strategies to support them in their development. According to Dickins and Feels (2005) many SMEs are facing difficulties in finding sustainable finances such as long-term loans just because of the high risk connected with the enterprises with small assets. The commercial banks do not want to finance the SMEs because of the risk. On the other hand, the SMEs being considered as with higher risk than the big ones, the SMEs have to pay higher interest rates for the loans from the commercial banks.

Many researchers, amongst whom, Jovanova (2012) say that in the conditions of crisis when the commercial banks are more rigorous in approving the loans, it is necessary to find new ways of financing of the Macedonian enterprises.

The scope of research is covering the explanation of the mentioned objective and will depend on the knowledge and past research made by different authors in the field of entrepreneurship and management of small business, as well as, from analysis of the economic development strategies provided by home and foreign institutions.

This paper contributes to the exciting literature by familiarizing the SMEs with additional sources of funding for their ongoing development and business activities. This is very important to ensure the survival and sustainability of SMEs, something that a country's economy growth and development depend on.

2. IMPORTANCE OF SMEs IN COUNTRY'S ECONOMY DEVELOPMENT

Before we start analyzing the importance of the SMEs within an economy, it is important to define SMEs as a classified group. In most cases the European Commission's definition is the one that is widely accepted.

According to the European Commission an enterprise is concerned to be entity engaged in an economic activity, irrespective of its legal form. This includes, in particular, self-employed persons and family businesses engaged in craft or other activities, and partnership or associations regularly engaged in economic activity.[1] Main criteria to define the SMEs are: number of employees, turnover or Balance sheet total.

Table 1: Company category classification

Company category	Employees	Turnover	or	Balance sheet total
Medium-sized	< 250	≤ € 50 m		≤ € 43 m
Small	< 50	≤ € 10 m		≤ € 10 m
Micro	< 10	≤ € 2 m		≤ € 2 m

Source: http://ec.europa.eu/enterprise/policies/sme/facts-figures-analysis/sme-definition/index_en.htm

According to the data from the table above, the SMEs can be divided into three categories: middle sized with less than 250 employees, small with less than 50 employees and micro with less than 10 employees. In the Republic of Macedonia the classification of micro, small and middle sized enterprises is regulated by the Trade Companies Law[2] according to which:

- Middle sized enterprises either have up to 250 employees or annual income less than 10 million euros and average assets value less than 11 million euros,
- Small enterprises either have up to 50 employees, annual income less than 2 million euros and average assets value less than 2 million euros,
- Micro enterprises are the ones that have up to 10 employees and less than 50.000 euros annual income.

It can be seen that according to the number of employees, the criteria are as same as the European ones when it comes to the classification of the SMEs, the difference is in the average assets value and the annual income. However, most often is the number of employees that is used as a standard definition when classifying the SMEs.

The level of importance of the SMEs can be measured according to the number of employees and to which extent they take part in the creation of new values in the economy. The small enterprises are considered to be the moving force of the changes in the economy as well as, sources of significant innovations. The research made by Edinburgh Group[3] shows that more than 95% of the total number of enterprises in the world is in the category of SMEs, which employs approximately 60% of the employees in the private sector work. The SMEs play a key role in the employment not only in the developed countries but also in the developing and in the countries with low incomes. The data for the employment between 2002 and 2010 saying that in average MSEs are with 85% of the total number of employees just proves the previously stated. In figure 1 the contribution of the SMEs to the employment in different countries can be seen.

[3] Edinburgh Group (2013): Growing the global economy through SMEs, p.8.

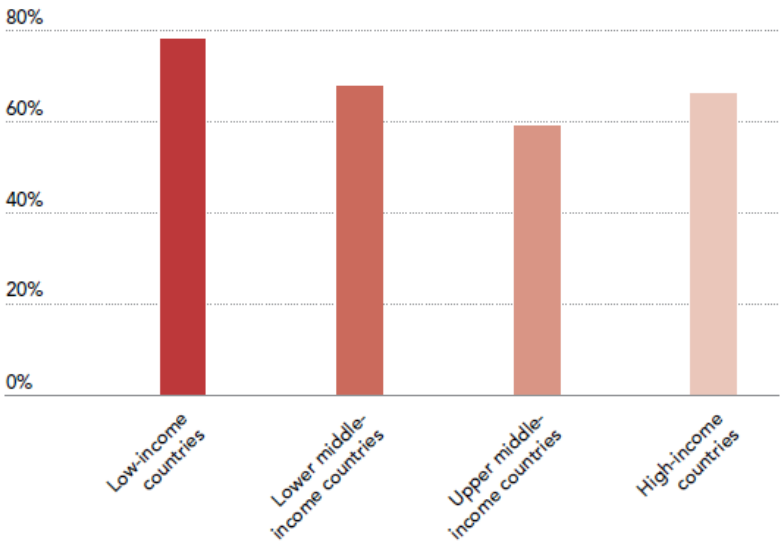

Figure 1: Contribution of SMEs to employment (median values)

Source: Edinburgh Group (2013): "Growing the global economy through SMEs, p.8.

According to the data of the National Office of Statistics of Republic of Macedonia, there were 71290 active business entities in 2013. Enterprises with 1 to 9 employees took 85% of that number. On the second place were the enterprises with no or unknown number of employees (6.2%),then the enterprises with 10 to 19 employees follow with 4.2%,after them were the enterprises with 20 to 49 employees-2.5%; 1.8% of the enterprises with 50 to 249 employees and only 0.3% have more than 250 employees[44]. The number of active business entities in Macedonia for 2013 is presented in Table 2.

Table 2: Number of business entities by number of employees

Total						
	0[1)]	1-9	10-19	20-49	50-249	250 +
71 290	**4 415**	**60 599**	**2 989**	**1 787**	**1 291**	**209**

1) Including business entities with unascertained number of persons employed

Source: www.stat.gov.mk

According to Stojanovska (2014) the sector of small and medium enterprises plays a major role in the Macedonian economy which is shown by the fact that the percentage of employees in SMEs is higher than the one of the big companies, reaching its peak in 2007 with 83%. The percentage of 63% of the SMEs in the GDP shows that SMEs are carriers of the economic growth of Macedonia. This means that SMEs have major impact on the range and the dynamics of the economical development of our country and also they maintain the economical and social stability. We would like to point out here that there is a two-way connection between the SMEs and the economic development. In other words as SMEs influence the level

[4] www.stat.gov.mk. March 2014.

of economic development so the higher level of development stimulates establishing new SMEs as well as strengthening and development of the existing ones.

The small and medium enterprises are the moving force of the development of every national economy. The positive impact of the SMEs is evident through the following: decreasing of the unemployment rate, bigger GDP, higher level of exports and higher level of innovations of the certain country. This is the reason why the government creates such polices to push forward the development of the SMEs sector and to solve many other different problems in this sector.

3. THE PROBLEM OF FINANCING THE SMALL AND MEDIUM ENTERPRISES

Analyzing the problem of financing the SMEs the fact that Macedonian economy is open and it was not immune to the economic crises in 2008, must be taken into consideration. Namely, during the crisis when the businessmen hesitate to invest and when the demand for the SMEs's products drops, they face the problem of collecting their charges which has impact on their liability. In the situation presented before, the enterprises, especially the start-up ones, can hardly find the necessary finances. Being very hard to access financing schemes, made it difficult for the SMEs to plan their long-term development, and postponed the process of establishing new ones-as mentioned previously-which are the carriers of the economic development of Macedonia.

Talking about the sources of financing of the SMEs in Republic of Macedonia, we must say that the commercial banks, as a center of the finance market, are the ones that provide the SMEs with different kinds of loans and thus the banks are the most often and biggest finance supplier. Nevertheless, the banks decide to give loans to highly liable and stable enterprises (lower risk), rather than to start-up, new enterprises (higher risk) just because of the not yet so stable conditions of the global economy. The commercial banks give loans to start-up enterprises if only they are ensured that the business in question brings enough money, so that the loan installments can be paid and the loan as a total can be paid off.

Dimovska and her research that she did back in 2012 in five banks in Macedonia can only prove the previously stated. The research gave answer to the following question: What is the impact of the global financial crisis on SMEs lending in your bank? All of the banks involved in the research gave the same answer, that the global financial crisis makes giving loans to SMEs highly risky as a result of the macroeconomic instability.[5]

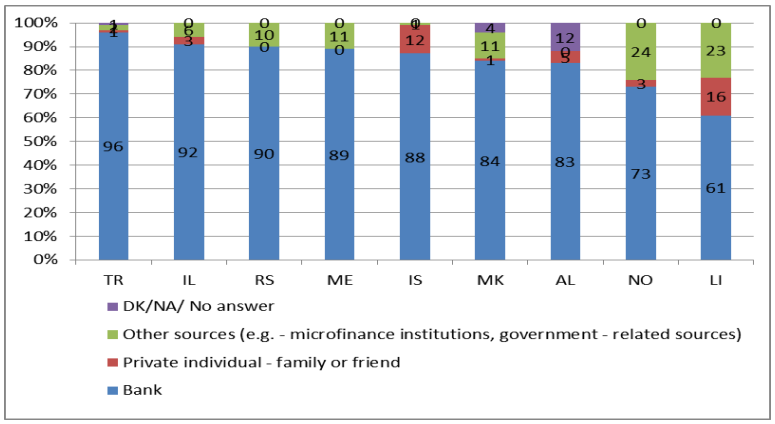

Figure 2: Provider of the most recent loan
Source: European Commission (2013): 2013 SMEs' Access to Finance survey, Analytic Report, Brussels. p.45.

Researching about this question further, the European Commission says that although the Macedonian banks are more rigorous when approving loans, they are still the biggest part of the finance source for the SMEs sector. Namely, in 2011 and in 2013 a very high percentage of the total loans, 84%, were given by the banking sector (Figure 2).

[5] Dimovska, Efimija. (2013).Evaluation of SMEs financing in Macedonia from the "supply side" perspective, CEA Journal of Economics, Vol.8, issue 1, Skopje,p.11.

The fact stands that the entrepreneurs first ask the banks for loans-but the banks are not the sole creditors at the finance market. Further on, an analysis of several alternative sources is presented, sources that have been available to the businesses in Macedonia recently.

4. KINDS OF ALTERNATIVE SOURCES OF FINANCING THE BUSINESSES

The European Commission in the progress report for Republic of Macedonia for 2013, points out that the development of SMEs is obstructed because the SMEs can hardly approach finances and that is actually their biggest challenge. Although there is a certain progress of the Government made by lowering the administrative and legislative barriers, still there are a lot of challenges for the SMEs in providing the support, the innovation and in approaching the finances.[6]

Having into consideration the situation with financing of SMEs in Republic of Macedonia, SMEs should do further research in where and under what conditions they can access the much needed capital. Here, we would like to mention again that finding new sources other than the commercial banks was imposed to the SMEs because of the global financial crisis.

In the recent years the finance sources have diversified and their numbers have enlarged. Thus, for the Macedonian entrepreneurs there are many different sources, such as[7]:

- Business angels' network
- European Bank for Reconstruction and Development (EBRD)
- SEAF1 Macedonia
- Technological development and innovation fund
- Development Foundation "Crimson Capital"
- Sortis Invest

- **Business angels' network -** Business angels are successful entrepreneurs, owners, managers who have capital, knowledge and skills and are ready to invest in sustainable business projects that can make profit fast. The goal is for the business angels to help the start-up businesses financially and in return get either shares of that certain company or a percentage of the profit.
I2BAN is the first official Business angels' network in Macedonia established in 2011 and its goals are:

  - Grouping and gathering the most successful Macedonian businessmen to connect them with the best investing opportunities amongst the new companies,
  - Creating more finance sources for the new companies.

I2BAN puts together the entrepreneurs with the richest people in the country and the region, something that makes the additional finance sources more approachable especially for those entrepreneurs with innovative projects.

In the developed countries business angels are very real and an excellent opportunity for start-up businesses. In the USA $20 billion is invested by the "business angels, while in Europe the number is lower-some $4 billion per year[8]. The Macedonian business angels' network is comprised of 15 home investors that have capital of 40million €.

- **European Bank for Reconstruction and Development (EBRD)** is one of the biggest investors in our region, playing a major role in attracting FDI. So far, the EBRD, s target has been the financing of the private sector and projects that will create employment. EBRD made a strategy for Republic of Macedonia for the 2013-2016 period with priorities such as: attracting FDI, local economic development, efficiency in energetics, sustainability of the integration within the region. Within that framework, EBRD realized successfully two projects: BAS-Business Advisory Services and ECD-Enterprise Growth Program, obtaining help for the home companies to improve their business performances, as well as, developing new managerial skills. Both projects previously mentioned, definitely improve the competence of the home companies[9].

The owners of the small and/or medium enterprises in Republic of Macedonia should have in mind the fact that EBRD improved the financial support for them by making contracts with the commercial banks. EBRD, so far, has made contract with Ohridska Banka - Societe Generale for on-lending to local companies. A loan up to 6 million € will be used to finance energy efficiency investments and a second loan of 1 million € will be provided for competitiveness improvement of SMEs.[10]This credit line project is available for: private enterprises, trading enterprises, as well as for public and/or private companies-providers of local services. The maximum amount allowed for private sector project is 2 million € and for the public sector 2.5 million €.

Also the contract made between EBRD and NLB Tutunska Banka is for 4 million € that will help to improve the economic efficiency of the Macedonian companies. The advantage of this credit line (mentioned previously) for the potential applicants is that the successful projects do not pay out 15% of the loan they got.

- **SEAF 1 Macedonia** is an investment fund that provides not only finance but also business help for the SMEs. 80% of the money in this fund is supposed to be obtained by successful Macedonian entrepreneurs-working in foreign countries, from the international SEAF, as well as from capital and pension funds. This fund is particularly for highly risky investments in the Macedonian companies. But still, time is needed to find potential investors willing to invest part of their capital in Macedonian economy.

- **Technology development and innovation fund (TDIF)[11]** has a goal to: promote and provoke innovations, improve the approachability to finance services and innovations, develop the infrastructure which will lead to innovations and technological development, as well as to establish a strong partnership between universities and research centers on one side and the private sector on the other in Macedonia. This fund provides finances through four financial instruments:

- Co-financing grants for start-up, spin-of companies and innovations,
- Co-financing grants and conditional loans for commercialization of the innovations,
- Co-financing grants for transferring technologies,
- Technical help with business-technology accelerators.

This fund is established and enhances the development of innovative projects that will enlarge the competence and the quality among the small businesses.

- **Crimson Capital** is an international lender in emerging market development by stimulating trade, finance, investments and sales. The services that it provides are as follows[12]:

- Finance for SMEs (debt, equity, trade finance, leasing, factoring)
- SME Development
- Trade, Export and Investment Promotion
- Competitiveness and Restructuring (manufacturing, agribusiness, technology
- services)
- Capacity Building of managers, Consultants and business associations
- Agriculture and Agribusiness (including food processing)
- Loan workouts and Financial Restructuring
- Enterprise restructuring and improvement
- Industrial and manufacturing operations improvement
- Marketing and sales
- Training and train-the-trainer programs

Crimson Capital-Macedonia informs that the foundation is financing projects or companies that have an American partner with at least 25% ownership.

- **Sortis Invest** is a Bulgarian investing and consulting agency for financing projects that mean enlarging the existing business, finding and approaching new market etc. Together with financing concrete/real projects, the Agency offers consulting services concerned with corporate financing, merging and acquisitions.

All these mentioned above sources of financing are only a part of the additional ways of the SMEs in Macedonia to find capital to develop and strengthen the existing businesses or to start a new one.

[10] http://www.ebrd.com/pages/news/press/2013/131218b.shtml March 2014.

[12] www.crimsoncapital.org, January 2014.

The entrepreneurs should know that before applying for finance help they have to make a profitable and sustainable business plan, then get informed and analyze the positive and negative effects of each and every possible and available source of finance help. As we mentioned before, in this still fragile and sensitive global finance situation, this is the only way that the entrepreneurs can get the capital they need.

Regardless what type of finance help they choose, the SMEs' owners should have all the necessary information concerning the different kinds and opportunities for financing. They should also be aware of the level of risk-meaning whether the company can or cannot generate income that will pay out the loan in due time. Otherwise the SME can come to apposition of non-liability, not being able to develop as planned, not being able to pay the obligatory installments and eventually lose the business completely.

5. CONCLUSION

The small and medium enterprises play a key role in the economies of all the countries in the world, regardless the level of their development. The importance of the SMEs can be seen in:

- The biggest percentage of employees in the country goes to this sector,
- They have a big share of the GDP,
- High level of innovations and technological development.

Although the SMEs play a major role in the economic development in many countries, they still face problems. If we regard the administrative and legislative procedures as one of their problems, the second one would certainly be the approachability to appropriate sources of financing. Thus this is what the SMEs are facing in Macedonia, too. In order to overcome this problem, efforts are made toward awareness and being better informed about what and how can Macedonian companies choose as a source of financing that are actually available to finance and support the development of investments.

The high risk level that exists among the SMEs is the cause of the entrepreneurs to face difficulties when asking for finance for their businesses. The reality in Republic of Macedonia is that SMEs mainly seek for financing in the commercial banks and they are still dependent on the banks.

Macedonian companies are getting more and more aware of the fact that their own assets and the loans from the commercial banks are simply not enough for developing the technology and investments. So, in order to enlarge the list of possibilities of how to get the financial help, Macedonian entrepreneurs should be better informed and understand the variety of financing sources available now. The alternative financing sources such as: Business angels' network, European Bank for Reconstruction and Development (EBRD), SEAF1 Macedonia, Technological development and innovation fund, Development Foundation "Crimson Capital", Sortis Invest are a good instrument for the start-up businesses as well as for the sustainable development of the existing SMEs.

Abstract: *Investment decisions are made in accordance with the situation in the financial markets, the level of portfolio diversification, the results of technical and fundamental analysis, as well as in line with the expectations and preferences of investors and managers. This paper discusses the role of risk in decision-making, and gives the basic concept of behavioral finance and its applications. Adequate management of investment portfolios provides a harmonized relationship between risk and return, and considering the fact that all decisions in the financial markets are made based on predictions and expectations, it is clear that the influence of the irrational should not be underestimated. Empirical evidences proved that there are number of situations in investments and capital market transactions when market participants often act very unpredictably. Behavioral finance is supplement to the standard finance theories by bringing in behavioral aspect into decision-making process This paper represents a theoretical basis for future empirical research on the subject of behavioral finance.*

Keywords*: Behavioral finance, decision-making process, market efficiency, risk,*

1. INTRODUCTION

Global financial markets are influenced by a number of factors: economic processes related to different countries of the world, institutional and political constraints, lack of transparency in operations, information asymmetry etc. However, one of the most important factors refers to the perceptions and reactions of participants in the financial markets. For each investor, doing business in the financial markets is a constant process of decision making. The aim of this paper is to briefly describe the emotional factors that have an influence on the price changes in the market, i.e. on making investment decisions. The analysis of the rational and irrational investment decisions could partly be explained by considering the psychological effects of an investment activity. As Bikas et al. (2013) states in their work, the main difference between traditional and behavioral finance is the fact that traditional finance does not address the question of "why" investors make one or another decision.

Bikas et al. (2013) suggest that investment in financial markets instruments in recent decades is becoming increasingly popular in the circles of individual investors. Communication with people on the other side of the world is no longer a problem, so the information is spread very quickly, and decisions are made in a relatively tense atmosphere. Undoubtedly, investment decisions depend on the type of investment and expectations that are linked to it. However, very often short-term investment decisions are not based on logical arguments, and are more often made on the basis of your current mood or just received information.

In an attempt to explain the decisions and actions of financial investors, a completely new theory has been suggested in the literature which is based on the concept of behavioral finance. Some authors like Bikas and Jurevičienė (2009) and Jurevičienė et al. (2012) have used this theory in order to explain the decisions regarding personal finances and the way in which clients of financial institutions decide on savings.

Behavioral finance is the result of connecting the various sciences (Ricciardi & Simon, 2000): **Psychology** – through which the behavior and thinking is analyzed, i.e. how human behavior is conditioned by the physical and psychological characteristics and the external environment; **Finance** – which explain ways to define the optimal structure of assets and resources; and **Sociology** – which analyzes the impact of sociological factors on people's attitudes and values.

In their research, Jurevičienė et al. (2012) classified behavioral finance as macro and micro-finance. Macro aspect refers to the analysis of defects of market efficiency hypothesis and micro aspect focuses on the behavior and inconsistencies in decision-making of individual market participants. Both approaches separate finance from strictly rational decisions, as well as from mathematical and statistical models, thanks to which, a large number of procedures were explained in the past.

Financial experts have been trying to make an empirical model that will show which factors influence the investor's competence. Graham et al. (2009) have concluded that investors who trade frequently have a more diversified portfolio of those investors who are characterized by passive strategies. In addition, investors with a strong self-confidence feel strongly that their decisions are more accurate, and portfolio of securities better structured.

2. DECISION-MAKING AND RISK

In everyday life, people often find themselves in a situation to make a choice among a range of options and make different decisions, from the mundane, which are not very important, to those of vital importance. Making individual and group decisions is the subject of decision theory which was created in the mid-twentieth century through contributions from different scientific disciplines, economics, statistics, psychology, political science, sociology, philosophy (Hansson, 2005). In the framework of decision theory two perspectives have been developed, normative and descriptive (behavioral) decision theory. Normative theory was formed to meet the needs of the economy and is concerned with how decisions should be made. It describes the behavior of an idealized, fully rational and informed decision maker who is governed by the principle of maximizing their benefit and offers a variety of methods of making good decisions adequate for different circumstances. In contrast to the normative, descriptive decision theory has been developed primarily in the field of psychology and focuses on the question of how decisions are really made. The role of the decision maker is given to a man with a natural cognitive limitations and psychological factors which lead to deviations from the ideal, rational decision-making (Pavličić, 2007).

Decision is the selection of one from a set of at least two options which can achieve the desired objective. Decision theory assumes that the set of possibilities is closed, i.e. their number is limited and they are mutually exclusive. Also, all possible events have to be fully understood and mutually exclusive (Hansson, 2005).

Depending on whether the circumstances in which decisions are made (the state of nature, events) are predictable or not, it is possible to talk about decision-making under three types of conditions - certainty, uncertainty and risk (Peterson, 2009). For all three types of situations normative theory offers models which lead to making rational decisions. It is understood that perfectly rational decision maker always knows what he wants and strives to achieve it governed by the principle of maximizing personal benefit. Decision-making under conditions of certainty refers to the cases when only one state of nature occurs in the implementation of a specific action, and it is known in advance. In this case, the outcome of each selected alternative is known in advance. Based on personal preferences, each option is assigned a number which expresses its importance, utility for the decision makers and it is usually expressed in money. In the event that the probability of occurrence of each outcome is unknown, the decision is made in terms of (total) uncertainty. If the probability of the possible outcomes when choosing certain options is known, the decision is made in terms of measurable uncertainty, that is, in terms of risk. In such conditions, the utility of each outcome is weighted by the probability of its occurrence resulting in a number that represents the expected value of the outcome. Rational decision involves selection of option with maximal total expected value. However, for making specific, individual decisions which are not repeated, the expected value is not a reliable basis for selection. This has been shown by the **St. Petersburg Paradox** which reveals that in terms of risk the values function of money is not always a linear relation with subjective utility, which is attributed to it. This finding implies the use of selection methods based on the maximization of mentioned subjective expected utilities (EU designation of Expected Utility). To calculate its value, the procedure of standard game is used, and it requires ranking the options on the basis of individual preferences, and choosing numerical interval in whose range the values assigned to individual options will be able to move.

In his paper, Virlics (2013) states that if the utility function is linear, it means that the indifference to risk is present, that is, it does not matter whether we choose a certain outcome or a risky action of the same expected value, one outcome of which is better than the certain one, and the other worse. Only in this case there is a linear relationship between the value of money and the expected utility attributed to it. However, in reality, the other two forms of function are much more common. A function that is convex downward reveals an individual who shows aversion to risk and will always prefer a certain outcome to the risky option. Although the majority of people in everyday life act like this, there are people and situations which are dominated by the tendency towards risk. In this case, the utility function is convex upward showing preference to the risky option. Principles of normative theory show how a perfectly rational individual should make decisions in the circumstances of certainty, uncertainty and risk.

However, in everyday life, one often does not have access to all the necessary information related to the set of possible alternatives, states of nature and outcomes. The criteria of normative theory are too strict even when it comes to preferences of real decision makers. The preferences are often time unstable, logically

inconsistent and thereby mutually conflicting. Since the 1970s different studies have been conducted aiming to explain the actual process of decision making. The empirical findings that have emerged from these studies were the basis for the creation of behavioral theory. In addition, it has been found that decision-making is not always defined by utility maximization, but is affected by a number of factors which, among other things, are of emotional nature. Kahneman and Tversky (1979) have defined one of the most important theories explaining the causes of deviations from rational choice under the conditions of risk. Based on a series of conducted experiments, the aforementioned authors have concluded that in humans there is a tendency to overestimate the chances of unlikely events occurring and underestimate the chances of medium and highly likely events occurring. Kahneman and Tversky (1979) assume that in assessing the utility of the outcome there is a value that represents a standard, a reference point. Each outcome is compared to it and is therefore seen either as a profit, which is assigned a positive value, or a loss, which is assigned a negative value. In this way, a function value is formed and is the basis for decision making. It has been shown that the function has the shape of the letter S, and it reveals two important phenomena. First, it seems that people are more sensitive to identical differences in values of outcomes if they are close to the reference point than when they are significantly distant from it. For example, an increase in funding from 1000 to 2000 dinars is perceived as greater than the increase from 10 000 to 11 000 dinars. Another important feature of the value function reveals the existence of the phenomenon of loss aversion – the losses and gains of the same value are not evaluated in the same way, as the losses are viewed as larger. The loss of 10 000 dinars is experienced more intensely than a gain of 10 000 dinars (Kahneman and Tversky, 1979).

Normative decision theory is based on the concept of statistical probability, while in the process of making individual decisions it does not make much sense to rely on statistical probabilities. A solution is offered in the form of the concept of subjective probability, which is distinctive only to a particular decision maker. In order to determine the numerical subjective probability, the lottery method is used (Pavličić, 2007).

Analysis of the decision-making process in economic theory shows that the decision-making process is based on an objective analysis of the investment and the possible outcomes, as well as on the subjective perspective of investors. Neuroeconomics shows that the psychological and emotional impact on the decision-making process can have an informative and very useful role. The analysis of investment risk in terms of behavioral finance explains some of the decisions made irrationally, and the fact that the perception of risk greatly affects the optimistic or pessimistic attitude of the investor opens the door for new research on this topic.

3. BEHAVIORAL FINANCE CHARACTERISTICS

When analyzing investment process, there are studies whish emphasis that investors spend too much time studying investment behavior and not enough time focusing on investor behavior. In spite of what an investment does, it is the decisions of the investor to buy or sell that finally determines success or failure. This fact is the fundamental premise in behavioral finance.

It might be said that the most valuable contribution of behavioral finance can be perceived in better understanding of how investors value assets they would invest in. Asset valuation performed by investors and academics relies on evident factors but, on the other hand, experience has showed that human side is very influential during the investment decision process. Connecting the knowledge of how people make decision with investment process would hopefully enhance portfolio performance.

For a long period theoretical and empirical evidence suggest that capital asset pricing model (CAPM), efficient market hypothesis and other rational financial theories were successful in predicting and explaining events and processes in financial markets. But, in time, more and more anomalies and behaviors has occurred that could not be explained by existing theories at that time. Empirical evidences proved that there are number of situations in investments and capital market transactions when market participants often act very unpredictably. Behavioral finance is supplement to the standard finance theories by bringing in behavioral aspect into decision-making process. Contrary to Markowitz and Sharp, behavioral finance deals with individuals and ways of gathering and using information. Behavioral finance is particularly in evidence in stock market anomalies, share valuation, acquisitions and loss-making projects (Pike and Neale, 2006).

The traditional understanding of EMH is illustrated in the following diagram. The key idea is that in an efficient market, all available information is reflected in the market price of securities.

A critical assumption in the traditional framework is that this information, no matter which form of it is being observed, leads directly to the investment decision. These decisions relate to the purchase, sale, issue of securities, or a decision to continue with keeping the securities in the portfolio.

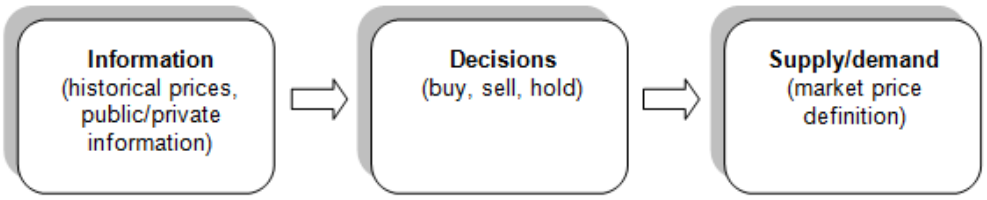

Diagram 1: Traditional model of investment decision-making process

In an efficient market, the market price fully reflects the available information. The only goal of the behavior in this model is the maximization of profits. Buyers and sellers can and do make decisions to optimize their expected return tailored to a particular level of risk.

Diagram 2: Behavioral model of investment decision-making process

In this model there is an additional phase which is located between the available information and the decision to invest. Relevant information, including historical rates, accounting ratios or plans to take over a corporation etc., is inevitably processed by the investors whose behavior is the subject matter of behavioral finance.

Errors in processing affect the investment decisions and, therefore, affect the price in the market. Market prices, defined by supply and demand, can fully reflect the available information, as well as the errors in processing the information.

Nobel Prize laureate in economics for 2002, Daniel Kahneman and Amos Tversky have integrated economy and psychology, and in the process, laid the foundations of behavioral finance. Their work is focused on the process of decision-making under conditions of uncertainty.

They have proven that human decisions are systematically different from those predicted by rational models of decision-making, which is the assumption of traditional economics. Their alternative model, the theory of loss aversion (Prospect theory), provides new insights into the perceived behavior of decision makers. Kahneman and Tversky (1979) have also shown that, by using heuristic shortcuts, decision makers systematically deviate from the principles of probability.

Their work represents a revolution in the field of finance because it has shown that behavioral biases, and in particular the theory of loss aversion, generally gives a better indication of how decisions are made in risky situations.

During the processing of information by investors, there are a few distinctive mistakes (Bodie et al. 2009):

- **Prediction mistakes**: According to the research conducted by Kahneman and Tversky, people attach great significance to recent experiences at the expense of previous convictions (memory bias). According to them, if a company has announced good business results and if a great profit is predicted, the expectations of future price growth are generally too optimistic in relation to the real business of the company. This is manifested in the growth of share prices and a higher P/E ratio, which later leads to a drop in prices and the ratio when investors realize their bad judgment.
- **Overconfidence**: People have it in their character to overly trust in their abilities and the correctness of their beliefs and decisions, and they take actions in the financial markets with too much confidence. This compares to a phrase that there are no bad drivers because they all think they drive perfectly. Excessive self-confidence usually results in more active trading, although according to Barber and Odean's research (2000), it has been determined that 20% of investment accounts with the largest turnover have seven percent lower average returns than 20% of the accounts with the lowest turnover.

- **Being conservative:** Being inert in processing the new information related to the market or companies usually results in overly slow responses to new evidence, causing a delay in trading.
- **The size and representativeness of the sample:** Investors often make decisions on a small sample of information, trying to determine the trend of price movements on the basis of a small amount of information in a short period of time. For example, if a company has published good results in a several quarterly reports, it can be considered as a sufficient signal for investment and can lead to an excessive price growth, although there is a large discrepancy between the market value and intrinsic value of shares. After a certain period, this leads to a shift in the trend since the initial investors' expectations about the company's business trends are usually not met.

And if there was a case in which information is process perfectly, it does not necessarily mean that fully rational decisions would be made. Irrational behavior has a significant influence on investment decisions and the perception of risk and return.
One of the factors that affects rational decision-making is **formulation**, i.e. the way in which relationship between risk and profit, or loss, is formulated. People usually behave differently to risk if it is presented to them with the option of gain, or an option of loss (e.g. tossing a coin and the possibility of gain if the right side is called, or loss if you choose the wrong side of the coin).

Mental accounting is a special type of formulation, which implies that people separate certain decisions in investment, according to the degree of risk. It is very often the case that an investor holds a portion of his portfolio in very high-risk stocks, while having a separate savings account with minimal risk, as a balance. This behavior is manifested in easier decisions to spend the dividend income, which is not the case when it is needed to sell the stocks which have brought the same rate of return, to hold the shares which are making losses (reluctance to realize losses, because at the time of sale they becomes real), as well as to take a greater risk with the realized profit from trade, because it is the earned money and does not mean spending the investor's substance.

Safe decision-making, i.e. investing in well-known large companies, provides an alibi in trade losses, because those investments are considered "safer" than if the money was invested in young and lesser known companies. In this way, loss regret has its justification in the absence of happiness, not in a bad estimate in investments. Furthermore, investing in young companies, through mental accounting, is recorded as the expected and higher return because they carry higher risk.

If rational investors could take full advantage of the irrational investors' errors, then the irrational behavior would have no impact whatsoever on the price movements of stocks, because the rational investors would use any deviation to invest and, in doing so, return the rates to the appropriate level. However, in the behavioral theory there are several factors which limit this possibility:

- **Fundamental risk**: Even if a share is undervalued, it does not mean that the purchase of these shares at the appropriate time is the right choice, because it can happen that the price of the stock continues to fall. It may happen that the purchase of undervalued stocks at the wrong time leads to further losses (even though they are short-term) which can cause a margin call (if it is traded with margin) or that the investors leave the fund which has poor short-term results and has invested in this way.
- **Trading costs**: They are especially conspicuous in the sale of overvalued stocks, the so-called short selling. Some funds or investors do not have the opportunity to trade like this, or can do so only if, in a short time, they buy shares to cover this position, but it carries a high risk of loss.
- **Model risk**: There is always a risk that a wrong model is being used in estimating the value of shares, which gives the illusion that a share is undervalued, but it might actually be its real value. This constant risk limits the trading activity and makes it less attractive.

According to Bikas at al. (2013) traditional finances lies on basic paradigms that portfolio is based on the expected return and risk and is subject to risk based capital asset pricing models, such as CAPM etc. On the other hand traditional finance does not respond to the questions like: why does an investor trades, how does an investor trades, and how does an investor composes portfolios, questions on which behavioral finance tries to give the answers.

4. BEHAVIORAL FINANCE AND THEIR APPLICATION

The emergence of behavioral finance and behavioral economics occurs primarily as a response to those circumstances in making economic decisions which cannot be explained by the postulates of the traditional economy. Postulates of the traditional economy are based on the rationality of market participants when making financial decisions, as well as on the efficiency of the market. A typical feature of behavioral finance is that it uses the findings of social sciences, especially psychology. Psychological studies are based on

limited human rationality, the evident differences found between individuals when it comes to experience, education and expectations, which is a direct consequence of the social and economic status of the individual. Todorovic (2011) points out that behavioral finance, based on the observation and study of the behavior of investors and managers, seeks to add cognitive psychological elements to sophisticated mathematical and statistical models of modern corporate finance.

Behavioral economics can be applied in a variety of areas, especially in modern finance which can no longer be explained only in terms of basic economic principles. Other areas in which behavioral economics is applicable include: organizational economics, public finance and neuroeconomics, and there is also an emerging need for the application of behavioral finance in new areas of psychology.

Behavioral finance is largely successful in explaining the ways in which certain groups of investors behave, especially what kind of portfolio structure they select, and the way in which they trade (Jo and Kim, 2008). Some studies (Grinblatt and Keloharju, 2001; Huberman, 2001; Benartzi, 2001) have shown that ambiguity and familiarity of decisions are the reasons for the insufficient diversification of the investment portfolio. In addition, it often takes fewer resources to investigate local firms than the foreign ones. Guided by this fact, managers prefer local companies' stocks, choosing those with a high expected return. Rationally speaking, the number of transactions should be low because of the high transaction costs. However, the volume of trade on stock exchanges worldwide is extremely high. Best behaviorist explanation for this contradiction is the overconfidence that the investors and portfolio managers have. The hypothesis automatically predicts that people who are more confident will trade more and, consequently, because of transaction costs get lower returns. Several studies (e.g. Shefrin and Statman, 1995) have shown that investors are reluctant to sell assets if, by doing so, they realize a loss or a price which is lower than that at which the assets were purchased. There are two behavioral explanations for this situation. The first explanation implies that investors have an irrational belief when it comes to refunding, while the second one refers to the aversion to loss.

Odean (1999) argues that the attention effect has a great influence on the decision to purchase the shares. It has been shown that individual investors are more inclined to purchase the shares which are designated as "high-attention stock" than to sell them. Barber and Odean (2002) have also come to the conclusion that individual investors typically purchase only a smaller number of shares which have attracted their attention. They create "portfolios of attention" on the basis of several criteria: stocks with above average trading volume, stocks with returns which are well below and above the average, and stocks which are published in the newspapers. Jo (2003) has examined whether managers are considering the psychology and investor's interests when planning the issues of shares. The results of his research have shown that investors prefer companies which are considered to act in a socially responsible way and which attract public attention through marketing campaigns.

Shefrin and Statman (1999) offer numerous behavioral explanations of the fact that investors expect regular dividend payments. The first reason relates to the concept of self-control. Another rational reason for preferring dividends refers to the so-called mental accounting. Shefrin and Statman claim that, by paying the dividends, companies allow investors to avoid regrets for buying a particular stock and for investing their money for those purposes. Baker and Vurgler (2002) argue that changes in dividend payment policies may have a negative effect on the investor's opinion of the company whose shares they have in their portfolio. In addition, their study has shown that it is easier to control the irrational investors than the irrational managers. Heaton (2002) analyzes the consequences of manager's excessive optimism, or a situation in which managers overestimate the likelihood that their company's future performances will be good. Knyazeva (2007) and Yu (2007) have focused on the role of financial analysts in the process of monitoring. They find that the control mechanisms improve the level of connection between managers and shareholders, and give managers an incentive to conduct proper corporate policies. Jo and Kim (2007) argue that the improved transparency in a corporation will reduce the information asymmetry between the different stakeholders, discourage managers to seek self-interest and increase the company's value. In their work, these authors have concluded that the transparency of information is negatively correlated with unethical manipulation and profits, and positively correlated with long-term performances of the company.

The application of behavioral theories has brought about the need to define investment portfolios based on personality and gender. Pompian and Longo (2004) have conducted a study on this topic and came to the following conclusion. Classifying the investors by type, personality and gender, enables the advisors to create programs that mitigate individual bias, encouraging investors to consider long-term strategic directions. Only a few studies have examined the relationship between gender and bias in behavioral finance, and the authors Barber and Odean (2002) have dealt with this phenomenon the most. The conclusion of their study is related to the fact that men have more confidence than women and that it is

reflected in the trading behavior. These authors have found that, over a period of six years, men traded on average 45% more than women. In addition, single men traded 67% more than single women.

Research in the field of behavioral corporate finance is heading in two directions. The first emphasizes that the investors are not fully rational and the markets are not fully efficient, and, therefore, stock prices deviate from their fundamental values. This means that financial managers need to shape the financial and investment decisions taking into account the irrationality of investors. The second approach emphasizes that the managers are not fully rational. Behaviorists in corporate finance consider a postulate in which managers believe that, when making financial and investment decisions, they are working to maximize the fundamental value of the company, but, in reality, they are not doing so because of the psychological traps. Generally speaking, behavioral finance tends to contribute to the reduction of market irregularities, the rational behavior of managers and investors, and the improvement of the quality of investment decisions.

5. CONCLUSION

Although the standard financial theory advocates that investors should have more diversified portfolio, empirical research has shown that very often decisions are made intuitively and according to investors' personal preferences. Real investment strategy should not rely on market efficiency since it is clear that not all the information is publicly available. Furthermore, it often happens that investors direct their attention and expectations to only one type of investment or to specific market instruments. Behavioral finance seeks to explain the way in which market participants make decisions, and to justify the consequences caused by them, aiming to defining a successful investment strategy. The premise of behavioral finance is that conventional financial theory does not take into account the way in which people make complex decisions when having limited information. The proponents believe that one of the reasons for this drawback is the fact that it is relatively easy to acquire data on prices and returns, but it is much harder to study behavior. The aim of this paper is to stimulate discussion and further research in this area, particularly in the context of improving market strategies and proper understanding of the decision-making process in the field of finance.

Abstract: *In this paper the authors analyse implementation of the fund accounting concept in the process of managing non-profit organisations. Control of budget, that is, funds can be ensured by implementing various concepts, including, inter alia, the fund accounting concept. Although its implementation has a long history in the USA and other developed countries, developing countries start paying more attention to the use of public funds and other resources in non-profit organisations only in later stages of development. The paper will highlight the main advantages and disadvantages of this concept, with a view to considering possible introduction of the concept into official or unofficial financial reporting of non-profit organisations in the Republic of Serbia.*

Keywords*: non-profit organizations, funds, control, accounting.*

1. INTRODUCTION

In the circumstances of crisis, control of utilisation and spending of funds in companies is gaining importance. Increasing efficiency of spending and elimination of spending of funds that do not have long-term effect on productivity and profitability of a company should allow survival of operations of businesses in those circumstances. Companies would thus be able to create profit, which represents the key objective of their foundation. On the other hand, non-profit organisations, being business entities whose main objective is not creation of profit, may very easily get bad publicity of the general public and critics if they do not ensure efficient spending in the challenging economic circumstances. These business entities are established for the purpose of conducting activities, the results of which should meet the needs of general public. Alternatively, the entire social community of a certain country should have benefit from the operations of those entities.

Therefore, unlike companies where utilisation of funds should generate income, preferably much higher, in order to ensure higher business result, non-profit organisations use funds to conduct certain activities that are not supposed to generate income and ultimately profit. Non-profit organisations do not need extended reproduction, as it is the case with business entities, to continue operations because the funds they are spending should not be generated by conducting an activity, but they obtain those funds otherwise. In the challenging economic conditions, financial resources raised by these entities are more limited than in regular economic circumstances, therefore control of utilisation of these funds is more important. In such situations, all government authorities are faced with above constraints, not only economies of developing countries. Accounting of non-profit organisations (fund accounting) is one of the concepts used in the process of control of utilisation and spending of funds in non-profit organisations. In the first part of this paper, the authors will analyse how drawing up the budget can be used in the process of managing the spending in non-profit organisations, while in the second part of the paper the authors will focus on the fund accounting concept in non-profit organisations, its advantages and disadvantages in practice.

2. NONPROFIT ORGANIZATIONS, BUDGET AND CONTROL

Non-profit organisations can be financed by governments and therefore they are called governmental non-profit organisations, or can be financed from other sources, in which case they are called non-governmental non-profit organisations. Examples for non-profit organisations can be: governmental units, universities, hospitals, professional organizations, museums, theatres, voluntary organizations... For instance, in 1989 in the USA, out of 7,000 hospitals in the USA, approximately 90% were non-profit organisations (Forgione & Giroux , 1989). Today, out of 5,273 hospitals, about 73% are non-profit hospitals (Health Forum LLC, 2014). As we can notice, activities and/or business conducted by non-profit organisations depend on the needs of the society, not on the possibility to earn profit, although that intention is changing over time due to introduction of corporate governance in all areas of functioning of one country. Legal and physical entities investing funds in these organisations will not be granted share in the equity of the organisations, as it would

be a case with business entities. On the contrary, these entities will not receive any reward in the form of money; therefore assessment of quality of performance of these entities may not take profit as a basis of assessment. It is also the reason why financial reporting and financial reports of these entities are different from companies. With the above in mind, absence of profit in these organisations does not represent certain form of penalisation or control of funds utilisation, as it is a case with corporate entities; therefore, it is necessary to establish control over managing spending of financial resources otherwise. For instance, limitations in utilisation and control of funds utilisation can be established by persons donating funds, because they wish the invested funds to be used for achieving a specific target, for example, construction of buildings, care of people or granting scholarships to certain individuals, etc. On the other hand, in case of governmental non-profit organisations, control over utilisation of funds is achieved by drawing up the budget.

Considering that public revenues represent all revenues generated through mandatory payments by taxpayers – legal entities and natural persons using certain public goods or public service, as well as all other revenues earned by the beneficiaries of budgetary funds and funds of organisations for mandatory social insurance, it is very important to ensure their transparent monitoring. That is the purpose of the national budget. A budget is a one-year or three-year plan in case of capital expenditures, which shows how the collected public funds will be spent over the observed time period. Beneficiaries of the budget funds can be direct and indirect. For example, in the Republic of Serbia, direct beneficiaries of the budget funds are government authorities and organisations, that is local government authorities and organisations, whereas indirect beneficiaries of the budget funds are judiciary bodies, budget funds, local communities, public enterprises, funds and agencies established by the local government which are financed from public revenues, the purpose of which is defined according to special law, institutions established by the government of local government which are controlled by the founder through direct beneficiaries of the budget funds according to the law regulating rights in terms of management and financing. Furthermore, organisations for mandatory social insurance and beneficiaries of Health Insurance Fund (health and pharmaceutical institutions founded by the government or local government) are also seen as beneficiaries of public funds.

The budget foresees how much money will be collected from citizens and corporate sector during the observed period. It is adopted by the highest representative body, the parliament of a country, province or local self-government. Structure of revenues shows who is responsible for creation of revenues, while structure of expenditures shows economic, social and other goals. The legal act according to which the legislative power, that is, the Parliament, approves expenditures and other expenses, and/or revenues and other income, borrowing and other financial transactions for every year is the Law on the Budget of the Republic of Serbia. This Law also contains stipulations relevant for its implementation. In the event when the budget is adopted for the period of three years, revenues and income and/or expenditures and expenses are disclosed for each year separately. On the other hand, decision on the budget is adopted at the local level. It is the most important local political document, that is, legal act by which revenues and expenditures are foreseen at the level of local community for the period of one year. Moreover, direct or indirect beneficiaries of the budget funds are obliged to prepare a financial plan in line with the guidelines for budget preparation and the guidelines for preparation of mid-term plans and projections within the mid-term framework of expenditures provided for by the Fiscal Strategy. Utilisation of funds of non-profit organisations is naturally controlled through financial reporting and preparation of financial reports which may be official and unofficial.

3. FUND ACCOUNTING AND GOVERNMENTAL ACCOUNTING

As mentioned above, financial reporting related to non-profit organisations is different from financial reporting intended for business entities. For long time professional organisations show intention to unify the global accounting standards which are used by companies, whereas the difference in standards of non-profit organisations is considerably larger. There is also a difference in the financial reporting between government and non-governmental on-profit organisations. The first organisations usually have dual financial reporting, that is, they prepare both mandatory and official financial reports in compliance with the accepted accounting standards (e.g. IPSAS - International Public Sector Accounting Standards) and internal or unofficial financial reports, which allow better control over the utilisation of funds.

On the other hand, non-governmental non-profit organisations commonly only organise unofficial financial reporting, except in special cases. Governmental accounting is usually understood as official financial reporting of governmental non-profit organisations, whereas fund accounting represents a concept which usually refers to internal financial reporting of both governmental and non-governmental non-profit organisations, although it can also be applied to governmental accounting, if regulated so by state regulations. It is commonly considered that this concept cannot serve as the basis for quality control of spending by governmental non-profit organisations, if it is independently used as a concept.

The concept of fund accounting is based on the term “fund” which has been since 1900 referred to as the account in which money is collected for specific ultimate purpose (James, 1950). This concept has been used in governmental accounting in the USA for an entire century (Ingram, 1986). Implementation of the fund accounting concept is usually recommended for expendable fund entities, because other two types of funds (proprietary and fiduciary fund entities) also require implementation of other financial reporting concepts (Jeter & Chaney, 2011). In case of expendable fund entities all collected funds will be spent over certain period, one year or during some other specific period. The purpose of spending these funds must be pre-defined and the funds must be spent exclusively for that purpose. An example for these organisations can be a fund intended for implementation of capital projects, such as construction of a highway or debt service fund created to account for interest and principal payments on long-term debt (Jeter & Chaney, 2011). In addition, debt service fund can have a separate principal account and interest account in which funds can be used only for that particular purpose.

In case of fund accounting there are no revenues, expenses and financial result as measures of successful functioning, but fund resources (inflows), decreases in fund resources (outflows) and change in fund balance. Term “expenses” is not commonly used in fund accounting, because this term is mainly used in the context of revenue generation, that is, in financial reporting of companies each expenditure and revenue must be presented against each other. Bearing in mind that in non-profit organisations revenue does not represent a goal and as such cannot be found, in fund accounting we commonly use the term “expenditures”. This term shows spending of funds which will not lead, as a result, to creating certain production outcome – service or product and it will not be opposed to revenue. However, fund accounting is often used in combination with concepts of accrual accounting and budgetary accounting, in order to ensure better and more efficient funds utilisation control.

4. ADVANTAGES AND DISADVANTAGES OF FUND ACCOUNTING

Advantages and disadvantages of fund accounting are usually classified in four categories (Hoek, 1996):

- economic (efficient allocation of funds),
- financial governance (considering the state apparatus performs different activities, one concept may not meet all requirements),
- political and administrative.

What is frequently mentioned as a drawback of the fund accounting concept is spending of the funds for the particular purpose for which they are earmarked, but to an unnecessary extent. IRS (Internal Revenue Service) in the USA is an organisation which has been criticised for excessive spending. According to Chubin (2013), an official appearing before Congress testified that the disputed conference in California would have cost $ 1million less if it had been held in another city. However, the funds planned for the conference reached the amount of $4.1 million because the funds were simply available and allowed numerous benefits for the conference participants, such as tickets for baseball match and the like (Urbanski, 2013). According to the same source, IRS spent in the period 2010-2012 approximately $50 million for organising about 220 conferences for employees.

Although at first glance misappropriation (inefficient allocation) of funds by non-profit organisations includes use of cash, in practice that misuse very often, almost always, refers first to utilisation of fixed assets. The reason for that is use of cash basis accounting concept which does not see acquisition of fixed assets as acquisition of assets that can be used over longer period, but as outflow of cash funds incurred by acquisition of fixed assets. The above practice would not be the case in financial reporting of companies where outflow of funds would be recognised as purchase of assets that would be later depreciated. Therefore, non-profit organisations need not justify utilisation of fixed assets because those assets technically do not exist in the records (Tanzi & Prakash, 2000). This is the reason why it often happens that state schools and similar institutions in the city centre or at attractive locations are sometimes no longer used or half-empty, because governments simply do not have records how public assets are opportunistically used for present purposes. It is often the case that certain ministries in the government do not even keep track of the fixed assets managed by its organisations.

According to Chubin (2013), the fund accounting concept should no longer be used as it leads to excessive spending and lower control of spending by employees in the U.S. government. The author points out that it is necessary to stop comparing the budgeted inflows of money with the actual inflows and the budgeted with the actual expenditures and start using revenues and expenditures as companies do and, in other words, introduce corporate spirit into these organisations. From the aspect of allocation of funds, it is assumed that beneficiaries of funds will spend all allocated funds as the following year they would otherwise receive lower

amount of available funds. Another reason for spending funds is a possibility that beneficiaries will not later be able to justify the funds allocated. The above practice causes surplus of employees who are still employed, surplus of public procurement or replacement of still functional and usable assets. It is assumed that implementation of the corporate financial reporting would reduce expenditures and number of employees, whereas introducing the reward system for employees for efficient utilisation of funds would increase employees" motivation to use funds economically (Chubin, 2013).

Among arguments in favour of implementation of this concept may include that the problem is not comparing of the budgeted with the actual inflows of funds and expenditures, but inadequate determination of marginal values of available funds. In other words, maybe the problem lies in the budgeting process. After all, fund accounting, as we have proved, refers to the organisations where, as a rule, spending is not continuous (which would be the budgetary accounting concept), but it is time-bound. Accordingly, as it is noted (Reiffe, 2013), the purpose of the fund accounting concept is to separate funds with limited use from the funds where there are no such limitations and to monitor the use of those funds for pre-defined purpose and therefore it is not connected with the determination of the budget amount. Furthermore, implementation of the corporate financial reporting may not automatically cause reduction of expenditures and lead to more efficient utilisation of funds, as it is intended, but might lead to increased revenue, in this case inflow of available funds, in order to enable inefficient spending of funds.

Those criticising this concept stress that it leads to reduced comprehensibility of the information it produces. It is considered that the main stakeholders do not obtain information that would be relevant to them for making business decisions. Further, they state that the concept is much more focused on harmonisation with legal regulations than on estimation of efficiency of funds utilisation and it may conceal unjustified use of funds.

Bearing in mind that the fund accounting concept has long been implemented, objections to this concept have also followed it throughout its use. For instance, in the 1970s, financial problems of New York City became more notable through considerable fall in the sales of city"s bonds in 1974, but it did not affect the rating of the city"s bonds until 1976 (Herzlinger & Sherman, 1980). Many market analysts pointed out at that time to inadequacy of the financial reporting concept because it did not timely warn investors of possible worsening of the bond rating until it became obvious. It was later confirmed that the reasons for worsening of the city"s financial standing resulted from poor internal control and inadequate accounting system organisation.

The research conducted by Ingram (1986) confirmed similar findings, indicating that there is no evidence that governments deliberately apply this method in order to make financial reporting more incomprehensible. The research results show that this concept produces useful information for key stakeholders in situations when investors wish to invest in municipal bonds (Ingram, 1986). Ironically, despite all disadvantages and advantages of the fund accounting implementation, the most important change in relation to improving comprehensibility of financial reports in international, but also local practices would actually be to make these reports more publicly available These organisations are commonly exempt from tax payments, therefore all stakeholders paying tax should be allowed access to the financial reports of non-profit organisations and be able to analyse them. Although according to the law non-profit organisations are obliged to make their financial statements publicly available in almost all countries worldwide, as it is done by companies, they rarely comply with that stipulation so that users of these reports are short of information relevant for business decision-making. (Herzlinger & Sherman, 1980).

5. CONCLUSION

The aim of creation and development of the fund accounting concept is to increase comprehensibility and fair presentation of transactions which are typical for non-profit organisations. Importance of applying this concept is manifested in clear monitoring of funds earmarked for specific purposes, how much funds has been spent and for which purpose and how much is available for achieving the main goal of these organisations. Irrespective of their non-profit nature, financial reporting of these organisations still needs to be economical. Although one of key disadvantages of the fund accounting concept is complexity of information it produces, which is also related to high costs for obtaining such information, use of this concept is justified if the benefits exceed costs. Considering the economic conditions in developing countries, stricter control of spending public funds is highly important. The aforementioned also refers to non-governmental non-profit organisations which are operating based on investment from funds of individuals or organisations because it is important for the owners of allocated funds that funds are used for performing pre-defined activities. We believe that it necessary to apply different concepts in financial reporting in order to ensure that their main functions are met.

Abstract: *Integral performance measurement systems have been in a focal point of both scholars and practitioners for more than three decades. In today's business environment which is characterized by tremendous competitiveness and globalization of business, performance measurement becomes a critical success factor. In spite of the fact that performance measurement systems receive significant attention, studies focused on critical perspectives are still at the infantile phase. This paper aims to provide a theoretical overview of upsides and downsides of currently used integral performance measurement systems.*

Keywords*: business performance, performance measurement systems, financial indicators*

1. INTRODUCTION

Integral performance measurement systems have been in a focal point of both scholars and practitioners for more than three decades. Many authors have argued that performance measurement is a key success factor for decision making. From the qualitative point of view, aforementioned statement can be viewed from the prism of paradigmatic maxims such as "what can not be measured can not be managed" or "you get what you inspect, not what you expect."[1] However, the quantitative confirmation to the statement is not easy to provide, regarding the fact that the term – integral performance measurement systems – has been ambivalently interpreted by various scholars (Franco-Santos et al., 2012). The same term is used by Bititci et al (1997). On the other side, scholars simultaneously use the term comprehensive performance measurement system (Hall, 2008; Franco-Santos et al., 2012), business performance measurement (McAdam and Bailie, 2002), and strategic performance measures (Atkinson, 1998; Ittner et al, 2003; Bourney and Widener, 2007).

In spite of the fact that performance measurement systems receive significant attention, studies focused on critical perspectives are still at the infantile phase. This paper aims to provide a theoretical overview of upsides and downsides of currently used integral performance measurement systems. Specific objectives of the study aim to contribute to the current body of knowledge in the area by emphasizing critical points of common integral performance measurement systems. More precisely, the study will address the issues of performance measurement normalization, information optimization, adequate structures of relations among particular performance measures within the system, a synthetic of performance measurement and the issues of design, implementation and development of performance measurement systems.

To the best of author"s knowledge a study of this kind has never been conducted before. The study is a part of the comprehensive study which addresses the issues of design, implementation and usage of integral performance measurement systems.

The remainder of the paper is organized as follows: the second section elaborates on the role and importance of business performance measurement systems, thus emphasizing the potentials of appropriate design and usage. The third section presents a review of most commonly cited integral performance measurement systems both from the point of view of the practical usage and citations in the academic literature. The fourth section provides the set of critiques to aforementioned systems. The fifth, and the last chapter provides concluding remarks, managerial implication and recommendations for further research in the area of business performance measurement systems.

[1] The first one is bind to a management guru Peter Drucker, whereas the second one is attributed to the consultant, Oliver Wright.

2. THE ROLE OF INTEGRAL PERFORMANCE MEASUREMENT SYSTEMS

Modern business environment characterized by ubiquitous competitiveness and globalization, performance measurement becomes a critical success factor. Business performance measurement systems aim to align a variety of organizational activities, processes and resources with overall and specific business objectives and strategy. Simmons (1991) indicates that these systems can support the formulation and communication of business strategy. Determining, structuring and adequate emphasizing of particular performance measures and comparing them to predefined management ambitions makes strategy more specific. Thus, business performance measurement systems enable the lower level of management structures (supervisors) to comprehend business objectives (Drew and Kaye, 2007; Mooraj et al, 1999). Thus, business performance measurement systems are useful to both higher-level (Ittner and Larcker, 2003; Kaplan and Norton, 2006) and lower-level management (Wouters, 2009). Nevertheless, empirical studies are not unanimous regarding the statement that effective measurement system necessarily leads to the achievement of strategic objectives, which is confirmed in the study conducted by Verbeeten and Boons (2009).

Business performance measurement systems also have a controlling function. In its rudimental form, this function was primal and was consisted of diagnostic control, where employees knew exactly what had to be improved in order to increase overall efficiency (Simmons, 1995). Furthermore, each performance measurement system has to connect long-term strategic organizational objectives with comprehensible and measurable determinants, creating the basis for comparison with both external and internal elements. Business performance measurement systems have to facilitate the establishment of standards for inter-organizational and intra-organizational comparison. This function can be defined as diagnostic, as it indicates the degree of the achievement of organisational objectives. Business performance measurement systems set the reliable basis for business decision making process, and subsequent performance management (Bisbe and Malagueño, 2012). A systematic and comprehensive measurement of performance should indicate whether efforts within an organization have effects on the achievement of preset objectives. If these efforts are compatible to predefined objectives, they will be rewarded. Therefore, business performance measurement systems also have the role of evaluating and rewarding employees (Van Veen-Dirks, 2010). An adequate business performance measurement system facilitates proper and rational communication of predefined strategy through an organization as a whole. This function was discussed in a myriad of different studies (Atkinson, 2006; Murby and Gould, 2005; Braam and Nijssen, 2004; Kaplan and Norton, 2004; Kaplan and Norton, 2000). Performance measurement drives asymptotical communication of the vision and mission of an organization. Additionally, performance measurement systems should prevent the appearance of information overload (Großwiele et al, 2012). A proper system has to refine data in order to provide management with the filtrated set of information useful for the decision making process. Effective communication, as a result of proper functioning of performance measurement system, should enable a successful coordination of activities and processes within an organization. Thus, performance measurement system has a communicating and coordinating function in an organization. This is why performance measurement systems have been recognized as an important management tool not only in managerial accounting and financial management, but also in other functional areas of management, such as marketing (Löning and Besson, 2002), operations management (Evans, 2004; Andrews et al, 2001), and human resource management (Bontis et al, 1999).

Scholars and practitioners are currently focused on the usage of integral performance measurement systems, meaning both the implementation and creation of the strategy (Gimbert et al, 2010; Kaplan and Norton, 2008; Bourne et al, 2000). This is especially important noting that 85% managers spend more time considering operational measures of realization than strategic ones. Nevertheless, this function of performance management systems has not been sufficiently investigated, so it will not be a topic of a further discussion in this paper. Performance measurement represents a connection between organizational objectives and results, which leads to business operations optimization. This shifts the focus of activities towards results, supports communication between organizational departments and individuals and creates information feedback regarding objectives achievement. Recent studies indicate the significance of performance measurement systems for formulating and reformulating strategy using “bottom-up” approach (Widener, 2007; Henry, 2006; Tuomela, 2005; Bisbe and Otley, 2004). Performance measurement system enables the creation of an information feedback which limits the communication constraints and determines the base for continuous strategy implementation. Consequently, this leads to long-term approach to objectives achievement and elimination of potential short-term sub-optimizations.

Finally, educational function of performance measurement has to be mentioned (Melnyk et al, 2004). Employees identify measured elements as something of importance for their organization. If something is identified as important, more efforts will be put in a realization of such measures. Naturally, this should stimulate professional training in related areas by continuous improvement and education.

3. A REVIEW OF INTEGRAL PERFORMANCE MEASUREMENT SYSTEMS

The field of measuring business performance still lacks the standardization which affects non-cohesiveness in defining performance measurement systems. Marr and Schiuma (2003) emphasize that there is no single body which would gather and systematize an immense body of knowledge. The diversity and non-cohesive approaches in defining performance measurement systems are also evident. Depending on observed criteria, different authors have given their own definitions of integral performance measurement systems. For instance, Ittner et al. (2003) suggest that performance measurement systems provide information which might advance their chosen strategies and demonstrate a cause-and-effect link between non-financial areas and cash flow, profit, or stock price. This definition indicates strategic nature of the system and the necessity of determining chronological sequence of managerial actions which are based on previously defined performance measures. On the other side, Hall (2008) points out that "comprehensive performance measurement systems include a more diverse set of performance measures, and performance measures that are linked to the strategy of the firm and provide information about parts of the value chain. A combination of various indicators in a functional system is in a focal point of this definition. Both aforementioned definitions are related to a function of performance measurement systems."

Nevertheless, definitions where features of performance measurement system can be also found in literature. Cheng et al. (2007) assert that performance management systems "supports using a wide set of financial and non-financial performance measures". Hence, defined function of integral systems is to provide management with information for strategic decision making by combining financial and non-financial data.

With regards to the typology of integral performance measurement systems, the most influential ones are (similar typology was given by: Garengo et al, 2005; Jamil and Mohamed, 2011; Yildiz et al, 2011):

(1) Performance measurement matrix (Keegan et al, 1989; Fitzgerald et al, 1991),
(2) Performance pyramid (Lynch and Cross, 1991),
(3) Balanced scorecard (Kaplan and Norton, 1996),
(4) Performance prism (Neely et al, 2002),
(5) Performance measurement based on assessment of business excellence (EFQM, 2012) and
(6) Integral performance measurement model for SMEs (Laitinen, 2002).

All the aforementioned systems share similar features. For instance, the base performance indicators are financial indicators, and none of the systems is complete regarding the functional business performance areas.

4. THE CRITIQUE OF INTEGRAL PERFORMANCE MEASUREMENT SYSTEMS

The initial disadvantages of business performance measurement systems were related to selection of one performance measure which is believed to be the best reflection of state and success of organization as a whole or its particular component. This is especially related to aggregate financial indicators, such as profitability (Chenhall and Langfield-Smith, 2007). This phenomenon is defined as a performance measure mono-dimensionality. The advantages of this mono-dimensional approach are its relative simplicity and potentially high inter-entity comparability of achieved results, where financial indicators are still having a stronghold in modern literature as the most relevant measure (Atrill, 2006; Hagos and Pal, 2010; Shim, 2008). In a relatively simple manner, decision makers are able to perform corrective actions based on abovementioned business parameters in order to improve business performance. Nevertheless, the overall performance can not be expressed with single indicator, no matter how well it represents organizational success or failure. This is the reason why organization has to be observed from multiple perspectives, and to make a balance between performance indicators (Bourne et al, 2000)

Further, as a response to performance measurement system based on single indicator or small group of indicators, concepts of multiple measures of performance were developed. Many authors point out that users of such business performance measurement systems are facing the effect of "information overload" (Iselin et al, 2010; Nudurupati et al, 2011). Meyer and Gupta (1994) note that inclusion of additional indicators is not always correlated to previously implemented performance measures, which leads to inconsistent usage of different indicators. The consequence of such management policy is loss of relevance of business performance measurement system (Kennerly and Neely, 2003). Due to lack of unique and developed methodology for their integration and utilization, the practice of unarticulated use of various business performance measures can not be considered a business performance measurement system. Additionally, Lebas and Euske (2007) emphasize that the aim of business performance measurement system is simplification and abstraction of reality, but not the opposite.

Furthermore, the opinion that improving performance of organizational components leads to improving performance of organization as a whole was widely accepted. This set the thesis that efficient work of

individuals and departments inevitably leads to organizational success (Fry and Cox, 1989). The thesis of hierarchical compatibility of performance measures implies that organizational performance measures can be optimized by optimization of local performances. Such approach eliminates the importance of organizational structure complexity as a factor. Nevertheless, this approach is not universal and can not be applied in practice due to fact that optimization of global performance can not always be achieved by optimization of local performance.

Finally, managers are frequently facing unorganized data and information regarding business performance. Current business performance measurement systems have not created mechanism for integrating all relevant information or reliable basis for creating functional relations between particular performance measures. Possible difficulty in establishment of such systems is related to potential suboptimization, meaning that individual performance are partially optimized, without considering their cause-effect relations. Hence, optimal partial performance do not necessarily lead to optimal global performance of an organization.

Despite decades of efforts of academics and practitioners, discussed integral business performance measurement systems show several disadvantages and inconsistencies. The major criticisms of aforementioned systems are based on the following issues:

(1) Performance measure normalization,
(2) Information overload,
(3) Relationships among performance measures,
(4) Integration of performance measures,
(5) Design, construction and implementation of integral performance measurement systems.

Performance measure normalization. In order to create integral performance measurement system, each performance measure has to be uniformly expressed, and normalized. This is very challenging task due to fact that some performance measures are quantitatively expressed, while the others are qualitatively expressed. Even in the case of quantitative performance measures, normalization is not necessarily simple. For instance, some scales are continual, while other can be discrete. Depending on the level of measurement, theory suggests classification of scales into nominal, ordinal, interval and ratio scales. Likewise, data or measures can be classified into nominal, ordinal, interval and ratio data. There are a few papers which investigate performance measure normalization. Even the authors who are making an effort to explain the normalization methodology base their interpretation on logic and common sense rather than on particular findings. Lohman et al. (2004) suggest the normalization methodology which is based on linear scale from 0 to 10. They justify this methodology by high readability and relatively simple interpretation of aforementioned scale.

Information overload. The recent study conducted by Groβwielle et al. (2013) indicates at least two significant aspects of this problem. The first aspect is related to the efficiency of collecting too much information. In particular management has to consider which economically optimal amount of information will be collected, considering the fact that information are not free. Except for a few studies, cost of collecting performance measures information has not been thoroughly investigated so far (Johnston et al, 2002). The second and probably more significant aspect of this problem is cognitive by a nature. This is related to a managers' ability to process the large amount of information. These issues have been in a focal point of both psychologists and human resource managers. For instance, Marois and Ivanoff (2005) point out that human brain, no matter how complex, has a strictly limited capacity for information processing. This also applies to decision makers in companies and other organizations. Information overload causes confusion of managers and can result with a stress or other disorders in decision making process (Bawden and Robinson, 2009). In accordance to the joint effect of aforementioned factors, the objective of integral performance measurement systems should be providing decision makers with optimal quantum (volume) of information.

Relationships among performance measures. Performance measurement science distinguish three types of relationships between performance indicators (Norreklitt et al, 2000; Malina et al, 2007), which can be logical, empirical or hierarchical. According to Groβwiele et al. (2013), logical relationships arise from definitions and mathematical transformations. Theoretically, profit represents mathematical difference between income and expenses which is a striking example of the definition-based relationship. Furthermore, profitability is an incremental mathematical transformation, as it represents the relation between profit and business assets. Empirical relationships are based on reality observations and establish either deterministic or stochastic relationships between performance measures. Deterministic relationships are quite rare in managerial sciences, which is the reason why academics and practitioners are focused on identifying stochastic relationships. For instance, it is stated that the asset turnover is directly negatively correlated to the sales margin. This may not always be the case, but most often it will. Finally, hierarchical relationships are being established in the case of the ranked order of performance measures. Ranking is usually based on the objective relations, although subjectively defined ranking also appears in the practice. The most evident

example of financial hierarchical performance measurement system is DuPont analysis or Economic Value Added™, where all performance measures are hierarchically classified.

Integration of performance measures. Information overload problem solving requires identification of a few synthetic indicators which will represent the actual financial position and earning power of an organization. The solution of aforementioned problem can directly or indirectly lead to new issues and discussion topics, known in literature as the problem of synthesizing performance measure. Synthesizing performance measure can be achieved by various operational techniques. For instance, Franceschini et al. (2007) suggest three approaches:

(1) The concept of relative importance,
(2) The concept of the minimum set of coverage and
(3) The concept of indicator correlation level.

Design, construction and implementation of integral performance measurement systems. Creation of performance measurement system is not one-time process, but the process that should be continually adjusted, in line with changes in external and internal business environment (Beamon and Ware, 1998; Medori and Steeple, 2000). Performance measurement system design, construction and implementation methodology is not uniform. This is why various steps and procedures are needed in order to achieve full functionality of the system. Folan and Browne (2005) stress out that modern design of performance measurement systems requires establishment of documented mechanism for selecting performance measures into integral system. Aforementioned mechanism uses brainstorming for selecting performance measures. Due to subjective nature of this method, Kaplan and Norton (1993) suggest series of workshops and interviews in order to make selection of performance measures more objective. On the other side, Neely et al. (2000) described a pilot process of performance measurement system construction. They suggest incremental changes in aforementioned procedure, which can be described as "the nine steps to performance measurement system implementation" (Neely et al, 1995).

5. CONCLUSION

This paper discusses the role and functionality of the modern integral performance measurement systems. Performance measurement represents a connection between the organizational objectives and results, which leads to business operations optimization. This shifts the focus of activities towards results, supports communication between SBUs and individuals and creates information feedback regarding objectives achievement.

The study finds that modern integral performance measurement systems have weaknesses regarding some of the important criteria for integration, design or functionality of the system. The most important issues are weak possibility of normalizing indicators used within the systems, the information overload and myopia of the system, poor base for demonstration of cause-and-effect relationship between the measures and among the measures and strategic objectives, the lack of a sound base for the integration of financial and non-financial performance measures, and the lack of procedures for the unified design, construction, and implementation of the system. This conclusions sum up the main recommendations for further research in the area. Performance measurement systems have advanced in last three decades, particularly in the area of moving towards the less introvert measures. However, they still lack in the field of uncritical adoption of boilerplate mechanisms which are not applicable in each and every organization.

Abstract: *In this paper, we have used the fuzzy logic approach to predict future credit ratings for countries. The proposed fuzzy model is implemented in MATLAB software. As model inputs we have taken data from the World Bank for 14 countries around the world, for the period from 1996 to 2013. The model is built using historical data and expert knowledge, and then tested for randomly chosen years. Results that are obtained in this way are then compared to the real sovereign credit rating grades.*

Keywords*: credit rating, prediction, fuzzy logic.*

1. INTRODUCTION

Credit rating represents forward-looking opinions about risk due to unexpected changes in counterparty's credit quality. The sovereign credit rating is a credit rating assigned to a national government or another sovereign entity. A credit rating of a country represents its political, social and economic stability. This rating should reflect some basic information about an observed country like riskiness of investment in a particular country, probability of bond issuer default, the ability of a government to reconcile its obligations, Central bank's borrowing cost and similar vital characteristics of a county's creditworthiness. Nowadays, financial markets are unstable and hard to keep track of, so in this study we seek to predict future credit rating assigned to a country by using some basic county's indicators, historical rating grade changes and probability of credit quality change.

When determining which predicting technique to use, analysts look for forecasting method that minimizes forecast errors. Fuzzy logic turns to be one of a new ways for predicting movements of different factors in the economies. It is designed to solve problems in the same way that humans do: by considering all available information and making the best possible decision given the input. It assumes that we have advanced knowledge about entities and movements we are trying to predict.

Data used in this study are explained in Section 2. The same section gives detailed explanations concerning input data selection criteria and data transformation process. Section 3 presents the proposed fuzzy logic model with detailed specification of inputs, outputs, fuzzy rules and overall model structure. The results of the proposed model are presented in Section 4. Finally, Section 5 concludes the paper.

2. DATA

In this study dataset of fourteen countries are taken into account. These counties are mainly chosen by the criteria of the frequent sovereign credit rating grade changes over time. These grades are published by some leading rating agencies like Moody's, Standard and Poor's, Fitch and other. Each of them use their own model based on public and non-public data to determine agency's opinion on government creditworthiness. The analyzed countries are: Argentina, Brazil, Dominican Republic, Estonia, Greece, Hungary, South Korea, Romania, Russia, Slovakia, Slovenia, Turkey, Uruguay, Venezuela. Data sets cover the period from 1996 to 2013.

2.1. History of credit rating grades

Historical credit rating time series used in this paper are published by Fitch rating agency. According to qualitative ordinal scale that Fitch publishes (Fitch Inc., 2011): "AAA" ratings denote the lowest expectation of credit risk. They are assigned only in cases of exceptionally strong capacity for payment of financial commitments. This capacity is highly unlikely to be adversely affected by foreseeable events, "AA" ratings denote expectations of very low credit risk, etc. These ratings are followed by sovereign categories which are considered to be increasingly riskier to invest in. Rating category "D" indicates that a country is in a state of default.

These series of data contain rating of sovereign debt in chronological order. However, they need to be slightly modified to suit to the country-year data format convenient for further manipulation.

For targeted countries that for single year have more than one credit rating grade, provided by Fitch as an opinion on risk of loss due to credit risk, arithmetic mean rounded by fewer is taken as a grade for the observed year. What is meant here by the credit rating mean? If we assume that, each credit rating category can be expressed as a unique integer value instead of a combination of letters, then we can introduce a presumption that the average value of this rank ordered values assigned to letters can be a suitable estimation of credit rating grade. Missing observations of country's rating for some years are handled in such manner that the average value of the credit rating grade between two observations we are familiar with is assumed for observed year.

2.2. Transition matrix

Since Fitch sovereign rating history is used for obtaining necessary data about historical rating grade changes, therefore Fitch's transition matrix is selected as a next very important input parameter further in this process. Transition matrix consists of migration probabilities from one to another credit rating category over the given horizon. It also reflects different trends in the credit quality change across the major credit categories. For the purpose of this study, Fitch's one-year transition matrix is used, with the intention to these migrations match the one-year interval of already mentioned historical rating observations.

2.3. Country indicators

In order to explain the variability of sovereign credit rating some basic financial, health, economy and growth country indicators are taken into account. All of the indicators are mostly official-source data from the World Bank. They were selected in such order that in some way can affect and be related to the country's credit rating grade. In this model are included following indicators:

- Unemployment rate refers to percent of the total labor force that is unemployed. It represents the share of the labor force that is without work but available for and seeking employment. It is assumed that this rate is inverse to credit rating grade.

- Gross Domestic Product Growth (GDP growth) represents the annual percentage growth rate of gross domestic product at market prices based on constant local currency. Here, we suppose that the growth of GDP will raise observed country's ability to meet its obligations.

- Central Government Debt expressed as percentage of GDP. Debt is the entire stock of direct government fixed-term contractual obligations to others outstanding on a particular date. It includes domestic and foreign liabilities such as currency and money deposits, securities other than shares, and loans. It is the gross amount of government liabilities reduced by the amount of equity and financial derivatives held by the government. (World Bank Source, 2013) The bigger the debt in percents of GDP is, the country's financial situation is considered to be worse.

- Under-five mortality rate is the probability per 1,000 that a newborn baby will die before reaching age five, if subject to current age-specific mortality rates. Estimates developed by the UN Inter-agency Group for Child Mortality Estimation. (World Bank Source, 2013) It is believed that countries with lower mortality rates of children and thus probably more developed health system will have healthier economy as well.

- Lending Interest Rate is the bank rate that usually meets the short- and medium-term financing needs of the private sector. This rate is normally differentiated according to creditworthiness of borrowers and objectives of financing. (World Bank Source, 2013) Higher interest rates compensate higher risk of losing money and these high risks are associated with uncertainty of the country's overall economic situation and its creditworthiness.

- Inflation is measured by the consumer price index reflects the annual percentage change in the cost to the average consumer of acquiring a basket of goods and services that may be fixed or changed at specified intervals, such as yearly. The Laspeyres formula is generally used. (World Bank Source, 2013) High inflation may signal country's inability to settle its obligations without inserting the new banknotes into the system.

2.4. Data transformation

After all necessary time series are provided, in order to bring all of the variables into proper proportion, data is normalized. In this study, data standardization or z-score method is used to scale all the variables appropriately. To adjust values in such manner, the mean of the sample mean is subtracted from the raw observed value and divided by its standard deviation:

$$z = \frac{x - \bar{x}}{s} \qquad (1)$$

Bearing in mind the nature of the selected indicators there was a possibility that some of them are correlated. To remove this correlation and thus redundancy present in the input data, Principal Component Analysis is used. Although this procedure will reduce our data set into fewer principal components, some losses concerning described variance in the data will be suffered. A principal component represents the weighted sum of the initial variables and accounts for the share of observed variable's variance.

3. FUZZY LOGIC MODEL

It turns to be that in finance and economics, many phenomena are fuzzy, but are treated as if they were crisp. Fuzzy logic is built on a mathematical logic that attempts to solve problems by assigning values to an imprecise spectrum of data in order to arrive at the most accurate conclusion possible. Knowledge can come from experts, from historical data or from some other source. Fuzzy logic is also often applied by advanced trading models/systems that are designed to react to changing markets. It is already widely applied in finance which led us to decide to use it for predicting future movements of countries' credit ratings.

With the help of fuzzy logic, we can define terms such as "high/low risk of bankruptcy" and "high/low probability of credit rating goes up/down" which will help us define rules and predict future credit ratings more accurately.

The fuzzy model is implemented using the Fuzzy logic toolbox in MATLAB. First, we defined inputs, transfer functions, rules and outputs. Then, output is generated using inputs and rules. The structure of our model is shown on the picture below (Fig. 1).

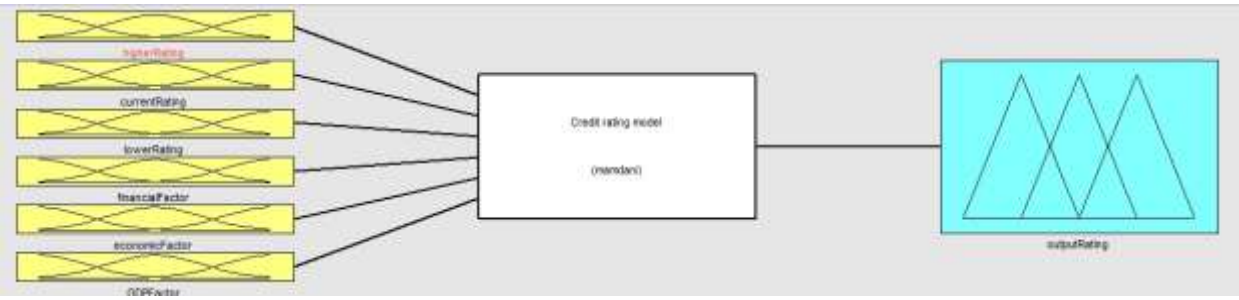

Figure 1: Fuzzy model structure

3.1. Model inputs

We have six input variables in our fuzzy model divided into two major groups. Groups are determined by direct or indirect influence of inputs on the future credit rating of countries.

Inputs that directly influence future credit rating grade are the following:

- Probability of credit rating upgrade (credit rating grade goes up),
- Probability of credit rating downgrade (credit rating grade goes down),
- The probability that credit rating stays the same.

These probabilities are obtained from credit rating transition matrix and depend on possible country's credit rating grade. For each grade, probability that a country's creditworthiness within the credit group will move up, down or stay the same, differs.

Inputs that indirectly influence future credit rating are country's indicators transformed by using statistical tool – Principal Component Analysis. Initial number of indicator variables are reduced on the three linearly interrelated factors that together explain 67.8 percent of the total variance. First of them mostly consists of

two variables – mortality rate and inflation, second is mostly constructed using unemployment rate and central government debt, while third consists of GDP growth rate only. These factors are respectively named:

- Financial factor
- Economic factor
- GDP factor

Every input, in both of these groups, has a numerical value that in general can be considered low, average or high. For each input, we have three membership functions that have a Gaussian shape which role is to map crisp input values into these fuzzy values. As a result of this mapping, initial crisp values are transformed into the degrees of membership to the membership functions. The shape of the functions is same for each of the three functions within the group. The tolerance for these functions overlap here is twenty percent. Minimum and maximum in the input domain are minimum and maximum in our time series data, which are different for every input.

A domain for functions which maps crisp value of an input variable into the value that is considered low is defined using following formula:

$$D_{low} = [a, \quad a + 0.3 \times D + 0.2 \times (a + 0.3 \times D)] \quad (2)$$

where:

$$D - input\ domain$$
$$a = minimum(D)$$
$$b = maximum(D)$$

A domain for functions which maps crisp value of an input variable into the value that is considered average is defined using following formula:

$$D_{avg} = [a + 0.3 \times D - 0.2 \times (a + 0.3 \times D), \quad 0.7 \times D + 0.2 \times (b - 0.7 \times D)] \quad (3)$$

A domain for functions which maps crisp value of an input variable into the value that is considered high is defined using following formula:

$$D_{high} = [0.7 \times D - 0.2 \times (b - 0.7 \times D), \quad b] \quad (4)$$

In the first input group, i.e. group with direct influence, to each of the inputs are assigned three membership functions that represent low, average and high probabilities that a certain outcome presented by that input will occur (Fig. 2). Simplified example may be that if a value of an input variable named probability of credit rating downgrades mostly belongs to the high probability membership function, we can conclude that it is very probable that in next year credit rating for the observed country will go down. Values that correspond to every possible credit rating, and in this model represent values on x-axis, are provided from one-year Fitch transition matrix. On y-axis are degrees of membership to the function i.e. probabilities that the credit rating will indeed go up/down or stay the same, depending on the value on x-axis. Domains for this group of inputs are shown in Table 1.

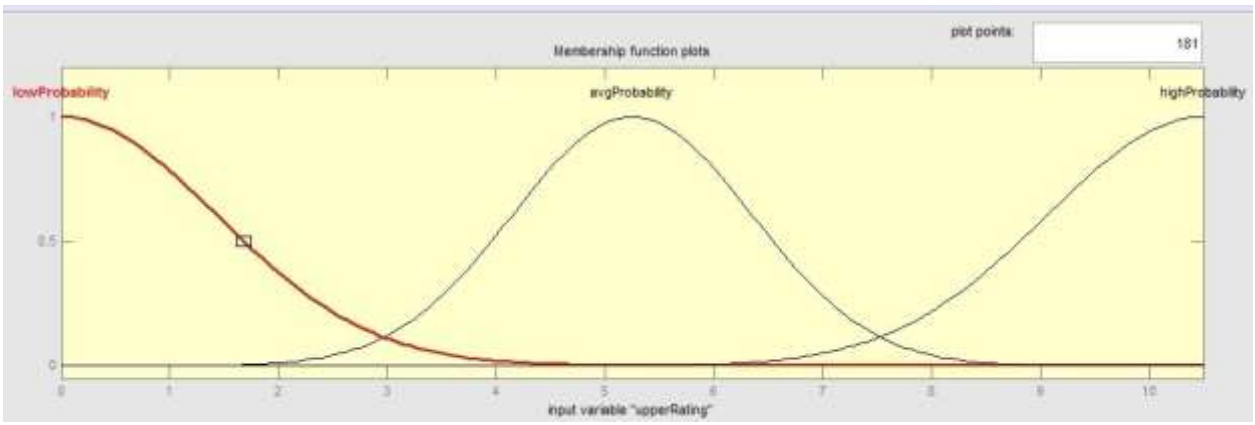

Figure 2: Membership function for rating upgrade

Table 1: Domains for first group of inputs

Name of the input	Domain	Low probability	Average probability	High probability
Higher rating	0 - 10.5	0 - 4.6	1.7 - 8.8	6.2 - 10.5
Current rating	79 - 98.52	79 - 88.1	82.2 - 94.9	89.9 - 98.52
Lower rating	2.19 - 10.5	0 - 5.9	3.7 - 8.8	6.95- 10.5

For the second group of inputs, i.e. group with indirect influence, membership functions represent values that are considered low, average and high values of factors (Fig. 3). Values on the x-axis are observed values of the factors. On y-axis is the degree of which these observed values are low, average or high. Domains for this group of inputs are shown in Table 2. An example, specific for our data set, may be that if value of financial factor is sixty-eight we consider that factor value is high.

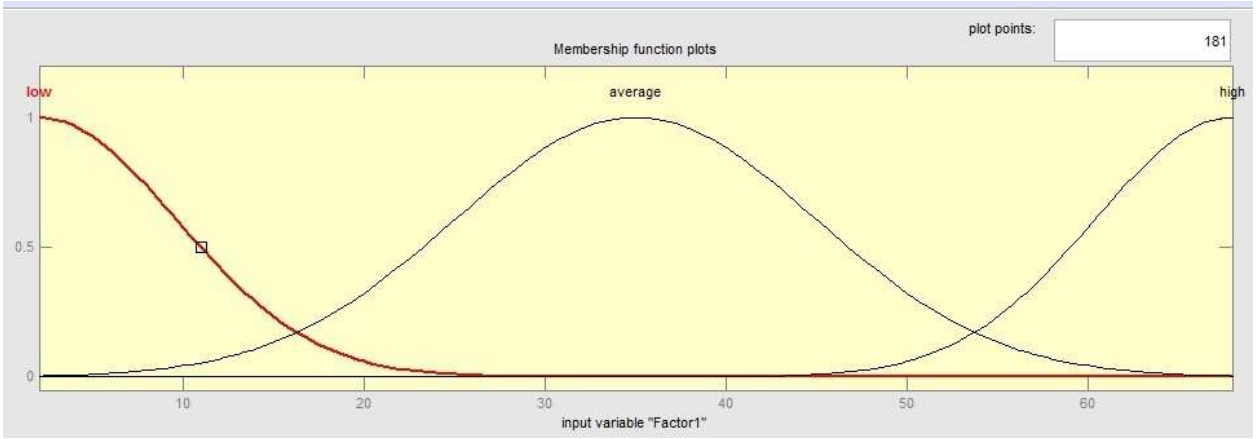

Figure 3: Membership function for financial factor

Table 2: Domains for second group of inputs

Name of the input	Domain	Low value	Average value	High value
Financial factor	2 - 68	2 - 26.9	1 - 59	43.9 - 68
Economic factor	3.2 - 66.4	3.2 - 27.9	1 - 65.4	41 - 66.4
GDP factor	(-10.9) - 18.3	(-10.9) - (-1.1)	(-10) - 17	7.6 - 18.3

3.2. Model rules

Rules are in simple "IF - THEN" shape. "IF" part of the rule consists of several conditions connected with operator "AND". In every rule, for IF part of the rule, we take one out of three possible values for each factor (low, average, high). "THEN" part consists of output taking value that indicates whether credit rating in the next year will go up, down or maintain its current value. Each rule has specific weight. Weights go from 0 to 1, where 0 is no priority and 1 is highest priority, in case that overlaps happens. The model consists of thirty-two rules (Fig. 4). An example of rules that we used is:

IF (upperRating is highProbability) AND (currentRating is averageProbability) AND (lowerRating is lowProbability) AND (Factor1 is low) AND (Factor2 is average) AND (Factor3 is high)
THEN (outputRating is higher) (0.7)

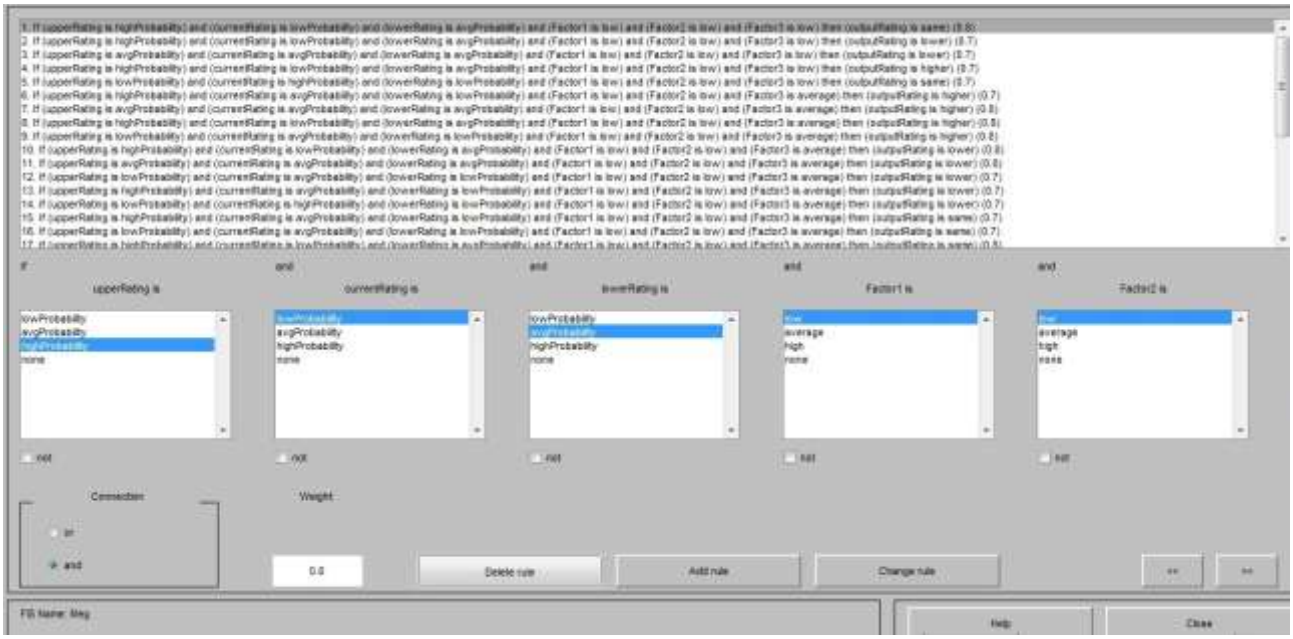

Figure 4: Rules

3.3. Model outputs

We made one output, which represents the future movement of credit rating. The future value of credit rating can be lower, higher or same as a credit rating for the country today. For output, we have three membership functions that have a triangular shape (Fig. 5). Membership functions are not overlapping because we want to achieve crisp output, which will tell us if credit rating will go up, down or stay the same. We also present domain of our output variable (Table 3). We use the centroid method for defuzzyification of output.

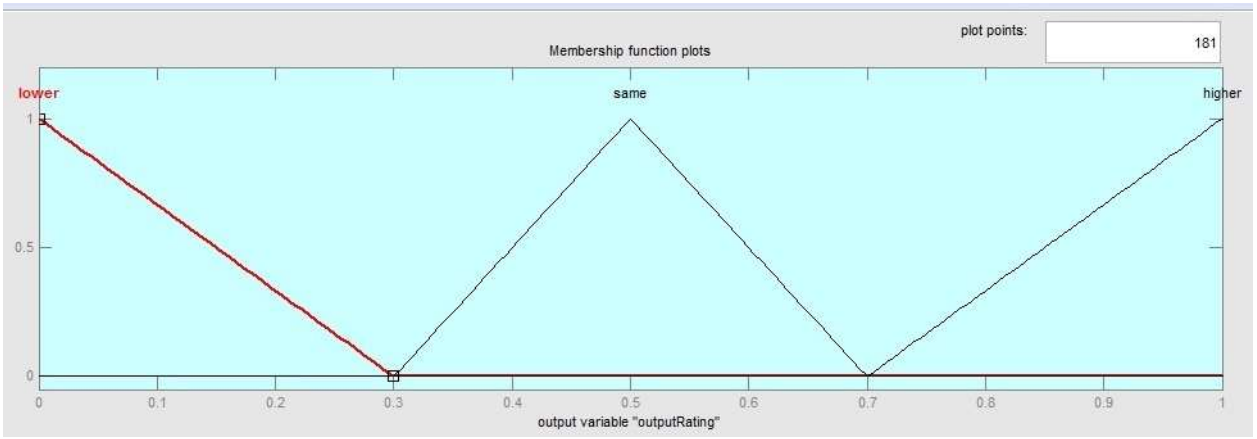

Figure 5: Output

Table 3: Domain for output

Name of the output	Domain	Lower (downgrade)	Same (without change)	Higher (upgrade)
Output rating	0 - 1	0 - 0.3	0.3 - 0.7	0.7 - 1

4. RESULTS

For each country in our survey, we semi-randomly have chosen 3 years within the period from 1996 to 2012. These three years are picked in such manner that in the next year credit rating went up, down or stayed at the same level for each observed country. We took one occurrence of each of these possible outcomes, if such an example existed in the dataset. Then we calculated our prediction for credit ratings for those years, and compared it with real results. We present all of the input values along with the obtained results (Table 4). The last 3 columns of the table are results that we obtained, real results and column which indicates whether we successfully guessed following credit rating grade or not.

Table 4: Results

Country	Year	Upper rating prob. [%]	Same rating prob. [%]	Lower rating prob. [%]	Financial factor	Economic factor	GDP factor	Current credit rating	Our prediction	Real results	Correct / Incorrect
Argentina	1998	8.37	85.02	6.61	9.32	16.34	3.85	BB	Same	Same	Correct
Argentina	2000	8.37	85.02	6.61	8.54	20	-0.78	BB	Same	Lower	Incorrect
Argentina	2009	10.5	79	10.5	10.04	23.28	8.46	CC	Higher	Higher	Correct
Brazil	2001	8.37	85.02	6.61	24.46	25.75	1.31	BB	Same	Lower	Incorrect
Brazil	2003	9.52	86.9	3.58	27.54	30.44	1.14	B	Same	Higher	Incorrect
Brazil	2009	6.99	88.71	4.3	16.71	24.53	-0.32	BBB	Same	Same	Correct
Dominican Republic	2005	10.5	79	10.5	16.85	17.9	9.26	C	Higher	Higher	Correct
Dominican Republic	2008	9.52	86.9	3.58	15.9	16.7	5.25	B	Same	Same	Correct
Estonia	2001	2.98	92.86	4.17	6.48	6.07	6.28	BBB	Same	Higher	Incorrect
Estonia	2004	2.98	92.86	4.17	4.39	5.4	6.34	A	Same	Same	Correct
Estonia	2005	2.98	92.86	4.17	4.3	4.73	8.85	A	Same	Same	Correct
Greece	1999	6.99	88.71	4.3	6.6	40	3.41	BBB	Same	Higher	Incorrect
Greece	2002	2.98	92.86	4.17	4.57	46.48	3.43	A	Same	Same	Correct
Greece	2009	2.98	92.86	4.17	3.32	48.85	-8.76	A	Same	Lower	Incorrect
Hungary	1999	6.99	88.71	4.3	10.02	25.26	3.19	BBB	Same	Higher	Incorrect
Hungary	2001	2.98	92.86	4.17	8.28	22.07	3.17	A	Same	Same	Correct
Hungary	2007	6.99	88.71	4.3	6.48	26.24	0.11	BBB	Same	Same	Correct
Korea	1997	6.99	88.71	4.3	5.44	3.5	4.6	BBB	Same	Lower	Incorrect
Korea	1998	8.37	85.02	6.61	7.23	5.99	-6.85	BB	Same	Higher	Incorrect
Korea	2001	6.99	88.71	4.3	4.74	6.94	3.97	BBB	Same	Same	Correct
Romania	1997	8.37	85.02	6.61	68	9.27	-6.1	BB	Lower	Lower	Correct
Romania	2002	9.52	86.9	3.58	21.94	11.82	5.1	B	Same	Higher	Incorrect
Romania	2008	8.37	85.02	6.61	10.45	6.42	7.93	BB	Same	Same	Correct
Russia	1997	8.37	85.02	6.61	19.23	24.36	1.4	BB	Same	Same	Correct
Russia	1999	8.37	85.02	6.61	39.84	30.38	6.4	BB	Lower	Lower	Correct
Russia	2003	8.37	85.02	6.61	12.7	16.55	7.29	BB	Same	Higher	Incorrect
Slovakia	2004	6.99	88.71	4.3	7.18	20.8	5.06	BB	Same	Higher	Incorrect
Slovakia	2005	2.98	92.86	4.17	5.08	19.61	6.65	A	Same	Same	Correct
Slovenia	2003	2.98	92.86	4.17	5.08	19.61	6.65	A	Same	Higher	Incorrect
Slovenia	2008	3.54	93.43	3.04	3.87	8.86	3.59	AA	Same	Same	Correct
Slovenia	2011	3.54	93.43	3.04	2.5	15.49	0.7	AA	Same	Lower	Incorrect
Turkey	1996	8.37	85.02	6.61	42.61	12.51	7.37	BB	Lower	Lower	Correct
Turkey	2002	9.52	86.9	3.58	27.12	30.07	6.16	B	Same	Same	Correct
Turkey	2004	9.52	86.9	3.58	15.67	26.82	9.36	B	Higher	Higher	Correct
Uruguay	2002	9.52	86.9	3.58	35.68	38.34	-7.73	B	Same	Lower	Incorrect
Uruguay	2006	9.52	86.9	3.58	8.5	27.19	4.1	B	Higher	Higher	Correct
Uruguay	2007	8.37	85.02	6.61	42.61	12.51	7.37	BB	Same	Same	Correct
Venezuela	1999	8.37	85.02	6.61	20.07	17.85	-5.97	BB	Same	Same	Correct
Venezuela	2002	9.52	86.9	3.58	20.19	17.8	-8.86	B	Same	Lower	Incorrect
Venezuela	2004	9.52	86.9	3.58	15.82	22.27	18.28	B	Higher	Higher	Correct

The final performance of the model is shown in the last column of Table 4. We can see that we correctly predicted 25 out of 42 samples. That is 59.52%. We conclude that we have predicted correctly all samples where credit rating is not changing, 18 out 18, with percentage of 100%. Samples where credit rating goes up are predicted correctly 4 out of 14, with percentage of 28.57%. Samples where credit rating goes down are predicted correctly 3 out of 10, with percentage of 30.00%. Therefore, changes in credit rating are harder to predict. This may happen because for each credit rating category the highest probability is that the country will keep its current rating in the next year.

5. CONCLUSION

The importance of a credit rating assigned to a country, as a major indicator of its creditworthiness, is constantly growing. The ongoing economic crisis heightens the need for reducing uncertainty in financial markets.

In this paper, we proposed and tested new fuzzy logic model to be used as a tool for preventing this uncertainty. The leading idea was to approach to the problem from nonstandard angle that uses fuzzy logic as a main tool in our work. Fuzzy logic is relatively young scientific method, and therefore, there is room for

trying to exploit its specific characteristics to our advantage. Since finance itself nowadays is much more fuzzy than crisp, there is a reason more for trying to implement fuzzy logic methodology.

From numerous data sources we obtained some vital country's indicators which variations we suspected can cause credit rating migrations in the time period from 1996 to 2013. We also provided probabilities with which these migrations, according to the transition matrix, may occur for each credit quality class. Finally, historical changes of rating grades are taken into account. After standardization and principal component analysis, all of these input data are transformed into input variables of a fuzzy model. These input values are processed using fuzzy rules based on common sense deduction, expert knowledge and advanced understanding of modeled movements. After the defuzzification process crisp, output rating prediction is obtained.

On a given sample, we managed to predict nearly sixty percent of one-year credit quality migrations. We had more success in predicting situations when credit ratings do not change, but less with predicting changes. Obtained percentage of successful predictions are satisfying, having in mind that there are high probabilities that credit rating will not change in period over one-year, and yet, it does, much more than it is assumed in the beginning with transition matrices. These findings may be of a great interest to investors interested in placement of funds in international market. It provides an opportunity to assess possible future credit risk associated with a country by using publicly available data as a model inputs.

After completing the research, we draw the opinion that this model can be improved in several ways, and that it should be one of the leading goals of our next research on this subject. We suspect the following ways to make the performances of the proposed model better:

- Including more countries and longer time period in our research,
- Changing the rules so they catch more variability in the data (credit rating changes),
- Including more factors in our model,
- Having more strict rules for boundaries of membership functions and domain,
- Changing shape of membership functions.

Abstract: *Accounting information systems feature as vital segments of the organisational structure of any corporate entity. Only a well-organised accounting information system can produce financial reports meeting the needs of numerous users of accounting information contained in them. High-quality financial reports serve as crucial sources of any corporate entity's competitive advantage, given that they contain high-quality information that a corporate entity can use in its operation with the aim of gaining competitive advantage, and are a product of a well-organised and devised information system. This article will look into the issue of organising an accounting information system, quality of financial reports and the information it produces, factors affecting the quality of financial reports and the confidence of the users of financial reports in their contents, and also the consequences of decisions made based on thus produced financial reports, competitive advantage based on financial reports, and its significance for companies' future business operations.*

Key words: *accounting information system, quality of financial reports, accounting information, users of financial reports, business decisions, competitive advantage.*

1. INTRODUCTION

As a part of a corporate subject's organizational structure, accounting function can exist in various forms. It can exist as an independent organisational unit, or a constituent of another organisational unit. Regardless of how the accounting function is organised, it should be set up so as to produce high-quality information that will meet the needs of all users, both internal and external. Accounting staff constituting the accounting function is the vital factor of its successful work, for the human factor plays the dominant role in the quality of any performance, including accounting tasks. The final objective of it all is financial reporting that should meet the needs of numerous accounting information users.

As products of the accounting function, financial reports are not intended only for the needs of the accounting staff, but also of all the stakeholders both within and outside a corporate entity. Information contained in financial reports is used by both accounting staff and other human resources and services of the corporate entity, tax authorities, inspectors and other public bodies. They are particularly significant for meeting the needs of the management, as the foundation of their decisions, and the prerequisite of the corporate entity's successful operation. The given financial reports also contain the sources of a corporate entity's competitive advantage, which create a stable basis of its future development, and are the result of a well organised and conceived accounting information system.

The accounting function and accounting profession in general have often been neglected in domestic business conditions without plausible reason. In numerous situations, accounting staff have faced disdain, the effort they invested has been underrated, and the significance of the information produced by account misunderstood. This is a consequence of inadequate accounting knowledge and the opportunities provided by the accounting information system. Lately, however, this area has seen significant advances, primarily as the outcome of the contemporary market environment where modern corporate entities operate, characterised by expressed instability, dynamic developments and high levels of risk that corporate entities face on a daily basis. The accounting function and staff are likely to get a much more significant role, resulting from contemporary market trends where corporate entities exist.

2. THE ACCOUNTING FUNCTION AS THE DATABASE OF BUSINESS ENTITIES

Operation of contemporary business entities is inconceivable without a well-organised accounting function. Its significance stems from the broad range of data it receives, transformed into information, and distributed to numerous users. The accounting function's role is reflected in accounting, registering and disclosing all the relevant transactions numerically expressible in terms of value within the corporate entity. Accounting is often erroneously identified with bookkeeping (by those inadequately familiar with accountancy), which is, in fact, wrong, as bookkeeping is only a segment of accounting. The view that accounting and bookkeeping are synonymous therefore represents a wrong approach to consideration of accountancy. Accounting is a much broader concept, and, apart from bookkeeping, it also includes (Dmitrović Šaponja, Petkovič and Jakšić, 2011, 10):

1. **accounting planning** – enables presenting the future business operations of corporate entities using monetary units, unlike bookkeeping, which is past oriented;
2. **accounting supervision or control** – aimed at protecting the integrity of a business entity's assets, and providing reliable and timely accounting information to numerous financial report users;
3. **accounting analysis** – a segment of the corporate entity's overall business analysis; and
4. **disclosure** – producing accounting information with the aim to meet the needs of numerous financial report users.

Each corporate entity can be regarded as a business system, with the accounting system as one of the constituents. To enable the corporate entity to function smoothly, all its subsystems must be well connected and mutually compatible. Operating functions are mutually reliant and connected.

As regards the organisational aspect of accounting in a corporate entity, the following two organisational forms of the accounting function can be identified in the corporate entity:

- independent organisational unit and
- constituent of another organisational unit, mostly the Finance Department.

Depending on the size of the corporate entity, the accounting function can be organised as centralised or decentralised. In current business condition, when the national economic system comprises a large number of small and medium sized corporate entities, they often do not organise this function within, but rather outsource service of professional accounting agencies, which they entrust with keeping accounting records for a certain remuneration.

The modern-day business and economic practice has seen the emergence of new forms of organisation in accounting, based primarily on cost-effectiveness in the organisation of accounting, these new forms being (http://www.vikrevizija.hr/usluge/organizacija-racunovodstva.html, accessed April 10, 2014):

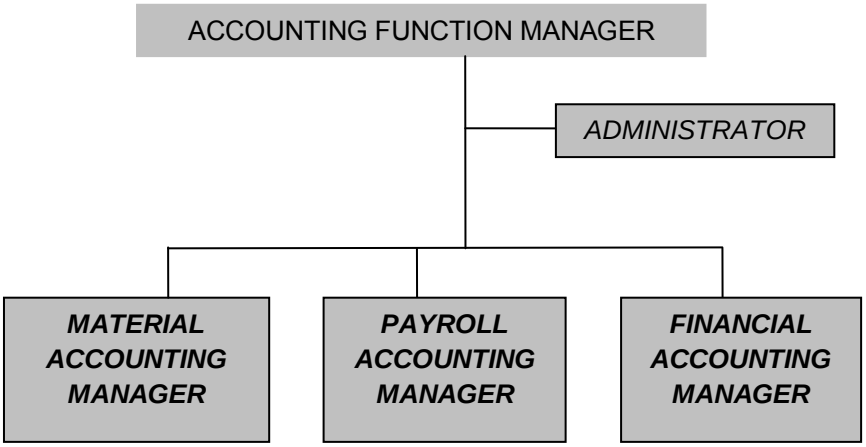
> in-house accounting service,
> outsourcing the services of accounting agencies,
> combination through outsourcing third persons and part-time work.

The in-house model of organising the accounting function means that the accounting function is within the corporate entity itself, performing all the tasks as required by the corporate entity, employing qualified staff, and featuring as a constituent of the corporate entity's organisational structure. The outsourcing-based organisational model of organising the accounting function is almost dominant nowadays, in view of the increasing number of small and medium-sized corporate entities, who would find it cost-ineffective to organise their own accounting service, and therefore use the services of professional accounting agencies, who keep records of their operations and perform all the accounting operations for them, charging appropriate fees. The third model of approach to organising the accounting function includes hiring accountants who are retired, or employed in another corporate entity, to perform the accounting tasks.

In order to fully accomplish all the tasks set before it, the accounting function must employ appropriate human resources. The staff are the core and essence of the accounting function. Professionally trained and educated staff can perform the tasks set before them with high-quality performance. An additional requirement is constant additional training of the current staff, which is an indispensable prerequisite for successful performance and functioning of the accounting function. At this point, it must be stressed that the

accounting staff are the foundation for successful performance of the tasks set before the accounting function. When performing tasks set before them, accountants should adhere to strict ethical requirements of professionalism, effectiveness and efficiency. This will contribute to the reputation of the entire profession, which has been somewhat compromised over the past period.

One of the forms of organising the accounting function within a corporate subject may be:



Graph 1: A model of organising the accounting function (www.vus.hr/Nastavni%20materijali/Osnove%20menadzmenta/12.%20Poslovne%20i%20procesne%20funkcije%20u%20poduzecu.pdf, accessed April 15, 2014)

Graph 1 shows only the core, or the basic organisational structure of the accounting function. Each corporate entity, in accordance with its needs, divides this structure so that the accounting function can fully perform the set tasks.

The prerequisite for successful operation of every corporate entity is good cooperation between all three above mentioned systems of the business entity. Their close cooperation results in the fulfilling the corporate entity's objectives. As a constituent element of these three systems, the accounting function monitors the movement of the total assets at the corporate entity level, and performs the accounting control of operations of all the organisational units in a corporate entity. This requires the accounting function to cooperate closely with other functions that it provides with necessary data on the other hand, while drawing the necessary data on the other. A well organised accounting function should provide data that are a prerequisite for economic and cost-effective operation of the corporate entity. Such an accounting function will supply information required by the management for successful operation, that is, provide the management of a corporate entity with the following information, which are not only prerequisite for high-quality business decision making, but also a prerequisite for the corporate entity's survival (http://web.efzg.hr/dok/OIM/inacinovic/PRED%20Organizacija%20poslovnih%20funkcija.pdf, accessed April 25, 2014)

- periodic performance in production;
- movement of assets
- sources of finance
- results of annual operation.

All the aspects of considering the accounting information are supposed to enable accomplishing the overall objective of this system, which is to establish a connection between the users of accounting information and the effects of earlier made business decision. This is due to the fact that each business decision is made based on relevant information that should result in certain effects.

3. FINANCIAL REPORTS – THE FINAL PRODUCT OF THE ACCOUNTING FUNCTION

The main products of the accounting function are financial reports, which are to supply high-quality and relevant accounting information to numerous users of accounting information. To provide financial reports that will be a reliable representation of corporate entity's state, it is essential for information used for producing those reports to be reliable, relevant, and based on appropriate documentation.

These financial reports meet the needs of numerous users of financial reports. The most significant users of financial reports definitely include managers, who base all their business decisions based on these. Only reliable and high-quality accounting information can feature as a basis for making relevant business decisions. Based on data contained in financial reports, managers analyse operations, identify weaknesses, identify the level and dynamics of cost fluctuations, etc. Although these data are historical, they feature as basis for predicting the corporate entity's future operations. There are other users of accounting information, equally significant, who should be neglected, such as: the employees and trade unions, the in-house services, business partners, banks and other creditors, government bodies, etc. Information contained in financial reports must meet the required quality characteristics, for only such information serves as a reliable basis for business decision making.

To be qualitatively adequate, information contained in financial reports must possess the following characteristics (Dmitrović Šaponja, Petkovič and Jakšić, 2011, 17):

1. **truthfulness** – means obtaining information from reliable accounting documents, for only such information serves as a reliable basis for high-quality business decisions;
2. **usefulness** – which means that accounting information must be reliable, i.e. accurate and impartial on the one hand, and adequate on the other, meaning that they must meet the users' requirements and requests;
3. **comprehensibility** – this is information that do not require substantial time for interpretation, and are tailored to the user's level of knowledge; if accounting information is not adapted to users for whom it is intended, it is practically useless, which means that the same information will be presented in a certain way to the management, and differently to the corporate entity's expert services:
4. **cost-effectiveness** – all the information yielding benefits that exceed costs; to be useful, the use of accounting information must produce effects much higher than the costs of its production.

All information must be tailored to the user, i.e. that the same information will be presented differently to different users. Regarding the central tenet of this article, which is considering the role and significance of accounting information for the purpose of business decision making, the table below will show what kind of information is required by individual levels of management:

Table 1: Relation between accounting information system and various users

Management LEVEL	**Character of Accounting Information**
Top management	Accounting information tailored for the purpose of strategic planning
Middle-level management	Accounting information for management control
Operative management	Accounting information contained in analytical records

Source: Dmitrović Šaponja, Petkovič and Jakšić, 2011, 18

The domain of a corporate subject's top management includes strategic planning, which means decisions pertaining to the corporate subject's long-term business objectives, i.e. decisions of strategic importance for business operations, considering the effects of numerous business alternatives. The middle-level management uses accounting information aimed at management control, considering the achieved results and effects compared to the plan. The operative, or junior management uses analytic records, relying on data from bookkeeping to the greatest extent.

4. COMPETITIVE ADVANTAGE THROUGH THE PRISM OF THE ACCOUNTING INFORMATION SYSTEM

A corporate entity's competitive advantage stems from its ability to create value for its customers exceeding the expenditure that the corporate entity invested in the process of creating this value. The greater the difference between the created value and costs incurred in creating this value, the better the given corporate entity's competitive position. To reach this goal in the appropriate direction, it is necessary for products and services provided by the corporate entity to be completely adapted to buyers' demands and requirements, and to continuously research and monitor changes in the buyers', i.e. consumers' demands, and adapt on time through producing commodities in accordance with their needs, performing this task better than its competition.
When a business entity has gained a good market position and, consequently, achieved significant competitive advantage, it must constantly be ready to enhance and adapt its production and services to consumers' demands, as competitive advantage is not a permanent category, which, once achieved, remains in force forever. Actually, corporate entities should continuously improve their effectiveness and efficiency in order to maintain and retain their competitive position. To keep competitive advantage, it is necessary to take into account the impact of a whole range of factors: the essence of competition is managing financial, material and information resources, based on the knowledge and skill of innovating and preserving the distinctness of the achieved advantage; then, the choice of the appropriate market and products on which a corporate entity will capitalise its competitive advantages in the most acceptable manner, and finally, the choice of competitors in order to target the competing suppliers that will provide us with a great opportunity to demonstrate our advantages in the consumers eyes, and thus gain consumers' favour. If each of these factors is taken into account, we can literally expect a significant improvement in quality and retain competitive advantage.

In the context of the analysis of competitive advantage, we shall analyse Figure 1, which shows the correlation between financial performance and competitiveness:

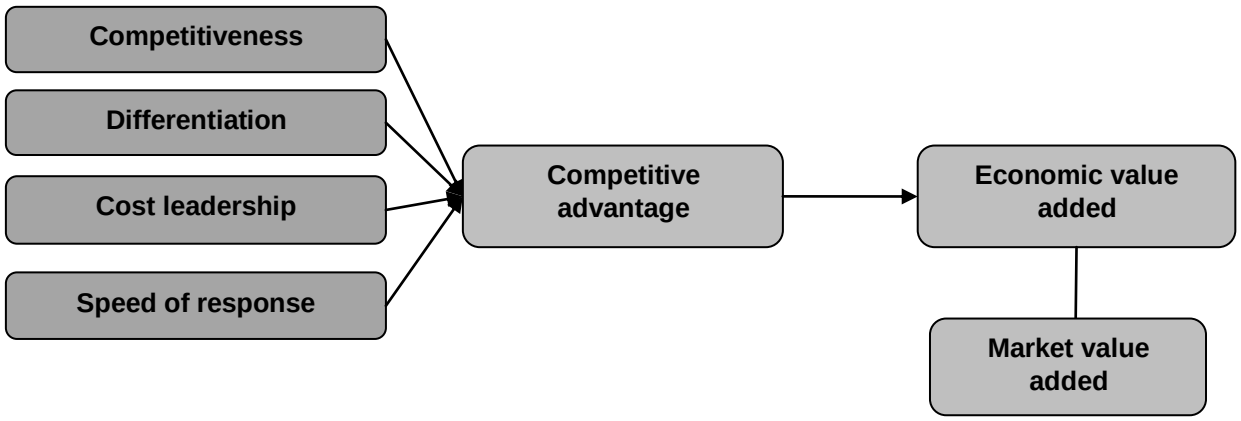


Figure 1: Financial performance and competitiveness
Source: Todorović, 2003, 486

Addressing the task of analysing competitiveness and sources of competitive advantage, Figure 1 shows that four factors are decisive for achieving competitive advantage: competitiveness, differentiation, cost leadership and speed of response. Based on achieving competitive advantage by means of these factors, economic value is gained, and very quickly transformed on the market into market value added. Thus, growth in market value creates prerequisites for the best and highest-quality competitive position possible.

To secure survival in the contemporary business environment, a corporate entity must work daily on creating and building its own competitiveness. The increasingly dynamic, complex and turbulent milieu requires making business decisions containing a growing strategic component, thus imposing the inevitable question: How to achieve it? Although the answer to this question is complex and requires further elaboration, it can be pointed out with a high dose of certainty that this is virtually impossible without a well-organised and constructed accounting information system.

Accounting-based planning primarily refers to choosing a corporate entity's business objectives and forecasting the avenues of achieving them. This indicates that planning permeates all the activities of a business entity – both those related to long-term objectives (of strategic character) and those of operative character. It is these decisions of strategic character that should support finding and achieving a corporate entity's competitive advantages. The aims of accounting-based planning are achieved through the business decision making process, coordination, direct management control, and staff motivation. In addition to strategic objectives, the account-based planning also defines the corporate entity's operative goals, viewed both on the level of the business entity and the level of individual organisational segments, which enables the management to maintain control of the achievement and take timely corrective actions in order to remove possible diversions from the planned goals. This indicates that and accounting information system provides information both on planned values and the current state, which shows the extent of realisation of the devised plan.

If the accounting information system is to enable the corporate subject to find and create competitive value and raise the efficiency of overall business operations, the information that it produces, as the platform for business decision making, must be true, timely, useful and cost-effective. This implies that account information contained in financial reports as the final product of the accounting information system is of high quality, meaning that they can meet their users' needs.

Besides financial information, an increasing significance for achieving competitive advantage in contemporary business environment is gained by non-financial information. This stems from the fact that the sources of competitive advantage in the contemporary corporate setting should increasingly be sought in knowledge and intellectual resources available to corporate entities, given that people are the asset in whose heads is stored the strongest source of competitive advantage. People, with their knowledge and experience, constitute the fundamental factors of a business entity's progress and development.

Another vital factor through which accounting information systems influence competitive advantage is the model of its organisation. The earlier mentioned modularly organised accounting information system is less efficient compared to integrated information systems. The essence of the integral accounting information system is reflected in the fact that once entered into the system, a piece of information is used in all further instances of processing. This is also its key advantage in relation to the modularly organised accounting information system, in addition to the possibility of online data entry. Thus constructed, interaction of accounting models enables the business activity of one cycle to initiate changes in other cycles automatically, which is the core advantage of thus devised accounting information system.

5. CONSLUSION

Appropriately organised and well systematised accounting policies should result in high-quality financial reports. This implies good internal organisation of the accounting function, its proper position in the organisational structure of the corporate entity, and well chosen and professional accounting staff. Only in cases when all these elements combine can a high-quality and reliable financial report be expected.

Through financial reports, the accounting function confirms and establishes its position as the main information system in a corporate entity, as it is the hub of information used by all the stakeholders interested in the performance of a given corporate entity. Financial reports produced by the accounting function are the chief source of information for all interested users, which requires a high quality of reports to be provided by the accounting function.

The existence of corporate entities in modern-day market conditions implies a well-organised and conceived accounting information system. Its good organisation and existence is what constitutes competitive advantage. Only the corporate subjects that manage to provide stable sources of competitive advantage can expect to survive in the forthcoming period. This indicates that competitive advantage is a *conditio sine qua non* of market existence and survival of corporate subjects in the global corporate setting.

Abstract: *Dynamic changes embodied in globalization and development of information technology, as well as a loss of confidence caused by the global financial crisis significantly affect the accounting information system, ie. the accounting profession, and therefore on financial reporting. International Accounting Standards / International Financial Reporting Standards as the language of business should facilitate the harmonization of financial reporting of companies around the world. The emergence of the web as a result of acceleration of the transactions, and thus increasing the volume of information. Changes in the field of documentation and reporting procedures on the one hand and the growing expectations of stakeholders for appropriate financial reporting in the contemporary conditions, on the other hand. Without standards for the exchange of information through web accounting profession has long been burdened by inefficient reporting process based on a variety of different software applications (pdf, xls, html, doc) which are usually incompatible with each other. At the end of the nineties appeared XBRL - extensible business reporting language for the exchange of structured business information that is widely accepted. XBRL is the financial reporting led to the Internet and facilitate communication with information from the financial statements to numerous users.*

Keywords*:* accounting information system, financial reporting, information, International Accounting Standards / International Financial Reporting Standards, XBRL standard

1. INTRODUCTION

Accounting information system if it is well organized should present the relevant information from the financial statements of financial position, asset and profitable position, ie. on the effects of activities of the company. In the twenty-first century, it faces with many challenges and opportunities. Financial statements establish communication between the information generated within the accounting information system and the many different users of the information. Conceptual Framework and International Accounting Standard 1 (as it provides the core structural elements of financial statements that are required for all companies when creating financial reports throughout the world) are very important elements in the function of harmonizing financial reporting. The effects of management decisions are looked at from the point of impact to moving the performance and value of companies, periodically are reviewed and evaluated through the financial statements and the specific economic analysis. Mentioned was made much easier due to the application of modern information technology. Online exchange of information is carried out with the XBRL standard based on XML - standardized business language for transmitting data over the Internet. This paper will discuss the importance of professional legal regulation in the financial reporting and business intelligence within the XBRL International Standards.

2. SIGNIFICANCE OF REGULATORY FRAMEWORK IN THE FINANCIAL REPORTING PROCESS

Throughout the world, many companies prepare and create financial statements for external users. Though these financial statements may look like similar from country to country, but there are diversities due to different social, legal and economic circumstances. Mentioned different circumstances have led to the use of different definitions of the constituent segments of the financial statements, such as the assets, liabilities, equity, income and expenses. They have resulted in the use of different criteria for the recognition and measurement in financial statements. That is why the International Accounting Standards Board has the task to reduce the differences with effort to harmonize regulations, accounting standards and procedures relating to the preparation and presentation of financial statements. The Board focuses on the harmonization of financial statements that are compiled to provide information relevant for decision making in the economic sphere.Thus prepared financial statements meet the common needs of most users. Economic decisions are made by almost all users, for example:
(Conceptual Framework for Financial Reporting (2014), p.3-4.),

- To decide when to buy, hold or sell a share in the capital,
- To assess the stewardship or responsibility of management,

- To assess the entity's ability to pay and provides other benefits to its employees,
- To assess the safety of the amount lent entity,
- To determine tax policy,
- To determine the profit and dividend distribution,
- To prepare and use national income statistics, and
- To regulate the activities of the entity.

Mentioned Board is aware that the state institutions of various countries for their own purposes may establish different or additional requirements. The above mentioned requirements should not affect the financial statements that are published in the interests of other users. In accordance with the accounting model based on recoverable historical cost and the maintenance concept of nominal financial capital financial statements are usually prepared. The conceptual framework is drawn up so as to be applicable to a range of accounting models and concepts of capital and its maintenance.

The purpose of the conceptual framework is:
- To assist the Board in the development of future IFRS as well as the review of existing IFRS,
- To assist the Board in promoting harmonization of regulations, accounting standards, procedures relating to the presentation of financial statements by providing a basis for reducing the number of alternative accounting treatments allowed by IFRS,
- To assist national bodies responsible for setting standards in the development of national standards,
- To assist persons who prepare financial statements in the application of IFRS, as well as in addressing issues that have yet to become the subject of IFRS,
- To assist auditors in forming an opinion about whether the financial statement in accordance with IFRS,
- To assist users of financial statements in interpreting the information contained in the financial statements prepared in accordance with IFRS, and
- To those who are interested in the work of the IASB with information about its approach to the formulation of IFRS. *(Conceptual Framework for Financial Reporting (2014), p.4.),*

Base of the conceptual framework makes the target of general-purpose financial reporting. Providing financial information about the company is a point of general purpose financial reporting. The information obtained from the reports are the benefits to all stakeholders ie. customer (lenders, existing and potential investors and other creditors).

Since the yield (dividend, the increase in the market price, the payments for principal and interest) that investors expect from investing in debt instruments or the purchase, sale and holding of equity instruments depend on the decisions of investors (both existing and potential). Expectations of lenders, investors and other creditors are depending on their assessment, dynamics, amount and perspective future net cash inflows to the company. As noted, investors need information on which they will be able to estimate the future cash flows of the company. Necessary information in good part they take in general purpose financial statements. They are actually the primary users of the information from mentioned financial statements.

The financial statements provide information in order to be able to assess the value of the company by investors, lenders and other creditors. General purpose financial statements do not provide the full necessary information to them. To make a proper business decision should be supplied with relevant information from other sources also, such as the perspectives of enterprises and the economy, the political climate, general economic conditions, etc.

In the process of developing standards of financial reporting The Board strives to provide the required information for the largest number of primary users. Information about financial position, ie. the economic resources of enterprises, the effects of transactions that change the company's resources are useful for decision making.This is so because they are the basis for identifying financial strength (liquidity, solvency, the need for additional financing) and weaknesses of the company. Information on the results of operations help many users to understand the yields that the company realized with its available resources. Also, this information shows how management do their activity of efficient and effective using of company resources.

For the evaluation of past and future capability of the company, for the accumulation of net cash inflows are important information about the result of the firm. Also, the company's ability to cumulate the future net cash flows provide information on the company's cash flow because from them we can see how the company spends cash, borrow, how pay off debts and other indicators that can affect both the liquidity and solvency. Assessment of financing activities and investing, liquidity and solvency provide information on cash flows (for more details see Conceptual Framework for Financial Reporting, Chapter 1).

Information from the general purpose financial statements to meet many users must be relevant, useful, credible, verifiable, comparable, timely and understandable. (for more details see Conceptual Framework for Financial Reporting, Chapter 3).

Accounting information system of the company has a duty to provide financial reporting for which quality and relevance is with management of the company directly responsible. The key assumption for making quality business decisions is the quality of information. This is why the need to improve the quality of financial reporting becomes more and more important.

International Accounting Standard 1 - Presentation of Financial Statements (IAS 1 below) provides the basis for presentation of general purpose financial statements, sets general requirements for the presentation, gives guidelines for their structure and makes minimum requirements for their content ie. prescribe the basis for presentation of financial statements that is it's main goal. It applies to all general purpose financial statements.

A complete set of financial statements under IAS 1 includes: a report on the financial position at the end of the period, a report on the profit or loss and other comprehensive income for the period, statement of changes in equity for the period, cash flow statement for the period, notes comprising a summary of significant accounting policies and other explanatory information, comparative information relating to the previous period and a report on the financial position at the beginning of the previous period when an entity applies an accounting policy retrospectively or makes a retrospective restatement of items in its financial statements or when it reclassifies items in its financial statements. (IAS 1, paragraph 10) The above-mentioned set of financial statements is otherwise called the Annual financial statement.

However, under the new Law on Accounting regular annual financial statement entities that apply IFRS include: balance sheet, income statement, statement of other results, statement of changes in equity, cash flow statement and notes to the financial statements. Micro-entities prepare a regular annual financial report that includes a balance sheet and income statement. Regular annual financial statements of other entities (political, trade union organizations, foundations, chambers, churches, etc.) includes a balance sheet, income statement and notes to the financial statements.

It is evident that the professional and legal regulations is in conflict as far as the name of mandatory annual financial statements. In Serbia, the prevailing is legislation. Association of Accountants and Auditors of Serbia as a member of the International Federation of Accountants (IFAC) has translated IAS / IFRS in 2009. provided that translated the five new IFRS which came into force on 2013th (four of them), and one will come in 2015th. Translation of these standards The Ministry of Finance published in the Official Gazette No. 35 until March 27th of 2014. (no sooner), and very important professional titles and certificates accountants are canceled and they are actually crucial, because only a true certified professionals should be involved in the accounting profession because of the objectivity of financial reporting.

For recognition, evaluation, presentation and disclosure of items in the financial statements big companies apply International Financial Reporting Standards. Medium-sized enterprises can use International Financial Reporting Standards or International Financial Reporting Standards for Small and Medium Enterprises. Small enterprises can use the International Financial Reporting Standards for Small and Medium Enterprises. Micro enterprises can use Regulation issued by the Minister of Finance or International Financial Reporting Standards for Small and Medium Enterprises.

In Serbia until July 2013. valid was the Law on Accounting and Auditing (Official Gazette 46/06, 111/09 and 99/11) who was sorting companies into three groups, to large, medium and small, according to the criteria: average number of employees, operating income and average value of commercial property, which is replaced by the new Accounting Act of 16th July 2013. (Official Gazette of RS, no. 62/2013). companies are divided into four groups, in large, medium, small and micro, which show the following table:

Table 1: Types of enterprises

Legal entities are classified according to size	Applying the criteria of the Law on Accounting and Auditing	Applying the criteria of the Law on Accounting
Large	1.163	552 (0,46%)
Medium	2.971	1.283 (1,07%)
Small	116.285	9.649 (8,01%)
Micro	-	108.935 (90,46%)
Total	120.419	120.419 (100%)

Source: IFRS and Current Regulations (2013)

From the table it is evident that Serbia has at the most micro enterprises (90,46%), at least large (0,46%).

3. FRAMEWORK FOR BUSINESS REPORTING BY INTERNATIONAL STANDARDS XBRL

The use of XBRL standards (eXtensible Business Reporting Language) is of great importance to the business of each company and the perspective of its use are very wide. Regulatory bodies (institutions that have the authority to prescribe certain standards of conduct in the collection of certain information, for example: Commission for securities, stock exchanges, tax authorities, insurance companies, banks, etc.) are commonly used until now classical methods of reporting based on a paper form or unstructured electronic methods of HTML (Hypertext Markup Language) or PDF (Portable Document Format) format. Each regulatory body ("a collector of business information") may prescribe the use of electronic and other structured methods in relation to XBRL (eg. Private electronic methods developed for their own use). In our business environment just mentioned is already present. In a particular required format regardless of whether the data is structured or unstructured single entity (or other applicant data) can transmit business information to data collector. The aforementioned diversity present in the world indicate a need of unification of business reporting.

Recent way of financial reporting is on the website, these are due to the presence of certain experiments in the implementation of possible variations in the development stages. By analyzing we got an answer that there are many different varieties of reporting that companies show on their web sites. Accordingly, interested parties can gain an impression at first glance that there are no clear rules in the presentation of financial statements on the Internet in terms of what exactly is allowed and what should not be allowed in the preparation and presentation of annual financial statements on the Internet. The SEC (Security Exchange Comity) in the United States specifically provides for uniform application of legal rules in the work process, regardless of whether it is implemented in hard copy or electronic technology, in his act that deals with working with securities of values.

The technology which allows precise setting and standardization of new features is based on the use of special software tools standard XML (Extensible Markup Language) - the language created by the W3C (World Wide Web Consortium). XML allows you to create web pages that include identifying information about the items on the Internet such as statements, currency, orders, invoices and similar. International standards, XBRL was also formed on the same model, based on XML language, the protocol developed by the General Accounting Board. The study of comparative financial web site in relation to paper reporting documentation showing that a number of companies on their web site show only the summary information, others do not want to present a complete financial statement.

There is the fact that new technologies, and therefore the implementation of the XBRL standard brings new challenges and new risks (Audit and Control Implications of XBRL, The Canadian Institute of Chartered Accountants, Information Technology Advisory Committee, Toronto, 2002).

Many accounting organizations are set reasonably question how big a business risk is if the business decisions use information from reports prepared using XBRL. The analyzes showed that the risk of errors related to the accuracy of the mappings balance sheet items and the appropriate uses of the related taxonomy.In case the information for the purposes of the financial statements in XBRL methodology are included, there is a need to apply additional controls to ensure that the data are of high quality, accurate and possess the required integrity. The use of XBRL technology does not mean that it will also be prepared and printed financial statements. Companies can choose that a method of financial reporting financial document that has been prepared in accordance with the taxonomy ISA (International Accounting Standards) to be published and posted, and only on the web site. Legislator allows mentioned in the world. From the aforementioned it follows that by analysts and others interested in business analysis can run their own analytical processes of such published data and prepare their comparative report, connect them with information obtained from other companies and shape within a new business report. With the technology of XBRL the mentioned process can be automated and used for retrieval of data from a variety of sources periodically for analysis management.

In the near future, XML will require control data transfer, which is based on the operations of the supply chain. Using the Internet in the process of automation of operations of exchange and transfer of data to be performed manually (including processing purchases, payments, invoicing, delivery, etc.) business environment is expected to adapt the XML standard needs of different activities to almost instantly reduce the total cost of operations.

Since XML exponentially affect the acceleration of business iterations and anyone who wants to start their own business should pay attention to this fact. Regular reporting in addition to shareholders at the same time provide information for decision-makers and others involved in the business chain. In this context, the decision making community (so-called XBRL) was established, which is an adaptation of XML technology for the chain of business information. It is believed that the business process designed to technological solution XBRL reporting has a key advantage over conventional current mode of reporting that is now compiled and distributed. XBRL allows the shortened time period of preparation and low cost of preparation, provides simplified access to information, the ability to cross information by expanding the analytical capabilities as well as better conditions for investment decisions.

In order to timely protect against possible shock of the financial markets it is necessary to examine developments in global business practices in recent years to conclude that measures should be taken. The most appropriate illustration can give us the case of Enron (big American energy giant was formed in 1985th, before all the gas, and then with electricity, which is the middle in 2001st had about 21,000 employees). Enron's was accounting fraud with poor corporate management and much more. The collapse of Enron implies a total systemic failure of American institutions of capitalism.

Enron's management misled the board of directors. Failed their tasks: internal audit function, external auditors, their lawyers, business printed reports. In other words, American institutions of capitalism that are being advertised and imposed all over the world as it should be operating all are easily betrayed at Enron. The greatest failure of American free-market capital and a direct failure of the SEC is actually Enron. SEC as a government "watchdog" was required to provide adequate and timely disclosure of relevant corporate information, he just not succeeded.

Bankruptcy of Enron and WorldCom accounting is concerned about the workers and small shareholders on the adequacy or inadequacy of GAAP (Generally Accepted Accounting Principles) and a GAAS (Generally Accepted Auditing Standards). The main problem and a potential cause of accounting scandals at opinion of a specialist after numerous analysis is reflected in the quality, or low-quality business disclosure of financial results and the quality of audit reports. Enron was applying the method to mark-to-market accounting for all aspects of their business while reporting to the SEC and public disclosure to analysts of securities. His reporting to the SEC was not objective.

After the accounting scandals of Enron and WorldCom, the U.S. Congress adopted a special law called the "Sarbanes-Oxley Act." This act introduces a new strict rules to protect investors by improving the accuracy and reliability of corporate disclosures. XBRL standard allows many customers to compare the financial performances of the company as opposed to a group of companies. Registered confidence of working with XBRL standard is fully in accordance with the requirements arising from the "Sarbanes-Oxley Act"-a.

The new system of trust should provide SEC with tools for checking to oversee corporate reporting and control their compliance with the criteria defined in the said Act. The tools that have been developed along with the XBRL standard facilitates comparison of the information obtained, and it is considered and expected to be able to eliminate fraud in a timely manner (early acceptance of income, inadequate capitalization of expenses, excessive reserves relating to income, inadequate management of income, etc..). XBRL is characterized by proliferation and the ability of their access to information.

Indicia including XML and XBRL will enable accounting systems to accumulate data from different databases in a concise reporting entities and translate the information needed to create all the elements in internal or external report. XML increases the speed of the internal and external shareholding reporting.

XBRL can optionally be used for that connection ie. linking of selected documents and reports back to the store such data on the disk of the new user, and the operation can be no security risk that should identify which management uses such information. Risk refers to the possibility that the link be exploited and compromised by hackers or others. In this case, additional security measures should be consider, and clear configuration used quality "firewall" with which network and server protect against unauthorized entry and measures such as the use of cryptography data from XBRL methodology. Clear attitude on the safety and security of financial settlements developed using XBRL has to have every accountant and auditor. Must remain the same as in the case of other traditional financial statements of the general a security approach and core control, only the protection technology to be adapted to new technological opportunities.

Application of new technology solutions can include the necessary accounting files that will be digitally signed or individual signed - such files within a document provided by the client by the auditor.

The first implementation of XBRL standards were achieved by the Commission for the Securities, the stock market, banks, tax and customs administration. The first implementation of the current conditions XBRL have accepted a variety of business organizations, auditing and accounting agencies, software for accounting and business intelligence, as well as individual analysts and investors.

At the global level, XBRL is implemented by the SEC (Security Exchange Commission), American Institute of Certified Public Accountants (AICPA), the Australian Prudential Regulations Authority (APRA) (first developed a program for the collection of regulatory data in XBRL). National Tax Administration of Japan leads the world in the application of the XBRL reporting standard and the Tokyo Stock Exchange (Tokyo Stock Exchange) in Asia. The current situation regarding the implementation of XBRL Europe show the following table.

Tabel 2: Progress in the implementation of XBRL standards in Europe

Most European Union countries, as can be seen, permits or provides for the implementation of XBRL. There are between five and seven million of financial statements in this format in Europe. Regions of the world where the fastest developing XBRL are USA, Japan, Europe, China and Australia.

4. CONCLUSION

At the beginning of the twenty-first century is increasingly question whether the current system of financial reporting appropriate to the era of modern information technology. The globalization of business and accounting response to it have caused the development of global financial reporting tools, as well as global regulators that promote the development and improvement of the quality of financial reporting. The development of information and communication technology makes a major changes in the financial reporting process and the exchange of business information. The development of communication and information technology has enabled the relocation of financial reporting on the Internet. Thanks to the aforementioned business information is now available to everyone, anytime and anywhere. For this purpose, dominant is usage of the International standard for the exchange of business information XBRL.

Its application brings all participants in the financial reporting supply chain advantages such as cost savings for preparation, processing, disclosure and in time. XBRL does not require changes in existing accounting standards, or require companies to disclose more information. XBRL enables automated exchange of information between different business applications while dramatically reducing human involvement.

Benefits of XBRL reflect the savings in cost and time by automating the process. Completely redefine the accounting practice of applying XBRL, increasingly require a high level of analysis with a view to ensuring adequate informational support in decision making. XBRL is a relatively new and software support on which it relies, and may cause some problems of compatibility of software applications. XBRL as each standard has a limited life cycle, and probably will in future pass under appropriate changes. Because XBRL entirely relocated financial reporting on the Internet raises the question of information protection and security.

RECOGNITION VERSUS DISCLOSURE IN FINANCIAL REPORTING

Aleš Novak[1]
[1]University of Maribor, Faculty of Organizational Sciences, ales.novak@fov.uni-mb.si

Abstract: *Empirical evidence from the academic literature on capital market effects of recognition on the face of the primary financial statements versus disclosure in the notes to the financial statements is not straightforward. Therefore, the purpose of this paper is to contribute to the recognition versus required disclosure debate in the standard-setting context by exploring possible reasons for perceived differences between the recognised and disclosed amounts. Since in our opinion the preparers of the financial statements take less care about disclosures relative to recognised items, demonstrated auditors' greater tolerance for misstatement in disclosed amounts and allowed substantial non-compliance with disclosure requirements even in strong enforcement regimes, we believe that all these arguments strengthen the case for the general preference for recognition in the standard-setting context.*

Keywords*: disclosure, disclosure framework, efficient market theory, financial statements, notes, recognition*

1. INTRODUCTION

The question whether share prices reflect amounts disclosed in the notes to the financial statements and those recognised on the face of the primary financial statements similarly is of interest to standard-setters, regulators, financial statements preparers, auditors and hence also for academics.

Efficient market theory (EFM) suggests that the markets adopt a substance over form approach and incorporate all publicly available information, irrespective of the mode of disclosure, i.e. whether the amount is disclosed on the face of the primary financial statements or in the notes.[1]

But some (value relevance) empirical research suggests that under certain conditions note disclosures are less strongly associated with market values (of equity, i.e. share prices), as for example Bernard and Schipper (1994), Aboody (1996), Davis-Friday et al. (1999), Davis-Friday et al. (2004) and Ahmed et al. (2006). One of these conditions is if investors inappropriately undervalue disclosed amounts either through lack of expertise or due to the cost of processing note information. Secondly, recognition may imply greater relevance[2], in which users correctly assign lower weight to disclosed amounts (Jifri and Citron, 2009, p. 124).

On the other hand, some more recent empirical results of Jifri and Citron (2009)[3] suggest that, for particular classes of firms (firms engaged in R&D); the market perceives recognised and disclosed amounts equivalently, which is consistent with the efficient market hypothesis (EMH).

We can thus conclude that the empirical evidence from the academic literature on capital market effects of recognition versus disclosure in the notes to the financial statements is not straightforward. Therefore, the purpose of this paper is to contribute to the recognition versus required disclosure debate in the standard-setting context by exploring possible reasons for perceived differences between recognised and disclosed amounts. The paper has the following structure: it begins with recognition and disclosure as financial reporting concepts (Section 2); proceeds with limited attention and processing power (Section 3), explores auditor behaviour related to recognised and disclosed numbers (Section 4), while Section 5 concludes the paper.

[1] It is worth noting that some disclosed items in financial reports are not recognised—and likely never will be—because they cannot be expressed in numbers or, more narrowly, in currency units. Examples include the qualitative description of accounting policies, a summary of inputs to the calculation of a recognised number, and a sensitivity analysis (Schipper, 2007, p. 301).
[2] Relevant financial information is capable of making a difference in the decisions made by users. Information may be capable of making a difference in a decision even if some users choose not to take advantage of it or are already aware of it from other sources. Financial information is capable of making a difference in decisions if it has predictive value, confirmatory value or both (IASB, 2010, paragraphs QC6-7).
[3] Paper exploits the unique UK regulatory framework in which accounting for goodwill moved from note disclosure to balance sheet recognition. According to Jifri and Citron (2009, p. 125) paper adds to the literature in a number of ways. Firstly, it studies the recognition vs. disclosure issue in a new context, that of goodwill accounting. Secondly, it investigates whether the relative importance of recognised and disclosed amounts varies by type of firm, specifically whether or not firm engages in R&D.

2. RECOGNITION AND DISCLOSURE AS FINANCIAL REPORTING CONCEPTS

Although there is no extant academic theory of accounting or standard setting, both world's most important standard setters, namely the International Accounting Standards Board (henceforth IASB), which issues International Financial Reporting Standards (henceforth IFRS); and the Financial Accounting Standards Board (henceforth FASB), the accounting standard-setter from the USA; articulate their theory of accounting and standard-setting in their conceptual frameworks[4] (Barth et al., 2001, p. 78).

On the 28 September 2010 the IASB and the FASB announced the completion of the first phase of their joint project to develop an improved conceptual framework for IFRS and US generally accepted accounting practices (GAAP). That actually meant the issuance of Chapter 1 *The objective of financial reporting* and Chapter 3 *Qualitative characteristics of useful financial information* of the improved conceptual framework. Chapter 2 will deal with the reporting entity concept. Chapter 4 contains the remaining text of the IASB's *Framework for the Preparation and Presentation of Financial Statements* that was published in 1989.

The project's overall objective is to create a sound foundation for future accounting standards that are principles-based, internally consistent and internationally converged. The improved framework builds on existing IASB and FASB conceptual frameworks. Since this conceptual framework project is conducted in phases, as a chapter is finalised, the relevant paragraphs in the IASB's Framework (1989) will be replaced.[5] When the conceptual framework project is completed, the IASB will have a complete, comprehensive and single document called the *Conceptual Framework for Financial Reporting*.

Paragraph OB3 of the IASB's Conceptual Framework for Financial Reporting from 2010 (henceforth Framework 2010) states that ~~t~~he objective of general purpose financial reporting is to provide financial information that is useful to existing and potential investors, lenders and other creditors in making decisions about providing resources to the entity."

As a basis for a theory of required disclosures, however, it is viewed that the objective of providing decision-useful information as insufficiently discriminating, in at least two ways. First, that objective is too general to be helpful in ruling out items from further consideration. For example, the provision of decision-useful information would be consistent with requiring disclosures to reduce information asymmetries between investors and managers (that is, forcing the dissemination of information that management already has), and it would be consistent with requiring disclosures that mandate the collection and dissemination of new information (Schipper, 2007, p. 303).

Second, objective in Chapter 1 unfortunately also does not help with the distinction between recognition and disclosure (Schipper, 2007, p. 303). This difficulty applies elsewhere in the IASB's Framework 2010 as well: recognition is specifically defined in paragraphs 4.37-4.39, but disclosure is not. In addition to defining and describing recognised items, it states that disclosure is not a substitute for recognition (paragraph 4.37) and provides recognition criteria (paragraph 4.38): An item that meets the definition of an element should be recognised if:

a) it is probable that any future economic benefit associated with the item will flow to or from the entity; and
b) the item has a cost or value that can be measured with reliability."

In contrast to the detailed treatment of recognition, IASB's Framework merely discusses disclosures (without defining them) and provide some examples[6]. That discussion is not definitive with respect to the question of

[4] A conceptual framework could be seen as an attempt to operationalize the accounting theory (Higson, 2003, p. 62). Davies et al. (1999, p. 53; in Higson, 2003, p. 63) define a conceptual framework as a statement of generally accepted theoretical principles which form the frame of reference for a particular field of enquiry. In terms of financial reporting, these theoretical principles provide the basis for both the development of new reporting practices and the evaluation of existing ones. The IASB's framework can be interpreted as a given, external set of high-level principles or norms, which reflect fundamental value judgments made by the Board. In the IASB's regulatory context, decisions regarding the identification, definition and hierarchy of these high-level principles are made in the political sphere, that is, after considering constituents' views (Fülbier at al., 2009, p. 462). Solomons (1986, p.116; in McKernan, 2007, p. 173) identifies defence against politicization as one of the key functions of conceptual framework for financial reporting. If there is a sound conceptual framework then the basis for the standard-setting decisions can be more widely understood, not only by politicians but also by other market participants, and hopefully will make the actions of the standard-setter more defensible (Boyle, 2010, p. 301).

[5] FASB's conceptual framework consists of Statements of Financial Reporting Concepts (SFASs). On 28 September 2010 FASB actually issued SFAS No. 8 that replaced SFAS No. 1 *Objectives of Financial Reporting by Business Enterprises* and SFAS No. 2 No. 2 *Qualitative Characteristics of Accounting Information*.

[6] For example, the current IASB's Framework in paragraph 4.41 states that the financial statements also contain notes and supplementary schedules and other information. For example, they may contain additional information that is relevant to the needs of users about the items in the balance sheet and income statement. They may include disclosures about the risks and uncertainties affecting the entity and any rights and obligations not recognised in the balance sheet (such as mineral reserves). Information about geographical and industry segments and the effect on the entity of changing prices may also be provided in the form of supplementary information.

what disclosures are, conceptually, expected to achieve in the communication of decision-useful information. However, the discussion in the Framework is indicating that recognition is a special case of disclosure, restricted to items that meet certain criteria, that is, disclosures in the notes differ from recognised items because disclosed items fail one or more of the recognition criteria. That yields following inferences. First, because recognition is subject to special criteria, and because IASB's Framework state that disclosure and recognition are not substitutes, it is evident that disclosure and recognition are not financial reporting alternatives—they are not intended to serve the same purpose. Second, items that meet the definitions of financial statement elements but fail one or more of the recognition criteria should be disclosed, and the most likely criterion to matter for this distinction is reliability[7] (Schipper, 2007, p. 303).

One rationale for relegating amounts to the footnotes is that the information is less reliable due to significant uncertainty associated with measurement of the amount (Johnson and Storey, 1982). For example, opponents to expensing stock compensation often argued that the estimates arising from Statement of Financial Accounting Standards (SFAS) No. 123's *Share based payment* and IFRS 2 *Share based payment* fair-value method are unreliable (Malkiel and Baumol, 2002). Under this rationale, reliability can determine information location.[8]

However, standard setters may determine information location for other reasons (Bernard and Schipper, 1994). Despite the fact that Schipper (2007, 302) stated: "It seems implausible that a standard setter would not require the recognition of highly reliable items unless those items do not meet the definitions of financial statement elements", former FASB members have indicated that the decision to allow disclosure rather than recognition has been driven by political pressure in some cases (e.g., Beresford, 1997). This suggests that information location decisions can be influenced by considerations other than those described in the conceptual frameworks.

On the other hand, the concept of limited attention and processing power (Section 3) and auditor behaviour related to recognised and disclosed numbers (Section 4) in our opinion strengthen the case for the preference for recognition in the standard-setting context.

3. LIMITED ATTENTION AND PROCESSING

Paper by Hirshleifer and Teoh (2003) represents a step towards bridging what appears to be an increasingly wide gap between the views of many accounting and finance researchers (specifically, the views of 'hard core' believers in market efficiency) and the views of just about everyone else in the world with respect to the perceived efficiency of capital markets (Lambert, 2003, p. 387).

Their approach departs from theories in assuming that investors have limited attention and processing power. Limited attention is a necessary consequence of the vast amount of information available in the environment, and of limits to information processing power. Attention must be selective and requires effort (Hirshleifer and Teoh, 2003, p. 339).

In their model, owing to the limits to investor attention, the information that is presented in prominent, easily processed form is assumed to be absorbed more easily than the information that is less prominent, or that is only implicit in the public information set. Thus, (some) investors neglect relevant aspects of the economic environments they face. Although inattention maybe seems foolish as inattentive investors lose money by ignoring aspects of the economic environment, but if time and attention are costly, such behaviour may be reasonable (see Barth et al., 2003 below).

[7] We agree with Schipper (2007, p. 311) that there is no general agreement with regard to either the construct of reliability itself or its measurement. Some appear to believe that reliability is the ability of information to be vouched to, or confirmed by, an external archival source. Others appear to believe that reliability means the item's measurement is characterized by a high degree of consensus among independent measurers (a notion that subsumes the first idea of reliability). Still others appear to believe that reliability refers to precision of measurement (which is related to but differs from the consensus-of-measurers notion of reliability). Because attempts to explain what reliability was intended to mean in the standard-setting context have proved unsuccessful, the IASB and FASB sought a different term that would more clearly convey the intended meaning. The term *faithful representation*, the faithful depiction in financial reports of economic phenomena, was the result of that search. The IASB and FASB claim that term encompasses the main characteristics that the previous frameworks included as aspects of reliability, so the term reliability disappeared from the IASB's Framework 2010. For more on qualitative characteristics in the IASB's Framework 2010 see Novak (2013).

[8] The evolution of stock option accounting in the framework of U.S. GAAP from the initial adoption of SFAS No. 123 to the passage of SFAS No. 123R encompasses three reporting environments for stock option expense: (1) voluntary note disclosure, (2) voluntary income statement recognition, and (3) mandated income statement recognition (Frederickson et al., 2006, p. 1089). Frederickson et al. (2006) find out that mandated income that mandated income statement recognition, as required by SFAS No. 123R, leads to higher user assessments of reliability than either voluntary income statement recognition or voluntary note disclosure, options allowed under SFAS No. 123. Users view voluntary note disclosure as the least reliable reporting alternative.

The paper develops a theoretical model in which a nontrivial fraction of investors are ‚inattentive' (unsophisticated) and either miss important information disclosures entirely or systematically misinterpret their implications. In such a world, accounting measurement rules, earnings management activities, and discretionary disclosures have an impact on stock prices even when these features bear no relation to the underlying cash flows of the firm (Lambert, 2003, pp. 387-388).

Moreover, these features have an impact despite the existence of ‚attentive' investors who have the ability to ‚see through' them.[9] The paper derives a link between reporting and disclosure decisions and stock prices, and goes on to analyse how sophisticated managers would make reporting and disclosure decisions to exploit the inability of the market to price their firms ‚correctly', thereby increasing the stock prices of their firms (Lambert, 2003, pp. 387-388).

One of the conclusions Hirshleifer and Teoh (2003, p. 380) make is that limited attention may help explain why investors are insufficiently sceptical of firms that are positioned to conceal liabilities, such as off-balance sheet contractual provisions, for example operating leases.[10] Limited attention may also help explain, without appealing to political or contracting constraints, certain peculiarities in the structure of accounting rules. In the age of information technology, it has become cheaper to require detailed reporting of numerous transactions (for a given level of resources devoted to auditing). Actual accounting reports differ from such a standard in ways that, from a pure reporting perspective, seem either irrelevant or harmful. For example, accounting rules permit aggregation, which ‚throws away' information. A limited attention approach suggests that even from a pure reporting perspective, aggregation can make sense, because investors may have trouble processing disaggregated information. Similarly, redundancy can be helpful when different presentations ease the processing of that information for different uses.

Similar theoretical paper by Barth et al. (2003) compare disclosure with three types of recognition: aggregate recognition with disclosure, separate recognition, and aggregate recognition without disclosure. They assume that investors decide whether to acquire accounting expertise. In doing so, investors trade off the cost of expertise acquisition against informational benefits they obtain from understanding disclosures. They assume that the expertise acquisition is costly because understanding disclosures requires accounting expertise beyond that needed to understand recognised amounts.

If information is disclosed only in the notes, users of financial statements have to expend time and effort to become sufficiently expert in accounting to know (a) that there are items that are not recognised in the financial statements, (b) that there is information about those items in the notes, and (c) how to assess the note disclosures. Because gaining that expertise is costly, some users of financial statements, i.e. those whose perceived expertise acquisition costs are higher than perceived informational benefits, will not become accounting experts. Therefore, information that is merely disclosed may not be fully reflected in share prices.

When comparing the disclosure regime with the separate recognition regime, they find that recognition always increases price informativeness. This is because in this regime recognition results in the disclosed amount being freely available to all investors. However, when aggregation is a part of recognition, as it is in the aggregate recognition with or without disclosure regimes, the results are more complex. In particular, in the aggregate recognition with disclosure regime, they find that recognition of an accounting component that results in a higher (lower) quality recognised amount does not always result in greater (lower) price informativeness.

Lambert (2003, p. 399) agrees that individual investors cannot possibly process everything or even pay attention to everything that is of potential relevance to the valuation of the firm. In such a world, summary statistics can be of value, even if their role is to reduce economic search costs and is unrelated to psychology reasons. The big questions are: how important are these effects, and what factors influence their importance?

[9] Model assumes that since the attentive investors all have full information, they all calculate identical expected values. Inattentive investors are assumed to calculate the wrong expected value relative to the expected value calculated by attentive investors. Moreover, all inattentive investors calculate the same wrong value. Inattentive investors are assumed to utilise the same value for the residual variance of cash flows as do attentive investors. As a result, they trade just as aggressively based on their (incorrect) assessment of firm value as do attentive traders based on their correct assessment. In what sense are market prices inefficient in this equilibrium? They are inefficient in the sense that the price is not the same as it would be if everyone was attentive (Lambert, 2003, p. 392).

[10] Under the operating lease, the lessee does not recognize any lease asset or liability in the balance sheet. Nevertheless, in contrast, it is obliged to disclose future expected rental payments in the notes to the financial statements. For operating leases having initial or remaining non-cancellable lease terms in excess of one year, the following information shall be disclosed in the notes to financial statements: future minimum rental payments required as of the date of the latest balance sheet presented, in the aggregate and for each of the five succeeding fiscal years, and the aggregate for the periods beyond five year. The usefulness of only a lump-sum amount disclosure beyond five years is in our opinion questionable. For more on lease accounting see Novak (2011).

4. AUDITOR BEHAVIOUR RELATED TO RECOGNISED AND DISCLOSED NUMBERS

Paper by Libby et al. (2006) examines whether auditors are willing to tolerate more error in disclosed numbers than in recognised numbers, which should reduce the reliability of disclosed numbers. They report two experiments that examine audit partners' willingness to tolerate misstatements in recognised and disclosed amounts.[11]

Results from the experiments indicate that auditors require much greater correction of misstatements in recognised amounts than they do for the same amounts that are only disclosed. Debriefing data indicate that this effect is intentional. Even though recognition increases expected client resistance to correcting the misstatement, auditors view recognised misstatements as more material than disclosed misstatements and indicate a willingness to pressure the client more to correct recognised misstatements. Recognition also increases the amount of time auditors expend making a correction decision.

These results suggest that auditors believe their misstatement-reduction responsibilities vary between recognised and disclosed amounts, at least in part because they view misstatements in disclosed amounts to be less material. To the extent that financial markets and contracts rely less on disclosed numbers, setting higher materiality thresholds for disclosed numbers could be viewed as consistent with current accounting and auditing guidance. Therefore, allowing more misstatement in disclosed amounts in such circumstances may be a rational response by auditors to the lower risk of litigation or reputation loss associated with disclosed amounts (Libby et al., 2006, p. 535).

However, the lower reliability produced by auditors' greater tolerance for misstatement in disclosed amounts may reduce the overall quality of information available to users. It is unclear whether such an effect was intended by regulators, particularly in cases in which disclosure has been allowed as a political compromise. These results have potential implications for the interpretation of prior research, and for accounting standard setters and auditing regulators (Libby et al., 2006, p. 535).

From a financial-reporting research perspective, the results from Libby et al. (2006) indicate that prior findings of reliability differences between recognised and disclosed amounts may be caused, in part, by differences in the extent of misstatement reduction provided by auditors. Thus, accounting standard setters' information-location decisions may to some extent be ‗self-fulfilling prophesies' with respect to information reliability. Accounting regulators might consider whether an unintended consequence of relegating information to the notes to the financial statements is that the reliability of such information could be reduced by the interpretations and actions of auditors.

Similarly, decisions to require recognition may have a positive effect on information reliability because recognition encourages auditors to require correction of detected misstatements[12]. In addition, Bischof et al. (2011) demonstrate that required disclosures are not adequately enforced and that, in their case banks, get away with substantial non-compliance with disclosure requirements.

5. CONCLUSION

In the framework of literature on capital market effects of recognition versus disclosure we support Jifri and Citron's (2009, p. 123) conclusion that further research should investigate the extent to which market assessment of recognised versus disclosed amounts depends on the accounting item in question, its method of valuation and processing through books of account as well as the characteristics of the firm. For example, empirical results from Bratten et al. (2013) suggest that recognized and disclosed amounts are not treated

[11] One experiment reports data from 44 Big 4 audit partners, and varies whether a misstatement relates to stock-compensation expense that is recognised or disclosed. The other experiment reports data from 33 Big 4 audit partners, and varies whether a misstatement relates to lease liability that is recognised (as a capital lease) or disclosed (as an operating lease). In both experiments, they hold constant the company's economic circumstances, the sign, quantitative materiality, and certainty of the misstatement, and client opposition to correction of the misstatement (Libby et al., 2006, p. 534).

[12] It is also important to note that the effect of information location on post-audit misstatement depends on its effect on both managers and auditors. Libby et al. (2006) held constant the amount of pre-audit misstatement, and demonstrated that auditors tolerate more misstatement in disclosed amounts, which produces greater post-audit misstatement in disclosed amounts. Pre-audit misstatement may not be constant in practice. Since recognised amounts may be more important in valuation and contracting, client managers may face greater incentives to create pre-audit misstatement in recognised amounts than in disclosed amounts. Alternatively, managers may create more pre-audit misstatement in disclosed amounts in anticipation of more lax auditing. A useful direction for future research is to better understand how information location affects the extent of pre-audit misstatement.

differently by capital market participants[13] in the leases setting in which the disclosed amounts (in the notes to financial statements) are *reliable* and the disclosed information is *readily identifiable* and *easily processed*. However, in our opinion, for non-sophisticated users of financial statements the information location in any case indeed matters.

Since different stakeholders try to influence the information-location decisions (recognition versus disclosure) by the standard-setters by considerations other than those described in the conceptual frameworks, it seems that they believe that the information location in practice really matters. Our paper suggests a couple of reasons for the perceived differences between recognised and disclosed amounts. We believe that the relegation of amounts to the notes to the financial statements generally reduces informativeness of financial reports, especially for non-sophisticated users, and reduces the reliability of financial information. In our opinion, the preparers of the financial statements also take less care about disclosures relative to recognised items because the inadequate auditor pressure. Libby et al. (2006) demonstrated auditors' greater tolerance for misstatement in disclosed amounts, while Bischof et al. (2011) revealed that sometimes the preparers get away with substantial non-compliance with disclosure requirements, even in Western European countries with supposedly strong enforcement regimes. All these factors in our opinion strengthen the case for the general preference for recognition in the standard-setting context.

Therefore, it should not come as a surprise that currently the note disclosure problematic is receiving a lot of attention in the accountancy community. For example, European Financial Reporting Advisory Group (EFRAG) and the national standard-setters of France Autorité des Normes Comptables - ANC) and the UK (Financial Reporting Council FRC) in July 2012 issued a discussion paper titled *Towards a Disclosure Framework for the Notes*. It emphasises that a Disclosure Framework should contain a clear definition of the purpose of the notes, which should drive what (financial) information should be included in the notes and what belongs elsewhere. FASB launched the Disclosure Framework project back in July 2009 and in July 2012 issued Invitation to Comment – Disclosure Framework, a document very similar to the joint discussion paper of EFRAG, ANC and FRC.

In addition, the IASB formally added a short-term initiative on disclosure to its work programme in December 2012 as a part of its response to its Agenda Consultation 2011. The objective of the initiative was to explore opportunities to see how those applying IFRS can improve and simplify disclosures within the existing disclosure requirements (Deloitte, 2013).

[2] Faculty of Hotel Management and Tourism, aleksandra.stankovic@kg.ac.rs

Abstract: *Given that today's banks operate in circumstances that characterize the dynamic changes in the environment, utilizing a certain strategy of an organization is much more complex work than just creating the strategy. The authors choose this topic because of the increasing importance of financial information to create competitive advantages for banks in the current business conditions globally. Significant insight into the accounting information of strategic importance can be achieved just by estimate based on published financial statements. Analytical framework that can be applied to the published financial statements of competitors should be treated as part of the assessment of competitive advantages for banks. This type of financial analysis should include the monitoring of trends in sales of banking products, profit levels, structure of the assets and sources of funding. Through the integration of information which strategically oriented management accounting provides from the environment and the bank itself, it generates information that can serve to improving the quality of strategic financial decision. In this context, it is important to have continued cooperation of management accounting with senior management, corporate and competitive strategy, as well as with other functions represented in the organizational structure of the bank.*

Keywords*: bank, financial information, competitive advantage, strategic management accounting*

1. INTRODUCTION

Financial statements can provide data about the summary of economic information. Financial analysts determine the appropriateness of management forecasts which imply the choice of accounting methods and calculation and are focused on the analysis of the cash flows and transparent disclosure in the notes to the financial statements, so that conclusions and judgments made on the basis of financial analysis adequately reflect the economic realities of actual financial performance of the bank. Analyst reports can provide information to investors about whether the financial decisions of the bank are valid or whether managers overestimate the economic performance of banks in order to protect their personal business interests and increase their bonuses.

Important role in that process has the internal control as an essential support in controlling financial flows and financial reporting service which should provide specific reports for liquidity management (see more Knežević, Djurić & Dmitrović, 2012a). Sources of risk in banks are contained in their assets and liabilities. Therefore, it is impossible to manage risks in banks without quality financial reporting. Accounting reports, meaning that information contents are prepared as a basis for decision making and their customers are the carriers of management and decision making bodies. The financial statements as carriers of accounting information on the financial position of the entity at the end of the period, the overall result of the entity for the period and cash flows of the entity are used for making economic decisions by wide range of users.

Efficient asset management is particularly important for long-term survival and development of the bank in the market in which it operates [see more about techniques for measuring the efficiency in banks (Knežević, Marković & Barjaktarović Rakočević, 2012c).

In the first part the emphasis will be placed on the link between the process of financial decision making and accounting as a source of information, in the long-term, while in the second part it will be evaluated more strategic aspects of financial performance of the bank.

2. FINANCIAL DECISION MAKING IN BANKS FROM THE STRATEGIC POINT OF VIEW AND ACCOUNTING

Since every decision can only be as good as its information base, the quality of bank management decisions also depend on the extent to which it can successfully optimize decision-making basis. Information thus becomes the strategic resource management. In addition, the information system is intended to serve primarily inclusion, storage and distribution of relevant information. In other words, information systems are expected to provide the right information available at the right place at the right time. Adequate management information system in bank basically consists of two related parts: accounting and reporting.

Ongoing challenge faced by managers, consultants and researchers is how to harmonize the functional activity and discipline with each other and at the same time to support corporate strategy. Part of the burden of adjusting strategy and management accounting, including management control and performance measurement refers not only to the dynamic nature of the strategy in different contexts, but also to the spread of different views and strategies for academics and practitioners. For optimal information funding decision is that bank management needs to build accounting that would be a leading instrument. Accounting as main source of information in banks should provide the following information:

- What is the bank's earnings in certain activities;
- What is the interest in specific transactions with customers;
- Which, how much and where the related costs for banking services arise;
- Which contribution to the result of banks certain types of businesses, groups of customers or business units have;
- Which structure of operations show profit profile and risk profile;
- Which business conditions have effects on the level of results;
- What is the relationship between profitability flow and cash flow in the bank and so on.

In defining the strategic direction of the bank, it is necessary to include the following essential elements (Djurić, Knežević & Barjaktarović Rakočević, 2011):

1. Definition of profile of the bank;
2. Analysis of the macroeconomic environment;
3. Projection of future business activities and identification of the target of operating results.

The concept of strategy implies the use of formal information management systems. Achieving the goals requires analyzing information in the process of decision making. If a strategic decision is structured and planned venture it will draw significant attention. It is necessary for management to proactively identify internal and external strategic opportunities and threats, without denying the possibility of strategic innovation. It is assumed that managers formally analyze the competitive advantage and meaningful assessment of the distribution and use of resources, as part of a development strategy. Formal information systems will provide such analysis. Strategic management accounting is a good tool for managers to make sound business decisions (see more - Knežević, Milosavljević & Dmitrović, 2010).

Strategic goals of the bank can be the following:

1. Long-term profitable business with an adequate protection of capital;
2. Growth of market share;
3. Growth credit portfolio;
4. A long term implementation of the social responsibility concept.

From management accounting strategic orientation is expected strong information support that will enable the implementation of preventive measures aimed at eliminating ineffective results in the bank. It is essential that the bank has the ability to successfully manage unplanned changes in funding sources, for which the accounting estimates are necessary, which suggests that the bank is adequately responding to market changes.

Dynamic changes in the external environment are the main reasons for the necessary changes, which require closer cooperation between strategic managers and management accountants, especially in the monitoring and analysis of the costs, as well as their design, especially in the business environment which is characterized by risk and uncertainty. In addition, it is very important and powerful information support in the area of measuring the profitability of individual banking products and changes related to key customers of the bank.

Strategically oriented management accounting is a multipurpose information resource oriented towards management and future, and focused on strategic business units. Simmonds (1981) has defined and described that strategic management accounting focused on the comparison of companies with rivals. He advocated the collection of information necessary to determine the share of the market, price competition, cost and scope. A bank that follows the market share can measure the extent to which it win or loses competitive position.

Given the fact that the strategic development of the bank is directly connected with the plans of the bank, it is important to note that strategic planning directly depend on information management accounting. In other words, there must be a high degree of coordination between planning and reporting.

Bearing in mind that the market environment has become more dynamic and competitive, in order to operate successfully banks are forced to continuously improve their activities in terms of having more accurate predictions of future operations. However, banks can no longer allow themselves to have any inconsistency between anticipated revenues and expenditures. With the growing importance of the budgeting process in the banks, the need for more detailed reporting system is on the rise.

In the strategic analysis of competitors of an observed bank, it is necessary to answer to the following questions:

1. Who are the strongest competitors?
2. Whose strategic actions largely affect the observed bank so that special attention needs to be given to their activities?
3. What are the goals of past strategy of competitors?
4. What are the objectives of the current strategy of competitors?

Benchmarking is based on the idea that own business is compared with the strongest competitors in order to be able to use the obtained knowledge in attempt to improve own business.

The market justification of certain market undertake includes identifying information about own customers and suppliers, competition and trends in the industry in which it operates. It is necessary that analyze current and anticipated future competitors.

Strategic planning is the process of defining the strategy of the bank, as well as the decision making process in order to enable the implementation of approved strategies. Crucial issue of each bank is to define the direction which the bank should follow. Based on the strategic plan operational plan is carried out, which is usually focused on a period of one year. Organizational activities are undertaken in order to design various interests, including bank, specific authority, and institutional pressures.

The strategic plan of the bank consists of two parts: qualitative and quantitative. The qualitative part of the analysis includes the analysis of macroeconomic scenario, the SWOT analysis, the bank's mission, strategic direction and action plan, which should enable the achievement of defined plans. Quantitative methods include the application of financial models into strategic financial management of the bank. The chosen strategy of the bank is to be then translated into a set of objectives (Djurić, 2010). In the context of strategic planning it is necessary to mention the concept of the Balanced Scorecard, which reflects the intention to maintain a balance between short-term and long-term objectives between financial and non-financial measures as well as between the backlog and leading indicators. Hence, the point is that the management takes the bank towards achieving strategic goals. The central queston for the bank management is “how well are we doing”?

In assessing the commercial bank performance it is essential to define the criteria from several aspects (Knežević, Barjaktarović Rakočević & Djurić, 2011):

First – financial perspective: revenue management, market share, profitability capacity, asset management;

Second – a client's perspective: to win the client before others, customer profitability, customer retention, special financial services;

Third – internal business process perspective: creating information systems, information support for management, maintaining the quality of the business;

Fourth – perspective for learning and professional development of managers: knowledge and development of managers, teamwork, policies for stimulating and rewarding.

It is important to mention the role of the banking controlling which is used for adequate information communication in the bank, so that the variance between the strategic and operational objectives and the results achieved will be as small as possible.

From strategically oriented management accountant is expected to anticipate the financial aspect of business events and create a business vision using bank management accounting information.

For an adequate cost management it's necessary to have evaluation of alternative strategies or plans that display all costs. In order to design appropriate information model of strategic management accounting for banks involve various experts: management accountants, experts in planning and analysis, financial and other bank managers, experts in information technology and more. Monitoring the activities of competitors, especially in the domain of actual performance management team of the bank may make positioning of the bank in the future in relation to competitors.

Significant support for improving business performance of strategic business units is expected from the marketing manager. Marketing surveys estimate future outcomes and results in order to facilitate decision making on different options of cost estimates which are in line with corporate objectives. Managers involved in managerial accounting are trying to identify the cost structure of competition and based on that determine the prices of banking products taking into account to offset the inflationary effects of the variables observed. Adequate assessment of price competition begins with an analysis of costs and continuing analysis of the impact of possible changes in prices of other competitors in the financial market, which requires accounting analysis. Afterwards, a scope of market influence is considered. Of course, competitive advantage is not possible to express as a single variable, but rather as a group of indicators that show competitive picture that will serve the strategic managers to monitor whether the bank is moving in the right direction. The possession of information about the costs of competitors allows the bank to recognize when a competitor is trying to change the relative competitive position, for example to management prices.

In many areas related to the environment there is increased interest in transparent calculations and analyzes that often include in addition to economic and financial calculations. At the level of the business system so-called accounting for environment is identified as a segment of financial accounting as well as a segment of the strategic orientation of management accounting. Social responsibility is particularly important for the bank's reputation in terms of increase of financing of environmentally sustainable projects, funding projects that increase energy efficiency and more. For this purpose predictive information is necessary, both financial and non-financial.

3. STRATEGIC MANAGEMENT OF THE FINANCIAL PERFORMANCE OF A BANK

Banks are entities in the financial markets and the overall financial system of the economy and thus banks have become directly or indirectly trigger and control mechanism of the financial system, without which the process of reproduction was virtually impossible. As specific financial institutions banks are at the central point of the financial system, because of the function they perform and the relative magnitude of financial resources that is on their accounts.

In banking, as well as in many other industries, business reputation is particularly important and this significantly affects the overall financial performance. For each bank, regardless of how the bank is present in a particular market, the biggest threat is the loss of business reputation. Safety of a bank is a basic prerequisite for the acquisition and preservation of its long-term reputation in the public. One of the parameters of safety of a bank is its assets, or assets that it has in the performance of its business activities and the realization of the target performance – profitability, solvency and liquidity.

For the implementation of the strategy that leads to the achievement of financial performance targets it is necessary to solve the three generic questions:

1. Which dimensions of performance does banking institutions tend to develop?
2. How will the goals be properly set?
3. What rewards and / or penalties should be linked to the achievement of performance standards?

Strategic management of bank performance can be represented as the activity of management bank solvency in order to define the optimal relationship at two levels: maximizing yield and meeting the demands of regulatory institutions that are focused on preserving the stability of the banking system, while minimizing risk to the business.

Directing the bank's business activities towards the realization of the strategic performance of the bank is a very complex process, because of contradictions of objectives of shareholders and depositors of the bank. Information horizon of management accounting in the function of the realization extends to the following strategic objectives of the bank:

- Identify opportunities and weaknesses of competitors in terms of cost components (cost banking products), the relative share of the market and the level and structure of fees and commissions;
- The trend of expanding or narrowing the scope of the bank's domestic and international markets in the field of financial indicators;
- Comparison of actual strategic goals and objectives with planned, types and causes of deviations and taking corrective measures to eliminate the negative deviations.

Performance measures play a critical role in the organization, in order to check how efficiently the banking institution achieves its goals, as well as identifying necessary improvements. For the analysis of financial performance (see Table 1), it is necessary to perform financial projections of the balance sheet and the income statement with expected trends and calculate of the following indicators of business (Djurić, 2010).

- Net profit / Average assets - Net profit / Average shareholders's equity - Operating and other expenses/Interest income - Operating and other expenses/Net non-interest income - Operating and other expenses/Assets - Net interest income/Interest-earning assets - Net income from interest and fees/Interest-earning assets - Interest income/Interest-earning assets
- (Interesed earned – Interesed expensed)/Total assets - Interest-earning assets/Total assets - Average interest rate on interest-earning assets - Average interest rate on interest-earning liabilities
- Total capital/Total assets - Primary capital/Total assets - Deposits and other accounts up to three months/Shareholder's equity
- The growth rate of total assets - The growth rate of interest-earning assets - Loan growth - The rate of growth of deposits - The rate of growth of income - The rate of profit growth
- Total loans/Deposits - Liquid assets/Total deposits - Liquid assets/Total assets - Liquid assets/Current liabilities - Liquid assets/Deposits up to three months - Liquid assets/Risky off-balance sheet liabilities and total deposits - Gross advances/Deposits and other accounts
- Cash generated from operating activities/Net profit
- (Current deposits – Previous deposits)/Previous deposits - (Current loans – Previous loans)/Previous loans - Debts/Net worth - Non-performing loans/NPLs and discount - Regulatory capital/Risk-weighted assets - Sales/Number of bank employees - Profit before tax/Number of bank employees - Net interest income/Average assets earned from interest - Provisions for loan losses/Average loan portfolio - Operating and other expenses/Total expenses - Operating and other expenses/Net income from interest and fees - Operating and other expenses/Net other financial income - Overheads/Total operating income - General expenses and provisions for losses/Average total assets - Operating expenses/Average assets - Regulatory capital/Risk-weighted assets - Provision for loan losses/Average loan portfolio - Provision for loan losses/Average total assets - Reserve for loan losses/Gross loan portfolio

Table 1. Financial indicators for banks

From a strategic point of view market share analysis of banks in individual segments is significant. Besides, the analysis of the strategic business plan is important to the bank in terms of the level of investments in information systems, and from a spread of branch expansion, in order to be possible to make a realistic assessment of future growth and strengthen the market position of the bank.

From strategic management accounting series of indicators related to the competitive position are expected, with particular emphasis on market leaders, close and slow competitors. The reduction in market share shows a loss of competitive position of the bank, with implications for future reduction in profits, while increasing market share points to improve the competitive position of the prospects for increased profitability in the future.

Changes such as new cost allocation methodology, new approaches to estimating the value of money and greater participation in the budgeting process initiated intensive communication between managers and accountants. The focus of banks today is productive budget oriented product profits and reduced costs. Different information systems are used for a variety of organizational levels. For example, the five-year budget plan and five-year profit forecast sales trends are used to support systems executives *(Executive Information System*s), while on the other hand, the administrative-level control system for the preparation of the annual budget and capital investment analysis for sales management use management information system, while at the same organizational level in the analysis of profitability, costs and sales by region using decision support systems (*Decision Support Systems*). Accounting information system is part of a management information system (*Management Information Systems*) and has the characteristics of bank information systems, which produce a variety of information for different purposes (see more – (Stanković, Mitrić & Knežević, 2012); (Stanković, Knežević & Mitrić, 2013).

Financial information is also an important source of information for reporting on risk management - liquidity risk and for identify the strength and weakness of banks and banking partners for the future and for benchmarking own performance.

Effective reports supported by adequate banking software of the operating risk for the bank provide managers with detailed information for strategic decision making. Such reports are useful for the board of directors, executive committee, operational risk managers and executive risk managers and they have early-warning character. Strategic management accountants need to be oriented towards learning new skils (Coad, 1996).

Information from published balance sheet can be used for calculation of Herfindahl–Hirschman index. According to the regulatory provisions of the Federal Reserve System (Fed) the degree of concentration determined by the Herfindahl–Hirschman Index is calculated as the sum of squared share of individual bank in the overall category which is observed (assets, deposits, loans) with the value of the 1,000 points at the low concentration level, the value of 1001-1800 in moderate concentration, a value above 1,800 shows the existence of strong competition. By calculating this indicator it is possible to compare the degree of concentration of the banking sector in Serbia with the average of, for example, Central and Eastern Europe, or Southeast Europe.

Information from the financial statements may serve as sources for the application of various quantitative methods such in research as:

- I-distance method – measuring the efficiency of banks (see – (Knežević, Jeremić, Žarkić Joksimović & Bulajić, 2012b));
- Correlation and regression analysis (see – (Knežević, Marković & Živković, 2013));
- Data and Envelopment Analysis – DEA (see – (Knežević, Marković & Barjaktarović Rakočević, 2012)).
- DEA Windows Analysis Approach for Mesuring the Efficiency of Serbian Banks Based on Panel Data (Savić, Radosavljević & Ilievski, 2012).

4. CONCLUSION

Significant insight into the accounting information of strategic importance can be achieved based on evaluation of published financial statements. Analytical framework that can be applied to the published financial statements of competitors should be treated as part of the assessment of competitive advantage. This type of financial analysis should include monitoring sales trends, profit levels, as well as assets and liabilities of the bank. Accounting of competitors and strategic prices are the most widespread application of strategically dimensioned management accounting. Strategic management accounting is an evolutionary, systematic process that is constantly evolving and adapting and changing according to the changes in the bank and environment, as a function satisfying changing information needs of the business and financial decision-making strategic orientation.

An important piece of information for the assessment of competitors' costs can be obtained in part by the follow-up of technological innovations, which have important information about investing in research and development. Long-term orientation of banks towards investments implies that the bank as a profit and economically oriented institution continually seeks new opportunities to improve the competitive position and to increase awareness of the cost of competitors. Trends of competitors should be followed through systematic data collection about their development. Trend analysis of competitors involves measuring the current achievements of a bank to be able to predict future actions and achievements of competitors.

In certain countries accounting has very high application in performance evaluation of competitors based on published financial statements.

It is first necessary to create conditions for the proper integration of the system of management accounting in the information system of the bank, and then assign a strategic dimension to it. Banking institutions should measure output that are exact, and all other output that have an impact on the bank. It is important to use tools of management accounting for strategic decision making in banks.

MUNICIPAL BONDS AS A MODEL OF PROJECT FINANCING OF INFRASTRUCTURE PROJECTS

Ljiljana Zipovski[1], Slađana Benković[2]
[1]Banca Intesa a.d, Beograd, Serbia
[2]Faculty of organizational sciences, University of Belgrade

Abstract: *The development of the capital market in Serbia came to a sudden stop directly affected by the outbreak of the global financial crisis, i.e. since the last quarter of 2008. The bank-centric ambient and insufficient development of diversified investment instruments in Serbia, due to systemic risks which Serbia is facing, requires further consideration of new models of business investments, particularly in the field financing long-term infrastructure projects. This paper highlights prospects of financing infrastructure projects using municipal bonds, taking into consideration advantages and disadvantages of this type of financing and pointing on potential dangers and opportunities of this model of project financing. The improvement of cooperation between local governments and competent state institutions is a prerequisite for the realization of options and potentials for the development of municipal bonds as securities to finance infrastructure projects.*

Key words: *municipal bonds, project financing, infrastructure projects, municipal bond risks, Serbian financial market*

1. INTRODUCTION

In the past fifteen years, many states worldwide welcomed the project financing as the driving force for rendering various services related to the improvement of infrastructure. The UK government, a pioneer in this field, and a country whose experience in financing projects of great social-economic importance, from private funds in early „30th of the last century, made a significant contribution in accepting, adjusting and implementing the concept of project financing of infrastructure projects at all levels in the countries worldwide.

It is commonly stated that project financing is the form of financing which includes the community as well. Thus the comprehensive analysis should cover economic costs, revenues and benefits on one side, and risk to be accepted by all participants involved in the realization of the project, on the other side, in order to finalize it within the foreseen timeframe. Only under such circumstances one may say that the project realization is certain.

Project financing has numerous advantages in relation to direct i.e. corporate project financing. However, these benefits are often visible only after careful analyzing and smart financial engineering. The organization of project realization, its legal structure and financial plan should reflect the nature of the project, since different elements such as risk, expected profitability, eligibility of participants, requests and amounts of collaterals related to securing the borrowed financial assets with financial institutions, then the ability to achieved tax savings, financial situation of the project sponsor, expectations of the Government of the domicile country, expectations of local self-governments, and many other factors may influence the delivery of the project.

It is often stated that project financing may be defined as "founding of an independent project company, financed by the capital of one or more sponsors and without the right to compensation based on granted loans for the purpose of investing capital in assets (East Asia Analytical Unit, 1998). The project financing is most often used for new, independent, complex infrastructure projects with a high-level of risk and huge discrepancy of information available. Likewise the stakes of the sponsor"s capital are decreasing, and the burden of financing is provided in the form of tranches of syndicated loans.

Parallelly, the issue of municipal bonds is often stated as one of the source of financing the development of infrastructure of local governments. Therefore the purpose of this paper is to point out on potentials of municipal bonds as the source of financing of infrastructure projects through the concept of project finance. Furthermore, this paper is also to underline constraints of the issue of municipal bonds, which is the exact reason why this concept has never took root sufficiently as a concept of obtaining additional funds in Serbia.

The paper is divided in several chapters. The *Chapter I* is dedicated to the role of banks in project financing of infrastructure projects, the *Chapter II* elaborates on municipal bonds as a model of project financing of

infrastructure projects, while the *Chapter III* provides a brief overview of options which municipal bonds offer as an alternative model of financing. The next chapter presents experiences which other countries in the region had in using municipal bonds as the source of project financing, followed by the chapter giving the review of revenues. The last one is reserved for concluding remarks.

2. ROLE OF BANKS IN PROJECT FINANCING OF INFRASTRUCTURE PROJECTS

During the phase of initial overview and structuring of project financing, leading banks i.e. banks-loan-providers, became the project insiders in working with project sponsors. At the same time they became accountable for loan financing by means of overall syndicated loans by attracting other banks which became members in loan syndication (Gatti et al, 2008). As the respective loans do not include the indemnity clause, i.e. they relate to financing of Project Company with or without limited support from the sponsor, the loan syndication itself (deriving from syndication of the capital of financial institutions which fund the project) is in many way responsible for operational risk. By assigning the project a higher l*everage*, the operational risk must be reduced to an acceptable level. This is exactly where one of the key advantages of project financing lies– it is possible to allocate a specific risk of the project (risk of project realization and operational risk, risk of generating revenue and risk of adequate pricing, and risk of political influence and expropriation) to those participants who deal best with them (Brealey et al, 1996).

As for credit lines intended for project financing of infrastructure projects there is no significant correlation between the use and project closure timeframe. The issue related to liquidity of this model of project financing is mainly the consequence of inevitable reliance on cash flow of the project, expected higher *leverage ratio*, and volatile level of risk immanent in certain stages of the project.

There are many reasons behind “pros and cons“ for both loans and bonds when considering project financing as the model for financing infrastructure. Thus Yascombe (2010) points to the fact that credit risk associated with investment in project, in particular the one referring to a long-term projection of inflation, cannot be curbed with bank arrangements; however, when it comes to the issue of bonds, on specific markets they can be derived based on inflation index (inflation-indexed bonds). Additionally, money collected through the issue of bonds may be withdrawn in bullet, whilst with the loan arrangement it may not be the case.

At the same time, loan arrangements may be rather flexible when it comes to repayment of borrowed funds, and in case of refunding of assets collected by means of bond issue, it is provided by repurchase i.e. c*all* option. Furthermore, banks are very prudent is controlling all changes which refer to the project agreement and project company whilst creditors bond buyers control only large-scale cases which have a considerable impact on coverage of cash flow of the project or security.

It is true to say that due to the fact that obtaining financial resources from financial institutions such as banks is often dependent on situation on the capital market and level of financial resources needed for financing infrastructure projects. Thus, during 2013 the banking sector in the whole Europe and even in Serbia shows a dramatic decline in lending activity of economy. Namely, in the first eleven months of 2013, lending decreased in net amount of EUR 0.9 million which is 9% compared to December 2012 (NBS, 2013). In the circumstances of moderate lending activity, evidently reduced risk appetite, and high share of NPL (Non-performing loans) of commercial banks in Serbia, the question is to how to finance infrastructure long-term projects. This at same time implies the need for new, i.e. alternative models of project financing.

Table 1. Indebtedness of local governments of the R Serbia by creditors as of June 30, 2011

in EUR 000

Number	Name of creditor	Total amount	Repaid amount	Outstanding amount
1	EIB	265,000	510	264,490
2	EBRD	208,087	40,822	167,265
3	Banca Intesa a.d, Beograd	106,024	25,442	80,582
4	AIK banka a.d, Niš	54,630	5,220	49,410
5	Unicredit Bank Srbija a.d, Beograd	25,343	6,070	19,273
6	Komercijalna banka a.d, Beograd	13,501	1,027	12,474
7	Hipo Alpe Adria Bank a.d, Beograd	12,334	2,499	9,835
8	KBC banka	6,508	89	6,419
9	Republic of Serbia Development Fund	4,221	0	4,221
10	Others	3,563	885	2,678
11	Erste bank a.d, Novi Sad	2,176	97	2,079
12	Raiffeisen bank	3,205	1,937	1,268
13	Bank Austria credit ansalant AG Vienna	1,355	507	848
14	Vojvođanska banka a.d, Novi Sad	2,071	1,493	579
15	JP Vodoprivreda Ćuprija	956	569	387
16	NLB Continental banka, Novi Sad	580	325	255
17	CrediAgricolbanka	547	382	165
18	Agrobanka AD Beograd, filijala Zaječar	152	118	34
19	VB leasing	26	14	12
	TOTAL:	**710,282**	**88,006**	**622,276**

Financing local self-governments has a small stake in placements of majority of commercial banks. Consequently financing local self-governments is out of focus, thereby undermining the necessary understanding of financing local governments in relation to banks (Peteron George, Fellow Senior). However (Kovac, 2011)a more flexible cash flow of bonds is detrimental in favor of bonds relative to bank loans, provided bonds are used for financing the entire sums of capital payments only upon maturity. Thus, if needed or intended, the repayment of the respective sum will be financed using a financial instrument from a new issue of bonds and that way liabilities based on payment may be „renewed".

Although commercial banks in Serbia after long cooperation with local governments" structure gained knowledge on needs for financing development and capital projects, in particular throughout the crisis period, the empirical research showed that long-term projects are still beyond their focus. The above stated may be proved from the Table 1,which shows high share of international financial institutions, much as 70% financing local governments in Serbia compared to commercial banks, state fund, and other creditors. The main reason for this is steep prices i.e. high interest rates, and limited potential for investment in large projects.

3. MUNICIPAL BONDS AS A MODEL OF PROJECT FINANCING OF INFRASTRUCTURE PROJECTS

Municipal bonds belong to a special category of bonds issued by public bodies in order to finance projects related to goals of local government development. It is important to note this type of financing as bonds are structured the same as project bonds. Municipal bonds refer to bonds issued by public entities such as states, governments, provinces, local governments to other entities, for financing costs of business or specific projects. This type of bonds can be sold by public offering to small investors or specific institutional investors.

According to some managers this type of funding predates not only project financing through bond issue but the very project finance in general. As a matter of fact, the US municipal bond market has existed and developed over 100 years and in the meantime became the largest market. The market expanded due to the fact that interests are tax-free (which decreased funds the market accounts) and it is usually issued for a relatively low value, which makes them particularly suitable for small-scale projects. According to (Daher,

1997)municipal bonds are an important segment in the US bond market and are a primary source of financing local infrastructure. The development of emerging markets will be a great challenge as in those markets borrowing by local governments is largely restricted to bank loans.

At the same time it is to be emphasized that other countries began to use this type of instrument as well, for instance Eastern European countries (Poland, Check Republic, Bulgaria, Hungary, Estonia and other) and countries in South America (Brazil, Argentina, Columbia, and other) most often issuing them on European market.

Instruments of this type may be grouped in the following categories (Gatty, 2008):

- General Obligation bonds (GOs),
- Project Revenue bonds and
- Dedicated revenue bonds.

General obligation bonds (GOs) are securities where debt service is guaranteed with full trust and credibility of the issuer, which depends on its power to define the tax environment and related liabilities, from which the borrowed funds will be repaid eventually.

Project Revenue bonds are bonds with debt serving as a loan, guaranteed i.e. secured by cash flow generated by the project itself. The main difference between these bonds and project revenue bonds is that the issuer is a public entity instead of SPV. Bonds are often named after the sector for which funds are collected; so there are bonds related to the airport revenue, highway revenue, hospital revenue, sports revenue, water and sewer revenue, bonds related industry revenue etc. Funds collected from the issue are transferred by a public entity to a private company for the purchase of the plant or facility, and the generated revenue will be later used to repay the borrowed funds through the issue of bonds.

Finally, *dedicated revenue bonds* present a special category of bonds where a debt is guaranteed with a specific cash flow generated through public entity revenue. In depth, this cash flow is not tied to any specific project but revenues generated from taxation, such as for instance production and selling of alcoholic beverages, cigarettes, fuel, gas and the like where a public entity is the party with the right to dispose of collected funds or to transfer them to higher level of administration.

The categorization of municipal bonds according to timeline and from the aspect of purpose (Fabozzi, 2008) is divided to:

Short-term municipal bonds, typically sold to receive funds based on tax or revenue from the sale of bonds issue.

Long-term municipal bonds for financing:

a) Long-term capital projects, such as: schools, bridges, roads and airports, and
b) Long-term budget deficit arising from ongoing operation.

(Peteron George, Fellow Senior) emphasize two models of lending to local governments which needs to be addressed: (i) bank loans, used for financing investments in Western Europe to a largest extent during XX century and still being the primary source of financing and (ii) municipal bonds, as the ground of indebtedness of North America. According to them, emerging countries should build and strengthen credit markets by selecting features of both models and encourage competition in a fair way between lending by banks and bond issue.

4. MUNICIPAL BONDS AS AN ALTERNATIVE MODEL OF INVESTMENT

In order that municipal bonds reach potential foreign investors easily, one of the preconditions is determining / assigning rating by international credit rating agencies, such as: Moody"s, Standard&Poor"s and Fitch.

At the end of 2010, the credit agency Standard&Poors improved the credit rating to the RS from BB- to BB, as it was assessed that the RS will be able to meet all criteria in future in order to receive the candidate statues for accession to the European Union.

Following the improved credit rating of the RS, local self-governments Kraljevo, Novi Sad and Valjevo were the first in Serbia to receive the credit rating from the international credit rating agency Moody"s, which was

the impetus for the issuance of municipal bonds. In fact, issued bonds by virtue cannot have a better credit rating that the domicile country of local governments.

This is supported by the review of credit ratings of municipalities in Serbia assigned by Moody"s in 2010 as shown in Table 2 ((Moodys, 2010).

Table 2. Credit ratings of municipalities in Serbia assigned by Moody"s in 2010

Name of the local self-government	Credit rating level
Novi Sad	Ba3
Kraljevo	B1
Valjevo	B1

The assigned credit ratings are the result and appraisal of budget performance of local governments and direct limit of debt exposure, as well as limited flexibility from the aspect of profit and loss and high infrastructure needs. In fact, managing the expenditure side of the budget is a „bottle neck" for a vast majority of local governments in Serbia, which additionally resulted from the global financial crisis to the detriment of income side, i.e. shortening of own sources of financing, and aggravating adequate management of finances of each town in particular.

Novi Sad was assessed as a town well managing the budget, which was argued by stable operating margin especially in 2009, when costs and expenditures were considerably cut in order to amortize the drop in business revenue by 8%, as the result of upcoming recession. It was suggested that the town recorded no direct debts and had sound cash reserves which provided for covering of budget deficit in 2009.

According to (Moodys, 2010) the credit rating B1 assigned to Kraljevo is reflecting a flexible strategy of implementation of investing in infrastructure, which ensured balanced budget performances and keeping the debt level three years behind. In the process of assessment regarding the assigned credit rating to Valjevo (Moodys, 2010) it is stated, inter alia, that the credit rating demonstrates adequate budget and debt policy management of the town in the last four years, with a balanced debt level and adequate management of debt servicing.

Eventually, in case of analyzing arguments made by the credit rating agency Moody"s, one might conclude that the issue related to credit risk and liquidity risk management was a key and decisive factor in assigning credit ratings to above stated local governments.

From an empirical standpoint risks were recognized from the perspective of institutional investors acting as underwriters and/or agent, to which municipal bonds issued in Serbia are exposed to at pricing, in the period of reviewing the issue of first Serbian municipal bonds. Municipal bonds expose investors to common risks related to investments: credit risk, interest rate risk, call risk, liquidity risk, and unique risks – risk structure and tax risk as stated by (Fabozzi, 2008) in specific relating to most developed US market. Basic risks recognized in Serbia, in the process of preparing for the issue of municipal bonds in the municipality Pančevo in its initial phase included interest risk, credit risk, liquidity risk, currency risk and regulatory risk, all together influencing the country risk, as calculated according to the equation below:

$$\sum (\text{interest risk} + \text{credit risk} (\sum \text{liquidity risk} + \text{currency risk} + \text{regulatory risk}) * \rho_0) \quad (1)$$

P_0 – 100% weight value

- Interest risk directly correlates with pricing from the aspect of the commercial bank acting as underwriter / agent relative to alternative source of lending to local governments in the form of loan approval. A pricing aspect is defined mostly in the recognized risk, in particular in the part related to establishing risk appetite the value of which is reflected in the invariable portion of total price i.e. margin. A high percent of invariable price indicates that this type of placement is more risky compared to lending to local governments.
- The credit risk has been also recognized particularly with local governments which have no assigned credit rating. However, the existence of the credit rating is not a sufficient factor which local institutional investors will follow and take as key i.e. decisive factor; this is supported by the fact that Kraljevo and Valjevo have not issued municipal bonds.
- The Liquidity risk is considered as *primus inter pares* among risks. Actually, the majority number of local governments is facing budget deficit i.e. balance deficit. Under global financial crisis, local

governments are directly hit by drop in revenues from current operations, which resulted in taking more active role in cost cutting, in order to maintain current liquidity. The liquidity related issue means that the underwriter / agent may project cash flow in their own balances when paying out coupons, with quarterly, semi-annual or annual dynamics. The liquidity risk is related to the non-existence of secondary market of municipal bonds on organized market, and thus disabling institutional clients, i.e. pension funds, investment funds, insurance companies and individuals to approach it.

Finally, a stable macroeconomic environment with sound movement of local currency inflation movement within bounds of targets set by the central bank, and strong fiscal policy and existence of secondary market where municipal bonds were traded, are vital for the development of this segment of securities. Limitations recognized for the development of this instrument are insufficient knowledge, uncompleted institutional framework, complex issuing procedure and the risk of failure in case of issuing through public issue.

Issuing municipal bonds in Serbia may probably be intended exclusively to known investors i.e. commercial banks, and partially to institutional investors. Listing on the organized stock exchange market would provide access to a wider range of investors, which is a direction to follow in future. The issue related to currency risk and pricing of municipal bonds, in case of closed circuit of investors, is one of the essential topics. Bearing in mind this concerns deals with long-term maturities over five that is ten years, the pricing of placements for this type of securities requires a significant pricing approach, in particular if the potential investor is a business bank. In fact, the question of lending vs. municipal bonds in the trend of reducing credit rating of Serbia will go definitely in favor of lending due to much favorable price.

Basic advantages of municipal bonds have been recognized in: (i) option to issue bonds in tranches, (ii) importance of transparency and option for citizens" to follow the development of an infrastructure project, (iii) long-term maturity of lending, (iv) and flexibility of financing to suit needs of citizens.

Nevertheless, there are significant potentials in: (i) harmonization of institutional framework under the competence of state institutions of the National Bank of Serbia, RS Ministry of Finance, Securities Commission, Belgrade stock exchange, to provide for development of alternative platform and decreased of set limits, (ii) broader investment base of institutional clients, insurance companies, pension and investment funds, and citizens on primary market, by way of which the dispersion itself would significantly influence price reduction of securities and (iii) monitoring the price of own debt and call option to additionally encourage secondary market.

Lastly, as potential threats may be observed lack of skilled personnel in local governments, lack of transparency immanent to Serbia in transition, lack of confidence of citizens and other institutional groups as well.

5. EXPERIENCE OF OTHER COUNTRIES IN THE REGION WITH MUNICIPAL BONDS AS A SOURCE OF PROJECT FINANCING

Experiences from the Region related to issuing municipal bonds are important especially in Croatia, Serb Republic, Romania, Hungary and Bulgaria. However, these experiences largely refer to the period of high rates of lending activity of listed countries, and the fact that this concerns in which this instrument developed before the outbreak of global financial crisis. Experiences from regional countries i.e. their local government units are different: with different currency marks, different dynamics of repayment, different purposes, and existence of secondary trade channels.

Municipal bonds of the city of Rijeka, Croatia were issued before the start of global crisis in three tranches, between 2006-2008 totaling EUR 24.5m and a 10 year-maturity. The secondary trade is enabled through the national Zagreb Stock Exchange with the purpose of issued municipal bonds to develop sports and culturally oriented projects.

Municipal bonds of the Serb Republic have been actively supported by local business banks, insurance companies, and citizens through secondary trade on Banjaluka Stock Exchange. The citizens, in fact, recognized the option of alternative instrument investing with higher yield than offered by traditional savings in commercial banks.

Table 3. Issued municipal bonds in surrounding countries between 2006 and 2011 by Bloomberg

Issuer	Nominal amount of issued municipality bonds	yield	Issue date	Maturity date	Secondary market
Croatia					
Rijeka	EUR 24.574.513,0	4,13%	28.06.2006.	18.07.2016.	Zagreb Stock Exchange
Republic of Srpska					
Srbac second emission	KM 1.000.000,0	3,00%			Banjaluka Stock Exchange
Jahorina, Pale	KM 15.000.000,0	6,00%			Banjaluka Stock Exchange
Novi grad	KM 2.000.000,0	3,13%			Banjaluka Stock Exchange
Gradiška second emission	KM 7.000.000,0	3,00%			Banjaluka Stock Exchange
Romania					
Foscani	RON 28.000.000,0	ROBOR3M + 0,9%			Bucharest Stock Exchange
Hungary					
Budapest	EUR 10.000.000,0	EURIBOR6M + 4,1%	27.01.2010.	27.01.2025.	Not listed
Bacsalamas Varos Onkoroman	CHF 3.713.000,0	CHFLIBOR3M + 1,35%	11.03.2008.	11.03.2023.	Not listed
Budapest	CHF 9.230.000,0	CHFLIBOR6M + 0,4%	04.10.2008.	30.11.2026.	Not listed
Budapest	CHF 12.382.000,0	CHFLIBOR6M + 2,2%	31.03.2006.	31.03.2031.	Not listed
Budapest	CHF 3.311.260,0	CHFLIBOR6M + 2,2%	31.01.2007.	31.01.2022.	Not listed
Csorvas Varos	CHF 943.000.000,0	CHFLIBOR3M + 1,0%	19.03.2008.	19.03.2023.	Not listed
Gyon Gyios Varos	EUR 2.952.000,0	EURIBOR6M + 4,75%	22.02.2010.	15.12.2024.	Not listed
Herend Varos	EUR 551.000,0	EURIBOR6M + 5,0%	24.02.2011.	31.03.2026.	Not listed
Bulgaria					
Vama	EUR 6.000.000,0	EURIBOR6M + 4,45%	25.06.2010.	30.06.2020.	

According to Romania"s experience, the driving force of municipal bonds listed on the local Stock exchange, as shown in the table above, was the increasing autonomy of local governments and a 17-year maturity. This market considerably developed on respectable stock exchange"s listing municipal bonds of the city of Bucharest on the London Stock Exchange in the amount of EUR 500m.

The main feature of issued municipal bonds of Hungary and Bulgaria is lack of listing on stock exchanges.

6. DISCUSSION

This paper explored municipal bonds in Serbia as an alternative model of project financing of infrastructure projects. We came to the conclusion that the state i.e. the Republic of Serbia partially enabled access to potential domestic investors through regulations. The proof is evidenced by changes (Public debt law, 2011)on one side, by which citizens as clients are enabled to invest in municipal bonds issued in Serbia. While on the other side as determined by the central bank"s bylaws (Decision on more detailed conditions and maximum amounts of voluntary pension fund assets investment and manner of investing such assets abroad, 2011) the defined limits curb investments of pension funds, since the level of cca. EUR 5m for the value of issue is a rather high threshold for circumstance on Serbian municipal bond market, as this instrument is in its infancy.

We have also concluded that the option to access organized secondary market is only general, as the (Law on capital market, 2011) stipulates that the issuer of municipal bonds is not bound to list them on the market, thus denying potential access to citizens as clients, which leads to another conclusion that the only potential investors are actually business banks from the banking sector of Serbia.

Municipal bonds could potentially enhance and improve infrastructure projects and development of local governments. As we are expecting the downward trend in rates on FX and dinar savings of citizens to continue, the placements of which are burdened with a tax treatment of 15%, municipal bonds for citizens, tax-exempted, would be an alternative instrument of investment. The basic risk in Serbia pertaining to municipal bonds is identified in political risk as frequent changes of government indicates instability in the horizon of “received mandates”, and that potential investors perceive the state to be a “bad boss” in managing financing at a local level.

In circumstances when the credit rating agency is lowering the credit rating to the Republic of Serbian, as it was the case on January 17, 2014, when the Fitch agency announced the downgrade of credit rating from BB- to B+, the rated local governments cannot hope for potential investors with acceptable price, meaning more competitive price, than if the local government decides to take up a commercial loan from business banks. Until the mid-2014, another four local governments are expected to make a public invitation at the territory of Serbia.

In line with the previously stated, prospects for development of municipal bonds market are limited, on one hand due to the slowdown of credit function of commercial banks is Serbia as the result of discouraging legal frameworks. Further directions of the research should lead towards monitoring and analyzing the alignment of regulatory framework of competent state institutions, towards lifting existing restrictions which curb development of these securities, and monitoring the trend which implies reduction of bank-centric economy in Serbia, on one hand, and development of alternative instruments of capital market, on the other.

At the same time the cooperation of local governments and state institutions need to be enhanced in order to realize options and potentials in implementing development of a new alternative instrument for financing infrastructure projects.

7. CONCLUSION

A new source of financing in the form of municipal bonds in Serbia has not seen its light conceptually as this type of instrument was first time issued in the period of global financial crisis. Apart from this, another aggravating factor was a dramatic fall in banks‟ lending activities because of which the new instrument was not considered as an alternative to loans alongside business banks. A case in a point is the local self-government Užice. Namely, the offered price of the loan was far more favorable than of formerly granted loans, and also better relative to the price offered for a municipal bond.

The limiting factor for alternative financing of capital and development projects through municipal bonds requires both institutional and legal frameworks, in order to finance much-needed finance projects. Listing on organized markets and ability to access provided not only to business banks and institutional clients, but citizens as well, in one of essential conditions. The role of the underwriter in cooperation with a local government could considerably „animate“ citizens in local governments if this instrument is offered through local branches, provided the issuer offers the guarantee for issued securities. Main weaknesses of municipal bonds versus loans may be noticed unambiguously in costs and complex procedures. Furthermore, listing municipal bonds on local stock exchanges entails services related to preparation of project documentation, costs of listing, marketing costs, and substantial formalities than it is the case with loans.

HEDGE FUND MANAGEMENT COMPANIES AND DATABANK TRANSPARENCY

Selena Totić, Aleksandar Đoković, Nemanja Milenković

Faculty of Organizational Sciences, Belgrade selena@fon.bg.ac.rs

Abstract: *Research in the field of transparency of hedge fund industry has been extensive in the last decade. However, most of the studies focus on transparency of hedge funds' performance measures. Our approach is more general, since we are studying the overall transparency of big management companies, in order to find patterns in their behavior. We use concepts of transparency scores and answer densities to see if management companies have uniform policy in disclosing information and thus attracting investors through databanks. The results proved that transparency was mostly individual portfolio manager's decision and that it was difficult to relate it to specific investment strategy that management company applied. Moreover, through answer densities we found that low transparency regarding specific questions, was common for all strategies and all management companies.*

Keywords: *hedge funds, transparency, strategies, information disclosure, answer densities*

1. INTRODUCTION

When it comes to hedge fund industry, whose size is rapidly growing[1] in the last decade, the accuracy and availability of information, as well as precise measurement and reporting are of an extreme importance. Given that there is no sole definition of hedge funds, as a starting point we will adopt the following one: "Hedge funds are privately organized, loosely regulated and professionally managed pools of capital not widely available to the public" (Lhabitant, 2004). The key points in this definition are private nature of hedge funds and low availability to public. Since hedge funds are only open to a limited range of professional or wealthy investors who meet the criteria set by regulators, they are exempted from many regulatory requirements that govern the ordinary investment funds. Among these the most important ones are investment freedom and reporting requirements. Mainly, hedge fund managers may use every type of financial instruments, from cash, equities, fixed income to the most sophisticated derivative products. They are even allowed to invest in illiquid assets. Moreover, as opposed to mutual funds and long only funds, they may combine "long" and "short" positions and use unrestricted amounts of debt financing (leverage). In order to focus on investments and performance, rather than on cash management, hedge funds usually impose some restrictions, such as lock-up periods, gate provisions and minimum notice time to restrict redemptions in periods of market stress. Their primary goal is to achieve target returns irrespective of current market conditions (therefore they are called absolute returns). For this, hedge fund managers are rewarded through incentive scheme that combines management and performance fees. Management fee is usually 2% of the assets under management, whereas performance fee is typically 20% of the annual hedge fund profits. Since high fees are very attractive, in order to ensure that managers will behave in best interest of their clients, most hedge funds request their manager to invest huge portion of their personal wealth alongside other investors. Moreover, there are often limiting restrictions on payment of performance fee, such as high watermark[2] and/or hurdle rate[3].

From the regulation prospective, hedge funds are free of any type of disclosure of its holdings and positions. However, in the wake of latest financial crisis, increasing calls to reform the financial regulatory system of hedge funds were heard from government authorities and investors worldwide. New regulations should tackle the area of registering, reporting, disclosures and prudential requirements for either hedge funds or hedge fund managers and oversight of new risk regulator. While registering is already well established in markets such as UK and USA, financial industry largely opposes applying bank-like capital rules or mutual fund-like investment restrictions. In favor of the latter goes that hedge funds attract capital of high net individuals and institutions through private placements and these investors are likely to be educated enough to assess the risk of their investing decisions, thus not in a need of regulatory supervision. Nevertheless,

[1] Current estimate of hedge fund industry assets under management (AuM) ranged is $1.75 trillion managed by over 10000 funds (http://www.eurekahedge.com/news/Eurekahedge_Jul_2012_Global_Hedge_Funds_Key_Trends.asp)

[2] High watermark is the highest net asset value (NAV) of a fund up to date. If the NAV of a fund declines throughout the year no performance fee will be payable to investment manager.

[3] Hurdle rate is the level of return that the fund must achieve in order to charge performance fee.

hedge fund managers recognize the need for improved transparency and increased self regulation. In line with this in 2009., The Asset Managers' Committee ("AMC") issued a comprehensive Report that sets a new standard of best practices to answer the call of the President's Working Group on Financial Markets ("PWG") to reduce systemic risk and foster investor protection. This report should serve as self-regulation guidelines for hedge funds and also investors' guidelines for due diligence of hedge funds. The first key area stressed in this Report is disclosure and the greater transparency of information provided to investors. The regulatory response comes in 2011., in the form of Directive on Alternative Investment Fund Managers (AIFMs) published in the Official Journal of the European Union which "aims at establishing common requirements governing the authorization and supervision of AIFMs in order to provide a coherent approach to the related risks and their impact on investors and markets in the Union". The Directive presents the huge step from fairly regulated hedge fund markets in EU towards bank-like regulation framework. Among `the set of new rules regarding authorization, leverage management, supervision, of a special interest for this research are transparency requirements and marketing of units or shares of EU alternative investment funds (AIFs). According to the Directive, AIFM are obliged to disclose to investors the following: description of the investment strategy and objectives of the AIF; description of the procedures by which the AIF may change its investment strategy or investment policy; the identity of the AIFM, the AIF's depositary, auditor and any other service providers and a description of their duties and the investors' rights; a description of the AIF's valuation procedure and of the pricing methodology for valuing assets, including the methods used in valuing hard-to-value assets; a description of the AIF's liquidity risk management, including the redemption rights both in normal and in exceptional circumstances, and the existing redemption arrangements with investors; a description of all fees, charges and expenses and of the maximum amounts thereof which are directly or indirectly borne by investors; the latest net asset value of the AIF or its latest market price of the unit or share; the identity of the prime broker and a description of any material arrangements of the AIF with its prime brokers and the way the conflicts of interest, etc.

By taking a closer look to regulation and the current state of hedge fund transparency, one can easily draw the parallel between new disclosure requirements and "data vendors" requirements, such as TASS/Tremont, Hedge Fund Research and Eurekahedge. Moreover, the decision of a hedge fund to market its shares or units is similar to decision of disseminating information through the aforementioned databanks. The analysis of databank transparency can serve as a good marker of how far away are hedge funds of prescribed disclosure policies. In addition, it illustrates the willingness of hedge fund managers to reveal certain information to potential investors. The focus of this study is to actually interpret the lack of specific information that managers omit when delivering data to databank vendors. In this aspect, we try to explain what investors can infer from the missing data that they obtain from database vendor. We concentrate on management companies managing more than thirty hedge funds while implementing different strategies.

Given that hedge funds are businesses, like any other type of business in order to attract clients they need to market themselves. However, since advertising in hedge fund world is not allowed, the hedge fund managers can promote themselves either through the word of mouth, investors meetings, conferences, or through specialized database vendors who sell this information to qualified investors. Form the visibility point of view, releasing frequent information about their business through database vendors is the best and easiest choice for hedge fund managers. Still, the question is how accurate and transparent is the information provided in this way. Many studies have attempted to quantify the level of hedge funds transparency and database transparency, but most of them mainly focus on level of performance transparency.
Anson (2002) gave an interesting comment on transparency – "Hedge fund transparency is like pornography – it is hard to describe, but you know it when you see it." For Anson there are three main reasons for which investors seek transparency. The first reason is for risk monitoring purposes, in the sense that investors want to be sure that hedge fund managers are operating within stated risk levels. The second one is the risk aggregation, so that investors can be aware of the total risk of their investment portfolio with respect to industries, economic sectors and markets. The third reason for which investors seek transparency is to see if the managers are really following the strategy they claim to apply. With respect to latter, Gibson and Gyger (2006) were investigating the style consistency in the hedge fund industry and showed that the investment style of some managers depart through time from their reported styles. Mackey and Melton (2010) analyzed if hedge funds followed their stated strategy as well. Goltz and Schroder (2010) conducted a comprehensive study of hedge fund managers and investors on current hedge fund reporting practices. They found out that from investors' point of view information disclosure was inadequate, especially disclosure regarding information about fund's liquidity and operational risk exposure. Moreover, the survey proved that 92% of all industry practitioners believe that the quality of reporting is strongly related to fund's overall quality. Liang (2003) investigated the discrepancy, and thus accuracy of hedge fund returns across different databases. He found out that audited funds had a much lower return discrepancy than non-audited funds. Bollen and Pool (2009) investigated the presence of misreporting in the hedge fund industry and demonstrated that approximately 10% of returns in the used databases were distorted.

Since hedge fund reporting to database vendors is voluntary it may cause different types of database biases. Self selection bias is strongly related to manager's decision in terms of reporting to databases or not. For example if the hedge fund is well performing and wants to attract new capital, it will incline to report to database. On the other hand, if hedge fund is poorly reporting, he doesn't have an incentive to report to database. However, in many cases well established hedge funds do not want to report because they already achieved their business goals, or already have investors who want to enter the fund, or do not need additional capital. From the previous, the conclusion might be that databases tend to have average performing funds because of self- reporting bias. Aiken and al. (2010) conducted a study in which they made a comparison of the non-reporting hedge funds and reporting hedge fund performances and evidenced that on average self-reported hedge fund returns were positively biased. Grecu and al. (2007) investigated why funds stop reporting their performance data. Their findings prove that hedge fund returns significantly worsen towards the end of the reporting lives, which suggests that funds cease to report because of their poor performance. In the study we will examine the database transparency from the perspective of completeness of information provided by hedge fund managers. The focus will be on missing data in database and the reasons for their non-disclosure. This will be related to different strategic management concepts that hedge fund managers apply. The study relies on research of Lumbers (2012) in which the set up for measuring database transparency, as a percentage of non-answers with respect to total number of answers, is introduced.

2. DATA AND METHODOLOGY

This research is based on the data provided by Eurekahedge Europe and Eurekahedge North American hedge fund databases, as available in August 2011. At this point in time, European database of hedge funds contained 4783 funds, whereas North American database contained 5102. Each hedge fund was supposed to give information regarding basic details, fund details, management details, unique identifiers, fees and redemption schedule, industry focus, countries, service providers and profile and strategy description. The maximum number of answers for each fund is 92, but often differs across funds. For the purpose of this research we excluded data provided by Eurekahedge and also questions on which hedge fund managers cannot answer with certainty, thus ended up with 48 column variables in our research.
Since the main goal of our research is to analyze the behavior and consistency of management companies with respect to their willingness to communicate their information to investors, we took the sample of companies that manage more than 30 hedge funds. The basic information about management companies and hedge funds that they manage is given in the Table 1.

Table 1. Basic information about management companies

Management company	Number of funds under management	Number of live funds	Number of dead funds	Number of strategies applied
RAB Capital plc	108	34	74	7
Gartmore Investment Management plc	100	54	46	4
Henderson Global Investors	62	42	20	6
Sinopia Asset Management	62	58	4	2
Amundi Luxembourg SA	55	40	15	5
Marshall Wace LLP	51	51		1
Polar Capital LLP	48	35	13	3
Superfund Asset Management	46	46		1
Martin Currie Investment Management Ltd	39	39		1
York Capital Management LLP	35	35		2
DB Advisors	33	9	24	4
Total	639	443	196	

As we can see from the table, 10 management companies manage 639 hedge funds of which 443 are live, while employing from 1 to 7 investment strategies. Eurekahedge accounts for 15 different investment strategies, but the management companies that we included in the research apply 10 different investment strategies: arbitrage, CTA/Managed futures, distressed debt, event driven, fixed income, long/short equities, macro, multi-strategy, relative value and others.

The majority of academic research in the field of hedge fund industry is based on modeling the data provided by the large databanks. The common problem for all the research is how to overcome the missing data. The

usual solutions are to exclude the hedge funds that do not provide complete data, or to interpolate the missing data. In this study we will actually focus on the missing data, and the notion of transparency will be related to missing data or "non-answers". For most of the subscribers to hedge funds databanks the information provided by the databank is a first step in their due diligence process of hedge fund as a potential investment. They want to get as much as possible information in order to understand the investment strategy, returns and riskiness of a hedge fund. For a hedge fund manager, the databank serves as a shop window through which they market their products. They want to reveal information in order to attract their clients, but on the other hand they want to keep amount of secrecy that will not jeopardize their competitive advantage in the market. The more information the hedge fund managers provide to databank, in this case Eurekahedge, we consider them to be more transparent. In order to gauge the transparency of hedge fund managers we use the methodology proposed by Lumbers (2012) which is based on counting blank answers or "non-answers" and assessing their transparency score as a proportion of non-answers of total number of questions After assessing transparency scores for each management company and each strategy, it is important to see what are the main drivers of low transparency. This was measured through answer density which is defined as a proportion of non-answers for each question with respect to total number of hedge funds.

3. RESULTS

In order to see if management companies have consistent approach in their disclosure within each strategy they employ, we analyzed the transparency in more detail for each company and each strategy. While looking at different management companies, especially columns Manager profile, we observed that most of the companies have more than one portfolio manager for each applied strategy. For this reason we analyzed the transparency of each portfolio manager within the strategy and the management company and reported his/her average transparency (number of non answers). The results are presented in Table 2.

Table 2. Breakdown of Non-answers across companies, strategies and managers

Management company	Strategy	Number of managers per strategy	Number of funds managed	Average number of funds managed	Average number of Non answers per manager	Max number of Non answers	Min number of Non answers	Range of Non answers
RAB Capital plc	Arbitrage	1	2	2	0	0	0	0
	Event driven	1	4	4	1	1	1	0
	Fixed income	3	15	5	2.2	5	2	3
	Long/Short	7	54	7.71	3.77	0	7	7
	Macro	1	4	4	5	5	5	0
	Multi-strategy	1	6	6	5.67	7	4	3
	Others	3	23	7.67	3.71	5	2	3
Gartmore Investment Management plc	Arbitrage	1	3	3	11.33	12	11	1
	CTA/Managed futures	1	3	3	11	11	11	0
	Long/Short	19	91	4.79	5.35	14	2	12
	Relative value	1	3	3	6	6	6	0
Henderson Global Investors	Arbitrage	1	6	6	4	4	4	0
	CTA/Managed futures	1	1	1	7	7	7	0
	Fixed income	1	6	6	2.67	3	2	1
	Long/Short	9	28	3	5.32	8	2	6
	Macro	1	6	6	6	6	6	0
	Multi-strategy	4	15	4	5.33	9	3	6
Sinopia Asset Management	Fixed income	2	62	31	5.27	25	4	21
	Long/Short	1*	2	2	25.5	27	24	3

Amundi Luxembourg SA	Arbitrage	1*	31	31	9.81	13	5	8
	Fixed income	1*	8	8	9.37	10	7	3
	Long/Short	2*	12	6	7.41	10	5	5
	Macro	1	3	3	7	9	5	4
	Multi-strategy	1*	1	1	10	10	10	0
Marshall Wace LLP	Long/Short	1	51	51	5.39	6	0	6
Polar Capital LLP	Fixed income	1	12	12	5	5	5	0
	Long/Short	5	33	6.60	6.82	11	2	9
	Macro	1	3	3	2	2	2	0
Superfund Asset Management	CTA/Managed futures	1	44	44	8.5	11	7	4
	Long/Short	1	2**	2	7	7	7	0
Martin Currie Investment Management Ltd	Long/Short	11	39	3.55	5.28	7	4	3
York Capital Management LLP	Distressed debt	1*	1	1	22	22	22	0
	Event driven	3*	34	11.33	12.24	27	6	21
DB Advisors	CTA/Managed futures	2	2	1	7	7	7	0
	Distressed debt	1	1	1	7	7	7	0
	Long/Short	6	29	4.83	6.1	11	5	6
	Multi-strategy	1*	1	1	26	26	26	0

* Some management companies do not gives answers to Managers profile question for all of their funds, therefore we treat them as if they are having just one manager (which is the whole company)

**These two funds classified themselves as CTA/Managed futures, but in their Strategy description field they explained in details that they are Long/Short equity funds

From Table 2. we can see that the average number of funds per one manager across different management companies varies a lot (from minimum 1 fund to 51 funds). Management companies with the highest average number of funds per manager actually didn't want to reveal the details about their portfolio managers and simply left the company name in Manager profile column. Regarding the data, one can also notice that when management companies don't give the data about portfolio manager, they tend to be less transparent (for example DB Advisors Multi strategy has 26 non answers, York Capital Event driven strategy has 27 non answers, which is less than 50% transparency score). Moreover, if we look at the column - average number of non answers per manager we can see that this number significantly varies across strategies in the same management company. For example if we look at RAB Capital, the average number of non answers per manager following arbitrage strategy is 0 (100% transparency score), whereas average number of non answers per manager following multi strategy is 5.67 (88.67% transparency score). This might lead us to the conclusion that actually strategy dictates the degree of transparency of management company. However, from the table we can also see that transparency for the same strategy vary a lot among management companies. Therefore from these two observations we can conclude that transparency mostly depends on the portfolio managers and his willingness to disclose information. This is easily seen from the last column-range of non-answers within the strategy. It is interesting to see that for some strategies such as fixed income this range is not big (maximum range 3), whereas for some strategies such as Long/Short equity is much bigger (maximum range is 12). This clearly indicates that within the same management company and the same strategy, portfolio managers have different views on transparency.

In order to test this assumption we look for single portfolio managers that are running more than one hedge fund within management companies. The important result we have found is that even portfolio managers that are running more than one fund do not show consistency regarding the information disclosure. For example, portfolio manager at Gartmore Investment Management plc. running 9 long/short equity hedge funds, tend to have different level of information disclosure for different funds that he manages. Also, it is interesting to see that management companies such as Henderson Global Investors (committed to Hedge Fund Standard Board's standards in 2010.) and Amundi Luxemburg SA (according to the information available on internet

the most transparent one), which are publicly building an image of very transparent ones, still suffer from the same inconsistencies in their managers' reporting. Therefore we can conclude that the databank transparency of management companies is practically in hands of their portfolio managers. If we look at management company as any company and databank as its way of advertising itself, than portfolio managers are given the freedom to be marketing managers. The question is how much freedom should they have in this sense, bearing in mind that they all work for the same management company? This is still to be defined by the management companies and perhaps the strategies they implement.

In order to see which are the questions to which managers are most reluctant to give answers we estimated answer densities, for each of these. Therefore, we evaluated the answer density across each column in Eurekahedge databank. For better understanding, questions are categorized according to answer density in the following manner:

- High transparency with answer density range from 90% to 100%
- Medium transparency with answer density range from 50% to 89%
- Low transparency with answer density below 50%

High answer density is characteristic for basic characteristics of hedge funds (fund name, flagship, closed, limited, dead, dead reason), most of the fund details, fee and redemption schedule and profile and strategy description, since these are the common details that each fund can provide. Medium answer density is common for part of fund details such as fund size, firm's total asset, minimum investment currency, minimum investment size, equalization/share classes, investment in private placements, managed accounts offered, UCITS and service providers. Low answer density is characteristic for fund capacity, annualized target return and annualized target volatility. In Table 3. only densities below 50% across strategies are given.

Table 3. Answer density across strategies

	Arbitrage	CTA/MF	Distress debt	Event driven	Fixed Income	L/S Equity	Macro	Multy Strategy	Relative Value	Others	Total
Fund Capacity (US$m)	4.76%	0.00%	0.00%	0.00%	5.94%	9.73%	43.75%	0.00%	0.00%	21.74%	8.29%
Firm's Total Asset (US$m)	23.81%	94.23%	100.00%	100.00%	92.08%	74.93%	81.25%	86.96%	100.00%	100.00%	79.03%
Minimum Investment Currency	45.24%	84.62%	100.00%	94.74%	76.24%	96.17%	100.00%	100.00%	100.00%	65.22%	87.79%
Minimum Investment Size	45.24%	84.62%	100.00%	94.74%	76.24%	96.17%	100.00%	100.00%	100.00%	65.22%	87.79%
Equalisation / Share class	47.62%	11.54%	100.00%	57.89%	94.06%	83.78%	62.50%	86.96%	100.00%	100.00%	75.90%
Annualized Target Return	78.57%	0.00%	0.00%	10.53%	80.20%	25.07%	31.25%	26.09%	0.00%	0.00%	33.49%
Annualized Target Volatility	40.48%	0.00%	0.00%	10.53%	80.20%	17.70%	12.50%	17.39%	0.00%	0.00%	26.29%
Principal Prime Broker/ Broker	26.19%	11.54%	50.00%	73.68%	28.71%	79.65%	43.75%	91.30%	100.00%	100.00%	62.44%
Legal Advisor (offshore)	50.00%	36.54%	0.00%	68.42%	83.17%	59.59%	62.50%	26.09%	100.00%	100.00%	61.66%
Legal Advisor (onshore)	26.19%	11.54%	50.00%	10.53%	90.10%	80.83%	93.75%	65.22%	100.00%	100.00%	69.33%
Manager Profile	100.00 %	100.00%	50.00%	73.68%	98.02%	99.41%	100.00%	95.65%	100.00%	100.00%	97.50%
Strategy	100.00 %	100.00%	50.00%	73.68%	98.02%	99.41%	100.00%	95.65%	100.00%	100.00%	97.50%

Fund capacity is the question with the lowest answer density (8.29%) and thus can be regarded as the most controversial. According to Eurekahedge, fund capacity is "an estimate of the size of the fund relative to the turnover of the market it invests in, with the aim of assessing when assets under management become too

large to effectively execute funds investment strategy". In other words, fund capacity is the cap on funds assets under management beyond which fund strategy will not give the desired returns. It is imposed by the portfolio manager and not all the funds have it, therefore to some extent the lack of answer to this question may be the result of the latter. Still, fund capacity is an important feature for both the investors and the competitors. For investors it is the signal for how far away is the fund from being closed to any further investment. For competitors, it is the benchmark for how much the fund is potentially ready to invest in a certain strategy. Given that for some strategies, managers seek to exploit the specific inefficiencies in the market, the greater the investment capital introduced into the market, the lower the potential gain. Therefore, the fund capacity for competitors serves also as a fund's opinion of the overall capacity of the certain strategy. Capacity is correlated with how narrowly or broadly particular strategy is defined. The broader the strategy definition, the greater the capacity. In this sense, macro strategies tend to have the greatest capacity, since they are neither constrained with specific markets nor with specific assets. On the other hand, event driven strategies, which depend on the size and number of special events; and arbitrage strategies, which depend on specific discrepancies in prices, tend to have lower capacity effect. Regarding transparency, this can be interpreted as funds implementing strategies with greater capacity should be more transparent, since there is enough room for everybody in this "game". Our results support this hypothesis, since macro funds have the greatest transparency, whereas event driven, CTA/Managed futures and arbitrage funds have the lowest transparency.

Assuming that the databank is the hedge funds' display window through which they market their products, it is very interesting to see that annualized target return and annualized target volatility have very low answer density. If we look at the hedge fund as a product, the main reasons for which investors are willing to buy this product are target return and/or target volatility. In this sense, the low density is like selling a yacht, but not telling the potential owner how fast can it goes and how safe it behaves on turbulent sea. Knowing that the foundation ground of most portfolio theories relies on the relationship of risk and return, i.e. on how much risk investor is willing to take for the given return, the question is why hedge fund managers are reluctant to give this information? One possible rational explanation is that hedge fund managers are afraid of not fulfilling the target annualized return and therefore would be looked upon unfavorably by their investors. This is specially the case for strategies that are depending on specific market cycles such as event driven strategies, or for strategies that are connected to very volatile markets such as CTA/Managed futures. On the other hand, for fixed income strategies, which have very deep and developed markets, is easier to forecast returns and volatility.

Results from Table 3. also show that total answer density for annualized target volatility is lower than total answer density for annualized target return. For some strategies these densities are the same, but for some strategies they are lower. The potential explanation might be that some managers are willing to take greater risk (volatility) in order to achieve target returns, but they do not want their investors to be aware of that, since that might influence their investment decision. Moreover, as already mentioned for some strategies markets are very volatile (commodity markets) an assessing volatility is a difficult task. Finally, for some strategies such as distressed debt and event driven strategies, it is not easy to calculate target returns and volatility and therefore these data are not provided.

4. CONCLUSION

The aim of the paper is to examine how management companies within hedge fund industry use information transparency in attracting their clients. The data provided was analyzed with respect to transparency score and answer density measures. Both of these measures are based on the proportion of non answers, where non answer is observed each time the manager didn't provide an exact answer to the given question (left the blank answer or n/a or Not available). Given that transparency scores are defined as a proportion of non-answers of total number of questions, they were used to analyze the transparencies of different management companies. The results proved that transparency of management companies was not uniform and that it did not depend on particular strategy that company implements. Moreover, scores showed that transparency mostly depended on single portfolio manager's decision regarding each hedge fund he/she manages. In addition, we found that portfolio managers tend to have different transparency scores for similar hedge funds they managed, thus showing significant inconsistency in transparency. On the other hand, answer density defined as a proportion of non-answers for each question with respect to total number of hedge funds, gave us some useful insights about the issues that all hedge fund managers face regarding transparency. The low answer density scores for fund capacity, annualized target return and annualized target volatility were common for each management company and each hedge fund. However, there were slight differences in these answer density scores among strategies. These differences were explained with the specific characteristics of each investment style. Nonetheless, low answer density for questions such as target return and target volatility was quite surprising, since these are starting points in investor's decision making processes regarding investing into hedge funds.

Abstract: *Emerging markets have enabled foreign investors to gain the highest rates of return compared to returns they could have achieved by investing in developed markets. Although some data suggest that those rates started to decline, those markets still represent the most attractive market for investments. The high rates on investments have been followed by high investment risk, which was mainly caused by political instability and poor macroeconomic policies. This has influenced the local currencies volatility and has forced foreign investors to start using currency derivatives in order to hedge this risk. The aim of the paper is to present a review of currency derivatives and to point out to appropriate hedging strategies using currency derivatives that can be applicable in emerging markets. Besides, the paper provides a brief analysis of currency risk hedging practice in some of emerging market economies and its perspective.*

Keywords: *Currency derivatives; currency risk; emerging markets; investment; hedging.*

1. INTRODUCTION

Emerging markets (EMs) have grown rapidly during last more than two decades because of the potential they have been given to potential investors in almost all economic sectors. According to World Bank report (2014) equity market capitalization among emerging market economies has increased from approximately US$250 billion in 1990 to over US$12 trillion in 2012 with an annual growth of approximately 14%. This impressive increase was followed by annual growth rate of gross domestic product (GDP) of 4.9% at the end of 2012 in emerging market economies while in developed countries GDP has grown by only 1.5%.

During the specified period, international interest in emerging market local currency investments has grown sharply except for a period 2008-2009 when capital inflows in these markets have been significantly reduced. However, in 2010 according to Institute of International Finance (2013) capital inflows started to recover, so in 2012 they exceeded the size in pre-crisis period were roughly US$350 billion. This has happened despite the much higher rates of inflations in emerging market economies compared to developed countries. World Bank announced (2014) that an average inflation rate in EMs measured by consumer price index were almost three times higher than in developed markets. This can be explained by the efforts of monetary and fiscal authorities made to attract the investors, especially through capital flow barrier reduction and high rates of return on investments. In this regard, the rates of return on investments in EMs have been considerably higher than those of developed markets. For example, between 1999 and 2006, the S&P 500 returned 3.3% annually compared to 18.5%, as reported by Morgan Stanley Capital International Index (MSCI). According to AGF Investments (2014), in 2008 this return became very negative (-41.8%), but soon it recovered, so in 2013 its value was 23.4%. Between 2009 and 2013 the gap between S&P 500 and MSCI was very volatile, but the latest data suggest the narrow gap could be expected.

The aforementioned higher growth rates of return were accompanied by a higher investment risk. The sources of this risk were economic (e.g. high inflation rates, current account deficit, fiscal imprudence etc.) and political (political instability, corruption etc.). Some authors have argued that emerging market economies were exposed to risk even if they eliminate all the potential risks because of their inability to borrow abroad in their home currencies (Eichengreen, Hausman and Panizza (2003)). According to them this would lead to a much higher percentage of emerging markets‟ debt being denominated in foreign currencies than in local currencies and could become a trigger for capital outflow. However, Burger, Warnock and Warnock (2012) showed that Ems seem to have overcome this problem. The authors provided data of fast grow of local currency debt markets. Besides this, it is worth mentioning that sometimes investing risk is out of the control of country‟s financial authorities. In other words, occasional developed market investors‟ misinterpretation of the emerging markets‟ behavior could lead to dramatically reduction in capital inflows. Moreover, for Ems it could be valuable to take into consideration the following risks: credit risk, exchange rate risk, interest rate risk, maturity risk and speculative risk. Likewise, the influence of developed market‟s fiscal policies should be taken into account because of its strong influence on the emerging markets‟ currencies value. That is why some authors Calvo (2005) and McFadden (2004) have proposed to deal with these risks through policies promoted in conjunction with developed economies, such as greater supervision of financial intermediaries, compliance with international accounting standards and clear lending standards. But, even if the suggested were implemented, it could not solve the problem regarding daily, weekly or monthly fluctuations in currencies that underlie the value of emerging market prices of securities. So, it seems that one possible solution can be currency risk management.

Currency risk, also known as exchange rate risk or foreign exchange rate risk represents a possibility of loss contingent on a future change in foreign exchange rate. According to Cusatis and Thomas (2005), this risk can be defined as the risk that a company"s financial performance will be affected by exchange rate fluctuations. By hedging the risk investors in Ems can enhance their returns and/or reduce the losses. In addition, investors can obtain emerging market currency exposure though investing in local currency emerging market bonds, or through forward contracts and options. Gilmore and Hayashi (2011) claim that the risk-return profile of long investments in emerging market currencies have been historically quite attractive. Importantly, the return of emerging market currencies mostly comes from their high "carry," as they typically have higher yields than developed market currencies. Recently, however, interest rate differentials have converged across the world, making it somewhat unlikely that the historical performance of emerging market currencies will be repeated over the next decade. Because of different risk aversions in different emerging market countries followed by their fragile financial systems, hedging currency risk becomes necessity.

2. CURRENCY DERIVATIVES

Because foreign investors are involved or might be involved in operating in emerging markets, they are or they might be exposed to exchange rate risk. This risk can be used both, to capitalize or to hedge against expected exchange rate movements.
In general, a currency derivative is a term contract between two parties, a buyer and a seller, whose price is partially derived from the value of the underlying currency that it represents. Currency derivatives increase the liquidity of investments in emerging markets which usually suffer from illiquidity. Those instruments enable its user (investor) to perform (exercise) the contractual obligation at the predefined price. In this way, currency derivatives can be used not only to hedging the risk in emerging markets, but also as a tool for price discovering as well as a mechanism for dealing with counterparty risk.
As Henderson (2006) suggests, the characteristics of emerging markets influenced their specific currency management. First, liquidity risk caused by emerging market currencies less liquidity than currencies of developed markets. Second, convertibility risk because a majority of emerging market currencies are still not convertible on the capital account, and only a few are still not fully convertible on the current account. Third, several emerging market currencies still have varying degrees of exchange rate controls, which also distort exchange rate pricing and economic activity. Fourth, emerging markets have structurally high levels of inflation compared to developed markets which are usually followed by higher interest rates and resulted in high forward premiums. Fifth, capital inflows can depress market interest rates. Sixth, forward rate bias is lower in emerging markets than in developed markets, which means that emerging market currencies tend to appreciate on a real basis and then collapse to adjust for the trade balance deterioration caused by that real exchange rate appreciation. Seventh, implied emerging market volatility below developed market volatility is a buy signal. Finally, implied emerging market volatility is a very poor predictor of future exchange rates.

Currency risk can be hedged with following currency derivatives:
- Currency forwards,
- Currency futures,
- Currency options and,
- Currency swaps.

Currency forwards are contracts between two parties to buy and sell a specified amount of a currency at a specified exchange rate (forward rate) on a specified date in the future. The most common currency forwards are for 30, 60, 90, 180, and 360 days, although they are available for longer periods (up to five years). Currency forwards can be deliverable and non-deliverable.

Currency futures are standardized contracts that are specifying a standard quantity of a given currency that is to be exchanged for another currency at a specified exchange rate on a specific settlement date. By entering the currency future buyer of a contract is entitled and also obliged to pay a specified exchange rate for a foreign currency on a future date, while seller is obliged to sell a foreign currency at the same specified exchange rate on the same date in the future. These contracts are traded on organized exchanges and they are available for several widely traded currencies, but they are also available on some cross rates

Currency options represent the standardized agreements between two parties which grants one party (the option buyer) the right, but not the obligation to buy or to sell specified quantity of a specified currency at a specified exchange rate (exercise price) within a specified time period or at a specified date (expiration date). With regard to right they give to a buyer, currency options can be call (give a buyer a right to buy currency) or put options (give a buyer a right to sell currency). Currency options can be exchange traded (options on the

physical (underlying) currency obtained via brokers from an exchange) and over-the-counter options (obtained directly from banks). Exchange traded options have standardized time periods and strike prices and only a certain number of currencies are traded. As opposed to this, over-the-counter currency options are flexible instruments that enable the buyer to choose the currencies, time period, strike price and the contract size, in order to match the particular exposure requirements at the time.

Currency swaps are over-the-counter currency derivatives. They represent the agreements between two parties to exchange the principal and interest in one currency for another currency at a predefined exchange rate (i.e. swap rate) on several future dates. They are available for short-term and long-term maturities (up to ten years).

Besides those so-called vanilla currency derivatives, in practice and especially in emerging markets emerged a range of currency derivative variations and combinations, such as currency coupon swap, currency swap/fixed rate currency swap, forward swap, interest rate swap, quanto swap, swaption, exotic options etc. Currency coupon swap combines the interest rate swap and the fixed rate swap in one currency for a floating rate interest in another currency. Currency swap/fixed rate currency swap involves the purchase of a currency for spot settlement and, at the same time, the sale of the same currency for forward settlement. Forward swap represents a swap agreement that begins at a specified future date. Interest rate swap is an agreement between two parties to exchange interest payments on currency principal (notional). Quanto swap is a complex swap in which one party agrees to pay to another party the notional and interest based on the foreign currency while the notional amount is in domestic currency. Swaption represents a combination of option and swap, so it gives a buyer the right, but not the obligation, to invoke a swap at agreed-upon terms at a specified date in the future. Finally, investors in emerging markets can use a numerous different exotic currency options. These options are more complex and sophisticated than the other instruments because they incorporate special features that extend the fundamental contracts. For example barrier options are options which payoff depends on both the value of the underlying currency and the values at various intervals across the life of the agreement.

3. HEDGING WITH CURRENCY DERIVATIVES

Currency risk in emerging markets can be hedged by using all the currency derivatives. However, the use of those instruments varies among emerging market countries both in currency derivative types and variations as well as in volume, depending mainly on a financial market development and efficiency and government decrees. In this regard, hedging with currency derivatives can be classified as

(1) Hedging with currency forwards,
(2) Hedging with currency futures,
(3) Hedging with currency options, and
(4) Hedging with currency swaps.

Hedging with currency forwards provides an investor the opportunity to lock in the exchange rate at which they can buy or sell a particular currency on specified date in future. These contracts are not standardized, i.e. counter parties negotiate all contract terms. In this way contract gets the flexibility. Given that these instruments can be arranged not only for short-term, but for long-term periods also, they are frequently used in emerging markets that are relatively illiquid compared to developed markets. Long-term currency forwards can be used for hedging currency risk when investors know that they will be exposed to currency risk during the long period in the future because of their investment horizon duration.
Investors in emerging markets frequently use relatively new type of currency forwards called non-deliverable forward contract**.** Like a regular currency forward, this contract represents an agreement regarding a position in a specified amount of a specified currency, a specified exchange rate, and a specified future settlement date. However, non-deliverable forward does not result in an actual delivery of currencies at the future date. Instead, the agreement specifies that a payment is made by one party to the other party based on the exchange rate at the future date. Besides this, currency forwards can be used in at least one more form, i.e. it is possible to hedge currency risk with so-called convertible forwards. These forwards represent a combination of a vanilla calls and vanilla forwards. In other words, an investor buys a vanilla call and, at the same time, sells a down-and-in put. It converts to a plain vanilla forward during the exercise period, positioning the investor to profit from a contrarian move in the spot rate.

Hedging with currency futures enables the foreign currency owner or the owner of a security denominated in foreing currency to minimize the exchange rate exposure by establishing a fixed exchange rate that is to be applied on a specified date in future. Besides, these contracts provide a potential foreign investor a fixed rate at which he or she can buy a particular currency or foreign security.

Investors can use currency futures for currency risk control of their portfolios. In other words, investors can change the sensitivity of their international portfolios‟ value to exchange rate movements in foreign exchange market. In this regard, investors will buy currency futures if they expect increase in their home currency price. This can enable them to reduce the losses in portfolio component denominated in foreing currency. On the other hand, if investors expect a decrease in their home currency, they will sell currency futures and receive gains on portfolio denominated in foreing currency.

Currency options permit investors (hedgers) to eliminate unfavorable exchange rate fluctuations while still benefiting from favorable exchange rate fluctuations. Currency option users are banks, supranational and sovereigns (issuers of debt in foreign currencies), multinational companies, investors in foreign currency securities etc. They commonly use currency options as an investment or funding tool, as well to cover foreign exchange rate exposure or to lock in profit. Hedging with currency options can be used for hedging current or forecasted (future) open currency positions and/or positions in foreign securities denominated in foreing currency. In this regard, investors can hedge by buying currency call option if they have to create a long position in foreign securities and hedge themselves from price increase. Otherwise, investors would use put option to protect themselves from potential loss if foreing exchange rate depreciates. Hedging with currency options is more expensive than hedging with other currency derivatives because it requires the payment of an option premium when the hedge is established.
Exchange-traded and over-the-counter options are suitable for hedging purposes. Because of emerging markets low efficiency and development, hedging with over-the-counter options is more common. Within this options type there a large number of different options tailored to investors‟ special needs. In this regard, it would be useful to consider at least two hedging strategies: common hedging strategies with currency options and hedging strategies with exotic options (exotic is referred to their special characteristics regarding price, exercise etc.).
Common currency option hedging strategies are (Bogojevic Arsic (2009)): long call, long put, bull spread, bear spread, calendar spread, and long straddle, long strangle, call ratio backspread, and put ratio backspread.
Long call currency option is used when a user is very bullish (positive) on the markets, while a long put currency option can be used when a trader is very bearish (negative) on the market. Bull spread currency option is used when a user thinks the market will go up somewhat or at least is a bit more likely to rise than fall. This is a good position to have when user wants to be in the market but is unsure of the bullish expectations. On the other hand, bear spread currency option may be adequate when a user thinks the market will fall somewhat or at least is a bit more likely to fall than rise. This is a good position to be taken if a user wants to be in the market but is unsure of the bearish expectations. Calendar spread involves a simultaneous purchase and sale of call currency options that differ only in their time to maturity. These options have the advantage of allowing for modest exchange rate appreciation depending on the exercise price, which can easily occur with an emerging market currency. Long straddle currency option is frequently used when market is quiet and when there is an expectation that the market will start to move but there is uncertainty as to the direction. As opposed to this, long strangle currency option could be a better hedging tool than long straddle if market is stagnant and continues to stagnate in the future. Hedging with call ratio backspread option is desirable when the market experienced a large downside move which was followed by stagnation. Otherwise, put ratio backspread currency option is normally entered into when the last major move in the market was upside direction followed by stagnation.

Among different exotic options that can be used, in emerging market the most commonly used ones (Bouzoubaa and Adel (2010)) are: barrier currency options, average rate currency options, compound currency options, variable notional currency options, multifactor currency options and structured currency options.
Barrier options are essentially a European style options with fixed maturity, fixed call and put currencies and fixed strike price but with an additional “trigger” level. There are a number of different types of barrier options but their common feature is that they are either activated or terminated if a predetermined spot foreign exchange rate, or trigger level, is traded at any time before the expiry date. Investors in emerging markets frequently use standard knock in and knock out options (that enable reduction in the premium associated with the trigger, i.e. exchange price for a call or put options) and window options (that provide a period (“window”) during the option‟s life for which the barrier is valid). Average rate currency options are cash-settled instruments and are exercised against the average of a series of exchange rate fixings rather than the spot foreign exchange rate on the expiry date. These options are widely used for hedging because of their simplicity, cost effectiveness (less costly then entering into a series of currency options), flexibility and choice (a buyer can select any date for the fixings to take place). Compound currency options are essentially the options on options, giving the buyer the right to buy (compound call) or the right to sell (compound put) an underlying currency option with fixed parameters, at a fixed premium on or before a specified date. In return for an additional upfront premium, the buyer has a predetermined period of time (the compound period) over which to decide whether or not to purchase the underlying currency option. Thus, the compound currency

options allow the buyer greater flexibility in the timing of the hedge and reduces the upfront premium cost, in return the overall cost is greater (or the premium receipt is smaller for a compound put). The compound currency options can be used for contingent foreign exchange exposures where the upfront cost needs to be minimized, or where extra flexibility is required in the timing and level of a hedge. Variable notional currency options are differ from European style currency options in that the principal amount of the option increases by a predetermined ratio as the option moves into the money. The ratio by which the principal increases is set on the initial deal date and can be varied to suit individual requirements. These currency options are ideal hedging instruments for corporate users whose exposure increases as the currency rises or falls. Multi-factor currency options provide protection against two exposures, such as commodity prices and foreign exchange rates. Such an integrated strategy addresses a company"s major risks in a coordinated way, at a lower cost relative to a traditional European option. In the multi-factor option, payoff of the option on one asset class is dependent upon the price behavior in the other asset class.
Finally, structured currency options represent a wide group of exotics. The commonly used options of this type are forward extra currency options (essentially the European options that turn into a currency forwards if a trigger level is reached) and contingent premium options (essentially currency options whereby the premium is paid only if the options are in-the-money at expiry).

Hedging with currency swaps provide long-dated forward cover of foreign currency exposure, especially against the currency flow of foreign currency debt. The currency swaps can be used in combinations with other derivatives, such as cross-currency swap and cross-currency basis swap. Cross-currency swap (or circus swap) represents a currency swap combined with an interest rate swap (floating versus fixed rate) so that the loans on which the service schedules are based differ by currency and type of interest payment. On the other hand, cross-currency basis swap means that an investor purchases a standard currency swap while simultaneously receiving a floating interest rate in one currency for a floating rate in another currency. This position allows an investor to profit from interest rate differentials while assuming no more risk than found in a basic currency swap.

4. CURRENCY DERIVATIVES IN EMERGING MARKETS

The availability of currency derivatives in Ems is influenced by a degree of development of these markets and the openness of their governments to foreign investment and floating exchange rates. Therefore, the hedging with currency derivatives varies among these markets. Ems refers to a large number of countries all over the world, so it is possible to consider this issue by analyzing currency derivatives use in Africa, Asia, Central and Eastern Europe and Latin America.

4.1. Currency derivatives in Africa

In many African countries, financial markets are not enough developed to carry out anything beyond basic currency forwards, futures and swap. For example, in Nigeria currency forwards are subject to a maximum tenor of three years, which is considerably better compared to 180 days tenor in 2006. Authorized dealers are now allowed to engage in swap transactions between themselves or with retail/wholesale customers. These transactions with deliverable forwards and swaps are restricted to a maximum tenor of three years. The non-deliverable forward market is underdeveloped and has very poor liquidity. Unlike Nigeria, Kenya has a free-floating currency (Kenyan Shilling) that is fully liberalized and convertible. There are no restrictions on transactions relating to the current and capital accounts and no foreign exchange controls. However, most of trading occurs in vanilla currency forwards, futures and options, while there is still no available foreign exchange protection for periods longer than one year.
The most developed currency derivative market has South Africa. According to African derivatives guide book (2010), hedging can be done by using currency forwards (tenors of up to 10 years and average daily volume of US$1 billion), futures (on notional underlying swaps in 2, 5 and 10 years contracts), currency options (tenors up to 5 years and transaction average size of US$25 million), options on futures, and cross currency swaps (available for period up to 10 years).

4.2. Currency derivatives in Asia

Asian markets represent one of the world"s fastest growing regions for the development of currency derivatives. Singapore has one of the most advanced financial services industries in the region and is at par with international standards. It attracts high levels of overseas investments as it builds a reputation as an offshore financial center. Singapore has one of the most developed currency derivative markets in Asia, i.e. one of the most liquid over-the-counter currency derivative markets (after Japan). A study prepared for ISDA

(2013) suggests that investors can hedge currency risk by non/deliverable currency forwards with settlement in US dollars, currency futures, conventional and exotic currency options, and currency swaps.
The South Korean market is relatively open and attracts worldwide interest, especially after Korea Futures Exchange is launched. Financial system of South Korea is fast developing and enables sophisticated currency derivatives use, both conventional and exotic ones (such as "knock-in-knock-out" foreign exchange options for hedging against the appreciation of the local currency in relation to the dollar) (Prates and Fritz (2013.). Although currency derivatives market was stagnant in 2012 due to decrease volatility of interest rate and foreign exchange markets, in the study prepared for ISDA (2013) it is expected to grow in the future.
China is one of the fastest growing economies in the world, so is its financial market. Though the over-the-counter derivatives market in China developed quickly, the market is still immature, as measured by the number of products, liquidity, market structure, and existing infrastructure with a slightly stagnation and even decline during the last few years. In Chinese market is possible to hedge currency risk with a range of currency derivatives, such as currency forwards (deliverable and non-deliverable forwards), currency swaps (non-deliverable and non-deliverable forward swap), currency non-deliverable options and currency swaps (Zhang and Chan (2011).
Similarly, the Indian foreign exchange market has grown significantly in the last more than ten years. However, existence of government restrictions regarding currency derivatives use prevents financial market"s further grow. Despite this, in India is possible to hedge with non-deliverable currency forwards, options, swaps, forwards, swaps, forward swaps, swaptions, quanto options, and ratchet options.

4.3. Currency derivatives in Eastern and Central Europe

In Eastern Europe there is a wide variation in currency derivative developments. Among countries that belong to this region, it"s worth focusing on Russian Federation and the European Union member states (Czech Republic, Hungary and Poland).
Since the Russian government allowed ruble to float more freely in 2006, the investment in this county become sizable and led to growing currency futures use by international investors. This has influence the currency derivatives use on the Moscow Interbank Currency Exchange. Besides this, in 2013 US dollar to Russian ruble cross- currency swaps and currency swaps were introduced with maturities from intraday to five years.
The currency derivatives market of the Czech Republic is small compared to those of developed markets, but its currency derivatives market is active, stable, and tightly regulated by the Czech National Bank. Currency derivatives activity has significantly grown since 2004, when trading began to center on the euro. In particular, the volume of currency forwards has been relatively large for the last several years because international investors have sought the higher interest rates in the Czech Republic, motivating them to exchange their home currencies for the koruna to buy Czech bond issues. But, in general the currency derivatives can be used in a very basic manner, i.e. the hedging is possible with conventional currency forwards, currency futures and a few currency options.
After 2001, Hungary began to experience higher currency risk, which fostered the development of basic currency derivatives, which are traded on the Hungarian over-the-counter market. The most widely traded derivatives are based on different currencies (e.g. Euro, US dollar, Swiss franc etc.) and ad currency futures are most popular contracts. Based on these trends, it is safe to say that the market for currency derivatives in Hungary will broaden and deepen at a solid pace. The recent crisis has adversely affected Hungary which currency derivatives turnover has largely decreased between 2007 and 2010 (Mihaljek and Packer (2010), while there were difficulties exchanging Euros and Swiss francs for domestic currency in foreign currency swap markets. However, since 2009 local currency swap market has recovered.
Since 2000, Poland has advanced in its use of futures and options, beginning with the use of four currency pairs. Today there are five currency pairs used. The currency pairs serve as a basis for further developments in currency derivatives, such as currency forwards, currency options with expiration up to five years and cross-currency swaps with the maturity of at least ten years.

4.4. Currency derivatives in Latin America

Latin America are still relatively fast growing region but which is characterized by political and economic instability, across all the countries, especially among the most developed ones, such as Argentina, Brazil and Mexico.
Argentine did not get a chance to recover from the financial crisis that began in 2002, when new so-called international financial crisis occurred in 2007. In this regard, Argentina is still in recovering phase. All these have significantly affected the currency derivatives market. Non-deliverable forward contracts are available only in large amounts, which disable small investors to use them for hedging. Besides, currency risk can be hedged with basic currency futures, currency options and swaps.

Since the mid-2005 Chilean authorities have allowed freely floating of peso, which has influenced the currency derivatives growth. However, even in 2010, currency derivatives are currency forwards (which are mostly non-deliverable), futures, and swaps. The use of exotic contracts is usually avoided, although in some situations knock in and knock out options were used for hedging purposes (Avalos and Moreno (2013)
Brazil has the most advanced capital markets and most sophisticated currency derivatives market in Latin America, with both basic hedging and sophisticated instruments available. As such, the Brazilian Mercantile and Futures Exchange, where currency derivatives and other instruments are traded, are considered one of the most developed exchanges among western emerging markets. Large daily turnover in interest rate derivatives has affected the increase in currency derivatives use.
Because of the volatility of Peso and the high level of corruption in Mexico, investors have always had the incentive to hedge currency risk. Free float of peso has led to great currency derivatives market growth. Hedging can be done with all currency derivatives, while since 2002 currency options and currency swaps has become dominant instruments.

4.5 Emerging markets outlook

Emerging market economies had impressive growth rates during the period of 2003-2007. However, the global financial crisis influenced their growth rates slow down in period 2008-2010. Since 2011 growth rates of these economies started to recover and increase. According to World economic outlook (2014), the growth in emerging market economies is expected to be slightly over 5 percent in 2014 with an expectation of its further increase in 2015 and 2016 (i.e. lower than during the pre-crisis period). Africa is expected to have a moderate growth with an exception for North African countries that are expected to grow at a much slower rate (approximately 3% on average). Growth rates of the emerging market economies of Asia are forecasted to remain at 5.3% in 2014 because of tighter domestic and external financial conditions before rising to 5.7% in 2015, helped by stronger external demand and weaker currencies. China represents an exception from this because of the very high growth rate which is forecasted to remain unchanged at about 7% in 2014-2015, after a modest decline in 2012-2013. Besides, the forecast for India suggests an increase in GDP growth at 5.4% in 2014 and 6.4% in 2015 (assuming the investment and export growth after recent rupee depreciation). Only a modest acceleration in activity is expected for regional growth in Latin America, with growth rising from 2% in 2014 to 3% in 2015 which will be due mainly to growth rates in Mexico.
The past twenty years there were big changes in private capital inflows to EMs. These flows have increased substantially both in absolute terms and as a share of those markets GDP and have been characterized by large fluctuations in response to changing global financial and economic conditions. According to World Bank (2014), in the 2009 financial inflows have averaged around 6 percent of GDP in EMs. However, financial crisis has influenced the decline in capital flows, so World economic outlook (2014) provides an expectation of capital flows decline in EMs by about 0.6% of their GDP by 2016, as global asset portfolios are rebalanced toward developed market economies. Briefly, a financial crisis calming in developed markets will affect not only the decrease in capital inflows in EMs but also the increase in exports and interest rates. The increase in interest rates could cause significant damage on emerging market economies by raising domestic and external costs of debt servicing.
Inflation rates in EMs have been growing in after financial crisis period with exception for some counties in 2012-2013 in which inflation rates experienced slightly decline (e.g. China, Korea, Kenya, Poland, Romania, Russia etc.). Nevertheless, the inflation rates in these markets are expected to remain high compared to developed markets as a group.
Furthermore, in 2002-2007 the majority of emerging market currencies experienced appreciation against the U.S. dollar. According to IMF report of representative exchange rates against U.S. dollar (2014), in 2008 emerging market currencies depreciated with exception for few countries (such as Czech koruna and South African rand). In 2009-2010 the majority of emerging market currencies appreciated against the U.S. dollar with exception for a number of countries (e.g. Russian ruble in 2009 and 2010 or Czech koruna and Hungarian forint in 2010). In 2012-20103 there were both appreciations and depreciations in emerging market currencies, so it could be expected that those trends will prevail in the future. In general, in 2014-2016 the depreciation can be expected to continue in large number of emerging market economies, for exception for some Asian economies, Russia and some European economies. Finally, volatilities of the emerging market currencies have been notable dropped in 2007 compared to volatilities in 2000, while in period 2008-2013 the volatilities have grown.
With regard to currency derivatives in EMs it should account for more use of currency derivatives in future because of foreign investors need to hedge when investing in portfolios in emerging market securities, especially when direct hedging is not possible, i.e. when only cross-hedging is feasible. Besides, currency derivatives can be used to hedge currency risk in global portfolios. Finally, currency derivatives can be an efficient hedging tool for hedge funds and corporations in EMs that are strive to enhance their portfolio returns through foreign exchange (i.e. enhancing a “portable alpha”).

5. CONCLUSION

EMs have made considerable progress in last twenty years although they have been adversely affected by a number of financial crises in the world. Those markets have unique potential for further growth, but there are lot of problems waiting to be solved in the future, especially those related to trade and financial restrictions removal and free float of currencies. It should not be oversight the influence of the U.S. on the financial stability especially if economic growth slows. Furthermore, in EMs the financial as well political risk will always exist. A part of this risk can be reduced by hedging. Those markets need foreign investors‟ capital and they can be attracted by enough developed currency derivative market. Despite the projected growth rates, inflation rates, capital inflows, currencies „depreciations (appreciations) and currencies‟ volatilities, it is reasonable to expect slow improvement in emerging market economies in next two or three years. In addition, the more sophisticated use of currency derivatives can be anticipated (both in number and types) and more emerging market government incentives for investment and currency derivatives use.
Given that foreign investors will be always exposed to exchange rate risk, their need to hedge this exposure will never disappear, but will grow with emerging market growth.

Abstract: *State capitalism is related to direct state interventon in the national economy and some forms of state involvment always exist, even in developed economies. Contemporary meaning of state capitalism refers to developing economies and emerging markets, as well as countries where socio-economic reforms toward market liberalisation ocurred. In those countries and economies state has key role in transition process, through founding and managing State Owned Enterprises (SOE) and providing them resoruces, but simultaneously using those enterprises for promoting political interests of ruling party. In addition to explaining term and examples of state capitalism worldwide, in this paper will be presented forms of direct and indirect state intervention in the business of insurance companies and investment funds, as institutional investors on financial market. Global investment phenomenon of sovereign wealth funds will be particularly explained. The aim of this paper is to identify and clarify situations in the business of insurance companies and investment funds, when state intervention is needed, as well as to point out consequences of excessive interference of state in the economy and financial market, disturbing laises faire principle.*

Keywords*: insurance, investment funds, state capitalism*

1. INTRODUCTION

The model of state capitalism that has been applied in the last twenty years in emerging economies and markets such as China, Russia and Brazil is a slightly different model of direct state intervention compared to models realized in the last fifty years in OECD (Organization for Economic Cooperation and Development) countries and across Europe, Japan and other countries destroyed by The Second World War. The modern meaning of state capitalism has appeared along with the socio-economic reforms toward market liberalization, that occurred in countries still governed by Communist Party (e.g. in China), or carried through privatization processes (e.g. Soviet Union and other South East Europe – SEE countries), as well as in „petrostates“ such as United Arabian Emirates, governed by royal families. The common characteristic of all those countries is that economic decisions have been made and resource have been allocated by leading political establishment, not by free market. Having in mind global financial crisis in 2008 and its consequences, free market model showed its shortcomings and this is the reason and alibi why governments of many countries have been intensified their entanglement in the free market. According to the definition of The United Nations Conference on Trade and Development in a state-owned company the state owns at least 10 percent of the share capital and has significant control through: full, majority or significant minority ownership (Sprenger, 2008). In some countries, such as Russia, government is a minority shareholder in the equity of some companies, but owns golden shares and has main role in making decision and allocation of company's resources. Economic and strategic decisions of State Owned Enterprises (SOEs) influence not only performance of these enterprises and domestic market, but global market too. SOEs in China and Russia participate the most in the stock market capitalization in those countries. The other side of medal is that SOEs are usually misused by leading political party in order to promote and realize its political gains and interests and to strengthen its ruling position.

2. STATE CAPITALISM AS GLOBAL PHENOMENON

The well known and the richest companies owned by government are oil companies. Among world's largest oil companies, measured by their reserves, 13 of them [1] are owned and operated by governments and they control more than 75 percent of global oil reserves and oil production. At the same time, private multinational oil companies hold just three percent of the global oil reserves and produce just ten percent of the total oil production (Bremmer, 2009).

[1] some of those companies are Saudi Arabia's Saudi Aramco, the National Iranian Oil Company, Petróleos de Venezuela, S.A., Russia's Gazprom and Rosneft, the China National Petroleum Corporation, Malaysia's Petronas, and Brazil's Petrobras.

In some countries, usually developing, governments realize their political interests through privately owned national champions. These companies have private equity, but gain competitive advantage on the base of preferences given by government in form of favorable credits, contracts or subsidies, not on the base of increasing productivity and efficiency. Positive aspect of fostering national champions is that they can be considered as special joint venture, combined of state resources and the most valuable knowledge and experience of the best multinational companies and their management. There are couple of examples in the China's automobile industry and electronic industry, where China's national champions took over the global car maker *Volvo* and giant of electronic industry *Siemens*. Although national champions are private companies and a lot of them, especially in emerging markets are listed on the Fortune Global 500, they are in more favorable position compared to other private companies as their competitors. On the Fortune Global 500 list, according to revenues in billions of US$, there are a lot of Chinese government companies, such as Sinopec group (4th place), China National Petroleum (5.), State Grid (7.), Industrial and Commercial bank of China (29.), China Construction Bank (50.), Agricultural Bank of China (64.), Bank of China (70.), China Mobile Communication (71.), China State Construction Engineering (80.), China National Offshore Oil (93.), China Railway Construction (100.), China Railway Group (102.) and other state owned companies. There are also a couple of Russian state companies on the Fortune Global 500 list, such as Gazprom (21.), Rosneft Oil (99.), Sberbank (228.). [2]

Besides the remarkable financial results of these companies and their importance for the national economy and financial market, it has to be noticed that those results are mainly achieved due to the government support and those companies are used as an instrument of manifesting power of political establishment and realizing political interests. According to McKinsey, in 2013 there were 8000 companies worldwide whose revenue exceed US$ 1 billion, and 75 % of those companies came from developed countries. McKinsey forecasts that by 2025, there will be additional 7000 companies with revenue above US$ 1 billion and 70 percent of those companies will come from emerging markets, with dominant position of China's companies.[3] Regarding this forecast and development of state capitalism in the last twenty years, similar trend can be expected in the next decade, which means a considerable number of companies from the emerging economies, have revenues above billion of US$ and are owned by state and governed by professional management. Empirical evidence from China suggests that SOEs are more successful in the realization of infrastructure projects, such as railways and airports, than in the boosting of innovation. There are also negative effects of favoring private champions and SOEs that are reflected in the repression of private sector and decreased productivity and efficiency, whereby costs of subsidies and credits given to the national champions and SOEs, are transferred to the final consumers through higher prices of goods and services.

Regardless evidence of using SOEs as a tool of ruling political party, different forms of direct state intervention in economy has been existed since the ancient societies, and were especially popular in the 20th century in conditions of Great depression and other global financial crisis. It indicates that SOEs are not exclusively related to developing or emerging economies. The role of government and its interference in the economic sectors was particularly necessary after The Second World War and reconstruction processes throughout the Europe, Japan and other countries destroyed by the War. SOEs as a manifestation of visible hand of government are usually founded in energy sector (oil, gas, electricity, coal), telecommunication and mass media, railway, air transport, financial and banking sector. Ten years ago according to the OECD data, SOEs in France and Italy had the biggest asset value and total equity vale compared to SOEs in other OECD countries. According to the number of SOEs employees as a percentage of total employment, France was at the fourth and Italy was at the ninth place. French government has 85 % of shares in EDF (energy company), Japan has 50 % of shares in Japan Tobacco, Germany has 32 % of shares in Deutsche Telekom. Total value of SOEs in OECD countries is nearly US$ 2 trillion, with the workforce of 6 million people. [4] Governments of some countries use direct state intervention as an instrument of realization developing strategies and goals in order to boost development of some sectors, industries, regions or national economy as a whole. Through SOEs government realizes some measures of fiscal policy and supports achieving of socio-economic goals such as decreasing rate of unemployment, especially of population under thirty. Having in mind importance of SOEs for national economies and their influence on the global market, even more OECD countries are interested in reforms and professionalization of SOEs board of directors. It requires higher level of autonomy and competence of members of boards in SOEs and less political influence reflected in the political representatives in boards. There are also some countries without state representatives in SOEs boards, such as Norway, Denmark and Netherland. Number of state representatives in the SOE's board depends on the ownership model (sector, dual, centralized) that is applied in a country. System of fees and incentives has to be properly set for the members of SOEs boards similar to remuneration systems in private companies. In many OECD countries there is a trend of revision of

[2] http://money.cnn.com/magazines/fortune/global500/index.html
[3] http://www.smartplanet.com/blog/bulletin/half-of-fortune-500-companies-will-soon-come-from-emerging-countries/
[4] The Economist, January 2012, Something old, something new - A brief history of state capitalism http://www.economist.com/node/21542922

fees and incentives of SOEs boards' members in order to harmonize their incentives with same items in private sector. Members of SOEs boards should also be focused on creating and increasing value of SOEs, such as they are members of board in some company with private equity. It is hard to expect that these principles of corporate governance that have already been implemented in SOEs in OECD members countries, will be soon applied in the governance of SOE's in China, Russia, Brasil and other emerging economies.

Regardless obvious state support and unequal treatment of SOEs and enterprises with private equity in terms of availability and price of financial sources as well as other business conditions, return on equity (ROE), productivity, efficiency, cost control, innovative activities of SOEs are still below the same performance measures of private sector's enterprises. In the period 2001-2009 in China average return on equity of SOEs was only 1.47 percent, a several times less than ROE in private sector. Some older studies indicate that the higher state participation in the equity is, the lower productivity is. There are also some exceptions such as *China Mobile* and *China National Petroleum Corporation* that achieve excellent financial and business results, although Chinese government has majority ownership in these enterprises. [5]

3. STATE INTERVENTION IN THE BUSINESS OF INSURANCE COMPANIES AND INVESTMENT FUNDS

Free trade is the base of useful division of labor worldwide. Through regulations state may affect the restriction of free trade of goods and services and cause violation of the basic postulates of free and competitive trade. Theoretically, state intervention is justified in situations of market or regulatory failure, such as: natural monopoly (e.g. oil, gas), public goods (e.g. law, order), merit goods (e.g. health, education) and externalities (positive or negative outcomes of activities that influence a lot of community members (OECD comparative report on corporate governance of state-owned enterprises, 2005, p. 9).

There are a couple of arguments justifying the role of the state in the implementation of protectionist policies in the insurance market. One of the reasons is potential threat of domination of foreign insurance companies in the domestic insurance market. If domestic insurance companies do not have sufficient market power, capital, and expertise they could not compete with global insurance companies that have significant financial resources, a strong market reputation and experience. These restrictions are generally introduced by developing countries in order to facilitate the development of domestic insurers. There are also macro-economic and political reasons, as well as protecting national security. The key justification for preventing the entry of foreign insurers and reinsurers is to prevent the outflow of premium abroad which can be a real threat regarding that insurance companies with foreign capital tend to realize as many activities in their origin countries.

Government can use some measures in order to restrict free trade which has a negative impact on the competitiveness of the national markets and those measures are known as protectionist. For insurance and reinsurance companies which intend to enter new markets or already doing business in markets besides their national market or out of their centrals, different customs and non-tariff barriers may have negative impact. Those protectionist measures are usually in the form of tariffs, quotas, subsidies and public procurement. Customs have a protectionist effect on the domestic insurance sector in the country in which they are introduced, with positive impact on the balance of payments and increase of state revenues, but their summary effect is negative, as it reduces competition and thus exert a direct negative effect on both the market and consumers.

Customs are rare in the insurance, but different tax treatment of domestic and foreign insurers could be classified as tariff barrier. Non-tariff barriers are informal or indirect restrictions or regulations that hamper the free trade and thus directly limit fair competition. The most important non-tariff barriers are subsidies. Subsidies can be targeted directly towards favoring domestic insurers. Subsidies can be in the form of direct government incentives to obtain insurance coverage of domestic insurers, as well as in the form of tax refunds or tax incentives. For example, in Switzerland domestic insurers are allowed to form reserves in case of catastrophic damages. The way of realization of public procurement has a significant impact on business of insurance companies, while practices of favoring domestic companies were not subject of review under the General Agreement on Tariffs and Trade (GATT) [6]. For example in the U.S. is allowed a preference of

[5] The Economist, January 2012, Mixed bag - SOEs are good at infrastructure projects, not so good at innovation http://www.economist.com/node/21542929

[6] GATT is transformed to the World Trade Organization (WTO) in 1995; one of the basic goals of WTO is reduction of tariffs and other non-tariff barriers.

domestic companies in the sectors of products or services, until their price does not exceed the amount of more than 12 % of the price offered by the foreign company.
Restricting access to the market is not in accordance to the fundamental principles of free and fair international trade and there are numerous different examples. It is required in some countries that insurance and reinsurance companies have majority of domestic capital. Some countries may restrict the access to foreign insurers in all cases except when a specific type of insurance cannot be obtained from domestic insurers. Finally, there is also limitation in terms of risk transfer to reinsurers, which appears in the form of obligatory assignment of risk to domestic reinsurers first.

In addition to these differences in the tax burden, preference in public procurement and the introduction of quotas for the foreign insurers, there are also possible differences in regulations regarding the types of activities that are permitted to domestic and to foreign insurance companies, then it is possible to introduce higher capital requirements in the regulation of solvency for foreign insurers or to restrict them access to the national trade associations.

3.1. Direct state intervention on the insurance market

On the insurance market, in addition to creating regulatory framework, state usually participates in promoting insurance and its importance, as well as improving confidence in the institution of insurance. The role of the state in the providing of social insurance is present in all countries, with some variability in the volume of services. Social security provides protection of incomes of individuals and their families in the old age, in case of death, disability, impairment of health, maternity, unemployment and injuries and it is an important instrument of state policy.

It is common that the social security system included 1) the pension and disability insurance, 2) health insurance and 3) unemployment insurance. In addition to the social insurance state traditionally has a role in providing other forms of insurance for which private sector is not interested. In group of insurance for which there is no initiative of private sector, especially important are deposit insurance and export insurance. The role of government in providing social insurance is important in most countries, including the developed as well as the UK. In this country, for example, the cost of health insurance provided by the state or the national health service exceeding one hundred billion pounds while total premiums of voluntary health insurance starts at around 4 billion pounds.

Increased probability of catastrophic events over the last decade drew attention to the limits of insurability within a market economy. Through the institutions that personify state, the state is interested to provide insurance protection for all risks and all insureds and when private insurance companies do not offer insurance for catastrophic risks, the state usually directly involves in the insurance business (Njegomir, 2011). The direct role of the state in the insurance market is realized through the founding of state insurance companies or through financial support to the private sector when the state has a role of (re)insurer of the last instance, similar to the role of central bank that appears as a last resort in order to provide liquidity in the banking system. Through its institutions, state may appear in the role of (re) insurer of last resort when it can provide reinsurance coverage for the private insurance sector. For example, in the region insurance companies achieved poor results in the insurance of agriculture (Njegomir, Pejanovic, 2011) and government intervention in the form of subsidies for insurance premiums is required. However, a direct state intervention in the form of compensation that occurs in the region is not justified, regarding the little interest in insurance, which should be the primary form of protection of agriculture (Njegomir, 2011).

The role of the state as an insurer of last resort the most efficiently can be achieved through the establishment of national pools. National pools are pools of insurance and reinsurance companies, with the state support. These pools are formed to secure insurance coverage for major risks, such as earthquakes and floods, which are considered fundamental and which are beyond the control of individuals or groups and have extremely negative consequences for the entire population, economy and infrastructure. In the UK there is a state-sponsored program of support in the form of Pool Reinsurance Co. Ltd. In Spain there is Consorcio de Seguros for terrorism insurance, in France there is state-supported pool GAREAT for terrorism insurance. In Germany there is a typical pool with state support, for reinsurance of risks of terrorism, consisted of 16 insurers and reinsurers and called EXTREMUS.

Mega catastrophes that emerge with increasing probability in recent years, are beyond the capacity of the insurance market, but even the states, which indicates the need for the partnership between the public and private sectors on the global level, and Organization for Economic Cooperation and Development – OECD has very important role in it (Messy, 2005).

Finally, the extreme situation of the direct role of the state in the insurance market is the nationalization of the entire insurance sector, as was the case in the former socialist countries. Through the process of transition to the market system, followed by collapse of the socialist socio-economic system in the late eighties and early nineties, insurance sector was privatized. Completely planned and by state regulated insurance sector is inferior in comparison to the private insurance sector In countries where the insurance sector was systematically state directed, insurance companies are considerably smaller, with less developed organizational structure, smaller volume and diversity of services within insurance coverage and usually they not operate on international insurance market, unlike insurance companies from market oriented economies. Also, a key reason against the government interference in the business of insurance companies, except in circumstances where it is absolutely necessary, is a lack of positive investment effect that private insurance companies realize on the capital markets (Dorfman, 2008, p. 75).

3.2. Sovereign wealth funds as a state visible hand on the financial markets

Sovereign Wealth Funds (SWF) are state owned investment funds with diversified portfolio of government bonds, shares in domestic and international companies, real estates, precious metals. Although some state owned investment funds have been founded in the fifties of the twentieth century (Kuwait Investment Authority in 1953), influence of SWFs on the global market has become even stronger from 2005. Having in mind relationship of SWFs, state capitalism and emerging economies, from 2005 have started some kind of financial race between SWFs and investment funds that come from USA and Europe. Financial crisis of 2008, that especially hit financial markets of USA and Europe, additionally spurred performances of SWFs and emerging markets.

Countries that continuously have high export revenues and surplus in foreign exchange, establish SWF in order to realize and maximize long term return on investments, but at the same time to promote political interests of leading party. This is the way how some countries form huge pools of capital available for financing business of SOEs and national champions as well as for foreign direct investments (FDI), but simultaneously sustain stability of national currency, prevent increase of inflation rate and avoid direct budget financing of SOEs. Nowadays the biggest SWF is The Abu Dhabi Investment Authority with capital of US$ 627 billion that is equal to some of the largest US mutual funds, which indicates their size and importance on the global financial market. The biggest ten SWFs are shown in the table 2:

Table 1: Top ten global SWFs and their assets (in billion of US$) in 2013

Country	SWF name	Assets (billion of US$)	Inception	Origin
Norway	Government Pension Fund - Global	838	1990	oil
UAE – Abu Dhabi	Abu Dhabi Investment Authority	773	1976	oil
Saudi Arabia	SAMA Foreign Holdings	675,9	n.a.	oil
China	China Investment Corporation	575,2	2007	Non-commodity
China	SAFE Investment Company	567,9	1997	Non-commodity
Kuwait	Kuwait Investment Authority	410	1953	oil
China – Hong Kong	Hong Kong Monetary Authority Investment Portfolio	326,7	1993	Non-commodity
Singapore	Government of Singapore Investment Corporation	320	1981	Non-commodity
Singapore	Temasek Holdings	173,3	1974	Non-commodity
Qatar	Qatar Investment Authority	170	2005	Oil and gas

Source: Sovereign Wealth Fund Institute http://www.swfinstitute.org

Data in table show that the SWFs are concentrated in the Middle East (UAE, Saudi Arabia, Kuwait and Qatar). According to the fund source, for 59 % of SWFs fund sources are oil and gas export revenues. Chinese and Singapore SWF are also among global top ten funds. According to the region, 40 % of SWFs come from Asia, 35 % from Middle East, 17 % from Europe, 3 % from Africa and 3 % from America

(Sovereign Wealth Fund Institute). All SWFs can be divided into stabilization funds and saving funds. Stabilization SWFs have main purpose to reduce the volatility of government revenues, while typical saving fund is Government Pension Fund of Norway, global number one SWF according to the assets value (US$ 838 billion) and that is not used for promoting political interests of Norway government. SWF Temasek that comes from Singapore is also represent of favoring financial instead of political interests through its business. Some funds can be characterized as development funds, with the main goal to promote development of some regions or industries (e.g., IT sector). In 2007 total net value of SWFs was US$ 4000 billion. In March 2014, market size of SWF is US$ 6357 billion, comparing to their market size in December 2013, which amounted to US$ 6106 billion. Although International Monetary Fund (IMF) requests from SWFs to increase their transparency, SWFs mainly ignore those requests. Even more, the recent trend among SWFs from emerging economies is that they create joint ventures (China Investment Corporation and the Qatar Investment Authority in 2009) and consortiums (Government of Singapore's Investment Corporation, China Investment Corporation, Abu Dhabi Investment Council and six other SWFs signed agreement in 2010) and ignore the most important western financial intermediaries.[7]

3.3. Indirect role of state on the insurance market

By definition the role of government is to protect its citizens and property from the destructive forces of nature and the risks associated with human activities and to create conditions for the undisturbed operation of the private sector and to support economic activities based on market principles. Regarding that state intervenes directly and indirectly on the insurance market.

Indirect state intervention is realized through the regulation conditions of business of insurance companies in order to protect the insured. Government intervention in the insurance sector is also necessary because of the problem of information asymmetry. On the insurance market problem of asymmetric information appears on the side of the customers or insureds and the insurers, too. On the one hand, insureds are less familiar with the characteristics of individual insurance products as well as the adequacy of the insurance companies in terms of their ability to ensure solvency, or to be a guarantor of undertaken obligations if insurance cases are realized. On the other hand, insurance companies do not always have enough information about the object of insurance as well as the risk, which causes emerging of situation of adverse selection, moral hazard and insurance fraud. The role of government is to promote symmetry of available information, particularly with regard to the insurer. Having in mind fact that insurance companies are professionally engaged in insurance activities, which means their favorable position in relation to the insureds, the state regulates the activity of insurance in order to protect the insured.

Numerous examples of bankruptcy of insurance companies imply the necessity of the state regulation of insurance sector. Identifying and understanding the factors that affect the problems of insurance companies helps in improving regulation. Analyzing the market failures of insurance companies in the United States between 1969 and 2010, rating agency AM Best came to the conclusion that the key causes of bankruptcies of insurance companies inadequate approach to insurance risk management, whether in terms of inadequate reserves, rapid growth or impact of catastrophic damages. Results of the study are presented in the table below.

Table 2: Causes of market failure of insurance companies in USA, period 1996-2010

Period	Participation in total number of companies
Inadequate reserves	40,3%
Rapid growth	13,6%
Frauds	7,8%
Problems with related persons	7,8%
Investment problems	7,3%
Catastrophe damages	7,1%
Considerable changes in business	4,0%
Problems in reinsurance (realization of credit risk)	3,6%
Other	8,6%

Source: 1969-2010 P/C Impairment Review, Best's Special Report, A.M. Best, May 2, 2011

[7] The Economist, January 2012, New masters of the universe - How state enterprise is spreading http://www.economist.com/node/21542925

The role of government in a market economy is necessary regarding that Smith's "invisible hand" is not absolutely capable to provide the best allocation of resources in each case, especially in order to improve the efficiency at the level of society. The absolute dominance of the "invisible hand" is limited by the market failures which were first identified by Keynes who analyzed the causes of the Great depression in the thirties of the twentieth century.

Taking into account the identified causes of market failures as well as bankruptcies of the insurers, key reasons for the regulation of insurance sector directed towards the protection of the insureds as consumers, that are mentioned in the literature are: 1) prevention the insolvency of the insurance companies, 2) protection of the insured due to their lack of information and bargaining power in relation to the insurer, 3) ensuring fair insurance premium, given the imperfections of the market mechanism of premiums regulation, and 4) the achievement of social objectives and benefits by providing a wide availability of insurance coverage (Njegomir, 2011, p. 211).

Indirect role of the state, or its agencies, on the insurance market are related to regulation of insurance business or creating a regulatory framework that will ensure the effective and efficient business of insurance companies. Areas of regulation include: founding of insurance companies; determining allowable organizational forms; solvency; application of accounting standards in the assessment of assets and liabilities; insurance premiums; market behavior, including corporate governance, consumer protection, the level of competition and licensing of brokers and insurance agents; taxation and abandonment the market, including liquidation, restructuring and abandonment some segments of the insurance business.

Through completely free market mechanisms could not be established insurance premium high enough to cover costs and provide a reasonable profit to insurers, but also low enough to be available to insureds. State intervention in order to ensure fair insurance premium is required and it is achieved in two ways: 1) indirectly, through regulation of solvency is prevented the uncontrolled and unfair competition and 2) directly, by approving the tariffs of insurance premiums. Bearing in mind that priority to the market mechanisms should always be given and interventions should be applied only in case of inefficiency of market mechanisms, big insurance companies are indirectly favored, because of lower relative share of the costs of regulation in total revenue of big in comparison with smaller insurers. Increasing cost of regulation cause additional adverse effect manifested in reduced funds for innovations that are necessary in terms of continuously changing environment and the emergence of new risks.

Regulation of insurance can be directed towards the need to achieve social goals, especially the wide availability of insurance services for all who need insurance. In some situations, the regulatory authorities may force insurers to accept insureds that otherwise would not be accepted and to lower insurance premiums. Examples of regulatory pressures on insurers are known throughout the world and commonly associated with forcing insurers to offer insurance services at regular premiums in areas that were exposed to catastrophic damages. Such measures can cause the abandonment of certain types of insurance and the necessity of state intervention as insurers.

3.4. Indirect state intervention in the business of investment funds

Indirect role of the state in the sector of investment funds is realized by creating a regulatory framework, the adoption and implementation of laws and regulations. On the financial markets of the USA, as the most developed and the most important world's market of investment funds in terms of their numbers and diversity, as well as the interest of shareholders to invest in the funds, Securities and Exchange Commission (SEC) is the central supervisor institution for the entire financial market. All countries with regulated financial markets, regardless of the level of market development, have central supervisor institution such as SEC on the USA financial market. In the countries of our region, the regulatory and legal framework for the business of investment funds has been created 10 to 15 years earlier than it was done in Serbia and thus investment funds industry in those countries is more developed and potential investors are more aware and informed about possibilities of investing in funds. Investment funds on these markets have suffered significant consequences of the global financial crisis of 2008 and some financial markets are still being recovering. In Serbia, in 2006 was adopted and entered into force the Law on Investment Funds, then the Law on market of securities and Law on Capital Market in 2011 (Službeni glasnik 46/2006, 47/2006, 51/2009, 31/2011) and the regulatory framework for the business of mutual, closed and private investment funds has been completed. Republic of Serbia Securities Commission is supervisory institution that grants, suspends or withdraws licenses and keeps registers of Investment fund management companies, approves membership of their boards of directors and supervises operation of those companies and their funds. Financial reports and auditor reports of Investment fund management companies and each fund have to be submitted to the Securities Commission.

4. CONCLUSION

State capitalism as a recent global phenomenon has appeared twenty years ago along with the socio-economic reforms toward market liberalization. The leading representatives of state capitalism are China, Russia, Brazil, as well as Middle East countries, rich in oil and governed by royal families. They have main characteristic that leading political establishment decide about economy and resource allocation, denying free market. Global financial crisis of 2008 that especially hit western economies gave tail wind to the emerging economies that continuously mark growth and their state owned enterprises and national champions are generators of country's development and progress. Although in state capitalism government uses SOEs and national champions for promoting its political interests, a lot of Chinese and Russian SOEs are listed in Fortune Global 500 index, even in top ten companies according to the revenue. The adverse by-side effect of state capitalism is repression of private sector that cannot compare to the SOEs that have privilege treatment and government support in terms of resources, prices, interest rate, etc. Nevertheless productivity and return on investments of private sector are still above the same indicators in the business of SOEs.

In business of insurance companies and investment funds, as institutional investors, state intervention is represented in form of direct or indirect state interference in the free market. Indirect state intervention is manifested in creating regulatory framework for business of insurance companies and investment funds. Through the regulation state should provide safety of business of insurance companies in order to protect insureds, as well as fair market competition. Similar situation is related to the business of investment funds, having in mind that investors and capital are usually looking for secure zone for investments.

On the insurance market, in addition to creating regulatory framework, state usually participates in promoting insurance, as well as improving confidence in the institution of insurance. Direct state intervention in the insurance sector is also indispensable in providing social security which means protection of incomes of individuals and their families in the old age, in case of death, disability, impairment of health, maternity, unemployment and injuries and it is an important instrument of state policy. State usually directly involves in the insurance business in order to provide insurance protection for all risks and all insureds in situations when private insurance companies do not offer insurance for catastrophic risks. Through its institutions state can have the role of (re)insurer of last resort by providing reinsurance coverage for the private insurance sector.

Sovereign Wealth Funds (SWF) are state owned investment funds that have become global investment phenomenon in the last decade and expression of visible hand of state on the financial market. They realize remarkable returns despite the global financial crisis of 2008 and its consequences. SWFs are particularly related to emerging markets and economies, but their role and importance on the global financial market have been changing and they even more threat to key financial institutions and investors on the markets of USA and EU.

All these indicate that visible hand of state in the business of insurance companies and investment funds is welcome in the setting regulatory framework and enriching supply of these institutional investors in case when private sector is not interested or cannot profitably operate. In other cases, state represses fair competition and private sector and slow down its development, that have negative long term consequences for the financial market and the entire society.

Abstract: *Security analysis evolved through decades, and introduced various asset-pricing models for stock selection. Developments in theory and modelling varied from efficient markets with rational investors to inefficient markets with irrational investors. This paper aims to present different asset-pricing models and to review empirical findings on their effectiveness in explaining expected returns. Based on the review of contemporary researches, this paper provides the insight into important macroeconomic and microeconomic factors, which have influence on the cross-section of expected returns.*

Keywords*: Valuation, asset pricing models, CAPM, APT, investor sentiment*

1. INTRODUCTION

What is the value of a certain asset and what return it will generate? These are the most challenging questions for various market participants such as investors, regulators, and portfolio managers. The answers to these questions will either fulfill investment objectives, or fail them. Valuation represents an estimation of an asset's value that can be based on variables assumed to be in relation with future returns. Estimation of value can also be obtained by comparison with similar assets. Investments analysts use different valuation concepts and models to select stocks, infer market expectations, evaluate corporate events, to render fair opinion, evaluate business strategies and models. Main use of different concepts and models is for stock valuation. Valuation can be performed as a part of an overall portfolio management process. In the planning phase of a portfolio investment process investor identifies investment objectives, constraints, and an investment strategy. Different investment strategies can either use those concepts and models, or do not. With indexing strategies analysts just try to replicate an index, there is no requirement for judgment of individual securities. Valuation is crucial for active investment strategies, where analyst is trying to produce superior risk-adjusted returns with a portfolio different than some benchmark. Valuation of a particular company is a task within an overall portfolio management process. Valuation process assumes understanding of the company that is being valued, forecasting its performance, and selection of an appropriate valuation model for a particular valuation task (Stowe et al., 2007).

Empirical researchers examined market efficiency of both developed and emerging markets. Evidences found in these studies are opposite. Market efficiency usually depends on the sample that is taken or it is associated with a certain situation. Hence, nature of markets is difficult to determine. This results in that that it is very challenging to pick the right asset pricing model for a specific market. Applicability of the known asset pricing models is connected with rational investor assumption, where expected return represents fair value of investors' portfolio. This is just an assumption, which does not hold in the real market setting. It is frequently argued that investors are following sentiment. Hence, sentiment could be factor that would help in return predictability (Majumder, 2014).

This paper is going to present different models that are available to investors, and to discuss empirical findings of recent research, and discuss its applicability. In the second part of the paper, theoretical foundations of different valuation models will be presented. Third part, will give insight into empirical evidence of performance of modern finance models. Also, in third part of the paper, important behavioral factors that drive expected returns will be presented. Fourth part will provide concluding remarks.

2. SECURITY VALUATION PROCESS AND MODELS

Each security valuation represents a process that consists of few steps. First step assumes understanding and evaluation of an industry as a whole, assessment of company's competitive position and its strategies. In order for us to be able to understand company, it is important to analyze corporate economic and industry context in combination with management strategic responses to it. Second step assume forecasting of company's performance from two perspectives, company's economic environment and its financial

characteristics. In this step macroeconomic analysis is integrated with financial statement analysis, and numerical forecasts are created. Besides quantitative factors it is important to create some qualitative forecasts as well, where assessment of quality of earnings is one of the essential ones. Forecasts represent inputs in value estimation. Third step is a step when appropriate valuation model is selected. There are several value perspectives that can be used as a base for different valuation models. The most important value concept is intrinsic value (Stowe et al., 2007).

Valuation is an integral part of an effort to produce positive excess risk-adjusted return or abnormal return or alpha. If there is a difference between estimates of intrinsic value and the market price of an asset, that means that any recognized mispricing will be part of the holding-period return estimate which represents forecast of the total return. An expected holding-period return represents the sum of the expected capital appreciation and investment income. Therefore, assets alpha in a forward sense represents, the difference between expected holding-period return and fair return on the asset given its risk. Mispricing raises questions about market efficiency. In the traditional efficient markets formulation, the best available estimate of an intrinsic value is assumed to be assets market price. The rational efficient markets formulation assumes that no rational investor will incur expenses of gathering information except if he expects to receive higher return. Furthermore, if trading costs are taken into consideration than market price can even more deviate from assets value. Moreover, rational investor assumption was often challenged and new valuation approaches are formulated. Forth step, of a security valuation process, is a conversion of forecasts into a valuation, and a fifth step is giving recommendation to the investors (Stowe et al., 2007).

2.1. Valuation models

Third step of security valuation process assumes model selection. Stowe et al. (2007) distinguish between two broad types of valuation models, absolute and relative valuation models. An absolute valuation models produce a point estimate of intrinsic value that can be compared with market price of an asset. Present value models, as a type of absolute valuation models, assume that the value of an asset must be related to the returns, or asset's cash flows. Present value models based on dividends are dividend discount models. Besides dividends, cash flows can also be defined at company level. Hence, present value models used for valuation of corporate cash flows are free cash flow models and residual income models. The application of present value models for common stock valuation engages uncertainty, that stem from inputs in these models, mainly cash flows and discount rates. Corporations can also be valued with another type of absolute valuation models, called asset-based valuation models . These models assume that company can be valued based on the market value of its assets/resources. Relative valuation models give assets value relative to the value of an another asset. Rationale for these type of models is that similar assets should have similar prices. This type of valuation is implemented using different price multiples, like price-earnings (P/E) multiple (Stowe et al., 2007; Bogojevic, 2004). Bogojevic (2009) distingueshes two approaches for determining cost of equity capital, approach based on the dividend discount model (which can be used in fundamental analysis) and approach of the Capital market line. Also, basic models of risk and return are CAPM and APT. In time, many of their extensions were created in attempt to overcame to drawbacks of those basic one's.

Haugen (2001) distinguishes between different periods of evolution of academic finance, the old, the modern, and the new finance. Summary of Haugen's view of the evolution of security analysis is presented in table 1. In the old finance period, security analysis was focused on accounting statements and law. Introduction of new finance era came with Harry Markowitz portfolio optimization and Capital Asset Pricing Model (CAPM) (Sharpe, 1964), and is completed with the efficient market hypothesis. These building blocks of the modern finance assume rational investor behaviour. Stock prices change randomly from one period to another, and they are responding instantly and accurately to the new information. Risk of an individual stock can be measured with beta, which represents the sensitivity of a security's periodic return to changes in the periodic return to the market index. Modern finance thinking was challenged with discovery of myriad of market anomalies, such as January effect, or small stocks premium. The new finance paradigm dismisses rational investor's behaviour, and assumes that markets are inefficient. It is necessary to measure the behaviour first, and then to try to find reasonable explanations for it. Hence, stocks with particular characteristics are more likely to yield premium returns.

Table 1: Summary of Haugen's view of evolution of security analysis

Evolution of security analysis		
Old finance	Modern finance	New finance
Financial statement analysis	Rational investors'	Irrational investors'
Law	CAPM	Behavioural asset pricing

Capital market theory extends portfolio theory and introduces CAPM which allows pricing of all risky assets. CAPM is used for calculating the required rate of return which can be compared with an estimate of the assets expected rate of return during specific investment horizon. Based on the result obtained it can be observed that asset is undervalued, properly valued or overvalued. CAPM gives required or expected rate of return when risk-free rate is enhanced for risk premium, and this transition is helpful when one wants to value an asset because it provides a discount rate which can be used in any valuation model. CAPM is a single risk factor model which takes into account volatility inherent in an individual security or portfolio of securities. Only relevant risk is a covariance of the asset with the market portfolio (Reilly & Brown, 2002). Due to unrealistic assumptions of CAPM there are several extensions of this model and one of them is inter-temporal capital asset pricing model.

The arbitrage pricing theory (APT) assumes that there are several risk factors or indexes, but it does not specify how many of them are there or what precisely are they (Ross, 1976). The APT assumes that stochastic process that drives asset returns can be represented as K factor model. Risk factors used in APT that influence returns can be either macroeconomic or microeconomic (Reilly & Brown, 2002). There are several multifactor models used in practice such as Chen, Roll, and Ross (1986), Fama and French (1993), Carhart (1997) extension of Fama and French model, and BARRA model.

Models of new finance are behavioural pricing models. Behavioural finance presents mixture of behavioural and cognitive psychological theory and conventional economics and finance. This field of finance emerged due to inability of efficient market theory to explain different empirical patterns. The underlying assumption of behavioural finance is that individual investors' decisions and market outcomes are systematically influenced by information structure and characteristics of market participants. Humans behave in irrational manner, and therefore make forecast errors and also, do not follow risk aversion concepts. Such behaviour has influence on the efficiency of capital markets and performance of corporations (Baker&Nofsinger, 2010). It is complex to incorporate investors' behaviour into valuation of assets. Szyszka (2010) gives an overview of different classes of behavioral asset pricing models. They can be classified into belief-based models and preference-based models. Belief-based models are models of investor sentiment, DHS model, and Hong and Stein's Model. Preference-based models are Models of Shifting Risk Attitude and Probability Misperception Model.

Model of investor sentiment suggest that attitudes of investors match to two behavioral patterns. First pattern, suggest that investors believe that profitability of a corporation oscillate around some mean value. If company would report increased profitability, investors would react adversely in fear that such news would be eliminated in the next period. Hence, price adjusts to the new information with delay. Humans tend to change their beliefs slowly when encountered with new information; they would need confirmations by successive results. Barberis et al. (1998) associate such investor behaviours with cognitive conservatism. Second pattern, correspond to the belief that profitability of corporations follow specific trend. In this case investors put emphasis on the latest results (Barberis et al., 1998). Barberis et al. (1998) associate this attitude with the representativeness heuristic. This means that investors give probability to the specific event based on the similarity with the precise characteristics of the sample, which will lead to an error. The weight of individual characteristics, which comply with some pattern, will be overstated, and the real statistics will be understated. Thus, their conclusions are based on the short series error.

Daniel et al. (1998) model (DHS) is based on the assumption that investors can be either informed or underinformed. Underinformed traders do not have any influence on the market. Informed traders are overconfident and because of that, their decisions can have an impact on the market. These types of traders are subject to calibration bias. Investors assume that their analysis is more precise than regularly available market information. Model of investor sentiment suppose that investors overreaction is due to a sequence of signals of similar significance and underreact to the new information. DHS model distinct overreaction and underreaction depending on whether information is public or private. DHS model does a good job in explaining short-term continuations, long-term trend reversals, as well as long-term continuations. However, this model assumes that investors' reaction is incomplete when new information is published for the first time (Szyszka, 2010).

Hong and Stein (1999) also assume that there are two types of investors in the market, and they have bounded rationality. First type of investors is the type who uses fundamental analysis, and they track new information which can affect the value of a company. Second type of investors is momentum trader, who favors short-term price trends. All investors analyze only certain subset of publically available information. Fundamental information reaches investors slowly, causing certain delay in their reaction. They are focused on forward looking information, ignoring historical trend. Momentum traders only care about price movements.

Barberis, Huang, and Santos (2001) propose preference-based model, based on three ideas. Investors are interested in the level of their wealth and they are concerned with fluctuations in its value, also they are more stressed with reduction in the level of their wealth than to its enhancement. Investors are risk takers after they have realized gains, and they are risk averse when they have experienced losses. This model is trying to explain investors' behavior when capital markets are analyzed from an aggregate level. Dacey and Zielonka (2008) proposed another preference-based model. Investors want to maximize their personal utility, and therefore they are prone to two types of errors. An error may occur due to the investors' faulty estimate of the probability of the events. Errors may arise when investors assign inaccurate weights to the estimated probability level in the weighing function of prospects theory. Furthermore, there are two types of investors rational and quasi-rational. There are fewer rational investors' in the marketplace and they correctly assign probabilities to the potential changes in assets prices. Reversely, quasi-rational investors make wrong estimates.

3. EMPIRICAL EVIDENCE OF PERFROMANCE OF ASSET PRICING MODELS

There is a vast number research that test efficiency of the capital markets. Also, in pursue of adequate model for stock selection, researches investigate the efficiency of both traditional and behavioural asset-pricing models.

3.1. Facts about modern finance models

Kim et al. (2012) tested CAPM, APT-motivated models, the consumption-based CAPM, inter-temporal CAPM, and Jagannathan and Wang conditional CAPM model in the Korean stock market. They found that the Fama-French five factor model gave the best results in explaining the inter-temporal and cross-sectional returns.

Hammami and Lindahl (2014) found that bank credit growth is relevant factor in stock pricing based on the US sample. They have included bank credit growth variable into ICAPM and determined that as a state variable it explains 94% of the cross-section of the average returns. Bank credit growth is priced in the expected stock returns. This state variable is important since it can predict business cycle variables and future labor income growth, and also according to them cross-section of expected returns. Marquering and Verbeek (1999) extended ICAPM by adding transaction costs and habit persistence. Habit persistence can be defined as high consumption in previous period followed with high consumption in the next period. Consumers that are used to high consumption levels would desire such level of consumption to persist. Introduction of transaction costs in consumption-based model did not show good results. However, when habit persistence was included in the model results obtained were improved significantly.

Mouselli et al. (2013) investigate the relevance of accruals quality to asset pricing, by introducing this factor to the Fama-French three factor model. Investors recognize the quality of financial reporting, and more precise accruals quality. Stocks with lower accruals quality exhibit on average higher returns than stocks that have higher accruals quality. Reasons for such findings are not attributable to size or book-to-market effects. Furthermore, costs of capital are influenced with accruals quality. However, Mouselli et al. (2013) concluded that accruals quality is not a good proxy for determining the information risk or it can be captured with other risk factors. This study found no evidence that accruals quality is a priced risk factor. However, this finding does not imply that earnings management is irrelevant; maybe different proxy for such actions should be considered.

Cowman and Joutz (2006) tested economic factors significance in multifactor asset pricing models. They have created Bayesian learning model under which unobserved components can be estimated using Kalman filter. They concluded that economic factors can be useful when pricing risk, and that industrial production and unexpected inflation make inference across financial markets.

Chou et al. (2012) found that well known asset pricing models are not able to explain industry returns. Hence, either efficient or inefficient theories cannot clarify industry returns. They have based their conclusions on the analysis of two industry asset pricing models, industry-based five-factor model and industry-augmented five-factor model which they compared with CAPM, Fama-French three factor model, and momentum augmented four-factor model. They found that economic fundamentals and information about industries help to predict stock markets. Furthermore, empirical results show that asset price anomalies (small firm effect, book-to-market effect, momentum effect) are related to industry classification.

3.2. Evidence of different behavioural aspects on asset pricing

Chan et al. (2004) tested effects of two psychological biases, representativeness and conservatism, on stock price behaviour. They based their research on trends and consistency of performance of the accounting data. Generally, biases are formed when investors analyze past information about companies, and based on those biases, investors can form expectation about company's performance and they can be satisfied or unsatisfied with their forecasts. They found evidence that behavioural theories based on representativeness are not sustainable. On the other hand, behavioural theories based on conservatism biases have some influence on the stock pricing. They found no evidence that past accounting performance trends over multiyear periods generate future return reversals. Their evidence weakens the likelihood that market inefficiencies stem out of representativeness and conservatism, based on different metrics and horizons.

Many studies have reported that investor sentiment and stock market returns are related. Such findings dispute classical asset pricing models (Kim et al., 2014). Sentiment can be defined as optimism or pessimism regarding future stock returns. Therefore, periods of high sentiment, represent periods in which majority of economic agents believe that future performance of stocks is going to be high (Berger & Turtle, 2012). Dergiades (2012) has found the evidence that investor sentiment is significant for predicting stock returns, mainly because of conditional variance of stock returns. Research is conducted for US stock market. Yang and Li (2013) also report an evidence of systematic and significant impact of investor sentiment on asset prices. However, general sentiment based asset pricing model still does not exist, and research is in an explanatory stage.

Changsheng and Yongfeng (2012) explored the impact of investor sentiment on asset valuation based on Chinese stock market data. They found that stocks with low book-to-market value and high P/E ratio are sensitive to investor sentiment. Therefore, investor sentiment has explanatory power for hot and value stock. Thus, investor sentiment should be taken into account in asset pricing, which is consistent with behavioral theory.

Proponents of investor sentiment theory argue that market sentiment and behavioural biases affect aggregate and individual returns. There are several sentiment matters, and among them is disagreement between investors. Investors can be optimistic or pessimistic, where their pessimism is not easily seen in market prices due to short-sale restrictions. Numerous studies reported that under short sale limitation, disagreement between investors' result in overpricing. Kim et al. (2014) investigated relation between such disagreement and stock market returns, with time-varying level of investors' sentiment. They found that higher level of disagreement among investors lead to lower returns during high sentiment periods. During low sentiment periods, there is no relation between disagreement and stock returns.

Information validity has great significance when valuing risky securities. When information about stocks is not transparent, investors could require additional compensation to buy those stocks. If this is the case those stocks would be more sensitive to the market sentiment. Berger & Turtle (2012) found evidence that stocks that are volatile, small, young, and intangible exhibit greater sensitivity to the market sentiment. There is inverse relation between known investor sentiment and marginal performance of non-transparent stocks. Stocks with transparent information display little variability in performance during different levels of market sentiment.

Chung et al. (2012) examined how well investor sentiment predicts cross-section of stock returns if different states of economy are considered. They found that predictive power of investor sentiment is only significant in the expansion state of the economy. In a recession state, investor sentiment has no predictive ability. In the expansion state of the economy has predictive power for portfolio returns which are based on the size, book-to-market ratio, dividend yield, earnings-to-price ratio, age, return volatility, asset tangibility, growth opportunities, and several anomalies. Their findings are based on in-sample and out-of-sample data.

Chen et al. (2013) examined asymmetric effects of local and global sentiment on the expected industry returns, in the Asian stock markets. They found that global optimistic views makes industry returns to be overvalued, and pessimistic view leads them to undervaluation. Furthermore, higher local sentiment increase returns of several industries, like basic materials, telecommunications, and utilities. Likewise, high sentiment makes industries attractive to optimists and speculators.

4. CONCLUSION

Is there a perfect asset-pricing model? Search for an answer to this question is like a quest for a holy grail. Fama-French extended model gave good results in explaining movements in Korean market. Cross-section

of expected returns was better explained with ICAPM when bank credit growth or habit persistence was included. However, traditional models are not found to be efficient in explaining industry returns. Investor conservatism has some influence on stock pricing. Furthermore, investor sentiment is found to be very important factor in explaining returns, in both developed and emerging stock markets. Its explanatory power is significant only in the expansion state of the economy. Also, there is a difference in a significance of global and local sentiment in explaining returns of companies from different industries. Further research is needed to be able to shed light on additional risk factors and biases that are necessary for inclusion in a sustainable asset-pricing model.

Abstract: *Risk is inherent in all lending. Portfolio management is a tool that is used when a loan is approved so as to manage that risk. Knowing the client and his business very well represents a base of quality lending bank business. Therefore, upon granting the loan, every bank monitors i.e. follows all granted loans. A monitoring goal is perception of total lending portfolio quality, as well as of each loan quality and detecting all problematic loans in the business bank assets structure. Problematic loans have a direct influence on credit portfolio. Problematic loan managing is one of the most important areas in banking but, in the same time, this is the biggest challenge. For sustainability and competitiveness of banking sector in Serbia, a long-term collaboration between banks and enterprises is required.*

This paper goal is to point on importance of management active portfolio, place and role of an independence monitoring function and in recognition all early signs warning on possibility of problematic loans appearance. As the level of problematic loans grows in Serbia, this work will show all possible measures and corrective actions for raising the loan portfolio quality.

Keywords: *loan portfolio, monitoring, loan risk, problematic loans*

1. INTRODUCTION

Most commercial banks consider lending as their principal business activity.
Nowadays, the banks perform their business in very unstable business surrounding in which they face different kinds of risks. There is no loan without any risk. On one side, the banks try to create a loan portfolio to be large as much as possible, in order to achieve satisfactory returns; on another side, company worthiness right estimation and granted loans monitoring are very important in the process of granting loans. Failure to perform obligations by the company, results in loss of a part or whole receivable. If several key clients of the bank failure to service their obligations on time, it may retract the bank in insolvency.

Profitability realization, in conditions of growing competition and rising risk, becomes a challenge for modern banking management. Therefore, procedure of collaboration between the client and the bank doesn't finish with granting the loan, but it's being actively continued until the loan is returned.
Loan monitoring is one of the most important elements of a strong portfolio management system. Experience has revealed that although annual audits of loan portfolios may address these risks, the preferred approach is continuous monitoring of the portfolio.

Since early signs and warnings should point to potential problems, even in those clients still being out of the phase of delay repayment, monitoring represents a significant segment of credit portfolio management which will be discussed in the following chapters.

2. LOAN PORTFOLIO GOALS

Loan portfolio comprises a group of loans, being classified by the bank management according to the loan users in several groups:

- commercial,
- investment,
- mortgage,
- agricultural,
- residential ,
- consumer.

Each loan portfolio consists of a wide range of short-term and long-term loans intended to legal and natural persons, economy, population, budget and other organizations.

According to Vunjak and Kovačević (2011, p.200), credit portfolio needs to have the following elements:

- type and maturity of the loan,
- interest rate structure and level,
- security (collateral) of the loan,
- protective clause in loan agreements.

Specific and measurable goals for the portfolio are established as loan portfolio objectives. The loan portfolio goals include the following:
- scope of portfolio,
- structure of portfolio,
- loan services,
- collection of loans,
- price of loan,
- achieved profit.

Implementing actions based on these objectives for most banks requires medium and long-term strategic plans and objectives for the loan portfolio. These strategic plans need to be consistent with the strategic direction and risk tolerance of the bank. They also must be periodically reviewed and appropriately modified thereto.
Determined loan policy and procedures being introduced to the employees in a quality manner, in written, represent a key instrument of management and provide a controlled growth in risk assets. Except of adopted loan policy and strategy for credit portfolio management, the bank also has to have a defined policy of credit risk management in all phases of granted loans.

According to Đukić (2011, p.114), quality procedures should cover the following:
- Respecting suitable criterion, policies and procedures for granting loans;
- Granting loans with an adequate mortgage or other mode of security that the bank may implement if a debtor fails to realize its obligations;
- Permanent monitoring of the loan portfolio being granted in order to monitor all problematic loans;
- In the case of problematic loans appearance, it is required to undertake all measures related to the loan restructuring, their collection or selling of receivables as well as realization of security offered.

In addition to respect of the principle of caution while granting the loan, diversification of loan portfolio mainly comes from obligations stipulated for the banks by regulatory bodies (Horne and Wachowicz, 2007).
Banks need to understand both the risk created by every credit they issue and how they are interrelated in the overall picture of their portfolios in order to successfully manage their portfolio. Historically, supervision of these individual loans has been the banks' focus when managing the overall risk, but, although this is an important approach, banks must also manage the risk in portfolio segments and the overall portfolio.
Credit risk management at the bank level, covers the loan risk identification, monitoring, bank exposure measurement and calculation of capital needed, as well as organization of adequate control function. Therefore, the banks make an effort in forming quantitative and qualitative approach for exposure measuring, i.e. capital costs calculation.
According to author's illustration, next figure represent differences in risk management approach:

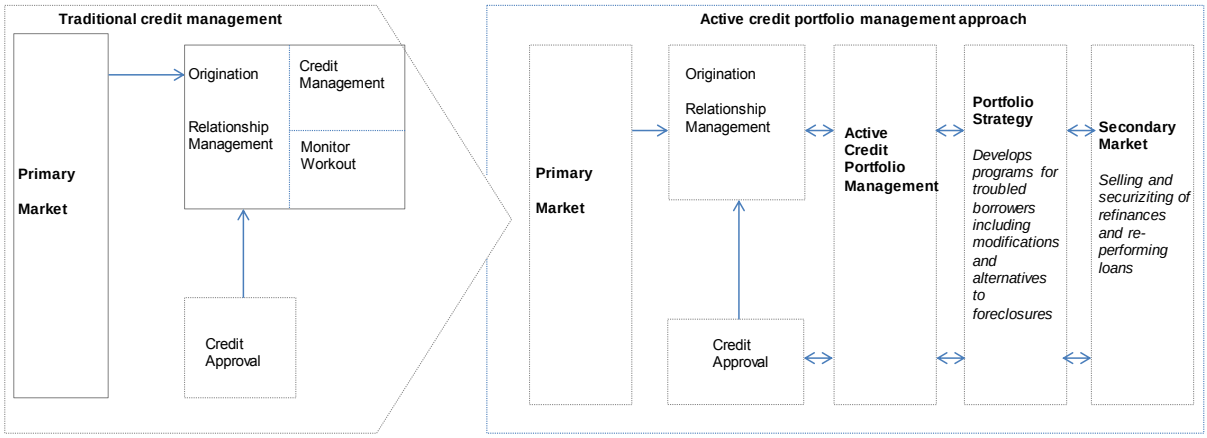

Figure 1: Credit portfolio management as a business model

Unlike the traditional approach to risk management focusing only on assets and liabilities of the bank balance, a modern approach considers the risk management growing from wide range of off-balance bank activities, integrating in this way the risk management at the level of the bank, as a whole.

The focus in traditional credit risk management is underwriting the loans measuring the risk. The bank needs to perform a system of monitoring in order to calculate the occurrence of default. Active portfolio management, however, identifies the concentrated risk on the basis of economic capital lost. The steps that could be taken to mitigate the concentration of risk are sell the loan, buy a form of protection against defaults or securitize the loan asset.
Loan policies, guidelines for underwriting and other bank procedures need to ensure the strategic objectives for the portfolio can be met. Banking represents taking risk, but at the same time making a profit so loan portfolios must reflect the risks and profits accordingly. Management roles and responsibilities are therefore a must for all banks. According to Fiordelisi and Salvatore Mare (2014), size is positively related with bank stability meaning that larger cooperative banks are better able to diversify their portfolio in that increasing bank soundness. Also, diversification may reduce a bank's collateral requirements, giving rise to a kind of scale economy in lending (Neuberger, 1995).

The goal of credit business control is to minimize the bank loses based on the loans, by performing a regular and systematic terrain checking of quality in all departments and affiliates of the bank whose affairs consider a loan risk for the bank.

Quality of credit portfolio depends on the credit risk level. According to Vunjak and Kovačević (2011), credit risk may be expressed as a relationship of potential loses and total credits. According to National bank of Serbia, credit risk also represents possibility of occurrence negative effects on financial result and capital as a consequence of default (Decision on Risk Management by Banks, 2013). There are 2 types of credit risks. One is connected to return on equity, and another one is related to paying interest, as an income to placed credit assets. The loan portfolio exposure to the credit risk considers greater engagement of the management.
Based on credit portfolio analysis, all credits may be divided on standard and problematic ones.

Problematic credits may be divided on the following categories, Ćirović (1995, p.131):

1. Substandard credits;
2. Suspicious credits and
3. Credits with loses.

In standard credits, capacity of the debtor looks like there are no any difficulties to be expected in returning that credit.

Substandard credits include those items where the debtors delay to pay their obligations at least 90 days, as well as restructured loans.

Suspicious credits have an increased risk of not being collected. They include the items of assets in which the debtor delays his payment obligations at least 180 days.

Credits with loses cover those credits being written off at the bank because they are considered as uncollectible.
Because of the credit portfolio important quality, bank management should be informed on conditions and quality of portfolio, as well as on poor-quality i.e. problematic credits. Credit portfolio analysis is done within a special department performing portfolio monitoring continuously.

3. LOAN PORTFOLIO MONITORING

Knowing the client and his business very well represents a base of quality lending bank business. Therefore, upon granting the loan, every bank monitors i.e. follows all granted loans. Monitoring goal is in perception of total lending portfolio quality, as well as of each loan quality and finding of problematic loans in the business bank assets structure.

Monitoring may be organized within credit department as a separate function or within department for risk management, but it is important to provide an independence and objectivity in portfolio quality analysis.

According to Vunjak and Kovačević, (2011, p.201), monitoring process provides:

- Quality credit portfolio;
- Consistent application of credit policy;

- Finding of problematic credits;
- Discovering of failures in releasing credits;
- Objective forming of reserves of the banks that are in the function of credit loses covering.

The goal of monitoring function is to find risk credits as soon as possible, as well as to inform the top management on quality of credit portfolio in whole and per credit groupings.

We differ a total credit portfolio monitoring and individual credits monitoring. **A total credit portfolio monitoring** covers the bank claims based not only on credit but also on factoring affairs, guarantees, letters of credit and credit cards. The aim of credit portfolio quality estimation is an evaluation of possibility that certain credit won't be paid off. Via credit monitoring, the bank estimates how large reserves should be formed in order to cover any potential loss.

Also, a classification of credit is checked according to Regulative of National Bank of Serbia (taking into consideration that each bank has right on internal classification, in accordance with International Financial Reporting Standards), possible changes in classification are monitored, a new classification of the debtors is determined if needed, quality of security offered is checked, as well as cash flows for the credit to be paid off etc.

According to Đukic (2011, p.24), the credit portfolio estimation should include app. 70% of credit amount and 30% of number of credits being covered. Credits with maturity more than 1 year are included completely.

In problematic credits, corrective actions are immediately undertaken through credits restructuring, requirements for additional security etc. according to Decision on the Classification of Bank Balance Sheet Assets and Off-balance Sheet Items (National Bank of Serbia, 2013), criteria being observed in classification of the debtors are as follows:
- Timeliness, i.e. delay in settlement of liabilities towards the bank;
- Financial state and creditworthiness estimation;
- Quality of security offered.

In order to determine all expected loses (EL) at the level of portfolio, it is required to determine all expected loses of each individual credit and those are calculated according to following parameters:
- Probability of default (PD)
- Loss given default (LGD)
- Exposure of the bank (E)

Expected loss in individual credit is calculated according to the following formula:

$$EL = E \times PD \times LGD$$

The bank calculates possibility of failure in performing liabilities of each individual client, while the rest of parameters may be calculated or standard coefficients may be taken. Expected loss at the level of portfolio is obtained as a sum of expected losses of individual clients.

Individual credits monitoring represents already granted credits control, with the purpose in giving information on situation development and changes in the company in the period of time from the date of granting credit or the credit previous regular analysis, followed by an analysis of all new financial data. This analysis should underline an influence of change to the main risks of the credit and sources of paying off.

Loan reviews:
- Analyse and evaluate individual loans, including risks of default or insufficient repayment;
- Evaluate lending policies and procedures compliance;
- Determine problems with faulty documentation;
- Suggest priorities for credit risk management;
- Recommend steps and establish procedures to overcome difficulties.

These types of estimations rely mostly on analysis of the debtor's creditworthiness. The goal of this check is that the bank needs to be sure in following:
- That economic and financial situation of the debtor isn't going worse;
- That the value of collateral isn't going down;
- That the credit is used with the purpose.

Warning signs indicating non performing loans and poor loan policy, regardless the size of some company, may be systematized in the following way, Rose and Hudgins (2005, p.545):

1. Unusual delay in financial reports receiving and in payment or in communication with the bank's staff;
2. When business loans are in charge, any sudden changes in methods used by the borrower on account of amortization, when paying pension contributions, the stock value, with respect to taxes or obtained income;
3. When business loans are in charge, outstanding debt restructuring or elimination of dividends or changes in the debtor creditworthiness;
4. Negative changes in prices of shares of the client to be debited;
5. Losses per net incomes in one or more years;
6. Negative changes in the borrower capital structure (coefficient of share capital /debt), liquidity (current coefficient) or at the levels of activity (selling coefficient in relation to the stock);
7. Deviations regarding the real selling or cash flows in relation to envisaged in time of application of the request for granting the loan;
8. Sudden, unexpected and inexplicable changes in balances of deposits held by the client.

It is very often that the company orderly settles its obligations but doesn't use the credit with the purpose. In that case the bank has the right to ask for the credit to be returned. A special attention should be directed to the new clients who are granted with long-term credits.

If untimely repayment of the credit occurs, the bank firstly considers the reasons that have led to this situation. If they are reasonable, the bank may extend deadlines for returning. If they are not reasonable, the bank may undertake the payment by security instruments activation or by judicial proceeding.

Monitoring importance is in the fact that it is not enough only to take care if the client delays with payment and then undertake some measures but there must be built such a system that will be able timely to recognize problems and to undertake all steps for preventing or decreasing the scope of damage before it happens. According to Chava and Purnanandam (2011), the positive correlation between bank-health and client performance is an outcome of the client’s health affecting bank performance and not the reverse.

4. NON PERFORMING LOANS MANAGEMENT

Despite all measures of caution envisaged by numbers of banks in their credit policies, some credits become problematic which means that the company failures its payment obligations in time or values of security, given as a collateral for loan, have been decreased.

Credit policy defines ways in which a bank can deal with non performing loans (NPL), since working out problem loans involves identifying problem areas and negative trends early, in order to better deal with the issues.
In the case that the bank doesn't charge the loan and interest within 90 days form maturity day, it is considered that problematic credit is in charge which requires a special treatment. When determined that non performing loans exist, they must be given to the referent for solving credits, who must find the reasons for problems and, together with the company, try to find some solution for collection of funds. A well trained referent who knows his/her client very well, will recognize all signs of warning pointing that external factors or bad management negatively influences the credit quality.

In non performing loans, it is required immediately to undertake corrective actions through the loan rescheduling, additional security, searching for new information etc. Credit rescheduling is an option which should be chosen by the bank only if it firmly believes in long-term future of the company. In the case of successfully performed suggested action measures, the client is to be excluded from the list of problematic loans.

Banking sector of Serbia, upon global economic crisis, is loaded, among other things, also with non performing loans.

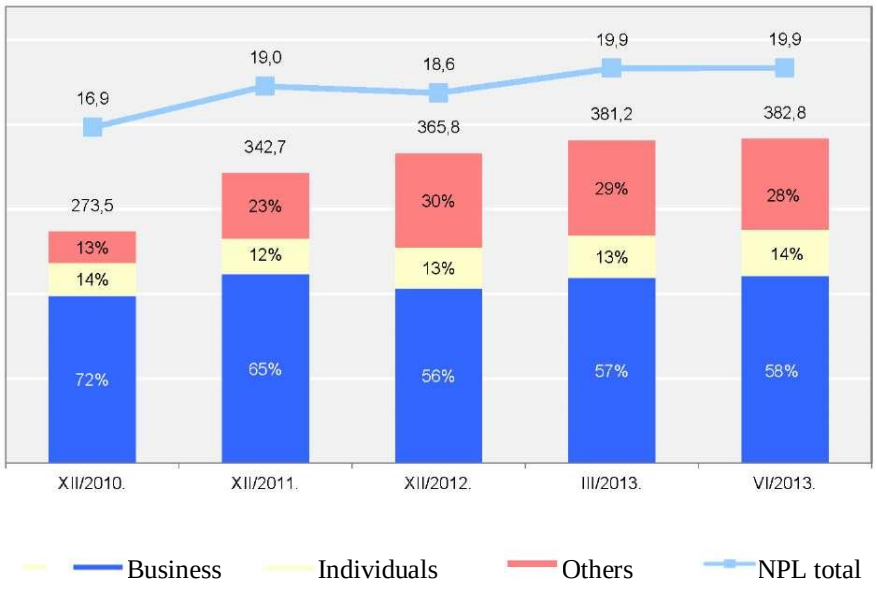

Figure 2: Non performing loans

As shown by the previously graph, according to the last data of National bank of Serbia related to the second trimester of 2013, (Banking sector in Serbia, Second Quarter Report 2013, p.14), total gross credits of banking sector with delay in repayment longer than 90 days, amounted 382,8 billion of RSD and made 19,9% of totally granted loans.

At the end of the second quarter of 2013, a share of NPL in economy amounted 58% and in population 14%. Observing the end of 2012 and first two quarters of 2013, a slight growth of NPL can be seen.

The main reason of NPL growth in Serbia is economy whose gross indicator increased from 18,6% at the end of 2012 to 19,9% in Jun of 2013. According to data of National bank of Serbia, branches with the greatest participation of NPL, with the date of 30.06.2013, are construction, business with real estate and education, processing industry and trade.

In addition to high participation of NPL, stability of banking sector in Serbia is not threatened taking into consideration high amounts of reserves of the banks for those purposes and according to international standards and domestic regulations. At the end of 2012, the NBS changed its regulative in order to provide

conditions for decreasing NPL in a banking sector. Certain limits have been eliminated in relation to the transfer of claims from the legal persons.

Although the NBS has brought the measures in the purpose of NPL decreasing, economic recovery and efficiency of legal system are even important. By decreasing an amount of NPL, the growth of credit activity is provided whose real realization will depend on existence of enough quality projects and clients.

Taking into consideration all stated data, an importance of monitoring relating to following the credits and timely spotting the potential problems, becomes more significant.

5. CONCLUSION

Each credit portfolio is consisted of the wide spectrum of short-term and long-term credits, intended to the natural and legal persons. The risk represents an unbreakable component of each credit business. Together with an increase of banking business, the credit risk is also to be increased. In narrower sense under credit risk we consider a possibility that the loan wont' be returned in maturity deadline, including interests. Timely repayment of the credit depends on possibility and will of the debtor to return the credit, which also depends on many factors, both those under control of the debtor and those under out of the debtor's control. It is not possible absolutely to avoid the risk, but it is possible to decrease it to minimum due to detailed estimation of creditworthiness and solvency of the company, and later with continued monitoring of the client's business.

By the business bank credit portfolio we define the strategy of risk management from the aspect of individual credit and total credit activity of the bank. Loan portfolio monitoring represents a quality observing and

continuous analysis of granted credits. For the function of monitoring is very important to be independent from other business functions in the purpose of objective perceive of problems and to inform the bank management on all kinds of issues.

Early signs of warning should indicate possible problems, even in those clients who are still out of delay phase, with the purpose in preventing the growth of bad placements and provide the credit portfolio to be qualitative as much as possible.

In this work there are stated the methods of discovering of potential problematic debtors, as well as early signs that can lead an experienced banker to make a more detailed analysis of certain part of the credit portfolio and to make possible every identification of possible problems in claims collection.

The identified problem areas in a loan review affect the whole process of portfolio management and signify the necessity for more detailed reviewing of these areas.
Successful collection of claims represents a mirror of one bank credit policy, its value and the credit portfolio value. However, despite all preventive measures, non performing loans happen. In the case that the bank is not able to collect its claims i.e. the credit and interest within 90 days from the day of maturity, it is considered that a non performing loan is in charge which requires a special treatment. In that case, it is needed immediately to undertake all corrective actions through rescheduling of the credit, additional security, searching for new information etc.

Banking sector in Serbia is also loaded with non performing loans. Observing the end of 2012 and first two quarters of 2013, a slight growth of NPL can be seen, but due to a high level of the banks reserving for those purposes and according to international standards and domestic regulations, stability of the banking sector is not jeopardized.

In order to make the portfolio management processes more effective, a review of policies for lending and underwriting criteria need to be performed as well, in a longer time stretch. Before implementing any proposed changes to policies or standards, management need to take into consideration their potential effect on risk tolerance limits, the complete risk profile of the bank, and the bank's ability to meet its portfolio objectives.

Abstract: *In this paper has been considered sustainability of the universal service in postal traffic. We analyzed certain models of financing and introduced fuzzy MCDM method for the selection of an appropriate financing model. After analyzing we adopted a regional approach to funding and shown an example of the application of the proposed model, implemented in the appropriate region.*

Keywords: *universal service, postal sector, MCDM, AHP, fuzzy, TOPSIS*

1. PROBLEM OF SUSTAINABILITY OF UNIVERSAL SERVICE

Number of competitors in the postal sector has increased. Based on the available empirical research, there is an increase of courier, express and parcel services (CEP services), while classic postal services stagnate or even decline (Dieke et al., 2013). Competition to public postal operator is most common in CEP services, and rarely in the field of universal service and the consequence is a decline in revenue for public operator. On public postal operator has also been imposed an obligation of providing universal service throughout the entire state territory. The concept of universal service corresponds to a set of postal services of a defined quality, the provision of which is ensured by the state laws at all points of the territory at affordable prices (Directive 97/67/EC, Directive 2002/39/EC, Directive 2008/6/EC).

The question that occurs in many countries is whether it is possible to further liberalize the postal market, increase efficiency and reduce the required additional financing of universal service, and provide reliable service to the entire population and the economy? Another question that arises is: how will the existing implemented strategy of providing universal services affect the economic development of the society and whether it will support balanced development of all regions in a country?

A considerable amount of research was conducted in order to analyze trends in the provision of the universal postal service (Gautier and Paolini, 2010; Jaag and Trinkner, 2011; Gautier and Wauthy, 2010; Jaag, Trinkner, Lisle, Waghe and Van Der Merwe, 2011). Results of these researches speak about the problems in the full opening of the postal service. From these studies it can be concluded that for the purposes of providing the universal service, there is a use of the methodology and methods of providing universal service in other sectors (telecommunications, electric distribution, etc...). The problem of providing reliable and efficient universal postal service and the implementation of the strategy, which will ensure this, is a challenge of great social importance. However, stated social significance is not in proportion to the existing research in this area. In many countries, there is no systematic approach to solving this problem. Greater importance is given to other forms of communication (telecommunications, information society, etc.).

Countries that have defined the strategy of postal services used their own experiences in other industries and sectors of the economy, as well as the experiences of neighboring countries that are also acceded to resolve this issue. In order to facilitate the provision of universal services in the whole territory, there was a conscious discrimination of customers in highly profitable areas, in respect to those in low profit areas. Unique service price on entire territory for some meant punishment, and for others meant prize. In addition, reserved universal postal service area that is accepted as a form of financing of universal service, prevents the entry of other postal operators into this segment which may be more effective, and public operator is not motivated to increase efficiency not having any competition.

Having that in mind, it is obvious that some essential questions about the strategy of providing universal postal services haven't been answered. Some of these issues should be reviewed and implemented a new approach to solving the problem of providing universal postal services and defining the strategy of providing.

During the evaluation of problems related to the provision of universal service experts are faced with imprecision, which may in some cases be too high compared to the value of the error that can be tolerated.

The decisions that needs to be adopted in solving real problem, inevitably includes consideration of material based on several criteria rather than considering only one dominant criteria. In order to overcome these difficulties methods of MCDM (multi-criteria decision making) can be applied. They were developed with the aim to set global preferences between the options, that is, to make the final decision based on the output ranking of alternatives (Mehmet Kabak, 2012). In this regard, the work relies on MCDM theory to facilitate the decision making process when choosing the model of financing the universal postal service. Taking into account that estimates of the parameters can be associated with uncertainty, subjectivity, imprecision and ambiguity the process of their evaluation is suitable for fuzzy analyzes (Teodorović, 1999).

Next part of the paper is structured as follows: the description of different models of funding universal service, the framework for their evaluation and proposition of the methodology.

2. MODELS OF FINANCING

Levels and methods of financing the universal postal service, is mainly determined by political factors, but cost estimates and defining the method for calculating is the job of regulatory bodies. There are different models in the approach to financing the universal postal service. This paper will discuss: Restricted area, compensation fund, pay or play, and financing through additional activities.

Reserved area of service is a specific segment of the national postal market over which the universal service operator holds the exclusive franchise as a base of effective, sustainable system of financing of this public service whose provision is guaranteed by the government. This reserved area must be accurately described in terms of three basic elements: type of service, mass of the shipment and protective prices. In establishing the reserved service area, the state decide what kind of postal services will be performed solely and exclusively by the public postal operator. The scope of services to be reserved depends on the needs of countries for providing postal service in accordance with the requirements of the Universal Postal Union. According to the directives of the European Commission, which are binding on all member states, as well as candidates for entry into the European Union, only letterpost services can be reserved for one operator (Directive 97/67/EC, Directive 2002/39/EC, Directive 2008/6/EC). The scope of the area in terms of weight of items varies depending on the maturity of the postal market and the level of development of the universal service operator. Without exception, the range of these variations is inversely proportional to the level of development of the postal operator and the maturity of the postal market. Terms of performing services in the postal market demand protection of services prices reserved for the universal service operator to ensure effective exercise of the right to that part of the market and minimize its vulnerability to unfair competition and predatory price setting by other postal operators. Regulations describing the reserved area, must establish certain minimum price of postal services to private operators or any other operators except the universal service operator.

Compensation funds in the postal sector are often discussed, but the possibility of their practical applications are limited. Questions that always arise when establishing any compensation fund, and which have the greatest impact on analysis through the established evaluation criteria are:

- Who should fill the fund and how to determine the amount of contributions,
- How to define the tax base (the amount of contribution) in order to collect enough funds to cover all costs incurred by the provision of universal service, while at the same time cause minimal distortion to the postal and the global market.

Way to fill the compensation fund can be made through: income tax, profit tax,"Lump-sum" taxation, the unit tax on each service (shipment) and so on.

Pay or Play is one of the more sophisticated models of financing universal service, which combines the question of how to finance the service and who should provide universal service. This approach has the same starting position as well as models of compensation funds in accordance with the requirements of financing and provision of universal services in sectors with high fixed costs and average price levels. Operators that operate exclusively in highly profitable sectors (low cost / high volume services) are required to pay additional benefits in the compensation fund. However, unlike traditional funds, where there is determined only one operator that provides universal service, and thus acquire the right to dispose of the entire fund, this model gives the right to every operator in the market to decide whether to provide universal service (" Play") or fill the fund (" Pay").

Financing through additional activities in development programs is related to the financing of universal service, with the revenue from the additional activities of the public operator, through participation in regional development and the information society. This model would involve a public operator and several private operators in the area where the monopoly, as a reserved area, is abolished. Universal service would be financed from additional activities, that is, with the increase of efficiency and profitability of the public operator.

3. EVALUATION FRAMEWORK AND METHOD

A method of selection of the optimal model consists of several steps (Figure 1). First of all it is necessary to define the characteristics that form prism through which each of the proposed models will be seen. Application of the AHP method will determine the weight coefficients which are conditioned by the characteristics of the observed area. Assessment of achievement of each criterion in the application of a particular model is realized by fuzzy sets theory, where is obtained a universal matrix of contribution of each criteria with respect to the discussed model which is applied to each area. The final step is the application of TOPSIS (Technique for Order Preference by Similarity to Ideal Solution) by which the selection of the most appropriate method of financing the universal service is made.

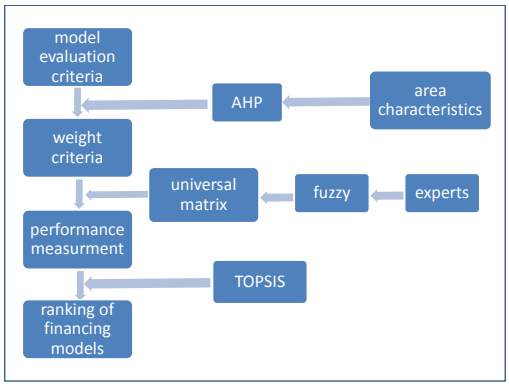

Figure 1: The process of selecting models of financing

3.1 Criteria for model evaluation

Models of financing the universal service may jeopardize the survival and development of operators in a given market. Models should provide contributions for public operators to compensate for the provision of universal service, allowing market entrance for the efficient, competitive operators and preventing the entry of inefficient operators. Operators should evenly divide the obligations arising from the necessity of providing universal service. Funding model should be" well-balanced" that is, to meet the criteria of **fair competition**.

The criterion of social equality, in practice, is a normative concept which determines criteria and assesses which sectors of society need to be more privileged compared to others in terms of the postal service. This assessment is performed mainly in relation to universal service. Criteria should answer the question of whether financing model ensures that strata of society similar economic power get universal service at approximately same prices.

Any of the financing models, may it be the least reliant on financial support from the state, **must comply with national and other positive regulations of the financial sector.** This primarily relates to the compensation fund, which is filled with general or special taxation, and whose resources the state uses to subsidize universal service. Any transfer of state resources, direct or indirect, which provides certain competitive advantages to the recipient or lead to disorder in the liberalized market, is considered to be unlawful government act. This does not mean that any financial help from the state to the provider of universal service will be construed as an illegal intervention.

Calculation must be **transparent** in order to avoid favoring the recipient in relation to its competitors. The compensation should cover only the most basic expenses incurred by the provision of universal service, in special cases can be considered a minimum profit of the operator. When the selection of public operator is not made through public procurement procedure, the level of compensation must be determined by analyzing the costs that would theoretically occur in the case of efficient service delivery. From the perspective of this criterion, the principle of operation of the model of financing should be available and clear

to all market participants. All participants should be able to understand the way in which amount of compensation is determined, who pays contributions for financing the universal service and the way in which those contributions are set. Also, information on the establishment of the fund and entities who have established it must be available, and then how to access the resources of the fund and the availability of specific operators in a given time to have access to the fund. All participants, if they wish, must be provided with the opportunity to meet the requirements for funding from the fund. All this information must be verified and published.

Collection of contributions to small operators reduces the possibility of new entrants to the market, and in the long run leads to its polarization and negative consequences for users. Accordingly, European Commission has put forward a proposal that in case of covering all the costs of providing universal service with funds collected from contributions of other operators, perform the allocation of contributions. Collecting contributions should be non-discriminatory and based on the **principle of proportionality**, and if there is no higher level of market presence, small operators should be freed of this obligation. Proportionality means that the given model of funding achieved a reasonable balance between the projected goals and objectives of the global market. It needs to be ensured that the model minimally affects other market mechanisms and introduces minimal distortion in the global economic plan.

Feasibility is determined by the complexity of financial schemes and information necessary for their establishment and management. Complex mechanisms with complicated procedures of implementation and exploitation require greater funding at practical use and there is increased uncertainty about achieving the projected goals. This criterion has a direct impact on the transparency, in terms of easier or more difficult access to information relating to the current situation and progress in terms of achieving the objectives of the designed model of financing.

Sustainability is key criterion for achieving the minimum cost of establishing a specific financing model. The main aspect of this criterion is that the model, first of all need to act on clearly defined objectives to be achieved. Every action in the framework of the model is to provide a sustainable universal service.

Reliable financing model is one that ensures the long term sustainability of the universal service. The mechanism that provides long-term security financing is much more convenient than those with short and unpredictable financial arrangements. It is important that the model is based on economic principles.

Implementation of a financing model should provide minimal distortion of economic efficiency and increase profit of the operator. In practice, there are three main aspects that can support the concept of efficiency: **allocative, productive and dynamic** efficiency. Financing models that promote redistribution allows operators to raise prices to the level of service that will reflect the cost of providing service, including a reasonable profit based on invested funds. Despite the fact that allocative efficiency is directly contrary to the recognized principles of universal service operators, particularly those large, are increasingly trying to prove its necessity. Production efficiency is based on the obligation of the operator to provide services at the lowest possible cost, with the optimum use of all available technological resources. In this context, financing mechanisms should provide incentives in procurement and implementation of optimal technologies, which will enable full utilization of potential at an acceptable cost. The model should also facilitate the selection of optimal operator which will be entrusted with the provision of the universal service and thus avoid the increase of fixed costs of service. Dynamic efficiency refers to facilitate innovative process, which leads to the development of completely new and enhanced services. The advantage of the dynamic efficiency is in the possibilities of development of universal service based on the applied mechanism, through new ways of providing services or the introduction of entirely new services.

3.2 Analytic Hierarchy Process (AHP)

Analytical Hierarchy Process is a systemic procedure for determining the relative importance of a set of activities or of criteria (Kujačić, 2002). The approach is based on three main components. The first is defined in the request of necessity to decompose the problem into a hierarchical structure. The second component relates to the measurement scale expressing the priorities in the elements (Saaty, 1986).
Dependence of criteria and sub-criteria on the alternatives and mutual dependence of criteria is formed by a matrix whose values are defined by a numerical (1 through 9) or semantic scale. The third component is to define the measurement mechanism for setting priorities in the hierarchy and consistency of assessments provided by experts. Calculating the priority is reduced to the determination of the appropriate vector of weight coefficients.

3.3 The theory of fuzzy sets

A small piece of information about a particular problem can be seen as certain, or deterministic. Problem of uncertainty that arises in information can lead to deceiving if the blur of human decision-making is not taken into account. Fuzzy set theory provides a mathematical basis for the representation of ambiguity and vagueness in human systems (Ross, 2004). Starting from the development of the theory of fuzzy sets (Zadeh 1965), a large number of papers deal with the problem of uncertainty in decision-making based on the theory of fuzzy sets. In this direction, this paper endeavors to encompass fuzzy subjective assessment of experts in terms of the financing model for the universal service.

Fuzzy numbers can be regarded as a generalization of the concept of trust (Teodorović and Šelimć, 2012). That is every fuzzy number can be specified with confidence interval and affiliations functions. Under the term fuzzy numbers is considered to be limited, convex and normalized fuzzy set (Dubois and Prade, 1978). The statement of the extent to which it met certain criteria as linguistic variables (eg, part ") can be represented by triangular fuzzy numbers in the range of 0-5. Triangular fuzzy number can be defined as a triple (a, b, c) (Fig. 2), where the affiliations function is defined as follows (Zimmermann, 1991):

(1)

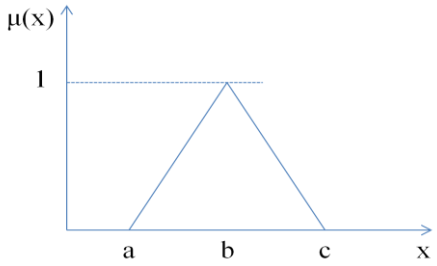

Figure 2: Triangular fuzzy number

Algebraic operations on triangular fuzzy numbers can be defined by means of arranged triplets:

$$(a1,b1,c1) \oplus (a2,b2,c2)=(a1+a2,b1+b2,c1+c2) \quad (2)$$

$$(a1,b1,c1) \quad (a2,b2,c2)=(a1-a2,b1-b2,c1-c2) \quad (3)$$

$$K \quad (a,b,c)=(Ka,Kb,Kc) \quad (4)$$

The concept of linguistic variable is very useful for dealing with situations that are too complex or ill-defined to describe understandably conventional quantitative expressions (Deng Yong and Chan, 2011). Each of these variables can be associated with affiliate function. In this paper, we used expressions in terms of the degree of achievement of the observed criteria: “unrealized”, “poorly realized”, “medium realized”, “very realized”, “and fully realized”. Experts were asked to give their opinion and each linguistic variable is demonstrate triangular fuzzy numbers in the range of 0 to 5 In order to provide a more objective evaluation of the fuzzy assessment, there was a aggregation of linguistic variables LV_{ij} alternative A_i for criterion C_j based on the expression:

$$LV_{ij} = (a,b,c) = \left(\frac{1}{n}\right) \otimes (LV_{ij}^1 \oplus LV_{ij}^2 \oplus ... LV_{ij}^n) = \left(\frac{\sum_{i=1}^{n} a_i + \sum_{i}^{n} b_i + \sum_{i}^{n} c_i}{n} \right). \quad (5)$$

Equation (5) shows that the average performance can be expressed in the form of a new triangular fuzzy numbers (Buckely 1985). As the result of the synthesis is a new fuzzy number, it is necessary to realize defuzzification (a technique of converting fuzzy numbers into solid real numbers). Defuzzification procedure is positioning the BNP (Best Nonfuzzy Performance) value. Many defuzzification techniques are available (Zimmermann, 1991), but the common defuzzification methods include the center of area, first of maximums, last of maximums, and middle of maximums (MoM). This paper used Center of Area method taking into account ease of use, where defuzzification value can be obtained:

$$BNP_{ij} = (c_{ij} - a_{ij}) + (c_{ij} - a_{ij}) / 3 + a_{ij} \qquad \forall i, j. \quad (6)$$

3.4 TOPSIS

Technique for order performance by similarity to ideal solution (TOPSIS), was first developed by Hwang and Yoon (1981) for solving a MCDM problem. It is based on the selection of the optimal alternative that is closest to the positive ideal solution and farthest from the negative ideal solution. An ideal solution is composed of all best values attainable of criteria, whereas a negative ideal solution is made up of all worst values attainable of criteria. Take the objective space of the two criteria as example which is indicated in (Figure 3.), A^+ and A^- are, respectively, the ideal solution and negative ideal solution, and observation A_1 is shorter in distance in regard to the ideal solution (A^+) and negative ideal solution (A^-) than A_2. As a matter of fact, the ups and downs of these two observations regarding to ideal solutions cannot be compared because there exists some tradeoff between the ups and downs. However, TOPSIS can help resolving this problem because it has defined such „relative closeness" so as to consider and correlate, as a whole, the distance to the ideal solution and the negative ideal solution.

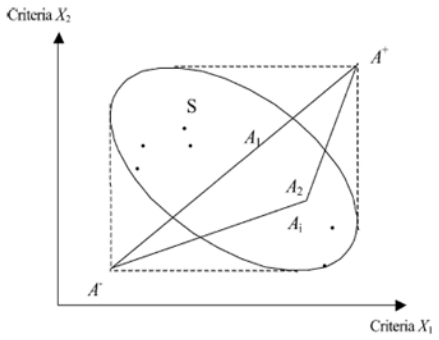

Figure 3: Position A1 and A2 with respect to the ideal and the negative ideal solution

The process of calculation is carried out through the following stages:

- forming normalized performance matrix,
- forming weighted normalized matrix by multiplying weight coefficients and criteria:

$$V_{ij} = w_{ij} \times r_{ij} \qquad \forall i, j. \tag{7}$$

where w_{ij} is the weight of criterion j, and r_{ij} normalized value of the j-th performance criteria for the i-th alternative;

- determining the ideal solution:

$$A^+ = \left\{ \max V_{ij} \middle| j \in J \right), \left(\min V_{ij} \middle| j \in J' \right), i = 1,2,\ldots,m \right\} \tag{8}$$

- determining the ideal negative solution:

$$A^- = \left\{ \min V_{ij} \middle| j \in J \right), \left(\max V_{ij} \middle| j \in J' \right), i = 1,2,\ldots,m \right\} \tag{9}$$

where J is associated with the benefits of the criteria, and J 'from the cost criterion,

- calculating the distance between the ideal and the negative ideal solution of each alternative.

$$S_i^+ = \sqrt{\sum_{j=1}^{n} \left(V_{ij} - V_j^+ \right)^2} \qquad i = 1,2,\ldots,n, \tag{10}$$

$$S_i^- = \sqrt{\sum_{j=1}^{n} \left(V_{ij} - V_j^- \right)^2} \qquad i = 1,2,\ldots,n, \tag{11}$$

- calculating the relative proximity of each alternative to the ideal solution:

$$R_i = \frac{S_i^-}{S_i^+ + S_i^-} \qquad i = 1,2,\ldots,n, \tag{12}$$

- ranking of alternatives in descending order R_i.

4. METHOD OF SELECTION OF PROPOSED MODELS ON A PARTICULAR AREA

Taking into account the diversity of various regions within one country, there is a need for special consideration of each of them in terms of defining the method of financing the universal service. Therefore it is necessary to observe the territorial units established by NUTS 2 standard. In each of these units observed, depending on the characteristics of the postal market and the aim sought to be achieved by the regulatory body, weights of the criteria are set for the evaluation of certain alternatives of financing the Universal Service. The determination of these weights is carried out by AHP method. The core of the system is a performance matrix for specific criteria by proposed alternative models of financing. Values of matrices are obtained on the basis of questionnaires filled by experts for financing models. The survey was conducted over 10 experts. The experts were asked to assess the realization of each criterion, via linguistic variables which are expressed by triangular fuzzy numbers in the range of 0-5. The possible values of these variables are: “unrealized”, “poorly realized”, “medium realized”, “very realized”, “and fully realized”. From the obtained fuzzy numbers, by applying BNP, we get defuzzicated values. Ranking of values is made by implementing TOPSIS, and then the selection of the financing model most similar to the ideal solution is made.

We will observe the territory of the Republic of Serbia. In accordance with the NUTS 2 standardization and looking at the highest concentration of competition we decided to consider the statistical region of Belgrade. Looking at the characteristics of the observed area weight coefficients of the criteria defined on the basis of AHP are: fair competition – 0.15, social equality - 0.1, compliance with state aid rules - 0.1, transparency - 0.1, proportionality - 0.1, feasibility - 0.05, reliability - 0.05, allocative efficiency - 0.1, productive efficiency - 0.1, dynamic efficiency - 0.1. Results of testing experts analyzed on the basis of equation (5) are given in Table 1. After measuring performance in the form of fuzzy numbers, made their defuzzification using the Center of Area (equation (6), so that it could be applied TOPSIS the procedure of ranking (Table 3).

Table 1: Fuzzy performance of financing model

criteria / alternatives	Reserved area	Compensation fund	“pay or play”	Additional funding
Fair competition	(1.81, 2.21, 2.47)	(3.90, 4.23, 4.58)	(3.52, 4.29, 4.7)	(3.91, 4.18, 4.24)
Social equality	(3.63, 3.93, 4.24)	(3.09, 4.06, 4.75)	(4.72, 4.84, 4.95)	(4.54, 4.63, 4.69)
Compliance with state aid rules	(4.75, 4.91, 4.94)	(4.49, 4.87, 4.96)	(4.15, 4.53, 4.76)	(3.97, 4.01, 4.06)
Transparency	(2.95, 3.12, 3.72)	(1.48, 2.39, 2.54)	(2.8, 2.94, 3.03)	(2.04, 2.9, 3.19)
Proportionality	(2.42, 2.87, 3.18)	(1.91, 2.40, 2.57)	(2.79, 3.16, 3.22)	(2.95, 3.37, 3.5)
Feasibility	(4.57, 4.68, 4.73)	(2.03, 3.39, 3.57)	(2.84, 3.22, 3.91)	(3.93, 4.27, 4.40)
Reliability	(4.67, 4.72, 4.87)	(2.75, 3.24, 3.77)	(2.74, 3.08, 3.31)	(3.39, 3.92, 4.12)
Allocative efficiency	(2.62, 3.31, 3.55)	(2.17, 2.89, 3.12)	(3.7, 4.34, 4.6)	(3.03, 3.48, 4.18)
Productive efficiency	(2.27, 3.20, 3.69)	(2.04, 2.48, 2.62)	(4.09, 4.38, 4.71)	(4.35, 4.43, 4.82)
Dynamic efficiency	(1.69, 2.12, 2.48)	(1.31, 2.40, 2.71)	(4.42, 4.68, 4.95)	(4.05, 4.21, 4.44)

Table 2: Overall performance measures of financing models

criteria / alternatives	Reserved area	Compensation fund	“pay or play”	Additional funding
Fair competition	2.13	4.24	4.17	4.11
Social equality	3.94	3.97	4.84	4.62
Compliance with state aid rules	4.87	4.77	4.48	4.01
Transparency	3.26	2.14	2.92	2.71
Proportionality	2.82	2.29	3.06	3.27
Feasibility	4.66	3.00	3.32	4.20
Reliability	4.75	3.25	3.04	3.81
Allocative efficiency	3.17	2.73	4.21	3.56
Productive efficiency	3.05	2.38	4.39	4.53
Dynamic efficiency	2.10	2.14	4.68	4.23

Table 3: Ranking of financing models

Rang	Model	The similarity to the ideal solution
1	“pay or play”	0.8047
2	Additional funding	0.7655
3	Compensation fund	0.4144
4	Reserved area	0.3299

5. CONCLUSION

The problem of financing the universal postal service captures the attention of the postal sector for many years. One of the basic principles underlying the role of postal services is facing the issue of sustainability, as profitability of postal system is becoming more and more basic benchmark in successful functioning. Past experience has shown that this business segment is unattractive for operators that have emerged from the market liberalization, so public postal operators have taken this responsibility. The reason for this may be sought in the financing model that is administered on the whole territory of the state.

Different characteristics of each region within the state should be considered in order to establish appropriate mechanisms to encourage other operators to take an active role in the provision of universal service. On the model that we presented, we came to the conclusion that the most appropriate model for the observed region is “pay or play”, while a reserved area that is currently in force took the last place in relation to the considered models of financing.

Abstract: *This study examines the comparative performance of Simple Moving Average (SMA), Linear Weighted Moving Average (LWMA), Exponential Moving Average (EMA) and Kaufman Adaptive Moving Average (KAMA). These moving averages are incorporated into the basic trend following trading system and tested on the BELEX15 stock components. Testing different values of the lag parameter showed that increase in its value leads to the increase in the profitability of trading strategy. Unexpectedly, LWMA performed the best, while KAMA performed the worst.*

Keywords*: Technical analysis; moving average; trading system.*

1. INTRODUCTION

With the development of technology, computer aided and technical trading systems become widely used by professional traders worldwide. Nowadays, there are numerous automatic trading systems in financial markets and many of them are using some kind of technical trading. The basics of technical trading are set by academicians in the sixties when Alexander (1964) and Fama & Blume (1966) dispute the ability of technical trading systems to produce excess returns. This opened wide academic discussions with the participation of many authors. Later studies, including Brock et al. (1992), LeBaron (1999), Ellis & Parbery (2005) and Metghalchi et al. (2012) and many others demonstrate various trading systems capable of outperforming the market.

This study examines the comparative performance of Simple Moving Average (SMA), Linear Weighted Moving Average (LWMA), Exponential Moving Average (EMA) and Kaufman Adaptive Moving Average (KAMA) on BELEX15 market index components. The observed moving averages are used as the models of trend within a basic trend following system. Different values of the lag parameter are tested for all four types of moving averages. Return on investment (ROI) is used to measure profitability of the trading system. The proposed trading system is run on all BELEX15 stock components and resulting ROI values are averaged to get overall results for each of the observed moving averages. These results are benchmarked to the “Buy and hold” strategy.

The remainder of the paper is structured as follows. Section 2 reviews moving average models used in this paper. In Section 3 the basic trend following trading system is presented. It is used for the purpose of testing moving average models from Section 2. Section 4 gives a detailed description of data and experimental settings. Further, the results are presented along with the corresponding discussion. Finally, Section 5 concludes the paper.

2. MOVING AVERAGES

There are several purposes in regard to trading that Moving Averages (MA) serve. A Moving Average is a good way to gauge momentum as well as to confirm trends, and define areas of support and resistance. Also, Moving Averages form the basis of several other well-known technical analysis tools such as Bollinger Bands and the MACD. One of the most important roles that the Moving Averages play in trading is a form of lagging (or reactive) indicator, which plots average asset prices over time. The main idea is to smooth the curve of points given by the close prices.

There are lots of types of Moving Averages which all take the same basic premise and add a variation. Most notable are the Simple Moving Average (SMA), which is the simple average of a security over a defined number of time periods, and the exponential moving average (EMA), which gives bigger weight to more recent prices exponentially. Also, widely used moving averages are the Linear Weighted Moving Average (LWMA), which gives bigger weight to more recent prices linearly, and Kaufman Adaptive Moving Average

(KAMA), which was created by Perry J. Kaufman (1995) and takes into consideration not only the direction, but also the market volatility.

2.1 The Simple Moving Average (SMA)

The Simple Moving Average (SMA) is arguably one of the oldest and the most popular of all technical indicators. Its rule is one of the most widely used technical trading rules by investors to analyze the stock and eventually strive to outperform the stock market. Technically, SMA is represented by the equation:

$$SMA_n = \frac{1}{n} \sum_{t=k-n+1}^{k} P_t \tag{1}$$

In equation 1 the number of periods included in the average is marked as argument n, the relative position of the period currently being considered within the total number of periods is marked as argument k, and P_t is the price at time t. SMA is also known as just “moving average”, “weighted moving average (WMA)” or as an “arithmetic average” because each price in the data series is equally weighted. In other words, Simple Moving Average (SMA) is calculated when you divide the sum of the prices for the past n days by the number of days (n days). There are no weighting factors applied to any of the data points, but one of the possibilities for improving SMA is weighting more heavily the market’s most recent behavior and so incurred other moving averages.

2.2 The Linear Weighted Moving Average (LWMA)

Linear Weighted Moving Average (LWMA) is used to smooth out price and volume fluctuations ("noise") that can confuse interpretation to emphasize the direction of a trend in a very specific way. Similarly to the EMA, the main idea of the Linear Weighted Moving Average (LWMA) is to apply more weight to the most recent price data, but there is a difference in weighting prices. In LWMA there is a less contrast between the weighting of earlier and more recent prices than in the EMA. The popularity of this moving average has been diminished by the exponential moving average, but none the less it still proves to be very useful. LWMA is given by the formula:

$$LWMA_k = \frac{\sum_{j=1}^{n} P_{k-n+j} \cdot j}{\sum_{j=1}^{n} j} \tag{4}$$

where k is the relative position of the period currently being considered within the total number of periods, n is the number of periods included in the average, $LWMA_k$ is the value of Linear Weighted Moving Average (LWMA) at time k, P_{k-n+j} is the price at time k-n+j. From this formula we can see that the oldest price included in the calculation receives a weighting of 1, the next oldest price receives a weighting of 2, and the next oldest price receives a weighting of 3, all the way up to the most recent price which receives a weighting of n (n is a number of periods).

The downside to using a weighted moving average is that the specific resulting average line could make it more difficult to discern a market trend from a fluctuation. For this reason, some traders prefer to place both a SMA and a LWMA on the same price chart. Though the linear WMA is more sensitive to trend changes than the simple moving average, it is less sensitive than the exponential moving average. Some traders find this method more relevant for trend determination, especially in a fast-moving market. LWMA is also called just “Weighted Moving Average (WMA)”.

2.3 The Exponential Moving Average (EMA)

As well as for all moving averages, the basis for Exponential Moving Average (EMA) is Simple Moving Average (SMA). There are two main differences between EMA and SMA:

- calculation method,
- the way that prices are weighted.

Calculation of the EMA is a little more complex than the calculation of the SMA, but in the age of computers it is facilitated considerably. EMA is represented by the equation:

$$EMA_k = P_k \cdot p + EMA_{k-1} \cdot (1 - p) \tag{2}$$

where k is the relative position of the period currently being considered within the total number of periods, $EMA_k$and EMA_{k-1} are the values of Exponential Moving Average at time k and k-1, respectively, P_k is the price at time k, and p is weighting multiplier.

For the construction of the EMA we have to calculate weighted multiplier p given by the formula:

$$p = \frac{2}{n+1} \tag{3}$$

where n is the number of periods included in the average. Weighting multiplier p is also known as “smoothing factor”, and limiting values of weighting multiplier are $0 < p < 1$.

Obviously, EMA has to start somewhere and for calculation of the first EMA (EMA_{n-1}, where n is the number of periods) we can use price value at that time, simple moving average, some other type of moving average, etc. According to Boylan and Johnston (2003), the best solution is to use an adequate SMA (SMA_{n-1}). That's because EMA needs a previous value and thus we need to start somewhere.

Essentially, EMA is a weighted moving average. The theory is that more recent prices are considered to be more important than older prices. So, the weighting is such that the recent days' prices are given more weight than older prices and that’s the reason why EMA reacts faster to recent price changes than a SMA. The Exponential Moving Average (EMA) is also known as "Exponentially Weighted Moving Average (EWMA)".

2.4 Kaufman Adaptive Moving Average (KAMA)

One of the most used types of all adaptive moving averages is Kaufman Adaptive Moving Average (KAMA), which was created by Perry Kaufman (1995) and first presented in his book Smarter Trading. He wanted to overcome two key shortcomings of different smoothing algorithms for financial time series:

- accidental price leaps can result in the appearance of false trend signals,
- smoothing leads to the unavoidable lag in predicting the trends.

Adaptive Moving Average (KAMA) is represented by the equation:

$$KAMA_t = P_t \cdot C_t + KAMA_{t-1}(1 - C_t). \tag{5}$$

The formula for KAMA is similar to the formula for the EMA, but the difference is that instead of weighting multiplier p Kaufman proposed smoothing constant C_t . In equation 5 the current (at time t) value of the KAMA is marked as argument $KAMA_t$, value of the KAMA in the previous period (at time t-1) is marked as argument $KAMA_{t-1}$, P_t is the price at time t, and C_t is smoothing constant.

Smoothing constant C_t is calculated every day as:

$$C_t = sc \cdot sc = (sc)^2 \tag{6}$$

where sc is scaled smoothing constant, calculated as:

$$sc = ER_t \cdot fast\ sc + (1 - ER_t) \cdot slow\ sc. \tag{7}$$

In equation 7 fast sc and slow sc are represented by the same equation as weighting multiplier p in equation 3. Kaufman (1995) realized that weighting multiplier p should be adjusted both for fast and slow trend speed, and because of that he introduced fast and slow smoothing constants. He suggested that the number of days in the fastest and slowest applicable Simple Moving Average should be 2 and 30 days, respectively. For that matter, fast and slow smoothing constants will be 0.6667 and 0.0645, respectively. Of course, these parameters are usually optimized and adapted to the market under study.

ER_t given in equation 7 is Efficiency Ratio at time t. Kaufman (1995) wanted to make a mechanism that senses market speed and “chopines” and gives feedback to the moving average. Based on this moving average adjust the speed of its smoothing. Efficiency Ratio is represented by the equation:

$$ER_t = \frac{D_t}{V_t} \tag{8}$$

where ER_t is Efficiency Ratio at time t, D_t is momentum or the n-day change in price, and V_t is volatility or the sum of the absolute value of daily price changes. D_t is calculated as:

$$D_t = P_t - P_{t-n} \tag{9}$$

where P_t and P_{t-n} are prices at time t, and t-n, respectively. V_t is calculated as:

$$V_t = \sum_{i=1}^{n} |P_t - P_{t-i}| \tag{10}$$

where P_t and P_{t-i} Are prices at time t, and t-i, respectively.

In other words, Efficiency Ratio measures the strength of the trend. ER divides the net price movement by the total price movement. The first and one of the most important steps in the construction of the KAMA is an estimation of the Efficiency Ratio. The limiting values of the efficiency ratio are $0 \leq ER \leq 1$. When markets are very noisy for the current amount of direction and movements of the market are in a larger range $ER \to 0$. The opposite of that, when prices are highly directional and changing of price contain relatively little noise $ER \to 1$.

Essence of trend-following methods adapt to different market conditions, and that is the starting idea of all adaptive moving averages. KAMA seeks to adapt its behavior, according to the combination of market direction and speed by use of the Efficiency Ratio (ER). Kaufman (1995) noticed four characteristic types of market for research and the development of KAMA: runaway markets (with very fast speeds), fast markets (with fast speeds), congested markets (with very slow speeds) and middle-trends with some volatility (slightly faster sometimes). He based his adaptive moving average on a theory that slow (i.e. Long-length) moving average will be preferred when markets are ranging and fast (i.e. Short-length) will be preferred when market prices are trending.

3. TRADING SYSTEM

In all presented moving averages common parameter is price P, but it is not specified which price. For parameter price can be used any of open, high, low and close price or some kind of combination of them. In this research, we decided to use close price because, in this context, close price is the best solution for including most of the distributions and corporate actions that occurred at any time prior to the next day's open.

The length of the moving average is very important parameter suitable for discussion. It depends on the analytical objectives. For short-term trends and trading short moving averages (5-20 periods) are the best, for medium-term trends better are longer moving averages that might extend 20-60 periods, and long-term investors would opt moving averages with 100 or more periods. It is widely known that some moving average lengths are more popular than others. One of the most popular short-term moving averages is a 10-day moving average. The 50-day moving average is quite popular for the medium-term trend. Perchance one of the most popular moving averages is the 200-day moving average which is long-term moving average, because of its length. It is not new to combine shorter and longer moving average and many chartists use the 50-day and 200-day moving averages together. Length of moving average is, usually, optimized for a specific market.

There are a lot of strategies based on the moving average. One of the most popular is connected to the crossover because the crossover is the most basic type of signal and is favored among many traders because it removes all emotion. Regardless of that, we decided to use another moving average strategy because of the type of our research. Since our research is based on comparative analysis of different types of moving averages, we decided to use the same strategy for all presented moving averages:

- Open long position if moving average is rising
- Close long position if the moving average is dropping

The main idea of this research is to compare different moving averages using the same strategy and we consciously decided to use this, tentatively, simple strategy. Also, we decided to use a control strategy “Buy and hold” where an investor buys stocks and holds them until the end of the time series.

4. RESULTS AND DISCUSSION

In this section we will describe data used for research and experimental conditions and settings. After that, we will present the results that we obtained and discussion of the results.

4.1 Data

Our target market is the Belgrade Stock Exchange (BSE). BSE was established in 1894. and by many criteria is behind larger stock markets. Regardless of that, according to the latest ongoings Belgrade Stock Exchange might have a promising future. We consider a set of 14 major stocks of the Belgrade Stock Exchange, which make the most important index of the Belgrade Stock Exchange called BELEX15 (AERO, AIKB, ALFA, ENHL, FITO, GMON, IMLK, JESV, KMBN, MTLC, NIIS, SJPT, TGAS, VZAS). Index basket constituents on the last revision day 31.12.2013. Data used for research purposes includes volume, open, high, low and close price of mentioned stocks.

Table 1: Data used for research

Symbol	Company	Period start	Period end	Number of observations
AERO	Aerodrom Nikola Tesla a.d., Beograd	7.2.2011	31.12.2013	733
AIKB	AIK banka a.d., Niš	9.1.2006	31.12.2013	2014
ALFA	Alfa plam a.d., Vranje	9.1.2006	31.12.2013	2014
ENHL	Energoprojekt holding a.d., Beograd	9.1.2006	31.12.2013	2014
FITO	Galenika Fitofarmacija a.d., Zemun	9.1.2006	31.12.2013	2009
GMON	Goša montaža a.d., Velika Plana	7.5.2012	31.12.2013	422
IMLK	Imlek a.d., Beograd	9.1.2006	31.12.2013	2014
JESV	Jedinstvo a.d., Sevojno	10.8.2009	31.12.2013	1111
KMBN	Komercijalna banka a.d., Beograd	18.6.2006	31.12.2013	1836
MTLC	Metalac a.d., Gornji Milanovac	9.1.2006	31.12.2013	2014
NIIS	NIS a.d., Novi Sad	30.8.2010	31.12.2013	846
SJPT	Soja protein a.d., Bečej	9.1.2006	31.12.2013	2009
TGAS	Messer Tehnogas a.d., Beograd	9.1.2006	31.12.2013	2014
VZAS	Veterinarski zavod Subotica a.d., Subotica	28.2.2007	31.12.2013	1730

In Table 1, we present all stocks used for research with their basic information including company name, period start, period end and the number of observations.

4.2 Experimental Settings

Developed system has some experimental settings and conditions. The value of the of commission is set at 0,0065 , which is the actual commission on the Belgrade Stock Exchange (BSE), and the value of starting account is 1 000 000 RSD. Purchase transactions can be done once a day at the opening of trading at a price that was achieved in the opening. It is assumed that any volume that our system is able to trade is realizable at specified prices. If volume is zero, i.e. if there is no trade, our trading system does not do anything. Also, one of the restrictions is that shorting stocks is not possible.

4.3 Results and Discussion

For all mentioned moving averages number of periods included in the averages is optimized. Limiting values of the number of periods included in averages are 2 and 100 with intermediate steps of 1. Herewith we would like to include all three main types of moving averages (short-term, medium-term and long-term).

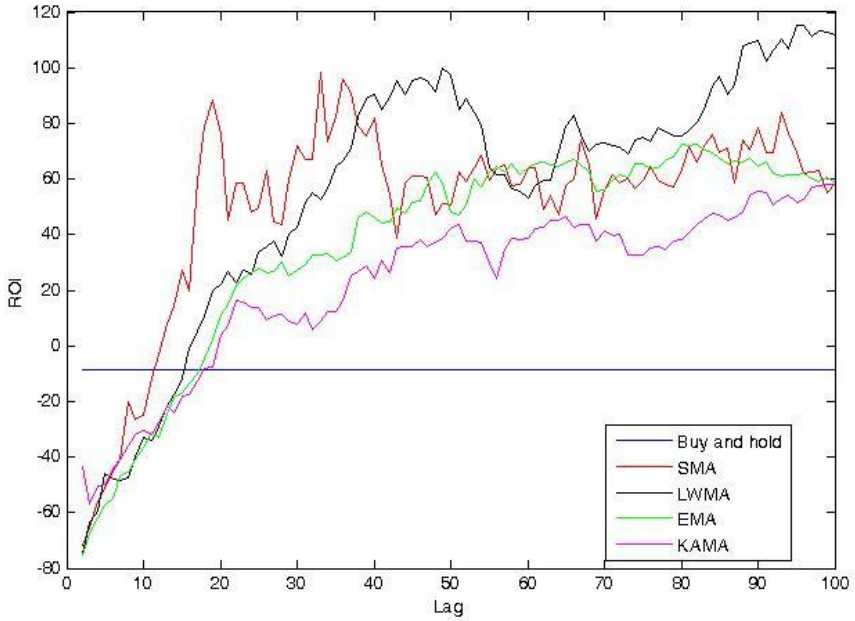

Figure 1: Comparison of moving averages with respect to average profitability (BELEX15)

In Figure 1 we present changing ROI depending on the lag, where ROI is return on investments and lag is optimized number of periods included in averages. ROI is, also, used to evaluate the efficiency of an investment and is given by the formula:

$$ROI = \frac{net\ profit}{investment} \cdot 100\% \tag{11}$$

We show ROI of all the moving averages compared with the ROI of control strategy “Buy and hold”. Generally, in this research Return on investment (ROI) is used as a ranking criterion.

It shows that the standard set of MA rules (SMA, LWMA, EMA, KAMA) performs poorly on short-term trends (length up to approximately 10) and it was expected. The main reason for this is commission, which is an advantage for “Buy and hold” strategy, because in that strategy, there is no trading until the end of the time series. Also, the average ROI of “Buy and hold” strategy is -8,398 and in short-term trends, average ROI for our moving averages is negative. For longer short-term trends with length in the range of approximately 10 and 20 average ROI of all four moving averages exceeds ROI of “Buy and hold” strategy and, soon, become positive. That happens to SMA, LWMA, EMA and KAMA, respectively. On medium-term trends, with length in the range of approximately 20 and 40, the biggest average ROI is for SMA and after that average ROI for SMA decreases rapidly to the middle, in the range of approximately 40 and 70, where it stays to the end of the time series. As regards of LWMA, its average ROI is in the middle, in the range of 20 and 40, and after that is mainly the best except when the range of lag is approximately 55 and 65. For LWMA profit has tendency to increase with increasing the lag. For lag higher than 20, profit for EMA is mainly in the middle between the profit for SMA and LWMA. Surprisingly, the average ROI for KAMA is the worst of all four moving averages, even it shows an upward tendency with increasing the lag. An interesting fact is that SMA, EMA and KAMA are converging together for lag higher than 95.

Two most attractive stocks on BSE are NIIS and ENHL. Ad hoc predictions were that we will get interesting results for these two actions and it turned out to be true. NIS (stock symbol: NIIS; English: Petroleum Industry of Serbia) is a Serbian multinational oil and gas company headquartered in Novi Sad, Serbia. NIS held a monopoly on all oil imports in Serbia until 2011.In Figure 2 we present close price for stock NIIS, as well as average ROI for all four types of moving averages depending on the lag, for the same stock.

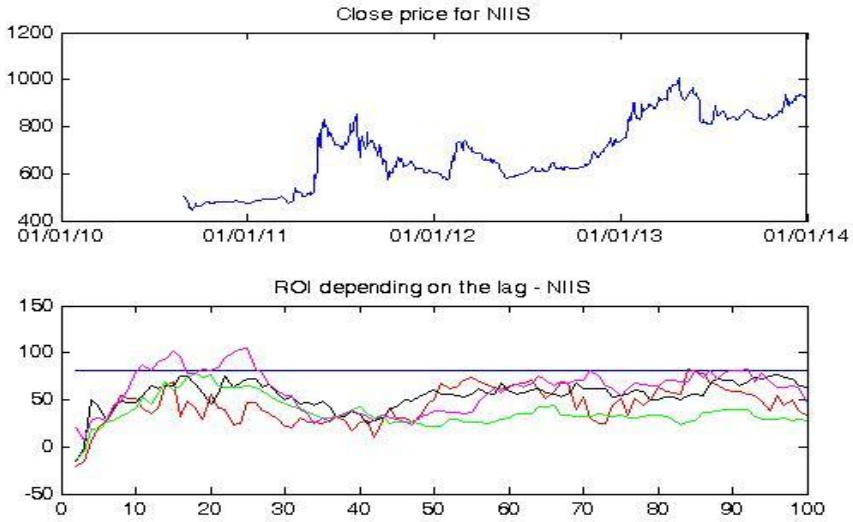

Figure 2: Comparison of moving averages with respect to average profitability (NIIS)

What is characteristic for this stock is the very high average ROI of "Buy and hold" strategy. One of the main reasons for this is, generally, upward trend of this stock. NIIS is the most liquid stock on the Belgrade Stock Exchange and has a strongly trended bull market. Also, very interesting are the results for KAMA for trends with length in the range of approximately 10 and 25. In that range KAMA has the best average ROI, excluding the two falls. Kaufman (1995) suggested KAMA with a length of 21, which results are good in this case, but not so good as KAMA with a length of 15 and KAMA with a length of 25. Except KAMA with mentioned lengths, all other moving averages with different lengths, mostly, has a lesser average ROI. KAMA as, conditionally speaking, "smarter" moving average gives better results on stocks such as NIIS.

Energoprojekt holding (full legal name: Energoprojekt holding a.d. Beograd) is a Serbian construction company founded in 1951 in Belgrade, Serbia. It enters into the composition of BELEX15 and BELEXline, the two main indices of the Belgrade Stock Exchange. This stock is very interesting for the investors and one of the highly liquid stocks. In Figure 3 we present close price for stock ENHL, as well as average ROI for all four types of moving averages depending on the lag, for the same stock.

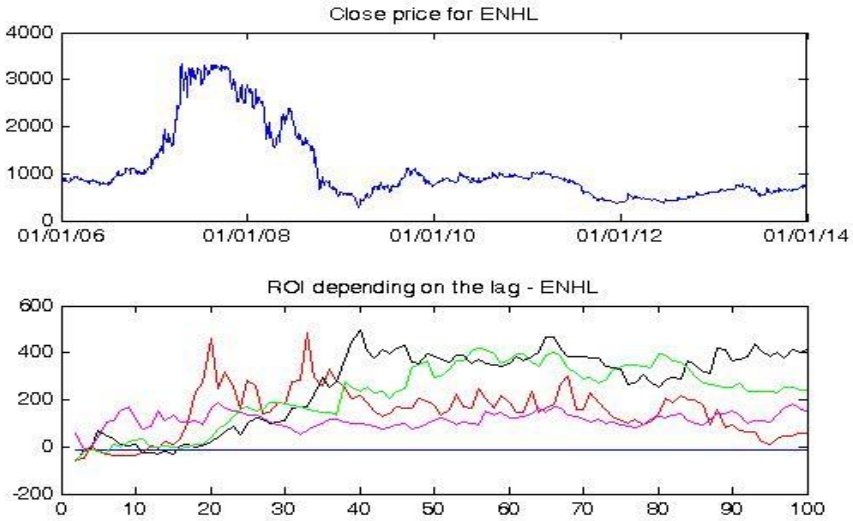

Figure 3: Comparison of moving averages with respect to average profitability (ENHL)

As we can see from the graphs, there is a very low average ROI of "Buy and hold" strategy, which is negative. This is, mostly, because of the influence of the financial crisis. Except for smaller lengths, results of "Buy and hold" strategy are the worst from all four moving averages. The best results are for SMA with a length of 20, SMA, with a length of 33, and for LWMA with a length of 40. In the middle-term trends, principally, SMA dominates. In trends with length longer than 40, there is "battle" between LWMA and EMA in which LWMA dominates. KAMA for trends with length longer than 10, has small oscillations.

5. CONCLUSION

In this study, we have compared four types of moving averages – Simple Moving Average (SMA), Linear Weighted Moving Average (LWMA), Exponential Moving Average (EMA) and Kaufman Adaptive Moving Average (KAMA). To compare the averages, we use them as models of trends within the basic trend following trading strategy. Trading strategy is tested on most liquid equities from Belgrade Stock Exchange (BSE). The selected equities represent the components of the BELEX15 market index.

Our study has shown that, on overall, basic trend following strategies can be profitable and can give better results than “Buy and hold” strategy. We found that increase in the MA lag parameter is followed by the increase in the profitability of trading strategy. The overall results show that LWMA outperforms other moving averages. Unexpectedly, KAMA performed the worst. Further, the resulting ROI for SMA, EMA and KAMA are converging for large values of lag parameter.

Abstract: *Benford`s Law is one of the most common technique for detecting anomalies and irregularities in accounting data. Its purpose is to analyses patterns of digits in numbers sets. Benford`s Law explain frequency for each digits of numbers in log-normally distributed data. The subject of this research is to determine does some of accounting positions (fixed assets and net result in absolute numbers available on the site of the Agency of legal entities) in official financial reports of 847 big Serbian companies which perform business in 2012, have behaviour in accordance with Benford's Law. By applience of Audit Command Language (ACL) it is confirmed main hypothesis of the research that Benford's Law can be applied on financial reports of Serbian companies, i.e. can discover fraud in financial results. The results suggest that data of fixed assets reported in Serbian company's financial statements do not deviate from Benford`s Law and it is proof that data are presented fairly. In contrast, data of profits/losses showed a deviation, which indicated the potential existence of fraud in the income statement.*

Keywords: *Benford`s Law, ACL, accounting, fraud, fixed asset, net result, management*

1. INTRODUCTION

In order to increase profitability and market share many companies expanded their activities on other industries by establishing or acquiring other companies in the country or abroad. Globalization has had impact on increase of international trade, but they have introduced a lot of problems connected to the book keeping and accounting. Different taxes on profit and other important items of financial reports resulted in favour of headquarter (profit is booked there) while expenses were booked in financial reports of daughter companies (majority costs belong to the mother company). Profit has been moved from country to country in accordance with headquarters' need.

At the same time, internationalism raised question of financial report validity. Different accounting regulation had made problems in monitoring and comparing daughters' businesses. In practice it was possible that there were different book keeping in two countries where one internationally active company was present.

Introduction of International standards of financial reporting (IFRS) was good step in solving the described problem. It uniformed and standardized regulation for creating and booking financial reports. Serbia implemented IFRS in 2004.

However, IFRS didn't solve all problems, because standards allow accounting judgement (Milojevic and Terzic, 2013). The fact is that IFRS requires intensively implementation of judgment which can have impact on bigger differences due comparison of financial reports of group of connected companies in different countries. Rules can be explained on different ways which can resulted in different results in appliance of the same rule. However, appliance of IFRS allows companies to prepare and analysed financial reports by applying the same basis all over the world.

The subject of this research is to determine does some of accounting positions in official financial reports of Serbian companies have behaviour in accordance with Benford's Law. The aim of the research is to check

[1] This research paper was part of the research project "Advancing Serbia's Competitiveness n the Process of EU Accession", No. 47028, during the period 2011-2015, financed by the Serbian Ministry of Science and Technological Development.

quality and validity of chosen accounting positions in order to make proper conclusion. The main hypothesis of paper research is: Benford's Law can be applied on financial reports of Serbian companies.

2. LITERATURY REVIEW

Phenomena known as Benford's Law was discovered by NewCobe in 1881, when he noticed that smaller digits at the beginning have higher frequent of appearance than bigger. Fifty years later, in 1938, Benford confirmed this regularity (Hill, 1998). Moreover, Benford expended analysis with determine frequency of appearance of the first digit in different data: length of the river, article numbers, demographical statistics etc. Digits results of those data were near to logarithms distribution.

Nigrini, used to analyse Benford's Law, and he stressed the importance of it in controlling data i.e. discovering fraud or mistake (Nigrini, 1996). Benford's Law is used to determine normal frequency of repeating some number in the data pool (Nigrini, 1999). This is silent confirmation that some pool of accounting data or number of voices on election or data in any experiment which isn't enough in accordance with Benford's Law, can be result of manipulation or mistake in data.

Benford's distribution is the only distribution of the first important digits which remains the same with the scale's change i.e. it is the same when the data is converted from one currency into another currency (Diekman and Ben, 2010). Pool of data has the higher probability to be under Benford's Law if the data comes from more various distributions. Engel confirmed that Greek's debt crisis could be predicted by digit analyses of euro stat data (provided by the Greek Government). He thinks that Benford's Law has full appliance in practice in this case (Engel, 2010).

There is a wide range of literature connected to the appliance of Benford's Law in accounting and auditing. For example in accounting, Carlslaw (1988), Kinnuen and Koskela (2003) and Van Caneghem (2002) did researches on "cosmetic profit management" and frauds. They confirmed that there are bases for suspicions on manipulation on chosen sample of companies, which were subject of analysis. Moller applied Benford's Law in auditing and tax auditing (Moller, 2009(.

Carlslaw did research in accounting filed on financial reports of New Zeeland companies in 1988, and he confirmed and documented their practice of profit management in line with Benford's Law. Accordingly, profitable companies expressed higher (lower) frequency of appliance of 0 (9) as second digit in profit. This shows that those companies manipulated with their profit where the second digit was higher than the first in order to increase the first digit (Carlslaw, 1988).

Benford's Law allows auditors to get information about probable frequency of appearance of determined digit in data. It helps them to discover the data which can't be visible by applying traditional methods of auditing financial reports. The templates of appearance of digits can lead to imaginary digits, systematic fraud, and mistake in data or subjective way of expressing data (Nigrini, 1996).

In the first row of the first page of the paper, below the space reserved for header, you should type the paper title. Names of the authors, names of the institutions and the addresses should be typed below the paper title, as shown at this page of the instruction. In the first empty row below the address of the first author, apply style "Line" or copy/keep the line from this template. Below the paper title and names of the authors, you should write a short abstract. Below the abstract, you should write key words.

3. METHODOLOGY

The sample subjects of analyses are:

- 847 big companies which perform business in Serbia, and they are part of internationally active companies and have connected companies locally in 2012 (in accordance with Law on Accounting and Auditing).
- Following items from balance sheet and income statement: fixed assets and net result.

As it is known, appliances of fair value, moment of accepting income, cost of capitalization, write off stocks or receivables, are items with whose correction it can be influenced on company's business. In this research we implemented tool for checking the data quality in terms of their surety and originality. In the case when original data is behaviour in accordance with Benford's Law, replacement of correct with imaginary data leads to discrepancy with the Law (Benford, 1938).

Authors decided to analyse:

- Fixed assets because companies were obliged to correct value of own assets with market value in accordance with IFRS. So, we authors were interested did companies do it on right way or not i.e. was there suspicion that Serbian companies expressed on false way value of own fixed assets.
- Net result (profit or loss) because this item is subject of manipulation and hot topic for domestic and international researches. Furthermore, higher net profit increases credit potential of the company, appetite of owners and strategy for the decrease for paid tax on profit to the state.

The basis of analysis was financial reports available on site of the Agency for legal entities. In order to process easier chosen balances' items we converted them into MS Excel, and then transferred to module ACL (Audit Command Language) to check Benford's Law in Practice. Authors decided to use ACL because of following reasons: Firstly, there is significant beneficiaries' forum with higher number of visitors comparing to other auditing software. There is huge number of experts which are capable to answer on any technical or methodology problem which can be appeared. Secondly, there is huge number of beneficiaries' groups organized on regions, which are determined by technological equipment level, geographical position and way of expressing data in financial reports. Thirdly, there is enormous number of publications which cover ACL module in electronic form and published books. Finally, there are more ACL than IDEA users. So, large companies rather will employ ACL than IDEA users (Coderre, 2009).

The following formulas were applied:

A. Frequency of appearance of the first digit in accordance with following logarithmic equation:

$$F_a = \log(1+\frac{1}{10}) \qquad (1)$$

Where is n leading decimal digit which is not 0 i.e. 1, 2, 3, 4, 5, 6, 7, 8, 9.

B. Other digits

In the case of number which starts with decimal digits nz

$$F_b = \frac{log_{10}\left(1+\frac{nz+1}{nz}\right)}{log_{10}\left(\frac{n+1}{n}\right)} \qquad (2)$$

Where z can have following values 0, 1, 2, 3, 4, 5, 6, 7, 8, 9.

C. Appliance of Benford's Law on any numbers

Number which starts with decimal numbers abc … opq,

$$\log\ 1+x\ \approx\left(x-\frac{x^2}{2}+\frac{x^3}{3}-\frac{x^4}{4}+\ldots\right) \text{ Taylor's seria (3)}$$

$$\log_{10}\ 1+x\ \approx\left(x-\frac{x^2}{2}+\frac{x^3}{3}-\frac{x^4}{4}+\ldots\right)/\log(10) \text{ (4)}$$

$$F_q=\frac{\log_{10}\left(\frac{abc\ldots opq+1}{abc\ldots opq}\right)}{\log_{10}\left(\frac{abc\ldots op+1}{abc\ldots op}\right)}=\frac{\log_{10}\left(1+\frac{1}{abc\ldots opq}\right)}{\log_{10}\left(1+\frac{1}{abc\ldots op}\right)}\approx\frac{abc\ldots op}{abc\ldots opq}\to 1/10 \text{ for increasing q (5)}$$

Table 1 showed that the first digits in real time of measurement, are generally speaking, logarithmically distributed, with the highest frequency of appearance of digit 1 (30.1%) and with the lowest frequency of appearance of digit 9 (4.6%).

Table 1: Probability of appearance of digits in collected pool of numerical data in accordance with Benford's Law

Digit	**Expected Frequencies Based on Benford's Law**		
	1st place	1st place	1st place
0		0.1197	0.1018
1	0.3010	0.1139	0.1014
2	0.1761	0.1088	0.1010
3	0.1249	0.1043	0.1006
4	0.0969	0.1003	0.1002
5	0.0792	0.0967	0.9980
6	0.0670	0.0934	0.9940
7	0.0580	0.0904	0.9900
8	0.0512	0.0876	0.9860
9	0.0458	0.0850	0.983

(Source: Nigrini, 1999)

It means that probability of the first digit is decreasing with the increased of its height. Distribution of the second digit has the same trend; decreasing trend is shortening with movement of the digit position on the right in collected pool of numerical data. In the case when numbers of some pool are ranked from the smallest to the biggest, they roughly follow geometrical distribution (roughly, because Benford's pool of data of two numbers can be identical). Pool of numbers is in accordance with Benford's pool of data if fulfills minimum following three conditions:

- Pool of data has to be homoginious: population of the town, surface of the lake, value of shares, etc.
- Data doesn't have low (especially zero) and up bound.
- Data can't be in passwords, such as telephone numbers, post codes, numbers of social insurance.

A reason why those data isn't in accordance with Benford's Law is clear [5].

It is important to emphasize that this distribution is not applicable on any scope of numbers. Firstly, scope of numbers should be big enough to allow distribution of digits. Some of authors discovered that scope which consists with less than 100 items won't be in accordance with Benford's Law. Secondly, numbers shouldn't contain artificial limitations or origin [15].

Limitations of the research are connected to the fact that all: analysed companies didn't have fixed assets and net result of company's performance is expressed in absolute number.

4. RESULTS OF RESEARCH

Results of applied Benford's Law on the leading digits of value of fixed assets of 847 big companies which perform business in Serbia are presented in table 2. Leading digits are expressed from 1 to 9, their number of appearance in the sample, expected number (count) in accordance with Benford's Law, value of Z statistics, as well as lower and upper bound of tolerance.

Table 2: Frequencies of appearance of the first digits expressed in fixed assets of Serbian big companies in 2012

Leading Digits	Actual Count	Expected Count	Z stat Ratio	Lower Bound	Upper Bound
1	243	246	0.209	221	272
2	141	144	0.233	123	165
3	88	102	1.449	84	121
4	88	79	0.972	63	96
5	66	65	0.094	50	80
6	44	55	1.436	41	69
7	57	47	1.356	34	61
8	51	42	1.374	29	54
9	40	37	0.346	26	49

(Source: Authors calculations)

We can conclude that frequency of appearance of all digits on the first place of accounting item fixed assets of big Serbian companies is in accordance with Benford's Law. By appliance of 0.10 level of surety, table 2 discovers that frequency of real appearance of all digits from 1 to 9 is statistically unimportant different from expected frequency of appearance (expected count). In Serbian case, 814 companies have 1 as the first digit of value of fixed assets, which represents 29.85% of total number of analysed data. In accordance with Benferd's Law expected count is 246, which means that this discrepancy is not statistically important, which we confirmed by calculating Z statistics, i.e. lower and upper bound of discrepancy. The similar situation is with other digits and their frequency of appearance on the first place, which is the best visible in Figure 1.

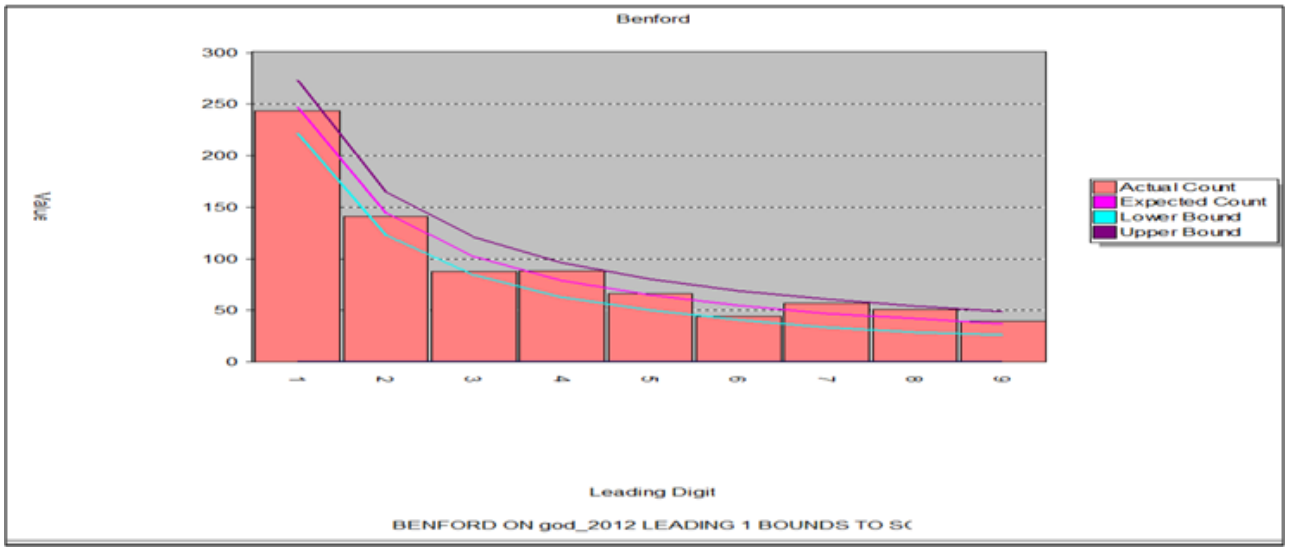

Figure 1: Frequency of appearance of the first digits in item fixed assets of big Serbian companies in 2012

On the basis of Figure1, where it is shown real and expected number of appearance of the first digit expressed in the item of fixed assets, and lower and upper bound, we can conclude that big Serbian companies expressed on the truth way value of own fixed assets. It is interesting that probability of appearance of all digits is in accordance with Benford's Law i.e. in prescribed borders. This finding is very important for auditors and state's bodies engaged on control of any company's business in Serbia.

Results of applied Benford's Law on the leading digits of value of net results of Serbian big companies, which are subject of analysis, are presented in table 3. Leading digits are expressed from 1 to 9, their number of appearance in the sample, expected number (count) in accordance with Benford's Law, value of Z statistics, as well as lower and upper bound of tolerance. In accordance with it, distribution of digits in profit of Serbian big companies is not in accordance with Benford's distribution.

Table 3: Frequency of appearance of the leading digits expressed in net result of Serbian big companies in 2012

Leading Digits	Actual Count	Expected Count	Z stat Ratio	Lower Bound	Upper Bound
1	**284**	255	1.687	229	281
2	148	149	0.392	127	171
3	83	106	2.320	87	125
4	71	82	1.229	65	99
5	70	67	0.310	52	82
6	60	57	0.384	42	71
7	45	49	0.826	36	62
8	**29**	43	1.844	31	56
9	**57**	39	2.918	27	51

(Source: Authors calculations)

Digits which aren't in accordance with Benford's distribution are 1, 8 and 9. Number 1 has the highest appearance on the first place, and it can be explained with nature of the position, which is difference between income and costs. For numbers 9 and 8 we can't find proper logical explanation. This finding is important for auditors, investors and small shareholders. For auditors, this result is important and useful in the moment of preparing and giving auditing opinion. For investors and small shareholders, it means that they should not accept financial reports without further analysis. Manipulation with achieved financial result can bring investors and small shareholders in bad position in terms of considering profitability i.e. earning situation of the company. However, we can conclude that this research should be expanded on longer period of analysis, which will cover period before and during the crisis, in order to confirm validity of prepared financial reports of Serbian companies.

Finally, we can conclude that the main hypothesis of the paper research is approved i.e. Benford's Law can be applied on financial reports of Serbian companies.

5. CONCLUSION

The main hypothesis of the paper research is approved i.e. Benford's Law can be applied on financial reports of Serbian companies. The sample consists of 847 companies which perform business in Serbia in 2012, where items subject of Benford's Law appliance are fixes assets and net result (profit or loss) expressed in absolute numbers. Authors used ACL model to determine applicability of Benford's Law on financial items of Serbian big companies.

Conclusions are following:

- Frequency of appearance of all digits on the first place of accounting item fixed assets of big Serbian companies is in accordance with Benford's Law. By appliance of 0.10 level of surety, table 2 discovers that frequency of real appearance of all digits from 1 to 9 is statistically unimportant different from expected frequency of appearance (expected count). In Serbian case, 814 companies have 1 as the first digit of value of fixed assets, which represents 29.85% of total number of analysed data. In accordance with Benferd's Law expected count is 246, which means that this discrepancy is not statistically important, which we confirmed by calculating Z statistics, i.e. lower and upper bound of discrepancy. Furthermore, we can conclude that big Serbian companies expressed on the truth way value of own fixed assets. It is interesting that probability of appearances of all digits is in accordance with Benford's Law i.e. in prescribed borders. This finding is very important for auditors and state's bodies engaged on control of any company's business in Serbia.

- Distribution of digits in profit of Serbian big companies is not in accordance with Benford's distribution. Digits which aren't in accordance with Benford's distribution are 1, 8 and 9. Numbers 1 and 9 have the highest and number 8 has the lowest appearances on the first place as result of executed research. The higher appearance of digit 1 can be explained by the character of the position, because group of companies intend to decrease payment of tax on profit. More frequent appearance of digit 9 and lower frequent appearance of digit 8 can be explained with intention of group of companies to expressed better result than it is, in order to create better picture in eyes of stakeholders of the companies. This manipulation is in accordance with human psychology, which says that it is more impressive when achieved result is 901,500,000 dinars (RSD) than 897,500,000. On the basis of calculated frequency of appearance of the first digit we can conclude that there are three group of companies in sample subject of analysis: the first one expressed truly correct results, the second group intends to express lower result in order to pay less taxes on profit, and the third group of companies intend to increase achieved net result with usage digits 8 or 9 on the second and third place in order to increase importance of the first digit. It can be said that the second and third group of companies are subject of management manipulation i.e. their plans to achieve their private aims.

  This finding is important for auditors, investors and small shareholders. For auditors, this result is important and useful in the moment of preparing and giving auditing opinion. For investors and small shareholders, it means that they should not accept financial reports without further analysis. Manipulation with achieved financial result can bring investors and small shareholders in bad position in terms of considering profitability i.e. earning situation of the company.

Limitations of the research are connected to the fact that all: analysed companies didn't have fixed assets and net result of company's performance is expressed in absolute number. Further researches will be

expanded on longer period of analysis, which will cover period before and during the crisis, in order to confirm validity of prepared financial reports of Serbian companies.

TESTING MOVING AVERAGE TRADING RULE IN CASE OF SERBIAN AND CROATIAN STOCK MARKET INDICES

Boris Radovanov[1], Aleksandra Marcikić[2]

[2] Faculty of Economics Subotica, amarcikic@ef.uns.ac.rs

Abstract: *This paper examines the Belgrade Stock Exchange Index (BELEX15) and the Zagreb Stock Exchange Index (CROBEX) with respect to simple moving average rules. Using standard statistical tests, our results indicate significant difference between trading rule profit mean and unconditional profit mean in both observed stock markets. Also, the implementation of various moving average trading strategies drives to significant difference between average buy returns and average sell returns. Although applied moving average trading rule strategies mainly generate more losing trades than winning trades, most of them comes with extra profit compared to passive buy-and-hold strategy. In addition, it seems that presented moving average rules have forecasting power for the recent sample, which could be due to the fact that these rules have not been employed by market participants.*

Keywords*: Moving average trading rule, stock markets, indices, profitability, weak-form efficiency*

1. INTRODUCTION

If stock prices demonstrate various regularities in observed sample of time, they will allow the market participants to run a profitable trading strategy and to reject the weak-form market efficiency hypothesis. Anyway, the absence of weak-form efficiency, in which information consider only historical price data, does not unquestionably convert into profitable information. To prove this statement, Park and Irwin (2007) review evidence on the profitability of technical analysis and reveal that previous studies are not able to bring reliable arguments supporting the benefits of technical trading strategies.

Brock et al. (1992) provided strong encouragement for further development of trading strategies. Also, the focus of this paper is on the methodology similar to that of Brock et al. (1992). Bessembinder and Chan (1995) conclude that two simple technical trading rules are successful in predicting stock price movements in Japan, Hong Kong, South Korea, Malaysia, Thailand and Taiwan. Mills (1997) showed that even though the used technical trading rules outperform profits of defined benchmark in the time interval, their predictive ability significantly decline after the observed period.

However, most lately, the attention of technical trading analysis has shifted to emerging stock markets which collectively deliver a significant alternative source of opportunities to potential investors. Parisi and Vasquez (2000) and Gunasakarage and Power (2001) found support for the profitability of technical trading rules in several South American and emerging South Asian markets, respectively. Chang et al. (2004) also found that technical trading rules are profitable on some emerging stock markets. Similarly, McKenzie (2007) tested three technical trading rules for seventeen emerging markets and indicated that some of the trading rules appear to earn significant returns but the forecast accuracy decreases for more recent sample periods. Same author claims that market inefficiency could be a constant feature of emerging financial markets. Than as well, Marshall et al. (2009) consider technical trading rules more profitable for smaller, less liquid stocks. Moreover, Mitra (2011) investigated moving average trading rules for the Indian stock market and observed that profitable opportunities from technical analysis holds as a puzzle in the stock market.

On the other hand, investment attractiveness and predictive power seem to disappear in the course of time. Hence, it is of significant interest to investigate whether the inducement of technical trading strategies keeps on hold for the most recent sample periods. Consequently, the basic goal of this paper is to investigate the profitability and predictive ability of technical trading rules in Serbian and Croatian stock market during the last couple of years.

2. MOVING AVERAGE TRADING RULES

Trading rules or their alternatives, trading strategies, are measuring algorithms that generate an output investment decision containing the information about buy or sell a stock for a given period of time. If there is more volatility in the stock price data, there are more potential opportunities to buy and sell stocks. Though

the stock market may have indicated a stabile long term price movement pattern, in the short term the price behavior is very noisy. Thus, active trading strategies should be more profitable in the short term with more variation than the long term.

There are many different trading rules according to possible application and predictive ability. This paper focuses on one widespread used method, called the moving average trading rule. It is based on moving averages which are series of simple partial averages of prices P over the previous n trading days, including the current day. They represent a measure of stock price momentum. Therefore, the moving average at time t for n trading days is computed as follows:

$$MA_t^n = \frac{1}{n}\sum_{t=1}^{n} P_t \tag{1}$$

Thus, the original time series of stock prices conducts two new series of partial moving averages, one for short term (s) and another for long term (l), as we present by relations in table 1.

Table 1: Application of moving average trading rule

Condition	Decision
$MA_t^s > MA_t^l$	Buy/hold position
$MA_t^s < MA_t^l$	Sell/stay out position

Considering the moving average rule, when the short moving average of stock prices is above the long moving average, the traders initiate buy or hold decision relying on believe that the short term price growth surpass the long term price growth in expected time period. Oppositely, when the short moving average is below the long moving average or when they are equal, the traders make a sell or stay out decision.

A typical number of trading days in short and long term moving averages depends on research assumptions. Hence, Brock et al. (1992) are used 1 and 5 days interval for the short moving average, and from 50 to 200 trading days for the long moving averages, while Charoenwong (2012) considered that the short moving averages can range from 5 to 15 days and the long moving average from 50 to 90 days. This paper implements 1 and 5 days interval for the short, and 100, 150 and 200 trading days for the long moving average.

3. TESTING METHODOLOGY

Moving average trading rule represents unquestioned evidence of the stock price predictive ability if expected stock prices depend on available buy/sell information. To measure such a relationship it is crucial to test the difference between expected returns of buy and sell signals or returns of buy/sell signals generated from the technical trading rules and returns of buy-and-hold strategy. Evident choice for this purpose is the t–test of differences between the arithmetic means of two subsamples, presented by the following expressions in two variants:

$$t^* = \frac{\overline{R}_b - \overline{R}_s}{\sqrt{\frac{\sigma_b^2}{N_b} + \frac{\sigma_s^2}{N_s}}} \tag{2}$$

$$t^* = \frac{\overline{R}_{b/s} - \overline{R}}{\sqrt{\frac{\sigma_{b/s}^2}{N_{b/s}} + \frac{\sigma^2}{N}}} \tag{3}$$

Where the $\overline{R}_b$ and $\overline{R}_s$ are mean returns following the buy and sell signals, $\overline{R}$ is the unconditional mean, σ_b^2 and σ_s^2 are the variances of returns generated from buy and sell signals, σ^2 is the unconditional variance, N_b and N_s are the numbers of buy and sell signals, N is the overall number of observed data. The index b/s identifies combined buy and sell signals. The results of the t–test will help either accept the null

hypothesis (there is no actual difference between mean returns) or reject it (there is an actual difference between mean returns). However, these results assume independent and stationary time series with asymptotically normal distribution.

4. DATA AND SUMMERY STATISTICS

As noted previously, implementing a well-known trading rule provides an initial test of the weak-form market efficiency hypothesis. If stock markets are efficient, one cannot achieve superior results by using technical trading rules. However, if market inefficiencies are present, profitability opportunities may arise.
Due to the research of moving average trading rule in the course of time, this paper work uses the period of time from January 2009 to March 2014 presented by 1301 daily stock market indices values. In analysis we use two stock market indices: the Belgrade Stock Exchange index (BELEX15) and the Zagreb Stock Exchange index (CROBEX). Both indices are recognized as indicators of average stock price movements in emerging financial markets.

Table 2: Descriptive statistics

Index	BELEX15	CROBEX
Mean	0.00002	0.00002
Max	0.08250	0.08563
Min	-0.07471	-0.07020
Std	0.01292	0.01173
Skewness	0.41144	0.25183
Kurtosis	8.97576	11.20887
ρ(1)	0.26031	0.11024
ρ(2)	0.10592	-0.01563
ρ(3)	0.04200	0.07012
ρ(4)	0.10409	0.02522
ρ(5)	0.04610	-0.00333

Developing stock market indices, such as BELEX15 and CROBEX, significantly alter in statistical features from developed markets. Table 2 encompasses descriptive statistics of daily returns for time series of two stock market index values. The results indicate decidedly leptokurtic characteristics of data series with some potential signs of skewness. Furthermore, the volatility, presented by standard deviation (Std), is approximately the same for both indices. Also, serial correlations ρ(i), estimated at lag i for each data series, are roughly small, except at the first lag of BELEX15. Such data provides large enough samples to generate robust trading strategies that accomplish long term excess profits.

5. EMPIRICAL ANALYSIS

The remainder of this paper considers the implementation of moving average trading strategies to the series of historical index return data. In this sense, we incorporate six different trading strategies derived from moving average trading rule. These trading strategies differ among one another in the length of short and long moving averages denoted in the parenthesis. Table 3 and 4 shows the results of applying different moving average trading rules and approve further comparison of buy and sell trade signals generated by those rules.

Table 3: Test results for moving average trading rule using BELEX15

Strategy	N(buy)	N(sell)	R_t(buy)	R_t(sell)	$R_t>0$(buy)	$R_t<0$(sell)	t-test buy-sell.	p-value	t-test uncond	p-value
ma(1,100)	476	662	0.00102	-0.00002	0.51185	0.49118	2.00164	0.04553	1.55948	0.11913
ma(1,150)	449	592	0.00159	-0.00142	0.54681	0.44026	6.34211	0.00000	4.56152	0.00001
ma(1,200)	420	571	0.00048	-0.00106	0.52643	0.47311	3.42192	0.00064	2.33675	0.01960
ma(5,100)	564	526	0.00121	-0.00116	0.53162	0.44332	5.10662	0.00000	3.74980	0.00018
ma(5,150)	441	597	0.00091	-0.00073	0.52216	0.46718	3.31362	0.00095	2.44021	0.01481
ma(5,200)	420	569	0.00000	-0.00071	0.47917	0.47655	1.49474	0.13522	1.00910	0.31311

First column of table 3 presents short description of applied trading strategy. Therefore, the moving average trading rule is expressed in parentheses with short and long moving averages respectively. Following two

columns N(buy) and N(sell) contain the number of buy and sell signals recorded during the sample interval of time. After those columns, the next two $R_t>0$(buy) and $R_t>0$(sell) are the fraction of buy and sell returns greater than zero in whole sample. The t-test (buy-sell) indicates the test statistics of differences between the arithmetic means of buy and sell signals. The following column, p-value, represents the probability of obtaining test statistics. The rejection of the null hypothesis is indicated by the probability column if p-value turns out to be less than a certain significance level, for example 5%. Finally, t-test (uncond.) presents standard statistics results of testing the difference between buy and sell one-day returns and unconditional one-day mean return.

Applied moving average rule presented in table 3 for BELEX15 demonstrates the existence of a significant difference in the number of generated buy and sell signals among all six trading strategies. However, the appearance of a trading signal does not necessarily represent immediate buy or sell action. A sell signal should be a precaution for investors to avoid potential stock investment activity until another convincing trading signal emerges. Otherwise, a buy signal without making any investment action could be an unquestionable evidence of maintaining the position of given stocks in the investment portfolio. Generally, the first trading signal in potential sequence of buy or sell signals is assumed to be of most interest due to the existing stock price autocorrelation. Such a mechanism of frequent generating trading signals gathers less credibility of the investors, but at the same time inspires the growth of activity at the stock market. Moving average strategies present different average return results considering a whole sample of time interval. Meanwhile, every applied strategy obtains a positive one-day average return on generated buy signals and a negative one-day average return on sell signals. Mentioned averages on buy and sell signals are significantly different than unconditional averages presented in table 1. Because of that, t-test of difference between conditional and unconditional average returns in case of BELEX15 shows significant difference with p-value less than 5% in four of six trading strategies.

Table 4: Test results for moving average trading rule using CROBEX

Strategy	N(buy)	N(sell)	R_t(buy)	R_t(sell)	$R_t>0$(buy)	$R_t<0$(sell)	t-test buy-sell.	p-value	t-test uncond	p-value
ma(1,100)	627	624	0.00023	0.00007	0.49945	0.48603	0.06954	0.94457	0.03316	0.97355
ma(1,150)	537	612	0.00089	-0.00083	0.51441	0.46827	4.73631	0.00000	2.54779	0.01096
ma(1,200)	470	627	0.00054	-0.00074	0.49703	0.48620	3.85213	0.00012	1.96337	0.04982
ma(5,100)	579	620	0.00038	-0.00046	0.48264	0.49169	2.22486	0.02626	1.34446	0.17903
ma(5,150)	545	604	0.00046	-0.00054	0.48545	0.48114	2.66328	0.00783	1.49647	0.13477
ma(5,200)	471	626	0.00013	-0.00029	0.46814	0.48392	0.35697	0.72117	0.18447	0.85368

On the other hand, testing results in case of CROBEX are presented in Teble 4. First impression about results is the increasing number of trading signals compared with the case of BELEX15, although we used the same size of sample in both cases. Furthermore, the fractions of buy and sell return greater than zero are just about the same. Anyway, there are significant differences between buy signals average one-day return and sell signals average one-day return in four of six implemented moving average trading strategies. Such results provide a confirmation that trading strategies produce useful trading signals. Thus the returns made from the trading rule in case of BELEX15 and CROBEX are likely to be predictable. Leaving these inefficient trading strategies, for example ma(1,100) and ma(5,200), this paper proposes a set of moving average trading strategies with significant predictive ability and a high possibility of making profitable investment. Finding the efficient trading rule in both stock market indices supports the rejection of the weak-form efficiency hypothesis. This fact once more reminds on perception improvement of applying technical trading rules in emerging stock markets such as Serbian and Croatian stock market. Both stock market indices indicate similar stock price movement patterns, as well.

Usually, there are more sell signals in observed sample of daily returns. In overall, moving average trading strategies generate sell signals in around 55.9% (BELEX15) and 53.5% (CROBEX) of all trading signals. This epilogue shows the signs of gently to entirely reduced stock market activity and draws attraction to the lack of market capitalization. Altough Pauwels et al. (2012) consider it as a support of the efficient market hypothesis. Despite this, moving average trading rule in case of BELEX15 and CROBEX is capable to generate positive returns over a whole sample period due to the fact that the profit gained by winning trades surpass the losses from losing trades.

4. CONCLUSION

The paper attempted to provide an extensive range of possible moving average trading strategies that are capable to improve forecasting ability of stock price movements in and out of the observed sample. Overall, the results of this study contain strong support for the moving average trading strategies we have investigated and signify that almost all buy and sell differences are positive. According to previous claim, the t statistics mainly reject the null hypothesis of equality between average buy and sell returns or average trading returns and unconditional (passive buy-and-hold) returns. Strictly speaking, adequate implementation of moving average trading rule in case of Serbian and Croatian stock market leads to the rejection of the weak-form market efficiency hypothesis. Furthermore, it is inherent to the emerging stock markets that applied trading strategies generate more losing trades than winning trades.

An implementation of trading rules represents just a fragment of a comprehensive investment portfolio management analysis. As a result, complete perception of the stock price or/and return movement patterns in observed sample of time requires tools of the fundamental investment analysis, which generally rely on experience of financial experts. Nevertheless, applied trading strategies offer insight in the behaviour of the stock markets. Therefore, previously done analysis does not appear appropriate for small investors to implement. Respectively, individual case of stock trades requires analogous procedure of testing performances of moving average trading strategies referred directly to potential investment chances.

Abstract: *This document presents the basic methodological concepts of national accounts related to the estimation of the output of credit institutions. The focus of the discussion will be the main source of income of these institutions coming from monetary intermediation – loans and deposits. The interest margin as the difference between the interest receivable on loans and interest payable on deposits in the system of national accounts is decomposed in order to disclose the pure property income and service charge - so called FISIM (Financial Intermediation Services Indirectly measured). This rather complicated statistical procedure often is misunderstood by the users of official statistics and in this paper we will try to explain the basic methodological concepts that are behind it and formulas for derivation of this macroeconomic statistical indicator.*

Keywords*: FISIM, SNA, ESA, Monetary intermediation, Interest margin, National Accounts.*

1. INTRODUCTION

Unlike business accounting that is primarily focused on determining the profit and enterprise value, the national accounts as a tool of macroeconomic analysis represents the statistical system aimed to capture the real economic activity of economic entities of a country. Basic statistical indicators that are used in this system, such as „output“ and „value added“ at the micro level of individual companies do not have their " real " or tangible manifestation in the form of cash flows and financial transactions, as is the case with business income and expenses disclosed in the financial statements of enterprises. This distinction between micro and macro level of the observation of economic activity may be most visible in the statistical treatment of credit institutions (banks and other credit granting companies). The structure of National accounts framework and principles governing national accounts are agreed internationally, and are explained in detail in the "System of National Accounts 2008" (SNA08). The SNA is endorsed by the five major international economic and financial organisations: the United Nations, the International Monetary Fund, the OECD, the World Bank and the European Commission. The European system of national and regional accounts – ESA is based on the SNA and represents the European standard for national accounting and is obligatory for all its member states.

Apart from standardized banking services, banks also generate service income by bringing together borrowers and lenders of money and lending at a higher rate of interest than they borrow. In the system of national accounts, the margin earned by the credit institutions from the difference between interest received on loans and paid on deposits is treated as a part of value of production (output) of these institutions together with other service charges and operating income. In the calculation of output, system of national accounts does not include any kind of property income such as interest, rents on land, dividends, extraordinary and non-operating income.

2. BASIC TYPES OF OPERATING INCOME OF CREDIT INSTITUTIONS

Banks and other credit institutions have two basic types of income:

1) Commissions and fees charged to customers (management of checking accounts, issuance of credit cards and processing of credit card transactions and billing, financial consulting, capital market services, wealth management and tax planning, brokerage services etc.). For this service, the bank explicitly charge for their services and there are clearly established tariffs so customers can immediately identify the costs of these services and banks their income and cash flow.

2) Other operating income such as the trade margins on foreign exchange and securities, income from rentals of its own buildings. As we have said, only the “regular” operating income is included in the output of

enterprises. Property income such as interest, dividends and rents on land are excluded from the national accounts concept of “operating income”. Moreover, income gained on sales of used capital goods, gains and losses from holding the financial assets, other extraordinary gains and losses which are part of net profit and loss of companies, in the national accounts methodology are treated as non-economic transactions which do not generate value added so they are excluded from the calculation of the output.

3) The interest margin as the difference between the lending and deposit rates. The largest part of the income of credit institutions comes from the monetary intermediation – i.e. from borrowing money at lower and lending it out at a higher interest rate to customers. In this difference the value of services of monetary intermediation is “hidden”, and for this part of the income does not exist an explicit fee or price because it is already contained in the said difference. Since there is no explicitly determined fee or price, the actual price of these services can vary from client to client and investment risk etc. For that reason this service of monetary intermediation by banks is called FISIM - or "financial intermediation services indirectly measured" and that is the official term which is used in national accounts statistics.

So, FISIM represents the value of financial intermediation services for which there is no explicit tariff but is included together with other components of operating income in the calculation of output of the banking sector. These three main types of income now face the operating expenses (so called the intermediate consumption) and increase the value added of the financial sector and eventually GDP of an national economy. Without this part of the output of the banks would had negative value added and that is the reason why the SNA1993 introduced FISIM as a concept in the system of national accounts.

3. CREDIT INSTITUTIONS IN THE SYSTEM OF NATIONAL ACCOUNTS

In the national accounts, each transaction must be recorded on the two sides - supply and use. The output of each manufacturer must end somewhere on the expenditure side of the system as either intermediate or final consumption. Commissions and fees as part of the output of banks are relatively easy to allocate and determine their “consumers” since the exact data exist in accounting system of banks so as in the book-keeping records of companies and enterprises (In Serbian official chart of accounts for business enterprises they have a special account for the recording of these transactions). But for the statisticians the biggest challenge and was accurately determine the allocation of FISIM by users for which no explicit accounting records both in banks and enterprises exist because and it is a “invisible” part of interest receivable and interest payable. For that reason SNA1993 and ESA95 (prior to the FISIM Regulation 448/98, which amended ESA95 now fully incorporated in the new ESA2010) established simplified rules for the calculation and allocation of this part of the output of the credit institutions, i.e. its use or consumption is calculated in a special way on the expenditure side of the system of supply and use in national accounts.

The solution for this statistical problem was found in the formation of a special, fictitious or nominal institutional sector that will perform the role of the "consumer" of FISIM for the whole economy. So, on the production side FISIM is included as part of the output increasing the GDP. On the expenditure side, now introduced was a nominal sector with only one item on the uses side and it included consumption of FISIM for all institutional sectors of national economy. He is subtracted from GDP as a kind of intermediate consumption of all the sectors of the national economy including so called “rest of the world – ROW” which designates the exports and imports of these services from abroad.

Detailed formula for the calculation of FISIM used by the Member States and which is still used for structural business statistics was presented in the Annex 6 of Regulation No 295/2008 for SBS. The Output credit institution is calculated by the following formula (Eurostat, 2008):

Table 1. Formula for the calculation of the output of credit institutions defined by SBS regulation No 295/2008

PRODUCTION ACCOUNT	**Sign** (+/-)
1) Interest receivable and similar income showing separately that arising from fixed-income securities These items shall include all income from: . Cash in hand, balances with central banks and post office banks . Treasury bills and other bills eligible for refinancing with central banks . Loans and advances to credit institutions . Loans and advances to customers . Debt securities including fixed income securities	+
2) Income from securities including: . Income from shares and other variable-yield securities [Note: The income from participating interests and the income from shares in affiliated undertakings has been excluded, because the income of productive factors received by a enterprise is not considered as production of that enterprise]	+

PRODUCTION ACCOUNT	**Sign** (+/-)
3) Commissions receivable (shall include income in respect of all services supplied to third parties): in particular: . Commissions for guarantees, loans administration on behalf of other lenders and securities transactions on behalf of third parties . Commissions and other income in respect of payment transactions, account administration charges and commissions for the safe custody and administration of securities . Commissions for foreign currency transactions and for the sale and purchase of coin and precious metals on behalf of third parties . Commissions charged for brokerage services in connection with savings and insurance contracts and loans	**+**
4) Net profit or net loss on financial operations (trading/dealing): including: . The net profit or loss on transactions in securities which are not held as financial fixed assets together with value adjustments and value re-adjustments on such securities . The net profit or loss on exchange activities . The net profits and losses on other buying and selling operations involving financial instruments, including precious metals	**+/-**
5) Other operating income	**+**
6) Sub-Total	

PRODUCTION ACCOUNT	**Sign** (+/-)
7) Interest payable and similar charges These item shall include all charges from: . Amounts owed to credit institutions: . repayable on demand . with agreed maturity dates or periods of notice . Amounts owed to customers: . savings deposits . other debts . Debts evidenced by certificates . Subordinated liabilities	-
= 8) Value of production (excluding value adjustments)	

4. CALCULATION AND ALLOCATION OF FISIM

In order to accurately determine the value of FISIM and its consumption, the new methodology introduced in 1998 required full allocation of FISIM to user sectors. The Part of FISIM consumed by business enterprises, government institutions, Non-profit institutions and other financial institutions, since it is a service related to their business oprations i.e. their economic activity is treated as part of operating costs (intermediate consumption) of these sectors and is distributed according to the deposits and loans of these sectors in banks. The second part of FISIM created in retail banking transactions with citizens i.e households (consumer loans, overdrafts, etc.) is treated as a final consumption of households . In this way, only part of FISIM now appears as intermediate consumption and there is no longer the fictitious institutional sector - the consumer of this service. This leads to an increase in GDP of one side and the final consumption of households on the other.

Distribution of FISIM to institutional sectors is based on the volume of deposits and loans which sectors have in transactions with banks and so-called „internal reference rate“. The reference interest rate is "basic" or minimum price of money that banks have to pay to get it and then deploy as loans to their customers. It's pure interbank interest without the risk premium and costs of monetary intermediation. According to the above mentioned EU regulations, the reference interest rate is calculated as the average interest rate on interbank loans). Upon this „pure“ interest rate, banks are adding the service charge for monetary intermediation i.e. FISIM and so a market interest rate is made.

So, interest that customers of banks receive as a income from their deposits is actually only residual from this pure interest that banks pay for obtainining money on interbank money market after the implicite service charge – FISIM is deducted from it. On the other hand, interest that customers pay for their loans and credits is actually the pure interest on wich a margin of service charge for monetary intermediation has been added.

Figure 1. shows the National Accounts concepts of interest received and payable and the distinction between actual interest and the „pure“ interest of banks on which the service charge margin for the monetary intermediation has been added or deducted.

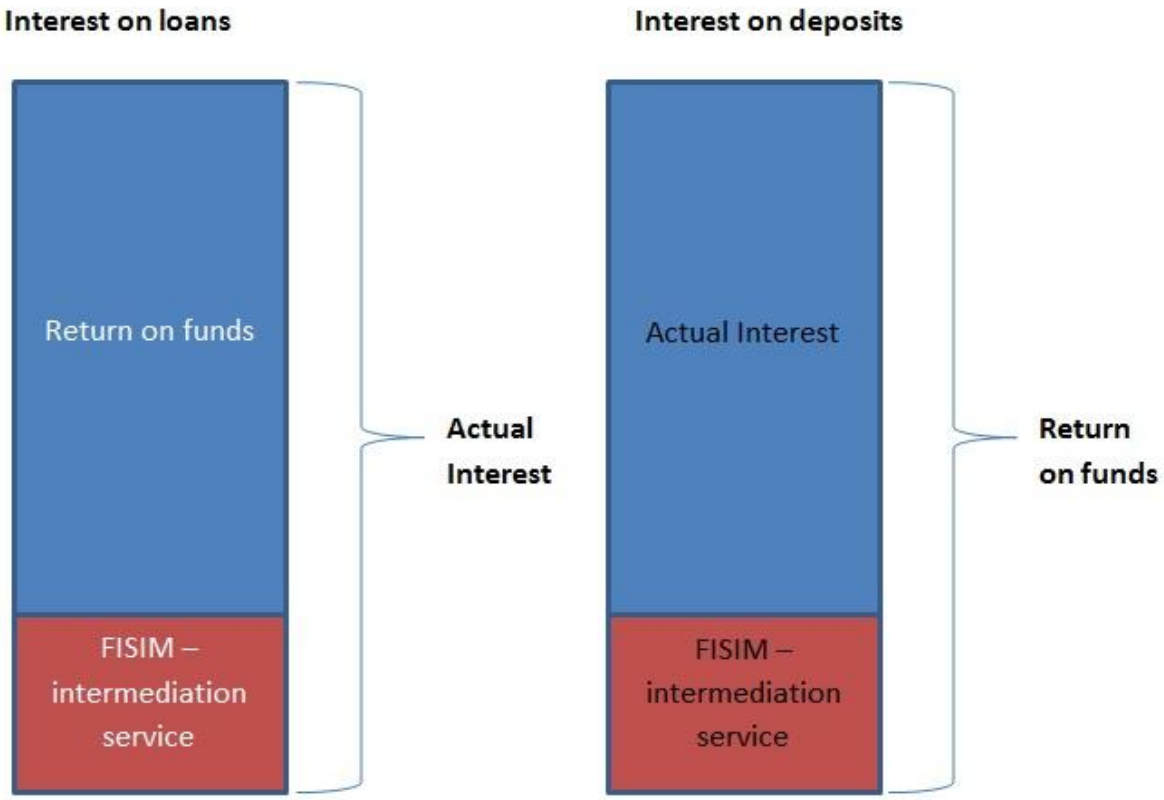

Figure 1: Relationship between different parts of interest in the monetary intermediation

As we have said, the total FISIM by an institutional sector *j* is obtained as the sum of FISIM on loans granted to the institutional sector ($FISIML_j$) and FISIM on deposits of the institutional sector ($FISIMD_j$).

$$FISIM_j = FISIML_j + FISIMD_j = RL - L_j r + D_j r - RD$$

Where RL is interest receivable on loans and RD interest payable on deposits. L is average stocks of loans and D average stocks of deposits. Internal reference rate is represented with *r*.

Rearranging this equation (3), we get:

$$FISIM_j = RL_j - RD_j - (L_j - D_j)r$$

Total FISIM is obtained by summing the FISIM for each institutional sector *j.*

FISIM together with other above mentioned components of operating income represents the value of production of credit institutions i.e. output.

Practically, for the statisticians, the calculation and distribution of FISIM to its user sectors necessiate data on each institutional sector concerning deposits, loans and accrued interest. For the calculation of internal refrence rate i.e. pure interest, data on interbank loans is required.

Now, we will show one simplified example for the calculation of FISIM for the sector of non-financial corporatons:

Reference rate - 5 %
Average stocks of deposit of business enterprise in banks - 100.
Total interest receivable by companies in respect of deposits - 3.
The average interest rate of 3 /100 = 3 %

Average stocks of loans of companies - 200
Total interest expenses of companies - 20
The average interest rate on loans : 20/200 = 10 %

FISIM on deposits will be (5 % - 3 %) * 100 = 2
FISIM on loans will be (10 % - 5 %) * 200 = 10
Total FISIM is 10 +2 = 12

The total interest margin is 20 - 3 = 17. If we subsctract from this interest marigin actual net interest 5 (200-100)*5% we will have the service charge for monetary intermediation.

The same formula applies for the other institutional sectors and the for the estimation imports and exports of FISIM data on deposits and credit transactions with non-resident credit institutions are required together with „external reference rate“ – interbank reference rate in transactions between resident and non-resident banks. The above presented calculation should also include finance leasing companies and other credit granting institutinons.

The ESA methodology for the calculation of the output of credit institutions and its allocation of in all EU countries has led to an increase in GDP because one huge part of it is now not deducted as a intermediate consumption but as a final consumption of households. Depending on the share of loans of households in the total volume of loans, the impact was larger or smaller.

5. CONCLUSION

Measurement of the output of banks and credit institutions in the system of national accounts represents rather complicated statistical procedure that requires reliable data on structure of deposits and loans as well as interest rates by different institutional sectors of national economy. National accounts methodology makes distinciton between actual inerest and „pure“ interest on which costs of intermediation service charge in the form of FISIM is added and charged to customers. In order to calculate the output of credit institutions SNA2008 and ESA2010 determine procedure for derivation of this statistical indicator and its separation from interest as property income.

Abstract: *Inability and/or difficult access to financial services consequently forces individuals, especially those most vulnerable, to look for solutions outside of authorized financial institutions. Such solutions are usually less safe and more expensive, and for this social group actually mean a return to the vicious cycle of poverty. Postal financial services are used by more than a billion consumers worldwide. The data suggest that several hundred million people who do not have accounts with banks or other financial institutions, use the Post for basic services, payment services, money transfers, money orders in the domestic and international financial transactions. In this paper, we have analyzed the role of postal financial services in the process of financial inclusion. By applying the survey method we have analyzed the following: the involvement of residents in the financial sector of the Republic of Serbia, the expectations of the financial sector and the opinions and level of satisfaction with the postal financial services. On the basis of obtained results, concrete proposals for further development of postal financial services in the Republic of Serbia are presented.*

Keywords: *post, finance, services, inclusion.*

1. INTRODUCTION

In the postal sector, there are numerous successful examples of postal-financial services, such as: the Postal Savings Bank of China, which has 475 million customers; Brazil's Correios with 10.2 million accounts opened in 10 years through a partnership with a bank; Namibia Post, which banks 20% of the total population in the country; India Post, which covers risks for 20 million people through its postal life insurance policy and holds 250 million of savings accounts; Papua New Guinea Post which is one of the three main competitors for mobile financial services in the country; Serbian Post which makes 150 million financial transactions per year in a country of 7 million inhabitants and so on (Berthaud&Davico, 2013).
Postal operators, in all their activities, have always relied on a business model based on large volumes and low cost. Financial services combined with the universal postal service and public postal network give the mandate to the Post to become a part of global fight against financial exclusion of the population.
Three major historical patterns explain the reasons why the postal organizations have begun to provide financial services:

- *First*, in most countries, the government has mandated the postal administrations or post savings banks to become an active participant in government development policy through the provision of public services to population that has no access to banks in the country. A good example of this is the formation of Postbank Lao and Vietnam Postal Savings Company (World Bank, 2006). The government's goal was to use the postal network to deliver the funds to enterprises and local government in rural and remote areas, such as Sri Lanka and India. Most countries in Western and Central Asia used a similar model. Not long after, the option of saving as another public service was offered.
- *Second*, offered financial products - mainly the service of savings via the post can be a source of government financing. The Post invests collected savings into government bonds or other financial instruments, as it is the practice in most African countries. The practice in India and Pakistan serves as another alternative, where post offices serve as the Government representatives in the sale of securities.
- *Third,* the government had in mind the income arising from financial services as resource for covering the cost of the universal postal service.

Post office's range of services depends on the legal and regulatory provisions under which financial services are offered. Post uses several models and methods of providing financial services, such as:

- *The Post as a part of the Ministry of Telecommunication and Postal Services* do not represent a separate entity, they do not have separate structure and are managed by the Minister (India, Yemen). Provision of financial services is performed within the same legal framework.
- *The Post is a separate legal entity whose ownership belongs to the state.* Within the post there is a sector which conducts financial services without a certain balance or statement of profit and losses.
- Many different legal entities (such as postal savings banks and postal services) conduct/provide financial services (the Philippines, Serbia, Montenegro). There may be a cooperative agreement (agreement on the type/level of services) which regulates the quality of services, payment of commission, cost-sharing,

training of personnel, accountability. This agreement defines the conditions under which these organizations work together and use the term "postal".

- *Post and postal savings bank wholly or partially belong to private investors* , which is not in accordance with protection of the principles of the public interest (Kavanagh, 2013).
- Post Offices focus on their core business, while financial services are handed over to specialized institutions such as commercial banks (Brazil, Malaysia, and United Kingdom). Financial products are sold under the brand name of postal organizations (Estonia) or the operator providing that service. The contract binds the post and financial institution. Posts can choose their partners by means of tenders, which has been done in the case of Brazil's Correios in Brazil, when the firm *Bradesco* was selected. However, in some countries (India, Pakistan) post offices on the basis of agent agreement, sell state bonds and other financial services (World Bank, 2006).

2. IMPORTANCE OF FINANCIAL INCLUSION AND THE ROLE OF POST IN THE PROCESS OF FINANCIAL INCLUSION

The concept of financial inclusion appeared for the first time in the UK in 1995. At that time, financial exclusion was primarily observed in the context of geographic accessibility. Nowadays, it is more than clear that financial exclusion is far more complex and that it does not only include access to variety of financial products and services, but also the possibility of their use.

The European Commission stresses that the "financial exclusion refers to a process whereby people encounter difficulties accessing and/or using financial products and services in the mainstream markets, and these products and services meet their needs and enable them to lead a normal social life in the society to which they belong" (Petrovic & Kaplanovic, 2012).

According to a survey by MasterCard "The Road to Inclusion", millions of people in Europe are fully or partially excluded from the financial flows. The average age of people who are completely excluded from the financial flows is 40 years old. The largest part of this financially excluded group (40%) in the last three months did not receive any form of payment, salary, welfare or anything similar. 35% received some type of salary in that time frame. 81% of them have lived in the same country all their life. Rather than benefiting from the characteristics of bank accounts such as transferring funds from one account to another, electronic banking or even the subsequent ability to buy merchandise at a discount over the internet, most people in these groups use cash to pay the rent (98%) and bills for utilities (95%), and stash their money in a secret hiding place in the house. Only in Western Europe, there are 93 million people who do not have a bank account or partially use services of banks.

United Nations – UN defined goals of financial inclusion as follows:

- Access at a reasonable price for all households to a full range of financial services, including savings or deposit services, payment and transfer services, insurance and credit services (Leonelli, 2002)..
- Sound and safe institutions, governed by clear regulations and standards.
- Financial and institutionalized sustainability, continuity and certainty of investment.
- Competition to ensure choice and affordability for customers.

Universal Postal Union - UPU has repeatedly made detailed studies and initiated activities to identify the role of post in the process of financial inclusion. The aim was to provide basic financial services (savings, payments and money transfers) to population without access to such services.

Advantages of post in achieving financial inclusion over other providers of financial services[1], particularly in relation to the banking sector, are reflected in the widespread postal network and confidence that post has especially among the poor.

Postal sector worldwide has more than 660,000 post offices, which makes it one of the largest distribution networks. This is particularly important for developing countries where, according to the World Bank study, the number of postal units and offices (500,000) is almost twice higher than the number of branches of commercial banks (275,000). Moreover, what is particularly important is that widespread postal infrastructure allows the postal system to provide services to the whole population. This is what differentiates the postal financial system and the private banking sector which seeks to allocate their institutional resources to the wealthier segments of the population, in order to obtain maximum profitability.

In addition to the extensive network of postal branches, advantage of post is also computer network for electronic data exchange. It facilitates the provision of payment system (Abdallah&Shakurova, 2012)..

[1] Financial services providers, can be divided into groups:

- Major commercial profit-oriented providers (banks and insurance companies);
- Commercial social-oriented providers (savings banks, postal banks and joint organizations):
- Alternative commercial (savings-credit cooperative and other micro financing institutions); i
- Alternative commercial profit-oriented financial services providers.

A typology of business models for postal financial inclusion (Berthaud&Davico, 2013) can be represented as follows:

- Post as a real estate provider – post can rent the space within postal units to financial service providers. Process of financial inclusion will depend on the financial partner which rents space from the post.
- Post is CM (CM - cash-merchant) – Post offers a single private partner or multiple partners the use of its units and staff for transactional financial services.
- Postal transactional financial services - Postal money orders generally form part of the traditional financial postal services and are a part of its core business.
- Post and partnership with a financial service provider - In this business model the Post usually offers the whole range of products of its partner.
- Post and unlicensed postal and financial services - This model involves provision of savings and credit services directly by post. In some countries, depositors of savings accounts benefit from a preferential tax exemption up to a certain amount. Northern, Western and Southern Africa, Western Europe, South Asia, East Asia and the Pacific are the regions with the highest postal savings. In Algeria, for example, the post has 15.1 million, i.e. 63% of savings accounts of the total 24.1 million accounts in the country. The Post in Algeria performs this service on the basis of the Postal Act, which allows the Post to offer these services without a banking license.
- Post and licensed postal financial services - More and more countries are exploring the possibility of creating a postal bank. The Post of Japan generates 90% of its income by its financial services, France with 23%, and Morocco with 62%. However, creating a postal bank is followed by some challenges. First, there is a regulatory challenge in securing a banking license. Second, capital requirements are a major obstacle (government and private sector). In Belgium, postal bank is a joint venture with the private sector, i.e. the Post owns 50% of the capital while a large banking group owns the rest.

The World Bank defines 6 basic types of financial products and services (World Bank, 2006):

1. insurance,
2. bank accounts,
3. savings,
4. credits,
5. transfer
6. financial consulting.

In developing countries, 2.7 billion people or 70% of the adult population does not use financial services of authorized financial institution (Mylenko, 2010).

Inability and/or difficult access to financial services consequently forces individuals, especially those most vulnerable, to look for solutions outside of authorized financial institutions. Such solutions are usually less safe and more expensive, and for this social group actually mean a return to the vicious cycle of poverty. More than 100 million people, i.e. 27% of the population in Central and Eastern Europe and Central Asia are located outside the banking sector or poorly covered by it. Proportion of the population that is not involved in banking relations varies from 25% in Central Europe to over 80% in Central Asia. The lowest offer of financial services is in rural areas (Petrovic & Kaplanović, 2012).

The current crisis solicits the need for the state to conduct an active policy of financial inclusion. In many countries and in different ways, such a policy is already implemented. The fact is that the postal sector, known for its values (user trust, quality, reasonable prices) receives a significant role in the implementation of this policy (Petrovic & Kaplanović, 2012).

The purpose of financial inclusion, and therefore the role of the post office is to bring excluded populations to regulated financial flows in order to provide financial support and improve the quality of their life.

The concept of financial services provision through the post office is not new, but in the practice it had a large number of unsuccessful implementation. The latest challenge is to determine what more can be done in order to offer postal financial services to the population without access to a bank, according to their needs, while on the other hand ensure that the postal network performs these services on a sustainable basis.

Postal network can have an active role in bridging the policy of digital division by connecting postal units through the platform for networking and with adequate technical support and internet (e-government, e-sales) to rural areas.(World Bank, 2006).

Inclusion through the postal network can be viewed at three levels: local, regional and global:

- Inclusion at a local level is provided on the basis of the proximity of access to basic financial services for low and middle income households, access to integrated commerce, communications, delivery/shipment and payment services to micro, small and medium enterprises (MSME) and access to the total population.
- Regional inclusion is provided through integration of MSMEs into regional chains of trade and supply.
- Inclusion at the global level is achieved through special services for migrants in relation to their remittances and postal accounts, as well as through international trade benefits for MSMEs.

The process of financial inclusion, in addition to positively affecting financially excluded population groups, also has significant positive effects for the post. Combined with traditional postal services, postal financial

services, and especially postal savings through more intensive use of the postal infrastructure, in return give the post reduced costs and increased efficiency. The total income generated from financial postal services in the world (excluding Japan) grew in the period from 2001 to 2008 from 14.1 to 29.4 billion dollars.
There are different projects and institutions which support financial inclusion worldwide.
Alliance for Financial Inclusion (AFI) is the largest and most important network of financial inclusion in the world. AFI was founded in 2008, as the project funded by Bill & Melinda Gates Foundation and supported by AusAID to promote the development of a reasonable policy of financial inclusion in developing countries. AFI network counts more than 105 institutions from 88 member countries from 2008 to 2013. In 2011 AFI has adopted Maya Declaration, a set of common principles and objectives of the development policy of financial inclusion.
Center for Financial Inclusion (CFI) is a movement that was formed in 2008. To help establish financial inclusion around the world, CFI defined full financial inclusion as sustainable if users have access to complete package of financial services, at affordable prices in a unique way, equally, without discrimination. The vision of CFI is to fully implement the inclusion through a stable and competitive service provision. Access to financial services is accelerated as a result of the following: micro insurances are booming and reaching half a billion of insured people; the potential market is between 1.5 and 3 billion people; a large number of financial policy makers throughout the global community promotes financial inclusion The *Basel Committee on Banking Supervision* (*BCBS)* and The *Financial Action Task Force* ((*FATF*)). Central banks and ministers of finance from over 80 countries participate in the Alliance for Financial Inclusion (AFI); focus is on the importance of the customer. Generally, financial inclusion involves various directions and steps, such as:

- Opening a bank account without unnecessary details and conditions, available to almost the entire population. Banks are advised to enable an overdraft on this account.
- Simplification of procedures and norms for opening an account.
- The involvement of intermediaries in providing financial and banking services.
- Using technology: Banks are advised to make effective use of legal, informational and communication technologies and to provide easy performance of all banking services through intermediaries.
- In order to assist the poor and vulnerable, cheap an easily accessible credits are available for this layer of population.
- Establishment of permanent bank branches in rural areas.

Financial inclusion has its shortcomings and risks. Above all, risk of excessive debt of population. This problem is solved by defining an optimal set of basic financial services. However, the benefits of financial inclusion are numerous, from the lower prices of financial services to greater access to the financial sector, and the development of competition in the banking market and the development and improvement of existing financial services.

3. FINANCIAL SECTOR IN THE REPUBLIC OF SERBIA, POSITION AND PERSPECTIVE OF THE POST OF SERBIA

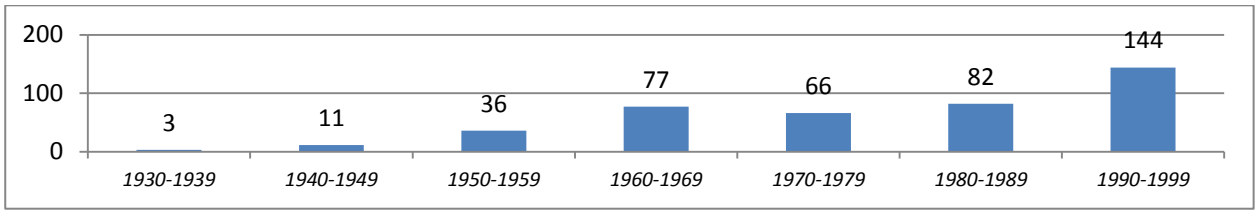
At the end of the first quarter in 2013, 32 banks were doing business in Serbia. Banks owned by foreign entities continue to have a dominant share in the banking sector by approximately 75% of the assets and profit of the banking sector. Banks which originate from the European Union have the share of 70.7% (69,2% from countries where euro is used) and the banks originated from Russia and USA have the share of 3,6% and 0,3% respectively. While the relation of asset to capital according to the origin of ownership in banking sector is almost the same, banks owned by domestic entities (primarily state-owned banks) still have more developed branch network, as well as a larger number of employees, i.e. 36% of the organizational network and 28, 4% workforce in contrast to 25,4% share in balance sheet and capital. Of the total number of banks, 22 of them operated with a positive result that is a total of 12.63 billion dinars, while 10 banks operated with losses of total 1.78 billion.
Financial services that are performed in the units of postal network in the Republic of Serbia can be divided into:

- services performed in the name of post and for their own account,
- services performed on behalf of the bank and for the account of bank.

Post performs various financial services as a part of their own business to private and legal entities, in accordance with the regulations governing this area (laws, regulations, manuals, price list etc.) and contracts signed with clients. Services performed by post but on behalf and account of bank are also regulated by general laws, special agreements with banks, as well as internal regulations, which were adopted by both the bank and post office for the performance of these services.

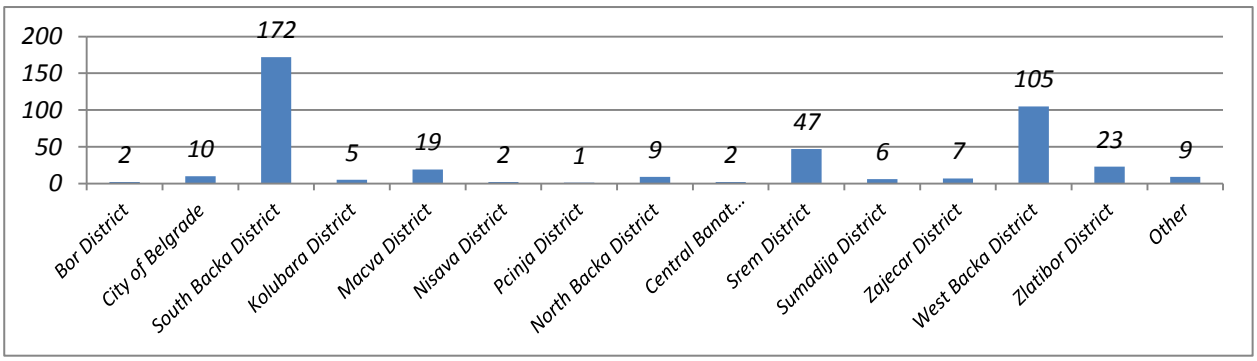
3.1. Analysis of the involvement of people in the financial sector

For the purposes of this study, 419 inhabitants of the Republic of Serbia were surveyed of whom 191 (46%) were males and 228 (54%) were female. The average age was 36 years. The oldest respondent was 72 years old and the youngest 19 years old. The graph 1 shows the number of respondents by age.



Graph 1. number of respondents by age

Graph 2 shows the number of respondents per the administrative districts of the Republic of Serbia. The largest number of respondents came from the South and West Backa District (277). Although the survey included the respondents from other districts (133), as well as residents of the Republic of Serbia whose permanent place of residence is outside the Republic of Serbia (9).



Graph 2. respondents by place of residence

Of total 419 respondents, 162 (38.66%) are employed in the public sector, 63 (15.03%) are employed in the private sector, 7 (1.67%) are entrepreneurs, 168 (40.09%) are unemployed and 19 (4.53%) are retired. Confidence in the banking sector has presented 222 (53%) respondents. 102 respondents are satisfied with their financial situation, while a higher number is not satisfied (319 respondents). Another interesting fact is that 40 out of 168 unemployed persons are satisfied with their financial situation. This fact indicates that these people make significant income while unemployed in the form of gifts, income from property, and income from deposits, insurance fees, scholarships and other.

220 respondents regularly receives income from employment (of which 28 respondents have other sources of income), 42 respondents have income outside regular employment occasionally working on contractual basis (of which 16 respondents have other sources of income). 36 respondents receive pension, of which 19 receive old-age pension and disability pension, while others receive survivor pension, and belong to the group of unemployed persons (those are usually students and persons who earn income outside of employment). Public aid (welfare, material benefit, alimony, child support, scholarships) receives 44 respondents and they also have other forms of income such as gifts and awards. Solely from gifts and gains, 46 respondents generate income. 373 respondents have bank accounts, while 46 respondents do not have a bank account. It is also indicative that the of 46 respondents who do not have accounts, 22 of them receive earnings from casual employment in cash, while 14 respondents receive money from pensions and public through money order.

Of the total number of respondents, 268 are partially satisfied with the services of banks in Serbia, while 58 respondents are not satisfied with the service. Even though 9 respondents have not used banking services, but the number of those who used several different banking services (current accounts, loans, electronic banking, etc.) is bigger than this. 17 respondents use cards to pay over the Internet, 89 own credit cards, while 190 respondents use debit cards. Credits that are most commonly used are: cash loans (50 respondents), residential (27 respondents), consumer (19 respondents). Electronic banking is used by 59 respondents.

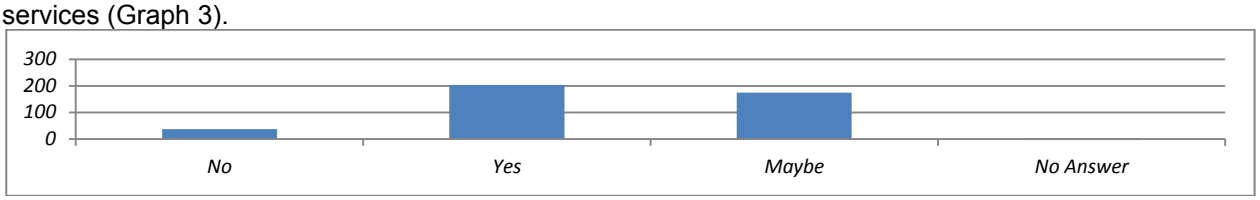
At the same time, respondents were asked about the services they are unable to use and there is a demand for these services. Therefore, 74 respondents are in need of e-banking services, but need more information about those services, and 115 respondents are in need for some form of credit, but their personal financial situation or the conditions under which these are granted, does not allow their use.

Respondents have listed reasons for not using banking services and those can be broken down as follows:

- no need for additional services (45)
- inadequate working hours of banks (29)
- The Bank has no branch in their neighborhood (5)
- lack of information about the services of banks (125)
- poor personal financial situation (172)
- bad portfolio of banking services with high commission and bank interest (14)

3.2. User expectations of the financial sector

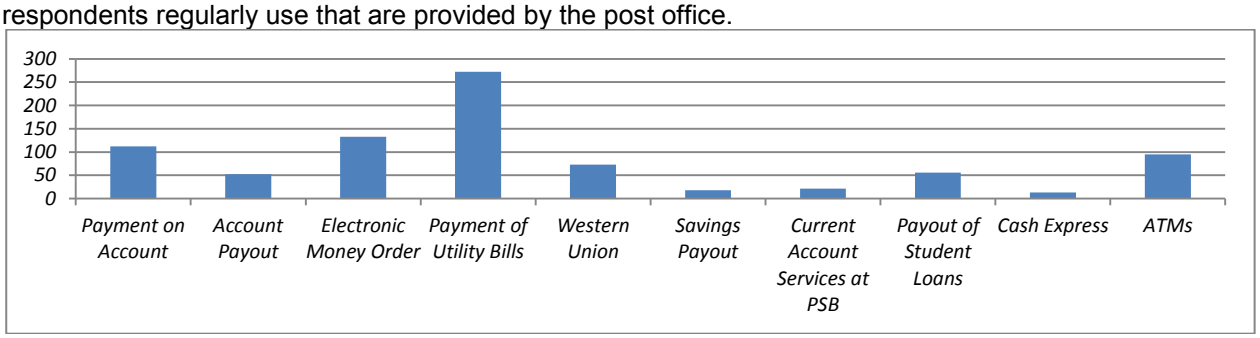
Respondents expect the banks to decrease bank interest and commission (154). Mainly, people expect lower interest rates on cash loans and overdrafts. Then, credits without interest and loans to pay for food for the winter, fuel, utility costs (heating and electricity), taxes and other costs incurred in order to satisfy the existential and basic needs. Greater availability of insurance (health and pension) is expected on behalf of 10 respondents.
A larger number of respondents (203) believe that the post office can provide greater availability of financial services (Graph 3).



Graph 3. Do you think that post can provide greater access to financial services?

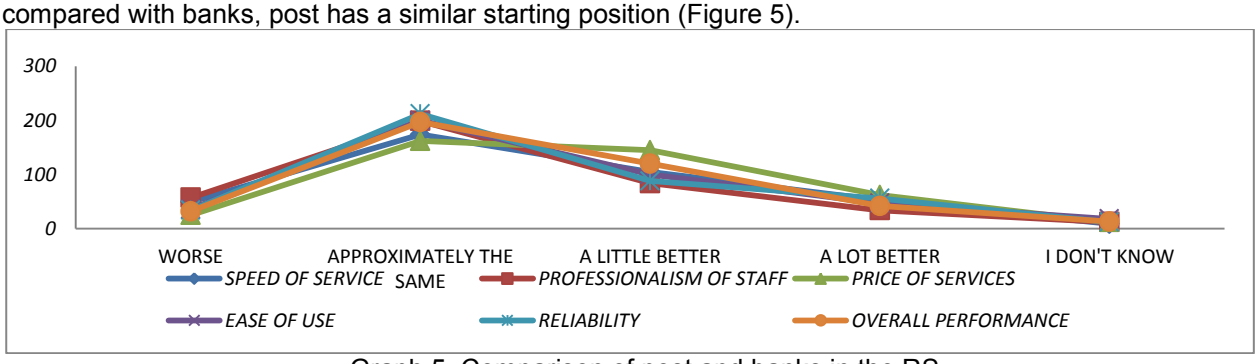
3.3. Assessing the role of post in the development of financial sector

Respondents use certain payment services regularly and give priority to the use of these services at the post office in relation to the bank (for example, payment of utility bills). Graph 4 represents services that respondents regularly use that are provided by the post office.



Graph 4. Services that customers regularly use in the post

Certain aspects of postal financial services (cash operations) such as speed of service, professionalism of staff, ease of execution, range of products and service quality, respondents have assessed as satisfactory, and the price of services as moderate in relation to quality. Availability of service information is satisfactory, as well as availability of forms and the speed and efficiency of handling documents.
Respondents believe that the post has yet to act in order to improve each of these aspects. However, compared with banks, post has a similar starting position (Figure 5).



Graph 5. Comparison of post and banks in the RS

3.4. Perspective of post and redesign of postal financial services

Based on different evaluation of respondents and valuing resources of post, such as:

- Developed ICT solutions (computer network PostNet, technological application solution PosTis, the certification body of the Post, participation in e-government project, etc);
- Postal network with approximately 1,500 locations throughout the RS;
- Contractual relationships with banks, utilities and other organizations and institutions, we have concluded that the process of financial via Post of Serbia can be implemented.

The following arising question relates to the choice of model which will be used. So far, posts in the RS have not performed full set of contractual business/obligations/agent services for banks (credits, savings, issuing credit cards etc.).

Its operations have primarily been based on cooperation with the Postal Savings Bank, which is an independent business entity. Apart from the expansion of the network and services of the Postal Savings Bank, the issue of providing banking services to vulnerable population and that in rural areas the RS, which are geographically and economically excluded from the financial services sector, still remains unsolved.

Post in RS, in the process of financial inclusion should improve the quality of existing financial services, customer relationship and ensure provision of new services such as:

- service of user profiling of favorable financial services based on e-government, with the aim of reducing the cost of obtaining the necessary documentation from different parts of the administration (land certificates, proof of unemployment, confirmation of the amount of social benefits, the number of household members, etc.).
- services for vulnerable and poor population - loans with no interest or loans with a lower interest rate for food, clothing and footwear, housing costs and treatment, based on the earned income (public aid, welfare, scholarships, etc.);
- insurance services, primarily health care and retirement, with the possibility of savings and access to funds prior to the expiration of the insured period (bearing in mind the social profile of the user).

This approach requires a broader initiative with the support of the government and the financial sector. Current provision of this type of services by post is only possible through a contract with banks on the performance of agent activities, and participation of state funds for subsidizing these types of crediting and e-government services.

Another possibility is that post performs these services without a license or to be provided with a banking license to a limited set of services.

4. CONCLUSION

Development of the financial sector in the Republic of Serbia in the future will depend on availability of certain financial services and opportunities that a large part of the population becomes involved in regular financial flows. If the current trend still continues, there will be a reduction in the number of branches of banks, and greater geographic exclusion of the population. Post as a provider of financial services and a public postal network as a resource, this can quickly stop this trend and assist in the implementation of services for socially deprived part of population.

In further research, it is necessary to define the criteria for profiling users of financial services and to determine the set of services that will optimally meet their needs.

Abstract: *Export credit agencies are financial institutions that promote exports and facilitate investment in foreign markets that are considered risky. These agencies can be organized as banks, insurance companies or financial corporations and are mostly owned by the state, and do business in order to support national exports and investment. Special emphasis is placed on the work of the Berne Union, as an important link in the chain of world trade. By establishing special agencies for export financing and providing capital for their activation, state creates capital by which export credit is continuously funded, and thus the main branches, pillars of the industrial development of the country and the state, are maintained and developed.*

Keywords*: export business, export credits, export financing, credit insurance, export credit agencies, the Berne Union*

1. INTRODUCTION

The development of international economic relations, increasing intensity of foreign trade and growing competition in the global market require that the method of payment of exports of goods and services represent an increasingly important element of competitiveness in the global market. In today's business environment, international trade financing is one of the most common forms of business financing. International trade of goods and services is done in very difficult conditions which are linked to a number of risks that are far greater than those that occur in domestic (internal) trade. Due to the possible adverse consequences, it is of great importance for exporters to neutralize the negative effect of export risk or at least to minimize it to a certain extent.

Many countries highlight export growth as the primary goal of their economic policy. In this way, a certain foreign income is ensured, thereby strengthening macroeconomic stability, increase in production and employment and providing regular servicing of external debt. Considering this, the whole set of measures is developed by economic policy-makers with the principal aim: export growth. As a part of this system an important place is occupied by export credit agencies. Established as agencies they are provided to support local businesses in entering foreign markets, primarily through financing and insuring export activities and investment. Almost all countries have this type of agencies, and they have a particularly significant role in the initial stages of development and in terms of market penetration and development of activities on high-risk foreign markets. These institutions may be part of the state apparatus (NEXI, Japan and the ECGD, UK), a special state agencies (the Ex-Im Bank, U.S. and AOFI from Serbia), institutions of private capital under the state influence (Hermes AG, Germany) or mixed-ownership institutions (SACE, Italy). The development of the globalization process and the establishment of regulations on the multilateral level have led to the introduction of rules on the work of export credit agencies. This partly limited their work, but their importance is still relevant, so that they still occupy a special place even in developed countries.

The Berne Union (International Union of Credit and Investment Insurers) has led to the cooperation at the international level and embracement of sound principles in export credit insurance and investment abroad, as well as to equalize the conditions under which the coverage of export credits and investment is approved abroad. The globalization of the world economy imposes the need for our country to be included in the global flows and the exchange of goods and services, labor and capital and thus to define the modern models of support for exports.

2. CREDITING AND INSURING EXPORT BUSINESS

With growing competition in a global market the ability to sell goods and services increasingly depends on the terms of payment. Manufacturers sell their products on credit in order to be more competitive in the global market and provide a greater product placement. In addition to crediting exports of capital goods, other activities are credited that enhance the placement on foreign markets, such as: market research, project development, preparation of production for exports, import of the necessary raw materials and components needed for manufacturing, etc. An international trade crediting is one of the most prevalent forms of international business financing of business entities in international economic relations. Crediting international commercial transactions is realized through export credits. Export credits can be repaid under commercial market conditions or with the official state support through export credit agencies. Depending on

to whom is export credit granted, and who is the user of credit,we can make difference between: supplier's credit and buyer's credit.

Stimulating exports, due to their positive effects on the growth of national income, is a continual task in almost all countries. An important place in this field occupies facilitating export financing under more favourable conditions.(Mladenović, 2010, p.126) The term ***export financing*** involves two interrelated transactions:

- Export credit insurance against commercial and non-commercial risks and
- Providing financial support for exports by issuing guarantees and credit approval toexporters or buyers abroad by commercial banks or specialized institutions for export financing and insuring. (Vapa – Tankosić,2010,p.119)

Supplier's credit / exporter's credit is the financial arrangement of export credit agencies in which supplier / exporter of goods and / or services is credited and may be in the form of direct financing of exporters, refinancing or co-financing through commercial banks' supplier, that is, exporter. Export credit agencies approve this type of credit to domestic suppliers / exporters based on the concluded foreign trade transaction, and in accordance with the general and specific rules for crediting export transactions. Credit approval is conditioned by acceptable collateral, as well as by ensuring payment of export business (insurance policy assigned for the benefit of creditors) and the transfer of receivables based on export contract to the agency. In addition to direct financing of exporter / supplier, agencies may exercise refinancing of export transactions through commercial banks of exporter, wherein the agency places its funds through commercial banks with a more favourable interest rate than the market rate. In case of co-financing exporters, the agency places a part of the funds to the exporter under the agreed conditions (conditions depend on the category of exporters and export business), while the other part of the credit is financed by a commercial bank under the terms of the agency agreement. One form of export credits with the official state support, that are approved by agencies for crediting export transactions is ***a credit to foreign buyer or buyer's commercial bank***. It is a financial arrangement in which a bank or financial institution approves the credit directly to the foreign buyer or the bank of the importing country for financing the purchase of goods and / or services. They are usually in the form of interbank credit lines aimed at establishing long-term relationships with financial institutions in countries that are of strategic importance for exports.For exporters this business of exports on credit is virtually cash credit, because it is charged by the real creditors (a bank), and a foreign buyer repays the credit to the bank creditor based on the contracted repayment schedule, so that this bank bears the risk of debt collection. An agreement to credit buyer or buyer's bank is a financial arrangement that is very favourable for exporters, since the exporter is charged immediately after the delivery, while the credit is repaid by the buyer / bank from abroad. Thus the exporter avoids the risk of export charges and ensures liquidity in the banking business. This type of credit agreement is conditioned by acceptable credit insurance. Consumer credit program or a commercial bank abroad may also be in the form of:

- independent credit to customer or a bank abroad or
- in the form of co-financing export transactions together with commercial banks.

The amount of credit that can be approved by agencies can even be 100% (usually for credits with repayment period of up to two years) to the maximum 85% for export transactions with repayment period[1] up to 10 years. In accordance with the rules of the OECD (The Organisation for Economic Co-operation and Development), the repayment period for financing the construction of hydroelectric, thermal power stations and renewable energy sources can be up to 15 years. Interests for credit users are determined based on the creditworthiness of the bank, the State of export, the types of foreign trade transaction and the like, although one must comply with the minimum interest rates established by international rules (the rules of the OECD). This type of crediting is conditioned by, in addition to the usual collateral (mortgages, pledges, deposits, etc.), credit insurance with export credit agencies, and the insurance premium is usually paid in advance.

3. THE METHODS FOR APPROVING AND EXPORT CREDIT INSURANCE

Crediting as an important factor that affects the competitiveness of exports is closely related to the emergence and development of export credit insurance, because a significant part of the foreign trade transactions is concluded on credit. Hence receivable arises from the foreign debtor that carries a number of

[1]The repayment period is the time from the moment of the obligation to pay for goods or services to the moment of the final payment and depends on the type of goods and services that are exported. For the export of raw materials, intermediate goods and consumer goods, short-term credits are mainly granted with repayment period of up to one year. For the export of equipment and capital goods credits are approved with repayment period of 1-5 years, while long-term credits are approved for implementation of investment projects abroad, delivery and installation of plant investment and their repayment period is over 5 years.

risks and the inability to collect debt. There are basically three types of approval and export credit insurance, and these are:

- export financing or refinancing,
- subsidizing interest rates,
- guarantee and export credit insurance

Governments of countries usually analyze the effects of interest rates on the price of export products and the competitiveness of exporters. Interest rates are subsidized most frequently, so that the bank that approved the credit charges fewer funds than exporters. This is done by a mechanism of refinancing credits granted by commercial banks.

The purpose of the insurancemechanism is that the state should provide sufficient security (reduce the debt collection risk) for the banks which finance exports and stimulate them to grant export credits. The insurance contract is defined as the contract by which the insurer with the premium charge undertakes to indemnify the insured in case of insolvency of the insured person, who is credited by the insurer within the provided coverage limits. (Radović,1989,p.39)

Credit insurance for exports is often performed by specialized agencies for credit insurance for exports through export insurance and financing. This is a case-in-point for all countries. However, these agencies may differ from country to country in terms of status and organization, as well as other characteristics. They may be state-owned, privately owned, or they may be private, but work on behalf of the state.

Export Credit Agencies (ECAs) may (in whole or in part):

- directly finance exporters for export of goods and / or services on credit;
- co-finance exporter with exporter's commercial banks;
- refinance commercial banks for credits that they granted to exporters and foreign buyers for export of goods or services on credit;
- subsidize the difference in interest rates on the funds mobilized in the capital markets at commercial interest rates and lower interest rates by which export credits are approved to foreign buyers.

Some of these agencies provide cover for short-term business and some just for medium-and long-term business. Regardless of the differences in terms of ownership, state-owned agencies are more prominent. Exceptions are: Austria (*OeKB*), France (*COFACE*), Germany (*Euler Hermes*), Portugal (*COSEC*) and the Netherlands (*Atradius*), which have agencies for credit insurance against political and commercial risks in private ownership. Export credits with the official state support are largely conditioned by the participation of the goods of domestic origin in exports (usually a minimum of 50%) and insurance claims while respecting international credit conditions (minimum interest rates) and insurance (minimum premium amount) in order to avoid unfair competition, or subsidizing exports. Export credits with the official state support aim to facilitate and promote national exports, and therefore the national economy as a whole.

According to the operations carried out, that is, the types of instruments that are used to achieve the goals, agencies are divided into:

- Agencies that perform export credit insurance exclusively, while financing activities are left to the banking sector. Such agencies include: Office National du Ducroire (Belgium) , Serviziassicurativo del Commercio Estero - SACE (Italy) , ECGD (The UK), Guarantee Institute for Export Credit - GIEK (Norway);
- Agencies that provide export business, whose activities are supported by a special agency that finances exports. Thus in France, COFACE is a leader in credit insurance, while Natexis finances exports. In Germany, HERMES provides export business, and KfW finances exports, while in Sweden the Exportkreditnamnden - EKN is in charge of insurance, and AB SvenskExportkredit - SEK is in charge of export credits;
- Agencies that provide services of insurance and crediting of exports and issuance of guarantees in export business. These agencies are: Ex-Im Bank (The USA), Export Development Canada - EDC (Canada), Slovenian Export Corporation - SEC (Slovenia) and ATRADIUS NV (The Netherlands).(Berneunion, http://www.berneunion.org/about-the-berne-union/berne-union-members/)

Another important activity of the agencies in addition to credit and export insurance is ***to provide information and consultancy services***. This activity involves the supply of information to exporters, which in terms of breaking into a new market can be of great importance. (Kjell& Kirsten, 2005, p.676-695) In this context, agencies provide their clients with a wide range of information on the creditworthiness of customers,

banks, institutional framework and legislative regulations in the country of (potential) importer, etc. These pieces of information provide a clear picture of a particular country (foreign partner) by whichrisks are reduced to a certain extent, and therefore the hidden costs of doing business.In this sense, a positive example is the Canadian EDC (Export Development Canada), which supplies its customers with a set of databases including research of regulatory environment and economic conditions in certain countries. In addition, the EDC has the function of mediator in the sense of establishing contact between Canadian exporters and potential partners from other countries, which greatly facilitates the undertakingof initial steps of Canadian exporters on the road to conquer new markets.

4. INTERNATIONAL UNION OF EXPORT CREDIT INSURANCE - THE BERNE UNION

International union of credit and investment insurers - the Berne Union has led to an international cooperation and embracement of sound principles with export credit insurance and investment abroad, as well as to equalize the conditions under which coverage of export credit and investment abroad are approved. The Berne Union was founded in 1934, by a group of private and state-owned export credit insurers from France, Italy, Spain and the United Kingdom. (Berneunion, http://www.berneunion.org/about-the-berne-union/) Registered headquarter is in Bern, which means that the law of Switzerland is applied, but headquarter of a very active secretariat is in London. During time, this extremely important and influential international non-profit association, widened its membership and broadened the range of activities.

The main condition for membership in this association was that an institution ensured*receivables*to significant extent from*non-commercial*–political risks. Insurance claims from commercial risks is also present in these institutions, with the difference that the insurance of *non-commercial* risksis the main characteristic and purpose of association due to its multiple features, non-compactness of these risks, opportunities for simultaneous occurrence of a large number of risks, difficult or almost impossible actuary in a way that it exists in all other types of insurance, insurance institute combinations and measures of foreign policy, geopolitics, national export strategy and development, diplomacy and other public law elements.

Since the mid-nineties until now, the national export credit agencies has joined this association and / or other organizations from countries that have completed the process of transition as well as some countries that have succeeded in an attempt to move from the status of developing countries to the status of developed countries. (Stamenković&Rujević – Džodžo,2008, p.25)***The main aim of the Berne Union*** is the promotion of international practices of export credit insurance and foreign investment, and the acceptance of common principles of insurance, mutual exchange of information about customers, banks and countries. It cooperates closely with international financial organizations. The changes in the market of credit insurance in the early nineties had a major impact on the organization of the Berne Union.Namely, along with the globalization of the world economy came a major expansion of network of branches and subsidiaries of insurers, members of the Berne Union, privatization and acquisitions.

Special activities of the Berne Union include the acceptance of harmonized basic rules and standards in the implementation of insurance, that is,export credit guarantee and investment, and the development and implementation of insurance-related innovative financial products for export and debt collection. The Berne Union, within determining insurance policies, forms the key guidelines for export credit insurance for certain types of products and services, relies on the categorization by the OECD, regarding a list of risks of countries, brings the basic principles and recommends requirements in export credit insurance, guarantee of payment, investment insurance in some investment countries.Members of the Berne Union, in relation to the official export credits (export credits with state support mostly through ECAs and for the corresponding products and the duration over two years), are obliged to adhere to the OECD Agreement on guidelines for officially approved export credits (height of a minimum advance payment, the credit duration depending on the type of export, development of a country, credit risk and country risk, the minimum interest rate, provided that these conditions are reviewed every six months, and the interest rate on a monthly basis, appropriate protective clause, etc.). The present arrangement does not cover the export of military equipment and export of agricultural products.With regard to the premium insurance, since 1998, the OECD members have reached an Agreement on minimum premium rates that must be charged with export credit insurance, in order to avoid the possibility of subsidized transactions, in case of applying lower premium than the prescribed minimum. This agreement is known as "The Knaeppen" packageand within it all the countries are divided in eight categories (the OECD countries with high amount of annual income tax, very low political risk etc. belong to the category "O"), so that the premium is determined depending on the category to which a ranked country belongs in terms of risk, the percentage of credited part of a business and life insurance coverage. Categorization of the OECD countries according to the level of risk is reviewed every six months.

Table 1: Rules of the Berne Union in terms of the credit duration

Types of goods and services	Credit duration
Raw materials, primary products and semi-finished products	Maximum 6 months
Consumer goods and consumer services	Maximum 6 months
Durable goods	Maximum 2years
Parts and components including related services	Maximum 6 months, , exceptionally up to 5 years if it is justified
Quasi capital equipment, including related services	Depending on the contract value, maximum 5 years
Capital goods and project services	Maximum 5 years, or more if it is in accordance with the agreement with the OECD
Complete factories	Maximum 5 years, or more if it is in accordance with the agreement with the OECD

Source: Bern Union General Understanding, January 2001

Depending on the type of goods that are exported, members of the Berne Union agreed on the maximum duration of the credit, as shown in Table 1.

The Berne Union and its members are an important link in the chain of world trade and its member states record a steady growth in business, or in the extent of coverage of export business and investment with state support. The Union concludes agreements, issues recommendations and encourages the exchange of information through three committees - for short-term business, for the medium / long-term business and through the committee for investment insurance. According to estimates, about 90% of world trade is carried out with the support of one or more instruments of trade finance. (Kovačević, 2013, p.12) The importance of export credits mostly includes the following information on the insured amount of export credits.

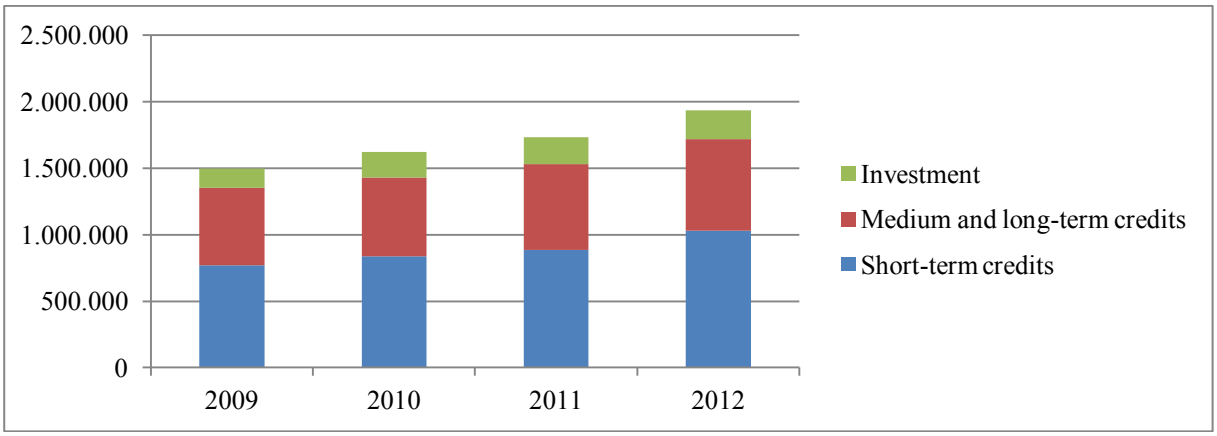

Figure 1: Investment, medium and long-term credits, short-term credits

Source: Berne Union Statistics 2008-2012, http://www.berneunion.org/wp-content/uploads/2013/10/Berne-Union-2013-Charts-and-numbers-for-website.pdf

From the chart we can observe a dominant share of short-term credits (up to 12 months), with a tendency of growth in the period 2009-2012. The same tendency can be seen in the movement along the demand for medium-and long-term credits. The increase in demand for insurance of medium-and long-term credits is characterized by the appearance of environments in which systemic risks occur, and in this segment of the market credit agencies play a crucial role. During the current crisis they mitigated the basics of credit insurance and increased the offer in order to reduce market tensions.

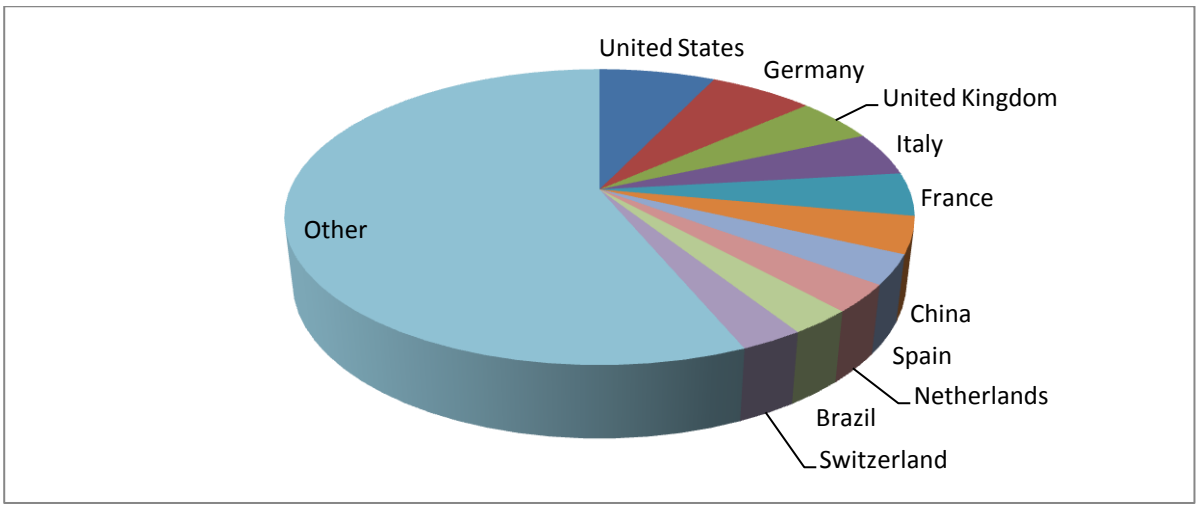

Figure 2: Short-term credit insurance by countries

Source: Berne Union Statistics 2008-2012http://www.berneunion.org/wp-content/uploads/2013/10/Berne-Union-2013-Charts-and-numbers-for-website.pdf

The previous chart illustrates the participation of short-term credit insurance by the countries with the highest credit amount. The United States has the largest amount of insured short-term credits amounting to USD 73,538,000, and immediately after the approximate amounts of short-term export credits belong to Germany and the United Kingdom.

When it comes to the insured medium- and long-term credits by countries, Russia has the highest amount of these credits amounting to USD 9.386 million, and immediately after, the United States amounting to USD 9.224 million. The share of the ten countries that have the highest achieved volume of insured medium-term and long-term export credits can be seen in the following chart:

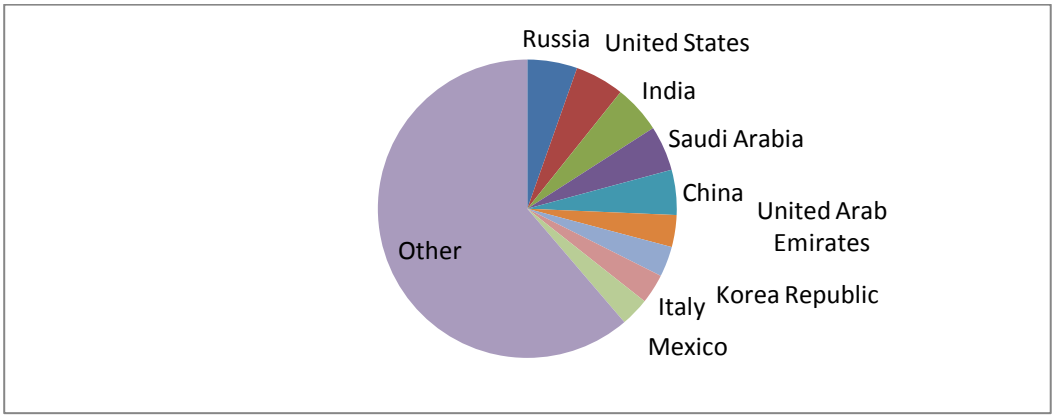

Figure 3: Medium and long-term export credit insurance by countries

Source:http://www.berneunion.org/wp-content/uploads/2013/10/Berne-Union-2013-Charts-and-numbers-for-website.pdf

In addition to the Berne Union, there are other associations of export credit insurers worldwide with state support. One of them is the International Credit Insurance & Surety Association (ICISA), which has 40 member states, and some of them are members of many such associations (e.g. Euler Hermes, Atradius and Coface, as well as the leading reinsurance companies Munich Re, Swiss Re, Hannover Re, Partner Re and Converium). Similar to the Berne Union, ICISA sets as its main aim the mutual exchange of information, promotion of international practices of export credit insurance and representing the interests of insurers at the international level (in the EU, the World Bank, the UN, etc.). The total number of registered agencies (public and private) that deal with financing and export credit insurance is 163 in 79 countries, provided that in this area there are a number of multilateral agencies (Corporation Andina de Fomiento, Banco Latino Americano de Exportaciones, MIGA, Afrieximbank, Inter Arab Investment Guarantee Corporation).

5. SERBIAN EXPORT CREDIT AND INSURANCE

In the mid-fifties, Yugoslavia began to export capital goods and carried out investment projects abroad, along with the demand for export business financing. Our country was among the first developing countries that started the implementation of the crediting system and export credit insurance and investment abroad. From 1957, which is taken as the starting year, a number of phases in the development of export support were allocated, in particular, medium-and long-term exports:

- period from 1957 to 1965 when this was the responsibility of the *Yugoslav Bank for Foreign Trade (later Jugobanka)*;
- period from 1968 to 1979 when the *Export business credit and insurance fund* operated;
- period from 1979 to 1997when the export business support through the export insurance and financing instruments was performed by *the Yugoslav Bank for International Economic Cooperation* in accordance with the specific Law;
- period from 2002 until today: in 2002 with the establishment of the *Insurance and Financing of Foreign Affairs Fund* (at the federal level) and in 2005, with the *Agency for Export Credit and Insurance of the Republic of Serbia*.

Financing exports of capital goods and implementation of investment projects abroad started in 1957, and it was the responsibility of the *Yugoslav Bank for Foreign Trade* - later Jugobanka. (Trifunović, 1988, p.59-67) Until 1965 funds for crediting exports were provided by the General Investment Fund of the Federation and by the Yugoslav Bank for Foreign Trade. The beginnings of export credit insurance are linked to the *National Insurance Institute* and the decision making about the management of the National Insurance Institute that assigned, among other things, the performance of the insurance of export credits.(Gazivoda, 2004, p.34)However, due to the lack of a legal instrument that would determine more precisely how this activity would be performed and due to the lack of experience in the field of export business insurance, the country resorted to adopting the business concepts of foreign insurance companies. Thus we adopted *The Regulation for insurance claims from foreign and public utility services and other companies for exported goods on credit*, by following the model of the internal rules of German insurance company *Hermes*. The commercial risks were the subject of insurance exclusively, while the *Yugoslav Bank for Foreign Trade*dealt with the non-commercial risks insurance. Non-commercial risks insurance could not be provided without the adequate state guarantees, and funding from the budget.

The Agency for Export Credit and Insurance of the Republic of Serbia Inc. (*further referred to as* ***the Agency***) was founded by the Law on the Agency for Export Credit and Insurance of the Republic of Serbia in 2005, as well as other state institutions with the aim to "encourage and promote exports and development of economic relations between the Republic of Serbia and other foreign countries." (*Official Gazette of the Republic of Serbia,2005*)
The task of the Agency, in order to improve the strategic requirements of the export economy and to change the structure of exports of the Republic of Serbia, is to act jointly with all the development, financial and other institutions, and private companies and institutions when there is a mutual interest. An initial funding for the work of the Agency for Export Credit and Insurance of the Republic of Serbia in the amount of 25 million euros has been earmarked from the budget of the Republic of Serbia.
The Agency in its business policy defines the following services:

- crediting export business (including direct crediting, co-financing and refinancing credits through commercial banks of exporter);
- insurance claims of exporters on the basis of export business;
- international and intrinsic factoring;
- issuance of state guarantees (this service is not yet approved, but, according to information from the official website, it is under review); and
- consulting. (The Agency for Export Credit and Insurance of the Republic of Serbia,www.aofi.rs)

First of all, it is evident that the Agency for Export Credit and Insurance of the Republic of Serbia in its operations, such as the Fund, supports mainly short-term business. The Agency, according to its business policy requires certain conditions when it comes to foreign affairs and exporters who apply for certain services.
Conditions are divided into general and specific, that is binding and non-binding.

- General Binding: export in value of at least 1.0 million euros in the previous year; a net operating result in the previous year; share of domestic origin goods at least 51% of the value of goods subject to exports and financing;
- Specific binding conditions: positive creditworthiness of the borrower; positive profitability of export project; positive quality assessment - the collateral safety;

- Additional non-binding conditions (the fulfilment of these conditions implies the favourable conditions in obtaining services, such as the achievement of positive net export effect and a major exporter status. (Unković&Stakić, 2011, p.132)

Based on these conditions it can be concluded that the conditions are primarily formulated in order to achieve basic principles for agency formation - liquidity, safety and profitability. Only hints of support for a certain goals of economic policy (net financial effect) are found at additional, non-binding conditions. Agency is allowed in the discretion to determine by its acts the conditions and the way to maintain the real value of assets, as well as other measures to protect against the risk of its operations. Business policy of the Agency is largely based on the previous principle, which can best be seen from the fact that the credits are granted to a foreign currency, while the exchange rate at which the repayment of credit is done cannot be lower than that at the time of closing a business. Thus in case of strengthening the domestic currency, revenues of the Agency increase based on exchange rate differences.

The Agency pays a special attention to establishing and maintaining successful relationships with international financial institutions, development banks, export credit agencies and commercial banks. It actively cooperates with chambers of commerce and other state institutions in order to find the best solutions for their clients. From 2011 it has been affiliated to the European Association of Public Banks and they have signed a cooperation agreement with a Greek state export credit agency-ECIO.

In 2011, the Agency concluded 58 contracts of insurance claims based on the export activities of domestic customers in relation to 1124 foreign buyers.(The Agency for Export Credit and Insurance of the Republic of Serbia, www.aofi.rs) From May 2006, when the first insurance policy of export receivables against commercial risk has been issued, the number of insurance contracts has significantly increased. In the main part of the insurance portfolio the most frequent is the metal industry with a share of 20.38%, followed by paper manufacturing with a share of 17%, wood processing with 7% and chemical products with 6%.

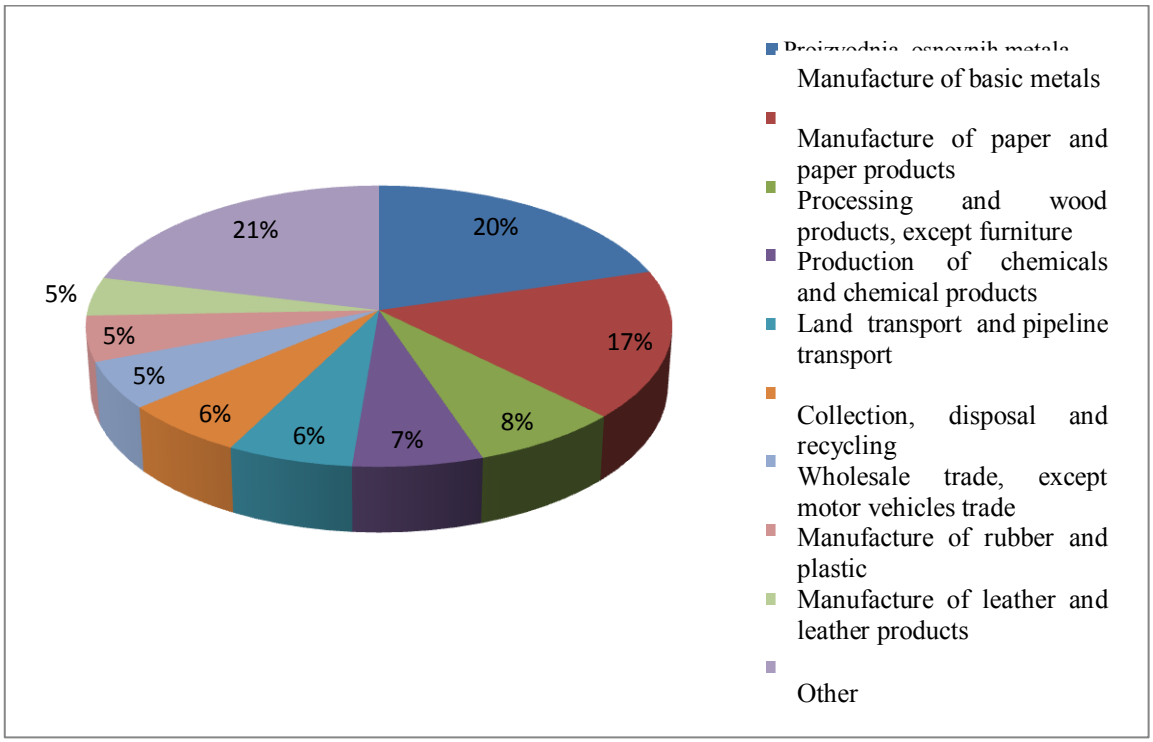

Figure 4: Diversification of the main portfolio in relation to industry branches
Source: The Agency for Export Credit and Insurance of the Republic of Serbia http://www.aofi.rs/wp-content/uploads/2011/12/AOFI-GI-2011-srp-web1.pdf

The EU countries are leading in the total amount of exposure in the structure of export business. Among them Italy has the predominant participation.Countries in the region are significant destination of Serbian export products. Diversification is the branch of activity and represents the measures implemented by the Agency in response to the still current world crisisin order to achieve the effect of reducing the harmful effects of the crisis. The effects of the economic crisis are particularly reflected in the area of buyers' liquidity. In 2011 the Agency received a total of 36 damage claims. During the reporting period 8 damages per insured events were paid (settled), and according to the amount of damages Germany had the largest

share.Through the possibility of paying compensation, Serbian exporters recognize the importance of risk sharing arrangements and insurance debt collection, as well as its impact on preserving the liquidity of companies.

During 2011, the Agency granted 57% of realized credits with a maturity of 6 months, while the remaining 43% of the credit had a maturity of up to one year. Given the evaluation of professionals and acceptance of a controlled risk in its portfolio, the Agency, despite the effects of global economic crisis on Serbian exporters, achieved the collection of overdue credits of about 95% with the use and activation of a variety of collateral, while the remaining 5% of delayed credits were covered by high-quality collateral.

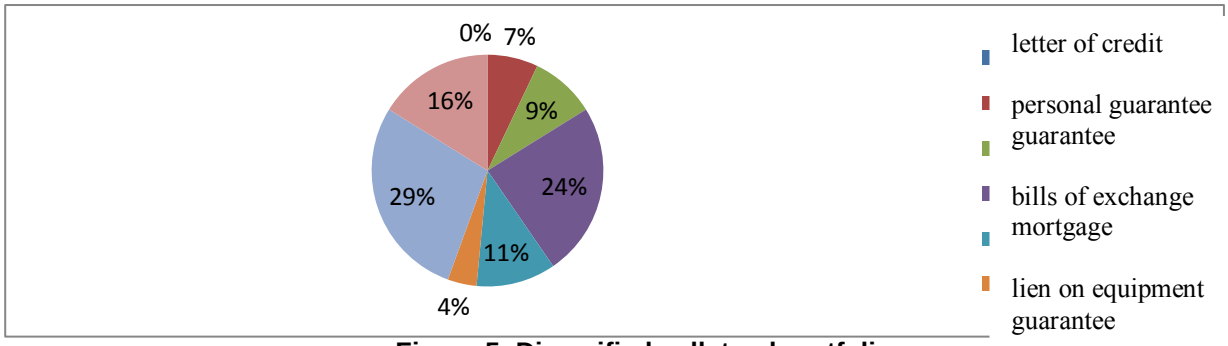

Figure 5: Diversified collateral portfolio

Source: The Agency for Export Credit and Insurance of the Republic of Serb -content/uploads/2011/12/AOFI-GI-2011-srp-web1.pdf

During 2011, the Agency has realized 64 credits amounting to EUR 10.575 million to exporters who belong to small businesses, 70 credits amounting to EUR 21.74 million to exporters belonging to medium-sized enterprises and 56 credits amounting to 43.97 million to exporters-large enterprises, as can be seen in the chart below.

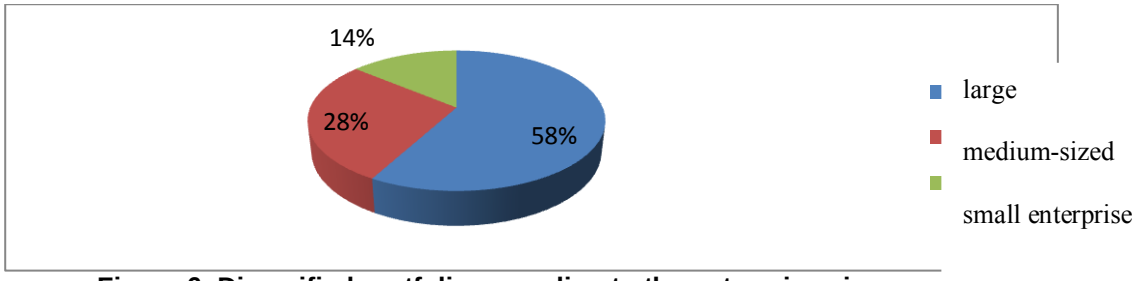

Figure 6: Diversified portfolio according to the enterprise size

Source: The Agency for Export Credit and Insurance of the Republic of Serbia, http://www.aofi.rs/wp-content/uploads/2011/12/AOFI-GI-2011-srp-web1.pdf

Businesses operating in the food industry had the highest share in the use of short-term credits, amounting to EUR 30.415 million, representing 40% of all placements. Companies of manufacturing (40% of all placements) and metal (10% of all placements) industry also had a significant share in the credit portfolio of the Agency. The share of other industries can be seen in the following chart:

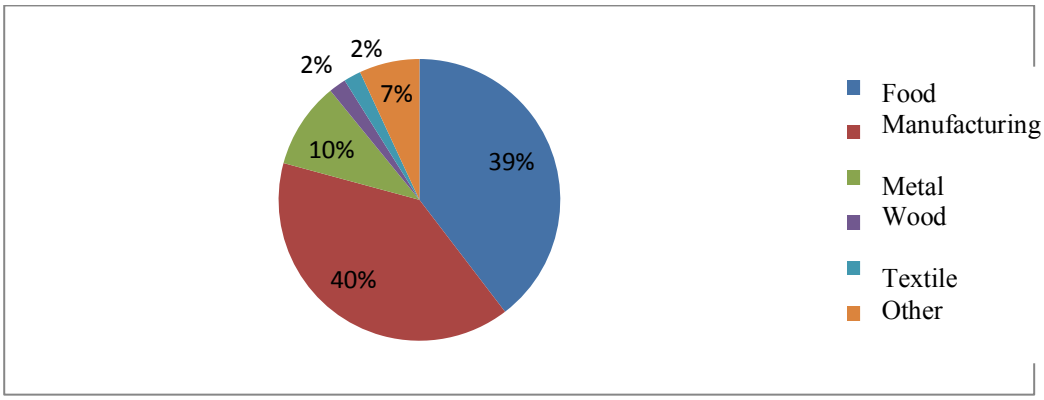

Figure 7: Diversified portfolio according to the industry

Source: The Agency for Export Credit and Insurance of the Republic of Serbia, http://www.aofi.rs/wp-content/uploads/2011/12/AOFI-GI-2011-srp-web1.pdf

The EU affairs have the largest share in the structure of credited export business amounting to about 59%, because precisely there are the biggest trade partners of Serbia. Then, there are:export business with the former Yugoslav republics, which participate with 29% of the Agency's portfolio and operations with Russia with an amount of 12%. By crediting concrete export contracts, the Agency supported the export of goods to the Russian market with EUR 9.12 million, EUR 8.07 million to the Dutch market, EUR 6.77 million to the Italian market, EUR 6.58 million to the market in Bosnia and Herzegovina and EUR 5,540 000 to the German market. The presented data are shown on the following chart:

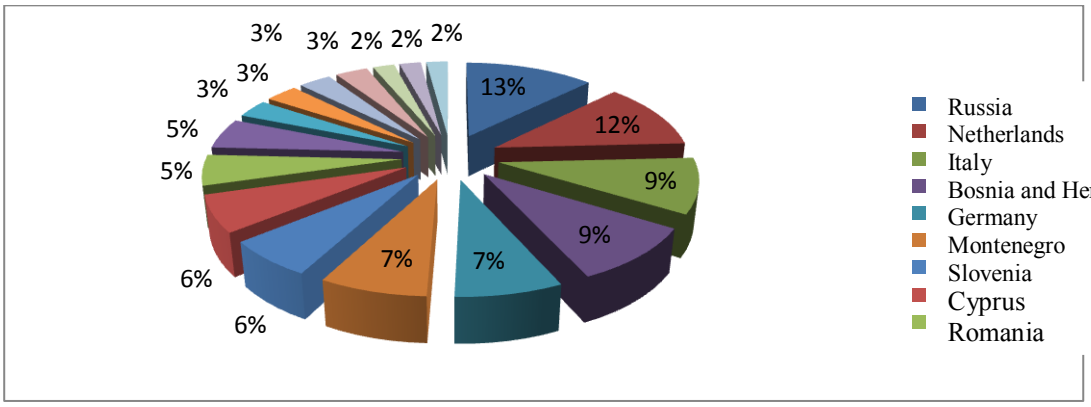

Figure 8: Diversified portfolio according to the country of export

Source: The Agency for Export Credit and Insurance of the Republic of Serbia, http://www.aofi.rs/wp-content/uploads/2011/12/AOFI-GI-2011-srp-web1.pdf

After the commencement of the transition process, that is, from 2001, Serbia has faced with the problem of high foreign trade deficit, and the current account deficit. As an imperative, there is a need for increasing exports in the future. Despite the existence of export credit agencies, Serbia still does not have the sufficient capacity to support stronger exports. In order to provide more efficient support to their exporters, the Agency provided its clients with information on the creditworthiness of existing and potential customersin addition to crediting under favourable conditions in cooperation with the similar agencies in the region and credit-rating agencies abroad.

6. CONCLUSION

Organized institutional support for exports is of great importance, because in this way the competitiveness is strengthened in the market. A demand for agencies for crediting and insuring exports grows by intensifying foreign trade. This should enable the secure exchange of goods and services. In developed countries, insurance agencies are specialist institutions that employ the export crediting programs in the name and on behalf of the Government and by their support for crediting exports, the risks and costs of conquering new markets are significantly reduced. Agencies for Export Credit and Insurance differ from country to country, and we cannot say that there is a typical agency.
It is important to highlight that the state is of great importance and plays an important role in supporting export credit agencies.State aid to the exports is a part of a general economic policy of the state because it has the task of contributing to the achievement of positive effects of national enterprises in foreign markets within the support of exports. State support of exports is usually in the form of insurance, which means that the state issues guarantees, on its behalf and for its own account, on the basis of insurance business and export financing, so it may be the insurer or reinsurer of risk and thus can provide favourable financing conditions for its exporters or commercial banks. The work of government agencies for insurance and financing export business is subject to international regulations that coordinate the work of these agencies at the multilateral level.

In the area of regulation, the Berne Union, the OECD, the World Trade Organization and the European Union achieved the long-term results. The Berne Union and its members are an important link in the chain of world trade and its member states record a steady growth in business, that is, in the extent of coverage of export business and investment with official state support. The Union concludes agreements, issues recommendations and encourages the exchange of information through the three committees - for short-term business,for the medium / long-termbusiness and through the committee for investment insurance. There is a dominant share of short-term credits (up to 12 months), with a tendency of growth in the period from 2009 to 2012. The same tendency can be seen in the movement of demand for medium-and long-term credits.The increase in demand for insurance of medium-and long-term credits is characterized by the appearance of environments in which systemic risks occur, and in this segment of the market, credit agencies play a crucial

role. Countries that were analysed, through its economic policies indirectly affect the performance of foreign trade activities, since export growth is one of the key factors that affect the economic prosperity of the country, andthe USA, Russia and Germany have a dominant share of insured credits.

The awareness of Serbian economic characteristics and current export performance of the domestic economy imposes the need for designing appropriate economic development strategy with special emphasis on the strengthening of the export sector. Policy of strengthening the export sector should be supported by a strong economic sector with a large number of competing companies that operate in a competitive environment. Only under such conditions, the existence of adequate export credit agencies may be additional support to strengthening the export sector. For this purpose it is necessary to redefine the current role of export credit agency that would facilitate the fulfilment of its basic function, in the optimal way and under the given conditions.When designing the policies for encouraging exports through strengthening export credit agencies, special attention should be paid to regulation in this area. Due to the fact that Serbia is still not a member of the European Union there is a possibility for more flexible operation of existing agencies. That possibility, along with the necessary condition for enhancing the competitiveness of the domestic economy and the existence of clearly conceptualized system of export incentives, provides a reasonable basis for the growth of the export sector and the creation of realistic assumptions for long-term economic development.

Abstract: In this paper we presented a model of program budgeting as a contribution to modern trends of an economical handling of public expenditures. It will also be the topic of this paper to prove that certain development goals of public institutions and authorities can be achieved by economical execution of planned expenditures. Links between the realization of the goals and execution of expenditures will be displayed using the developed model of program budgeting, which otherwise is not possible with line budgeting of expenses.

Keywords: execution of expenditures, program budgeting, carriers of execution, development goals, capabilities.

1. INTRODUCTION

In the first decade of the twenty-first century in the Republic of Serbia a preparation for the introduction of multi-year budgeting according to the model of most countries in the region was started. The result is the fact that since 1st January of 2014 all public expenditures within the budget of the Republic of Serbia must be expressed through program budgeting. While in the world multi-year ("mid-term") budgeting began in the 60's and early 70's, today this approach has become more or less universally accepted in most countries.

Modern strategic form of budgeting which soon became represented in more than 72% of countries around the world is the model of program budgeting. Because the program budgeting focuses on planning, that is the expected results, as well as monitoring which was achieved in the previous period by using of the approved resources. Also, program budgeting clearly introduces the component of liability (for direct users of budget resources) for implementation of the program and thus comes to improving the process of managing performance of the program.

Phases of the model of program budgeting are: planning, programming, budgeting and execution. Planning, as the first phase of the model of program budgeting involves making plans continuously, from long-term to short-term with established goals of development of public authorities and institutions. Programming is the second phase of the model of program budgeting of defense expenditures with which adopted planning documents are translated into programs, projects and activities for a specific time period within available resources, for the purpose of maintaining and developing the capacity of public authorities and institutions. Budgeting involves making a financial plan for the purpose of expressing funds required for the implementation of plans and programs. The focus of this phase model of program budgeting is to convince the Government of Serbia and the members of the National Assembly of the Republic of Serbia with arguments that it is necessary to provide the necessary resources to implement the program and to develop and maintain the established level of capability. Execution is the last stage of the model of program budgeting. The point of this phase is to provide consistent implementation of plans, programs and budgets, and with a goal to build capacity of established public authorities and institutions.

Planning and execution, as the first and last phase of program budgeting are ongoing processes that, unlike programming and budgeting phases are occurring continuously, while the phases programming and budgeting are occurring in cycles in accordance with the budget calendar of activities of the Law on the budgetary system of the Republic of Serbia.

In most scientific and expert papers mainly the phases of planning and budgeting are dealt with, while the programming and especially execution phase have remained least explored. Therefore, the case of this study is to track the execution phase of expenditures and/or financial plan according to the set activities and programs, taking into account the already mentioned limitations, in order to achieve the specific goals of state authorities respecting the principle of economy.

2. PROCESS OF EXECUTION OF PROGRAM BUDGETING

The process of execution of program budgeting takes place with the realization of planned subsistence needs through engagement of arranged budget resources and creation of obligations for payment, as well as payment of obligations created, that is final expenditure of budget funds according to the annual plan.

Execution phase in the process of program budgeting is a dynamic process that permeates all three previous stages of this process, as shown in Figure 1. It is very important to note that as a result of the execution phase, is the answer to the question of whether the set goals are reached.

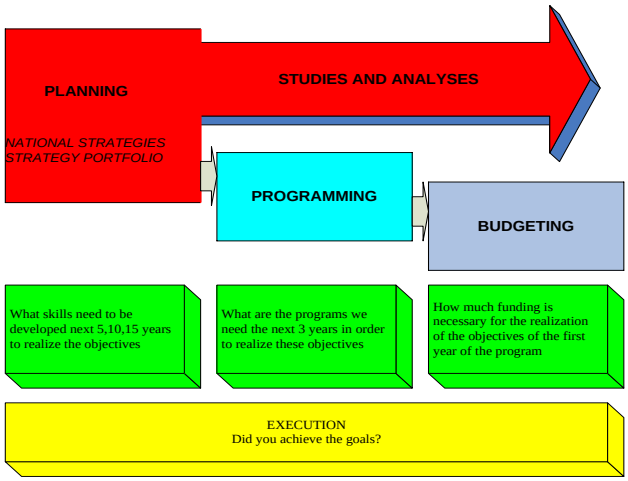

Figure 1: Phases of program budgeting

Monitoring the execution phase is a process by which supervision and control of the implementation of plans, programs and financial plan is done in order to achieve the expected results and achievement of goals. By analyzing the execution of plans, programs and financial plan the degree of achieving the goals, deviations, causes and proposal of corrective measures is determined.

With corrective actions consistent implementation of plans, programs and financial plan is achieved. Correction of plans, programs and the financial plan is done by a competent body in case of a change of the situation or when their execution is not possible. The execution phase is viewed through the implementation of plans and programs. However, following the execution of the financial plan, realization of activities, projects and programs is followed as well, for whose realization funds are necessary, so it is especially described in this phase.

Optimal management of execution of tasks in the planned dynamic requires the presence of back links that provide timely and accurate information on the functioning of the process of program budgeting.

Regardless of the reality of assessment of planned assumptions and rigor of the taken proceedings in relation to the planned regulation, it is normal to expect some differences and discrepancies between planned and actually completed tasks. To minimize the generated differences between the actual and planned conditions it is necessary to establish mechanisms for successfully organized collection and

transmission of data on the actual situation, determine the difference between the actual and planned conditions, and efficient functioning of corrective factors that include additional actions with a goal to minimize deviations of actual in relation to the planned situation.

The difference between planned and actual results may occur as a result of lack of data, thus misjudgment and ultimately inadequate plans. In addition, it can occur as a result of inefficient organizations and oscillations of influencing factors in the environment.

By monitoring the implementation of the annual plan by using computer technology or other standard procedures, variations of possible interventions are determined, with which the results of possible deviations will be reduced to tolerance limits. By choosing one of the possible variants of correction of the flow of information in the return turn continues, until the system is brought into balance.

3. PLANNING BASED ON RESULTS - TARGETED PLANNING

Planning based on the results or targeted planning, involves selection of the best action for the realization of the given goals and results of the defense system. As shown in Figure 2, the model of program budgeting, which is based on the results, in reality usually involves "confrontation" of defense's objectives and available resources.

System analysis allows, in this context, the decision-maker to select the preferred option among alternative choices and the program through selection of variants and models for estimating the optimal alternative (Method Pattern, CPE, Elektra, stochastic analysis, game theory and coalition, scenario method, Delphi survey, multi-criteria analysis, simulation model, matrices of realization of the objectives of Morris-Hills etc.). In essence, system analysis allows, "adaptive slipping" from the global long-term plan to an encrypted plan with iterative graphics, respecting aleatory boom variables and time horizons of alternative strategies in the simulation of the program (F.S.Quade). This basically determines the policy of distribution and allocation of resources within a long-term strategic planning, mid-term program orientation and annual operating budget choices.

The development process is different for each budget beneficiary. The development process of budget funds user can be viewed as a process of changing its structure and a way of functioning which has a goal to present the existing potential of the existing state (S0) into a new better state (S1). This conversion is a complex and dynamic process that, according to Nikola Čubra (1973), can be symbolically displayed in the following way (p.25):

„a) stages of development (translation) of the system from one state to another:

$$S0 \rightarrow S1 \rightarrow S2 \rightarrow S3 \ldots\ldots\ldots\ldots\ldots \rightarrow Sn \quad (1)$$

b) the quality of the system in each subsequent stage should be higher than the previous:

$$K0 < K1 < K2 < K3 \ldots\ldots\ldots\ldots < Kn \quad (2)$$

c) the intensity and speed of development show positive trends:

$$(K1-K0) < (K2-K1) < (K2-K3) < \ldots\ldots\ldots\ldots < (Kn-1) \quad (3)“$$

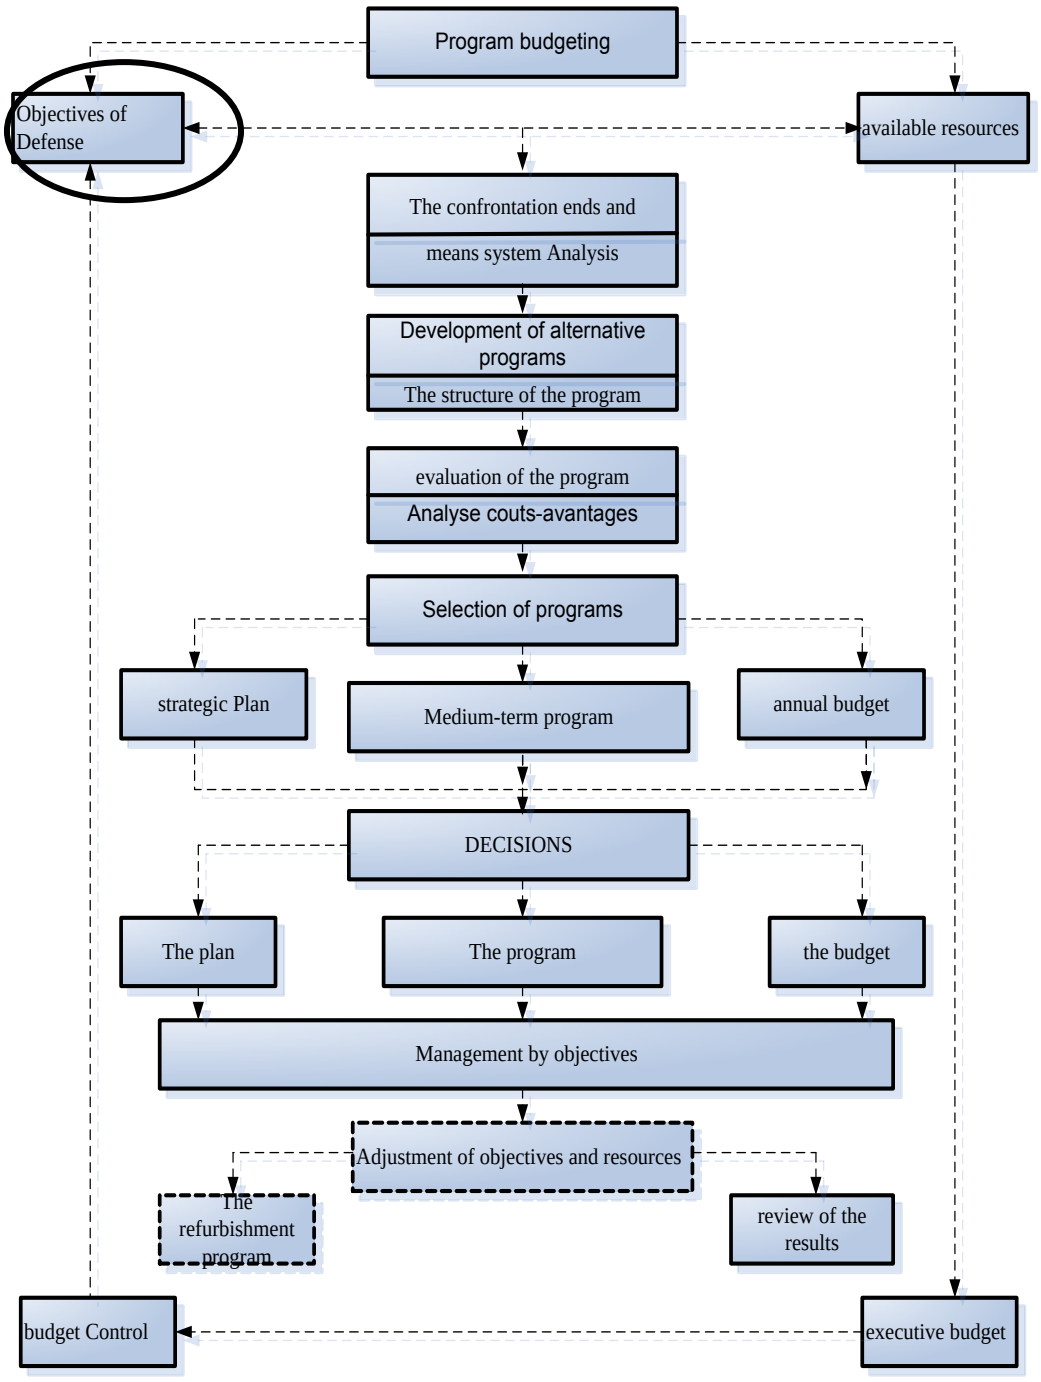

Figure 2: Ristic (1989) „The ratio of available financial resources and stated goals" (p.544)

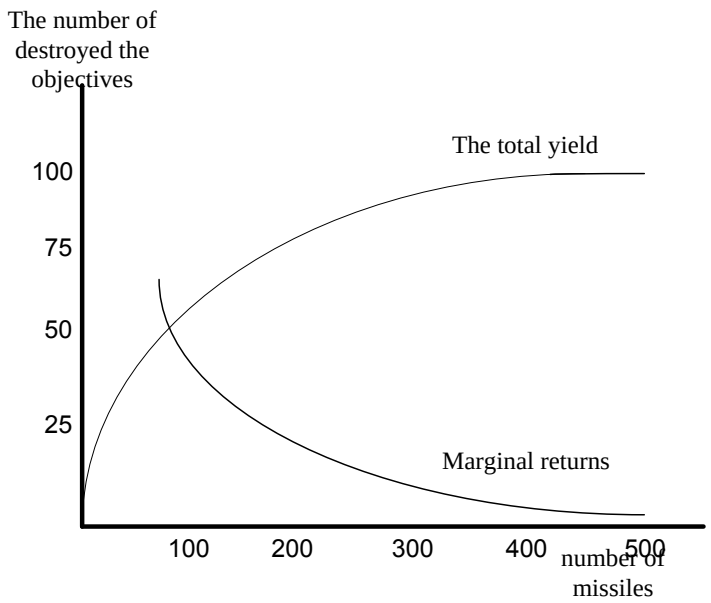
Based on the presented data, we can conclude that the system evolves continuously, which means that it is not desirable that any development phase is skipped. However, the transition from previous to the next state can be significantly facilitated and accelerated if, among other things, in planning, budgeting and execution of needs and expenses of users of budget resources, such organizational solutions, methods and procedures are used by which even with unchanged material conditions, a greater efficiency, that is, higher level of efficiency and effectiveness of budget beneficiaries is achieved or, what amounts to the same thing, with less expenditure of funds for expenses of budget funds it maintains its current level of efficiency which is considered sufficient.

Graph 1 Stiglitz (2001) „The role of marginal analysis in defense" (p.340)



For example, the use of marginal analysis, according Hitch (1966) for assessment of whether you should spend more on defense, it is necessary to know how much additional "protection" will you get from additional expenses in the amount of one billion dinars. Let us assume that the probability of successful hitting of the target with a rocket is 50% and there are 100 targets to destroy. So 100 missiles launched at targets "would achieve an expected score of 50 hits, 200 rockets - 75 hits, 300 rockets - 87 Hits", as shown in **Graph 1** (p.50-51).

It is noticeable that there are very severe diminishing returns. Each target can be destroyed only once, and some of the missiles will fall on already destroyed target. While the first hundred missiles would destroy 50 targets, the number of missiles increased from 400 to 500 would increase the number of targets destroyed only by three. Therefore, one shouldn't ask the question whether the 97 targets destroyed are worth spending 500 missiles, but rather, whether the goal of destroying three extra targets is worth spending hundred additional missiles. This type of analysis is not easy. Linking defense expenditures with its goals and demonstrating what could be gained from additional expenditures, it can be expected that it will bring much more rational decisions about how much is enough.

In the above mentioned the basic aim and essence of modern planning, programming, budgeting and execution of the needs and expenses of defense is contained. The main measure of quality is, therefore not at any price greater efficiency but sufficient or the greatest possible efficiency of the defense system in the current (real, actual bearing) economic and overall social conditions.

Selection and matching of the needs and expenses that are required for high-quality performance of all activities in the organization and preparation of the defense system in terms of actual, economic and socially real opportunities is a necessary but not sufficient condition for the effective execution of the stated objectives of the organization. The quality of use and consumption of available resources, i.e. the degree of economic rationality, also has an impact on the effective achievement of set goals of an organization. This is achieved through adequate and modern normative legal regulation of the financial functions of the organization as well as quality management of its resources.

4. ESTABLISHING LINKS ON IMPLEMENTATION OF FINANCIAL ASSETS WITH REALIZATION OF THE GOALS

Execution phase in the process of program budgeting is a dynamic process that permeates all three previous stages of the process, according Trandafilovic & Knezevic (2013). It is important to note that as a result of the execution phase, as shown in Figure 3, an answer to the question of whether we

achieve the set objectives, as defined in point A and represent the desired state - point B is got, (p.210-214).

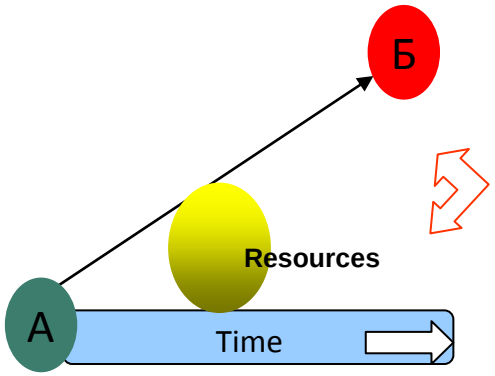


Figure 3: Defining the goals

If it is determined that the mid-term objective of the organization in the period from 2012 until 2014 is the following: "The financial position of employees is actually improved by 10% and the living and working conditions are favorable", and that for its implementation in 2012 is necessary to use 231.75 million dinars, in 2013. 297.90 million dinars and in 2014. 266.61 million dinars, which for the entire period amounts to 796.25 million, then it is precisely known for the projects and activities in the observed years how many of them contribute to the realization of that objective and how much it costs.

In Table 1, mid-term goals and projects are shown with activities for the realization of this goal in given years. Financial assets shown by years are expressed in millions of dinars. All three projects are shown, but for simplification, only the first project is presented with its activities while the second and third are with no activities with total expenditures by the observed years. Projects and activities are indicated numerically.

For the implementation of the mid-term goal, "The financial position of employees is actually improved by 10% and the living and working conditions are favorable" in the period from 2012 to 2014 were determined by three projects:

1. Redesign and construction of residential buildigs with signs O24, O25, O28, O29 and O32 at location "2 MZ Bežanijska hair" labeled 04-01-01;
2. Urbanization and construction of social housing marked 04-01-02 and
3. Buying apartments labeled 04-01-03.

During this period, expenditures are presented for the realization of the given projects for each year in total. However, in the project documentation all expenditure by economic classification of accounts are shown, so it is simplified to monitor the implementation of projects through the implementation of the financial plan and ultimately realization of the given mid-term objective.

In the framework of the given project activities for their implementation with related expenses per year are summarized. The sum of the costs of all activities in the project within one year is the cost of the project in a given year. The sum of all costs within the project during the entire period of its realization represents is its total cost.

Table 1. Realization of goals with projects

The financial position of employees is actually improved by 10% and the living and working conditions are favorable				
Designation of the project/activity	2012.	2013.	2014.	Total
IN TOTAL:	231.750	297.900	266.610	796.250

04-01-03	184.104	115.992	115.992	416.088

5. CONCLUSION

Introduction of program budgeting model by the Government of the Republic of Serbia is certainly a step towards to a more efficient and rational management of public expenditures. Compared to the old way of planning the budget, whose main focus was the appropriation by economic classification, i.e. budget

planning by expenditure items, the focus of program budgeting are the results that are realized and objectives that are achieved by engaging all of the planned resources (human and material). Thus, program budgeting is an approach, or a process whose goal is establishing a connection between the involved and proposed resources and the achieved results.

Defining objectives and building capacity is not at all an easy job, on the contrary. Because, in a situation of lack of financial resources, as is the case in recent years, goals must be redefined and some capacities have to give up from or accept the strategic gap and not give up anything that was already planned.

Programming creates the preconditions for the choice of the best variant implementation for the realization of set objectives using available resources. So, programming makes visible the connection between the abilities of the defense system and the budget, as well as between long-term vision and short-term plans, making them understandable to decision-makers and key stakeholders.

In order to link the execution of expenditure with realization of objectives, it is necessary to fulfill the following conditions: to ensure continuity in the planning, of long-term over mid-term till short-term

plans; for the programs to be compatible with mid-term plans (that arise from long-range plans); for programs and individual projects arise from defined long-term goals and present a realization of mid-term objectives; for the activities to be planned in the framework established by the program or projects and the expenses for the years are related to activities.

Observing short term positive effect of the introduction of program budgeting is that the purpose of the spending public funds is known. In long term growth of state institutions and organs is expected with optimal costs, and probably, the whole economy and society as a whole.

Abstract: *This document presents a system of programming budgeting, that is a model management with a goal of establishing relations between engaged and proposed resources, in fact achieved results. Special attention is dedicated to the need as well as to the achieved results of the applied model in order to dispose rationally and finally in order to conduct determined tasks efficiently..*

Keywords*:* programming budgeting, development, resources, management, defense system.

1. INTRODUCTION

Changes in society and therefore in state, that occurred in the last decade of the 20th century and in the first decade of the 19th century, have influenced by the fact that the rooted attitudes and opinions have changed within the society which are a reptil of old times when it was thought that the education and defense are too important from a political, sociological and human aspect to be able to undergo some kind of economic calculations. On the contrary, in the today's situation, management structure of the system of defense must act immediately and make concrete decisions according that and, also, being faced with the problem of limited resources.

The additional problem for the defense system of the early 21st century, is that the previous system of financial resources, particularly budgeting, was not sufficiently effective and did not corespond to the complex requirements that were demanded of the management structure of the defense system of Serbia. The planning area of the defense system of Serbia was largely undeveloped and the need to regulate this in a qualitatively new basis was reported as an imperative. There were no mechanisms to provide sufficient information if the planned goals and objectives of the defense system would successfully implemented, and whether if an appropriate allocation of the resources for the realisation of the planned objectives would carried out.

Managing of financial resources was reduced to an allocation of available financial resources, without interconnections between the tasks of defense and financial plans. Also, there is problem of converting strategic objectives into financial plans that can be linked to budget resources. The fact is, of course, that many aspects of pre-defined objectives are implemented within the regular activities in the defense, but without feedback.

Financial planning, mechanisms for the preparation of financial plans and regulations for their enforcement haven't, until recently, provided sufficient information on whether the defined objectives have implemented successfully in practice. Because of this it was very important to improve the links between financial plans and strategies, to provide appropriate mechanisms for monitoring the effectiveness of their implementation and consideration of future needs. The introduction of functional programmatic dimension into the existing budget classification was one of those mechanisms.

The modern view and the view of overcoming problems of increasingly limited incomes also in the public sector of the Serbian government, found the solution in the 'budget directed to results' or program budget. The role and place of the state in financing defense system is characterized by compromise in conflict resolution: to achieve the defined goal with minimal financial investment. The cause of this discrepancy is primarily the needs of the various growth opportunities that defense functions of the state require and its limited material and financial resources. However, the government of every state is obliged to, on the one hand, consider the economic situation of the country, and on the other hand, to give stable defense system, racionally using limited resources.

Management structures of the defense system, as an integral part of society and its problems were faced, already in the 20th century and in the first half of 21th century, on the one hand, with the problem of transmission of liabilities from year to year, rising debts to suppliers, costs of court udgements for the delay in payments, penalty and interests for late payments of accrued liabilities, and on the other hand, with limited

and insufficiently available financial resources. What necessarily required news and changes in management of financial and other resources of defense.

The significant changes have been implemented in the system of defense of The Republic of Serbia in recent years. The overall objective of the changes is the transformation of the system in line with modern security challenges and threats, that is needs and opportunities of The Republic of Serbia.

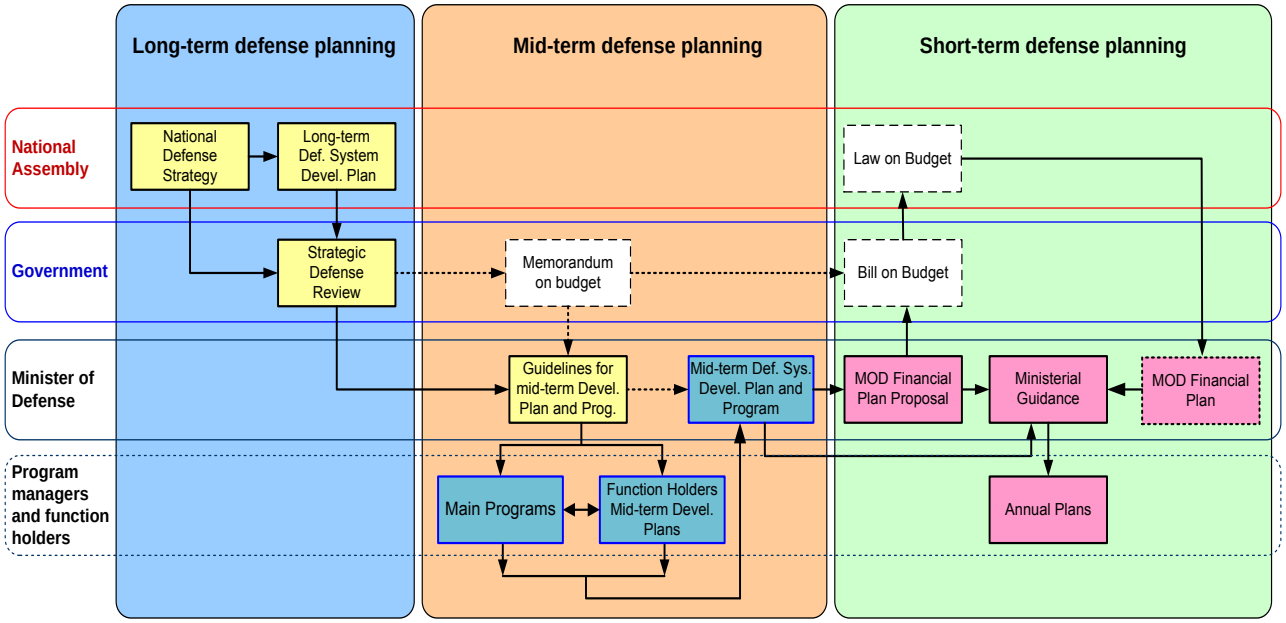
In order to ensure continuous growth in the quality of defense capabilities, increase efficiency of execution of the defense tasks, rational use of available resources, ensuring adaptability and flexibility of the process executing the defense tasks and coordination of development components of the defense system with the overall development of the State in the Ministry of Defense and the Army of Serbia in 2008. the system of planning, programming, budgeting and execution (PPBE) was introduced as a new management system of defense resources and in the final funding of developing programs and projects of defense system.

2. BUDGETING ANALYSIS OF DEFENSE SPENDING BEFORE AND NOW

Planning of the development of the defense system in the period before the introduction of program budgeting model was disintegrated and there was no continuity in the planning process. The development plans were made by the the office holders of the defense system each of them for themselves individually. Disintegration of planning functions, that existed before the introduction of a new defense resources management process, was a reflection of the existence of a large number of office hlders dealing with problems of planning. A particular problem was reflected in the lack of legislative and normative framework that would regulate this area.

Integration of the functions of development planning of the defense system, as it introduced a model known as program budgeting system PPBE, contributed to increase the overall performance of the Ministry of Defense and the Army of Serbia, because the defense system is viewed as a whole, fortified with all the tasks and resources required for their completion. Of course, the global financial crisis further complicates the problem, because the fundings for the tasks laid down by the Ministry of Defense and the Army of Serbia is getting more and more restrictive.

Decision makers in the defense system chose to introduce an integrated system of defense resource management, in order to bridge the created situation and to coordinate the requirements of the defense system and the possibilities of our society. Due to adoption and implementations of the PPBE system, integration of planning function as a first stage in the process of defense resource management comes into play.



Picture **1:** Model of Serbian Defense Planning-now

Continuity in the programming phase is ensured with the development and adoption of long-term development plans of the defense system on which the medium term plans and development programs are

made, which later serve for the development and implementation of short-term plans. Planning model which is represented in the defense system of the Republic of Serbia in 2011.is presented in picture 1.

Long-term planning is the process of setting objectives of the defense system for a longer period of time, as well as methods for their implementation. The long-term defense planning is an interdisciplinary process that involves many different activities. Activities are mutually dependent and precise coordination is needed. An interdisciplinary approach to planning requires close cooperation between the planners and military commanders, various specialists, political authority, etc.

The purpose of long-term defense planning is to consider the mission and tasks of the defense system and to establish realistic long-term objectives adjusted to the missions and tasks, as well as to determine the strategy of its realization. Long-term planning is oriented toward the relatively distant future and that represents a problem for planners as they face many difficulties that are the consequences of uncertainty in the future. Also, long-term defense planning should enable the appropriate development of defense system and avoidance of unwanteded effects.

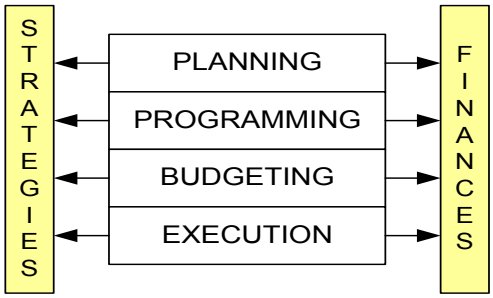
Medium-term planning is the process of determining the objectives of the defense system for medium-term planning period and the ways of their implementation. The objectives and priorities are determined by factors of development capabilities of the defense system that need to be realistic, purposive, implementable, measurable, time limited and classified according chronological and logical sequence.

Short-term planning is part of an integrated planning process that operationalized the medium term planning. In the defense system of the Republic of Serbia it includes a one-year planning period. Successful implementation requires the preparation of annual plans of a number of different plans that are differents in content, level of detailing, the time interval covered etc.

3. PROGRAMME BUDGETING EXPENDITURE OF THE DEFENSE SYSTEM

In the public sector reform and within it performance-based budget or PPBE system, expenditures are classified according to programs and projects, operational objectives of each program are determined , and performance indicators are established for each program and activity. PPBE system is one of the important components of a wider process of reform of public finances. Specifically, it means the introduction of an effective mechanism for monitoring the achievement of defined objectives.

In the current environment of public finances, it is difficult to translate strategic objectives into operational plans and projects of development of the defense system, which can be linked to the budget means (picture. 2). The fact is, of course, that many aspects of already defined objectives are being implemented within the ordinary activities of direct budget funding.



Picture 2: Converting strategic objectives into financial plans

However, operational planning, mechanisms for the preparation of financial plans and rules for the enforcement of them, within the line budgeting, which was represented by 2008. in the defense system, did not provide enough information about whether the defined objectives are being successfully implemented in practice. It was therefore important to improve the links between financial plans and strategies in order to provide appropriate mechanisms for monitoring the success of their implementation and consideration of future needs.

Therefore, the program budget is a comprehensive system of defense resource management - a system of monitoring results (performance management system). Key feature of the program budget is in a change of

budget focus from budgetary commitments on short-and long-term results and reached objectives of the defense system.

However, limited resources imposes, in fact, wanted it or not, accepting different, basically an economic standpoint, which is characterized by:

1. the need for the best utilization of resources available for the specific purpose
2. the influence by the consequences of decisions in the present to a quality of development in the future
3. the necessity to be efficient, which correspond to a care that the set objectives achieve with adequate real available resources and
4. the obligation to legally dispose and permanently control the expenditure of resources for implementation of planned needs.

To increase the efficiency of the management structures of the defense system, changes in the sphere of budget expenditures were necessary, just because of limitation and scarcity of available funding. Otherwise the time and attention of management structures would be focused on securing funding for a reconciliation of the regular needs of defense and would be lost to the efficiency of doing the basic tasks.

4. SECTOR PROGRAMS AS AN INOVATIVE WAY TO BUDGETS EXPENDITURES OF DONATIONS OF DEFENSE

Defense expenses are financed by funds from the budget and donations from the European Union through Sector Approaches (also known as Sector Wide Approaches – SWAps). Sector Approaches are usually seen as programme-based approaches (PBA) operating at the level of a sector. PBA is defined as follows, (European Commission, 2007):

„A programme-based approach (PBA) is a way of engaging funds EU in development sectors programme, such as a National defence strategy, a sector programme, a thematic programme or a programme of a specific organisation (defence).PBAs have the following features:

- ✓ leadership by the host country;
- ✓ a single comprehensive programme and budget framework;
- ✓ a formalised process of donor coordination and harmonisation of donor procedures for reporting, budgeting, financial management and procurement end
- ✓ efforts to increase the use of this systems for programme design and implementation, financial management, monitoring and evaluation.“ (p.24)

The European Commission (EC) is committed to delivering "more and better aid" for "legitimate strategies". One of the legitimate strategies is National defence strategy.

Sector approaches or sector-wide approaches (SWAps) are processes aimed at the development of coherent sector policies and strategies. They involve governments, donors and other sector stakeholders in a unified process and framework.

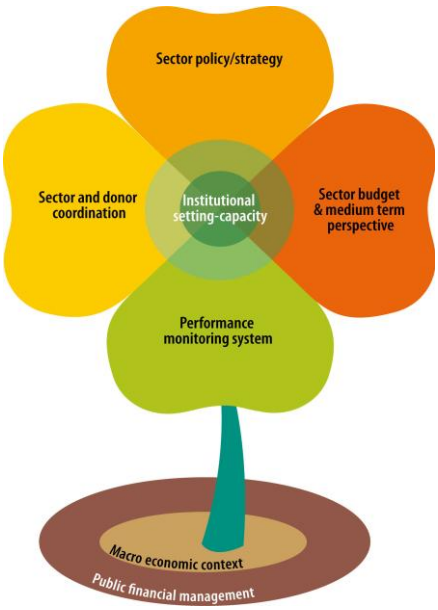
As mentioned above, EC decisions about whether and how to support a sector programme are based on assessments in seven key areas, (European Commission, 2007):

„The five elements of a sector programme

1. The sector policy and overall strategic framework
2. The budget and it medium-term perspectives
3. Sector and donor coordination systems
4. The institutional setting and existing capacities
5. Performance monitoring

And the two additional elements influencing the sector programme's performance

6. The macroeconomic framework
7. Public financial management (PFM) systems“ (p.27-35)



Limitations EC provide an insight into the basic concepts that are relevant to each assessment, identify key issues to be addressed and point to additional sources for more detailed guidance. The aim is to assist programme managers throughout the cycle of operations of EC support in reviewing the quality of sector programmes and deciding on appropriate support modalities.

Assessment of these areas would start during the programming and identification phases of the sector politics cycle, with the analysis then being completed during formulation. During implementation, these assessments would also need to be updated regularly in order to keep abreast of developments in the sector politics and each of the areas.

There are many overlaps between these assessments (for example, there are obvious connections between sector expenditure strategy, the macroeconomic assessment and the review of public finance management; all the other assessments may feed into the institutional and capacity assessment, and so forth).

Also, many of the assessments are also required for other aspects of EC work (e.g. a macroeconomic assessment will have been undertaken as part of limits preparation and to support any sector politics and so on. Those working on analyses should first of all draw on given limits, and if necessary update, existing assessments. Wherever there are relevant preexisting studies and materials, these should be drawn upon.

When it is possible, the EC works jointly with other donors, as well as with the partner government, on such assessments, and does so in ways that support the development of partner country capacity. The assessment required at the design stage of an politics sector is part of a continual process of monitoring and review of key issues. There are few, if any, absolute criteria involved in the assessments. Balanced judgements are required, which identify opportunities as well as risks, and which assess the direction of change as well as current levels of performance.

5. CONCLUSION:

The introduction of the new model of program budgeting, situation in the field of management of defense resource is changing drastically. Namely, there is a process that takes place continuously. All plans and programs are integrated into one unit. The financial plan of the defense, as a function of plan holders, serve to establish a connection between the proposed appropriation of resources and results achieved. Mechanisms for monitoring the implementation of goals achieved are being introduced, which is advantage compared to the state so far.

The system of financial management of defense resources is becoming a complex, dynamic, interoperable, and integrated process. The main purpose of this process is management of maintenance and capacity building of the Ministry of Defense and the Serbian Army to achieve the defense objectives of Serbia. Finally, the purpose of defense resource management process is the provision of conditions for achieving the mission and tasks of the defense system.

However, the process of resource management is not just a technical procedure, but also an important political process. In the event that there is no political will and consistency in terms of sustainability of the planned and predicted values, there is a risk that the budgeting process could turn back into the allocation of available financial resources, as it has been the case until the year of 2010.

Abstract: *The basic concept of control is to create a process that ensures the achievement of objectives with quality, conservation and management of funds within the law compliance and other regulations and procedures, preparation and production of reliable financial and business reports. The compliance of the requirement means that the business is complied with applicable laws, regulations, standards, agreed policies, postulates and with all the forms of behavior that these processes make legal and socially acceptable . With the implementation of internal financial control in the defense system, it is achieved and provided an efficient and rational using of funds for financing the costs of defense, on the one hand, and on the other hand, considerably reducing the possibility of significant irregularities, fraud, corruption and the emergence of organized crime .*
Keywords: *Public sector, budget system, internal control, financial management and control, Ministry of Defence, Army*

INTRODUCTION

With signing of the Stabilisation and Association Agreement between the European Communities and their Member States on one hand and The Republic of Serbia on the other hand, in Luxembourg on 29 April 2008, The Republic of Serbia, among other things, signed commitment to gradually harmonize its legislation with the achievements of the Union and their consistent application. Article 92 of the Agreement regulates cooperation in the area of public internal financial control (PIFC) and external audit, i.e. public internal financial control (including financial management and control and functionally independent internal control) aand external audit systems in Serbia, in accordance with internationally recognized standards and methodologies as well best practices in the European Union.
The current projection of internal control in public sector defined by the Law on the Budget System and the existing internal regulations are good basis for establishment of a comprehensive integrated system of internal control in the MoD and SA, which the Strategy for the Development of internal financial control in the public sector of the Republic of Serbia relies on. The Strategy is projecting both common activities aand the activities related to internal control and to the implementation of financial management and control in public sector until December, 2014.

1. INTERNAL CONTROL IN PUBLIC SECTOR

Internal control is defined as a process that is carried out by employees in an organization with the intention to achieve certain goals. The definition is broad and it covers all aspects of business control, thus making direct concentration on the specific goals easier.
The system of internal control is defined by the International External Audit Standards as "a system that includes all policies and procedures of internal control which the management of a legal entity has accepted to assist in achieving its objectives in terms of ensuring that the business is conducted properly and efficiently to the greatest extent possible, including adherence to management policies, keeping of the assets integrity, prevention and detection of fraud and error, accuracy and completeness of financial records and timely preparation of reliable financial information." [1]
The goal of a system of internal control establishment is a successful management and accomplishment of the mission, i.e. the set goals of the organization, and providing conditions for good and economic managing of public funds.
When talking about internal control in the public sector, it should primarily be based on the analysis of: the system of internal financial control (PIFC) and the system of financial management and control (FMC) .

[1] Savez racunovodja i revizora Srbije, (2002), Ocena rizika i interna kontrola, Medjunarodni standardi revizije, Serbia: Belgrade, p. 173

2. INTERNAL FINANCIAL CONTROL (PIFC)

Internal financial control in public sector is a term developed by the European Commission in order to assist in understanding and application of well-developed control systems in the EU accession process.
Internal financial control in public sector is a comprehensive system of financial and other controls established by the head of an organisation in public sector, with the aim of successful management and achievement of the organization's objectives. [2]
Besides, the internal financial control in public sector includes the entire system which is established by the government in order to control use of the budget funds and it includes all measures for control of government revenues, expenses, assets and liabilities and all internal control systems as well as procedures in the public sector, thus helping to create conviction that public funds are spent and used purpesfully. [3]
Internal financial control in the public sector should be considered within the overall field of public finance, which extends from creation of the state budget, through the approval and its execution, to the safe deposit issue, fiscal and debt management, including accounting, reporting, procurements, internal control etc. The system of internal financial control in public sector also includes financial management and control in public funds, internal auditors of public funds and the harmonization and coordination of financial management and control and internal audit carried out by the Ministry of Finance - CHU.
"*Financial management and control* involve the entire system of financial and other controls and is implemented by the policies, procedures and activities with the mission to provide reasonable assurance that the organization will achieve its objectives.
The internal audit is an activity of independent and objective persuasion, but a consulting activity as well, designed with the aim of creating business improvement of an organization. It is functionally independent in its work, it is not a part of any business process or organizational unit of the organization, and in its work it is directly responsible to the manager of public funds. Functional independence is provided by independent decision-making about: the field of auditing, way of performing the auditing and reporting on the performed audit.
CHU is a special section in the Ministry of Finance which elaborates and directs the process of internal financial control in public sector. It carries out and is responsible for providing professional development, certification and monitoring of the internal auditors' work, professional development of managers and employees in public sector, in accordance with the internationally accepted standards. " [4]

2.1. The regulatory framework

The reform of internal financial control and internal audit in public sector in The Republic of Serbia which started in 2002 by adoptioning of the budget system Law as well as a number of secondary law acts, the internal audit on central level was established in the Ministry of Finance. Obligation of establishing the internal control system was regulated by the amendments of the Law on the Budget System [5] in October, 2006.
Based on this Law and in order to develop and implement the internal financial control in public sector as a comprehensive system of internal control, the bylaws regulating this area have been passed.
If certain laws passed in order to regulate this area are considered, two of them can be taken in special consideration - the new rulebook regulating the financial management and control and the rules governing the internal audit. Compared to the previous one, the new rulebook on financial management and control underwent minor changes in the title, while the major substantive has not been changed. Substantial changes primarily related the differences in defining of the terms, and defining of new terms, such as the managers' management responsibility, risk management, audit trail, etc. Other differences can be recognized in defining of the methods of reporting in such a way that the deadline by which the head-user of public funds has to report to the Minister of Finance on the adequacy and functioning of the financial management and control has been prescribed.
The system of internal financial control is built into the legislation and its aim is to provide the benefits of transparent and healthy system of internal control for numerous stakeholders in the entire process led by the

[5] Zakon o budzetskom sistemu, („Sluzbeni glasnik RS", no. 54/09, 73/10, 101/10, 101/11, 93/12, 62/13 ispr. i 108/13), articles 80 to 83 is defined establishing of a system of financial management and control, which should be carried out by policies , procedures and activities, with the main task to provide reasonable assurance that a user of public resources will achieve their goals.

government. Therefore, based on the legal framework, it is necessary to fully establish the organizational structures, job descriptions and criteria for monitoring and evaluation of the employees' work results, the way of delegating tasks and ways of reporting in the system of internal financial control in public sector. It should also be said that the Action Plan together with Strategy, is a plan of activities related to development of the internal financial control in public sector which includes: joint activities, activities related to internal audit and implementation of financial management and control, and the plan is scheduled to be carried out in the period from October, 2009 to December, 2014.

2.2. Directions of development of the internal financial control system

The concept of internal financial control in public sector developed by the European Commission, is functional in terms of raising awareness and prevention, primarily through a number of conceptual, legal and organizational activities. For this concept the starting point is that the government, recognizing the necessity of raising the level of transparency responsibility and accountability, should start analysis of its internal control systems. [6]

The abbreviation PIFC is often used inn literature relating internal financial control in public sector: [7]
P *- Public Sector;*
I *- Internal to the organization;*
F *- Financial systems mainly but not exclusively;*
C *- Control based on internationally accepted and recognized standards.*

PIFC involves a comprehensive system established by the Government, i.e. public sector organizations for financial management and control, internal auditing and reporting on the use of public and the EU funds. The aim is to ensure that the management and control of public funds (including foreign funds) are in accordance with the regulations, description of the budget and the principles of sound financial management i.e. efficiency, effectiveness, reasonable distribution and transparency.
Internal financial control can be defined as an activity undertaken by management, boards, and other factors of management of the systems in order to improve risk management and increase the likelihood of achieving the goals.
The internal control system is established by the head of the organization, or by a person authorized by the head to establish a system of internal control. Internal control is an important component of risk management. It is implemented on all levels, in all organizational units and all workplaces. When establishing the internal control, it is the head's obligation to to draw up Plans for establishing internal controls for all organisation units in its composition. After the first phase, i.e. the adoption of the Plan, the next step is creation of Procedures for financial risk management of the business and the Ordinance on internal control and internal control procedures.
Based on the foregoing, it can be concluded that the model of internal financial control in public sector covers not only the entire system of financial controls but also other sorts of control established by the head of the organization, with the aim to successfully manage and accomplish the objectives of the organization.
All the issues considered so far clearly show that the internal control, during the work-process, exercises control of the following issues: whether the business is conducted in accordance with the prescribed procedures, whether the solutions and decisions have been made in accordance with rules and regulations, whether the contracts are in accordance with the Regulation on job classification, whether coefficients of the workplace are in accordance with the Regulation, and whether the process of procurement has been conducted in accordance with the regulations, plans and financial plan.
PIFC is a system that takes into account all aspects, i.e. it combines internal control and internal audit into one system like with the COSO model, plus a new element ,i.e. a centralized organization which is responsible for harmonization and coordination of both internal control and internal auditing standards, as well as the rules applied to all parts of public sector.

2.3. The future role of PIFC

PIFC concept has evolved gradually as response to a variety of inter-related events. Since the internal control systems in the EU Member States were not harmonized, the candidate countries could not know

[6] De Koning, R., (2007). Initiative of the European Commission to build a new structure of public internal control in the candidate countries and third countries, Belgium , p.24.
[7] Zugic, R., Kostic, R. (2012), Kontrola i revizija u funkciji izvrsenja finansijskog plana MO, SYMOPIS 2012, Srbija: Beograd, p.1

which system was to be considered as example of good practice. That is why these countries asked the European Commission to recommend the best practices in terms of choosing the best system. They were advised to focus on introduction of the activities and institutions that would influence upon increase of the public interest in sound financial management in private and public sectors and upon creation of strong awareness of the far-reaching consequences of corruption, fraud and embezzlement.
PIFC concept has become a strategy in order to give an answer to a great concern that all countries have regarding corruption and to develop the principles of responsibility and transparency. The only system was the only one which could be, and actually is based on the principles of democracy and obeying the laws. It represents harmonization of the standards and procedures and synchronizes the public internal controls with the appropriate international standards. It should be emphasized that the harmonization concepts are logical and useful, so this concept should be enrooted and expanded in all the countries which have accepted it.
It is important that PIFC concept provides a strategic framework that is regularly reviewed and updated, which is available and supported by the highest authorities in charge of control. Within PIFC, CHU should develop and promote a self-assessment procedure in control and audit institutions. As for annual basis, a report on the state of PIFC should be made and submitted to the government. This concept has become a concept with a practical purpose, and its continues to develop as a tool by adopting latest relevant examples of good practice.

3. FINANCIAL MANAGEMENT AND CONTROL SYSTEM (FMC)

Financial management and control encompass the entire system of financial and other controls, including organizational structure, methods and procedures, not only the financial systems but also the operational and strategic systems of organizations in public sector.[8] This definition, as well as the entire contents of the basic principle of financial management and control, have been literally translated from the EU documents, i.e. the EU member states. However, by detailed analysis of individual member states, i.e. the ways in which certain terms are defined, the authors of this paper have presented and shown their way of understanding of financial management and control.
Financial management and control is the overall system of internal controls established by heads of the organizations in the public sector and the heads are responsible for that system. This system, through the risk management, provides evidenceassures that budget and other funds are managed and spent in a proper, ethical, economical, efficient and effective manner.
An internal control system is not an irrevocable chart carved in stone. On the contrary, an internal control system should be changeable according to the changes in its constantly changing surroundings and it should be constantly upgraded. This is especially important if the state leadership is in the early stages of the control nature changes, i.e. where the internal control system is on an early stage of development.

3.1. Purpose and importance of internal control

General purpose of internal control is supporting of public sector in achieving its mission.[9] Each organization should design its own internal control system in order to meet the needs and properly respond to the organization surroundings,environment of the organization, as well as to reach the set goals.
The first category of objectives is about compliance with laws, regulations, policies, plans and procedures relating the organization in public sector. It should be mentioned here that the laws and regulations represent a kind of mandate-authorization given to the organization in public sector in relation to the way of collecting and spending of the national and international means.
The second category of objectives deals with preparation of relevant, reliable and useful financial and management information, also including financial reports (interim and summary), which improve the decision making process and provide transparency and effective monitoring and surveillance.
The third category deals with *the main objectives* of a public sector organization, including level of its success (performances) and operational objectives, outcomes and results. "Effectiveness" refers to the objectives achievement, i.e. the extent to which the outcomes and results of specific activities, programs and projects correspond to the objectives or intended effects. "Efficiency" is the ratio between the already used

[8] Ministarstvo finansija RS, (2011), Centralna jedinica za harmonizaciju, Prirucnik za finansijsko upravljanje i kontrolu, Ernst & Young, Serbia: Belgrade
[9] CHU has defined in its internal documents (specifically Introduction to Internal kontorlu, Module 1, Ernst & Young , Belgrade , 2010), which are the official translation of legislation that is developed and applied by the EU, certain terms that need to be familiar with the beginning of the introduction to the basic characteristics of the financial management and control. The primary objectives of internal control are to ensure: 1) compliance with laws, regulations, policies, plans and procedures; 2) reliability and integrity of data and information; 3) the effectiveness and efficiency of operations and use of resources; 4) protection and preservation of resources.

resources and outcomes, and the results in achieving the goals. This means that the minimum resources should be invested to achieve the given result , i.e. the maximum result with the given quantity and quality of invested resources.
The fourth category includes protection and preservation of the organization's assets in public sector against misuse, losses, damage, mismanagement and mistakes. The key question related to the assets safeguarding is asset management, i.e. procurement, use and way of managing the assets.
Successful internal control system helps in streamlining processes and improves the level and quality of services, providing a reasonable assurance that the general objectives will be achieved. Internal control should increase the possibility to detect the frauds, to reduce the damage, misuse or mistakes, to prevent inappropriate activities, thus improving compliance Internal control is also the responsibility of all the employees and each ministry should provide conditions for integration of the internal control into these activites. The employees should be trained in methodology and concepts related to the internal control system.

3.2. The functions of compoonents of COSO model

COSO model describes internal control through its five basic elements-components, or financial management and control includes the following elements:

- Control environment;
- Risk management;
- Control activities;
- Information and communication and
- Surveillance and monitoring.

The internal control consists of five major interrelated components that are inherent in the way how the management lead the organization. These components are mutually connected and they are used as criteria for determining of the internal control effeciency. Among these five components (control environment, risk management, control and internal control activities, information and communication, and monitoring) there is a synergy and connection through which an integrated system that dynamically responds to the changed circumstances is formed. The internal control components are mutually connected and stem from the way in which business entities conduct business and they are integrated into the management process.
Control environment establishes the "tone" of the organization and influences upon awareness of the employees about the controls. It is the foundation for all other components of internal control, providing discipline and structure. If the foundation is not strong and if the control environment is not positive, the general system of internal control will not be effective enough.
Risk management involves identification, assessment and control of potential events and situations that may have an adverse effect on the achievement of the objectives of the public funds users. The precondition of risk management is defining of the general and specific objectives the organization should achieve. The task of risk management is to provide reasonable assurance that the objectives will be achieved.
Control activities are written policies and procedures and their implementation established to provide reasonable assurance that the risks of achieving the objectives are reduced to an acceptable level defined in procedures for risk management. They are implemented throughout the whole organization, on all levels and functions, by all employees and in accordance with the established business processes and job descriptions.
Communication is the exchange of useful information among employees and organizations as *support* to the decisions and coordination activities. The information should be transferred to the management and other employees who need them, in the form and within the timeframe that will help them to accomplish their duties.
Monitoring involves the introduction of a system for monitoring the financial management and control by assessment of adequacy and effectiveness of its functioning. Monitoring and evaluation of the system include consideration of the activities and transactions of the organization in order to assess the quality of work in a certain period and to assess the effectiveness of controls. Management should direct the monitoring activities toward the system of controls and accomplishment of the organization's mission. Monitoring and assessment of financial management as well as control done by checking of current situation, self-assessment and internal audit.

4. INTERNAL CONTROL IN DEFENCE SYSTEM

In order to provide conditions for the implementation of the budget as originally planned and approved by the highest authorities (Parliament), the budgetary control is organised in all contemporary budget systems.

As for establishing a safe and effecient internal controls in the defense system, the commanders are those who are responsible. The internal control process is carried out permanently in business activities with the beneficiaries through a formal, substantive check as well as control of the figures in the accounting and accompanying documents. [10]

Formal control of accuracy of the accounting documents determines if the documents have all the essential elements - attributes (the completeness of the documents and its preparation in accordance with applicable regulations are the issues that are determined).

Essential control of accounting documents accuracy determines whether the transaction contained in the accounting document has really been created by volume, structure, quality, time and other features.

Control of arithmetic accuracy of accounting documents determines the accuracy of the required calculations and accuracy of the results presented in the document. Control of formal, essential and arithmetic accuracy is confirmed in the accounting document by putting the clause "controlled by", the signature of the person who controlled the document and the date when the control was carried out. [11]

On the other hand, the system of financial management and control systems are established with all public funds beneficiaries. The person who gives orders is responsible for establishment of a financial management and control system, and both the person and the employees implement it in practise. Financial management and control system are established in accordance with the adopted regulations which regulate establishment and development of the Internal financial control system in public sector of The Republic of Serbia .

Monitoring is a special form of internal control and it is part of regular duty of the managers of organizational units of the Ministry i.e. commanders of material and financial authority on all levels, as well as the persons on other duties who are responsible for organization and implementation of financial and material business activities. This is a very efficient and cost-effective form of control, because it binds and integrates the component of control into the function of command and control, and builds it into the system of responsibility and accountability assumed by a subordinate, and all that in accordance with the principle of subordination. Monitoring is carried out: *on daily basis* by personal insight into work of the subordinates and *occasionally* by personal insight into the state, keeping and maintaining of the the property. Each MoD member, irrespectively of the duty MoD or SA, after detecting violations and irregularities in work and use of the resources, has obligation to submit a written report to the commander in charge and to suggest the measures to be taken to solve the found irregularities.

As for the aspects of use and management of budgetary resources of The Republic of Serbia, there are the following forms of internal financial control in Ministry of Defence and the Serbian Armed Forces (Figure 1): [12]

- *monitoring* – constant, daily control of resources and work carried out by army officers who are in charge of giving the orders;
- *control of legality, correctness and preparation of documents relating business transactions,* done by expert services personnel and financial agencies functioning as bookkeepers;
- *control in the Accounting centre*;
- *inspection activities of defence in Defence Inspectorate* which is, besides other activities, in charge of control of material and financial operations;
- *detecting and giving evidence of organised crimes, money laundering and corruption* (abuse of power, trading in influence, bribery) by the Military Security Agency and Military Police Agencies.

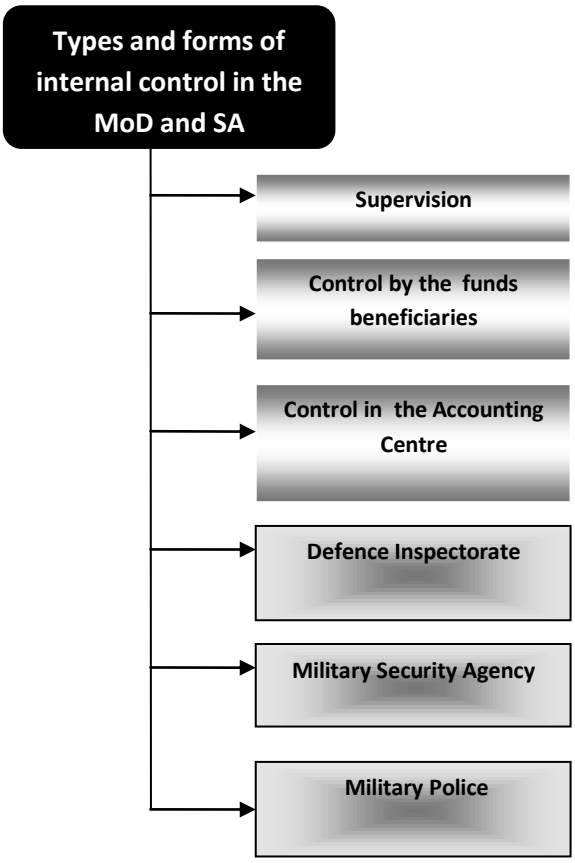

Figure 1: Types and forms of internal control in the MoD and SA

Based on the aforemntioned facts, it can be said that there is an organized system of internal control of spending and use of the budget funds in the Ministry of Defence and the Army. The system is based on accounting - financial data with the direct perpetrators of the approved budget funds and the Accounting Center of the Ministry of Defence.

5. FUTURE DIRECTIONS OF DEVELOPMENT OF INTERNAL CONTROL

The current system of control has been established neither in relation to the objectives planned by the public funds beneficiaries nor the risks which can influence upon achievement of the objectives. The existing controls are mainly directed to providing legality and regularity, but not to economy, efficiency and effectiveness.

To improve functioning of the internal controls in public sector of The Republic of Serbia, among other things, it is necessary to:

- prepare, harmonize and adopt the rules and procedures for financial management and controls in ministries and public sector organizations;
- develop a strategy for training of persons responsible for financial management and control in public sector organizations;
- establish the mechanisms for cooperation and monitoring development of financial management and control system;
- completely apply the Law on Public Procurement and controlled use of public expenditure in order to reduce the level of corruption.

To improve functioning of the internal control in the system of defense, it is necessary to:

- upgrade and improve the existing regulations, practices and organization of work in order to increase efficiency of material and financial operations and inspections;
- especially upgrade and improve model of instruction - the reminder for exercising the control of material and financial operations in the Army of Serbia, in order to prevent the occurrence of failures and eliminate risks in business and in inspections;
- especially exercise control of material and financial operations, that is to say, not within the control of compliance with laws, rules and regulations, or

- if control of material and financial operations is carried out within the control of compliance with laws, rules and regulations, to prolong the time for exercising the control;
- harmonize the existing standards of control in order to reduce the number of controls of all kinds and from all levels, and to provide the conditions for prolonging the time for exercising the controls.

It should be kept in mind that the entire system of internal control can only help public sector organizations to achieve their goals. It is not an "all-purpose remedy" and it can only provide control information related to progress or lack of progress of the organization in terms of achieving the goals.

CONCLUSION

Internal control means integration of the activities, plans, attitudes, policies, resources and efforts of the employees in an organization who work together in order to achieve all the goals and missions of the organization. Accordingly, the internal control is concentrated on the organization's mission.

Internal financial control in public sector, as a new concept of the budget system of the Republic of Serbia, establishes efficiency of public expenditure management along with introduction of multiple control systems. The emphasis is primarily on introduction of the internal control system of direct and indirect budget beneficiaries and mandatory social insurance.

The essence lies in the fact that it is necessary to improve the internal control of national and international budget funds, i.e. it is necessary to take certain steps which will guarantee long-term success in achieving benefits for public sector.

Financial management and control in public sector and in the defense system should be fully established and directed in such a way that the focus of the control exercising is not on the legality and regularity, but on the economy, efficiency and effectiveness of spending the public expenditure. Accordingly , the financial management and control system will function in an easier way and it will deal less with irregularities in business activities, thus being able to pay more attention to prevention and giving advice to the management. In that way, the risks in business will be reduced and the management will be assisted in making better decisions.

As a concrete conclusion, it can be emphasized that this issue should be constantly analyzed and updated, and that each organization should create its own system of internal control which will meet its needs and the environment in which it functions.

***Abstract**: Long-term practice of developed countries shows that partnerships between the public and private sectors are an effective way to achieve the objectives of the public and private sectors. The interest of the public sector is that, as a partner who defines the type and scope of work or services, to transfer the business of services to the private sector, and the interest of the private sector as a partner is earning profits, with a commitment of quality fulfillment of contractual obligations. Various forms of cooperation are used within which the public and private sector pool resources and capabilities in order to facilitate their effective use.*
Last year records showed a significant increase in cooperation between the public and private sector countries in transition such as Serbia. The PPP project is aimed at developing infrastructure and infrastructure management, public utilities, health care, environmental protection.

***Keywords:** public - private partnership, sustainable development, transition countries*.

1. INTRODUCTION

The need for public-private partnership was gradually developed since the beginning of the 80s of XX century, when serious criticism appeared on the inefficiency of public service providers and their inability to respond to identified needs. The role and importance of public-private partnerships as an effective way for a more rational use of limited resources and potential for development was growing. Peteri (2010) point out that "a partnership between the public and private sector are used to promote the business of stakeholders from different sectors in all countries" (p. 8).

Public-private partnership is based on the concept of risk sharing. There are a number of factors that influence the success of management of joint public - private projects. Large and technically complex infrastructure projects, with complex funding scheme, depend to a large extent on external factors. Peteri (2010) point out that "this is especially true in situations where the demand for these services is influenced by political decisions on the justification, the price to be paid for the service and the level and form of social subventions (p. 10).

The possibility of failure due to any of these factors is just one of the risks of success with public-private partnerships. There are other, internal risks, which are influenced by internal factors, such as the construction, management and technology. There is no single agreed definition on the concept of public-private partnerships. In practice, there are various definitions relating to the substance of public-private partnerships.

In a broader sense, the public-private partnership is defined as the implementation of all known types of cooperation between public and private partners, which, in many cases, leads to the establishment of joint ventures. Vladkov and Markov (2010) point out that "European Commission guidelines for successful public-private partners, define a public-private partnership as a partnership between the public and private sectors for the purpose of delivering a project or service traditionally provided by the public sector" (p. 22). Through this partnership, the strengths of each of the two sectors (public and private) are complemented in the provision of services or construction of facilities for the benefit of specific communities. Since each of the sectors is doing what it is best in, the services and infrastructure are offered to society in the most effective way, in economic terms. Such partnerships are characterized by the division of investment, risk, responsibility and profit among partners institutionalized public-private partnerships include the establishment of a joint venture by the public and private partners. The joint venture has a task to perform community service or providing public services.

In Member States, entities of public authorities sometimes resort to these structures, especially in the area of public service delivery at the local level. Institutionalized public-private partnership may be established either

by establishing a joint venture by the actors of the public and private sectors or taking control of existing public company by a private sector entity.

2. EXPECTED BENEFITS FROM THE PUBLIC-PRIVATE PARTNERSHIPS

Public-private partnership is one of the possible forms of cooperation, and it's based on recognition of the benefits that both the public and private sector achieve by pooling financial resources, knowledge and expertise to provide quality services to all citizens. For countries in transition this model is significant because it represents an alternative to full privatization. This partnership model provides a combination of social responsibility on the need to resolve a number of infrastructure problems and providing of quality services to citizens with finance, technology, efficient management and entrepreneurial spirit of the private sector.

Taking into account the advantages and disadvantages in providing public services, it is important to note that the most important role of public-private partnership to act as a new model of financing capital projects.

The main argument for the establishment of public-private partnership is the ability to obtain benefits for service users and local authorities, as a result of participation of private partners in investments in infrastructure, public services and public service management. In some countries, such as, for example, Hungary and Serbia, where public institutions, because of the legal and administrative constraints, were less able to respond to the needs of private companies, state government hoped that the stakeholders from the private and NGO sector be able to provide more and better.

Aleksic (2009) point out that "public-private partnerships are necessary during the fiscal restrictions, when the pressure on the public sector to reduce the number of employees and the total cost is extremely powerful. In some forms of public-private partnerships, public sector employees are employed by the private partner or licensee, thereby reducing the number of employees in the public sector. Public-private partnership aims to attract more resources into the public sector" (p.74).

The form of public-private partnership allows the public sector better access to modern equipment and management techniques. It is expected that the public-private partnership are going to improve the economy, because the existence of contractual obligations means that projects are completed on time and that their costs are rarely grow during implementation. The role and importance of public-private partnership is different and depends on the achieved level of social and economic development as well as the experiences, both positive and negative, in their implementation. The research practice shows significant benefits of public-private partnerships, as well as the problems that arise in their implementation.

Bogdanov (2010) point out that "the contribution experiences of public-private partnerships are relatively modest in countries in transition as the cooperation of the public to the private sector is still new and still have enough relevant empirical data to confirm the feasibility of cooperation. It can be concluded, based on the stages of development of public-private partnerships in developed market economies (U.S., UK, Denmark, Germany, etc...) that, in countries in transition, the cooperation between the public and private sectors are at the level of the first phase of development" (p. 221).

However, public-private partnerships must be used with great care. They are, without a doubt, more effective than the traditional means of public investment. Public-private partnerships can be used to exclude from the budget the investment and the need of the country to borrow. Yet on the other side of the state still bears most of the risk and potentially faces significant costs that could be borne by taxpayers. Each partnership is specific considering its form, duration of certain phases, the speed of the transition to the next phase, the intensity of cooperation and level of involvement. Because changes are permanent, it is necessary to continuously review the position of each actor. "Risk matrix" consisting of three different groups of risk: (http://www.easwmc.org/download/postconf/Hans%20Wiesmeth.pdf)

Table 1: Benefits and problems in the implementation of public-private partnerships

Use	Problems
Stable economic and social development of certain sites or companies	Insufficient experience in cooperation between the public and private sectors

The cooperation of a number of different stakeholders contribute to positive changes and improvements in various areas of the economy and society	Greater focus on the form and inadequate focus on the content of the cooperation within the framework of public-private partnerships
More efficient use of the limited resources of the community and the company, risk sharing	Incorrect assessment of the potential benefits, the necessary resources and credibility of partners in public-private partnership
Creating new capabilities and competitive advantages as a result of learning, acquiring and distribution of knowledge	Asymmetrical competence and power of stakeholders
Efficient implementation of strategies of all the entities involved	Abuse of political and economic power in the establishment of public-private partnerships
The affirmation of the concept of social responsibility of public and private sector	Institutional complexity of public-private partnerships and imprecisely defined partner accountability
Greater synergy effects and successful positioning of all stakeholders	Uncertainty in the design of new policies and strategies of public and private sector
Stable public-private partnerships bring greater flexibility of different subjects and groups, improving the image of certain locations (municipalities, cities, regions, countries) and businesses subjects	Blocking of new ideas as a result of delegating decision-making to others and the increased bureaucratization of decision-making
Enhancing national, regional, local and business competitiveness	Issues in the evaluation and implementation of control strategies

Source: Nenezić, Radulović, 2012, p. 67

Risks of construction consist of the following:

- Who is responsible for planning investments?
- Does the contract primarily specify the volume and quality of the services or the conditions relating to the characteristics of the property that is necessary for the provision of services (size, design and technical quality of the assets that will be used)?
- Does the state or contractor of public-private partnerships bear the risks arising during the implementation of the investment (for example, the risk of increased costs, and risk of financing due to poor project/performance)? What sanctions can be applied by the client in the event of failure, delay or inadequate realization of the investment?

Availability risk involves the question of whether the entire risk is borne by the state or a private contractor: (http://www.easwmc.org/download/postconf/Hans%20Wiesmeth.pdf)

- Who bears the risks that may occur during the operation (for example, the risk of downtime due to failures or natural disasters)?
- What are the sanctions that apply if the contractor is temporarily unable to ensure the availability of resources in the quality which is specified in the contract?
- Can it be possible that the state must contribute to finance property maintenance?
- Which party is responsible for maintenance and insurance of the property?
- What are the sanctions applied by the relevant ministries in the event of inadequate quality of service?
- Who bears the risk of an increase in operating costs?

Demand risks include: (http://www.easwmc.org/download/postconf/Hans%20Wiesmeth.pdf)

- Who bears the risk of demand?

- Is the private partner entitled to compensation in the event that the demand is less than expected or the one specified in the contract?
- Who bears the costs in case of a higher demand than expected or those specified in the contract?
- Can the contractor use the created goods for providing services as part of their activities to third parties?

Most of the project risks are allocated to the private partner, while mainly risks that they are considered to be a sector with a greater possibility of influence and management are allocated on the public sector. The entire risk of construction and demand risk and availability risk is expected to bourn by the private partner.

Ilic an Pasic (2011) point out that "public-private partnership aims to attract more resources into the public sector. PPP helps public companies to comply with restrictions relating to the public debt. It is of great importance in the EU member states with regard to the fact that one of the criteria is that the public debt should not exceed 60% of GDP. Form of PPP allows the public sector better access to modern equipment and management techniques. It is expected that the PPP will improve the economy, because the existence of contractual obligations means that projects are completed on time and that their costs are rarely grow during implementation" (p. 507).

3. CONCLUSION

For the success of public-private partnership it is essential that the partnership is established and developed on strong and sound foundations. It should be borne in mind that each partnership, as well as public-private, can be successfully implemented only if the objectives of the key players are compatible. In the case of public-private partnership that would include an appropriate level of quality service at a reasonable cost and with reasonable levels of return on assets.

In order for PPP to be successful it needs to have the character of long-term and stable cooperation between the partners. We should also not ignore the very important fact that PPPs increases the efficiency of use of public funds, and with the introduction of competition, reduces the corruption that is in the interest of all citizens and society as a whole.

It can therefore be concluded that the PPP is the future of joint financing, construction and management of infrastructure facilities, especially in countries in transition, in which the quality of infrastructure is a bottleneck in overall economic development and every quality investment in infrastructure is motivating impulse for the dynamic development of economy as a whole.

INCREASING CAPACITY LEVEL OF FINANCIAL MANAGEMENT IN PUBLIC SECTOR

Danica M. Leko
National Bank of Serbia, Nemanjina street 17, 11000 Belgrade, Bank Supervision Department / Off-site banking supervision division, danica.leko@gmail.com

Abstract: *Target of this paper is to, in an adequate way, articulate activities of financial management in public sector, and therefore, to make the research and recommend adequate measures for increasing capacity level of financial management in public sector, consecvently providing rational managing of public sector' assets.In the paper are used appropriate and adequate commonly used scientific research methods. Assessed is utilization of available legal and professional regulations for the follow-up and utilization of public assets.*
During the research and preparation of this paper, we came to the following conclusions:

- *financial management in public sector has a specific task: determining of needs for assets from public sources, their legalized utilization, with a purpose and availability of control over public sector*
- *financial management in public sector gets a new role and task by transferring to programing budget: obtaining of efficiency and effectiveness in providing public services*

It is specifically stressed (and to that conclusion, as a novelty, we came to in the paper) that all managers in public sector should participate in financial management, considering that budgeting, allocation, funds' management, accounts' setting, are very important skills of all managers in public sector. The paper can be used for the improvement and modification of public sector.

Keywords*: public sector, budget, program budget, financial management, efficiency and effectiveness of public sector' management, financial reporting, supreme audit institution of public assets****.***

1. INTRODUCTION

Public assets are the base for the application of public policies, and therefore for the realization of all basic functions that state has the obligation to provide. In the past, in all of the developed countries of the world, by custom, it was enough to present that the assets are utilized in accordance with appropriate laws, regulations and standards. Traditional responsibility finalized by providing simple proofs on execution according to legislations, whereas results measurement was based on respect of regulations and proof of respecting limitations defined by the budget.

Democracy development and development in general have drastically increased of the state responsibility. Many new democratic, social and other functions have been introduced. These are the characteristics of reached level of national development and national standard, having as a consequence increase of public sector and public expenditures. By increasing level of democratic development, public expectations are changed as well as of the citizens on the questions of transparent expenditures of public assets, and on effectiveness of the policies government is applying. In contrast to private sector, where the optimal effectiveness is equal to the optimum of high standards, in public sector this is not the case and benefit for citizens must be supplied by another way, whereas the final target has to be maximal efficiency of public sector and in given circumstance maximal benefit for nation.

Financial management function in public sector, therefore, acquires significant meaning.

This paper is particularly speaking on the subject of development and increase of the capacity level of financial management in public sector and contains specificities, needs and necessity of its establishment and functioning. Especially, it pursues analysis of responsibilities (accounts' setting of financial management).

2. STRUCTURE OF THE PAPER

The paper consists of the following parts:

- Main characteristics of the public sector
- Specificities of financial management in the public sector
- Capacity development of financial management in public sector
- Responsibilities (account setting) of financial management of public sector
- Concluding remarks

3. MAIN CHARACTERISTICS OF THE PUBLIC SECTOR

Public sector are the state and all of its entities having access to public assets and state property. These are: state agencies, public administration, army, central bank, entities of local self-government, independent regulatory bodies, and legal entities in which state or municipalities have major allotment. Public sector is a synonim for a government sector.

Purpose of public sector existance is satisfaction of public needs and performing of public functions. Public sector is, by IAS and IASPS in relation to national government, regional regulatory bodies, local municipalities, and similar governmental entities.

Public sector consists of:

- All beneficiaries of public assets
- Territorial autonomies and local administration
- Organization of obligatory social insurance
- Budget public funds
- National bank (in the part considering utilization of public assets)
- Public companies founded by the public assets client
- Public companies founded by the state
- Public companies in which capital or management are public assets client

4. SPECIFICITIES OF FINANCIAL MANAGEMENT IN THE PUBLIC SECTOR

Financial management in public sector comprises of affirmation of needs for funds from public sources, its assigned expenditure, keeping of accounting evidences and reporting on results and money spending. It has significant emphasis on legal functioning of governmental institutions and corporate management of state companies. It provides supervision over public sector and represents important factor of credibility of governmental institutions and companies.

Financial management represents aggregate of methods and techniques that provide public sector to manage funds in a systematic, effective, transparent and legalized way.

> Provides information for decision makers, introduces controls that prevent frauds and are creating motivation for sound public service and are helping public sector in money collection, funds' allocation, funds' expenditures, measurement of expenses and benefits of various programs, keeps evidence on funds, reports on funds' quantity used and plans on a long term.

Financial management encompasses methods and techniques for management of assets under disposal of public sector.

Institutions and companies from public sector possess significant fixed assets, and its' evidence, valuation, and amortization is subject to financial management. Budgeting of capital investments (building of facilities and purchase of equipment) also represents one of the domains of financial management. It provides respect of procedures, keeping of evidences and reporting. All of this is crucial for determining controls in institutions and companies of public sector, as well as public awareness that the needs of citizens are appropriately serviced and that budget assets are used in a legal way.

Financial management in public sector consists of three segments: Budgeting (obtaining and allocation of funds), Control of budget achievement (control of money spending), Reporting on budget accomplishment (accounts placing for spent money).

Budgeting comprises of money collection and allocation of resources. Major part of money in disposal of public sector originates from taxes, fees and other government incomes. Public sector incomes are not linked with defined assignments, but are allocated in the process of budgeting on various activities. There are also exceptions, when specific taxes and fees are allocated to specific programmes. Budget indicates to the publicity in which way the government intends to spend funds collected from the citizens. Budget represents limitations for expenditures, and at the same time certifies state representatives to spend budgeted assets.

Control of budget accomplishment. From the state representatives is expected to spend appropriately funds from public funds. Therefore, financial management implies existence of expenditure control. Government has to periodically and systematically supervise cash flow and to report to publicity. In this way it is ensured that accomplished financial activity will be aligned with the planned financial activity. Roles and responsibilities of different subjects, as well as dynamics of reporting, are defined by law. Information systems in public sector should assist these roles, in order to follow-up their development in achievement of planned financial activity.

Reporting on budget accomplishment. Public sector must prove to the publicity that collected funds are spent as per assignment. Usually information expected represent answers to the following questions: is the money appropriately allocated, is the money spent in assigned and legal way, are the expected results achieved, can we check the way of funds expenditure, is the external overview carried away or audit of financial reporting. Financial business in the past must be presented, revised and compared with the budget, in order to provide to the government and publicity proof that the funds are appropriately spent. Financial reports of governmental institutions and companies represent basic documentation on which evaluation of financial business in public sector is assessed.

5. CAPACITY DEVELOPMENT OF FINANCIAL MANAGEMENT IN PUBLIC SECTOR

Ability to provide resources necessary for realization program targets (budgeting), maximization of programing benefits in the budget scope (allocation), effective managing of budget assets (funds management) and realization of the results in a legal way (accounts setting), represent important skills of all managers in public sector. In practice, all managers should take roles in financial management.

Financial management means engagement of all managers. Managers in public sector often do not perceive themselves as managers who manage available resources, but rather managers who are carry out policies of certain specialized functions in the sphere of public sector. Due to complexity of public sector, financial function has its managers who are performing separately from managers on other functions (operational

managers). Often, certain pressures occur between financial and operational managers and they are considered as expected, even useful if contribute to solving problems in work.

Financial management in public sector should cover, i.e. establish methodology and strategy of development of three basic segments: budget methodology, control methodology and reporting methodology.

Budget methodology

Budgeting should have two main goals: determination of priorities of spending and effectiveness and efficiency of given services by public sector.

Fact that budget in public sector annual plan of expenditures in monetary units is legally defined. Expenditures are linked to satisfaction of population needs, but is timely limited plan, by which resources needed for goals' realization in each unit of public sector are defined. Budget is in fact a document by which different opinions, contained in governmental policies, are transformed into specific activities by resources' allocation. It articulates expectations on incomes and expense of government ministries, agencies and other institutions and therefore, presents basis for control of organization's work in public sector.

In terms of on financial management in public sector, managers have direct tasks:

- To manage cash assets during the current monetary year
- To participate in planning of cash assets for the following year and
- To justify utilization of cash assets in the past, as well as the way the funds have been used.

From this, it stems that the main goal of this way of budgeting control of expenses and responsibility of financial managers is to maintain expenditures of some categories of expenses on budget level. However, financial management should compare effectiveness and efficiency of public expenditure through linking of financing of organizations of public sector with results achieved (information could be used on the effect for realization of this link as for example evaluation ratio, results of the program, etc.). Primary goal of such financial management-budgeting is better determination of priorities in expenses, as well as establishment of closer link between financing and results. Especially such, as newer way of budgeting, is developed in the last three decades. Only in such way it is possible to increase pressure on public sector organizations to improve its effectiveness and efficiency of services provided. Financial management of public sector must provide more clear picture on the level of services provided, the amount of money, and with which results, in other words to link budget assets with the results.

Further development of the financial management level, actually capacity level of financial management should go in the way of program budgeting establishment, meaning to show purpose of expenditures or the way in which public assets are allocated by specific program. Assets are assigned, allocated to operational organization units or specialized programs in the way they will be spent. In such way, expenditures will be in a direct way linked with the purpose, actually with the goals of assets' beneficiaries, meaning that expending of public assets will be done in a meaning way.

Programing budgeting contributes to strengthening of responsibilities as people are appointed for each responsibility in some programs of public sector organizations and from them is expected to report on realization of those programs (such way of budgeting in Serbia in financial management of public sector should be applied from the year 2015).

Process of preparation and budget approval represents one of the most important tasks in each organization of public sector. Such task can be more or less complex depending on the business of each organization. Budget process must be transparent. Possibility of review is assumed in all activities that contributed in budget approval. Organizations' budgets from public sector are the subject of intensive

supervision. Not only by the management itself and the ministries, but also by all beneficiaries of goods and services that are financed through budget assets. Especially is important role of managers in public sector during the budget apporval process, as it is expected from them to „defend“ financing of their organizations and programmes.

Control methodology

Control of budget realization and expenditure of public assets should be organized through:

- Management control
- Risk management
- Cash flow management

From this, it is concluded that entire burden of control is not only on the financial management.

Management control system consists of organizational structure, processes and systems developed in public sector organizations for achievement of their goals. All of this can be perceived as series of different controls or control framework meaning: defined organization goals, delegated responsibilities and roles, standards for different types of effect, system for risk management, defined policies and controls, system for the follow-up of achieved results and system of internal and external audit. In which extend this system (control framework) will be effective depends generally on the importance of the controls in public sector organizations. Especially it is important that managers, on the highest levels of decision-making in the organizations, promote importance of the controls by their own behaviour and performance. Managers on the lower levels of decision-making should also participate in development of the system of management control and in their own sector respect requests from the system. Effective system contributes to achieving high level of performance on all organizational levels and more successful understanding of risk and decreasing of effects of adverse circumstances on the organization.

Risk management represents core of management control. Control implementation means anticipation of risks and diminishing of adverse consequences coming from different types of risks. For risk management it is crutical to establish steps and management systems for identification and risk assessment, as well as for diminishing their influence on the organization. In the context of financial management, risk management is related to the risks that could bring to financial losses and to risks that could adversely influence to the organization goals achievement.

Cash flow management includes step-by-step control during the monetary year related to follow-up of financial performances. These are additional steps, apart from „ex ante“ and „ex post“ procedures. It allows to make changes in the approved budget, in case of necessity. It allows answers on various questions set during the monetary year. System of cash flow management is effective if provides: projected cash flows on which comparison between achieved cash inflows and outflows is made, reports to responsible management levels on budget achievement, on necessity in budget changes and on reallocation of assets surplus and timely information related to assets inflow and their expenditures and on results organization is achieving and on which basis decisions could be made on possible changes in budget, on obtaining additional assets, as well as on reallocation of unnecessary assets. Goals of system development are: disposal of cash for payment of bills (liquidity), utilization of budget assets by purpose, but in a way that they wont be unused, expenses in the framework of approved budget, assurance of organizational assumptions and resources for timely reaction on program changes and activity plans and reallocation of available funds for financing

urgent, short-term priorities. In public sector organizations cash inflow happens according to the approved budget, therefore providing of funds for reconciliation of debts should not be an issue for managers. Therefore, more attention is given to expenditures’ management, in other words on cash outflow.

Reporting methodology

Reporting on budget achievement should cover accounting-financial reporting (accounting standards and principles, accounting basis, types of financial reporting, responsibilities for used public assets as well as audit of financial reports).

Budget accounting provides qualitative financial information and has following characteristics: it is based on the principals for collecting and presenting of financial information, prepares financial reports with the summary of all transactions effects, prepares information on achieved results for comparison with planned results, and exists for the public interest, as it shows in which way money is spent from the public funds. It covers various activities that are repeated in cycles, therefore for the functioning of accounting characteristic is accounting cycle.

Financial reporting presents process of building of financial reports at the end of accounting cycle, considers application of standard methods and given reporting forms, provides to publicity overview into organizational functioning in public sector. Result of reporting process are the most important financial reports: Balance sheet, Income statement and Cash Flow report.

Financial reports could be based on accounting or cash basis of accounting. We will give just in brief basic characteristics of both accounting basis, having in mind that from their choice depends improvement of financial management in public sector organizations.

Accounting basis of accountancy, is based on the principal of causality. Recognition (evidence) of incomes in accounting evidences when “earned” and recognition of expenses when goods and services are “used” for creation of incomes. Purpose is measurement of activity results th?at are achieved during the accounting period. It is more complex then cash base, as in accounting two additional important accounts are introduced: Receivables from customers and Payables. Allows more qualitative financial management as it provides complete picture on financial position of the organization. Provides better view on expenses that are not limited on one year. Application of accounting basis of accountancy presents condition for improvement of financial management in public sector organizations.

Cash basis of accounting. Incomes are recognized when money is received, and expenses when the payment is made. Accounting measures cash amount received and paid during the accounting period, therefore, activity result during the period cannot be measured. It is simple and easy to be understood. It does not provide full picture on financial position of the organization, therefore it provides limited possibilities for financial management. Cash basis of accounting is applied nowadays in many countries, but, on international level, it is noticed tendency of gradual transition to accounting basis. To this fact, necessity to improve financial management in public sector organizations contributes, therefore, results of the program made by these organizations are viewed over the longer period then one year.

Public sector in Serbia is used cash basis of accounting, but as well so called **modified accounting** basis. Modified accounting basis can be seen as partial application of accounting basis.

6. RESPONSIBILITIES (ACCOUNT SETTING) OF FINANCIAL MANAGEMENT OF PUBLIC SECTOR

Special concept of responsibilities in public sector has a broad sense, and implies obligation of an individual or the organization to justify its activity, to accept responsibility for those activities and to reveal results of those activities in a transparent way. Also, it implies responsibility for cash or other given property. Application of such concept consists of three elements: taking into account that population believes that the job for which someone is responsible will be done, providing detailed information on activities done and on

achieved results and accepting responsibility of results. Main characteristics of such concept are: delegation of authorizations and resources to individual or organization, account setting for results and results for which achievement someone is responsible, request to report on results, compliance with legislations and procedures and on efficiency of activity performance, as well as the evaluation on application of this concept which is given by the supreme auditor.

Financial management presents important instrument in application of account setting concept. Effective financial management is one of the most important conditions for establishment and application of account setting concept.

Effective application of responsibility concept provide transparency of public sector organization activity and imposes their credibility. The broadest population is convinced that public funds are spent in a legal way and that the public interest in this domain is respected in a appropriate way. Establishment of responsibility mechanism is useful and represents also one of the crucial factors of success of public sector organizations. Unfortunately, public sector organizations are disposed to different risks from the environment, therefore constant improvement of responsibilities and control is the best way to decrease adverse effects. Expenses of introduction and maintenance of control mechanisms should be appropriate to mentioned risks.

Role of audit in application of account setting concept

Audit contributes to effective application of this concept, as it provides confirmation: that the information given by the management are applicable by the standards and that they provide real situation in the organization, that it is truthful what is given in the reports, that the results organization achieved are in compliance with approved plans and programs and that the results are achieved in a legal and efficient way. Audit of financial reports refers only to financial information. Audit provides confirmation that the reports are made according to the international accounting standards for public sector. This type of audit in public sector is called supreme audit, and its function is to, in the public interest: verity legal aspects in performing tasks in public sector organizations, including expenditures and control of cash assets and other resources, provides opinion on financial reports given by the organization and checks effectiveness in program application which are under the responsibility of the organization. Independent from the government and other state institutions and directly reports government body (parliament). Quality of supreme audit is not oly reflected in its technical capacities to perform its functions, but also in the capabilities to perform audit which results might not be favourable for the organization that is under the subject of audit, and also to make available these results to the publicity.

Its performance and results of the work will definitely improve development and improvement of the financial management and the responsibility it has.

7. CONCLUDING REMARKS

By performing analysis of financial management function in public sector and having perception on possibilities of development of capacity level, with all their specificities, we came to the following conclusion:

- Restructuring of the public sector and public finances, indicated on numerous weaknesses in present functioning of the system, as well as the necessity for changes. Changes have been introduced into the budget system, and a significant step represented establishment of independent body that has a purpose to control process of public assets (Law on budget system, Law on Supreme audit institution).

- Completely different approach to management of public finances is introduced with the accent on establishment priorities and rationalization of expenditures, in order to boost business activities and effectiveness and economical providing of public services (transfer to Programming budget from year 2015).

- Financial management is very specific in public sector as it consists of determination of needs for money from public sources, its' appropriate expenditure, keeping of accounting evidences and reporting on results and spent money. Also, it has a huge impact on legal functioning of state institutions and corporate governance of government institutions. It provides supervision over the entire public sector and represents important factor of credibility of public institutions and companies.

- Complexity of public sector imposes to financial function of public sector numerous requirements. One of crucial, basic is that all of the managers have to take roles in financial management, as budgeting, allocation, money management, results achievement in a legal way, account setting, and represent important skills of all managers in public sector.

- Condition for effective financial management and maintenance of public trust in the legislative way of its performance is decision making in the organizations of public sector based on qualitative and available financial information.

- Changes of budget principals require changes of improvement, development of financial management, as well as increased engagement and necessity of crucial changes, in order to, as soon as possible, expect positive important results.

- Realistic limitations that could be expected in the development of financial management capacity of public sector are:

    - Limitations of capacity and training of employees in public sector
    - Inappropriate technical and professional support
    - Lack of adequate strategic plans of beneficiaries of public assets which would be the basis of adequate and appropriate choice of programme, but as well the indicators of success measurements.

HEALTH CARE MANAGEMENT

MULTIVARIATE MODELS FOR FORECASTING DEMAND IN AMBULANCE SERVICES

Aleksandra Marcikic[1], Boris Radovanov[2]
[1]University of Novi Sad, Faculty of Economics Subotica, amarcikic@ef.uns.ac.rs
[2]University of Novi Sad, Faculty of Economics Subotica, radovanovb@ef.uns.ac.rs

Abstract: *A highly complicating, but challenging factor that influences demand of health care services is randomness. Thus, the traditional planning techniques, which assume that the demand of ambulances is known upfront, are not applicable to this scientific problem. It is necessary to take into account demand variations over time and to implement them into forecasting models. In this paper original data are collected from local ambulance service in Subotica. Complex data analyses on the number of ambulance requests per day are performed in order to identify certain correlations and seasonal patterns based on the day of the week and the month of the year. In the next step multiple regression models are applied to obtain the forecast of demand. By checking goodness of fit to our data and accuracy of their short term forecasts, the models have been compared. Also practical relevance and usage of those models is discussed.*

Keywords*: forecasting, multivariate time-series models, multiple linear regression, health care management, modeling emergency medical services*

1. INTRODUCTION

In life-threatening situations where every second is important, an effective response of ambulance services can make difference between life and death. Thus, managing operations of ambulance services and other health care organizations is a question of extraordinary social relevance. Nowadays, health care systems are facing extreme pressures to obtain a desired service level in spite of the rapidly changing environment, scarce resources and financial challenges. Effective resource allocation is both a consequence and a solution for overcoming these challenges. Moreover, today's health-care systems are characterized by multiple objectives, multiple evaluation criteria, and multiple decision-makers within the system, while resources and budget are extremely limited. Managing scarce resources on the best possible way is the main task of operations research, since it focuses on the application of analytical methods to facilitate better decision-making. Application of operations research techniques can surely be very valuable for managing health care organizations, in order to achieve their objectives and obtain desired service level. The World Health Organization report stated that, “One of the most important roles of the World Health Organization is to assist countries in making optimum use of scarce health resources.” This is also a role for operations researchers. These public safety systems have received a great deal of attention in the operations research community, since they provide important services and the problems are amenable to mathematical modelling and solution.

Operations Research or Management Science exists as a scientific discipline since the 1930’s and the first papers dealing with the health care problems date from 1950’s. Despite the proliferation of papers in the academic literature, there are still major issues around getting quantitative models widely accepted and used as part of mainstream decision-making by clinicians, health managers and policy makers. Some possible reasons for this include (Teow K.L., 2009):

- Low levels of managerial/mathematical background in the health care sector
- Scientific papers are often written for operations research professionals, focusing on specialised and technical topics, and not reaching healthcare professionals
- Lack of process-related data for modeling
- Lack of in-house operations research expertise
- High cost of engaging external operations research consultants

The main goal of this paper is to present advantages that can be obtained by using quantitative models to aid decision making in health care sector, specially addressing demand forecast in ambulance service.
Most cities in the developed world have organizations that provide pre-hospital care and transport to medical facility. Demand for such services is increasing and the same trend is expected in the future. On the other side, due to global economic crisis and serious financial difficulties in most of the countries budgets became even more limited and reduced. Tighter budgets make efficient use of resources extremely important.

Goldberg (Goldberg J.B., 2004) mentions that “ability to predict demand is of paramount importance”, but this area has seen little systematic study. A highly complicating but challenging factor that influences the demand of ambulance services is randomness. Call arrival patterns tend to be highly time and location dependent. Also the availability of ambulance vehicles and personnel is random due to uncertainty in their occupancy times. Mostly, demand forecast for ambulance services can be divided into two categories, first dealing with spatial distribution of demand and second that investigates how demand evolves over time. In this paper we will examine if there are some patterns and regularities that explain variations of demand for ambulance services over time.

2. DISPATCHING PROCESS AND PRELIMINARY DATA ANALYSIS

In this paper we will investigate the data provided to us by Ambulance Service in Subotica, city of Vojvodina province, Serbia. Demand for emergency medical services (EMS) is presented as daily number of calls that arrived to the ambulance station. The data set which we use in this research provides us information about the daily number of EMS calls for three years period, from February 15th 2009 until February 15th 2012. We will use the data from February 15th 2009 to January 21st 2012 to estimate multiple regression models. The rest of the data will be used as a test set to validate models and forecasts. The analyses are carried out by Statistica and EViews software packages.

The preliminary data analysis is done to explore if the data of the number of ambulance requests show correlations and typical yearly and weekly arrival patterns. During three years period approximately 30 calls per day were dispatched. Figure 1 shows number of daily ambulance rides throughout our data set, so we can conclude that there is no clear trend visible over time. On 1st of January and 1st of May there are visible peaks, so larger number of emergency calls can be expected on these holidays. Figure 2 shows that the busiest months are May and March, and the less frequent months are September, June and August. On the figure 3 we can see that the largest amount of calls arrives on weekends and on Monday and the middle of the week is less frequent period.

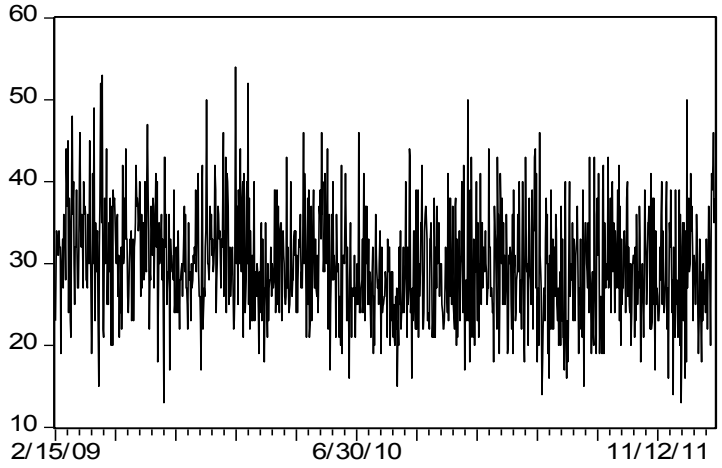

Figure 1: Number of daily ambulance rides

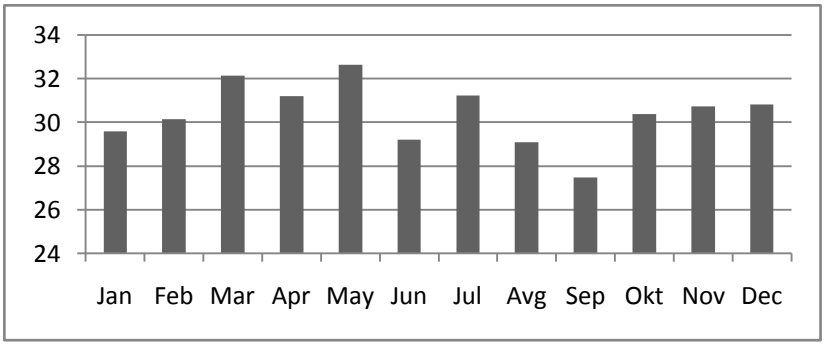

Figure 2: Mean number of ambulance rides per day, for each month of the year

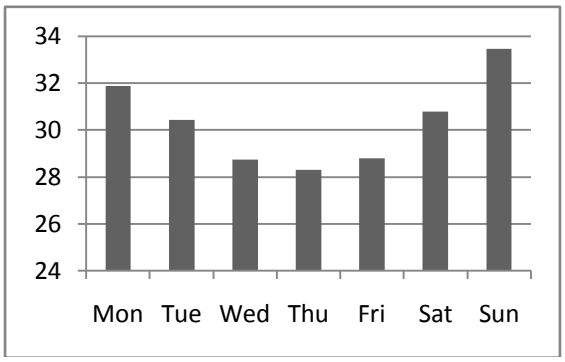

Figure 3: Mean number of ambulance rides per day, for each day of the week

3. TEST FOR CORRELATION OF THE DAILY NUMBER OF AMBULANCE CALLS

Figure 1 indicates that on a number of days a large number of rides occurred. To make a good analysis of the data first we need to determine the outliers and to omit them from further analysis. We define a data point as an outlier when its value is lower than the first quantile minus 1.5 times the interquantile range, or when its value is higher than the third quantile plus 1.5 times the interquantile range. In our dataset we identified eight outliers and they are omitted from analysis for correlation.

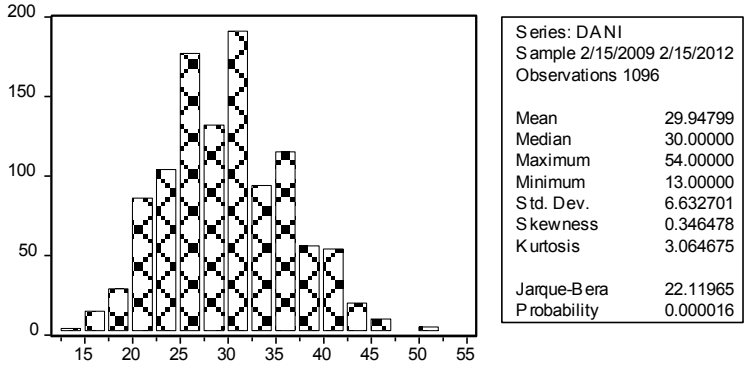

Figure 4: Histogram and basic statistics for number of ambulance rides per day

By looking for extreme values, yearly and weekly patterns we are able to categorize the number of daily calls by their distinct behaviour. Based on the value of Jarque Bera test of normality, that incorporates both skew and kurtosis, we reject the null hypothesis that the distribution is normal. Spearman's rho statistic is used to estimate a rank-based measure of association between bivariate data. This test is non-parametric and can be used if the data does not necessarily come from a normal distribution (Diebold F.X., 2004). The Spearman's rho statistic is based on the coefficient of correlation of the two groups of rank numbers x_i and y_i. For a sample of size *n,* the n raw scores X_i, Y_i are converted to ranks x_i and y_i, and ρ is computed from these:

$$\rho = \frac{\sum_i (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_i (x_i - \bar{x})^2 \sum_i (y_i - \bar{y})^2}} \quad (1)$$

After performing tests based on Spearman's rho we can conclude that the number of ambulance rides per day is positively correlated with the number of ambulance rides on a previous day ($p < 0,05$). The number ambulance rides per day is also positively correlated to the number of rides two days earlier and seven days earlier, both with $p < 0,01$.

4. MULTIPLE REGRESSION MODELS

Our preliminary analysis confirms the presence of the month of year and day of week effects, so we can use multiple regression to model behavior of number of ambulance rides per day. We have multiple explanatory variables, month of the year and day of the week, which we model in a linear manner. The multiple regression model, which we will use to forecast the daily demand of EMS is

$$Y_t = a + \sum_{i=1}^{12} b_i B_{i,t} + \sum_{j=1}^{7} c_j C_{j,t} + u_t \quad (3)$$

where Y_t is the t-th observation of the number of daily rides, indicator $B_{i,t}$ has value 1 if the month of day t is the i-th month of the year and value 0 otherwise, and the indicator $C_{j,t}$ has value 1 if day t is the j-th day of the week and 0 otherwise. Parameters of the regression model are b_i, c_j and u_t is the error term. The application of the regression model demands that residuals are i.i.d. Gaussian distributed. Estimates of the

parameters are obtained by using least square method to minimize the sum of squares of the residuals. To avoid the problem of multicollinearity it is necessary to set the linear constraints on parameters as following:

$$\sum_{i=1}^{12} b_i = 0, \quad \sum_{j=1}^{7} c_j = 0 \qquad (4)$$

Estimated multiple regression model for daily number of EMS calls is:

$$Y_t = 29{,}79 + 2.060C_{1,t} - 0{,}403C_{2,t} - 1{,}852C_{3,t} - 1{,}808C_{4,t} - 1{,}252C_{5,t} + 0{,}336C_{6,t} + 2{,}918C_{7,t} - 1{,}026B_{1,t} + 0{,}937B_{2,t} + 1{,}136B_{3,t} + 1{,}225B_{4,t} + 0{,}476B_{5,t} - 1{,}191B_{6,t} + 0{,}440B_{7,t} - 0{,}181B_{8,t} - 1{,}539B_{9,t} - 0{,}127B_{10,t} + 0{,}190B_{11,t} - 0{,}341B_{12,t} + u_t \qquad (5)$$

In this multiple regression model significant factors for the parameters month of the year and day of the week, (p< 0,05) are April, June, September, Tuesday, Wednesday, Thursday, Saturday and Sunday. Based on the results shown in the table 1, the largest amount of EMS demand can be expected in April, especially during the weekend.

Table 1: Significant parameters of multiple regression model

Parameter:	*a*	*b4*	b_6	b_9	
	Constant	April	June	September	
Coefficient:	29.79027	1.224539	-1.19056	-1.53877	
Parameter:	c_2	c_3	c_4	c_6	c_7
	Tuesday	Wednesday	Thursday	Saturday	Sunday
Coefficient:	-1.851524	-1.80774	-1.25211	2.918253	2.059951

To obtain relevant and adequate forecasting model it is necessary to examine the presence of autocorrelation of residuals. We applied the Ljung-Box test to the residuals after fitting the regression model to our data. The p-values are plotted in the next figure and since some p-values are smaller than 0,05 presence of autocorrelation of residuals can be identified. Hence, we need to improve the examined multiple regression model in order to exclude residuals' autocorrelation. It has been achieved by fitting an autoregressive (AR) model of order p to the residuals u_t.

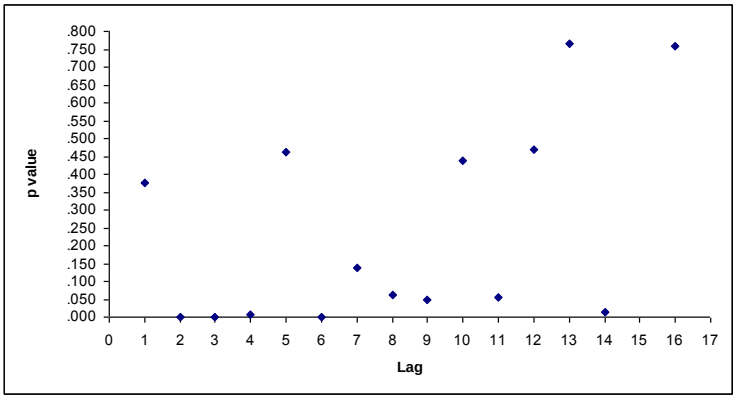

Figure 5: p-values of the Ljung-Box test applied to the residuals for the regression model with factors day of the week, month of the year

The improved multiple regression model for daily number of EMS demand becomes:

$$Y_t = a + \sum_{i=1}^{12} b_i B_{i,t} + \sum_{j=1}^{7} c_j C_{j,t} + \alpha_1 u_{t-1} + \ldots + \alpha_p u_{t-p} + e_t \qquad (6)$$

where e_t is i.i.d. normal distributed. In the previous section we tested for correlation between the number of rides per day and the number of rides seven days earlier. The outcome was significant hence we will take p equal to 7, the parameters α, which appear to be insignificant to the model will be omitted later on. The estimated improved multiple regression model with all parameters is presented by the following equation:

$$Y_t = 29{,}681 + 2{,}160C_{1,t} - 0{,}499C_{2,t} - 1{,}904C_{3,t} - 1{,}848C_{4,t} - 1{,}128C_{5,t} + 0{,}181C_{6,t} + 3{,}037C_{7,t} - 1{,}511B_{1,t} + 1{,}202B_{2,t} + 1{,}155B_{3,t} + 1{,}309B_{4,t} + 0{,}332B_{5,t} - 0{,}944B_{6,t} + 0{,}438B_{7,t} - 0{,}028B_{8,t} - 1{,}479B_{9,t} - 0{,}149B_{10,t} + 0{,}281B_{11,t} - 0{,}608B_{12,t} + 0{,}009e_{t-1} + 0{,}055e_{t-2} + 0{,}051e_{t-3} + 0{,}028e_{t-4} + 0{,}090e_{t-5} + 0{,}048e_{t-6} + 0{,}023e_{t-7} + u_t \qquad (7)$$

The estimated improved multiple regression model with significant parameters only (p<0,05) is presented by the following equation:

$$Y_t = 29{,}681 + 2{,}160C_{1,t\,t} - 1{,}904C_{3,t} - 1{,}848C_{4,t} - 1{,}128C_{5,t} + 3{,}037C_{7,t} + 1{,}309B_{4,t} - 1{,}479B_{9,t} + 0{,}090e_{t-5} + u_t$$

(8)

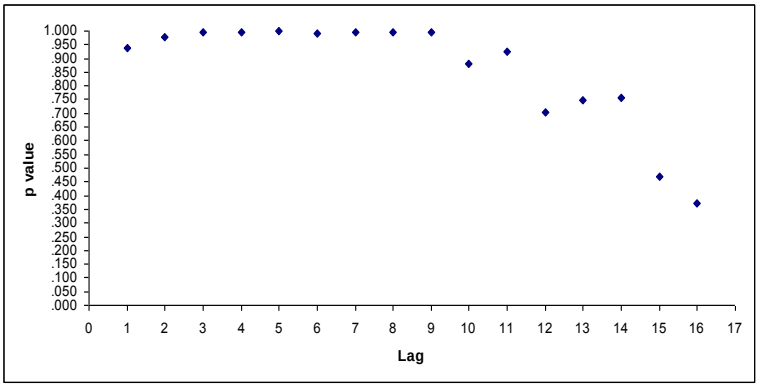

Figure 6: p-values of the Ljung-Box test applied to the residuals for the improved regression model with factors day of the week, month of the year

5. FORECASTING

In order to obtain adequate short-term forecast for daily number of ambulance rides we will discuss two regression models. First, we will use the improved multiple regression model with all introduced parameters (7) and secondly the model with only significant parameters (8). To decide which of the models is the most accurate to forecast the ambulance calls per day we look at forecasts generated by our models and compare them to our test set. Extrapolation will be done to generate forecast for the next 14 days.
There are different ways to measure the exactness of a forecast. In this research we will use three indicators: Root Mean Square Error (RMSE), Mean Absolute Error (MAE) and Mean Absolute Percentage Error (MAPE).

$$\text{RMSE} = \sqrt{\frac{1}{S}\sum_{s=1}^{S}(Y_{t+s} - P_{t,s})^2} \quad (9)$$

$$\text{MAE} = \frac{1}{S}\sum_{s=1}^{S}\left|Y_{t+s} - P_{t,s}\right| \quad (10)$$

$$\text{MAPE} = \frac{1}{S}\sum_{s=1}^{S}\left|\frac{Y_{t+s} - P_{t,s}}{Y_{t+s}}\right| \cdot 100\% \quad (11)$$

Those indicators examine the exactness of a forecast by calculating the forecast error, as the difference between original value Y_{t+s} in the test set S (s= 1,2 ..., S) and forecast value $P_{t,s}$ at day s. The smaller values of indicators suggest the better quality of forecast. The next table presents the values of RMSE, MAE and MAPE for both multiple regression models, for estimation period (February 15th 2009 to January 21st 2012) and for the test period (January 21st 2012 to February 15th 2012).

Table 2: Values of RMSE, MAE and MAPE for Multiple Regression Models

	Estimation period			Interpolation (test period)		
	RMSE	MAE	MAPE (%)	RMSE	MAE	MAPE (%)
Improved Multiple Regression Model	6,268113	2,541237	0,17875	4,211435	2,102894	0,19779
Improved Multiple Regression Model (significant parameters only)	6,54172	2,64712	0,18021	4,05712	2,185642	0,199785

By comparing the RMSE. MAE and MAPE values for regression models, we can conclude that the multiple regression model with all parameters generate the better forecast than the model with only significant parameters.

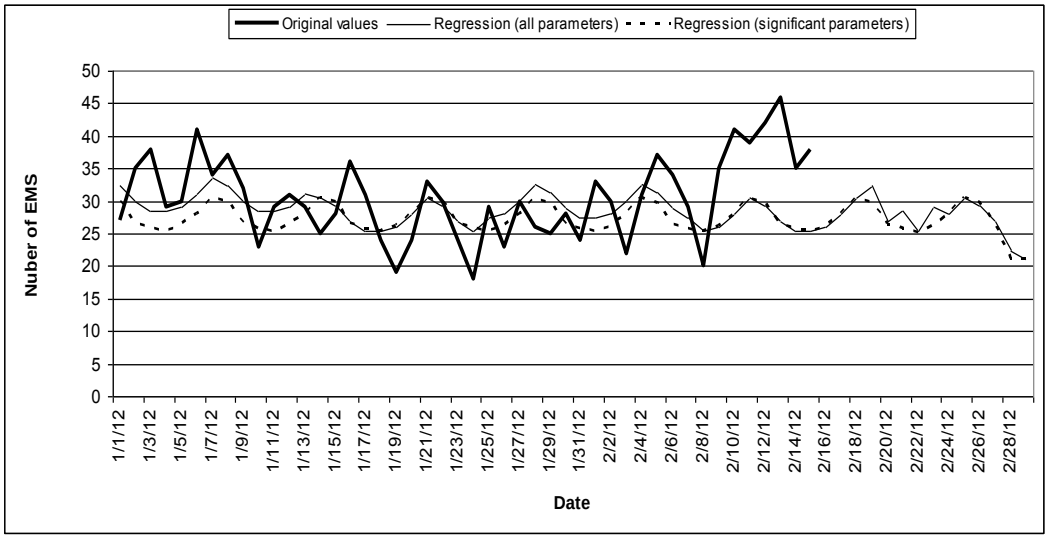

Figure 7: Original data and forecasts obtained by multiple regression models

6. CONCLUSION

Modelling the practical issues in field of health care management is a great challenge, both for health care specialists and managers. Implementation of obtained results provides the valuable basis for decision making process and leads to efficiency improvement, which is one of the most important goals for health care system.

This paper showed that the number of ambulance rides per day follows some patterns, which depend on the month of the year and the day of the week. These regularities can be of great importance for decision makers, when they determine the staff level or the necessary number of vehicles. Multiple regression models that take into account influence of the day of the week and the month of the year were used to forecast the daily number of ambulance services. In further research different forecasting models will also be examined in order to find even better way for predicting future number of daily ambulance rides.

[3]Faculty of Organizational Sciences, University of Maribor, Slovenia, uros.rajkovic@fov.uni-mb.si

Abstract: *Strategy of each country is care and maintenance of a healthy population. Information and communication technologies in the health care system have led to many changes. Their introduction has improved the quality of health care services to patients, rational spending time and reduce costs. This paper presents a parallel review of the development and implementation of e-health system in Slovenia and Serbia. Slovenia is a very good example of a successful development of information and communication technologies in healthcare system. Slovenia was one of the first countries to introduce health insurance chip cards and IT solutions are widely used in healthcare. In Slovenia, there is a project called eZdravje. eZdravje project consists of five modules. These are: A National Health telecoms network, e-Health portal, electronic health record, an Organizational module featuring the creation of the National Centre for e-Health, and a Training and Skills Development module. The implementation of electronic services in the health system of Serbia will be concluded in 2015. At this point, the implementation phase of hospital information systems is taking place. Introduction to hospital information systems and training is done by the team prepared for educating hospital staff and configuring and customizing the hospital information systems for the needs of the hospital.*

Keywords*: e-health, hospital information systems, Serbia, Slovenia*

1. INTRODUCTION

A state health care system is one of its most complex. Due to the importance and impact upon the status of health of its population and stemming from the relevant economic influence thereof, the state implements a large number of measures in health care system planning and management in order to ensure steady financing and a rational, high quality health care system, as well as to ensure basic health protection to all of its citizens within its available resources (Jovanovic Milenkovic, 2011, Frenk, 2010, Vujin, Jovanovic Milenkovic, 2012).

It should be noted that one of the major problems in health care and modern medicine in general, is the collection, handling, processing and use of data collected on a daily basis in large quantities and in the form of extensive documentation within medical institutions. Persons in their lives visit various medical facilities that are, by their geographical position, very often distributed. Therefore, sources of medical data generation are also distributed. Data can be also generated in the field (in temporary clinics or during home visits) which presents an additional factor of physical distribution (Jovanovic Milenkovic, Radojicic, Milenkovic, Vukmirovic, 2009).

Information and Communication Technologies (ICT) offer great opportunities and have an overall impact on national economies and global competition in the health care system. There are many papers that emphasize the importance of ICT through the inclusion of Internet users and IT literacy as indicators of socio-economic development (Jeremic, Markovic, Radojicic 2011, Jeremic, Vukmirovic, Radojicic, Djokovic (2011). ICT have the potential to be used in order to help citizens and health professionals for safer, better, more rational and better integrated health care. ICT is a mean to achieve the strategic goals of the health care system, i.e. (Jovanovic Milenkovic, 2011):

- Developing and improving management in all aspects of the system, by making decisions based on evidence from health professionals, consumers.
- Creating conditions for sustainable financing of health care system.
- Measuring critical dimensions of the health care system, such as accessibility, parity, quality and efficiency.

Ten years of experience in the medical application of information technology in health care in developed countries has shown high economic and medical reasons for investing in this area (Al-Lagilli, Jeremic, Seke,

Jeremic, Radojicic, 2011). The relative costs of investing in medical informatics today are very low compared to other costs in health care, and the effects of proper use are greater savings through rationalization of costs and the possibility for better planning and management in all aspects of the system. These effects are based on information generated and shared between the segments of the system, which allows for making better decisions and plans based on quality and updated information about the needs and the state of resources (Hillestad, Richard et al. 2008, Blaya, Fraser, Holt, 2010).

2. RANKING OF EUROPEAN HEALTH CARE SYSTEMS BY EHCI 2013 INDEX

Today, health systems in all countries play a bigger and more influential role in people's lives than ever before. Health systems of some sort have existed for as long as people have tried to protect their health and treat diseases (World Health Organization, 2000). The Euro Health Consumer Index (EHCI) 2013 is the seventh study made on European health care systems. The Index takes a consumer and patient perspective. This ranking takes into account six sub-disciplines:

- Sub-discipline 1 - Patient rights, information and e-health;
- Sub-discipline 2 - Accessibility (waiting times);
- Sub-discipline 3 - Outcomes;
- Sub-discipline 4 - Range and Reach of services provided;
- Sub-discipline 5 - Prevention;
- Sub-discipline 6 - Pharmaceuticals.

Index for year 2013 already includes all 28 European Union (EU) member states, Albania, Iceland, FYR Macedonia, Norway, Switzerland and Serbia (Björnberg, 2013). According to the survey, Slovenia is located at 18th position and Serbia occupies the last place on the list. Of the possible 1,000 points, the Serbian health system received 451 points (Figure 1.). The graph shows that the Netherlands is in the first position with 870 points.

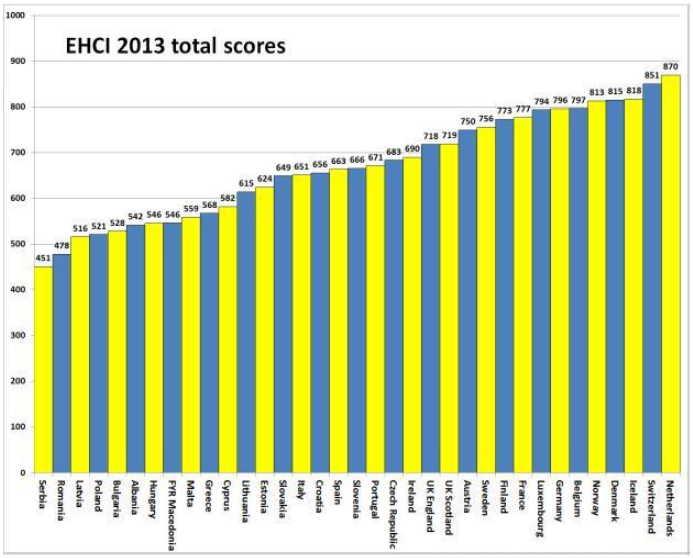

Figure 1: Ranking of European health care systems by EHCI 2013 Index (Björnberg, 2013)

Slovenia and Serbia are two countries which until 1991 constituted the former Yugoslavia. Due to this fact, the paper will provide a parallel review of the health systems in these countries. Considering the sub-discipline e-health included in the study EHCI 2013, the paper will review the development of e-health in Slovenia and Serbia.

2.1. DEVELOPMENT OF E-HEALTH IN SLOVENIA

Slovenia was the first of the former Yugoslav republics that became a member of EU, in 2004.

Slovenia is advanced in the area of social determinants of health (SDH)/health inequalities (HI), and yet there is need for a national framework which will clearly establish coordinated objectives and priorities for different sectors at the national and local levels, and enable the measurement of the effect of various policies on health (WHO Regional Office for Europe, 2014, Prijatelj V., Rajkovič, U., 2009).

Table 1. shows the basic statistical data related to the population of Slovenia and their life expectancy.

Table 1: The basic statistical data related to the population of Slovenia and Serbia and their life expectancy (WHO, 2014)

	Slovenia	Serbia
Total population (2012)	2,068,000	9,553,000
Gross national income per capita (PPP international $, 2012)	27,240	11,430
Life expectancy at birth m/f (years, 2011)	77/83	72/77
Probability of dying under five (per 1 000 live births, 2012)	3	7
Probability of dying between 15 and 60 years m/f (per 1 000 population, 2011)	118/51	175/86
Total expenditure on health per capita (Intl $, 2011)	2,519	1,195
Total expenditure on health as % of GDP (2011)	9.1	10.4

In terms of infrastructure 97% of Slovenian doctors use computers. 82% of practices have Internet connection. When it comes to the use of e-Health applications, 86% of Slovenian doctors use electronic patient data (European Commission, 2010).

Slovenia was one of the first countries to introduce health insurance chip cards and health care professionals are avid users of health ICT solutions. The missing piece was infrastructure to connect local systems allowing exchange of information to facilitate care coordination (Marand, 2014).

The objectives that the Slovene national project aims to meet are the following
(EUREGIO III Case study - National e-Health Project, 2011):

- Offer to all health care providers, specialists, general practicioners, pharmacists unified, secure and reliable access to all key patient information via a standardized Electronic Health Record (EHR) and other data sets;
- Facilitate better planning and management of the national health care system on the basis of good quality, accurate administrative, clinical, and economic data; improve access to all necessary information and the ability of citizens to participate in the development of quality health care services;
- Promote an active role and responsibility of citizens for their health and health care services;
- Improve access to health care for persons excluded due to disability, age or other reasons.

In Slovenia, there is a governmental project called eZdravje. It was initially designed to comprise five project modules (Figure 2.). These are:

- Three system delivery modules of

(a) A national health telecoms network - *zNET*,
(b) E-Health portal - *zVEM* and
(c) EHR dataset, components of the national electronic Health Information System (eHIS),

- An organizational module featuring the creation of the National Centre for e-Health, and
- A Training and Skills Development module.

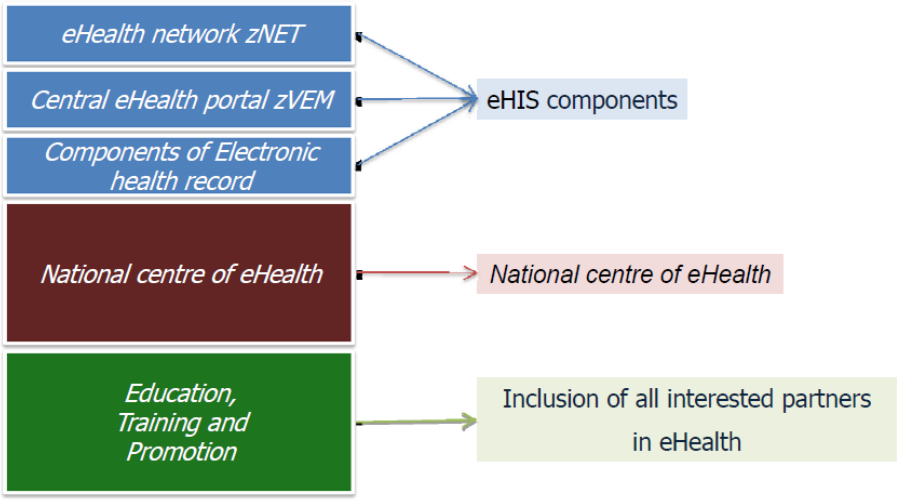

Figure 2: Project *eZdravje* and five project modules (EUREGIO III Case study - National e-Health Project, 2011)

Innovations anticipated by expert informants during the operational phase of the *eZdravje* system modules include (EUREGIO III Case study - National e-Health Project, 2011):

- Collaboration between ministries in operating the e-health telecoms network;
- The operation of the national EHR, and the perceived right and responsibility of individual citizens to access and keep their records updated;
- Use of the national electronic health insurance (HIC) user terminals for authentication.

Certain pilot projects progressed, *Lab-Poštar*, a pilot electronic personal health data exchange between laboratories and physicians by e-mail, moved into implementation during 2011. Work started on the EHR in late 2010 and resumed in 2011. Creating a team of experts to form the National Centre for e-Health also commenced, with them based at the Ministry of Health in the first instance. The Education and Training module progressed according to plan (EUREGIO III Case study - National e-Health Project, 2011).

A new pilot project has also been introduced, ePrescription, and is scheduled for implementation in regions where system platforms of stakeholder organizations are already interconnected. EPrescription will include the eTransmission of a prescription to the pharmacy and into a medication record.

The Health Insurance Institute of Slovenia has announced that it will introduce a new electronic health insurance card system across the country. Initially will be used to obtain information on insurance. The electronic health card is the basis for access to EHR and getting e-prescription.

The national roll-out follows a pilot at the Dr Franc Deganc General hospital in the Nova Gorica region of Slovenia, which was completed in March 2009. After the pilot ended the system was extended to more than 100 organizations in the Gorenjska and Primorska regions. In 2010 electronic health cards were used by more than 30,000 health professionals and two million patients. The system is the first in the country to cover both public and private insurance organizations (EHealth Insider, 2009).

Currently there are no telemedical services implemented at the national level in Slovenia. However, there are some pilot projects in the field of telemedicine carried out by specialized hospitals.

2.2. DEVELOMPMENT OF E-HEALTH IN SERBIA

Serbia is a democratic state located in the central part of the Balkan Peninsula, on the most important route linking Europe and Asia. Serbia has made significant progress in recent years, as it has seriously pursued social, economic, and political reforms in order to continue its progress towards eligibility for EU membership.

The Table 1 shows the basic statistical data related to the population of Serbia and their life expectancy.

Serbian Healthcare, for the second year in a row, took the last – 35th – place in Europe in the ranking of health care systems, according to a survey conducted for the needs of European Parliament. The World Health Organization (WHO) Country Office in Serbia was requested by the Ministry of Health and the EU to implement the EU IPA-funded Project: “Implementation of the Hospital Information System (HIS)”. One of the main goals of this Project is to customize and implement HIS proposed by the Ministry of Health in selected hospitals and to integrate them with the EHR system.

In Serbia, in line with the strategic implementation of the document e-Health 2015, hard-work on the development of health information systems has been done (Figure 3). In this moment, the development of HIS have three phases. The first phase of the project was health information Think Thank and IT development. The second phase was pilot testing and the third phase is full implementation of proposed IT solutions. The third phase will be completed during 2014.

According to the Action Plan, a strategic document e-Health 2015 first iteration of computerization of the health sector will be completed by year 2015 (Jovanović Milenković, et al. 2012). In an integrated health information system, all institutions and facilities in the health system will be interconnected (Ministry of Health, National Health Insurance Fund, the institutes of public health, health centers, hospitals, clinical centers, pharmacies ...) (Ausford et al. (2005).

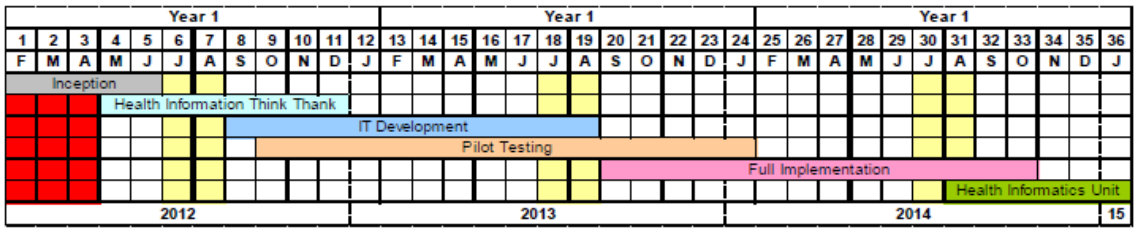

Figure 3: Phase of the project (The EU-IHIS project, 2013)

An analysis of the introduction and implementation of health information systems has been performed for three observed years: 2007, 2010 and 2013 (Table 2). The results showed that (The EU-IHIS project, 2013):

- Year 2007 was a base of policyholders and that only 40% of the insured were entered into the information system.
- Year 2010 was characterized by adoption of information systems in health centers and hospitals use, but EHR is still not used.
- In 2013 HIS was installed in 50% of hospitals, central base of insured beneficiaries is completed and usage of the EHR is in progress

Table 2: Analysis of the introduction and implementation of health information systems (The EU-IHIS project, 2013)

	Base of insured	Cental resource base	Hospital health care	Primary health care	EHR
2007	40%	0%	0%	5%	0%
2010	85%	60%	15%	15%	0%
2013	90%	100%	50%	85%	9%

The implementation of computerization of medical institutions of primary health care was in accordance with the project plan and the indicator of 85% computerized institution is achievable by the end of the project.

The introduction of HIS into organizations included in the project is designed to provide a set of elements that enable the improvement of the work process in health care sector. It is done in order to enable users to obtain a functional unit that will improve the quality of hospital business by a milestone. The implemented solution will become a foundation for improved internal communication and availability of information, avoiding multiple entries or copying data, data entry at the source with the implementation of appropriate coding, as well as better tracking of items that are billed to health insurance.

Introduction to HIS and training is done by the team prepared for educating hospital staff and configuring and customizing the HIS for the needs of the hospital. The introduction of the HIS aims to improve the treatment of the patient support, management and increasing the efficiency of administrative work. End-user training includes familiarization with the system, its features and functionality, as well as complete introduction to practical use in the workplace.

Project introduction of HIS shall be concluded by February 2015. The introduction of the HIS is planned in 19 hospitals, which will lead to further development and improvement of integrated health information systems in Serbia.

For now the introduction has been concluded in the following hospitals:

- The University Children's Hospital in Belgrade, in addition to previously implemented using ICT in the ambulatory work, HIS is covers full clinical practice.
- HIS in The Institute for Oncology and Radiology of Serbia - In addition to the system used in the wards and clinics, online appointment system of consultative examinations has been implemented successfully.
- Activities General Hospital Smederevo are completed on time and in the daily work of continuously increasing use of the system in the treatment of patients, approximately 20% per month. With such tendency of growth we soon expect all data on the treatment of patients to be administered through HIS.
- While the system was introduced during the summer months in general hospital Pančevo, professional approach to hospital management and employees is important to facilitate the work of the EU-IHIS team, which resulted in more than 90% of the users being trained for daily use of HIS.
- Implementation of HIS in the General Hospital Sombor, introduced in October 2013, resulted in much shorter times used for following the health card protocol. The program is easy to use and significantly reduces administration times.

EU IHIS project teams began the process of implementing HIS at the General Hospital Kruševac in January 2013, and in February 2013 at the General Hospitals in Čačak, Kikinda and Pirot. Until the end of May 2013, over 95% of users and IT staff at the General Hospital Kruševac were trained and the system was implemented in outpatient rooms and departments despite the lack of equipment necessary for full production. Even though the Health care Center "Dr Dragiša Mišović" in Čačak is in the process of separation from the General Hospital and the Primary Health care Center, the focus of hospital's management and health professionals remained using HIS. At the General Hospital Čačak, approx. 90% users have been trained. The work is also completed in the General Hospital Kikinda and the system is being used in the entire hospital, even though the hospital has only one IT expert. Thanks to the professional approach of hospital's management and commitment of users, HIS was implemented on time in all outpatient rooms and departments of the General Hospital Pirot. Thereby, the experience in HIS implementation in this hospital represents an example of good practice that will serve as a role model for system implementation in other hospitals involved in the project.

The Republic Fund of Health Insurance introduced electronic health cards during 2013. The cards were first introduced during the pilot project. The pilot project is taking place in Valjevo. Valjevo was chosen because all health centers, hospitals and pharmacies share a computer network with The Republic Fund of Health Insurance. The Fund plans to change million cards in 2014, and the rest in the following three years (The Republic Fund of Health Insurance, 2012). This kind of medical identification will enable faster and easier communication between medical doctors and pharmacies.

Early in 2015, patients will no longer receive paper prescriptions in health centers. Prescriptions to pharmacies will be forwarded electronically. All physicians in 158 medical centers in Serbia and 1,000 pharmacies will be networked into a system of making and issuing electronic prescriptions. Annually more than 60 million paper prescriptions are issued. They will be replaced by electronic prescription.

3. CONTRIBUTION AND FURTHER DEVELOPMENT

Development and implementation of electronic services in the health care system will contribute to the overall development of the health system of any country.

Implementation of the system should speed up organized and synchronized computerization of health care institutions in accordance with standards and accepted rules. Gradual interconnection of a larger number of computerized health care institutions will increase representativeness, importance and usefulness of data stored in databases (Jovanovic Milenkovic, Radojicic, Milenkovic, Vukmirovic, 2009).

All partners in the system must give contributions to the development of e-Health. Advantages of using this system are:

- Better communication between partners in electronic health system,
- Data collections for better patients care,
- Better medical documentations,
- Increase efficiency of work in health institutions,
- Increase standards of health care,
- Advanced statistical data analysis,
- Increased safety for patients and health care professionals (Rajkovič, Dinevski, Šušteršič, Rajkovič, 2011.)

4. CONCLUSION

The health care system and the directions of its development are the subject of interest of international organizations, agencies and other institutions, such as the World Health Organization, World Bank, the International Committee of the Red Cross and others. Application of ICT has fundamentally changed medical practice in developed countries, allowing for increased quality and efficiency of health services. Years of experience in applying ICT in the health care system show high economic and medical reasons for development and investment in this area.

This paper describes the main ICT trends in the field of health care systems. The paper provides a parallel view of two analyzed countries, Slovenia and Serbia.

Slovenia is a very good example of a successful development of ICT in health care system. Its major benefits can be summarized by a check-list as follows: benefits for citizens: speed, ease of use; benefits for the health care administration: costs control, and time savings. Development of the Slovene HIS is an on-going intensive process, and at present, provides a good opportunity for introducing of others solutions.

The introduction of electronic services in the health system of Serbia was launched. We conducted a pilot project. The implementation of health information systems in hospitals in Serbia is in progress and shall be concluded by the end of 2015. The speed of development and application of these systems in the world indicate that the implementation in Serbia is not a matter of necessity and cost-effectiveness, but only a matter of time.

This paper provides further perspective of using e-Health applications, through the use of specific electronic services. Health care requires continuous and systematic innovation in applying ICT for effective and timely decision-making quality.

Abstract: *Healthcare systems are one of the EU major concerns, and during the past years, more and more initiatives have been taken at the international and national levels in order to strengthen national healthcare systems as core components of the global health system. EHCI is one of the most popular methodologies for evaluating healthcare systems, which is introduced more than a decade ago, and in 2012, for the first time, it included Serbia in the evaluation process. This paper strives to upgrading the ECHI, using the I-distance methodology, and thus improving its flaws and drawbacks. It gives the special concern to Serbia and its position in the overall healthcare system ranking, and points out to the most wholesome directions to improve the Serbian global health.*

Keywords*: EHCI, I-distance, health, healthcare system*

1. INTRODUCTION

The topic of health is the subject that could never become obsolete. In the terms of globalisation, global health, as the public health of populations in a global context, is becoming more and more compelling. Therewithal, the term of the healthcare system has been defined, and, since 2000, more and more initiatives have been taken at the international and national levels in order to strengthen national healthcare systems as the core components of the global health system (WHO, 2014).

Healthcare systems can vary substantially from country to country, and in the last few years, comparisons have been made on an international basis. Back in 2000, the World Health Organization (WHO, 2014) have provided a ranking of health systems around the world according to criteria of the overall level and distribution of health in the populations, and the responsiveness and fair financing of health care services. Still, direct comparisons of health statistics across nations are quite complex.

This is why healthcare systems have attracted a significant amount of researchers' attention (Kringos et al., 2013; Smith, 2013; Parkhomenko, 2013; Schnitzer et al., 2013), especially regarding their economic impact and their efficiency (Hadad, Hadad, & Simon-Tuval, 2013). According to Bohm et al. (2013), there are five types of OECD healthcare systems, with three core dimensions: regulation, financing, and service provision, and three types of actors: state, societal, and private actors. Similarly, Lima de Freitas and da Silva (2013) argue that they have a large impact on optimal economic growth. Some countries invest a large amounts of money in their health (Blank, 2012), and until today, they have already entered the healthcare systems transformation process (Blank 2012; Lin, 2012; Steel & Morris, 2013). In this regard, due to reduced financial means and increasing demands on provision of service in healthcare and nursing, the time will come when prioritization in healthcare systems will be necessary (Beske, 2012).

A good healthcare system delivers quality services to all people, when and where they need them. The exact configuration of services varies from country to country, but in all cases requires a robust financing mechanism; a well-trained and adequately paid workforce; reliable information on which to base decisions and policies; well-maintained facilities and logistics to deliver quality medicines and technologies. One of the most popular healthcare systems methodologies is the Euro Health Consumer Index (EHCI), which was created in 2005. Therewith, EHCI was presented in Belgrade on December 18, 2013, along with the health outcomes of Serbia.

EHCI methodology consists of six indicators, and their sub-disciplines, and is described in detail in Section 2. The main limitation of the EHCI methodology is the fact that the weights assigned to each of these indicators are biased weights, as comprehended by experts who participated in ECHI construction. In order to overcome the limitations, we proposed an upgrade to ECHI methodology by applying I-distance method to set of six consisting indicators. Mathematical modelling of healthcare systems and e-health has always been a common topic (Zaitseva & Rusin, 2012; Milenkovic, Milenkovic, & Dobrota, 2012; Grigoroudis & Phillis, 2013; Hadad, Hadad, & Simon-Tuval, 2013; Adeyemi, Demir, & Chaussalet, 2013). I-distance method

creates the synthesized multi-criteria indicator, which does not imply the biased weights proposed by experts, but is based on the multi-criteria distances between entities instead. Furthermore, it can provide the insight to which of the indicators are most important for ranking countries. This is the main precedence for upgrading the original EHCI index, using the proposed I-distance methodology. The methodology is explained in detail in Section 3.

2. EHCI INDEX

The Euro Health Consumer Index (EHCI) is the study made on European healthcare systems, which takes consumer and patient perspectives in consideration. The EHCI 2013 is seventh study in a row, published by the Health Consumer Powerhouse (HCP, 2013), which offers reality checks for policy makers, empowerment to patients and consumers and an opportunity for stakeholders to highlight weak and strong aspects of healthcare (EHCI, 2013). In order to become a powerful actor, building the necessary reform pressure from below, the consumer needs access to knowledge to compare health policies, consumer services and quality outcomes. The Euro Health Consumer Index (EHCI) is an effort to provide healthcare consumers with such tools.

The HCP has become a centre for visions and action promoting consumer-related healthcare in Europe. It monitors and compares healthcare systems among 35 countries, including all EU member states as well as Canada, providing guidance to patients and citizens and reality checks to governments. In 2005, the HCP launched its first EHCI, which provides country policy recommendations for improvement, advising governments and healthcare systems on how to improve performance and strengthen the position of the healthcare consumer. Today the European Commission regards the EHCI to be the most informative and influential assessment of European healthcare (EHCI, 2013).

For a decade, the HCP has been publishing a wide range of comparative publications on healthcare in various countries. By ranking the 21 county councils by 12 basic indicators concerning the design of ”systems policy”, consumer choice, service level and access to information, they introduced benchmarking as an element in consumer empowerment. HCP aimed to select a number of indicators describing to what extent the national healthcare systems are “user-friendly”, thus providing a basis for comparing different national systems. Furthermore, since 2008 the HCP has enlarged the existing benchmarking program considerably. Last year's edition of Euro Health Consumer Index covers 48 healthcare performance indicators for 35 countries (EHCI, 2013).

The EHCI is built up with indicators grouped in six sub-disciplines, which cover 48 different indicators. The aim has been to select a limited number of indicators, within a definite number of evaluation areas, which in combination can present a telling tale of how the healthcare consumer is being served by the respective systems.

The ECHI 2013 sub-disciplines:

1. Patient rights and information
    - 1.1. Healthcare law based on patients' rights
    - 1.2. Patient organisations involved in decision making
    - 1.3. No-fault malpractice insurance
    - 1.4. Right to second opinion
    - 1.5. Access to own medical record
    - 1.6. Registry of *bona fide* doctors
    - 1.7. Web or 24/7 telephone HC info with interactivity
    - 1.8. Cross-border care seeking financed from home
    - 1.9. Provider catalogue with quality ranking
    - 1.10. EPR penetration
    - 1.11. Patients' access to on-line booking of appointments?
    - 1.12. e-prescriptions
2. Accessibility/Waiting time for treatment
    - 2.1. Family doctor same day access
    - 2.2. Direct access to specialist
    - 2.3. Major elective surgery < 90 days
    - 2.4. Cancer therapy < 21 days
    - 2.5. CT scan < 7days
    - 2.6. A&E waiting times
3. Outcomes
    - 3.1. Heart infarct case fatality
    - 3.2. Infant deaths

    3.3. Cancer deaths relative to incidence
    3.4. Preventable years of life lost
    3.5. MRSA infections/Abortion rates
    3.6. Undiagnosed diabetes
    3.7. Depression
4. Range and reach of services ("Generosity")
    4.1. Equity of healthcare systems
    4.2. Cataract operations per 100 000 age 65+
    4.3. Kidney transplants per million pop.
    4.4. Is dental care included in the public healthcare offering?
    4.5. Informal payments to doctors
    4.6. Long term care for the elderly
    4.7. % of dialysis done outside of clinic
    4.8. Caesarean sections
5. Prevention
    5.1. Infant 5-disease vaccination
    5.2. Blood pressure
    5.3. Smoking prevention
    5.4. Alcohol
    5.5. Physical activity
    5.6. Undiagnosed diabetes
    5.7. HPV vaccination
    5.8. Sugar intake
6. Pharmaceuticals
    6.1. Rx subsidy
    6.2. Layman-adapted pharmacopoeia?
    6.3. Novel cancer drugs deployment rate
    6.4. Access to new drugs (time to subsidy)
    6.5. Arthritis drugs
    6.6. Schizophrenia drugs
    6.7. Antibiotics/capita

The performance of the respective national healthcare systems were graded on a three-grade scale for each indicator, where the grades have the rather obvious meaning of *green* equals good, *amber* equals medium, and *red* equals not-so-good. A green score earns 3 points, an amber score 2 points and a red score (or a *not available*, *n.a.*) earns 1 point.

Having six non-EU countries in the Index, who should not be stigmatized for not being EU member states on indicator *Free choice of care in another EU state*, forced the introduction of a new score in the EHCI 2009: *not applicable*. These countries therefore receive the *n.ap.* score, which earns 2 points. That score was also applied on indicator *Provider catalogue with quality ranking* for Iceland and Malta, as they essentially have only one real hospital each.

In 2013, a *purple* score, earning 0 points, was introduced for particularly abominable results. It has been exclusively applied on indicator *Abortion rates* for countries not giving women the right to abortion.

Since the 2006 Index, the same methodology has been used: for each of the sub-disciplines, the country score is calculated as a percentage of the maximum possible (e.g. for *Waiting times*, the score for a state has been calculated as % of the maximum 3 x 6 = 18). Thereafter, the sub-discipline scores were multiplied by the weight coefficients given in the Table 1 and added up to make the final country score. These percentages were then rounded to a three digit integer, so that an *all green* score on the 48 indicators would yield 1000 points, while *all red* gives 333 points.

Table 1: Sub-discipline weights

Sub discipline	Relative weight (max 1000)	Points for a *green* score in each sub-discipline
Patient rights and information	150	12.5
Accessibility/Waiting time for treatment	225	37.5
Outcomes	250	35.71
Range and reach of services ("Generosity")	150	18.75
Prevention	125	15.63
Pharmaceuticals	100	14.29

Consequently, as the percentages of full scores were added and multiplied by (1000/Total sum of weights), the maximum theoretical score attainable for a national healthcare system in the Index is 1000, and the lowest possible score is 333. The preview of EHCI 2013 is given in Figure 1.

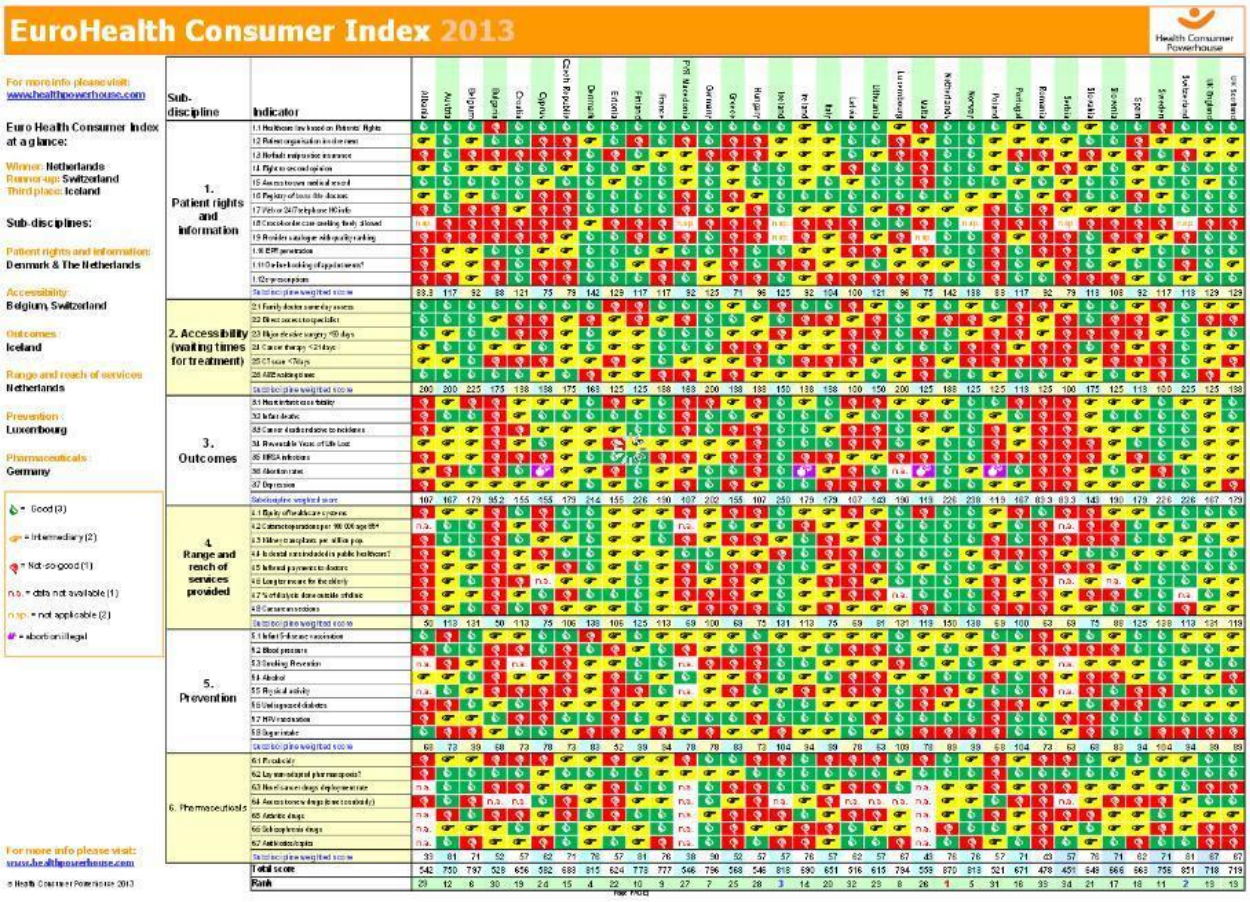

Figure 1: EHCI 2013 (EHCI, 2013)

3. I-DISTANCE METHODOLOGY

The common case with different ranking methods is that their bias and subjectivity can affect the measurements and evaluation. This problem can somewhat be surpassed using the I-distance method, a metric distance in an n-dimensional space, which has recently made a significant breakthrough (Jeremic et al., 2011a; Radojicic & Jeremic, 2012; Jeremic et al., 2012; Dobrota et al., 2012; Jeremic et al., 2013a; Jeremic et al., 2013b). It was originally defined by professor Branislav Ivanovic (Ivanovic, 1973; Ivanovic & Fanchette, 1973), who devised this method to rank countries according to their level of development based on several indicators, where the main issue was how to use all of them in order to calculate a single synthetic indicator, which will thereafter represent the rank.

For a selected set of variables $X^T = X_1, X_2, \ldots X_k$ chosen to characterize the entities, the I-distance between the two entities $e_r = x_{1r}, x_{2r}, \ldots x_{kr}$ and $e_s = x_{1s}, x_{2s}, \ldots x_{ks}$ is defined as

$$D(r,s) = \sum_{i=1}^{k} \frac{\left| d_i \; r,s \right|}{\sigma_i} \prod_{j=1}^{i-1} 1 - r_{ji.12\ldots j-1} \tag{1}$$

where $d_i(r,s)$ is the distance between the values of variable X_i for e_r and e_s, e.g. the discriminate effect,

$$d_i \; r,s = x_{ip} - x_{is} \quad i \in 1,\ldots k \tag{2}$$

σ_i the standard deviation of X_i, and $r_{ji.12\ldots j-1}$ is a partial coefficient of the correlation between X_i and X_j, $j < i$ (Ivanovic, 1973; Ivanovic, 1977).

In order to surpass the problem of negative coefficient of partial correlation, which can occur when it is not possible to achieve the same sign mark for all variables in all sets, it is suitable to use the square I-distance. It is given as:

$$D^2\ r,s\ = \sum_{i=1}^{k} \frac{d_i^2\ r,s\ }{\sigma_i^2} \prod_{j=1}^{i-1} 1-r_{ji.12\ldots j-1}^2$$

The I-distance measurement is based on calculating the mutual distances between the entities being processed, whereupon they are compared to one another, so as to create a rank. It is necessary to fix one entity as a referent in the observing set using the I-distance methodology. The ranking of entities in the set is based on the calculated distance from the referent entity.

4. RESULTS

The results of the I-distance method, as well as a comparison of the I-distance and the EHCI ranking, are shown in Table 2.

Table 2: ECHI Scores and Ranks, and its comparison to I-distance Scores and Ranks for 2013.

Country	EHCI Score	EHCI Rank	I-distance Score	I-distance Rank
Switzerland	852	2	35.56	1
Netherlands	871	1	34.81	2
Norway	814	5	31.49	3
Germany	795	7	29.91	4
Iceland	817	3	29.35	5
Denmark	816	4	28.68	6
Belgium	797	6	28.02	7
Finland	773	10	27.01	8
Luxembourg	793	8	26.7	9
Sweden	756	11	26.03	10
France	778	9	24.8	11
Austria	751	12	22.82	12
UK England	718	14	19.37	13
UK Scotland	721	13	18.38	14
Portugal	672	17	17.49	15
Ireland	692	15	16.98	16
Czech Republic	683	16	15.05	17
Slovenia	665	19	14.68	18
Slovakia	650	22	14.37	19
Spain	665	19	13.83	20
Italy	652	21	13.6	21
Croatia	657	20	11.25	22
Estonia	624	23	10.51	23
Lithuania	615	24	9.24	24
Albania	541	30	8.16	25
Cyprus	583	25	7.72	26
Greece	568	26	6.78	27
Bulgaria	528	31	6.09	28
Latvia	516	33	5.5	29
FYR Macedonia	547	28	5.39	30
Hungary	546	29	5.07	31
Malta	559	27	4.92	32
Poland	521	32	3.66	33
Romania	479	34	2.36	34
Serbia	451	35	2.2	35

Before commenting on the results, it is important to note that I-distance methodology as apposite for measuring the European healthcare systems, as ECHI is, since the Pearson correlation coefficient between the two is significant ($r=0.98$, $p<0.001$). Spearman correlation of ranks is also significant and strong ($r_s=0.98$, $p<0.001$).

As can be seen from Table 2, Switzerland obtained better score than the one gained by simple EHCI addition method, thus forcing its way to the top position, and repressing Netherlands to second position. Top five countries are Switzerland, Netherlands, Norway, Germany and Iceland, and thereby Norway and Germany have significantly improved their positions, while Iceland and Denmark were thrown back. Hungary, Malta, Poland, Romania and Serbia are the worst positioned countries, where Malta has significantly fell down, while for example Albania dug its way up the ranking list.

Some explanations for these changes in ranking positions can be found in Table 3.

Table 3: Importance of consisting indexes

Consisting index	Correlations
Outcomes	0.905**
Range and reach of services (“Generosity”)	0.796**
Pharmaceuticals	0.758**
Patient rights and information	0.667**
Prevention	0.652**
Accessibility/Waiting time for treatment	0.470**

** $p<0.01$

Table 3 presents the importance of the six consisting indicators that constitute EHCI. Most important indicator for the ranking process is *Outcomes*, and this is in accordance with the EHCI weight. It is followed by *Range and reach of services*, and *Pharmaceuticals*. Here within, differences are more conspicuous: *Range and reach of services* is middle weighted and *Pharmaceuticals* is least weighted by original EHCI. *Accessibility/Waiting time for treatment* is secondly weighted by EHCI, but according to I-distance method it is the least important for the ranking process. These results indicate that the weights assigned by experts are biased and non-objective, and, since I-distance is a statistically based methodology, it is obvious that it would generate nonbiased, objective, and more realistic results.

It is surely interesting to examine the position of Serbia within these results. Serbia takes the last place according to both EHCI and I-distance methodology. Figure 1 could somewhat explain these bad results: Serbia has very bad results regarding *Outcomes*, scoring the lowest (all red), which is similarly to Romania, who takes second worst position. Very bad results are also for *Range and reach of services* and *Prevention*. Since *Outcome* and *Range and reach of services* are most important for the ranking process, Serbian bad scores are somewhat expected, and it is clear that Serbia will have to work hard in order to improve its overall healthcare system position.

The first step has already been made. In the Serbian parliament health committee, there was a strong wish to learn from the EHCI findings, on how to improve Serbian healthcare, placed last in 2013 Index. When EHCI 2013 results were published, Serbia reacted very quickly by inviting HCP to come to Belgrade, to explain the outcomes and advise how Serbian healthcare can improve. Accordingly, Dec 18-19 the HCP management visited Belgrade as guests of the Serbian parliament (EHCI Belgrade, 2013).

Consequently, a number of reports emerged from these efforts. According to Milovanovic (2014), antiquated equipment and a lack of medical experts, as well as the poor condition of the health infrastructure itself, are only some of the problems in Serbia. Yet, Serbia took steps to improve its troubled healthcare system, as it started negotiations with the European Union. "We are working hard to improve the situation, but we are encountering numerous problems," Health Minister Slavica Đukić-Dejanović said. She also said that major changes are expected next year regarding patient waiting lists, and that an electronic information system, that will provide up-to-date data, is being rapidly developed (Milovanovic, 2014). The first centralised acquisition of medical supplies for hospitals in Serbia is also under way, a procedure that could save the state up to 25 million euros. The new procedure will be under the supervision of the health ministry, reducing the opportunity for corruption.

5. CONCLUSION

This paper’s results can lead to many various conclusions. As evidenced from Figure 2, European healthcare generally continues to improve but medical outcomes statistics is still appallingly poor in many countries.

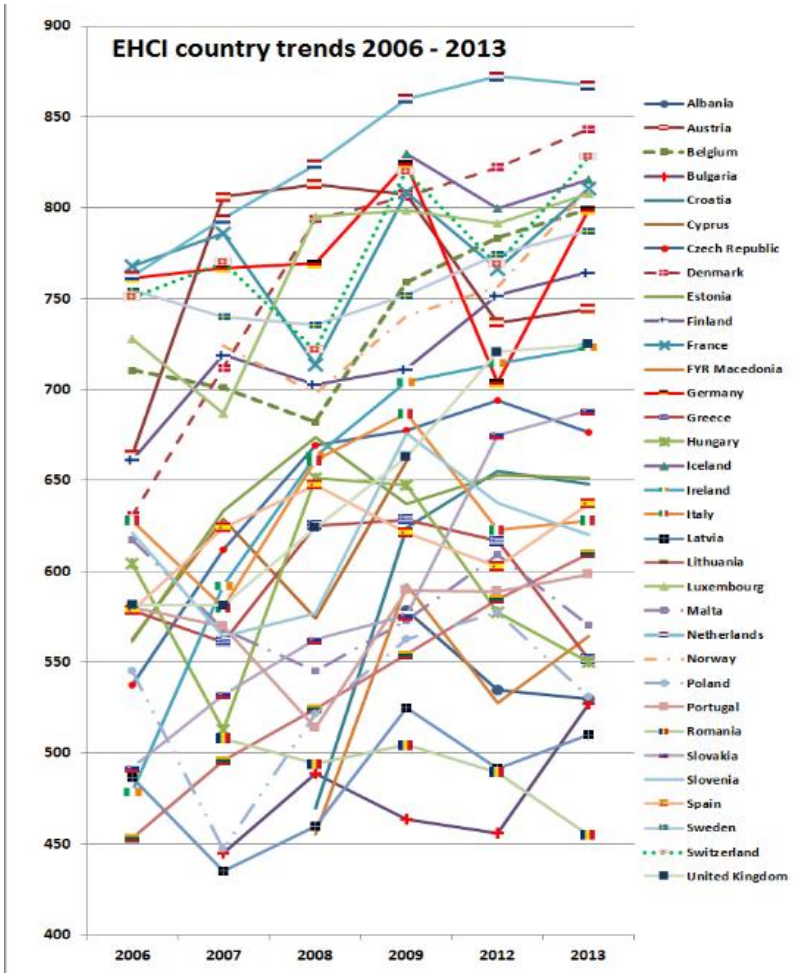

Figure 2: EHCI country trends (EHCI Belgrade, 2013)

Though still a somewhat controversial standpoint, HCP advocates that quality comparisons within the field of healthcare is a true win-win situation: the consumer will have a better platform for informed choice and action; governments, authorities and providers will have the sharpened focus on consumer satisfaction and quality outcomes; to media, the ranking offers clear-cut facts for consumer journalism with some drama into it. This goes not only for evidence of shortcomings and method flaws but also illustrates the potential for improvement (EHCI, 2013). This paper provides an important improvement regarding the introduction of unbiasness and objectiveness into healthcare systems ranking process.

Special attention is regarding Serbia, and the interpretation of its currently last position within ECHI 2013. Officials said that in order to reach European standards, Serbia needs to have more modern medical equipment and instruments in hospitals, and more medical residents and specialists, especially radiologists, cardiologists and oncologists (Milovanovic, 2014). "We need to have better organisation in our healthcare system. We have to use our sources and our knowledge in the most productive way," Djukić-Dejanović said.

What the EHCI was evaluating is of crucial importance for patients, such as rights of patients to information, waiting time for medical treatment, outcome of medical treatment, range of offered services and pharmaceutical means. Serbia does need to focus to improving these elements, especially the outcomes of medical treatments, as well as investments in healthcare system, in order to keep up.

Abstract: *Conflicts are a general phenomenon that can be observed at all levels of human life. They appear in the form of relationship between individuals, groups, families and in workplaces. This paper deals with the conflicts in health care organizations that are very specific regarding the types of services they provide, as well as the specificity and diversity of service users or patients who come to health facilities for various health needs. It also analyzes the factors that have resulted in the appearance of a conflict, and finds the possibilities of more efficient management and conflict resolution. The survey was conducted in private and public institutions of primary care, and displays reasons, origin, development, management, and possible ways of resolving the conflict. The paper provides the background how to identify latent conflict, remove it, manage and solve it.*

Key words*: Conflict, health care, conflict management, primary care*

1. INTRODUCTION

Conflict is a social condition in which at least two parties (individuals, groups, states) that have different starting points at first glance irreconcilable and when the differences which are important come to the surface making it impossible to continue working in harmony. The parties then seek different objectives that can be achieved and use different means for achieving certain goals. The differences are emphasized, whether they are real or perceived in relation to the objectives, needs, ideas or starting points between the parties.

The term *conflict* is of Latin origin *"conflictus"* which means "to hit each other." Ross (Ross 1993) defines conflict as a "conflict of motives ... a situation where a person is due to the conflict of motives called a conflict situation". Krkeljić and Slobig (Krkeljić and Slobig, 2001) define conflicts as "a state of antagonism with conflicting needs and desires (included at least two parties who want to win)." By analyzing the different views of conflict, many of them can be subsumed in whole or in part, on the one of the two views, or at least to contain some of their characteristics. They all agree that conflict is a process, is inevitable and is a normal part of life.

The simplest definition of a conflict is that it represents disagreements between human beings. It means that conflicts are part of life and every change with the ability to transform into a source of energy provides the ability to manage, in a constructive way. Creative potential conflict situations are emphasized in this paper as a part of our approach to resolving conflicts bearing in mind that there is no universal definition for such complex concepts. Much more important than the definition is the understanding of the nature of the conflict. The nature of conflict is two-fold, while on the one hand, conflicts can lead to violence and unintended consequences, on the other they may be a chance to change the current situation for the better and establish a new, productive relationships in the community in which we work. All interpersonal relationships are much more complex than we realize at a first glance. By analyzing various factors and circumstances that have an impact on the level of quality of interpersonal relationships, we come to the fact that the conflict in all spheres of human life is usually inevitable. There are many studies on interpersonal relations in various domains of psychological, sociological, cultural and other fields of knowledge, but as long as we are trying to expand their awareness of the information that we receive from different forms of science, we never have a complete picture about themselves or about others. Because of these different perceptions it comes to a halt in communication, which is usually manifested in the form of a conflict. There are many possibilities for the development of a conflict situation within a group, between the two groups, between the two people, as well as within the same individual. The essential feature of any form of conflict is a conflict of interests of opposite sides, the conflict of nations, ideologies and political groups, conflicts of race and religion, family conflicts or conflict at work.

Conflicts, however it seemed to have a social dimension that takes place between two or more persons, basically have a psychological core in which usually lies the frustration of basic needs. Importance of psychological dimensions of conflict is particularly important in the process of resolving or managing them. Conflict resolution implies that conflicts can be finished, completed, overcome, or permanently settled. Conflict management suggests a process view of the choices and behaviors that come into play during

conflicts implying that it is not an "on" or "off" phenomenon.[1] Some conflicts are enduring and the best we can hope for is to manage the level and manifestation of conflict - to sustain a good working relationship free from negative behaviors or violence.

2. CAUSES AND TYPES OF CONLICTS

2.1. Causes of conflicts

Causes of conflicts can be varied events in living and working environments arising from different interests and values which represent the core of all conflicts. The conflicts are caused by different factors: disagreements, differences, difficulties, or competition. It is impossible to give a precise list of all the possible causes of conflict. One of the reasons for the large individual differences between people is that one can never be completely sure that the behavior of someone causes adverse reactions. Many professionals involved in the conflict have tried to categorize of large number of possible causes of conflict. Christopher Moore (Moore, 1986) classifies the causes of conflicts in five categories of interests, values, data structures, relationships. In real life, people still do not comply with the satisfaction of a need for a specific order. Therefore, it is important to find out how the participants in conflict define their needs and priorities of the moment. Identifying the basic needs behind the views expressed in conflict situations is further complicated by the fact that the world around us perceives everyone in a different way.

2.2. Types of conflicts

The types of conflicts indicate the seriousness of the conflict, its intensity, and the approach to the solving process. Deutch (1969) created a view of conflict that remains a usable framework today claiming that the negative or positive nature of conflict can be determined by people's behaviors and produce either dysfunctional, destructive and unproductive responses (destructive conflicts) or, on the other hand, functional, constructive and productive responses (constructive conflicts). Finding compromise solutions within the objectives of the organization that will partially satisfy the demands of the opposing party is the best and the final outcome of each conflict.

2.2.1. Destructive conflicts

These conflicts usually reflect behaviors from rigid, competitive systems and are difficult to resolve and transformed into constructive conflicts. The characteristics of destructive conflicts are inability of the groups whose members are in conflict to find a solution to the problem so the conflict parties forget the substantive issues and transform their purposes to getting even, hostile to each other, which causes a negative emotional charge. In destructive conflict, no one is satisfied with the outcome, possible gains are not realized and the negative taste left over at the end of one conflict episode is carried over to the beginning of the next conflict

2.2.2. Constructive conflicts

Constructive conflicts are the conflicts characterized by the search for the solution of the problem. They are adaptive to the situation; person and issues of the moment are functional and constructive.These conflicts are assessed as a positive phenomenon in which optimal solution is promoted because they appropriately balance the interests of both parties to maximize the opportunities for mutual gains. In constructive conflict two sides are contradicted and may be in conflict showing an acceptable level of hostility or even aggression followed by an increased level of intolerance. Conflicts at the level of tolerance should be maintained and led to finding optimal solutions. Sometimes these conflicts transform into apathy and then nothing happens between the parties, which demands to express opinions and arguments of both parties, organize discussions and solve conflicts. Constructive conflicts contain creative adaptation born from a realization that one must know both one's own and the other's interests and goals and is able to find a mutually acceptable outcome.

2.3. Conflicts in Primary Health Care

The National Health Service Act[2] defines health as a state of complete physical, mental and social wellbeing and not merely the absence of disease or incompetence. This definition of health has been amended and according to the Ottawa Declaration[3], "health means a positive concept emphasizing social and personal resources, as well as physical capacities". Health and providing health services constitute the core of the primary health-care and is a conceptual model that relates to the processes and the ways it is organized as an integral part of national health care system. The essence of the primary health care in the narrow sense means prevention of illnesses and promotion of health guided by the principles of access, equity, essentiality, appropriate technology, multisectoral collaboration, and community participation and empowerment (WHO, 1978). Basis of primary health care lies in the affordability, fairness, equality, and continuity of these processes within the national health system and represents the first level of contact of individuals and families.

In primary care health institutions we usually encounter interpersonal (between two people), intergroup (between two groups), intrapersonal (within the individual) and organizational conflicts. Their cause may be found in the discrepancy of two or more members of the organization, which occurs due to sharing of scarce resources, tasks and different goals, attitudes or perceptions. Conflicts between patients and health care workers belong to external conflicts, affect and carry emotional frustration, unhappiness, sufferings, and usually cause psychosomatic illnesses. Therefore, the importance of studying the problem of conflicts in primary health care is essential very complex and requires a multidisciplinary approach.

3. SURVEY

The survey presented here was initiated by the findings of the experimental survey conducted for the purpose of collecting data based on our hypotheses about conflict management. The starting point of our assumption was that there was a greater level of conflicts that have led into worsening of the relationships in primary health care. The conflicts in this area can have various causes on the personal, group, organizational and inter organizational level, but also often negative consequences for individuals, groups and whole organization. The survey provided basic guidelines for working on this subject and outlined a general form and scale of the problem in the treated area. The survey has been done in the field of primary care (PC) denoting the health care services which play a role in the local community and providing services to patients same day with appointment or walk-in bases. Consequently, the health care employees must possess a wide breadth of knowledge in many areas.

3.1. Aim of Survey

The overall aim of our survey was to provide an insight into the current state of conflict management in primary health care while its particular aim was to gain insight into the issues related to which extent and in which way the conflicts could be resolved and managed. The results of this analysis may help facilitate mutual understanding of conflict situations and predominantly contribute to the harmonisation of relationships and better communication since primary health care professionals act as a first point of consultation for all patients within the health care system.

3.2. Sources of Survey

A specific target group, a poll of 168 respondents of four institutions of primary health care has been questioned – three private primary health care centers "Vizim" and "Jedro" from Belgrade and "Hemikal" in Valjevo and Public primary health care center in Valjevo. The tested employees at public and private health care institutions systematically provide personal and population-based preventive, curative and rehabilitative care services in primary care. These professionals are divided into two groups consisting of 79 primary care physician, such as a general practitioner (35 from public and 44 from private health centers) and 89 physician assistants or nurse practitioners (42 from public and 47 from private health centers).

[3] The Ottawa Charter for Health Promotion, First International Conference on Health Promotion, Ottawa, November 1986

3.3. Questionnaire analysis

A survey in the form of a questionnaire was conducted and conclusions were drawn on respondents' answers. The questionnaire consists of questions divided into Block A and Block B. Block A comprises questions that directly relate to personal information about respondents, while block B examines their views and answers to the posed questions.
The questions are divided into several categories and investigate the socio-economic characteristics of respondents, the nature and frequency of occurrence of certain types of conflicts, the reasons and the consequences of conflicts, the ways and solving strategies of conflict situations including questions which sought to understand how conflicts affect individuals and what their views on various aspects of the conflict are. We obtained interesting results and identified several problems.
The collected data were categorized and tailored for entry into Excel spreadsheet. By using the available functions and program measures data were separated and compared. Classification was made according to two parameters: educational level (university level and vocational affiliation level) and the type of health institutions (private and public).
For the purpose of this paper we are presenting some important figures showing some of the results of the treated problems.

3.3.1. Defining conflicts

We observed significant differences between employees in the private and public sector, regardless of the educational level in provided answers relating to the essential understanding of the onset of conflicts. In the private sector respondents think that none of the definitions of the conflicts represent the essence of the conflict, while in the public sector respondents agree with the given definitions. In both types of health care institutions, the most common reason for the conflict is a conflict with superiors as a type of interpersonal conflicts, followed by confrontation with patients as shown in public institutions, and disagreement with individuals from other departments in private institutions. The conflict generated from the relationship with patients is characteristic of the public sector in which, because policy makers under the present public health system, the end user - the patient is not highly valued and properly treated. In the private health sector the relationship with the patient is highly valued, and the complex demands of patients are not recognized as a source of conflict, or considered very rare. There is a noticeable difference regarding the educational level since respondents with university education see a source of conflict in relation to the patient three times more than those with a high school diploma. Perceived principle suggests that a sense of health care as a service activity is constantly fading with the level of education.

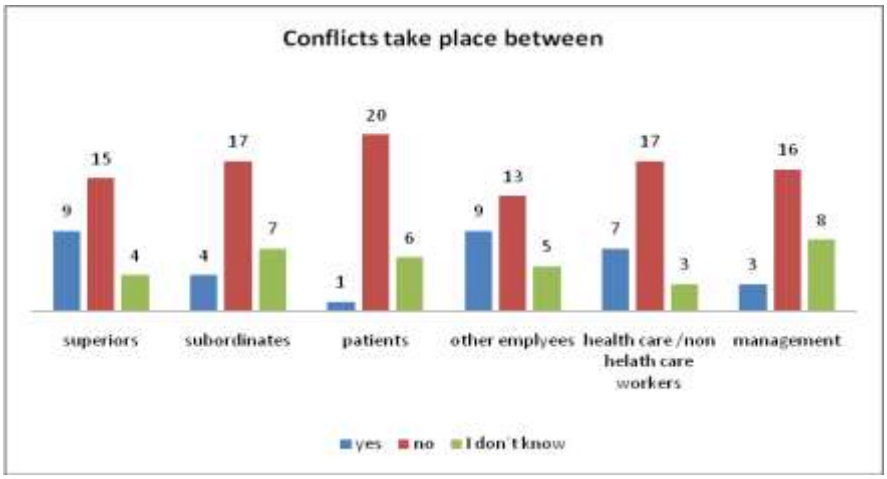

Figure 1 Defining conflict

In regard to the types of conflict that arise in primary health care, the analysis has shown that there are two groups of conflicts with the high frequency of appearance: the conflict between the individual and conflicts among groups. There is no statistical difference in the perception of values as the cause of conflict between levels management (adjusted on the table rarely/often). Also, there is no statistically significant difference in the distribution of responses among levels of education in terms of clearing the goals as conflicts. There was

no statistically significant difference in the incidence of conflicts due to cultural characteristics among respondents of different education levels.

3.3.2. Causes of conflicts

The most common cause of conflict in both private and public sector including both levels of education is the lack of information. This suggests that conflicts arise mainly due to organizational problems in both types of institutions and in insignificant number due to personal problems. Here we present two figures showing two most common causes of conflicts in primary health care: personal and organizational causes of conflict.

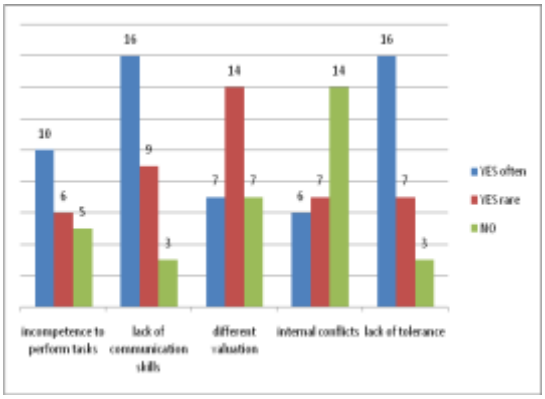

Figure 2 Personal causes of conflict

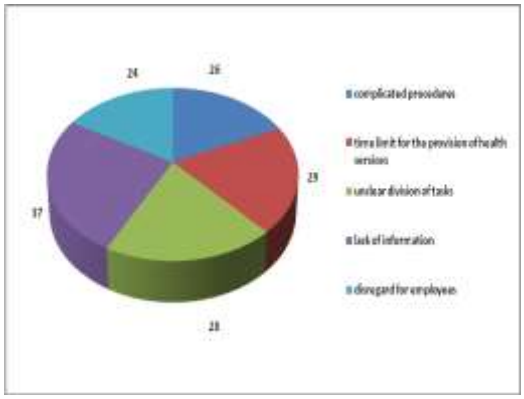

Figure 3 Organizational causes of conflict

Relating to personal causes of conflict, lack of tolerance has been chosen as the principal cause of conflicts by the largest number of respondents with high school education, connected with their view that the conflict relates to the relationship with superiors. Both groups pointed out that the lack of communication skills is the distinctive source of conflict and misunderstanding. The internal conflict in both groups is less frequently identified as a cause of conflict, but those respondents with a university degree are as double self-critical when it comes to this cause.

Significant number of respondents in the public health centers noticed that the causes of the conflict are the organizational issues and solutions offered by the management of the institution. The respondents from the public health care with high school education see the cause of the conflict in the disregard for employee and an unclear division of tasks, while respondents with university education state that the problem lies in the lack of time to provide health services. The private sector respondents with university education believe that the primary organizational causes of conflict are unclear division of tasks and a time limit for the provision of health services while the respondents with high school education have a problem with complicated procedures.

Lower wages, poorer working conditions, lack of equipment and a large flow of patients are seen mainly by employees in public institutions. In private sector, which creates a climate of better organization and concern for employees, those factors are less present.

3.3.3. Resolving and managing conflicts

The respondents in public health care express the process of resolving and managing conflicts in a different manner than employees in the private health centers. The difference is observed in the segment of the time limit for the provision of health care as stated by the public employees, especially those with a university degree, and to a much milder extent this problem is highlighted in the private sector. The introduction of a third party in conflict situations is acceptable for employees with higher education unanimously. Employees with a high school diploma are much more likely to opt for withdrawal. The position of both groups is balanced in terms of confrontation, ignorance and coercion.

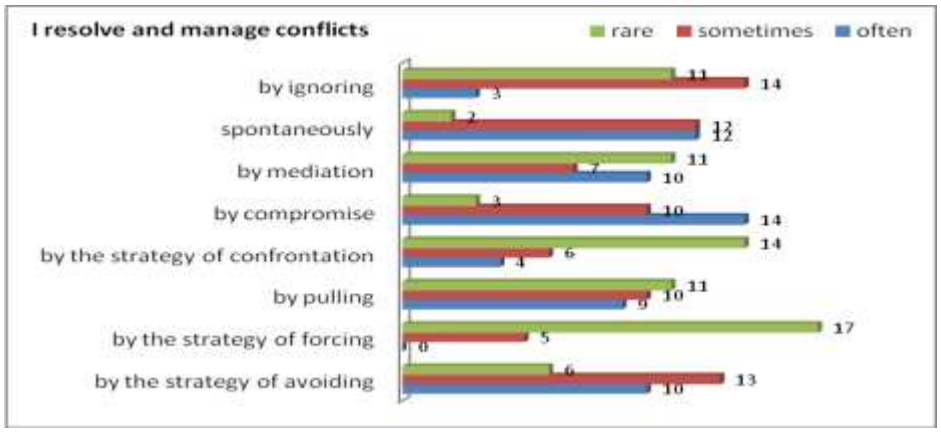

Figure 4 Conflict resolution

Compromise as the most common form of conflict resolution is represented in most of those employed in public and private health centers with a university degree. Employees with a high school degree in public health centers rather resort to ignorance and avoidance, as well as to methods of silencing conflict. The maximum deviation is noticeable in the method of mediation, which is almost totally avoided in public health centers, as opposed to private institutions, suggesting the existence of a relationship in which the focus is on the preservation of secure public position, without orientation towards resolving the conflict for the sake of development and achievement of goals. As a confirmation of this analysis, there is a deviation in terms of coercion. It is completely unacceptable in the private health centers, and appears as a method of public health centers under the auspices of tenure within the public health sector.

3.3.4. Respondents' Opinions on Conflict

Respondents were unified in their view that conflicts are not desirable in health care institutions. A significant difference is noted in the fact that respondents with high school education in a considerable number think that conflicts have negative effects and consequences on the health care institution, as opposed to the respondents with a university degree. The same difference in attitude is reflected in the fact that a number of respondents with university education considered conflicts sometimes as desirable for health institutions, while none of the respondents with a high school diploma declared in this option.

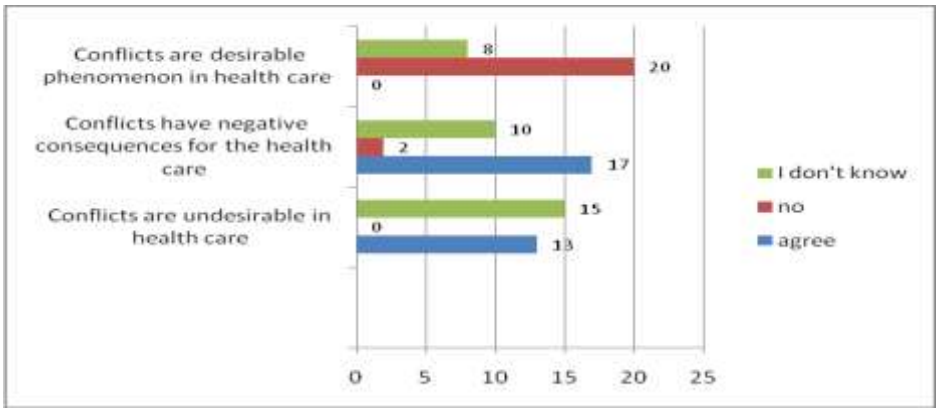

Figure 5 Respondents' Opinions on Conflict

4. CONCLUDING REMARKS AND RECOMMENDATIONS FOR FURTHER RESEARCH

Conflicts are irreversible state of personal and organizational systems and must be resolved and managed with great effort and difficulty. Identifying the nature and the event of conflict, the nature and the emergence and development of the conflict and selection of the best way of dismissal with respect to the least possible harm to people and organization are the key requirements placed before the participants in conflict.

The survey of conflict in personal and organizational levels still carry current task whose resolution can contribute to personal and organizational well-being. In order to achieve this, it is necessary to identify and categorize a clearer differentiation between the causes of the conflict, participants and their characteristics, frequency impressions, perceptions, consequences and ways to resolve and manage them. It is particularly important that employees in different levels of management are aware of all aspects in which conflicts are manifested, in order to manage them in the effective and purposeful manner, in particular in those cases where the conflicting parties are unable to accept ways to resolve them. The frequency of interpersonal and inter-group conflict requires a subtle analysis of personal and organizational values and recognition of cultural conditions of the system in which arises and develops personal, organizational and intergroup conflict.

Very often observed identical views of different management levels of the causes, consequences and indirect methods of conflict resolution indicate that employees of different levels of primary health care system are not in any way except by experience, educated for conflict management. For the realization of conflict resolution and management will be needed necessary research and systematization of their general and specific characteristics. Additional conditions that will examine updated and other issues related to various aspects of personal and organizational conflicts should be investigated. Until action or expression occurs, conflict is latent, lurking below the surface.

Looking at the developed countries as a reference case, a more team approach to health care and flexibility of resources is noticed. Since private health in Serbia begins with the application of these practices, it is clear that the change causes conflict in most cases. Negligence of employees as the cause of conflict in both groups necessarily results in conflicts. By adopting a different system of evaluation in health care institutions, employee sets new standards, both in the provision of health services, as well as in treatment of employees. Focusing on the process, not just the outcome one person desires, is key to productive conflict management. But above all, for several years now, health care experts have been issuing warnings about an impending disregard of government in expanding its role in primary health care. Health care reforms would increase government involvement in the Serbian health care system by enabling pre-employment and on-the-job training since healthcare workers need specialized skills, most of which require specific educational qualifications. Finally, by resolving financing problems in primary health care, the tensions between the opposing sides and conflict situations should be maintained at a moderate level in order that they function in harmony with one another.

HUMAN RESOURCE MANAGEMENT

HR SHARED SERVICES CENTERS AS PART OF A NEW BUSINESS MODEL OF THE ORGANIZATIONS

Mirjana Petković[1], Biljana Đorđević[2]
[1]Faculty of Economics Belgrade, mirjana.ekof@beotel.net
[2]Faculty of Economics Niš, biljana.djordjevic@eknfak.ni.ac.rs

Abstract: *In the attempt to find an optimal business model, HR function can give the specific contribution to this aim by restructuring its activities and organization. In this sense, recognizable tendencies in the design of modern HR function are the foundation of HR SSCs. It is expected that this centers, through centralization of processes, activities and resource, will provide high quality of services and expertise in the field of HRM and effective cost control. Consequently, it is expected that this centers will give contribution to greater profitability of organizations. Bearing in mind the distinctive place that HR SSCs may have in the business models of modern organizations, the aim of this paper is to draw attention to their basic characteristics, factors which conditioned their appearance, the benefits that can be generated, as well as the possible negative aspects of their foundation.*

Keywords: *business model, HR SSCs, HR function, advantages, disadvantages.*

1. INTRODUCTION

Environment in which the most organizations today operate is very dynamic and turbulent. In such environment sudden and nonlinear changes often happen thanks to the activities undertaken by the competition or thanks to the changes in the requirements of the market. If organizations are to survive and continue development in such environment they must constantly monitor events in that market and create business models which will make the best connection between the market demands, on the one side, and the organizations' intention to gain the highest possible profit, on the other side. This leads to the proposition that once established business model must change and adapt as the major variables on which it was structured changed. The basic variables in every business models are: the value for the customer, profit formula, key resources and key processes (Johansen, Christensen, and Kagermann, 2008).

Aside from the fact that changes in business models affect the way in which organizations design their transactions to create the greatest possible value (Amit, Zott, 2001), these changes almost always have an impact on the employees. Business models' changes may require the need for employees to change their behavior and to accept some new changes in their daily work routine. Besides that, in the case of radical business models' changes they may become the surplus in the organization (Robinson, Reilly, Wolfe, 2006). Business models' changing also affects the design and activities of the HR function. This happens because of the fact that HR function has always been expected to provide systems and procedures which will be adequate support for current business. Consequently, any change in the business model and/or strategy inevitably requires that the HR function has to reassess the portfolio of its activities, as well as the adequacy of its internal design.

Having in mind that modern business conditions are very complex and that organizations often need to adapt existing or to create new business models, the goal of this paper is to show the position of the HR function in business models immanent to modern business conditions, in particular the importance that could have human resources shared service centers (HR SSCs.) These centers, because of the benefits that can generate become an almost indispensable element of the interior design of the modern HR function, especially in the large organizations.

2. HRM FUNCTION PLACE IN THE NEW BUSINESS MODEL

HR function, with its services and expertise, was always expected to be support for the current business needs. Since this function in the past was usually considered as the cost center, this support was primarily provided by activities and internal design which were cost-effective. In that line, employees are often seen as a resource which should be “obtained” at the lowest possible price and their competencies used in the most efficiency manner.

Today, in modern business conditions, product price is not usually the main source of the organizations’ competitiveness. Employees as differentia specifica of organizations have become the main source of their competitiveness. Consequently, this influenced the changes in the position and the role of the HR function which has become strategically important participant in the process of overall organizational competitiveness. Nowadays, this function is expected to contribute to the competitiveness of organizations in the several ways (Mercer, 2011):

- by being more strategically oriented, and contribute creating competitive advantage through human resources,
- by supporting analytical business information and metrics to adopt confident business decisions,
- effectively perform HR services to their customers (employees and management),
- be a support line managers in the daily activities of management employees, and
- be cost effective.

To make the HR function respond to all these demands, in many modern organizations are implementing changes in its interior design. One of the most effective HR function redesign model is created by the renowned theorist in the field of human resource management*, Dave Ulrich.* His model is based on the idea that the modern HR function can cope with the challenges it faces if its activities are grouped into three sections called "three legs of the stool." “Three legs of the stool”, i.e. three groups of activities in the *Dave Ulrich`s* model are (Ulrich, 1995):

- *HR Business Partner.* Within this group of activities HR professionals are expected to communicate directly with company’s leaders and propose solutions relating to human resources strategy. These experts are not involved in the transaction activities in the field of HRM, but perform activities of consultants and planners connecting business with adequate HR programs;
- *Centers of Excellence and Expertise.* The focus of this segment of the HR function is to create HR policies and programs which primarily serve to the line managers;
- *Shared service center.* This center performs daily activities in the field of HRM, such as payroll, benefits administration and other transactional activities with a focus on achieving the highest possible efficiency.

Dealing with the question of the interior design of modern HR functions, researchers from consulting firm *Mercer* also supports the *Dave Ulrich`s* model, but suggest that in the relationship between these segments should dominate HR SSCs (Figure 1). The researchers of this consulting company based their view on the fact that if a larger segment of transactional services held in these centers, HR professionals can devote greater extent for its expertise to the strategic needs of the business when it comes to human resources. In addition, developed HR SSCs will enable bringing the effective strategic decisions concerning employees because it always requires a large amount of analytical information, reports, measurements, etc. (Mercer, 2011), which also falls within the purview of these centers.

With this shift in the design of the HR function and this function it would receive much greater strategic importance for the successful implementation of business models and the overall competitiveness of the organization.

3. HR SHARED SERVICES CENTERS

Since the HR function in the modern business environment is faced with the imperative of making contribution to successful implementation of the chosen business model, in which significant place could have HR SSCs, in the following text we will analyze their main characteristics (concept, factors which influenced their appearance, structure, functioning, advantages, disadvantages, etc.). By knowing these facts the leadership of the organization could make grounded decision as they are an optimal solution to the design of the HR function in the intention to be adequate support for current business needs.

HR SSCs are commonly ***defined*** as places which integrate people, processes and technology in order to effectively deliver HR services to internal customer (Corporate Leadership Council, 2006). Their appearance is related to the late 90's, usually as part of a broader process of restructuring the HR function in large organizations. This is confirmed by the results of some studies that have shown that these centers are integral part of the design of the HR function in two thirds of the companies that employ more than 5,000 workers, and in companies that employ between 250 and 1,000 employees this percentage is around 17% (CIPID, 2007). Geographically, the data show that HR SSCs are most common in the U.S. and the UK, but they are becoming commonplace in Australia, Canada, the Netherlands and the Scandinavian countries, too. Also, the increase of HR SCCS is recorded in the Western European countries, such as Germany, Switzerland and Belgium, but also in developing countries where these centers are formed with the arrival of large foreign companies and banks (Mercer, 2008).

Due to the growing practice of forming HR SSCs some authors see them as a new point in a continuum that reflects the evolution of the design of this function (Figure 1).

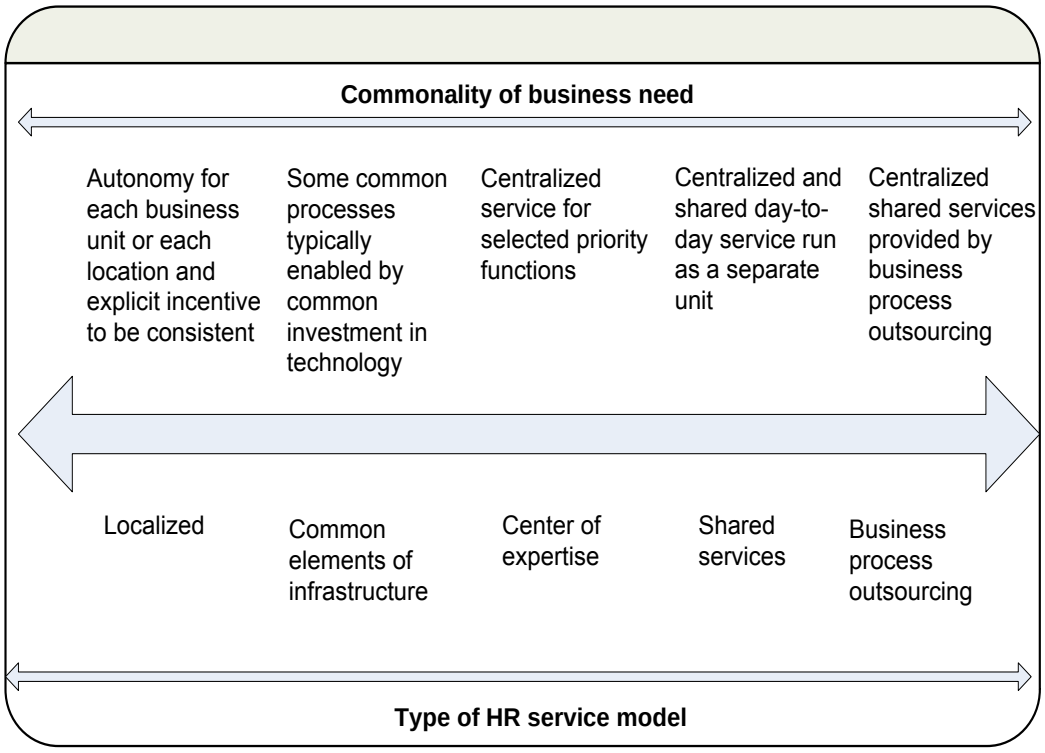

Figure 1: Continuum of HR services design

Source: Mercer, (2008). Finding your place on HR shared services continuum. Retrieved from http://www.mmc.com/knowledgecenter/Finding_your_place_on_HR_shared_services.pdf

Factors that caused the need for the HR function to make changes in direction of the formation of SSCs are, on the one hand the desire to meet the different needs of customers at the highest possible level, but on the other hand, to provide greater degree of standardization in service delivery. Proponents of this concept also believe that this is an effective way to provide greater consistency in the delivery of HR services and better

control costs. In this regard, there is an opinion that modern HR function has to be very agile and "very good at delivering differentiation when it is essential to business success, but ruthless at driving consistency when it is not essential" (Mercer, 2008, p. 2).

A factor that specially contributed to the appearance and the decision of many organizations to found them, is also a need to change the focus of this function where proportionally less time will be allocated to perform administrative activities, and more to its role as a strategic business partner. Consequently, the formation of HR SSC HR would provide professionals more space and time to deal with strategic issues which for the company have essential value. The other reasons for the formation of HR SSCs include the following (Reilly, 2000): increasing the customer satisfaction with services, the introduction of a single point of contact with customers, implementing the approach of an integrated "total solutions", providing greater cost transparency and consistency of information, achieving economies of scale for investment in technical and communication infrastructure and so on. Key reasons for the establishment of HR SSC in some companies are presented in Table 1.

Table 1: Primary drivers for creating shared services

Company	Key drivers
Bayer Group	• Increase quality • Improve speed of delivery • Reduce costs
Philips International	• Simplify HR service delivery for managers, employees, and HR business partners by standardizing processes • Leverage advanced technology to create "one-stop-shop" through HR portal • Enable strategic support to business through HR business partners • Increase cost agility
Siemens	• Increase consistency in support of "One Siemens" culture • Reduce costs and improve efficiency • Improve global metrics • Allow HT business partners to provide strategic support to business

Source: adapted according to Aon Hewitt's study (2011). Trends in Global HR Shared Services. Retrieved from http://www.aon.com/attachments/thought-leadership/Trends_Global_HR_Shared_Services.pdf

Positioning HR SSC in organizations can have different solutions depending on the assessment of the leadership of the manner in which these centers can contribute to the highest possible quality of service and efficient control of operating costs. Practice shows that in this respect are possible following ways (Corporate Leadership Council, 2006):

- *HR SSCs are located within a larger shared services function.* This solution is often in larger organizations. In this case of SSCs are usually grouped into shared services function with finance, information technology, security, etc.
- *Free-Standing HR Shared Services.* This solution means that organization create a shared services function focused solely on HR-related transaction.
- *Outsourcing HR Shared Services.* To provide better control of costs and to create a single point of contact for HR services, some organizations decide to outsource lower-level HR services. In this case HR personnel may focus on more complex HR issues, such as formulating HR

strategy, solve complex cases and manage vendor relationship. The vendor relationships usually assumes that group of HR personal contact the super vendor which then directs employees to the appropriate vendor with oversight of the relevant topic area, such as pension management or life insurance.[1]

Functioning of HR of SSCs in practice is usually multilayered, and usually consists of four levels. The first level is called *self-service* and implies that employees by using technology alone come up with the necessary information or the same change (e.g. personal data). Ideally, 60-70 % of such inquiries or requests should be realized in this way. The second level is called administrative service and assumes that representatives from SSCs take calls from the employees and by using online knowledge bases and by direct accessing to information about employees responds to their queries. The share of these requires is typically between 25 % and 30 %. The third level is called *subject expert* and means that experts in the particular field of expertise respond to users` questions or requests. These activities typically make up 10-15 % of all service requests. Finally, the fourth level is called *policy expert* and assumes that experts respond to users about highly specialized issues, for example in the field of labor law and the like. It is usual that such requests make up 5 -10 % of all service requests (Corporate Leadership Council, 2006).

Since HR SSCs already have enough long tradition, especially in the U.S., to some extent the practice of measuring their effectiveness is stabilized. The effectiveness of these centers is usually measured in three segments: financial aspect of their introduction, procedures and customer satisfaction services. Table 2 shows the most common indicators that are determining in order to monitor and evaluate the effectiveness of these centers.

Table 2: HR shared services metrics by category

Financial	Procedural	Customer feedback-based
• Cost broken down by offerings and utilization of offerings • Cost per full-time employees • Shared services cost growth relative to corporate revenue growth and/or corporate expenditures	• Number of unsolved customers' requests • Metrics for specific tasks (e.g., time to fill recruiting duties) • Six sigma • Users' time on hold • Utilization rates by phone, e-mail, fax, or Web	• Periodic surveys of internal customer population • Reviews of past calls for customer service quality • Surveys targeting specific user groups

4. ADVANTAGES AND DISADVANTAGES OF SSCs IN THE HR FUNCTION

The implementation of the concept of SSCs in the design of HR function has numerous advantages but also the potential risks. The benefits expected from the establishment of HR SSCs can be systematized into three groups (Schwarz, 2007):

- *Cost advantages.* Numerous studies have shown that the implementation of the concept of SSCs in the design HR function can reduce costs by an average of 25 % to 40 %. One part of costs saving resulting from the reengineering process and the effects of economies of scale, while a portion of the

[1] As a specific example of outsourcing HR services can be mentioned an example of Adecco Group, precisely the branch of the group which is located in Belgium and employs 700 workers. This branch for the Belgian labor market performs a number of HR services such as recruitment, selection, temporary employment, etc. At the same time the services that are provided by Adecco Belgium are specialized for various industry sectors. The companies that are their major clients are XPE Engineering & ICT Finance & Accounting XPE, XPE Pharma & Science, Glotel, Modis, 3W and Lee Hecht Harrison. Adecco has over 120 offices in Belgium, where some are located at the clients' places. The head office and shared service center for HR, Finance and ICT is located in Brussels (http://www.citrix.com/customers/adecco_belgium_en.print.html). This suggests that SSCs in the HR group activities today are not only seen as a concentration of activities within large global companies, but are also formed as a joint services for several companies. In this case they are usually located where the best conditions for performing are.

savings resulting from the savings in labor costs due to the elimination of those HR activities that would be otherwise duplicated, and from introduction of modern technology. In addition, many MNCs decide to form their SSCs in countries where labor is cheaper which also leads to savings in labor costs. Consequently, we can identify trends in these centers as moving from highly cost urban areas to rural areas with low labor costs. In this regard, practice shows that companies in the EU are increasingly opting to aggregate common services in countries with lower labor costs, such as Eastern Europe (Aon Hewitt, 2011).

- *Service advantages*. Standardization of activities as well as the effective delivery of HR services ultimately contribute to the quality of services improvement by standardizing on a certain level. In addition, improvement in human resource management and improvement in communication between the HR function and other business units enables better and faster transfer of knowledge and the improvement of overall organizational performances.
- *Strategic advantages*. Establishment of HR SSCs allows the HR function to focus on strategic issues. By improving its structural flexibility and release from routine tasks this function can focus on strategic corporate objectives. Therefore, this function can become a true strategic partner in achieving company goals.

On the other hand, the establishment of HR SSCs, as we have pointed out, is not without challenges. Some studies have shown that the formation of HR SSCs caused dissatisfaction of line managers because of the increased workload within HR administration. On the other hand, there were also complaints from HR professionals who claimed that these centers have limited their opportunities for career development. Other deficiencies of formation of HR SSCs ranged from reduced quality of HR services, to the fact that the formation of these centers was very expensive investment. Briefly, the potential risks of introducing HR SSCs can be systematized into the following three groups (Schwarz, 2007):

- *Financial risk.* Financial risk stems from the fact that the project of forming HR SSCs can be more expensive than it was originally planned. The increase in costs may be due to the fact that their establishment may take longer period of time due to different resistances or organizational weaknesses. Also, the establishment of HR SSCs usually requires significant investment in IT.
- *Process risk.* This type of risk is related to the potential risk of reducing flexibility in meeting the needs of service users because one of the principles underlying the operation of these centers is that wherever is possible procedural differences for internal users should be eliminated. Consequently, the formation of HR SSCs “by default “significantly reduce flexibility. Specific needs should be satisfied only when the HR SSCs are prepared for that and when it is justifiably[2]. In the case of such HR SSCs is provided high level of operational excellence, and high level of personalized solutions.
- *Employee risk.* Employee risk is associated with the fact that the employees could form resistance to changes that are planned to be implemented. It is a well-known fact that when organizations implement changes, the employees may demonstrate less or more resistance to them since every change means abandoning the previous well known pattern of behavior. This type of risk can even strengthen financial and procedural risk.

5. EXAMPLES FROM PRACTICE

The next few examples illustrate the process of formation, as well as the benefits generated by establishing HR SSCs that could serve as examples of good practice if the companies think about redesigning the HR function in this direction. However, this does not mean that establishing HR SSCs in each company you will automatically result in positive effects. The following examples show the starting circumstances from which listed companies launched in the formation of these centers and what practical solutions resulted from these

[2] In order that HR SSCs cope with the new challenges it is suggested that within them should be formed a suitable base of knowledge that will be combined with the best practices in this area, as well as the technique of case management. More in Hird, M., Marsh, C., Sparrow, P. (2009), "HR Delivery Systems: Re-engineered or Over Engineered?" CPHR White Paper 09/05.

circumstances. As every company has specific characteristics, these examples should be used only for critical analysis and identification of specific causal relationships.

Bayer Group. Bayer Group is a global company that is recognized worldwide in the areas of health care, nutrition and high-tech materials. It employs over a hundred thousand people in more than 300 subsidiaries worldwide. In this company HR SSCs were introduced with the objective to increase the quality of the HR services, the speed in their realization, and to reduce operating costs. Over time the company has achieved all these goals, but the focus remained on the quality of HR services.

Bayer HR SSCs operate on several levels: global, regional and country level. Global HR SSC is located in Germany, the regional center for Europe also in Germany, and there is the regional center for North America located in Pittsburgh. This company established several HR SSCs at the level of the state too, such as centers in Argentina, Mexico, Brazil and Japan.
Since the precondition for successful functioning of HR SSCs is the standardization of HR programs and activities, this company during the formation of these centers considerable attention dedicated to ensure standardization and consistency of the process. Besides that, this company tied to offer the best possible services in a given area (best-in-class solution). The process of standardization of HR services and processes in Bayer began in 2005. First, all HR processes and activities were identified, and then grouped into 28 different clusters. Through this analysis, Bayer has identified three types of processes:

- *Global processes.* These are processes that are implemented in the same manner at each location. This company has identified six global processes, including performance management, short-term incentives and merit increases.
- *Global-at-core processes.* These processes are with a consistent foundation, but some variations at the local level; these include recruitment and training.
- *C processes.* These are processes that are significantly different across countries and include payroll.

Bayer aggregated the administrative aspects of these cluster in its SSCs. In this way, all six global processes are administered in a consistent manner for all employees within this global company. Other processes that require local adaptation are administered through regional HR SSCs or centers that are located in different countries. In order to monitor the effectiveness of these centers Bayer established practice of monthly reports on the performances that are achieved (Aon Hewitt, 2011).

Phillips International. Phillips International is world known company in the field of health care, lifestyle and lighting. It employs over 100 000 employees in more than 60 countries. A key reason for the formation of HR SSCs was a simplification of HR services. This effort was part of a broader mission of Phillips which stresses operational excellence and consistency across all businesses. In order to simplify HR services, Phillips formed global SSC with the single point of contact for all leaders, managers and employees. In this way, experts within the field of human resources (HR Business Partner) are freed up to provide more time to deal with strategic aspects of employment and to be support to managers. With these changes, Phillips recorded increased productivity and reduced costs, although these were not the primary objective of HR function restructuring.

The process of simplification of HR activities in Philips successful illustrates the fact that when it comes to recruitment they removed e 15 "touch points" from HR business partners and eight form managers. In this way, HR professionals are freed up from administrative duties and a recruitment process was significantly simplified. A similar situation was with the other activities in the field of HRM (Aon Hewitt's study, 2011).

Nestle. Nestle is an example of a company that literally applies the Dave Ulrich's model since in this the company HR function is composed of three segments: business partners, centers of expertise and HR SSCs. Such organization of the HRM function is implemented in its three global zones in which this company operates: Africa, Oceania and Asia (AOA), American zones - North and South America and the European zone - Central and Eastern Europe. In addition, within 84 countries where the company operates, a three-part model also has been implemented. In other words, within a global three-part model of HR functions operate three-part model of the functions in each country where the company has operations.

The basic principles which the HR function in this company implements in its functioning are as follows (Hird, Marsh, Sparrow, 2009):

- Provide consistency and ease of HR activities when you cannot achieve a competitive advantage through diversities and complexities,
- Provide as much information at the lowest level in the company,
- Local HR strategy should be aligned with corporate strategy,
- HR SSC and HR centers of expertise are centralized and provide service to all segments of business unless it is important that certain practices are localized.

Although presented examples are those in which the formation of HR SSCs generated positive effects, the implementation the SSCs concept in the design of the HR function was not without problems. This is illustrated with the slogan of Bayer's HR transformation group: "Let's make it happen." Repeating this slogan enabled them to successfully face many problems that arose in the implementation of this project in order to realize it fully.

6. CONCLUSION

HR SSCs should be considered as part of the evolution of the HR function design that best integrate the advantages of modern technology and standardization, with the idea that the needs of the employees and management should be satisfied in the best way. At the same time, this enable freeing up HR professionals enough time and energy to devote to strategic needs organization in terms of human resources.

Previously examples in the paper points out that HR SSCs can have a significant role in the business model of modern organization especially as their focus of HR SSCs is to create the greatest possible value for the users of their services at affordable costs. Positive impact on overall organizational performance such designed HR function can generate due to the fact that only high-quality, professional, motivated and satisfied workforce can be a generator of business success. All this issues are depending greatly on the quality of the services that provide HR SSCs. Howevere, in this paper is also stressed the fact that there are some potential risks of introducing these centers, such as financial risk, process risk and employee risk. Knowledge of the potential risks of establishing HR SSCs should enable the organization's leadership not to implement them without previously critical access as well as to prepare appropriate organizational responses to them in advance.

In this regard, the example of Bayer tells us that implementation of the SSCs concept in the design of the HR function requires patience and progressively overcoming obstacles. Also, this example shows that it is very important that once established HR SSCs should be the subject of ongoing analysis of the effects that are generated so that corrective measures can be taken. Therefore, some authors point out that the concept of shared services is still evolving, and that is going on specific "shared services journey" (Schwarz, 2007). This means that concept of HR SSCs have potential to generate many positive effects, but there are also some weaknesses that should be overcome. The main downsides that should be taken in account are huge investment in technology, reduced flexibility for individual and business units need, perception that HR function has been depersonalized, resistance to changes, etc.

E-SKILLS FOR PUBLIC SECTOR EMPLOYEES

IN THE PROCESS OF E-GOVERNMENT DEVELOPMENT

Mimoza Bogdanoska Jovanovska[1], Tatjana Ratković[2]

[2]Faculty of Organizational Sciences, University of Belgrade, Serbia, ivanovic.tatjana@fon.bg.ac.rs

Abstract: *Public sector effectiveness depends largely on the skills of employees in public administration who face specific challenges due to the nature of their work. Modernization of public sector initiated by introduction of information and communication technologies (ICTs) has led to new demands regarding skills required for public sector employees emphasising the need for achieving digital literacy among them. This paper seeks to address a broad range of challenges faced by developing countries at the beginning of the process of e-government implementation, primarily referring to low level of ICT literacy and e-skills of public administration employees. The aim of the paper is to discover the variables with the highest influence on the process of e-government development in these counties, especially focusing on identifying the appropriate mix of specific skills (with particular emphasis on e-skills) required by public sector professionals (especially non-IT workers) involved in the process of e-government development and implementation. Conclusion of the paper is that a user-centric approach for acquiring e-skills in the public sector should be used in the process of e-government development and recommendations of various channels that may be used for acquiring of these skills are offered. This paper may present value to relevant bodies and institutions in developing countries intending to develop and implement the concept of e-government. The findings can also serve as guidelines for development of a possible curriculum for training and education of public administration employees in these countries.*

Keywords*: e-government, e-skills, human resources, public sector, public administration employees, leadership skills*

1. INTRODUCTION

Rapid transformation of society from industrial to informational, from bureaucratic to citizen-cantered, from service economy to knowledge-based one has influenced the development of human resources skills, making them much more pervasive and encompassing than ever before. The main initiator of these changes has been the introduction of information and communication technologies (ICTs).

Information age, associated with the digital revolution, has emphasized the need for digital literacy, or widespread use of basic IT skills (so-called electronic or e-skills) especially within the public sector. It has highlighted the critical role of e-skills for creation of effective and proactive policies aimed at sustaining investments in ICTs and protection of e-skills from becoming a bottleneck.

E-skills are becoming increasingly important in a knowledge-centric concept such as e-government. The main task of the public sector is to provide a substantial supply of high-quality services for the community in order to achieve efficiency and effectiveness in its performance (which is related to the purpose of citizen-cantered orientation). E-government refers to the achievement of this objective within the field of public administration through the use of ICTs (UN 2003).

2. THE CONCEPT OF E-GOVERNMENT

A commonly used narrow definition of e-government refers to service delivery on the Internet (West 2001). However, during the time definitions extended the scope of e-government from “the use of ICTs” towards “reforms in public administration”, stating that e-government “is not just automation of existing processes…but creation of new processes and new relationships” (InfoDev and CDT 2002, p. 5) between administrative institutions and bodies. So, e-government “has become an indispensable tool in reforming state administration and the work of local government, it is increasing the satisfaction of citizens regarding services, and creating a more flexible, transparent, public administration” (Molnár, 2006, p. 5).

E-government users include citizens, businesses, governments and public administration employees. According to World Bank (2005) e-government may build one of three possible relationships with its users: government-to-citizen (G2C), government-to-business (G2B) or and government-to-government (G2G). The

fourth and final relationship is the one between the government and its employees (government-to-employees or G2E), where the government is expected to provide e-learning and facilitate knowledge sharing among its employees using Intranet.

Regarding the implementation of ICT concept in government OECD (2003) and UN (2005) point out that successful e-government requires two main categories of human resources: well-balanced human resources in the public sector comprised of professional engineers in charge of system development, management and maintenance on one hand, and users (clients and public sector employees) equipped with IT knowledge on the other hand. Similarly, López-Bassols (2002, p. 3) notes that ICTs "offer the promise of new business and employment opportunities along with higher productivity gains, but also make new demands on skills…and adequate training programmes for various categories of workers''.

3. HUMAN RESOURCES AND THEIR SKILLS AS ONE OF THE MOST IMPORTANT FACTORS FOR E-GOVERNMENT DEVELOPMENT

Many studies attempted to identify the most important factors for development of successful e-government which lead to achievement of higher efficiency, effectiveness, transparency and accountability of government day-to-day administration. Numerous variables have been found to have impact on the implementation of e-government in developing countries, such as: changes in work processes, technical/human resources, organizational culture/values, vision/strategy/internal leadership, external/financial support, and laws/regulations/policies, with "technical/human resources" being one of the most important factors (Shin et al., 2008).

Human resources represent a set of individuals who make up the workforce of an organization, a company or an institution in any sector: private, public, NGO, etc. Human resources possess different skills, abilities, knowledge and qualifications needed for performing particular jobs. A skill may be defined as: (1) a learned ability to use one's knowledge, practice, and aptitude; (2) an ability to perform a task with pre-determined results within a provided amount of time and/or energy; (3) a special competence in performance. According to Skills Investment Strategy (2003) there are two types of skills- essential and occupational. Essential skills are enabling skills that help people perform the tasks required by their occupation as well as other activities of their everyday life. These skills provide a foundation for acquiring other skills and enhance individual's ability to adapt to changes in the workplace. Essential skills include reading, writing, analytical skills, verbal communication skills, computer skills and thinking skills, among others. Occupational skills refer to job-specific technical skills that are required in order to perform specific tasks for a particular job.

Skills may be acquired through a variety of channels (OECD, 2001; López-Bassols, 2002)- through natural abilities, formal education, work experience, training (on-the-job or external) and other (e.g. self-training, non-formal training). On-the-job learning is often considered as one of the most effective ways for gaining necessary knowledge and acquiring tacit skills (Barrett, 2001; Lucking, 2003; Ma, 2004; Tessema et al., 2007). Methods of skills development or training programs in organizations can be either formal or informal. The latter is done through on-the-job training and is less expensive, whereas the former is more structured and takes place in a classroom or e-learning setting and is more expensive. For example, an informal method can be used for acquiring basic IT skills, both in public and private sector. Experts suggest that formal training methods can be used for acquisition of Internet skills and technical e-skills either in classroom setting, e-learning, or by outsourcing to local and international institutes. Additionally, public sector may facilitate the process of acquiring IT skills through enhancing access of their employees to ICTs by providing low-cost PC programs (including the Internet).

3.1. SKILLS OF PUBLIC ADMINISTRATION EMPLOYEES

Well-balanced human resources in the public sector and provision of a variety of training programs aimed at developing users' knowledge and capacities are often considered as necessary prerequisite for maximizing the benefits of e-government (OECD, 2003; UN, 2005). Public sector effectiveness depends largely on the skills of employees in public administration who face specific challenges due to the nature of their work. However, it is not easy to fill the skills gaps in order to increase the ability to deliver excellent service to the community. Since skills cannot be easily measured, different proxies may be used for capturing observable employee characteristics, such as education (on the supply side) and occupations (on the demand side). These issues become even more challenging when ICTs are being introduced in work processes in public administration. Having this in mind it is necessary to identify the skills required for public sector employees in order to enable successful development and implementation of e-government.

In the past public administration employees were mainly required to possess only hard skills in order to be considered for a particular job-the emphasis was on technical competencies and functional expertise as

crucial determinants for successful performance. However, during the time the importance of soft skills has increased. Soft skills refer to the ability of an individual to communicate and interact with other employees in a positive manner. These skills are usually seen as a combination of communication and interpersonal skills, emotional intelligence, leadership qualities, negotiation skills and team skills (Deepa and Seth, 2013) as well as social skills - skills needed for working (collaborating) with people in order to achieve mutual goals (e.g. social perceptiveness, coordination and negotiation skills, persuasion and instruction skills, and team working skills) (Ben-ner and Urtasun, 2013).

Nalbandian and Nalbandian (2003) summarize skills necessary for public sector professionals as follows: administrative skills, political and policy skills, skills related to public service values education, and emotional and personal attributes. Administrative skills usually refer to achievement of collaboration and cooperation among departments, creation of opportunities for adoption of best practice as well as orientation of other employees toward accomplishment of organizational goals. Public sector employees need to possess political skills (Ferriset al., 2005; Ferris et al., 2007) which include networking ability, social astuteness, interpersonal influence and apparent sincerity (Ferris et al., 2005); they are expected to work on creating a climate which promotes and emphasizes issues related to loyalty, trust and commitment. They are also required to be committed to expressing public sector values, to educate others on those values, and to encourage the development of organizational values consistent with the values of the community (Nalbandian and Nalbandian, 2003). Another valuable skill for public sector employees refers to emotional intelligence- an understanding of feelings and emotions on one hand, and rational intelligence or reasoning on the other (Vigoda-Gadot and Meisler, 2010).These skills may lead to better performance in delivering service to customers, as well as higher work outcomes of public sector organizations (Rubin et al., 2005; Coté and Miners, 2006; Elfenbein et al., 2007; Vigoda-Gadot and Meisler, 2010). Special attention has to be paid to the significance of leadership skills for effectiveness of public service employees -public sector needs to identify and train employees in leadership skills in order to ensure responsibility. These skills mainly refer to the ability to communicate, motivate, coach, reward, involve and support others, as well as the ability to promote teamwork and collaboration among employees (Basheer and Sulphey, 2012).

Modernization of the public sector and introduction of new technologies has led to new demands regarding skills required for public sector employees. ICTs are affecting skills required and the nature and organization of work even for non-IT workers. Technological changes in the form of computer-based technologies entail an increase in skill content of jobs performed by skilled employees (Machin, 2001). By its nature IT work requires individuals to master codified and tacit knowledge as well as technical and abstract concepts, which are acquired through various formal (e.g. education) and non-formal channels (e.g. work experience).

3.2. E-SKILLS IN PUBLIC ADMINISTRATION

New information society and new concept of e-government require public administration employees to possess (beside essential and occupational skills) also cross-disciplinary, cognitive and problem-solving skills, understanding of the fundamentals of business and communication skills (including competence in foreign languages) as well as ICT-related skills (i.e. e-skills). Specific e-skills are needed for successful development of e-government which entails innovation of on-line services.

ICT skills (or computer technology skills) can be defined as:(a) the ability to learn, communicate effectively, collaborate, and solve problems regarding computer-technology-related tasks and projects; (b) the ability to use technology to support individual's work with people/things/data/information (e.g. use of technology in an engineering lab, design studio or research program; use of technology for development of print and on-line materials; or use of technology for organizing and presenting information or for creating and maintaining databases); and/or (c) the ability to support others in the use of technology (e.g. setting up computer work stations for people, teaching computer skills, troubleshooting technology-related issues, and maintaining and repairing computers and related equipment).

E-skills usually refer to a broad set of skills necessary in the modern workplace. Commission of the European Communities (2007) extended this definition stating that e-skills represent a set of skills, knowledge, and concepts that are needed for effective consumption in terms of access, locating, operating, managing, understanding, and evaluating e-services provided in different stages of e-government. There are five levels of e-skills necessary for public sector employees - non-IT workers (i.e. workers without formal ICT education, such as minimum bachelor degree in informatics as a background for occupational skills) (López-Bassols, 2002; European e-Skills Forum, 2004; OECD, 2005):

1. *Basic level of e-skills* which is close to ICT user skills. These skills generally refer to "digital literacy" and include skills required for confident and critical use of ICTs for work purposes, leisure, learning and

communication. Employees who possess these e-skills can use generic tools (such as Word, Excel, Outlook and PowerPoint) and have the ability to use ICTs for basic tasks and as a tool for working.

2. *Middle ("advanced") level of e-skills*. Employees who possess these e-skills are practitioners because these skills enable them to use advanced and sector-specific software tools. They have the ability to apply simple IT tools in general workplace settings and also have capabilities required for researching, developing, designing, strategic planning, managing, producing, consulting, marketing, selling, integrating, installing, administering, maintaining, supporting and servicing ICT systems.

3. *ICT specialist*. Employees with these e-skills possess professional skills in ICTs - they have the ability to use advanced IT tools to develop, operate, repair, maintain and create ICT systems.

4. *E-leadership skills*. Employees with these e-skills have the capabilities needed for exploiting opportunities provided by ICTs (notably the Internet). They are expected to ensure more efficient and effective performance of different types of organizations as well as to explore the possibilities for new ways of conducting administrative and organizational processes. They have T-shaped portfolio of skills, representing expertise both in using ICT and developing organizations, which means that a leader is expected to possess the following skills:

- Expertise or "deep knowledge" in a specific area (e.g. engineering) - a vertical set of skills;
- "Transversal skills" that enable collaboration across a variety of boundaries (e.g. negotiation skills; critical thinking; design and systems thinking, business and entrepreneurship etc.) - a horizontal set of skills;

Both vertical and horizontal sets of skills require a basic level of ICT user skills, as defined by the European e-Skills Forum (2004).

5. *ICT professionalism skills* represent the highest level of e-skills. Employees with these e-skills possess a comprehensive and up-to-date knowledge, accommodating a common ICT body of knowledge, as well as pertinent specialist knowledge and skills. They are able to demonstrate an on-going commitment to professional development via an appropriate combination of qualifications, certifications, work experience and non-formal/informal learning, as well as to deliver high-quality products and services and adhere to applicable regulatory practices and/or a code of ethics/conduct.

4. ACQUIRING E-SKILLS IN DEVELOPING COUNTRIES

Human resources in the public sector represent one of the fields which need a lot of investments within the process of e-government implementation. Developing countries are still at the nascent stage of e-government development. Even though they require sophisticated and up-to-date e-skills in the public sector, these countries are usually characterized by a low level of digital literacy. One of the reasons for this is inappropriate formal education system in these countries which is not adapted to existing needs for e-government development and does not provide programs aimed at acquiring of e-skills for non-IT workers in public administration. As a result, most employees in the public sector in developing countries with a lot of work experience possess high level of essential and occupational skills but lack e-skills. Beside this category of public sector employees, there is another category which consists of employees who possess basic e-skills (beside essential and occupation skills). These employees usually build up their e-skills through self-training or non-formal learning. Even though they are in better position comparing to the employees without e-skills, they still belong to the first ("basic") level of e-skills. Most of employees in the public sector belong to this category. These is only a small number of public sector employees in developing countries who possess "advanced" level of e-skills; they usually do not have formal education in ICT field but have acquired these skills through self-training, previous work experience and on-the-job training. Even less employees may be found at "ICT specialist" level; this level of e-skills is reserved for employees who acquired their professional skills in ICTs through the process of formal education and later upgraded through work experience and training programs (both on-the-job training as well as external trainings). The forth and the fifth level of e-skills is rarely found in the public administration of developing countries. It is a complex one and not so easily achieved especially at the beginning of e-government implementation process.

Training programs aimed at acquiring of e-skills in the public sector in developing countries should not be defined universally for all public sector employees; they must be well defined and goal-directed in order to satisfy the needs of each particular job position. Khan et al. (2010) propose e-skills acquisition methods for public sector employees: formal training methods (e.g. on-the-job training); informal training methods; PC and Internet access in the offices; public private partnership (PPP - joint training programs by government and private sector which are supposed to enhance e-learning through a government extranet where public and private sector employees can share knowledge and experience); e-learning (short term and long term programs); outsourcing e-skills training and development or inviting foreign experts to provide trainings in e-

skills; defining minimum requirements regarding IT skills for each position (for instance, ECDL - European Computer Driving License and/or MOUS - Microsoft Office User Specialist certificate); ICT training through media (radio, television, newspapers); periodic internships in IT departments/organizations; providing ICT training in collaboration with universities or institutes; socialization and capacity building through FAQ, providing manual book/guidance, and through help desk centre; stimulating and motivating employees for acquiring IT skills; make IT skill acquisition as one of the requirements of promotion in the public service; encourage life-long learning programs in the public service etc.

So, there is a necessity for long-term strategy related to e-skills development at the national level in developing countries. A common objective of ICT policies in developing countries refers to providing a minimum level of ICT knowledge for individuals and organizations, offering help to understand information technology and its cross-disciplinary effects, as well as providing a possibility of access to citizens and offering trainings in ICTs. There is also a need for deep scanning of current situation and existing skills in public administration as well as determining which e-skills are required for each position related to e-government and on-line service delivery. Special attention has to be paid to positions which require e-leadership skills. The results of this analysis should be used as a foundation for creation of long-term strategy for building up e-skills in the public sector. From a long-term perspective, there is also a need for some of the e-skills to be embedded in the formal higher education process in developing countries, in order to enable future generation of public sector employees to enter the public administration/government with basic or even advanced level of e-skills developed.

5. CONCLUSION

Continuous and fast development of ICTs on one hand, and changes in e-skills requirements on the other hand, have provided a complex target for policy makers whose job is to create educational and professional training systems at the national level, facing the challenge of delivering the skills needed for e-government. Despite their efforts, they still find it difficult to cope with the existing situation, and lifelong learning is still far from being a reality (Commission of the European Communities, 2007).

E-government facilitates the process of transition from a consolidated model of centralized, hierarchical, bureaucratic and operating government, in which “silo” functioning is dominant, to a new model of “horizontally integrated systems…which facilitate customer orientation’’ and move towards “e-government solutions that are sustainable” (UN, 2012, p. 63). Introduction of computer-based technologies has led to changes in skills of human resources (Ben-ner and Urtasun, 2013). There are strong reasons to believe that basic IT skills are becoming a new category of “general” competencies, such as analytical or literacy skills. IT skills do not only increase earning potential of IT workers, but they are also becoming necessary for a broad range of activities in the public sector.

However, at the very beginning of introduction of ICTs in the public sector, public administration employees are expected to show readiness and willingness (as well as basic digital literacy) to understand and participate in implementation of new technologies necessary for innovation and advancement of services provided by this sector. The next phase (implementation of e-government concept) requires even more specific, additional skills (e-skills) from public administration employees, especially non-IT workers, in order to be able to engage in a wide variety of uses within e-government. Different forms of formal and non-formal channels of education may be used for solving this problem - a user-centric approach for acquiring e-skills in the public sector should be used in the process. E-skills framework system should be used as a diagnostic tool to assist employers in public administration in determining more precisely and systematically the skills content of current jobs and new skills requirements. IT skills and competencies must be considered as one of the requirements for recruitment of new staff or promotion of existing staff in civil and public service. Developing countries need to create strategies and policy frameworks aimed at strengthening educational systems and facilitating workforce up e-skills in order to set up efficient and effective e-government. Finally, IT skills should become integrated into the concept of lifelong learning of public sector employees as one of necessary conditions to maximize the benefits of e-government, which is expected to facilitate the rapid diffusion of basic IT skills in developing countries.

[3] University of Belgrade, Faculty of Organizational Sciences, andjelkovic.jelena@fon.bg.ac.rs

Abstract: *Having in mind that human resources are considered the most valuable resource for a company, monitoring and assessing performance of individual employees represents a task of great interest for every organization. However, these issues become much more complex in international environment. International performance management represents one of crucial functions of international human resource management (IHRM). The aim of this paper is to provide a more comprehensive perspective of the process of performance appraisal (as a central part of performance management) of employees in multinational companies (MNCs) - expatriates and host-country nationals. The paper seeks to address the issues related to the way of conducting this process in international settings; it explores and analyses common problems and challenges faced by multinational companies regarding this IHRM process in order to identify certain elements for improvement of international performance appraisal. Conclusion of the paper includes recommendations for best practice of performance appraisal in international context, mostly focusing on: formulation of well understood, valid and reliable goals and performance criteria, providing training for the raters, providing regular feedback, use of multi-rater system, etc. This paper may present value to multinational companies which need to manage various categories of employees intending to improve performance appraisal of their international employees in their foreign subsidiaries. Having in mind that there is limited research (both theortical and empirical) regarding performance appraisal in MNCs, this paper is expected to partially fill the existing gaps in the literature.*

Keywords*: performance management, performance appraisal, multinational company, human resource management, expatriate, host-country national*

1. INTRODUCTION

Globalization has created many challenges for Human Resource Management (HRM). Today organizations are paying much more attention to employee performance than ever before. International performance management represents one of crucial functions of international human resource management, attracting considerable interest of both academics and practitioners. Effective performance management is necessary to ensure that employees perform their jobs effectively in all units of a multinational company disseminated throughout the world. However, unlike other aspects of international HRM (such as staffing, training or compensation), there is limited research regarding performance management in international context (Shen 2004). The literature in this field is based more on empirical research than on theoretical concepts (Claus and Briscoe 2009). Most studies refer to domestic operations, while the results usually may not be applied in MNCs. Lack of research conducted in international performance management suggests that issues regarding this HRM function that have been identified in domestic context will be exaggerated in international context (Harvey, Novicevic and Speier 2002).

2. INTERNATIONAL PERFORMANCE MANAGEMENT

The term performance management appeared during the late 1980s (Lindholm 1999). It refers to identification, measuring, managing, and developing performance of human resources in an organization. It evaluates the achievement of pre-determined goals and targets. Dowling et al. (1999) define international performance management as strategic HRM process which enables a MNC to assess and continuously improve performance of individual employees, performance of foreign subsidiaries, as well as performance of the whole company according to clearly predefined goals directly related to MNC international strategy. Although this aspect of performance management is not often emphasised, it also represents a part of control system of a MNC, which, among other control mechanisms, enables a MNC to achieve coordination and consistency of desired behaviour and outcomes expected both in MNC headquarters and its foreign subsidiaries (Dowling and Welch 2006).

Performance management is often considered as an extension of performance appraisal. It is claimed that individual performance management includes goal setting, performance appraisal and providing feedback (Dowling and Welch 2006). Performance appraisal represents one of central parts of performance management (Tahvanainen 1998; Suutari and Tahvanainen 2002), representing a practice used for evaluation of past performance of an individual employee. So, it can be defined as an ongoing process in which employee performance is being reviewed and evaluated. However, performance management also includes other important components beside performance appraisal, such as: strategic planning, communication of organizational strategy through individual objective setting, job analysis and design (aimed at identification of performance requirements in a particular job), feedback and monitoring, training and development, motivating employees, employee relations and compensation (Vance and Paik 2006). So, it may be claimed that performance management includes a systematic analysis and assessment of employee performance, as well as communication of that assessment to the employee aimed at improving performance over time.

3. PERFORMANCE APPRAISAL OF INTERNATIONAL EMPLOYEES

It is necessary to measure individual performance on a job, regarding employee's behaviour or outcome during a specific period of time (Tahvanainen 1998). Performance appraisal is often viewed as one of HRM topics most widely debated and studied (Wright 2002). Performance appraisal represents an evaluation of the output of an individual measured periodically against specific expectations. Performance appraisals can be a critical part of organization's success because they allow the company to retain and reward high performers (Smith and Rupp 2003).

Having in mind that performance appraisal done in a domestic context is already a very complex process, conducting performance appraisal is even more challenging in the global environment - managing employees originating from different countries and cultures makes it difficult. International performance appraisal mainly focuses on two categories of employees: host-country nationals and expatriates; although the majority of research within the area of international performance appraisal is focused on performance appraisal of expatriates. The nature and the way of conducting of performance appraisal in MNC subsidiaries are considered to be influenced by HRM strategy and structure in the company (Maley and Kramar 2007).

Performance appraisal enables a multinational company to observe, monitor and evaluate individual performance of its employees in the workplace in relation to pre-defined standards, as well as their contribution to the success of the company. Performance can be defined by following key elements: goals, measures, assessment and feedback to employees at all levels. Appropriate implementation of this process is expected to reduce the inconsistencies in information between MNC headquarters and its host-country subsidiaries. Good performance appraisal is supposed to enable efficient control of MNC subsidiaries and to emphasize orientation at organizational goals at all hierarchical levels (Schlegel and Britzelmaier 2011), as well as to provide a realistic evaluation of international operations in order to motivate the subsidiaries to improve their performance in the future (Schmid and Kretschmer 2010).

It is often claimed that performance appraisal is used for two main purposes: to help managers to make administrative decisions (particularly referring to compensation packages and promotions - including expatriation) and to accomplish developmental objectives (regarding training and development of employees) (Brumback 1988). However, many other purposes of performance appraisal have been defined in the literature, such as assessing employee efficiency in the workplace, recognition of individual performance, improving employee performance, as well as providing information for managers' decisions regarding rises in salary, promotions, training and development opportunities, selection of employees (especially regarding selection of expatriates), retention and termination decisions. From the perspective of an individual employee the uses of performance appraisal include the following: identification of individual strengths and weaknesses, identification of individual training needs, making decisions regarding determining transfers (to international assignment) etc. In practice performance appraisals often influences other HRM systems in an organization - HR planning, determining organizational training needs, evaluating achievement of goals or identifying organizational development needs.

4. CHALLENGES OF CONDUCTING INTERNATIONAL PERFORMANCE APPRAISAL

Although performance appraisal systems represent such an important part of human resource management system they are still not completely understood and appreciated (Abu-Doleh and Weir 2007) in multinational companies.

There are various problems related to the process of conducting performance appraisal in international settings. The literature has identified main failures in this field, mainly focusing on the following. There is usually a lack of formal and universal performance appraisal system for evaluating performance of expatriates (Bonache et al. 2001) and lack of agreement among researchers regarding the most effective and objective criteria for evaluating performance and what constitutes effective (or satisfactory) evaluation (Maley and Kramar 2007). Competences and bias of the rater are often considered as a challenging issue in international performance appraisal (Woods 2003).

It is also difficult to isolate only job-related factors in conducting performance appraisal in international settings (Dowling et al. 1994; Gregersen et al. 1996). Numerous studies attempted to discover key attributes which should be possessed by an individual in international assignment in order to complete it successfully; although, researchers still have not agreed on universally accepted answers to these questions (Schmid and Kretschmer 2010). This has resulted in MNCs measuring some attributes and behaviours of international employees which are inappropriate which may lead to dissatisfaction of international employees regarding their appraisals.

It is often claimed that multinational companies tend to assess the abilities of their employees in terms of technical competencies. However, it has been often noticed that technical competences may not be considered as sufficient criteria for success in international operations of MNCs (Dowling and Welch 2006). Research suggests that the use of certain qualitative criteria may be better methods for assessing effectiveness of performance appraisal in international context (Milliman, Taylor and Czaplewski 2000). These criteria may refer to evaluation of individual attributes of international employees, such as: personal attitude, cultural awareness, global (geocentric) perspective, cross-cultural skills (communication skills, learning skills, adaptability, tolerance) (Harvey i Moeller 2009).

One of the common challenges of international performance appraisal refers to the existence of a gap between the evaluations of the rater and the rate. Performance appraisal in multinational companies represents a very complex process, as there is no best way to evaluate performance of a geographically distant employee performing a job in environment not fully understood by the rater (Shen 2004) - geographic distance between the rater and rate often makes performance appraisal process difficult. Other factors which can increase the complexity of an international performance appraisal include: differences in socioeconomic and legal environment, different norms and policies, cultural differences, language barriers, time zone differences, gender or social status (Appelbaum et al. 2011). These factors can sometimes increase the gap between the rater and the ratee, which may result in unfair performance appraisal process from the perspective of the rate in the foreign subsidiary - whether expatriate or local employee (Piggot-Irvine 2003).

Research has demonstrated that employee perceptions regarding the fairness of their performance appraisals are useful determinants of success of performance appraisal systems (Erdogan et al. 2001). These perceptions often influence employee attitudes and behaviours (Narcisse and Harcourt 2008) and may result in employee resentment or unhappiness (Abu-Doleh and Weir 2007). Literature lists three categories of employee perceptions of fairness - distributive, procedural and interactional (Erdogan et al. 2001). Narcisse and Harcourt (2008) explain that distributive fairness of performance appraisal refers to relation between perceived justice of outcomes of the appraisal (ratings) and actual work performed; procedural fairness focuses on the perceived justice of performance appraisal procedures used; while interactional fairness refers to the perceived fairness of the interpersonal treatment of employees during the performance appraisal process.

5. RECOMMENDATIONS FOR IMPROVEMENT OF INTERNATIONAL PERFORMANCE APRAISAL

Researchers have agreed upon the importance of international performance appraisal process, but there seems to be a lack of agreement on the best practices to conduct this process in international context (Appelbaum et al. 2011). Designing and implementation of performance appraisal system (or improvement of an existing process) is never a simple and easy task. Various issues concerning implementation of this system might arise, such as: aspects of performance which are being assessed; way of defining or describing employee performance; criteria used for performance appraisal; type of scales used for evaluation; raters who conducts the appraisal; as well as the frequency of conducting performance appraisal (Abu-Doleh and Weir 2007).

It has been noted that satisfaction with the performance appraisal system by employees in international settings is more likely to be higher in the following situations: when the appraisal has a clearly defined purpose in the company (Lindholm 1999), when employees perceive performance appraisal to be fair (Bradley and Ashkanasy 2001), when there is regular communication and positive relationship between the

rate and the rater (Milliman et al. 2002) and when there is timely and accurate feedback (Sully De Luque and Sommer 2007).

Having in mind that performance appraisal is often considered to have a direct influence on job satisfaction and motivation of workers (Rusli and Nur Azman 2004), in order to achieve effective performance appraisal it is necessary to create an environment full of trust and open relationships between raters and ratees (supervisors and employees). Face-to-face communication between the rater and rate is often considered necessary for building the mutual trust; in order to enable this regular contacts between the rater and the ratee should be arranged (whether through regular visits of the rater to the foreign subsidiary where the rate is located or through the use of information communication technologies).

Performance appraisal needs to be based on valid and reliable criteria (Harvey and Moeller 2009). These criteria should be easy to access and understand and they should be motivating for all international employees regardless of their nationality (Shen 2004). Performance appraisal system has to be fair and to ensure equal treatment for different international employees within the same company (Woods 2003). Both employees whose performance is assessed and the supervisor (the rater) need to understand the purpose of conducting performance appraisal in the company. It is necessary that MNC provides competent raters in order to decrease the possibility for bias in conducting the appraisal. However, formulating objective performance measures that are both valid and reliable can be problematic.

The performance appraisal measures and the way of conducting this process are supposed to be well understood across the organization. It is crucial that the expatriate's and HCN's expectations are consistent with the expectations of the MNC. Employees (both expatriates and host-country nationals) need to know what they are expected to do in a particular assignment. Effectiveness of performance appraisal increases when goals are formal and written (Claus and Briscoe 2009). Employees should be included in the process of setting the goals. Regarding performance appraisal of expatriates, this process should be done during the international assignment (and not after repatriation).

Appelbaum et al. (2011) recommend that performance appraisal in a global environment should be done by 360 degree or multi-rater system, which allows the rater (manager) to receive feedback on ratee's (employee's) performance from various sources. In order to ensure appropriate use of performance appraisal and to decrease the possibility for errors regular trainings need to be provided for the raters in the following fields: setting goals and performance standards, coaching, counselling, conflict resolution, providing employee feedback. It is also important to emphasize the necessity for the manager (the rater) to take into account cultural differences between MNC home and host country when evaluating performance of a particular employee.

Feedback has been found to be a crucial part of a successful international performance appraisal. Regular provision of performance feedback is especially important in international context, where ratee (employee) and rater (manager or supervisor) are not located in the same country (Milliman et al. 2002; Sully De Luque and Sommer 2007). It is considered to be a key determinant for achieving talent development of diverse employees in MNCs (Sully De Luque and Sommer 2007). In case when employees receive feedback more frequently, they usually expected to perceive performance appraisal process to be more precise and timely. However, in practice international employees often do not receive performance feedback and might feel a lack of opportunity to discuss various problems (such as their career or personal needs) with their raters.

6. CONCLUSION

Literature review suggests that various issues may be related with inappropriate conducting of performance appraisal process in multinational companies. These issues and challenges mainly appear due to complexity of performance appraisal of international employees. However, elements for improvement of performance appraisal systems in MNCs have been identified in the paper. A performance appraisal system designed in suggested manner (in order to implement the proposed changes) may be successful and effective and lead to increased employee motivation and satisfaction, trust and commitment to work.

THE PRACTICE OF PERFORMANCE BASED PAY IN CENTRAL AND EASTERN EUROPE

Nemanja Berber MSc[1], Agneš Slavić PhD[2]
[1]Research Assistant, University of Novi Sad, Faculty of Economics Subotica, berber@ef.uns.ac.rs
[2]Assistant Professor, University of Novi Sad, Faculty of Economics Subotica, slavica@ef.uns.ac.rs

Abstract: *Employee's pay is one of the most mentioned factors of organizational motivational system. In contemporary business pay usually includes variable and fixed component. Fixed component is an element of the total reward, which usually is not influenced by employees' performances, and it is based on the organization's pay philosophy and structure. Variable parts of the reward are monetary or non-monetary elements such as bonuses, incentives, benefits, financial participation or some other non-monetary value for employees (work autonomy, training and development possibilities, work quality improvements, recognition). For the purpose of this study the practice of variable pay, based on data from CRANET research, was explored. The main goal of this research was to present the trend in performance based pay in countries in Central and Eastern Europe. The subject of the research was variable pay, consisting of financial participation and performance based pay, where authors decided to analyse four elements of performance based pay: bonus based on individual goals, bonus based on team goals, pay for performance and flexible benefits (as relatively new way of rewarding employees). The methodology and data used in the research was based on the CRANET project, where authors used existing data about HRM activities in organizations all over the world. For the purpose of the analysis author used data for 1147 organizations from 8 countries of the Central and Eastern Europe, Bulgaria, Czech Republic, Slovakia, Slovenia, Serbia, Hungary, Estonia, and Lithuania. Descriptive statistics and chi square were used to analyse performance based pay in specific sample of counties.*

Keywords*: performance based pay, variable pay, bonus, incentives, Cranet, Central and Eastern Europe*

1. INTRODUCTION

Employees' compensation, especially performance based pay, has always been a subject of many researches and debates in the world (Chiu et al., 2002; Weibel et al., 2010; Larkin et al., 2012; Bryson et al., 2012; Kalmi et al., 2012; Gupta and Shaw, 2014) and in domestic scientific and professional literature (Malinić, 2007; Bogićević-Milikić, 2007; Štangl-Šušnjar and Leković, 2009; Štangl-Šušnjar and Slavić, 2012; Berber, 2013; Janićijević, 2013). Connecting rewarding activities like human resource management and performance of employees, their satisfaction and organizational commitment indicates the importance of compensation and all other related activities for employees. Many authors state that the employees' compensation affects attraction of young talented employees and retaining existing staff in the organization.

The purpose of this paper was to explore the practice of performance based pay in organizations in several countries of Central and Eastern Europe. The subject of the research was variable pay, consisting of financial participation and performance based pay, where four elements of performance based pay: bonus based on individual goals, bonus based on team goals, pay for performance and flexible benefits (as relatively new way of rewarding employees) were explored and analysed. The methodology and data used in the research was based on the CRANET project, where authors used existing data about HRM activities in organizations all over the world. For the purpose of this analysis, there have been used data for 1147 organizations from 8 countries of the Central and Eastern Europe: Bulgaria, Czech Republic, Slovakia, Slovenia, Serbia, Hungary, Estonia, and Lithuania. Descriptive statistics, t-test and chi square were used to analyse performance based pay in specific sample of counties.

The paper was composed from three parts. In the first part of the research there have been made a research of available theoretical literature on incentive pay, where special attention was dedicated to the performance based pay. In the second part of the research there have been presented methodology and data used in the analysis, while the third part was consisted from the results and discussion.

2. THEORETICAL BACKGROUND

Variable salary may be understood as a reward paid to an employee for a partial or complete achievement of predetermined work assignment. This part of the overall compensation is variable in the sense that it varies in relation to the objectives and standards - organizational, group or individual goals. This type of reward points to the importance and correlation between effort and performance, on the one hand, and the rewards, on the other. Incentives are very important for any organization because they are the primary way to encourage desired behaviour among members of the organization (Jensen et al., 2009, p. 59). The goal of any incentive payment is to increase productivity and performance levels of employees, and to sure that one system of incentives is effective, it is necessary to be based on the following assumptions:

- Individual workers differ from work teams in terms of contribution to the organization, in terms of what they do and how they perform work activities.
- Overall organizational performance largely depends on the individual and group performance.
- In order to attract, retain and motivate those employees who achieve high levels of performance and achieve fairness against all employees, there is a need to reward employees based on their performance (Martochioo, 2009, p. 129).

Performance-based pay can be considered from different aspects. It can be a pay based on individual performance, team performance and organizational unit or the company. Pays are determined on the basis of realized production volume, cost saving, satisfied standard quality, as well as the result - profit increase (Štangl-Šušnjar and Leković, 2009, p. 1). Gittleman and Pierce in their study analysed pay based on performance as production bonuses and non-production bonuses, where production bonuses are commissions and piece rates, and non-production bonuses are employment incentive bonuses, performance based awards, recognition awards, and union-related bonuses (2013, p. 35).

Table1: Forms of pay for performance plans

	Individual	Collective
Fixed	Merit pay	
	Skill- or competency-based pay	
	Promotion	
Variable	Payment by results	Performance-related pay
	Piece-rate pay	Financial participation
	Commissions	Gain-, goal- and profit sharing
	Bonuses	Ownership
	Individual incentives	Group incentives

Source: Salimaki and Heneman, 2008, str. 159.

From table 1 it is obvious that pay for performance, or performance based pay, takes several forms, but the most important are individual incentives and bonuses, while in collective those are performance based pay and financial participation.

During researches in the past there has been found many differences in these plans. The number of such differences is crucial to the success of performance-related pay. The authors in this area identified several dimensions on which differences may arise in this part of the variable salary:

- ~~I~~s pay based on organizational, group, or individual performance?
- Is pay based on objective measures such as piece-rate or subjective measures such as supervisory ratings?
- What proportion of pay is variable?
- How big are performance-based pay differences between good and bad employees?
- Are pay criteria clearly specified to employees in advance?
- Is there a policy of pay secrecy?
- In group-level performance-based pay plans, is pay distributed to group members equitably or equally?
- Is performance-based pay supplemented with other rewards?" (Gupta and Shaw, 2014, p. 3).

Gerhart and Fang classified pay for performance programs on three dimensions: ~~t~~he emphasis on results-oriented (physical production output, sales, profits, total shareholder return) or behaviour-oriented performance (supervisor or customer ratings of specific behaviours) measures, the emphasis on performance measured at the individual employee or aggregate (group, unit, organization) level, and the degree of incentive intensity. According mentioned authors, all private sector organizations in the United States and in many other countries usually use multiple pay for performance plans with the design based on

factors such as job level, type of occupation, the way the work is organized, and the organization's strategy" (2014, p. 41).

Since the most common classification of variable pay is on short-term and long term incentives, authors described these two categories.
Namely, short term incentives are remuneration linked to short-term goals of the organization – usually annual, monthly or quartile financial performance of the organization. The most common example, both in theory and in practice, is bonus. Bonus is a reward usually paid to individuals for above-average performance; it can be a fixed amount or a percentage of a basic salary. It is always paid once, and it is related exclusively to the efforts made and the results obtained. Each new bonus is necessary to earn, this kind of reward involves continuous monitoring and measurement of employee performance. In practice, companies differ in the short-term bonuses in the way of payment, but all boil down to the same fact that these are rewards associated with specific effects, which are paid once, and as a percentage of the basic salary. In addition, bonuses may be paid based on individual and team performance, which is especially interesting for this research. Namely, in the past research related to the team or individual bonuses, the variable pay was preferable if it comes to be incentives for performance of the individual, rather than collective (team) and organizational performance. Employees are more optimistic about the probability of obtaining incentives if the variable pay is based on the performance of individuals (Kuhn and Yockey, 2003, p. 323).

Long-term incentives are related to the payments for achieving long-term goals of the organization, and include those payments that are related to economic value, profitability, market share, etc. The most common categories of employees who were awarded these types of incentives are managers. Long-term incentives commonly include financial participation in the ownership of the organization. Providing capital means involving employees in the capital structure of the organization, through stocks. Specifically, when an employee owns shares of companies, in which he is employed, it comes to the development of employee ownership culture, and to the better alignment of organizational and personal goals. Share based plans, stock options and profit-sharing are the most common forms of long-term incentives (Štangl-Šušnjar and Berber, 2014).

2.1. The Practice of Performance Related Pay in Europe

In the study of incentive pay in the world, authors Bryson, Freeman, Lucifora, Pellizzari and Perotin indicated that the variable pay is used in about 10-15 per cent of organizations in some Mediterranean countries (Portugal and Greece), Continental Europe (Belgium and Germany) and Anglo-Saxon countries (UK and Ireland), 30% and over 40% in the Nordic countries (Sweden and Finland) (2012, p. 3). These data are referred to the period of the 2000th to 2006th year.

On the other hand, researchers from Hungary and CEE countries (from the Cranet research period from 2004-2005) found that variable pay related to the specific level of performances is given far more often to all staff categories than financial participation, where profit sharing was mostly used (Karoliny et al., 2009). In the case of managerial compensation, European authors have demonstrated a strong impact of the regulatory environment on share-based compensation plans in the region, where state shareholding has a major impact on the existence of such schemes in Polish public corporations, which could be considered as evidence of the rigid, direct regulation of executive pay in contrast to the Czech and Hungarian practice (Festing and Sahakiants, 2011).

Berber and Štangl-Šušnjar (2013) performed a research on the compensation for professional workers, based on the Cranet data from 2008/2010, and found that performance related pay is used more often than financial participation in the case of professionals' rewards in the companies from the CEE region, similar to the results of Karoliny, Farkas and Poór from 2009 but instead of performance based pay, bonuses based on team goals are the most common form of professionals' rewards in the area of variable pay.

Performance based pay has been explained as a selection device and a response to heterogeneous worker preferences. Authors from UK explored the relation between the size of organization and performance based pay. Using a large Portuguese data panel in the analysis mentioned authors found that large firms are more likely to use performance related pay and pay higher wages (Coelho et al., 2011). Authors from Europe found that there are significant differences in the distribution of incentive pay schemes by firm size. Incentive pay is more common in large organizations, usually for professional workers (Bryson et al., 2012, p. 7).

After a brief overview of the most important attitudes related to the payment based on performance, it is analysed the current practice of rewarding in the world. Specifically, the research team of CRANET in the period 2003/2005 explored the level of use of the performance based pay in organizations that were involved

in the project. According Brewster, Sparrow and Vernon (2007, p. 133-135) there have been observed the following phenomena associated with the use of rewards based on performance:

- Usage of the incentives for individual performance for manual workers was the highest in Slovakia and Switzerland, over 35 % of organizations. Countries such as Canada and Sweden used this approach less than 10 %, while countries such as Turkey, Australia and the United States less than 15 %.
- Usage of the incentives for individual performance for administrative workers was the largest in Italy, almost 50%, followed by Greece, Switzerland, Slovakia, Germany, France and Austria, more than 35%. Countries like Sweden used this approach only in 10% of organizations.
- In Finland, a country with a strong unions and collective bargaining, there are a significant proportion of payments based on performance and in manual and in administrative staff.
- Similarly, for team performance for manual workers - the largest share of this approach had Slovakia and Italy, followed by Finland, while the rest of the surveyed countries used this form in less than 15 - 17%.

3. METHODOLOGY, DATA AND HYPOTHESES

Based on the previously discussed researches related to the incentive compensation, and in accordance with the available data and variables, two hypotheses were proposed.

> *H0: Organizations from the CEE region use performance related pay based on individual level more than incentives based on team level.*
>
> *H1: Larger organizations from the CEE region use performance related pay more than smaller organizations.*

The present comparative analysis of compensation was based on the worldwide data of the Cranet international network of business schools. This international organization organizes comparative researches on the policies and practices of human resource management, using a standardized questionnaire. The survey is undertaken approximately every four years with the purpose to provide high quality data for academics, public and private sector organizations, as well as HRM students, and to create new knowledge about human resource management practice in different countries of the world. The questionnaires are filled out by the HRM executives of companies with more than 50 employees. The Cranet questionnaire is divided into six sections (Parry et al. 2013, p. 4). Section IV on Compensation and benefits contains questions about the level of basic pay and bonus schemes, as well as on schemes in excess of statutory requirements. The research data were processed using SPSS software and MS Office EXCEL programme, using descriptive statistics and chi square test.

The objectives of this paper were to find out the level of usage of different variable elements of pay in compensation packages for managers, professionals, clericals and manuals in countries of CEE. The subject of the research was variable pay, consisting of financial participation and performance based pay, where authors decided to analyse four elements of performance based pay: bonus based on individual goals, bonus based on team goals, pay for performance and flexible benefits (as relatively new way of rewarding employees). Respondents were asked to give answers whether they use (yes) or not (no) four elements of performance related pay.

The Cranet 2008/2011 dataset was collected in 32 countries. In this paper the authors used data from 8 CEE countries (Bulgaria, Czech Republic, Estonia, Lithuania, Hungary, Slovakia, Serbia and Slovenia) to perform a deeper analysis of incentive compensation, with a total of 1147 organizations. In Serbia this research was done in 50 companies from the whole country, with 17,064 employees. Table 1 presents the sample.

Table 2: The sample structure

	Frequency	Percentage	Cumulative Percentage
Bulgaria	267	23,3	23,3
Czech Republic	54	4,7	28,0
Estonia	74	6,5	34,4
Hungary	139	12,1	46,6

4. RESULTS OF THE ANALYSIS

To explore the usage of the variable pay elements related to performance based pay authors used crosstabs technique. The results are given in following tables.

Table 3: Performance based pay for managers and professionals in CEE region

Countries	Managers				Professionals			
	Flexible benefits	Performance based pay	Team bonus	Individual bonus	Flexible benefits	Performance based pay	Team bonus	Individual bonus
Bulgaria	28.6	49.0	44.1	53.6	23.9	53.7	41.4	50.2
Czech Republic	42.6	37.0	38.9	53.7	40.7	35.2	44.4	48.1
Estonia	63.6	65.2	49.2	66.1	59.1	71.6	48.3	72.6

Source: Authors analysis based on CRANET data

From tables 3 and 4 it is obvious that incentives based on individual goals are more used than bonuses based on team performances. Namely, in table 3 there were analysed four elements of performance based pay for managers and professionals, while in table 4 those were clericals and manuals. More organizations use individual bonuses (for managers 58.2%, professionals 57.7%, clericals 46.4% and manuals 44.1% of organizations) than team based bonuses (for managers 42.1%, professionals 43.0%, clericals 34.4% and manuals 33.5% of organizations) in their compensation policy. Also, from these tables it can be concluded that flexible benefits are used less than other elements of incentive pay, which was expected, since those are relatively new elements of rewards, especially in compensation systems of transition and post-transition countries in CEE region. Performance related payments in terms of incentives are used more for professionals and manuals (55.1% and 50.2%, respectively) than for managers and clericals (53.7% and 48.3%, respectively). From tables 3 and 4 it is also evident that there is diversity among countries when the performance related pay is in question. In case of flexible benefits, organizations from Estonia, Slovenia, Czech Republic and Hungary experienced greater usage of these benefits in comparison with Bulgaria, Lithuania, Slovakia and Serbia. Also, this diversity is evident in case of all other three elements of performance related pay, but in some smaller degree than in case of flexible benefits. In addition, from table it is evident that the greatest usage of performance related pay is for the category of managers, then for professionals and clericals, while the lowest level of the usage of these elements is for manual workers.

For the purpose of testing first hypothesis (H1) authors used chi square test. Variables used in test were elements of performance based pay and size of organization (based on the number of employees). Results of the chi square test are given in table 5. The results pointed to the conclusion that, in case of the observed organizations, larger organizations use flexible benefits, performance based pay, team and individual bonuses in greater extent (percentage) than medium or small organizations. More detailed, in case of flexible benefits for all categories of workers chi square test showed that there are significant differences between large, medium and small organizations regarding the percentage of organizations that use flexible benefits (X^2 value and *p* value). If the p value is lower than 0.05, there is a significant association between size of companies and the usage of the performance related pay. Phi value shows that there are weak but positive correlation between the size and the level of the usage of performance related pay in CEE region. In case of incentives for performances (second element of PfP) there were found no significant association between size and PfP.

Table 5: Difference between the usages of performance related pay in CEE region regarding the size of organizations

Source: Authors analysis based on CRANET data

5. CONCLUSION

Incentive pay represents one of the most important elements of each compensation system. Based on several researches around the world, EU, CEE region, and empirical data from CRANET project, authors of this paper made several conclusions.

In CEE region organizations use individual bonuses more than bonuses based on team performances – a confirmation of the zero hypothesis (H0) of the research. Namely, organizations in CEE region use individual bonuses usually more for each category of employees, which is in the line with the findings of Kuhn and Yockey (2003) who found that employees respect more incentives based on individual performance. Also, flexible benefits are used less than all other elements of incentive pay, which was expected, since those are relatively new elements of rewards, especially in compensation systems of transition and post-transition countries of the CEE region. Performance related payments in terms of incentives are used more for professionals and manuals than for managers and clericals. This can be expected that monthly incentives are usually given to those workers that are directly connected to the working tasks – in this case those are exactly professional and manual employees.

For the purpose of testing second hypothesis there have been used a chi square test. The results pointed to the conclusion that, in case of the observed organizations, larger organizations use flexible benefits, performance based pay, team and individual bonuses in greater extent (percentage) than medium or small organizations. These findings are in the line with some past researches of performance related pay (Coelho et al., 2011; Bryson et al., 2012). This was a confirmation of the first hypothesis (H1). In the case of flexible benefits and bonuses based on team and individual performances for all categories of workers chi square test showed that there are significant differences between large, medium and small organizations regarding the percentage of organizations that use flexible benefits. In case of performance related pay there were found no significant association between size of organization and these incentives.

Regarding performance related pay, in the CEE region there is also evident a diversity among countries. In case of flexible benefits, organizations from Estonia, Slovenia, Czech Republic and Hungary experienced greater usage of these benefits in comparison with Bulgaria, Lithuania, Slovakia and Serbia. Also, this diversity is evident in case of all other three elements of performance related pay, but in some smaller degree than in case of flexible benefits.

All findings are interesting especially for Serbia, as a country that until 2008 has never participated in some similar global research related to the area of HRM. Comparing its own practice of performance related pay with organizations abroad, in the CEE region, EU or world, organizations from Serbia can gain knowledge and information about trends and contemporary HRM practices. Based on the results of the researches and comparisons, domestic organization can plan and prepare improvements in this area, which is in Serbia still underdeveloped and based on some nonflexible system. Organizations from Serbia should pay more attention to compensation practice when rewarding and motivating their employees, especially incentives, with focus on individual bonuses (since those elements of performance related pay were used mostly in the CEE region). Also, it is important to bear in mind that each compensation plan should be based on the preferences of employees, and aligned with the possibilities of organizations.

Abstract: *Deciding on the group level means of group decision-making, which requires knowledge on the specific techniques of group decision making. Quality of the expert group members, e.i. their competence, is crucial for the success of the decisions made.*

In the scientific literature, different approaches to group decision-making as well as to evaluation of the competence of the expert group members can be found. This paper presents an approach to assessment of the competence of the experts - participants of the "Analytic Hierarchy Process" group decision making on the selection of methods for assessing the quality of military drivers.

Keywords: *Assessment, Experts Competency, Group Decision Making, Work Quality, Military Drivers*

1. INTRODUCTION

The emergence of expert assessment is linked to the emergence of the first formally described and studied technologies of expert assessment in the 50s and 60s of the last century. At that time the first articles on group decision-making, expert decision aggregation in the process of multi-criteria decision-making, determining of the results of the collective expertise by Delphi methods and scenarios and about the experiences of their application were created.

Interest in the expert assessment increased with the increase of the level of the development and the complexity of the decision-making process in the narrow sense, and with the development of science and technology in general sense. During recent years, the use of expert assessment has become frequent as it became clear that the effective solutions can be obtained by use of the experience, knowledge and intuition of specialists-experts.

Unlike individual decision-making, in which there is no need for any special decision-making techniques since the decision-maker decides by him/herself, for group decision-making process knowledge regarding group decision-making techniques is essential. Group decision-making also involves a smaller or larger number of people, members of the group, which have to be organized, directed and led.

The composition of the expert group depends on the particular problem which should be addressed, on the expertise organizer's ability to hire (engage) highly qualified specialists as well as on ability of experts to participate in the work of the expert group. People, whose opinion would be of the best assistance in making of the appropriate decisions, should be used as experts *(Milicevic 2010).*

Proper selection of specialists for work in the expert group is very important because the quality of expert assessment mainly depends on the quality of the expert group. The quality of the expert group depends on the quality and number of experts. Most of the existing methods of expert's quality assessment can be divided into five groups *(Denisova & Zaitsev, 2002):*

- *Heuristic* assessment is given by a man and is based on the assumption that, through self-evaluation and mutual evaluation between experts, high quality of evaluation of the experts could be provided;
- *Statistical* assessment obtained by expert opinion of expertise objects;
- *The test* assessment obtained by special examination of experts;
- *Documented assessments* based on an analysis of the documentary data on experts;
- *The combined assessments* obtained by a combination of several methods.

This paper presents an approach to assessment of the competence of the experts who participated in the "Analytical Hierarchy Process" (AHP) group decision-making in the selection of the methods for assessing the quality of military drivers *(Lukovac 2010).* The Group of Experts (GEX), consisted of twenty officers of the Traffic Service of the Serbian Army, to whom the assessment of the quality of work of the direct perpetrators i.e. drivers, was one of the obligations, arising from the functional duty they perform. To assess their competency the model recommended for the assessment of competence of experts in the field of transport support *(Djorovic 2003),* which is a combination of methods based on heuristic (argumentation evaluation and self-assessment) and documented assessment (objective assessment based on documented facts) of the quality of the experts, was used.

2. ASSESSMENT OF COMPETENCE OF EXPERTS

According to the model which is recommended for the assessment of competence of the experts in the field of transport support, the coefficient of competence(K), includes three aspects of assessment *(Djorovic 2003):*

(1) objective assessment (K_d);
(2) assessment of the source of argument (K_a);
(3) subjective judgment of experts (K_s);

Coefficient of competence is calculated according to following formula:

$$K = q_1K_d + q_2K_a + q_3K_s \qquad (1)$$

For weight that determines relative importance of the partial coefficient the following values are proposed*(Đorović 2003):* $q_1 = 0.6$, $q_2 = 0.25$ i $q_3 = 0.15$.

The coefficient of objective assessment(K_d)represents contribution of individual traitsof expert to his/hers competence. As the dominant individualtraits following are recommended *(Djorovic 2003):*

- K_1–level of education;
- K_2–total length of service;
- K_3–current duty;
- K_4 –length of service in the current duty;
- K_5–published scientific and professional papers;
- K_6–participation in projects;
- K_7–professional activity outside the post;
- K_8–work quality evaluation;
- K_9–the awards;

Integral component of individual traitsand their level of importance (in a scale 1-10) are shown in Tables 1 to 9 *(Djorovic 2003).*

Table 1: Level of education

K_1 – EDUCATION LEVEL		
Number of component	Component	The proposed level
K_{11}	Postgraduate level PhDs	10
K_{12}	Postgraduate level magistarture(master)	8
K_{13}	Postgraduate level specialization	7
K_{14}	University degree	5
K_{15}	College	4
K_{16}	High school	1

Table 2: Total years of service

K_2 – PERIOD OF PRACTICE		
Number of components	Component	The proposed level
K_{21}	Over 20 years	10

K_{22}	15–20 years	8

K_{74}	Activity in the scientific - technical associations	7
K_{75}	Papers for scientific professional conferences	6

K_{76}	The right to perform duty of the expertwitness	3
K_{77}	Completed foreign language courses	1

Table 8: Work quality assessment

K_8 – WORK QUALITY ASSESSMENT		
Number of components	Component	The proposed level
K_{81}	Over 4.50	5
K_{82}	3.50–4.50	4
K_{83}	2.50–3.50	3
K_{84}	2.00–2.50	2

Table 9: Awards

K_9 – AWARDS		
Number of components	Component	The proposed level
K_{91}	State awards	10
K_{92}	Awards by universities and faculties	8
K_{93}	Awards by enterprises	6
K_{94}	Other prizes	5

The coefficient of objective assessment (K_d) is calculated as:

$$K_{di} = \frac{1}{10} \times \frac{\sum_{i=1}^{n} p_i t_i}{\sum_{i=1}^{n} t_i} \qquad (2)$$

Wherein:

- p_i – the level of importance of i^{th}trait expert;
- t_i – weight that determines the relative importance of i^{th} trait of expert $t_i \in (0–1)$ (for specific problem recommended value is$t_i = 0.5$ for the trait "Published scientific and professional papers" and " Professional activity outside the post", and for other traits $t_i = 1$);
- n – number of traits;

The coefficient of argument (K_a), in whose assessment expert determines the degree of influence (high, medium or low) of certain source tohis/hers opinion, is calculated according to the following formula:

$$K_a = \sum_{i=1}^{m} \sum_{j=1}^{3} l_{ij} \qquad (3)$$

Wherein:

- i – source index;
- j – source influence index;
- m – number of sources;
- l_{ij} – coefficient of the source of the argument (which is determined by the expert);

Table 10 shows the degree of influence (by levels) of certain sources on expert opinion.

Table 10: Sources of argumentation *(Djorovic 2003)*

No.	SOURCES OF ARGUMENTATION	Degree of influence		
		1 – high	2 – medium	3 – low

1	Theoretical knowledge	0.3	0.2	0.1
2.	Experience	0.5	0.4	0.2
3	Papers from the literature	0.2	0.1	0.05
4	Proposer consultations	0.1	0.05	0.025
5.	Intuition	0.1	0.05	0.025
6.	Other	0.1	0.05	0.025

Based on the previously mentioned, the coefficient of argument (K_a), is calculated according to the following formula:

$$K_a = \sum_{i=1}^{6} \sum_{j=1}^{3} I_{ij} \qquad (4)$$

Table 11: Ratios of competence of the expert group *(Lukovac 2010)*

EXPERTS	ASPECTS OF COMPETENCE ASSESSMENT			COMPETENCE COEFFICIENT
	K_d	K_a	K_s	$(q_1K_d + q_2K_a + q_3K_s)$
1.	0.43125	0.925	0.7	0.595
2.	0.59375	0.95	0.9	0.72875
3.	0.6	1	0.9	0.745
4.	0.5	0.925	0.8	0.65125
5.	0.38125	0.9	0.5	0.52875
6.	0.75	0.95	1	0.8375
7.	0.4875	0.9	0.7	0.6225
8.	0.5625	1.075	1	0.75625
9.	0.7375	0.9	0.9	0.8025
10.	0.3625	0.8	0.5	0.4925
11.	0.5125	0.9	0.8	0.6525
12.	0.7375	0.975	1	0.83625
13.	0.66875	0.825	0.9	0.7425
14.	0.45625	0.875	0.6	0.5825
15.	0.5625	1.025	0.9	0.72875
16.	0.5875	0.85	0,8	0.685
17.	0.74375	1	1	0.84625
18.	0.3625	0.975	0.5	0.53625
19.	0.5375	0.9	0.8	0.6675
20.	0.38125	0.9	0.5	0.52875
COMPETENCE COEFFICIENT OF THE GROUP OF EXPERTS				**0.6783125**

The last partial element of the total competence coefficient represents experts' subjective assessment of the degree of knowledge on the specific problem (on a scale of 1 to 10), which is multiplied by 0.1 and, as such, is the coefficient of the subjective assessment (K_s).

When the competence coefficient (K) is determined for each expert,competencies coefficient GEX is calculated as their arithmetic mean *(Djorovic 2003).* Table11 shows the individual competence coefficients of expert participants in this study, as well as determined competence coefficient GEX.

Competence coefficient GEX is considered acceptable if its value is greater than 0.5 *(Djorovic 2003).* Since calculated competence coefficient GEX is 0.6783125 (Table 11), it can be concluded that members of the GEX are competent to participate in group AHP decision making on the selection of methods for assessing the quality of military driver (K> 0.5).

3. CONCLUSION

A number of authors in scientific works, and becoming more practitioners - the real decision makers, indicate that the decision making based just on personal considerations or intuitionispractically impossible. In recent times, when there are opportunities, choice is to make decisions within the group, through so-called group sessions during which opinions are exchanged and knowledge of individual participants is enhanced, participants' experiences is exploited, the way for consensus is made and an important psychological effect of common interest in the success of the decision made is achieved.

Proper selection of specialists to work within the expert group is very important because their competence is essential for making successful decisions. One of the parameters by which the quality of the experts, and thus the quality of the expert group's is assessed, is rating of competence. In the scientific literature there are different approaches to assessing the competence of experts. For the assessment of the competence of the experts in the field of transport support a model which is a combination of methods based on heuristic (argumentation evaluation and self-assessment) and documented assessment (objective assessment based on documented facts) of the quality of the experts is recommended.

Abstract: *A method of process functions is one of the well-known analytical methods for assessing the level of organization and it is very suitable instrument for obtaining overview of existing organizing modes and diagnosing what needs to be changed or improved. By using the method of process functions organization of professional functions, organizational units, work areas, operational elements, work posts etc. can be evaluated. This paper presents a mathematical model for the analysis of organizational structure of administrative bodies. The organizational structure of administrative bodies of the Serbian Army (SA) has been analyzed in order to analyze the situation and optimize the existing organizational structure. Analysis of the state of organization is aimed at creating a picture of the current mode of organization and, on the basis of that, removing identified deficiencies. This model has been applied for the analysis of process functions and tasks of the administrative bodies of the organizational structure taking into account the fact that administrative bodies should be designed and sized so that they can meet the basic goals and tasks of their existence. Each task set before the administrative bodies should be completed in a quality and reliable way in all environmental conditions.*

Keywords: *process functions, assessment, organisational structure*

1. INTRODUCTION

The organizational structure of business systems is necessary to be designed and sized to meet the basic corporate goals and objectives. Almost every task set before the system management should be completed in a quality and reliable way in different environmental conditions.

One of the possible approaches to analyzing the degree of coordination and effectiveness of organizational structure is based on the division of the organization according to business and process functions and on their evaluation. Organizational or business functions relate to a group of different activities that are centered on a single task. This way, organizational and business functions are differentiated by type.

Process functions relate to particular phases of activity taking place within each organizational function and within each of the subdivisions of organizational functions, or work areas of organizational functions. The nature and number of business and process functions is not specified or definite. Some analysts, for example, believe that management and leadership does not make a business function, but that these activities belong to the administrative functions in accordance with the criteria that some of the authors of the science of organization mention (Fayol, 1947). Urwick (1964) believes that business and administrative functions at the same level of itemization should be the same or nearly the same importance and complexity. However, business and process functions formally the same rank differ by “difficulty” and complexity. This approach was also used when creating a model for assessing the infrastructure business functions *(Vešović & Bojovic, 2002).*

Several methods for assessing the organization can be found in the literature, but this paper presents the model for the analysis of the organizational structure of administrative bodies of the SA.

2. APPLICATION OF THE METHOD OF PROCESSFUNCTIONS

The term “process functions” includes the activities which are required to successfully complete the entire task at all levels of work posts in the organization *(Eric, 2000).* In the working process there are nine main stages - the processing function, Table 1.

Table 1: Overview of process functions with signs and meanings *(Đorović & Pamučar, 2008)*

Process functions	MARK	Meaning
Recording	Ev	Inclusion of all work events in the organization.
Informing	Ob	Submission of data and information to all work post in the organization.
Monitoring	Kt	Comparison of the performed activities with pre-set criteria, standards and guidelines
Analysis	An	Disassembly, comparison and conclusion on the causes of deviations.
Decision making	Odl	Re-intervention on the developments in the existing processes and the design of future processes.
Planning	Pl	Providing of the elements necessary for the implementation of decisions.
Harmonization	Us	Combining and directing individual efforts into the overall effort.
Organization	Org	Search and design of the appropriate organizational procedures and task execution.
Performance	Izv	Particular execution of tasks at all positions in the organization.

Tasks, prescribed by organizational order for the work of that institution, performed by the commander of the transport platoon in one of the institutions of SA is analyzed in this paper, Table 2.

Table 2: Overview of tasks with marks *(Lukovac 2000)*

MARK	TASK
01	Cooperation with the transport officer
02	Referring to the manager
03	Duty hours
04	Holding meetings at the level of the platoon.
05	Making orders.
06	Preparation of transport planning documents.
07	Document processing for issuing assignments to drivers.
08	Making reports.
09	Development of vacations plan for people in the platoon.
10	Implementation of additional training, retraining and conditioning of the driver.
11	Collecting data on the improprieties "material and technical resources" (MTS).
12	Cooperation with the technic officer in order to address the defects of the MTS.
13	Supplying of transportation means with necessary tools and equipment.
14	The organization and implementation of activities in the field of basic maintenance of MTS.
15	Sending transport means to the civil workshops.
16	Initiation of proceedings for compensation for damages to the MTS for which platoon is responsible.
17	Proposing expenses
18	Cooperation with the platoon maintenance commander in terms of eliminating defects in MTS.
19	The work organization of duty officer in the technical resources park.
20	Organization of control-pass station.
21	Determining the causes of traffic violations and accidents.
22	Implementation of activities to increase road safety.
23	Sending driver to systematic medical examinations.
24	Monitoring and evaluation of the quality of work of persons in the platoon.
25	The organization and implementation of fire safety measures.

Since each work post, does not have to contain all process functions, it is necessary to determine their relationship. Connections of tasks with process functions is determined by the table "tasks - processing functions" (Table 3), for a task that contains some of the process functions characters “+” is put in, where the summation of “+” signs represents the

sum frequency (F). If the task does not contain any of the process functions character "-" is put in the table .

Table 3: Overview of functional interdependence of tasks and process functions *(Lukovac 2000)*

PROCESS FUNCTIONS / TASKS	Ev	Ob	Kt	An	Odl	Pl	Us	Org	Izv	F

25	+	+	+	+	+	+	+	+	+	9
F	25	19	24	25	22	25	25	25	25	215

Since all tasks do not have the same importance, i.e. some are more, and others less important, it is necessary to perform their weighting. The weighting is performed by selecting one of the weights on a scale of 0 to 5, according to the criteria shown in Table 4.

Table 4. Criteria for the selection of weights of tasks *(Đorović & Pamučar, 2008)*

WEIGHTS	CRITERIA
5	A task performing is necessary, business would not be possible.
4	A task performing affects the entire business in great deal
3	A task performing affect economic efficiency of business
2	Failure to perform tasks causes deficiency in the business, but the business is yet possible
1	A task performing affects the integrity of the business
0	A task performing is not necessary

According to the same criteria, process functions are weighted as well because they all do not have equal importance for the business. Selected weights for certain tasks, as well as weights for the selected process functions, are result of a poll conducted with the person who performs the task which is subject to this analysis. Weighting of tasks and process functions is performed by the multiplying selected tasks weights with selected process functions weights. Obtained results are theoretical weights of tasks by process functions, i.e. for process functions by tasks, Table 5.

Table 5: Theoretical weights of tasks by process functions *(Lukovac 2000)*

Process functions / TASKS		Ev	Ob	Kt	An	Odl	Pl	Us	Org	Izv	Σ

Σ		110	170	318	330	500	550	440	440	220	3078

The next step is the rating of tasks by process functions on a scale of 1 to 5, according to the rate determining criteria based on perceived organizational stand on observed work post, shown in table 6.

Table 6: Rate determining criteria *(Đorović & Pamučar, 2008)*

RATE	RATINGS DETERMINING CRITERIA
1	Tasks are not performed.
2	Tasks are carried out periodically.
3	Tasks are carried out on its own initiative, but upon agreement
4	Tasks are carried out according to the instructions of superiors.
5	Tasks are carried out according to organizational requirements.

Rates of tasks by process functions are shown in Table 7, and are also the result of a poll conducted with the person who performs tasks that are the subject of this analysis.

Table 7: Assessment tasks for process functions *(Lukovac 2000)*

PROCESS FUNCTIONS / TASK	Ev	Ob	Kt	An	Odl	Pl	Us	Org	Izv
01	5	–	4	4	4	4	4	4	4
02	5	3	4	4	4	4	4	4	4
03	4	4	5	5	5	5	5	4	5

PROCESS FUNCTIONS / TASK	Ev	Ob	Kt	An	Odl	Pl	Us	Org	Izv
04	2	3	2	2	3	2	2	3	2
05	5	–	5	4	4	4	4	5	4
06	5	4	3	3	3	4	3	5	5
07	5	–	5	4	5	5	5	5	5
08	5	–	–	3	–	5	5	5	4
09	2	3	4	3	–	4	3	4	4
10	5	5	3	3	4	5	5	5	5
11	3	3	3	4	3	5	5	5	5
12	4	3	3	2	3	3	3	2	2
13	5	3	3	2	3	3	2	2	2
14	3	3	3	3	3	3	3	3	3
15	5	3	3	2	3	3	3	2	2
16	5	–	5	3	3	5	5	5	2
17	2	2	3	4	–	3	4	4	4
18	3	3	2	2	4	3	3	3	3
19	5	5	2	2	3	5	5	5	5
20	3	5	3	2	3	3	5	5	5
21	5	5	4	4	5	5	5	5	5
22	4	5	4	4	4	3	5	3	5
23	3	2	2	2	3	3	5	3	2
24	5	–	5	3	2	2	4	4	3
25	3	5	2	3	3	5	4	3	2

After rating the tasks by process functions the calculation of the actual task weights (P_s) is conducted by using following formula :

$$P_s = \frac{P_p \times O}{S_o} \quad (1)$$

where:

P_p - Required (theoretical) the weight of work,

O - Assessment of tasks by process functions,

S_o - Score scale (5).

The actual weights of tasks are shown in Table 8.

The next phases in the application of this method is calculating the average rate of tasks and process functions and, based on these ratings, ranging of tasks and process functions. Average ratings of tasks ($\bar{O}$) are calculated by using following formula:

$$\overline{O} = \frac{\sum P_s}{\sum P_p} \times S_o \quad (2)$$

Rang of the tasks based on their average rate is shown in Table 9.

Table 8: Actual tasks weights *(Lukovac 2000)*

PROCESS FUNCTIONS / TASKS	Ev	Ob	Kt	An	Odl	Pl	Us	Org	Izv	Σ

25	2.4	8	4.8	7.2	12	20	12.8	9.6	3.2	80
Σ	90.6	8	139.8	202.2	122	423	356	343.2	164.4	2261

Average rates of process functions (O_{pf}) are calculated using the weight given in tables 5 and 8, and according to following formula:

$$O_{pf} = \frac{\sum P_s}{\sum P_p} \times S_o \qquad (3)$$

where :

P_s - Actual weights of process functions,

P_p - Required ponder of processing functions,

S_o - Scale of rates (5).

Table 9: Rang of the tasks (Lukovac 2000)

RANG	TASK	ΣP_s	ΣP_p	$\overline{O}$	WEIGHT

8.	Informing	115.2	170	3.39	2
9.	Analysis	202.2	330	3.06	3
	Σ	2261	3078	3.67	

Law average ratings point out those tasks that are neglected in the organizational structure. All average ratings with a value below 3.67 indicate the tasks and functions that are critical points in the organization.

Average ratings of process functions indicate the importance that they have in the overall functioning of the organizational structure. If these ratings are very different, it points to the unadjusted leadership and management. In addition, average rating of business functions is the evaluation of the organizational level of the organizational structure. Average task ratings indicate the importance they have in the overall functioning of administrative bodies. As these ratings are very different ranging from 2.38 to 3.72, this means that the cause was the unadjusted task management.
Strengths and weaknesses of the existing organization and functioning of the organizational structure show the ranking of process functions. The ranking shows what process functions should be given more attention; this applies especially to those process functions that have high weights, and low average ratings. Average ratings of process functions indicate those process functions which have to be significantly changed and improved. This applies particularly to those process functions that are rated below average (Decision making, Monitoring, Informing and Analysis).

CONCLUSION

Average rate represents the level of organization of the particular workpost. Having in mind its numerical value of 3.67, it can be concluded that this is a level of organization that is characterized by the execution of the tasks based not on organizational rules, but on officers own initiative or instructions of superiors. This primarily applies to tasks that are rated with lower rates than the average rate, and in this case these are tasks that are ranked from 15th to 25th place (tasks marked with "09", "25", "17", "24", "14", "18", "23", "15", "12", "13" and "04"). Average rate of the process functions provides overview what process functions should be to significantly changed or improved. This primarily applies to those process functions that are rated below average rate (3.67), and in this case are "Decision making" (3.58), "Monitoring" (3.39) "Informing" (3:39) and "Analysis" (3.06).

Advantages and disadvantages of the organization level are shown by the rate of process functions and activities as well. This rate shows which process functions and tasks more need attention, and this applies primarily to those process functions and tasks which are assigned with high weights and have low average rate. From this point of view, in this particular case interesting tasks are marked with "14", "18", "15", "12" and "13", i.e. process functions "planning" and "decision making".

The results of this analysis should be viewed critically, because for detailed analysis the opinion of a number of persons who are familiar with concrete problem (or a group of experts in the field of transport support) should be should taken into account.

EDUCATIONAL ACHIEVEMENTS AS A DETERMINANT OF AN INDIVIDUAL'S FORMAL POWER

Miha Marič[1], Mitja Jeraj[2]
[1]Faculty of Organizational Sciences, University of Maribor, miha.maric@fov.uni-mb.si

Abstract: *The scope of this study was to define how educational achievements of individuals in Slovenia define their "formal power" in organizations where they work. The study was based on theoretical definitions of the concepts of formal power and education. A total of 509 people from Slovenia over 30 years of age participated in the study. We recognized a certain influence of educational achievement on the formal position in the organizational hierarchy. The main predictor of an individual's formal power in an organization is the individual's last achieved level of formal education. The average grade for the final achieved level of formal education and the initiative regarding the search for additional education has much less of an impact on power than the last level of education obtained. One of the most important practical implications is that education is one of the basic predispositions to having formal power but not necessarily always and not in every case.*

Keywords*: education, formal power, work, employees, HRM*

1. INTRODUCTION

The basic definition of power would be: "Power is the ability to implement one's will." The study of power in organization has been interesting topic for many researchers. Power is consider by many as one of the most important factors in an organization. Some authors suggest that power lies in the potential, and others suggest that power is only present in its use. There is also an ongoing debate what makes individual powerful (Marič & Ferjan, 2011).

Despite the importance of an individual's formal and informal power in an organization, there is very little research on what gives power, formal or informal combined, to an individual in an organization. In this article, we will explore the effect of an individual's education on one's formal power in an organization. We suppose that the education one receives leads to principal differences in one's power later on in an organization that one is working in. We could also say that the duration of schooling determines one's formal power in an organization. Those who have higher education usually gain more formal power and amenities depending on their working positions in some cases even regardless of their abilities.

In his book "Organization, Power and Change" (1995) Borum Finn states that there is reason to believe that the narrow connection between educational and professional competence and pyramidal location plays an important role. It creates the impression that there is a connection between the length of education and the ability to make decisions also in relation to non-professional issues. The inflexibility of the educational system widens the individual pyramidal strata and thus reinforces the authoritarian nature of the system. Education is one of the identified factors that contribute to one's personal power (Rees, 1999). One could argue that the shift from a capital-based to a knowledge-based economy represents a fundamental shift in power dynamics (Lynn, 2000).

2. AN INDIVIDUAL'S EDUCATION

The educational process offers individuals knowledge, skills and habits. Some describe it as the last level of education that one has achieved so far in their life (FAQ | Ministry of Higher Education, Science and Technology, 8.6.2009). It could also be important how many years of education one has and what was their average grade during the last level of their education. Knowledge is the capacity to act on information… it implies learning (Lynn, 2000). We could say that education is one of the predispositions to having knowledge, but not in everyone's case. Being included in the educational process does not necessarily mean that the individual has really gained that knowledge. Organizations are employing the most educated workforce in the history of the world (Burke & Ng, 2006) because they do not need more people willing to blindly follow orders or to do repetitive work; they need people of courage and initiative (Pinchot, 1992).

Different styles of upbringing have their effect on children's will and capacity to learn, and on their adaptability to the requirements of the school (Ferjan & Jereb, 2008). Bowles and Gintis (2002) found that

parental economic status is passed on to children in part by means of unequal opportunity, but that the economic advantages of the offspring of higher status families go considerably beyond the superior education they receive. Educational transformation also influences the social justice and the social status of the people (Unterhalter & Dutt, 2001). There are also various factors that influence the study progress (Jereb et al., 2009).

By the day more and more importance is given to lifelong learning (European Commission - Education & Training - lifelong learning programme - A single umbrella for education and training programmes, 2009) in which the formal education is in a way perceived a foundation for further lifelong work and education. It could easily be said that the higher level of formal education one has, the more involved in lifelong learning one has to have to keep up with everyday requirements of one's work (Ferjan & Jereb, 2005).

Lifelong learning (European Commission - Education & Training - lifelong learning programme - A single umbrella for education and training programmes, 2009) is sort of defined by additional learning per year, search for appropriate forms of additional education and of course not to forget, the training that is required by the employers or the organization in which one works. The learning process accompanies individuals in every phase of their life. The levels of education in the EU are also increasing with the following generations (The levels of education in the EU are increasing with the following generations: Evropa.gov.si, 8.6.2009).

3. AN INDIVIDUAL'S FORMAL POWER

Power is part of our lives, both private and organizational. Power is basically the ability to influence the desired outcomes. Power can be broadly defined as the ability to influence different outcomes, by pooling resources (human and material) to achieve the realization of certain things within the network of relationships (Rees, 1999) and at the same time to resist unwanted influence from others (Wagner & Hollenbeck, 2010). Individuals' who have power in the organizational environment often also have power even in their private lives and vice versa.

An individual's power in organizations can be best assessed with observations (Finn, 1995). However, on the other hand that is a long process, sometimes even subjective and would take a lot of man-hours to implement on a larger sample. That is why the power evaluating process takes part only on smaller samples at a time; for instance one company or one branch of a company at a time. Robbins (quoted in: Senior, 2002) argues: "Power has been described as the last dirty word... People who have it deny it, people who want it try not to appear to be seeking it, and those who are good at getting it are secretive about how they got it."

An individual's power is also very relative; one could have it one day and lose it on another (Mintzberg, 1983). Or one could have power in one group, and have none in another group of people simultaneously. Power is difficult to measure, since it can only be perceived (Marič & Ferjan, 2011).Power is difficult to measure, since it can only be perceived. From the social-psychological perspective, a person's behaviour is affected by his or her behavioural intentions, which are in turn influenced by an attitude and set of perceptions. Behavioural intention is regarded as a key antecedent in determining one's future behaviour (Wu et al., 2008). We could say that power concerns the capacity of individuals to exert their will over others.

In a company or in an organization there are basically two kinds of power: formal and informal power (Mintzberg, 1983). While formal power is defined, the informal power that is in many cases even more important is not so well defined. Here we will focus on individual's formal power within organizations.

Formal power comes from one's place in the hierarchy, one's duties and their position and is well defined. Hierarchical levels are adjusted to convey the relative authority of employees (Rosenbaum, 1980). Power resides in the position no matter who has it (Moorhead & Griffin, 2010) so it is similar to authority. When constructing a position in an organization the power of this position is determined. The person in this position has all the power and all the limitations that the position holds. Formal power on an individual's level consists of: legitimate power, reward power, coercive power and information power (George & Jones, 2008). Formal power basically comes from placement in the organizational hierarchy.

4. RESEARCH QUESTIONS

Below we will explore the influence of one's formal level of education with respect to an individual's formal power in an organization. Higher level of formal education is considered as a way of getting everything that one wants in life (often climbing the hierarchical ladder) and the thing that many consider as the cover of it all is power. There are several ways to gain power, and one of the most commonly perceived ways is education. For instance when one introduces himself as PhD, the all, at least the vast majority of people

around him think that he knows everything. Hogan (2005) claims that people respect someone who has a higher position (M.D. vs. orderly), more extensive education (Ph.D. vs. high school), and more experience (20 years of work experience vs. just out of school). That brings us to our research questions.

- *R1: What kind of effect does individual's higher level of formal education have on individual's formal power in the organization?*

- *R2: What kind of positions do individuals' achieve in the hierarchy of an organization compared to their achieved level of formal education?*

5. METHODOLOGY

Participants in this study were selected randomly. The sample consisted of 232 men and 277 women (N=509). The age range of the respondents was between 30 and 61 years. The average age of the respondents was 41.35 years, the average level of education was 5.26 (a little above completed high school), and the average place in the organization's hierarchy was 3.50 (middle administrative staff).

The questionnaire contained closed questions referring to: (i) general data (age, gender), (ii) education, (iii) an individual's formal power within an organization. An individual's formal power was measured through their place in the hierarchy of the organization. Individuals were asked about their place in the hierarchy of the organization that they are working in. We have developed and used the following hierarchical scale: (1) manual worker, (2) head of the shift, (3) routine administrative staff, (4) non-routine administrative staff, (5) expert, (6) lower management, (7) middle management, (8) top management.

The final "hierarchical" structure of the sample is shown in Table 1. We have developed a concept to classify the placements in the hierarchy ourselves and created eight degrees of hierarchical placement of individuals in the organization's hierarchy which relates to their formal power.

Table 1: Placement in the Organization's Hierarchy (n=509)

Hierarchical Position	*1. Manual Worker*	*2. Head of Shift*	*3. Routine Admin. Staff*	*4. Non-Routine Admin. Staff*	*5.Expert*	*6. Lower Management*	*7. Middle Management*	*8. Top Management*	*Total*
N	*164*	*43*	*76*	*38*	*84*	*32*	*38*	*34*	*509*
%	*32,2*	*8,4*	*14,9*	*7,5*	*16,5*	*6,3*	*7,5*	*6,7*	*100*

Mean = 3.50; Median = 3.00; Std. Deviation = 2.303;

The individual's *final level of formal education* was measured through the achieved degree of education. The following scale was used: (1) did not finish basic school, (2) finished basic school (8 years), (3) secondary school (2 years), (4) secondary school (3 years), (5) secondary school (4 years), (6) two year study, (7) higher education, and (8) master's degree, doctorate degree. The final formal educational structure of the sample is shown in Table 2. In Slovenia, the education classification from 1980 is used and has eight degrees (Ferjan & Jereb, 2008).

Table 2: Formal educational structure (n=509)

Education degree	*1*	*2*	*3*	*4*	*5*	*6*	*7*	*8*	*Total*
N	*6*	*41*	*20*	*74*	*159*	*60*	*112*	*37*	*509*
%	*1,2*	*8,1*	*3,9*	*14,5*	*31,2*	*11,8*	*22,0*	*7,3*	*100*

Mean = 5.26; Median = 5.00; Std. Deviation = 1.67;

- The *educational success at the last level of formal education* was measured on a grading scale from 6 to 10, where: (6) sufficient, (7) good, (8) very good, (9) almost excellent and (10) excellent which is in use by Slovenian universities. Primary and secondary schools in Slovenia use a grades scale from 1 to 5; because of which the grades from 1 to 5 were converted into grades ranging from 1 to 10 as follows: 1 converted into 5; 2 converted into 6; 3 converted into 7; 4 - 4,5 converted into 8; 4,5 - 4,75 converted into 9; 4,75 – 5 converted into 10.

Table 3: Average Grade at the Last Educational Level (n=509)

Average grade	6 – Sufficient (6,00-6,99)	7 – Good (7,00-7,99)	8 – Very Good (8,00-8,99)	9 – Almost Excellent (9,00-9,49)	10 – Excellent (9,50-10,00)	*Total*
Frequency	*48*	*199*	*181*	*53*	*28*	*509*
Percent	*9,43*	*39,10*	*35,56*	*10,41*	*5,50*	*100*

Mean = 7.7055; Median = 8.00; Std. Deviation = 0.96477;

Self-initiative regarding the search for additional training was measured through surveying the respondents about how often they search for appropriate additional forms of education and training. A grading scale from 1 to 5 was used, where: (1) never, (2) very rarely, (3) occasionally, (4) often and (5) permanently.

Table 4: Self-initiative Regarding the Search of Appropriate Education or Training Contents (n=509)

Self-initiative Regarding Education	*1 - Never*	*2 - Very Rarely*	*3 - Occasionally*	*4 - Often*	*5 - Permanently*	*Total*
Frequency	*126*	*130*	*149*	*76*	*28*	*509*
Percent	*24,8*	*25,5*	*29,3*	*14,9*	*5,5*	*100*

Mean = 2.51; Median = 2.00; Std. Deviation = 1.173;

6. RESULTS AND DISCUSSION

We can see that there are positive correlations between all of the variables. All the variables were measured on an increasing scale. As seen in the table above there is a positive correlation between the achieved level of education and all of the place in the hierarchical structure which we used as a measure of formal power in an organization are above 0,304 and are all statistically significant. Table 5 gives the correlation coefficients between the previously described variables.

Table 5: Pearson R Correlation Coefficients (n=509)

	Achieved level of education	*Average grade at the last level of education*	*Self-initiative regarding the search for additional education or training*
Average grade at the last level of education	*0,332**		
Self-initiative regarding the search for additional education or training	*0,488**	*0,235**	
Place in the hierarchical structure	*0,628**	*0,304**	*0,469**

** Correlation is significant at the 0.01 level (2-tailed).*

To continue, a regression analysis between the independent variables (*Achieved level of formal education, Average grade at the last level of formal education and Self-initiative regarding the search for additional education or training*) and the dependent variable (*Place in the hierarchical structure*) has been made and is shown below in Table 6.

Table 6: Regression Analysis for the Dependent Variable "Place in the Hierarchical Structure" (n=509)

Predicators	*Unstandardized Coefficients*		*Standardized Coefficients*	*t*	*Sig.*
	B	*Std. Error*	*Beta*		
(Constant)	-2,790	,621		-4,495	,000
Achieved Level of Education	,684	,054	,498	12,564	,000
Average Grade at the Last Level of Education	,218	,085	,091	2,567	,011
Self-Initiative Regarding Education	,402	,075	,205	5,323	,000

Dependent Variable: Place in the Hierarchical Structure

With the predictors *"Achieved Level of Formal Education", "Average Grade at the Final Level of Formal Education", "Self-initiative Regarding the Search for Additional Education and Training"* 43.3% variance of "*Place in the hierarchical structure"* is explained. The achieved level of formal education (β=0.498) has the most influence. Individuals educated differently have different abilities of reaching higher positions in the hierarchical structure which answers *R1*.

The answer to *R2* lies in Table 7 where we can see that not even one individual who has not completed primary school achieved a position in the hierarchy higher than the position of *manual worker*. On the other hand 35.15% of the individuals who achieved the highest level of formal education also achieved the top management positions in organizations and 94.6% of the achieved positions in the hierarchy that are at the level of experts or management (r=0.628 at p=0.01).

Table 7: An Individual's Position in the Hierarchy Compared to an Individual's Achieved Level of Formal Education (n=509)

		Position in the Hierarchy								*Total*
		Manual Worker	*Head of Shift*	*Routine Admin. Staff*	*Non-routine Admin. Staff*	*Expert*	*Lower Manag.*	*Middle Manag.*	*Top Manag.*	
Achieved Level of Education	*1*	100,0%								100.0%
	2	85,4%	2,4%	2,4%		7,4%			2,4%	100.0%
	3	75,0%	15,0%	5,0%	5,0%					100.0%
	4	62,2%	16,1%	4,1%	10,8%	4,1%	1,4%		1,4%	100.0%
	5	28,3%	13,8%	27,0%	10,2%	8,8%	5,0%	3,1%	3,8%	100.0%
	6	20,0%	3,3%	16,7%	6,7%	25,0%	15,0%	10,0%	3,3%	100.0%
	7	4,5%	2,7%	14,3%	8,0%	32,1%	10,7%	17,9%	9,8%	100.0%
	8			5,4%		35,15%	5,4%	18,9%	35,15%	100.0%
Total		32,2%	8,4%	14,9%	7,5%	16,5%	6,3%	7,5%	6,7%	100,0%

1 - did not finish primary school. 2 - finished primary school. 3 - secondary school (2 years). 4 - secondary school (3 years). 5 - secondary school (4 years). 6- two year study. 7 - higher education. 8 - master's degree. doctorate degree

Of course, characteristics do not fit every single individual but we still think that people who have achieved higher levels of formal education also have higher tendencies toward the top of the hierarchical structure and also have better possibilities of achieving higher positions.

7. CONCLUSION

An individual's power is an always important factor in one's personal as well as business life. Education is a factor in one's power yet the mere presence of formal education will not give you power as many believe. This study provides basic insights into the connection between one's formal education and power and it can be summarized as follows: an individual's formal education is one of many things that compose into individual's formal power. However, it does not explain the whole concept of power because there is an infinite number of variables that influence one's power and we can only explain them in parts.

Several limitations of this study need to be considered before interpretations of the results can be explored. First; the discussed findings and implications were obtained from a single study; generalizing the results should be done with caution. Second; the whole research was focused mostly on how an individual's education affects one's formal power. We have had that in mind already in the beginning when we were defining the goal of the study so that it is relatively simple with a concept that is influenced by many other variables that are not included in this study.

We can all agree that there is a lot more to power that just these variables that we used in our study to determine it but still even this simple study shows that there are some basic predispositions to having formal power and that one of them is formal education. Maybe in a way the findings are area specific because formal education is so emphasized in this study. However, it is still an interesting way for simplistically evaluating one's potential power depending on formal education.

One of the factors that influence an individual's power could also be the power of their parents and their social position. A similar study regarding the influence of social class position as a determinant of educational achievements has already been done (Ferjan & Jereb, 2008) and the results could also be used to determine power and its sources.

According to the findings, the perceptions and the "size" of an individual's formal power in an organization depends on one's level of formal education. One man once said that all people are divided into two groups; the leaders and the followers. Most people are simple followers but those who want to be leaders need power to achieve that someone will follow them. Leadership facilitates quality relationships and balances power (Pinchot, 1992).

Abstract: *The last quarter-century, a number of researchers and experts are engaged in the study of temporal concepts in databases. Justification of a large number of research papers is that conventional DBMS are not able to respond to some of the tasks imposed by the modern business environment. These tasks are related to tracking the state in real system on one hand, while on the other hand they are related to tracking the state of database itself. Furthermore, the study of information systems, as one of its goals, is to make better description of the real system and the problems that need to be addressed. The consequence of this is to enrich the semantic data models with brand new or older and expanded concepts and represent real system in better way. This paper aims to present a brief overview of temporal concepts and to show their application in one of the proprietary transaction DBMS, IBM DB2 10.5.*

Keywords: *Temporal databases, SQL:2011 standard, transactional databases*

1. INTRODUCTION

History of the temporal concepts in databases is long, complicated and with a lot of controversy. In short, there are two main periods. The first period is 1986-2011 and is called SQL/Temporal. Significant research works in this period are: (Snodgrass, 1986), (Snodgrass et al., 1994), (Snodgrass, 1994), (Darwen & Date, 2006). The second period is 2008-2011 and it is characterized by the fact that temporal concepts become part of the SQL: 2011 standard. Temporal concepts in SQL: 2011 standard is largely based on the SQL/Temporal, but there are significant differences (Kulkarni & Michels, 2012).

The rest of this article is organized in the following way: Section 2 gives an overview of temporal concepts and focus on temporal features defined in SQL:2011. Section 3 provides examples of temporal concepts in transactional database in IBM DB2 10.5. The last section gives conclusions and discusses future work.

2. BASIC TEMPORAL CONCEPTS

The problem that occurs in conventional databases is that only current state is memorized. Therefore, they are referred as snapshot database. We insert new data, change or delete existing data, but state before change is not memorized. Thus, a conventional DBMS are memoryless systems (Patel, 2003).

The problem can be solved using temporal concepts. In practice there is need to implement them, but information system designers, programmers, database administrators, users in one word, ignore and simplify that fact, because of the complexity. Application were required to implement support for temporal concepts were developed for a long time with a lot of code and proved to be incomplete. As an example, IBM made research in which they compared the implementation of temporal concepts in three possible ways (Saracco et al., 2012). The first is to incorporate them directly into the database. The second is implementation by using stored procedures and triggers. The third realization consists of triggers and application logic written in Java programming language. Result of the research is that the built-in support for temporal concepts is the best solution that can reduce the size of the program code up to 45 times.

Time in temporal database is viewed as ordered sequence of points in granularity which is determined by application. For example, if we need to develop application for HR, which task is to track period of time in which employee has worked in department, minimal granularity should be one day. This means that employee in one day can do his job only in one department. In reality, every day is flow of time, not a point, because it consists of hours, minutes, seconds etc. Chronon is term in literature that is used to describe this minimal granularity of application. The consequence of defining minimal granularity, for example a day, is that events that take place in this day are simultaneous events, although in reality it does not have to be.

There are two types of temporal information (Elmasri & Navathe, 2010). First group are time series. In that situation, event is connected with one point in a time in some granularity. For example, stock value of some

company at August 15, 2013. was 50$. In practice, to process these types of information companies are using dedicated software systems – time series database server (TSDS). They are not subject of this paper.

Second group are duration events, or facts and they are referring to specific time period in database. For example, employee may have worked in financial department from August 18, 2012 until January 1, 2014. Time period is represented by its start and end time points, for example [2012-08-18, 2014-01-01]. This time period can be represented as the set of all time points from its start-time to end-time, in the specified granularity (Elmasri & Navathe, 2010). If the granularity is day, then the defined period is the sum of all days from August 18, 2012 to January 01, 2014.

Temporal concepts links time of event, or a fact with time point in database. If an event has occurred in the real world, or fact proved to be true or valid and has its conjunction with time in the database, then the time is referred to as the valid time. Transaction time is the time to indicate that the information is valid in the database, ie. in the system itself. If database has support to each of these time dimension, it is indicated as bitemporal database. These basic concepts are described, from point of SQL/Temporal. There is a slight difference in terminology between SQL/Temporal and SQL:2011 standard. It is shown in the table 1.

Table 1: SQL/Temporal vs SQL: 2011 difference in terminology

SQL/Temporal	SQL:2011
valid time	application time
transaction time	system time
validtime table	application time period table
transactiontime table	system-versioned table
bitemporal table	system-versioned application time period table

2.1. Application time period tables

Application time period table contains PERIOD clause, whereby the user can define the name of the period. These tables contain two columns: one to store the initial time of period, and the other to store the end time of period. The values in these columns are defined by user. Additional syntax is provided for users to specify primary key/unique constraints to ensure that no two rows with the same key value have overlapping periods. Application time period table stores valid time, and they suggest when a fact or event is valid in the real world. Because user defines values for initial and end time of period, changes in database can be applied before they come in real world. That is proactive update, and it reflects state of table in a future. In addition, there is a retroactive update, where changes are entered into the database after they have occurred in the real world.

This temporal concept can be used to solve the following business requirements (Saracco et al. 2012):

1. A client challenges an insurance agency's resolution of a claim involving a car accident. The agency needs to determine the policy's terms in effect when the accident occurred.
2. An online travel agency wants to detect inconsistencies in itineraries. For example, if someone books a hotel in Rome for eight days and reserves a car in New York for three of those days, the agency would like to flag the situation for review.
3. A retailer needs to ensure that no more than one discount is offered for a given product during any period of time.

2.2. System-versioned tables

In contrast to regular tables, system-versioned tables preserve old versions of rows as table is updated. Table contains two additional columns where start time and end time of period is stored. Values in these columns are set by system. Users are not allowed to supply values for these columns. These tables keep all changes of state of table, so user can logically returns on some state of database. Because of that database with this time can be referred as rollback database (it isn't related with rollback operation of transaction) (Elmasri & Navathe, 2010). System-versioned tables contain PERIOD clause, with predefined name of period SYSTEM_TIME, and specified WITH SYSTEM VERSIONING. Rows whose periods intersect the current time are called current system rows. All others are called historical system rows. Only current system rows can be updated or deleted. All constraints are enforced on current system rows only.

This temporal concept can be used to solve the following business requirements (Saracco et al., 2012):

1. An internal audit requires a financial institution to report on changes made to a client's records during the past five years.
2. A pending lawsuit prompts a hospital to reassess its knowledge of a patient's medical condition just before a new treatment was ordered.

2.3. System-versioned application time period table

If database should store application and system time at the same time, in that situation we use combined approach, system-versioned application time period table.

This temporal concept can be used to solve the following business requirements (Saracco et al., 2012):

1. A client inquiry reveals a data entry error involving the three-month introductory interest rate on a credit card. The bank needs to retroactively correct the error (and compute a new balance, if necessary).

3. TEMPORAL CONCEPTS EXAMPLES ON IBM DB2 10.5

IBM DB2 10.5 version implements all previous mentioned temporal concepts. It should be borne in mind that concepts that are described by SQL:2011 standard have different names in IBM DB2 terminology. The differences are shown in Table 2.

Table 2: terminology differences between SQL:2011 standard and IBM DB2 10.5

SQL:2011 Standard	IBM DB2 10.5
application time period tables	tables with business time
system-versioned tables	tables with system time
system-versioned application time period tables	bitemporal tables

Temporary concepts are going to be presented in following examples. That will be done using Product table. In one point of time, discount for only one product should be enabled.

3.1. Tables with business time

Creation of table with business time in IBM DB2 is done using following command:

```
CREATE TABLE Product(
id INT NOT NULL,
name VARCHAR(20),
price DECIMAL,
discount INT,
bus_start DATE NOT NULL,
bus_end DATE NOT NULL,
PERIOD BUSINESS_TIME(bus_start, bus_end),
PRIMARY KEY(id, BUSINESS_TIME WITHOUT OVERLAPS)
)
```

In IBM DB2 implementation of temporal concepts, user doesn't have the possibility to define the name of the period. It is predefined as BUSINESS_TIME. Bus_start and bus_end columns present start and end time. Optional command BUSINESS_TIME WITHOUT OVERLAPS is used for primary key limitation. That means that 2 versions of the same product, which are valid in one same point of time, cannot exist. Inserting rows into Product table is shown in the following example:

```
INSERT INTO Product
 VALUES(1, 'Black Shoes', 150, 10, '2012-12-25', '2013-01-10'),
       (1, 'Black Shoes', 150, 5, '2013-01-10', '2013-01-31'),
       (1, 'Black Shoes', 150, 0, '2013-01-31', '9999-12-30'),
       (2, 'Moccasin', 100, 5, '2012-09-01', '2013-04-01')
```

Table 3: table with business time after INSERT statement

id	name	price	discount	bus_start	bus_end
1	Black Shoes	150	10	2012-12-25	2013-01-10
1	Black Shoes	150	5	2013-01-10	2013-01-31
1	Black Shoes	150	0	2013-01-31	9999-12-30
2	Moccasin	100	5	2012-09-01	2013-03-01

If we tried to execute following SQL statement:

```
INSERT INTO Product VALUES (1, 'Black Shoes', 150, 10, '2013-06-06', '2013-07-07')
```

An error would occur because of defined limitation for Period temporal data. Syntax for UPDATE command is expanded with FOR PORTION clause that supports temporal data. This clause is used to specify a period of time for which update is going to be done.

The result of next UPDATE statement, used for Table 3, is shown in Table 4:

```
UPDATE Product
   FOR PORTION OF BUSINESS_TIME FROM '2013-06-01' TO '2013-09-01'
SET discount = 20
WHERE id = 1;
```

Table 4: table with business time after UPDATE FOR PORTION

id	name	price	discount	bus_start	bus_end
1	Black Shoes	150	10	2012-12-25	2013-01-10
1	Black Shoes	150	5	2013-01-10	2013-01-31
1	**Black Shoes**	**150**	**0**	**2013-01-31**	**2013-06-01**
1	**Black Shoes**	**150**	**20**	**2013-06-01**	**2013-09-01**
1	**Black Shoes**	**150**	**0**	**2013-09-01**	**9999-12-30**
2	Moccasin	100	5	2012-09-01	2013-04-01

Two rows are processed with UPDATE command for product 1. Each of 2 original rows will split into 2 rows, as shown, because the command includes a part of period inside these 2 rows in the table.

For removing data from table with business time, operation can be limited to specific part of the time, by specifying FOR PORTION OF BUSINESS TIME clause. If a row should be deleted, and data are not fully included in that part of time, DB2 would provide that row information is saved.

Result for the following command executed over Table 4:

```
DELETE FROM Product
 FOR PORTION OF BUSINESS_TIME FROM '2012-09-01' TO '2013-01-01'
WHERE id = 2
```

is shown in Table 5.

Table 5: table with business time after DELETE FOR PORTION

id	name	price	discount	bus_start	bus_end
1	Black Shoes	150	10	2012-12-25	2013-01-10
1	Black Shoes	150	5	2013-01-10	2013-01-31
1	Black Shoes	150	0	2013-01-31	2013-06-01
1	Black Shoes	150	20	2013-06-01	2013-09-01
1	Black Shoes	150	0	2013-09-01	9999-12-30
2	**Moccasin**	**100**	**5**	**2013-01-01**	**2013-04-01**

It is possible to make temporal and non-temporal queries over table with business time. Non-temporal queries are classic SELECT commands that are also written for DBMS that don't support temporal concepts. Following 3 temporal conditions can be included in temporal queries:

- FOR BUSINESS_TIME AS OF . . . – enable the execution of query over data in specific point of time
- FOR BUSINESS_TIME FROM . . . TO . . . – enable the execution of query with condition from start to end time defined. IBM DB2 uses inclusively-exclusive approach, so end time is not taken into count
- FOR BUSINESS_TIME BETWEEN . . . AND . . . – data are selected from specific to specific time. Condition is inclusively-inclusive, which means that start and end point are included in condition for selection.

If following query is used with Table 5:

```
SELECT discount
FROM Product FOR BUSINESS_TIME AS OF '2013-03-20'
WHERE id = 1
```

The operation result is 0.

If we want to list conditions for buying product 1 in period from 2013-03-01 to 2013-07-01, following query can be made. The result is shown in Table 6.

```
SELECT *
FROM Product FOR BUSINESS_TIME FROM '2013-03-01' TO '2013-07-01'
WHERE id = 1;
```

Table 6: result of SELECT statement with condition FOR BUSINESS_TIME

id	name	price	discount	bus_start	bus_end
1	Black Shoes	150	0	2013-01-31	2013-06-01
1	Black Shoes	150	20	2013-06-01	2013-09-01

3.2. Tables with system time

Creation of table with system time is going to be shown. In IBM DB2 database, old rows are kept in history table – table that is separated from table with current data, with the same structure (Saracco et al., 2012). For IBM DB2 database table creation is done in 3 steps:

1. Create the base table for current data – it contains 3 TIMESTAMP columns, 2 for start and end point of system time and one for transaction start time. (In DB2 this column is used to follow the first execution of data changing command). These three columns can be specified with GENERATE ALWAYS, so on INSERT, UPDATE or DELETE command new values will be generated in database. Optionally, you may define these columns as IMPLICITLY HIDDEN so they won't show up in SELECT * statements.
2. Create the history table - this table has structure identical to the table that contains current data. This is easy step with CREATE TABLE . . . LIKE statement.
3. Alter the current table to enable versioning and identify the history table.

Now we will see these 3 steps. First is to create base table. We can do it with command:

```
CREATE TABLE Product(
id INT PRIMARY KEY NOT NULL,
name VARCHAR(20),
price DECIMAL,
discount INT,
sys_start TIMESTAMP(12) GENERATED ALWAYS AS ROW BEGIN NOT NULL,
sys_end TIMESTAMP(12) GENERATED ALWAYS AS ROW END NOT NULL,
trans start TIMESTAMP(12) GENERATED ALWAYS AS TRANSACTION START ID IMPLICITLY HIDDEN,
PERIOD SYSTEM_TIME (sys_start, sys_end)
);
```

Now we will create related history table.

```
CREATE TABLE Product_history LIKE Product
```

The last step is to enable versioning:

```
ALTER TABLE Product ADD VERSIONING USE HISTORY TABLE Product_history;
```

Suppose now that the following command was executed on April 13, 2012. Results are displayed for current row is in table 7, and history rows in table 8.

```
INSERT INTO Product(id, name, price, discount)
VALUES (1, 'Black Shoes', 150.00, 10);
INSERT INTO Product(id, name, price, discount)
VALUES (2, 'Moccasin', 100.00, 5);
```

Table 7: Product table after INSERT statement

id	name	price	discount	sys_start	sys_end
1	**Black Shoes**	**150**	**10**	**2014-04-13 17:53:25**	**9999-12-30 00:00:00**
2	**Moccasin**	**100**	**5**	**2014-04-13 17:53:25**	**9999-12-30 00:00:00**

Table 8: Product_history table after INSERT statement - empty

id	name	price	discount	sys_start	sys_end

For each row in database TIMESTAMP VALUES are generated for system time, and transaction start time. Value in column SYS_END is set to December 30, 9999. This means that these rows are current.

If we run UPDATE command on current rows, old versions of rows will be memorized in history table. Suppose now that the following command was executed on April 15, 2014.

```
UPDATE Product
SET discount = 30
where id = 1;
```

Row that keeps current data is updated and copy of old row is moved to history table as shown in table 10.

Table 9: Product table after UPDATE statement

id	name	price	discount	sys_start	sys_end
1	**Black Shoes**	**150**	**30**	**2014-04-15 12:53:25**	**9999-12-30 00:00:00**
2	Moccasin	100	5	2014-04-13 17:53:25	9999-12-30 00:00:00

Table 10: Product_history table after UPDATE statement

id	name	price	discount	sys_start	sys_end
1	**Black Shoes**	**150**	**10**	**2014-04-13 17:53:25**	**2014-04-15 12:53:25**

If data is going to be deleted, they are moved to history table. END_TIME of deleted data is time of the transaction. Suppose the following command was executed on April 20, 2014.

```
DELETE FROM Product WHERE id = 2;
```

Tables that show current and history rows are shown in table 11 and table 12.

Table 11: Product table after DELETE statement

id	name	price	discount	sys_start	sys_end
1	Black Shoes	150	30	2014-04-15 12:53:25	9999-12-30 00:00:00

Table 12: Product_history table after DELETE statement

id	name	price	discount	sys_start	sys_end
1	Black Shoes	150	10	2014-04-13 17:53:25	2014-04-15 12:53:25
2	**Moccasin**	**100**	**4**	**2014-04-13 17:53:25**	**2014-04-20 12:13:45**

Conducting the temporal queries in tables with the system time is functioning on the same way as they functioning in table with business time. The only difference is that the result can contain history rows.

Before we represent bitemporal tables, there is overview which compares the key characteristics of system time and business time (Mathias, 2012).

Table 13: key characteristics of system time and business time

Characteristics of system time	Characteristics of business time
Captures the time when changes happen to data inside DB2 database.	Captures the time when changes happen to business objects in the real world
Maintains a history of updated and deleted rows, generated by DB2	Maintains application-driven changes to the time dimensions of business objects
History based on DB2 system timestamps	Dates or timestamps are provided by application
DB2's physical view of time	Your application's logical view of time
Spans from the past to the present time	Spans past, present, and future time
System validity (transaction time)	Business validity (valid time)
Supports queries such as: "Which policies were stored in the database on June 30?"	Support queries such as: "Which policies were valid on June 30?"

3.3. Bitemporal tables

Next example shows how to create bitemporal table:

```
CREATE TABLE Product(
id INT NOT NULL,
name VARCHAR(20),
price DECIMAL,
discount INT,
bus_start DATE NOT NULL,
bus_end DATE NOT NULL,
sys_start TIMESTAMP(12) GENERATED ALWAYS AS ROW BEGIN NOT NULL,
sys_end TIMESTAMP(12) GENERATED ALWAYS AS ROW END NOT NULL,
trans_start TIMESTAMP(12) GENERATED ALWAYS AS TRANSACTION START ID IMPLICITLY HIDDEN,
PERIOD BUSINESS_TIME(bus_start, bus_end),
PERIOD SYSTEM_TIME (sys_start, sys_end),
PRIMARY KEY(id, BUSINESS_TIME WITHOUT OVERLAPS));
```

Once the table is created as bitemporal, it is necessary to make a copy of the same table. After that it is necessary to link created tables, and allow versioning. Complete procedure is explained in the previous section.

For example, assume that product 1 is created by user on 19 Apr 2014 with discount of 10%. Discount is set to go into effect on 01 May 2014.

```
INSERT INTO Product(id, name, price, discount, bus_start, bus_end)
VALUES(1, 'Black Shoes', 150, 10, '2014-05-01', '9999-12-30');
```

Suppose that on 20 April 2014, someone change the terms of discount for product 1. Discount is set to go into effect on 01 June 2014 and discount increases to 20%.

```
UPDATE Product
 FOR PORTION OF BUSINESS_TIME FROM '2014-06-01' TO '9999-12-30'
SET discount = 20
WHERE id = 1;
```

Because of simplifying the display instead of TIMESTAMP data type for the system time we will show only the date part. Tables Product and Product_history look like Tables 14 and 15 respectively.

Table 14: Bitemporal table Product

id	name	price	discount	bus_start	bus_end	sys_start	sys_end
1	Black Shoes	150	20	2014-06-01	9999-12-30	2014-04-20	9999-12-30
1	Black Shoes	150	10	2014-05-01	2014-06-01	2014-04-20	9999-12-30

Table 15: Bitemporal table Product_history

id	name	price	discount	bus_start	bus_end	sys_start	sys_end
1	Black Shoes	150	10	2014-05-01	9999-12-30	2014-04-19	2014-04-20

Now let's look at an example showing the advantages of the bitemporal concept. Customer calls contact center on 15 July 2014 and complains about the bill. Customer thinks that value of discount is not adequate and requires all changes in price and discount in the last year.

Database administrator can set following query:

```
SELECT *
FROM Product
 FOR SYSTEM_TIME FROM '2013-07-15' TO '2014-07-15'
WHERE id = 1;
```

Result of this query is presented in Table 16.

Table 16.

id	name	price	discount	bus_start	bus_end	sys_start	sys_end
1	**Black Shoes**	**150**	**20**	**2014-06-01**	**9999-12-30**	**2014-04-20**	**9999-12-30**
1	**Black Shoes**	**150**	**10**	**2014-05-01**	**2014-06-01**	**2014-04-20**	**9999-12-30**
1	**Black Shoes**	**150**	**10**	**2014-05-01**	**9999-12-30**	**2014-04-19**	**2014-04-20**

Bitemporal tables can implement temporal queries with 3 types of conditions: conditions with business time only, conditions with system time only and conditions with combination of business time and system time. First two types are already mentioned when we talked about system-versioned tables and application time period tables. Third type of temporal queries combine conditions of these two groups.
Following 6 temporal conditions can be included in temporal queries:

- FOR BUSINESS_TIME AS OF . . .
- FOR BUSINESS_TIME FROM . . . TO . . .
- FOR BUSINESS_TIME BETWEEN . . . AND . . .
- FOR SYSTEM_TIME AS OF . . .
- FOR SYSTEM_TIME FROM . . . TO . . .
- FOR SYSTEM_TIME BETWEEN . . . AND . . .

Suppose that tables Product and Product_history are presented with data in Table 14 and Table 15.
Result of following query, which is combination of conditions with business and system time, is presented in Table 17.

```
SELECT *
FROM Product
 FOR BUSINESS_TIME AS OF '2014-05-01'
 FOR SYSTEM_TIME FROM '2014-04-19' TO '9999-12-30'
```

Table 17: Resulting query which is combination of conditions with business and system time

id	name	price	discount	bus_start	bus_end	sys_start	sys_end
1	**Black Shoes**	**150**	**10**	**2014-05-01**	**9999-12-30**	**2014-04-19**	**2014-04-20**
1	**Black Shoes**	**150**	**10**	**2014-05-01**	**2014-06-01**	**2014-04-20**	**9999-12-30**

4. CONCLUSION

Temporal concepts in transactional databases enable users to implement tracking the state in real system and tracking the state in database itself, and combination of both concepts. Using temporal concepts we can remove basic problem of these systems. Temporal concepts, specified in SQL:2011, simplify the logic of applications, stored procedures and triggers, which would be used if we want to implement tracking the state of tables in database. IBM DB2 10.5 is commercial solution that fully supports temporal concepts. Future directions should consider joins with temporal condition - temporal joins.

Abstract: *Conventional relational databases represent state of the business entity at a moment. Although, data changes over time with insertion of new records, update of previous records or deletion of not needed records, these changes present a modification of the state of business entity. However, there exist applications where previous state of database should be kept. In conventional relational databases the attributes involving time are manipulated mainly by the application programs, with help from the database management system (DBMS). Therefore, a need to shift time manipulation from application to DBMS is identified and implemented in SQL:2011 standard. This research aims to evaluate performance of traditional relational DBMS (RDBMS) and temporal databases. Performance comparison is conducted in controlled, experimental environment using Oracle 12c DBMS.*

Keywords*: Temporal databases, SQL:2011 standard, DBMS, performance comparison*

1. INTRODUCTION

In majority of database systems time dimension of event (record) present one of the most important attributes in its application. This is especially true for analytical database such as data warehouses (Golfarelli & Rizzi, 2011). Every event important for operation of enterprise occurs at specific point of time. Also, object and relationships between two or more objects exist only for some interval point of time. Therefore, ability to model time of real world is one of the most important subjects in many applications such as financial application, medicine (Mahmood et al., 2013), web traffic (Mokbel et al., 2013) and geographical information systems (Siabato et al., 2014).

Traditional relational databases present state of enterprise at a current point of time. In other words, previous states of object or relationship between objects (after update or delete of some record) cannot be fully retrieved. However, historical data is needed in order to gain insightful knowledge from history and thus make better decision. In most applications this problem is solved on computer application side, which resulted in expensive development. Since this can pose a serious threat in real-time transactional systems need to mitigate this problem to DBMS is identified. In 1995, the ISO SQL committee initiated a project to create a language extension to support temporal features in SQL standard. A set of language extension based on TSQL2 (Snodgrass, 1995) were submitted for standardization at that time, but unfortunately these proposals generated considerable controversy and failed to get adequate support from the ISO SQL committee's members. In addition, there were no indications that key DBMS vendors were planning to implement temporal extensions in their products. Darwen & Date (2005) criticized TSQL2 language extension, which proved this language extension was not mature enough to be applied in real world systems. First, in each temporal table there were unnamed timestamp columns which are hidden from the user. Thus, user could not access this column through traditional relational theory simply referring to the columns by name. This property is inconsistent with the principles of relational database theory. It needed to include new syntax for expressing temporal queries and modifications. Additionally, new features were needed in the catalog in order to describe tables with temporal support. Second, statement modifier are said to be flawed because syntax for queries needed to change dramatically (adding VALIDTIME prefix before SELECT statement) which is not intended in relational theory to be used as statement operator. Finally, lack of generality was stated. Defined temporal intervals failed to include support for operations on intervals in general. Also, lack of generality is seen in question whether, if it is reasonable to use hidden columns for valid times and transaction times, would it not be equally reasonable to use hidden columns for other kinds of data. Eventually, the work on extending SQL language with temporal features was cancelled in 2001.

Second attempt to implement temporal features in SQL standard started in 2008, as proposal for system-versioned tables was accepted by INCITS DM32.2 and ISO/IEC JTC1 SC43 WG3. Additionally, application-time period tables were included. In 2011, a new set of language extensions for temporal data support were submitted and accepted by the ISO SQL committee. These language extensions are now part of SQL:2011

Part 2, SQL/Foundation (ISO/IEC 9075-2:2011, 2011) as T180 – System-versioned tables and T181 – Application-time period tables, instead of appearing as a new part (Zemke, 2012).

The goal of this paper is to test whether there is significantly different decrease in performance of temporal features compared to traditional relational databases in elementary functions (INSERT, UPDATE and DELETE). Tests are executed in controlled, experimental environment using following software setup: Oracle 12c DBMS and Windows 7 Ultimate (x64) operating system, and hardware setup: computer with 4GB of RAM memory and Intel(R) Core(TM) i5 M460 processor.

To best of our knowledge only few researches were made in this field. First research, conducted by Kaufmann et al. (2013), performed benchmark analysis of non-temporal and temporal queries (defined with SQL:2011 standard), where several combinations of selection of data was performed. In this research, based on provided schema, only SELECT statements were evaluated. Similar research, done for benchmark of bitemporal tables, was performed by Kaufmann et al. (2014). They came to conclusion that existing temporal database systems highlight significant optimization potential and insufficient support for common application use case. Testing was done on Oracle 12c DBMS. Temporal query processing in Teradata was performed by Al-Kateb et al. (2013). They discussed in depth the pros and cons of the rewrite and native implementation approaches. So far it seems that most of temporal features were implemented by IBM DB2 DBMS, which is presented in white paper by Saracco et al. (2012).

The remainder of the paper is structured as follows. Section 2 gives an overview of temporal features defined in SQL:2011 standard. In section 3 design of experiment, used for performance comparison of these two systems, is introduced. Section 4 provides experimental results for traditional table and temporal tables and results analysis. Section 5 provides conclusion and further research directions.

2. TEMPORAL FEATURES IN SQL:2011 STANDARD

Time itself is very complex concept. First, measuring of time is depended of application. In astronomy time is measured in eons and solar days, in production on daily level, in sales on day and time level and in chemistry can be on nanoseconds. Second, total order relationship cannot be fully developed, which means that one time element can have more higher level and lower level of granularity (i.e. for month, lower levels of granularities are week and day, while higher levels of granularities are semester and year). Third, time carries inherited inaccuracy (indeterminacy property). (Snodgrass, 1986)

2.1. Temporal concepts

In order to explain temporal features included in SQL:2011 standard several temporal concepts are going to be explained. These concepts are defined by (Anselma et al., 2013).

Definition 1: Chronon (time quantum or moment) *c* is basic inseparable time unit, defined on domain *TC*. Mathematically, $c \in TC$.

Chronon is the simplest time unit which cannot be divided to smaller units of time. It is defined on time domain *TC* called timeline, which is an ordered set of chronons $\{c_1,\ldots, c_i,\ldots, c_j,\ldots\}$, where $c_i < c_j$, $\forall i < j$.

Definition 2: Temporal element *TE* is a set of chronons, defined on domain *TC*. Mathematically, $TE = \{tc_1,\ldots,tc_n\}$, $tc_i \in TC$, $i=1,\ldots,n$.

Disjunctions of temporal elements are a natural way of coping with time indeterminacy, in which each temporal element models one of the alternative possible temporal scenarios, where any one of which could be valid.

Determinate times can be modeled through a disjunctive temporal element (DTE) containing just one temporal element (called singleton DTE). As a result of this, any determinate temporal element can be modeled with a singleton DTE.

Although, event (fact) can relate to temporal element of one record in database interpretation of that event can vary. Jensen (2000) defined two types of interpretation. First, if temporal element presents time or period of event in real world, then this point is *valid time* temporal element. Events of this type could present time in past, present or future. If database uses this concept it is called valid time database. On the other hand if time or period presents point of time where information was entered into database then this time or period is *transaction time* temporal element and databases which use this concept are called transaction time databases. However, there exists one more type of temporal elements, besides valid and transactional,

which is called *user defined* temporal element. In this case user defines semantic and meaning of temporal element. If table contains both valid time and transactional time then this table is called *bitemporal* table. Each of temporal features can be explained through following definition:

Definition 3: Given a schema $(A_1, A_2, \ldots, A_n)$ of non-temporal attributes defined on the domain $A_i \in D_i$, $i=1,\ldots,n$ temporal relation r is an instance of the schema $(A_1, A_2, \ldots, A_n \mid T)$, where T is temporal attribute. Then, r is defined on the domain $D_1 \times \ldots \times D_n \times TC$ in which empty temporal element and value equivalent tuples are not admitted.

With this definition expressiveness property is satisfied. This formalism allows one to express (i.e., to associate with each tuple) any combination of possible scenarios (i.e., any subset of the lattice of scenarios). Based on value of temporal element T, different types of temporal databases are presented. Each tuple $x=(v_1,\ldots, v_n \mid d) \in r$, where d is a DTE, is termed a valid-time tuple. If d is DTE which presents current (system) time stamp then this tuple is termed transaction-time tuple.

2.2. System-versioned tables

In SQL:2011 standard system-versioned tables are tables that include system timestamp and, therefore, correspond to transactional time. They must include PERIOD statement with two predefined columns and WITH SYSTEM VERSIONING statement. System-versioned tables must have two and only two additional columns, one for beginning and another for end SYSTEM_TIME period. These new columns cannot be changed by the user. In other words, system can only add or change values of these fields. As additional property of system-versioned tables history is saved. This means that with UPDATE statement close end time of updated record and creates new record with start time of current timestamp. Additionally, terminology for records that intersects with current time is called *current system rows*, while others are called *historical system rows*. Finally, only current system rows can be updated or deleted and every constraint can be applied only on these records.

In Oracle system-versioned tables are implemented through temporal validity feature which allows data that is older or no longer valid or not yet valid to be hidden from queries. In other words, only active data returned by queries. These features are achieved with FLASHBACK DATA ARCHIVE option, not needing to specify anything else on table level. With this feature user can query date as of some time and between some times (and this is defined in FROM part of statement). For this purpose, in this research, PERIOD has been created with hidden columns for start date and end date. User can access them (if he/she is SQL proficient), but cannot change values.

2.3. Application-time period tables

Application-time period tables are defined in SQL:2011 standard and relate to valid time or user defined temporal elements, since user defines and controls periods. These kinds of tables are defined with PERIOD statement with two predefined columns, one for beginning of period and another for end of period. In order to prevent user to create two or more records with same value, PERIOD can be included as primary key. Data manipulation (INSERT, UPDATE and DELETE statements) are executing in same manner as ordinary tables. In other words, user controls dates and times of PERIOD columns. Since user manipulates date and time columns, user can refer to any date and time (past, present or future). Additionally, one constraint is added, which disallows creating a record where end time is lower than beginning time. For UPDATE statements additional syntax is defined which allows row splitting. Row splitting means that if there exists record with period P and UPDATE query is updating subset of P then existing record will be updated (from records beginning time to UPDATE statement beginning time) and two additional rows will be created (one record from UPDATE statement beginning time to UPDATE statement end time and another from UPDATE statement end time to records end time) in order to maintain integrity of data. Also, for DELETE statements is defined additional syntax which deletes records that satisfy time period condition, but inserts additional two rows (one from records beginning time to DELETE statement beginning time and another from DELETE statement end time to records end time).

In Oracle DBMS application-time period tables are designed in similar fashion. Only difference is that start and end of period must be defined. Therefore, user can access and manipulate with period. Feature that disallows creation of overlapping period does not exist in Oracle 12c. Therefore, user must control insert and update of records.

3. EXPERIMENTAL SETUP

In the real world business applications can and should use a lot of temporal dimensions at the same time. However, for every data model additional temporal dimension increases the complexity. It is up to user (software developer) to make decision which database features to use. Therefore, in this research performance, in terms of execution time, of temporal features implemented in Oracle 12c is tested. If there is too much difference in execution time, then it will be unreasonable to use these features, but if there is no big difference a lot of benefits can be made. First, validation of data insertion is transferred to DBMS, which reduce possibility of human error in software design and speed up execution. Second, every record from past can be retrieved and used. Therefore, final user can, even if accidentally deletes or updates record see previous state of that record. Third, historical data can be used for analytical purposes, which can lead toward new business insights. On the other hand, if there are many data operations (many insertions, updates and deletes), then there is a reasonable doubt that database will grow much faster than ordinary, memory-less database. The goal is to inspect whether there exists statistically significant difference between execution time of INSERT, UPDATE and DELETE statements between these three groups. In this research comparison of execution time between two temporal and ordinary tables is made. Temporal tables used in this paper are system-versioned table, where transaction time is saved and application-time period table where valid time is saved. Ordinary table is table without temporal features included but having two additional attributes with timestamp data type, which are controlled through application. Experiments are conducted on Oracle 12c DBMS on Windows 7 Ultimate (x64) operating system in controlled environment on computer with 4GB of RAM memory and Intel(R) Core(TM) i5 M460 processor.

SELECT statement is omitted from this research since temporal databases will eventually generate more records and therefore execution time will surely be greater. Also, SELECT statement allows new features which are usable in different way and some of them cannot be recreated through ordinary SQL query. Analysis of SELECT statement in temporal databases is explained in detail in (Kaufmann et al, 2013; Kaufmann et al., 2014).

Oracle 12c adopted many temporal feature defined in SQL:2011 standard, but implementation is incomplete. First, a temporal data manipulation language (DML) API, temporal integrity constraints, temporal joins and temporal aggregations are missing. Also, support for multiple application-time period tables are missing too. On the other hand, Flashback Data Archive (system-versioned tables) allows user to go to history and check which record was active at a point in time. This feature is used with Temporal Flashback Query.

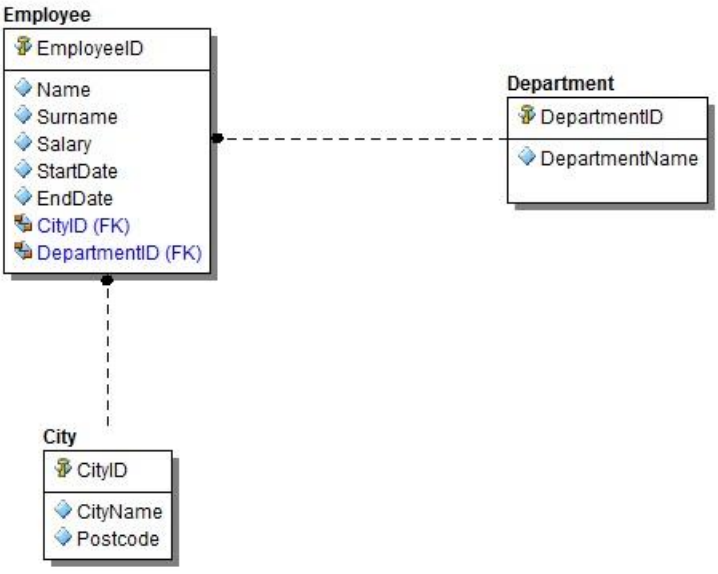

Figure 1: Idef1x schema of database

On Figure 1 Idef1x schema which is used for this research is presented. This model is used to keep records of changes of employee salary, city where employee lives and department. Columns *StartDate* and *EndDate* are temporal features. In case of system-versioned table these two columns are system times, while in case of application-time period table these columns are not overlapping time periods. SQL data definition language (DDL) for creation of tables is given below. First, ordinary table is created.

```
CREATE TABLE EMPLOYEE (
```

```
   EMPLOYEEID     NUMBER(38,0) NOT NULL,
   NAME           NVARCHAR2(250),
   SURNAME        NVARCHAR2(250),
   SALARY         NUMBER(38,2),
   STARTDATE      TIMESTAMP (6) NOT NULL,
   ENDDATE        TIMESTAMP (6) NOT NULL,
   CITYID         NUMBER(38,0) NOT NULL,
   DEPARTMENTID   NUMBER(38,0) NOT NULL,
   CONSTRAINT PK1 PRIMARY KEY ("EMPLOYEEID") )
```

Second, SQL code for system-versioned table is presented below. Since, system-versioned tables are implemented through Flashback Data Archive no need for any modification of SQL statement for creation of ordinary table, but in this paper PERIOD is created in order to get temporal validity features in transactional time. For system-versioned tables to work DBMS_FLASHBACK must be applied to tablespace. Since transactional time should not be changed start and end timestamp are marked as hidden, so it would not appear in SQL query. As a result of PERIOD part of statement, new constraint is added.

```
CREATE TABLE EMPLOYEE_SYS (
   EMPLOYEEID     NUMBER(38,0) NOT NULL,
   NAME           NVARCHAR2(250),
   SURNAME        NVARCHAR2(250),
   SYSTEM_START   TIMESTAMP(6) DEFAULT sysdate INVISIBLE,
   SYSTEM_END     TIMESTAMP(6) DEFAULT to_date('01-01-9999', 'dd-mm-yyyy')
INVISIBLE,
   PERIOD FOR SYSTEM_TIME(SYSTEM_START, SYSTEM_END),
   SALARY         NUMBER(38,2),
   CITYID         NUMBER(38,0) NOT NULL,
   DEPARTMENTID   NUMBER(38,0) NOT NULL,
   CONSTRAINT PK11 PRIMARY KEY ("EMPLOYEEID"),
   CONSTRAINT SYS_TIME1 CHECK ((SYSTEM_START<SYSTEM_END) and (SYSTEM_TIME>0))
ENABLE )
```

Finally, application-time period tables are implemented as temporal validity feature in Oracle 12c DBMS (in same manner as system-versioned table defined above). For system-versioned and application-time period visibility of data in tables with temporal support, `DBMS_FLASHBACK_ARCHIVE.enable_at_valid_time` procedure must be used.

```
CREATE TABLE EMPLOYEE_APP (
   EMPLOYEEID     NUMBER(38,0) NOT NULL,
   NAME           NVARCHAR2(250),
   SURNAME        NVARCHAR2(250),
   VALID_START    TIMESTAMP (6) NOT NULL,
   VALID_END      TIMESTAMP (6) NOT NULL,
   PERIOD FOR VALID_TIME(VALID_START, VALID_END),
   SALARY         NUMBER(38,2),
   CITYID         NUMBER(38,0) NOT NULL,
   DEPARTMENTID   NUMBER(38,0) NOT NULL,
   CONSTRAINT PK111 PRIMARY KEY ("EMPLOYEEID"),
   CONSTRAINT VALID_TIME1 CHECK ((VALID_START<VALID_END) and (VALID_TIME>0))
ENABLE )
```

For every table, defined above, following SQL command applies.

```
ALTER TABLE EMPLOYEE (
   CONSTRAINT FK1 FOREIGN KEY (CITYID) REFERENCES CITY (CITYID),
   CONSTRAINT FK2 FOREIGN KEY (DEPARTMENTID) REFERENCES DEPARTMENT
(DEPARTMENTID) )
```

For this experiment it is expected that temporal tables have slightly inferior performance since it needs more operations to process than ordinary table on all three tests. On the other hand, system-versioned tables should have better performance than application-time period tables since timestamps for start and end of period are not included (they are generated by default).

4. EXPERIMENTAL RESULTS

After conduction of 1000 INSERT statements, for three types of tables, results, shown in Table 1, were gathered. It can be seen that system-versioned tables performed the best with average of 8.21 milliseconds per insert, while application-time period tables performed the worst with 9.58 milliseconds insert on average. Also, each type had at least one long insert, which lasted over 100 milliseconds.

Table 1: Descriptive statistics of INSERT experiments

	Default			System-versioned tables			Application-time period tables		
	Mean	Max.	St. Dev.	Mean	Max.	St. Dev.	Mean	Max.	St. Dev.
Time	8.41	122.00	3.66	8.21	101.00	3.59	9.58	137.00	7.09

Since goal of this paper was to identify whether there exists statistically significant difference between execution time of insertion of data of different types of tables analysis of variance (ANOVA) test was conducted (since time execution have normal distribution). Results are shown in Table 2. Value of F statistic between groups is 21.351 with significance of 0.000, which means that there exists at least one statistically significant difference between groups. In order to see that information Levene homogeneity of variance test will be conducted followed by post-hoc analysis of variance.

Table 2: ANOVA test for INSERT statement

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	1089.549	2	544.774	21.351	0.000
Within Groups	76469.835	2997	25.515		
Total	77559.384	2999			

In Table 3 homogeneity of variance test is shown. Value of Levene statistic is 48.370 with 2 and 2997 degrees of freedom and significance 0.000 which means that variance between groups is different and therefore Games-Howell post-hoc test will be used.

Table 3: Levene statistic of homogeneity of variance

Levene Statistic	df1	df2	Sig.
48.370	2	2997	0.000

Table 4 shows that application-time period tables performed statistically significant worse with both ordinary and system-versioned tables, which leads that this type of tables requires more computer resources, but allows using temporal features.

Table 4: Games-Howell ANOVA post-hoc analysis

(I) Type	(J) Type	Mean Difference (I-J)	Std. Error	Sig.
Default	System-versioned tables	0.20100	0.16215	0.430
	Application-time period tables	-1.16600*	0.25227	0.000
System-versioned tables	Default	-0.20100	0.16215	0.430
	Application-time period tables	-1.36700*	0.25131	0.000
Application-time period tables	Default	1.16600*	0.25227	0.000
	System-versioned tables	1.36700*	0.25131	0.000

Second type of experiment was conducted for UPDATE statements using same settings as for INSERT statement. In other words every group had 1000 executions. Time execution, in milliseconds, is presented in Table 5. As in INSERT statements experiment, system-versioned tables have shown the best performance with average 7.9 milliseconds of execution time. Similar execution time had nontemporal table with 7.94 milliseconds of execution time. Since standard deviation is low, it can be concluded that results are stable. It

is worth to notice that application-time period table had worse result, but not by far with 8.03 milliseconds average execution time.

Table 5: Descriptive statistics of UPDATE experiments

	Default			System-versioned tables			Application-time period tables		
	Mean	Max.	St. Dev.	Mean	Max.	St. Dev.	Mean	Max.	St. Dev.
Time	7.94	183.00	5.64	7.90	30.00	0.94	8.03	26.00	1.52

In order to conclude whether there are statistically significant differences between groups ANOVA test is conducted. Results are shown in Table 6. Value of F statistic is 0.368, which is explained through significance of difference execution time between groups. Since significance is 0.692, it can be stated that there are no statistically different groups, which means that execution time is approximately the same. Because of that post-hoc test should not be executed.

Table 6: ANOVA test for UPDATE statement

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	8.579	2	4.289	0.368	0.692
Within Groups	34917.788	2997	11.651		
Total	34926.367	2999			

Third part of experiment refers to difference in execution time of DELETE statement. Time execution, maximum deletion time and standard deviation are presented in Table 7. Ordinary and system-versioned tables have shown the best performance with average execution time 0.27 milliseconds, but since standard deviation of system-versioned table is lower it can be stated that this deletion was more stable. Application-time period table was, again, the worst with average execution time 0.57.

Table 7: Descriptive statistics of DELETE experiments

	Default			System-versioned tables			Application-time period tables		
	Mean	Max.	St. Dev.	Mean	Max.	St. Dev.	Mean	Max.	St. Dev.
Time	0.27	30.00	1.08	0.27	2.00	0.51	0.33	2.00	0.57

In order to inspect whether there are differences between execution time ANOVA test was performed. Results are shown in Table 8. Since difference in time execution between groups is not significant, it is 0.141 which is greater than 0.05, it can be stated that there are no statistically significant differences between execution times between default, system-versioned table and application-time period table.

Table 8: ANOVA test for DELETE experiments

	Sum of Squares	df	Mean Square	F	Sig.
Between Groups	2.275	2	1.137	1.960	0.141
Within Groups	1739.317	2997	0.580		
Total	1741.592	2999			

Finally, difference between default table and system-versioned table was not statistically significant, but system-versioned table have shown better performance. Therefore, this kind of temporal table have shown that temporal feature is capable to improve software development, since developer does not need to develop date time validation before insert, update or delete of records. Additionally, database administrators can perform history checkup of data, which can be useful in many data analysis applications. On the other hand, application-time period performed slightly worse with statistically significant slower execution time in data insertion, and slower but not statistically significant execution time in update and delete statements. Since difference was a little greater than 1.5 millisecond, it is up to user to calculate whether application will perform slower with DBMS controlling data validation or not. It is worth to state temporal features requires intuitive upgrade of SQL skills, which can be learned easily. On the other hand, Oracle 12c does not have implemented as much temporal features as IBM DB2 database, which can explain execution time performances. One possible usage of temporal features is in analytical databases, especially for slowly changing dimension (dynamic hierarchy) type 2, where ETL process could be carried out with less chance for error.

5. CONCLUSION

Experiment have shown that there exists statistically significant difference between application-time period tables and other types of tested tables, where application-time period tables have shown worse results in execution time. These results are gathered on execution time of 1000 insert statements of each type (total of 3000 records) for each of three experiments.

Conclusion can be made on two levels. First, since there are no statistically significant difference between system-versioned table and ordinary table and execution time of system-versioned tables were faster or with same execution time in every test (INSERT, UPDATE and DELETE) than ordinary tables it is better for software developers to use temporal features of database for several reasons. First, complexity of tedious validation of data is transferred to database level and it is concern of DBMS. This provides better time execution and more reliable data in organization. Second, every historical event can be reconstructed using temporal queries, which can be used for analytical purposes. As application-time period tables is concerned no grounded conclusions can be made, since performance for INSERT was statistically significant worse and for UPDATE and DELETE were just worse. It is up to user to measure whether time execution or data validation and historical information are more important. Second, it must be stated that implementation of temporal features of SQL:2011 standard is incomplete (temporal DML API, temporal integrity constraints, temporal joins and temporal aggregations are missing) and theory about temporal dimension is still in development. Also, it seems to be that Oracle did not want to cope with complexity of time dimension (support for time integrity constraint does not exist) and help software developers to build better software. It does not transfer data validation fully on DBMS. One possible explanation for the lack of temporal features is speed of execution, which we tested here. Therefore, in order to get full picture of performances of temporal features defined in SQL:2011 these experiments should be conducted on other DBMS vendors which implemented temporal features defined in SQL:2011 standard. Compared with DB2 (Saracco et al., 2012) it seems that IBM have made more work on temporal support in database with features like history table in system-versioned tables and ability to create application-time period tables for record without overlapping.

In a future, plan is to inspect other DBMS and compare performances and possibilities each of DBMS vendors. Also, it would be interesting to evaluate different performance of other statement and see whether there is correlation between them. Finally, experiment can be performed on different, much more data intensive, data models and compare performances and evaluate how much database grows (primarily, to compare whether size of database will become unpractical to use compared to memory-less databases).

Abstract: *The subject of this paper is the identification of correlations between the use case model, data model and the desired user interface. Since use cases describe the interaction between the users and the system, implemented through the user interface with the aim of changing the state of the system, the correlation between these three components should be considered at the software requirements phase. Software requirements must somehow be formalized to accomplish the goal to be automatically processed and analyzed. On the other hand, these requirements need to use notation that is understandable for all participants in the software project. We strongly believe that controlled natural language with simple grammar can achieve this goal. Thereby, we have developed SilabReq project. This project includes SilabReq Language, SilabReq Transformation and SilabReq Visualization components. Using SilabReq components it is possible to establish the meta-model of software requirements which enables not only the design and implementation of the user interface, but also the automation of this process. In order to prove the sustainability of this approach, we have been development a software tool which performs the transformation of the model to an executable program code. As a final validation and verification, SilabReq project and the software tool for automation the user interface implementation process has been used for the Kostmod 4.0 project, which was implemented for the needs of the Royal Norwegian Ministry of Defense.*

Keywords: *use cases, use case specification, executable specification, user interface, user interface generation, prototype*

1. INTRODUCTION

The requirement specification, which is commonly represented by the use case model, should be detailed enough to provide the information necessary for the design and implementation of all elements of the software system - starting with the user interface, through application logic which encapsulates domain structure and system behavior, to data storage. However, the requirements specification often lacks the information required to design certain aspects of the system. In those cases, it is left to a programmer to interpret requirements and find solutions, which can often lead to results which do not meet the user's needs, e.g. when considering the user interface, one will find that the requirement specification rarely provides information about its appearance, content, types of components to be used, and so on.

The phases included in the software life cycle are the collection and specification of user requirements, analysis, design, implementation and testing. The design of the user interface starts only after the requirements phase has been completed, or even after the design of application logic.

Contrary to that, another approach to development exists - one which suggests designing the user interface parallel with the requirement specification. This approach is based on the way the user sees the software system, which can be summarized by saying that the user interface is the system! [Vliet, 2008] The reason for that is that the user is not familiar with the structural details and the ways in which the system is implemented. The requirement specification explains how the user wishes to execute a certain task using the software system. The execution of such a task entails an interaction between the user and the system, which forms a particular structure. According to this approach, the user interface should follow this structure so as to attain a higher level of software system usability. The early phases of creating a user interface often do not result in a fully functional user interface, but a prototype whose main goal is to emphasize the questions and presumptions that might not have been clarified using other approaches in requirements engineering. [Pfleeger and Atlee , 2006)]

A very important aspect in software development is the cost of a completion of software project. Given that the production of software is a series of intellectual and technical activities performed by highly-educated engineers, it becomes clear that the cost of the system greatly depends on the time and effort required for its production. The development of the user interface presents a significant part of such a process. [Kennard and Leaney,2010]. A survey [Myers and Rosson, 1992] found that 48% of a software system's programming code is related to the user interface, with about 50% of the entire development time being used for its implementation. Other research in this area has produced similar conclusions [Kivistö, 2000], regardless of the fact that tools which hasten this process and make it easier are utilized in development.

Due to the fact that the user interface represents a direct link between the user and the system, the user often alters the requirements regarding its appearance and structure during the development process. These

alterations occasionally cause changes to be made to the implemented system and often result in the discarding of the interface developed until that point. This means that the entire process must be started again. However, the user may find that even the new solution fails to meet their needs, as they often find it difficult to precisely define the requirement specification.

All these facts impose a need for the automation of the process whose goal is to devise a solution to speeding up the development of the user interface and cutting its costs. This tool would make a more efficient requirement specification process available. The user would then be able to quickly identify deficiencies in the requirement specification and remove them, resulting in the system which meets their needs as closely as possible.

The resulting user interface must be based on user requirements. The significance of software requirements in software development is best illustrated by the research which demonstrates that half of the factors which influence the success of a software project are linked specifically to software requirements. [6] Thereafter, this paper pays a great deal of attention to the process of collecting and specifying of software requirements.

The most widely used techniques for the collection of user requirements today are use case specification, [Cockburn,2000],[Jacobson et al.,1993] and user stories [Cohn, 2004]. The use case specification and user stories share certain characteristics (they are based on scenarios and user's aim oriented), but also differ in a number of ways (they vary in structure, the range of requirements covered, integrity, feasibility, and how detailed they are) [Stellman, 2009] [Cockburn, 2000] [Cohn, 2004]. The goal of both techniques is to specify the intent of the user - what the user wishes to achieve through a desired functionality. By considering the two aforementioned techniques for the collection and specification of user requirements, we can conclude that the use case specification presents a more acceptable solution than the user stories, especially when we wish to achieve automated development of certain software elements. The reason behind this is their structure, integrity, as well as the possibility of including additional details significant to different system aspects. The literature often suggests the use cases as the best choice when using the MDA (Model Driven Architecture) approach. [Fatolahi, Somé and Lethbridge, 2008].

Choosing a technique for the software requirements specification does not solve all the problems which can occur during this process, and which can later have significant consequences. One of the most common problems which occur during the use case specification process is the existence of ambiguities in use cases [Wiegers, 2006] [Silva et al., 2007]. All ambiguities in software requirements must be identified and removed as early as possible in order to avoid additional effort and save time [Frost and Campo, 2007]. Should ambiguity only occur once the implementation phase has been already reached, the necessary changes must be made, which is often very complex, time-consuming, and hard to trace [Lin, Prowell and Poore,2009].

In literature we can find a thesis: If ambiguous requirements are the enemy, the domain model is the first line of defense! [Rosemberg and Stewphens, 2007]. The literature [Cox and Phalp, 2010][Fortuna,Werner, and Borges, 2008] suggests the integration of the use case and the domain model as one way of ensuring validity of software requirements.

This paper will present the results of research whose goal has been to develop a model for the software requirement specification which would be semantically rich enough to enable the automation of the user interface implementation process.

The paper is organized as follows. In the next section, we present an overview of the Silab project and its main characteristics. Section III describes SilabReq project with emphasizes of its main component (SilabReq Language component). In Section IV, we present an overview of the SilabUI project. Finally, Section V concludes the paper and outlines some future works. The specification of the *Register new invoice* use case from the *Point of Sale System* is given in the Section III, while executable Java desktop UI prototype for this use case is shown in the Section IV.

2. AN OVERVIEW OF THE SILAB PROJECT

Silab Project was initiated in Software Engineering Laboratory at Faculty of Organizational Sciences, University of Belgrade in 2007. The main goal of this project was to enable automated analysis and processing of software requirements in order to achieve automatic generation of different parts of a software system.

At first project has been divided in two main subprojects SilabReq [Savic, Antovic, Vlajic, Stanojevic and Milic, 2011] and SilabUI projects that were being developing separately. SilabReq project considered formalization of user requirements and transformations to different UML models in order to facilitate the analyses process and to assure the validity and consistency of software requirements. On the other hand, SilabUI project considered impacts of particular elements of software requirements and data models on resulting user interface in order to develop a software tool that enables automatic generation of user interface based on the use case specification and the domain model.

When both subprojects reach desired level of maturity, they were integrated in a way that some results of SilabReq project can be used as input for SilabUI project.

As a proof of concept, Silab project has been used for the Kostmod 4.0 project, which was implemented for the needs of the Royal Norwegian Ministry of Defense. After finishing this project we have analyzed the results and we calculated that user interface for approximately 75% of total number of use cases have been

completely implemented using the Silab project, and other 10% needed minor manual development adjustments. For other 15% of use cases some parts of UI is also generated using Silab project, but it required much more manual development.

3. AN OVERVIEW OF THE SILABREQ PROJECT

It has been mentioned earlier that one of the advantages of the use case specification over other techniques for the collection and specification of requirements is its structure. This structure is not strictly defined, and different authors present the use case specification in different forms (templates).

Today's literature lists many different formats or templates for use case specification. [Malan and Bredemeyer, 1993][Bittner and Spence, 2003][Cockburn,1997][Coleman,1998.][Jacobsonet al.,1998] These templates primary provide guidelines for structuring use case description. They are a result of the need to standardize the use case specification, in order to ensure that the specification is complete and that the communication between team members in charge of the specification is comfortable.

The use case specification templates describe structural elements that each use case should contain. However, none of the those templates describes in detail the structure of the main scenario or the structure of scenario steps, except for some templates which recommend the numeration of the steps or the separation between the actions performed by the user and the ones executed by the system. The one of the key problems with use cases is their semantics, especially precise notation for specification of the use case actions. Because their semantic are poorly defined, it make them difficult to automatically process and analyze.

The authors [Cockburn, 2000] [Rosemberg and Stewphens, 2007] suggest that all steps in a scenario should be written in active voice, and in sentences with a Noun-Verb-Noun structure. The first noun signifies the doer - the user or the system as the subject of the sentence (depending on whether the action is performed by the user or the system), the verb represents the predicate of the sentence and denotes the action being executed, while the second noun marks the object of the action being performed.

The one of the key problems with use cases are their semantics, especially precise notation for specification use case actions. In his paper [Som´e, 2009], Some defines the abstract syntax of a textual presentation of the use case. The author emphasizes that certain elements (formalisms) of the UML languages such as actions, activities are formally defined through the meta-model (or the corresponding meta-class). On the other hand, UML has not formally defined meta-model for a textual description of the use cases, although text-based notation is a primary notation for the use case description. Therefore, the author defines the meta-model to describe the interaction between system users and systems. Jacobson has described steps in a use case as representing a transaction. He has identified four types of transactions:

- The primary actor sends request and data to the system.
- The system validates the request and the data.
- The system alters its internal state.
- The system replies to the actor with the result.

Even though Jacobson identified different actions in use cases the specification of these actions are left undefined in UML. In his work, Williams uses 4 basic actions (Input, Output, Computation, and Exception Handling) and 4 flow-of-control actions (Selection, Iteration, Inclusion and Extension) for use case specification [Williams, Kaplan, Klinger and Paradkar, 2005] In additional, in [Genilloud, Frank and Génova, 2006] authors were explained limitations of the graphical notation for use case specification and emphasize that use case specifications in natural language should describe the actors' actions of entering data, selecting an option, etc., and so that they can be easily read by system users and other stakeholders.

The SilabReq project includes SilabReq Language, SilabReq Transformation and SilabReq Visualization components. These components are shown in Fig. 1.

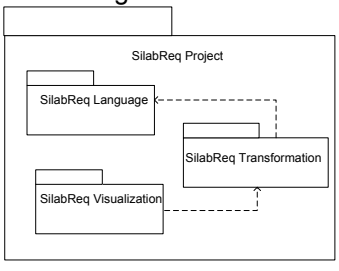

Figure 1. SilabReq main components

Because semantic of use cases are poorly defined, it make them difficult to automatically process and analyze. The goal of the SilabReq Language component is to solve these problems. The SilabReq Language component presents our SilabReq controlled natural language for use case specification [Savić, Silva,Vlajić,Lazarević, Antovic, Stanojevic and Milić, 2012]. It uses textual concrete syntax for definition of the use case context.

In order to accomplish goals SilabReq language is presented as a model. Thus, use cases can be automatically processed and analyzed. We have identified four different types of use case actions and we

have categorized them in two groups: actions which are executed by the user and actions which are executed by the system. Actor executes two types of the use case action:

- Action *Actor (user) Prepares Data for System Operation execution* (first type of user's action - APDSO)
- Action *Actor Call system to execute System Operation* (second type of user's action ACSO)

On the other hand, system executes two types of the use case action:

- Action *System Executes System Operation execution* (first type of system's action – SESO)
- Action *System Returns Results of system operation execution* (second type of system's action - SRR)

We have developed grammar for all of these actions and integrated them into SilabReq language. SilabReq is developed under XText framework. [XText] This framework is based on openArchitectureWare generator [oaW] framework, the Eclipse Modeling Framework (Eclipse Modeling Framework) [EMF] and Another Tool for Language Recognition (ANTLR) parser generator [ANTLR].

The SilabReq Transformation component is responsible for transformation software requirements into different models. Currently, we have developed transformations which transform SilabReq model into an appropriate UML model.

All of these transformations are defined through Kermeta language [30] for meta-modeling. Kermeta is the model-oriented language. Kermeta meta-model is fully compatible with Essential OMG Meta-Object Facility (EMOF) meta-model and Ecore meta-model, which is part of the Eclipse Modeling Framework (Eclipse Modeling Framework EMF).

The SilabReq Visualisation component is responsible for visual presentation of the specified software requirements. Currently, we have developed only UML presentation of these requirements. So, we can present SilabReq use cases through UML use case, UML sequence, UML activity or UML state-machine diagram.

The SilabReq Language component is the base component for the SilabReq project as well as the whole Silab project. Its main part is SilabReq language. The aim of this language is to be used for functional specification of the software requirements in use case form.

The abstract syntax of the SilabReq language is defined by meta-model, while SilabReq grammar is used to define concrete syntax of the language. One of the most import goals of the SilabReq project is to produce domain model [Larman, 2004] from use case model. In order to accomplish this goal we identified actions in use case which contain semantics that can be used to determine initial domain model of the system. In this section we present the meta-model of the SilabReq language and point out the part of this meta-model which is used to determine initial domain model. Fig. 2 shows the meta-model for SilabReq use case model.

We use SilabReq use case model (SilabReqUseCaseModel meta-class) to describe software requirements for particular software system. SilabReq use case model contains the users of the system (Actor meta-class), set of identified use cases (UseCase meta-class) and set of identified domain entities (DomainConcept meta-class). We have designed SilabReq language so that each domain entity that is determinate in use case specification must be declared firstly. Thus, we have reduced the possibility to use synonyms as well as homonyms in use case specification. Fig. 3 shows the meta-model for SilabReq use case.

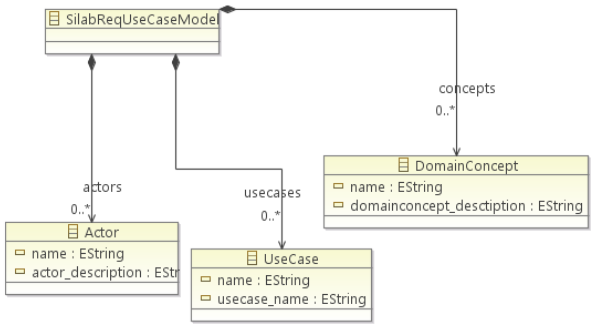

Figure 2: Meta-model for SilabReq use case model

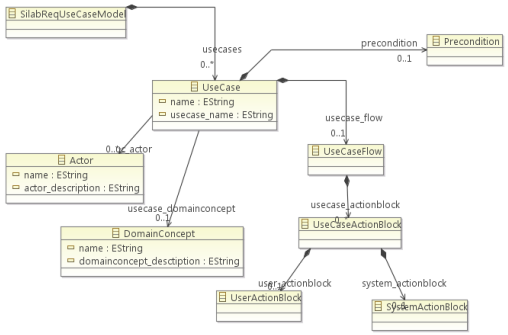

Figure 3: SilabReq use case meta-model

The following part of this section contains the specification of the *Register new invoice* use case from the *Point of Sale System* (Fig.4). This use case includes *Find customer* use case. Both of them are executed by the actor with Worker role.

Actor: Worker
Domain concept: Invoice
Domain concept: InvoiceItem
Domain concept: Product
Domain concept: Customer

UC: UC_FindCustomer "Find customer"
Actors: Worker
Use case domain concept : Customer
USE CASE FLOW
USER ACTIONS:
apdso: «1**»** Worker ENTERS data for search Customer "ID" or Customer "firstName" or Customer "lastName"
acso: «2**»** Worker **calls system to** find customer
SYSTEM ACTIONS:

```
    RESPONSE:
      SUCCESSFUL RESPONSE
        Data: SHOWS Customer  AND ALL CUSTOMER Invoice
      END SUCCESSFUL RESPONSE
    EXCEPTIONS
      "System did not found customer"  action "end use case"
    END EXCEPTIONS
    END RESPONSE
  END SYSTEM ACTIONS
  END USE CASE FLOW
END USE CASE

UC: UC_SaveInvoice "Register new invoice"
Actors:Worker
Use case domain concept : Invoice
  Precondition:
    Domain concept: Customer
    constraint description: "must be register in the system"
  End precondition
  USE CASE FLOW
  USER ACTIONS:
    include:UC_FindCustomer
    acso: «1» Worker calls system to create new invoice
  SYSTEM ACTIONS:
  RESPONSE:
    SUCCESSFUL RESPONSE
      Message: "Invoice is created"
      Data: THE LAST CREATED Invoice
    END SUCCESSFUL RESPONSE
    EXCEPTIONS
      "Invoice is not saved"  action "go to action 1"
    END EXCEPTIONS
  END RESPONSE
  END SYSTEM ACTIONS

  USER ACTIONS:
    apdso:«1» Worker ENTERS Invoice "date" when the Invoice is
created
    iterate
      apdso:«2» Worker CHOOSES Product which want to put on
InvoiceItem
      apdso:«3» Worker ENTERS InvoiceItem "quantity" per each
Product
      acso: «4» Worker calls system to add invoiceitem on the
invoice
    end iterate
    acso: «5» Worker calls system to save invoice
  SYSTEM ACTIONS:
  RESPONSE:
    SUCCESSFUL RESPONSE
      Message: "Invoice is saved"
      Data: THE LAST SAVED Invoice
    END SUCCESSFUL RESPONSE
    EXCEPTIONS
      "Invoice is not saved"  action "interruped use case"
    END EXCEPTIONS
  END RESPONSE
  END SYSTEM ACTIONS
  END USE CASE FLOW
END USE CASE
```

Figure 4. Use case specification in SilabReq language

The use case flow for the *Register new invoice* use case contains two pair of the user and the system blocks. The first block of actions is used by the actor to find an appropriate customer and to create new invoice. The second one is used by the actor to enter data for that invoice (actions form 1 to 4 in the second block).

4. AN OVERVIEW OF THE SILABUI PROJECT

The goal of SilabUI project is the identification of impacts of particular elements of software requirements and data models on resulting user interface in order to develop a software tool that enables automatic generation of user interface based on the use case specification and the domain model.

We can often find the recommendation to omit information about the user interface from the use case specification. [Larman, 2004] As one of the most common mistakes in the use case specification, authors mention existence of details related to the user interface. This recommendation comes from the legitimate concern that details related to the user interface can distract the stakeholders from the essence of the problem being analyzed when specifying software requirements. Information about the user interface is of no importance when describing the goal and the aim of the user, while the user's goal and aim are essential for use cases. However, the fact that information about the user interface is so often found within use case specification testifies to the necessity of establishing clear relations between the user interface design and the interaction between user and system as described by use cases. [Sinnig, Chalin, and Rioux, 2005]

A single use case can be realized through different templates [Antović, Vlajić, Milić, Savić and Stanojević, 2011]. By using the tools for automatic user interface generation created for the purposes of this research, it is possible to quickly and easily obtain a completely different user interface for the same use case by making simple adjustment of the selected template in the model. This way, the stakeholder can try out different templates during user requirement specifications, and decide which one suits their specific use case best. Templates are designed in such a way that they can be combined, which means that different templates can be used for a single use case and its parts.

The following part of this paper will provide an example of combining different templates into multiple depth levels. This example demonstrates one of the solutions, attained by automatically generating a user interface by utilizing a developed code generator, for a highly complicated use case which processes the entity in four levels of depth. The example shown is a part of the user interface designed for the project Kostmod 4.0, which was implemented for the needs of the Royal Norwegian Ministry of Defense. Even after familiarizing them with the potential problem, the customer decided not to deviate from their original plan. In the end, the problem was solved by combining a number different user interface templates (Fig. 6). The diagram shows a simplified data model - the part of the data model to which the aforementioned example refers to (Fig. 5).

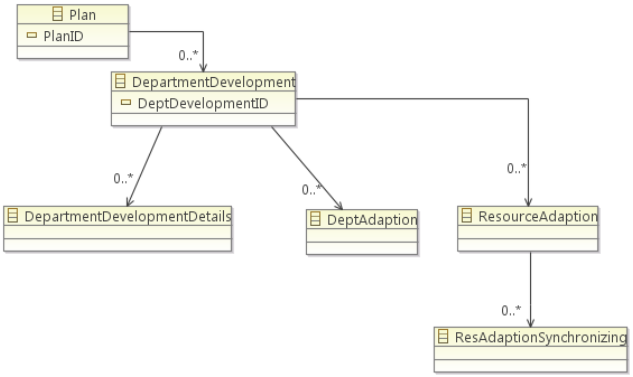

Figure 5. The part of the data model illustrating the example of combining different UI templates

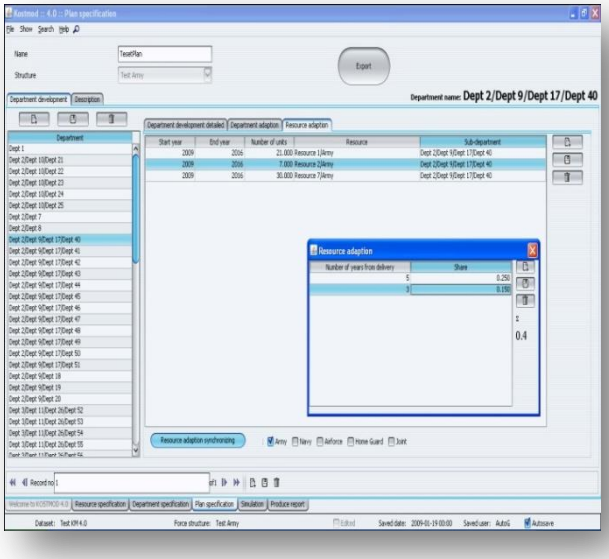

Figure 6. An example of combining different user interface templates with four levels of depth

The goal of SilabUI project was to develop a model for the specification of software requirements which would be semantically rich enough to enable the automation of the process of implementing the user interface. The basis for defining such a model are the relationship between the use case model, the data model, and the desired user interface, which were noted in the previous chapters. Considering how use cases describe the interaction between the user and the system, which is realized via the user interface and whose goal is to change the state of the system, the connection between these three components must be represented appropriately, so as to enable the automation of the user interface implementation. When defining a model, one must take care that the model follows good practice in the specification of software requirements, which means that it should provide a frame for the specification of requirements which will be understandable to all of the interested parties that take part in this process - from the engineers, to the final users.

The software requirement specification is supposed to contain information about the goal and aim of the user when executing certain system functions, and should not include implementation details, such as details about the user interface or the realization of other parts of the system. In order for the specification to remain completely in the domain of the problem, and not in the domain of the solution, it is necessary to split these two domains through a model, and make the problem domain independent of the solution domain, which usually contains one or more possible ways of realization. As the development of the model is based on the relationship observed among the use case elements, the data model, and the graphical user interface, a SilabUI meta-model has been developed. In order to enable the automatic generation of user interface through a model based on the illustrated meta-model, this model must be defined in a form which is suitable for manipulation by a Java program which will be used to realize a generator, but which is also readable and understandable by all the stakeholder during the process of requirement specification. XML is usually listed as the most suitable format for this purpose, as this language with a simple syntax is legible for both humans and computer programs.

In order to separate the specification of software requirements and information about the user interface, the user interface creation model would be specified using two separate XML documents. The first XML document represents the use cases, and part of the data model to which the use case relates, and this data is stored in the UIReq.xml file. This file can be manually created, but it can also be automatically created using SilabReq Transformation component from SilabReq project. The second XML document contains information about the elements of the graphic user interface, and every element of this document refers to a particular element from the defined UIReq.xml file. The content of the second document is specified in the UIReqExtension.xml file. The existence of the second document is not mandatory. In case the second document is not created, the default user interface elements (such as user interface templates and graphical components) will be used for displaying the use case described within UIReq.xml file. Should the requirement be that the user interface differs from the implied settings, these settings are specified in the UIReqExtension.xml file.

In order to prove the sustainability of this approach, a software tool – SilabUI generator was devised to conduct the transformation of the defined model into executable programming code. This will enable the creation of a user interface in the early phase of the software's life cycle. The figure bellow (Fig. 15) presents generated executable prototype the *Register new invoice* use case. This, in turn, gives the possibility to validate and verify user requirements, and reduces the time and effort required to implement the user interface. This software tool enables the generation of executable programming code for the interface of a

Java desktop application. The application can be used to perform basic operations on data from a relational database for a defined use case which, according to some research, includes up to 80% of all use cases describing a software system [Nakatani,Urai, Ohmura and Tamai, 2001].

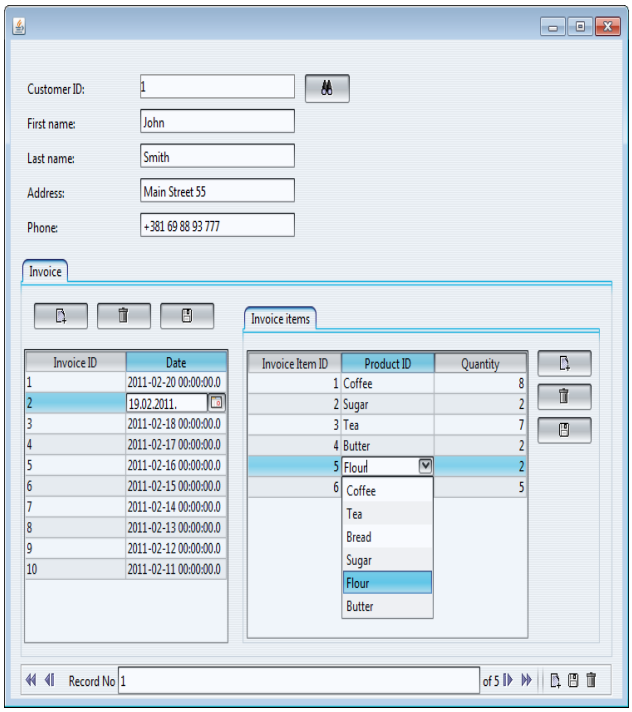

Figure 7. The prototype of the *Register new account* use case

5. CONCLUSION

This research considered the relationship which can be observed among the elements of the use case specification, the data model, and the user interface. Based on these perceived connections, a meta-model of software requirements had been developed - one which considers the elements of all three aforementioned system aspects. Using this meta-model, we can create a software requirement model which enables not only the formal specification of the user interface but the automation of this process as well. This process is supported through Silab project.

Potential further research in this area could relate to: (1) The examination of the applicability of the meta-model to various technologies and platforms (desktop applications in different technologies, web applications in different technologies and so forth), (2) The enrichment of the meta-model and generator so as to ensure support for the realization of various architectures of the resulting application, (3) The enrichment of the model with the possibility to specify more complex validation rules, (4) Ensuring the adaptability of the user interface (5) Generating different types of the automated tests.

SOFTWARE DELEGATES AS A METHOD OF CODE ORGANIZATION WITHIN CONTEXT ORIENTED PROGRAMMING ENVIRONMENT

Branko Stevanović, Saša D. Lazarević
University in Belgrade, Faculty of Organizational Sciences, slazar@fon.bg.ac.rs
Marvelsoft SA Lugano Switzerland, branko.stevanovic@marvelsoft.net

Abstract: *This paper will present a new approach in organizing elements and entities according to the specific demands of the Context oriented programming (COP) method in software engineering. Context oriented programming is defined by dynamic elements within the communicative organization of multiple entities and, as such is in contradiction with the usual software organization in programming languages with static type checking. After dealing with the mentioned problem for several years and existing published solutions created in the Software Engineering Laboratory at the Faculty of Organizational Sciences, the authors are presenting a new method of communication between entities and describe the outlines of reaching the solutions. In this way, advantages of Context oriented programming paradigm are presented in the modern static type checking programming languages, primarily C# which was used for the practical application of the presented model.*

Keywords: *software, software development, software pasterns, Context oriented programming, software engineering*

1. INTRODUCTION

Software engineers and architects community worldwide is constantly occupied with the search of better and more wholesome methods of describing real environments in computer software development. This search is fueled mostly through pressure of making quality software more efficient but also through the personal curiosity and challenges within the community. Context oriented programming is among newer methods of software development and presents an abstraction of context within software development. Context is a central place where all the executives of the practical tasks meet, scenario by which the task can and should be completed and finally, the skills required to solve the task successfully.
The paper will further examine all the entities that are taking place in developing COP software and will also include a short presentation of the application which authors use as a proof of the sustainability of the presented model. It will also include a theoretical overview of programming code organizations which influenced the implementation of the presented method of program structures. The paper will also describe the step-by-step solution for the problem at hand in detail.
In the next section will be introduced key elements and entities of COP model; the third section is about MixIn and Trait principle of organizing programming code; the forth section is about dynamic change of entities during the execution time; the fifth section is about the delegates' impact on the software design; the sixth section is about lambda expressions, anonymous methods and their place in method application; last sections, seventh and eighth, are dedicated to case study and application in practice.

2. KEY ELEMENTS AND ENTITIES IN THE PRESENTED COP MODEL

Within the suggested paradigm, context takes up the central place due to the fact that it determines the behavior of executive parts of the problem's solutions. In other words, different contexts require different behavior from the same executives in order to solve a context-defined problem successfully [1]. The paper will explore an example of the possibility of the same executive behaving in various solutions as well as the method by which it was applied in the suggested model. What is new and highly interesting is that the executive entity bears no knowledge of the ways to solve the problem prior to reaching the environment of the problem itself. Skills and knowledge required to solve a problem are only being awarded to the executive entity within the problems context, and in the end, upon solving the problem, the executive entity leaves the problem are with no saved knowledge of steps that brought it to

the solution. Each and every time the same entity encounters the same problem, it will receive the information all over again.
This method allows the entity to exist on a very simple level as it only bears information about itself, Changing the skills required to solve a problem, which is certainly a legitimate situation within software development, no changes will be required for the entity itself. It is protected in it's own ignorance (dumb entity) which in turn makes it simple and easy to maintain. Although the concept itself seems simple and logical, static type check languages have no easy solutions for the described method. Simply put, static checking types within those languages have to be fully described and formed prior to the execution time in order to pass the check during compiling. Workaround methods circumventing the static type check for the purpose of accomplishing the described functionality have been of interest to the authors of this paper for several years now and, after publishing other solutions we present a new way of solving the problem [2]
As already mentioned, COP model solution described in this paper contains several required elements:

- Context
- Scenario
- Skill
- Role

The following sections will further explore each of the mentioned elements:

2.1 Context

Context is the environment of the complete software process. Context is a singleton, there can only be a single one during the time of executing the application [3]. That's the place where roles meet their tasks. Context has no information of roles or tasks. It is externally initialized, mostly by the software's user and most often by the user's GUI. External initialization in the specific example means that the Scenario's name will be forwarded to the Context. Context has access to the catalog of scenarios which lists the known scenarios and related roles and skills. Engineering-wise, the catalog can be conceived in numerous ways, from a relational database entry to a simple text file. Application used as the example uses JSON (Java Script Object Notation) document as a catalog Based on the received Scenario name, context initializes the surrounding. Within our application, context uses the reflection space of the name and the possibility of dynamic creating of class instances in order to instance the already built Scenario. Scenario, further on, posses information about roles and required skills to complete the tasks successfully,

2.2 Scenario

Scenario bears information of the required tasks, it's executioners and the skills required for the task to be completed successfully. Scenario will instance all objects required for the completion of the task. Each scenario inherits the joint interface within the environment which acts as a contract that ensures a common collection of functionalities that are of interest for the environment. This allows for the coexistence of all scenarios. Scenario has the highest level of importance compared to other objects and also has the highest level of knowledge of other objects included in the process. Once instanced, scenarios does not communicate with context in any way.

2.3 Skill

Skill is the description of the algorithm used to solve a specific problem. It embodies the knowledge, the skill that the executioner has to possess in order to complete the task. The executioner is irrelevant for the skill meaning that anyone can execute the solution since the knowledge is in no way connected with it specifically. Executioner receives the required knowledge once it is required. In the same way, it 'forgets' it once the task is completed. Within COP, the knowledge is dynamically injected to the executioner during the executing time. Methods of injection the knowledge are the basis of interest of the paper's authors for quite some time and this paper is a result of exploring this specific problem. The methodology itself will be explained in more detail later in the text.

2.4 Role

Role or the executioner is the last required entity within the presented software model. The concept that the authors follow within their research is very well described by Koplin and Bjørnvig. According to them, the role entity should be knowledge-free or 'dumb', that is only the description of the entity and it's traits, not a description of the functionality. [4] Of course, in order for the executioner to complete the assigned tasks, there has to be a place where it will receive the necessary knowledge and also a way to activate that knowledge in order to complete the work. In the example application, each executioner inherits the Role interface that obligates each child object to implement the public method “DoIt” which is the place where the knowledge is provided and which can start the execution of the specific task.
This concludes the listing of the types of entities that form the presented model of Context oriented programming environment. This would also be a required minimum. The number of individual examples of each entity is not limited by anything other than the domain described by the software. Authors that wish to apply the model can implement other entities according to the needs of the software application they're writing. The authors of this paper themselves use other entities which do not fall strictly within the listed categories but are entities that further describe the domain that's being realized. The organizational model described in this paper is completely open to such independent objects.

3. PROGRAMMING INFLUENCES USED IN THE PROJECT

Software engineers are trying to fulfill the need for a different organization of the object oriented code for quite some time now, using different, more or less successful solutions. A distinct direction in new solutions is the tendency to compose objects out of different elements using a 'has a' rather than 'is a' approach. Suggested solutions which are explored in this and previous papers are Mixin and Trait objects which will be further explored.

3.1 Mixin principle of organizing programming code

Mixin objects are classes in object oriented programming that are ready to be 'mixed' with methods form other classes [5]. This allows for the avoidance of class inheritance thus following the Composition over Inheritance principle which, as a result, produces a readable code that can be used in multiple ways. [6] As per the original idea, Mixin delays the 'mixing' moment until the execution time. That way, Mixin also counters the primary idea behind the static type checking languages. This contradiction is being solved differently depending on the language used. C# can implement the Re-mix library (http://remix.codeplex.com/) which solves the basic problem of changing the class during execution time.

3.2 Trait principle of organizing programming code

Trait is by definition a "collection of methods used as a simple conceptual model for structuring object oriented programs" [7]. Trait is a simple group of methods that serve as building blocks for classes and are the basic element for code reuse. Scala programming language has trait usage implemented. Trait uses different language tricks, depending on the specific programming language in order to effectively and dynamically compose multiple classes into one. C# has no built-in ways to purely implement Trait concept. That way, Trait can only be seen as an influence while looking for original solutions within C#.

4. DYNAMIC CHANGE OF ENTITIES DURING THE EXECUTION TIME

The problem being considered here is directly connected with the basic characteristics of procedural programming languages. Among a number of different classifications, here, we're interested in the differences based on the built-in type checking mechanisms. In this respect, it's possible to isolate two major groups:

- Static type check languages
- Dynamic type check languages

Languages with static type check presume that each variable must be explicitly declared according to the type it belongs to because the type check will be completed prior to compiling, i.e. the compiling won't be possible if there's any doubts about the data type of each variable. This means that it's not possible to compile a program that includes a variable that can't be precisely attributed to a certain data type. The most widely used languages of

this kind are certainly Java and C#. The relation between dynamic and static type checks is of key significance for this research. Dynamic executive entity change during the execution time is the prerequisite for context oriented programming. This, of course, opens up the issue of implementing the paradigm in the static type check languages[8]. Previous papers we published explore several methods for dynamically changing user defined types during execution time. Some of the solutions presented directly stem from the evolution of C# itself. There's several possible ways of dynamically changing data types using new built-in language possibilities and that's by using:

- Type extensions
- Dynamic libraries

Both methods are the result of the Microsoft's DotNet Framework division's efforts in trying to bring C# closer to dynamic languages. The most probable reason is the growing popularity of web applications and languages such as JavaScript And Python [9]. It's a fact that a number of programmers today gains their first coding experiences using these languages and the goal is to bring C# closer to their way of thinking. It should be noted that after these changes, C# can't be easily classified as strictly a static type check language and the developer's tendency to make it more like dynamic languages must be taken into account.

Implementing dynamic entity characteristics using the Weaving method is not a part of built in C# capabilities but the result of the programming community's efforts to enable the Aspect oriented programming paradigm [10] in a DotNet environment. Weaving method is more of a brute force approach but is remains an effective form of changing user defined objects during execution time. [2]

5. DELEGATES, PRINCIPLES AND EXPLANATION OF THE SOFTWARE PARADIGM.

Delegates are not a new concept in OOP. They're not always called the same in different languages but all the relevant object oriented languages have a similar concept in place. In software engineering, the delegates influence the design to have each object delegate the assigned task to it's attached object, instead of doing it itself. That way, the responsibility of the software object is removed. Delegated object doesn't have to inform the delegator of the task completion.

In C#, the delegate is a type of data. It's a very important characteristic. The delegate is also a type with it's own signature in the form of a parameter list and the expect type of the return information.

Based on this, it's logical to expect that delegates in C# point to a method in a certain way. This is not a new concept either and has existed since C++ which had the concept of variable's function pointer which could be forwarded to a different entity as a parameter. Delegates in C# can also be forwarded as parameters to a different known instance. Delegate can activate each available method as long as the signatures' are appropriate i.e. as long as the elements of the parameter list are ordered by the same type and the expected result is of the same type as well. A typical delegate in C# would look like this:

```
public delegate int Calculate(int x, int y)
```

Calculate delegate can activate any operation that has two normal numbers as parameters and that expects two normal numbers as results as well. This way, it's possible to have a whole sequence of operations such as:

```
public int Add (int x, int y)
{
        return x+y;
}
```

or

```
public int Subtract (int x, int y)
{
        return x-y;
}
```

and of course, further on, the multiply method and many others as well, proved that the method signature is the same. It's obvious that, in this way, the concept of delaying the decision until the execution moment is possible, deciding on the specific method that has to

be called upon. Specifically, if during the execution, based on a dynamic condition two numbers need to be added, method Add will be called in the following way:

```
Calculate add = Add;
add(2,4);
```

The system will receive the return information as the sum of 2 and 4 (6). In the same way, if the conditions point to the need of subtracting the numbers, the Subtract method would be called in via Delegate in a similar way:

```
Calculate subtract = Subtract
subtract(2,4)
```

with the system receiving the value of -2 as the result.
What's even more interesting is the possibility to forwarded the method via delegate as a parameter. This way, the following method would be legitimate:

```
public int DistinctProcedure(Calculate operation)
{
        return operation(2,4)
}
```

and we could activate it from any available part of the application as:DistinctProcedure(add) orDistinctProcedure(subtract) etc.
This shows the general concept of placing the information during execution time into a different object which is the subject of this paper as well. A similar concept has been used in the example application and will be further explained.
The advantage of the method shown is the possibility to use the built-in capabilities of C# without the need for external libraries or complicated language tricks. Concept is known and used since the existence of C# as well.

6. LAMBDA EXPRESSIONS, ANONYMOUS METHODS AND THEIR PLACE IN METHOD APPLICATION

Lambda expressions have found widespread usage in numerous scientific and technical areas and their explanation in full overstretches the boundaries and possibilities of this article. In software engineering, lambda expressions have been used since the very first theoretical beginnings, Turing's universal machine and Turing's theory. C# borrows lambda expression elements on a large scale from mathematics, also with the theory of anonymous functions. The possibilities of lambda expressions in C# are relatively new and are present since version 3.0. What's written down in math as:

$$(x, y) \rightarrow x \times x + y \times y$$

can be written in C# as:

```
(x,y) =>{x*x+y*y};
```

The system will know to forward the values of the sorted couple to the anonymous function x*x+y*y and that it can await for the result of the function. Incorporating lambda expressions turned out to be a huge step forward for C#'s flexibility and compatibility. Anonymous functions also have their own technical specifications meaning that the system has no instanced method in memory, and thus, no references for the method either. Anonymous function has complete in-line execution - when the program flow encounters it, it executes the method and after execution there is no trace of it in the system until the next execution - that way, there's also no need to clear the system from methods or stack keeping etc. What's interesting for our research in regards to lambda expressions is the possibility (available since C# 3.0) to attach a lambda expression to the previously described delegates. This results in an encapsulated variable that carries with it complete information about the method being executed and, as such, can be forwarded as a parameter into any available part of the application. In the code itself, it's possible to write:

```
delegate int Calculate(int x,int y) = (x,y)=>{x+y;};
```

and to forward such a delegate as a parameter containing all the necessary information in regards to the execution of the required method. Even more compact, it's possible to make anonymous delegates and forward them as the method parameter. Since C# 3.0, special types of delegates have been introduced:

- Action (delegate with the return value of the void type)
- Func (delegate with the return value)

which make writing the previously mentioned expression as:

```
Func<int, int, int> calculate = (x,y) => x + y;
```

and forwarding it as a parameter in function:

```
DoIt (calculate, x, y);
```

which allows for a very compact way of information transferring which was of the prime interest for the research at hand.

In order to encapsulate functionalities in scenarios, authors use the Action<T> delegate type incorporated in C# which is a void type, meaning it sends no results back. Technically, there's no obstacles to do it via the Func<inT,outT> type and ultimately, there's no obstacles in using the delegates in the same way they were used prior to 3.0. It is necessary to adjust the scenario logic in those cases requiring return information.

7. DESCRIPTION OF THE APPLICATION USED AS A STUDY EXAMPLE:

The application used to confirm the theoretical model is created using solely C# 4.0 programming language. The development environment used was Microsoft VisualStudio 2012 (http://www.visualstudio.com/). Application's front end was developed using the WPF (Windows Presentation Foundation) technology but could also be completed using any other technology, bearing in mind that it's completely separated from the applications logic itself.

The idea was to create multiple scenarios which:

- don't have to be connected in any way
- share certain elements or entities

It's necessary to check the applications functionality in such conditions. That's how the following scenarios were created:

- Text manipulator
- Money transfer
- Square root computing using the Newton method
- Account cash payments

Scenarios' names themselves point to the fact that two of them share certain domain similarities and those are the money transfer and cash payment scenarios. It's also obvious that there's two additional scenarios that are in no way connected to the previous two. In this way, the application can be tested to solve a certain problem in three unrelated domains where each domain bears all the necessary elements that were described above but that there's also a domain that has all the elements but two scenarios solving independent problems as well. This domain proves the idea that a certain Role entity can be infused with different information and that it can successfully complete tasks requiring that information.

Meanwhile, there's no changes to the Role entity itself, as will be shown.

Each of the listed scenarios has it's individual characteristics. Most obvious ones would include the number and the type of parameters required to complete a task - the text manipulator requires the text to be edited, Money transfer has the accounts and money amount etc. A problem with unifying entities with different types and number of parameters is shown. This problem was solved in a way that has been present in C# for a long time and that's the making of a sequence of objects and using keyword params in order to inform the method that there's a possibility of no data showing as an argument[1]. This method itself is not particularly elegant since there's the need to convert the received parameters in the required data type. Still, it's efficient and simple enough for a junior programmer to use. Similar method is applied to the Main method in the command promp (console) of C# applications. The method is built in in the automatic creation of Console application projects within Microsoft Visual Studio environment. This makes the explained method familiar for most programmers using C#. This is probably the biggest compromise required for the survival of the entity consistence in the observed organizational model. Specifically, Role entity received a DoIt method that looks like this:

```
public override void DoIt(Action<object[]> action, params object[] args)
{
    action(args);
}
```

Skill entity now has an Action type property wit the following signature:

Action<object[]>

in order to be compatible with the DoIt method in the Role entity types.

[1] http://msdn.microsoft.com/en-us/library/w5zay9db.aspx

7.1 Text manipulator:

The text manipulator is the first scenario in the application. This is the simplest one, both logically and technically and it's purpose was solely to prove the concept on the simplest example. The scenario will be described since specifically due to it's compact and simple nature.
The task of the scenario is a menial one, inverse writing of the given text. The execution flow follows:

- User requests the context with the scenario's name text bia GUI
- Context looks for the Scenario within the catalog, based on the name given as a parameter
- Context creates the scenario and starts it's execution
- Context has no interaction with the started scenario anymore, it waits for the next new scenario request.
- Scenario knows who is included in the text manipulation and creates new TextManipulator instances, the Role type entity and instance TextManipulationSkill which is the skill type entity.
- It forwards the information to the TextManipulator in the form of an Action delegate with all the the necessary text transformation logic, as well as the text that needs to be changed as a second parameter of an object sequence type (object []).
- TextManipulator bears the DoIt method that was previously described. As soon as it receives the necessary arguments, DoIt method is executed using logic received as skill and application writes the inverted text at the user's screen.
- After executing the logic, all the entities from the TextManipulation scenario dissappear from the application's execution area automatically.
- Application is ready to execute a new scenario.

The same steps are used for all the other listed scenarios, the logic and the data is different but the sequence, being also the main algorithm of the system does not change with different scenarios. This results in a Context oriented programming environment as requested by this research.

8. TRANSFERRING MONEY AND CASH PAYMENTS, TWO SCENARIOS OF THE SAME ROLE

These two scenarios are no different to the already described Text manipulation scenario, in respect to the execution flow. The reason for explaining these two scenarios is the implemented realization of two scenarios with a single role. Both scenarios have the same executioner, a user type, class Accountant
that's being provided with different information for both of the scenarios and that can successfully complete the required tasks. This is in essence the proof of the concept described in regards to the Mixin organizational principle that speaks about creating a software code that requires no inheritance but works based on composition and valorizes composition over inheritance.
The usual way of creating a business application via Object oriented programming would be creating an Employee class and than a whole sequence of classes which would implement the Employee and provide it with one or more extensions in order to cover all the possible positions of the employee that are of interest to the application. In an average business informational center, this would very soon result in a huge number of classes which would complicate the understanding of the system and it's maintenance.
On the other hand, the shown model would contain the Employee class and than a sequence of skill classes which by themselves would be algorithms required for completing certain tasks. When needed, the Employee class would be provided with the required skills during execution time. We firmly believe that this would result in a more logical and easily understandable system, making it more simple to maintain as well.
Another observation is worth noting, in regards to these two scenarios. At the very beginning of this paper, we allowed for the possibility of enhancing the observed model with other entities, aside from the required ones. These entities would further describe the domain. In these scenarios, the Account entity is present - although not a pre required one, it is necessary for the domain's full description. This shows that the application works with no problems with additional user defined types, regardless of their form.

9. CONCLUSION

The goal of this paper was to point out to different possibilities of organizing large, mostly business applications written in C#. The paper describes one such system and the technical ways of making a functional solution possible. The described method is fully supported with built-in C# capabilities and requires no language tricks, external libraries or other exotic solutions. It only requires a slightly advanced understanding of the language and the good will to use according to the way shown. Applying this method in practice, however, is highly limited due to the established and worked-out solutions that are first of all satisfactory and also thoroughly backed up with literature, examples and experiences of the programming community. With this in mind, the authors bear no illusion that the suggested methodology would influence the practice significantly but they hope to contribute to the overall corpus of knowledge within the community by presenting and explaining an alternative concept which greatly differs from the mainstream solutions.

Abstract: *This paper presents the ability to monitor the performance and usage of a target computer system running on the GNU/Linux operating system and predefined command execution using Seraphim, open-source Linux kernel module. Seraphim's primary target audience are business users. It provides the vital ability to answer the following question: „Who has asked for which resource, and at what time did he ask?". Seraphim can also be used for various other puproses, for example in education purposes. It has a modular structure and is easily extendable. Seraphim is published as an open-source project, under the GNU/GPL license.*

Keywords*: Linux, security, monitoring, kernel, module, system programming*

1. INTRODUCTION

In the previous years there has been an increased number of cyber attacks on operating systems based on the Linux kernel (Sophos Security Threat Report 2013, 2013). Considering the reasons that the number of computers and handheld devices running Linux is on the rise (The rise of Android: from 32% to 65% in two years, n.d.), there is an increased need for security and resource monitoring. Therefore, there is also a need for adequate software tools specially suited for such a task. Seraphim was created to aid in the prevention of Linux based operating systems (such as GNU/Linux and Android) abuse by providing an interface to keep track of specific Linux resources and execute specific commands. Its target audience are business users; however it can be used for various other purposes, for example in education.In the next section, problem statement and motivation for developing Seraphim are given. Section three provides with three use cases for Seraphim in its different configurations, while section four gives a review of existing tools for Linux resource management and command execution. In the Section five, Seraphim structure and subroutines are described. Following section contains information about kernel communication. Section seven describes Seraphim logging facilities, while Section eight presents the command execution feature. At the end of the paper, conclusions and suggestions for future work are given.

2. PROBLEM STATEMENT

Looking at the usage of Linux in business (Linux Adoption Trends End User Report 2013, 2013), one can conclude that security and continuous control are a necessity. In these turbulent times, the ability of knowing who asked for which resources and at what time is of vital importance, also activities such as auditing and user provisioning are important parts of an identity and access management system (Milenković, Šošević, & Simić, 2012). At the moment, there is no adequate tool on the market that could provide these features effectively. Consequently, there is definitely a need for tool which would allow business users to effectively track their resource usage and execute predefined commands to aid overall security of the system.

Furthermore, such software can be used in education, specifically in computer security training, where it could provide insight into key resources defined before compilation, allowing the user to see how the system is responding to a given training scenario. Another notable usage would be in the field of Electrical and Computer Engineering, providing a safe and redundant solution to tracking resources while testing new software and hardware configurations, without having to attach an external debugger.

The software that is the topic of this paper, Seraphim, tends to provide the ability to monitor Linux kernel resources, execute commands and keep logs of given actions. The software is provided as open-source, under the GNU/GPL license. (Ţivadinović, n.d.)

3. USE CASES

Seraphim may be used:
- as an intrusion detection and prevention tool,
- as a hardware and software configuration testing tool,
- as a resource monitoring tool,
- to avoid memory dumping for analysis,
- for honeypot computers, and honey networks,
- for tracing scripts,
- as an educational tool.

In this paper we present use cases for the first three possible applications of Seraphim.

Considering Seraphim's usage in detection of intrusions, assume the situation where a crucial computer system has been compromised by the means of infiltration by unauthorized users. In this specific case, Seraphim can generate a report of resources compromised with the dates and times of them expressing unusual behaviour, and, if programmed, execute sanitation and prevention commands that would reinfore the security of the computer system while preventing the malicious user from further action against the target computer system. Without specific software for the detection and prevention of intrusions, the computer system is left vulnerable to infiltration and exploitation, both internal and external.

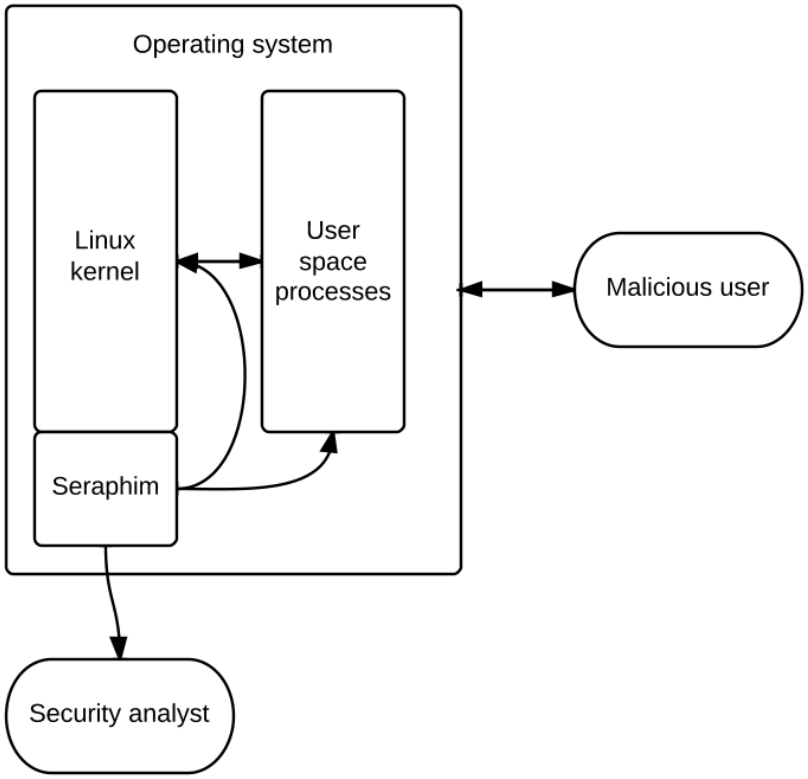

Figure 1: Usage of Seraphim as an intrusion detection and prevention tool

It is also noted that Seraphim can be used in the field of Electrical and Computer Engineering as a tool to track resources while testing new software and hardware configurations. The first step in using Seraphim for this purpose is to compile it with the list of resources that need to be tracked and, if required, commands that should be executed. After that, the person that is testing new software and hardware configurations must load Seraphim into the kernel before the testing begins. During testing, the person performing the tests can have direct access to predefined resources, vastly simplifying the cost and time required for testing with alternate tools, such as JTAG debuggers.

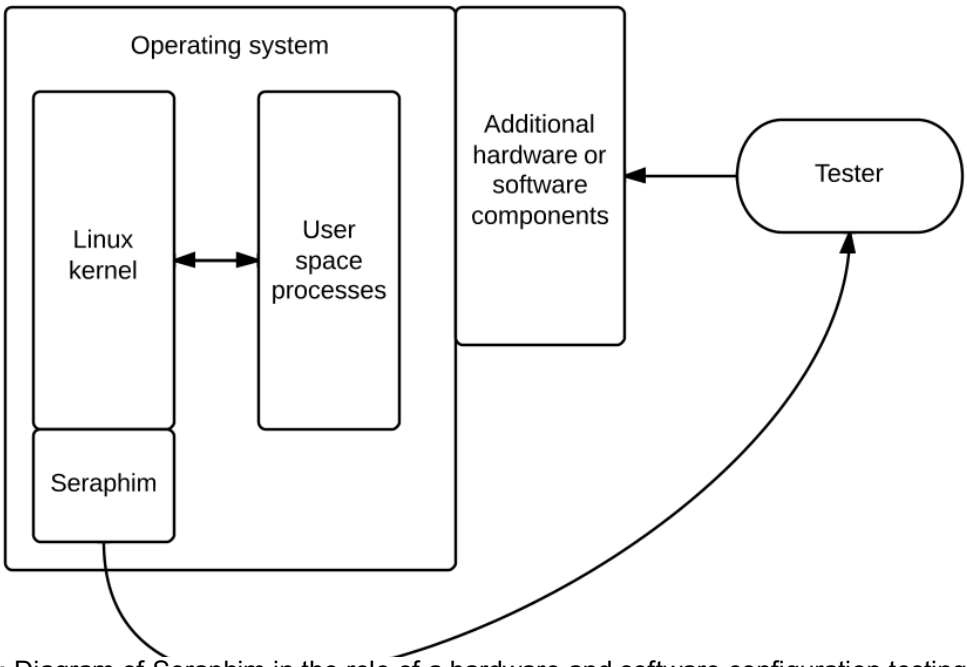

Figure 2: Diagram of Seraphim in the role of a hardware and software configuration testing tool

Another use case for Seraphim would be for constant resource monitoring with the goal of optimizing the target computer system, thus improving overall business performance. Employment of Seraphim as a resource monitor with the ability to generate periodical reports is similar to the last two use cases and requires the person gathering data for further analysis to predefine the resources that should be monitored and the required time intervals on which reports should be generated. These reports can later be aggregated and analyzed to show adequate steps to further optimization and improvement of business performance.

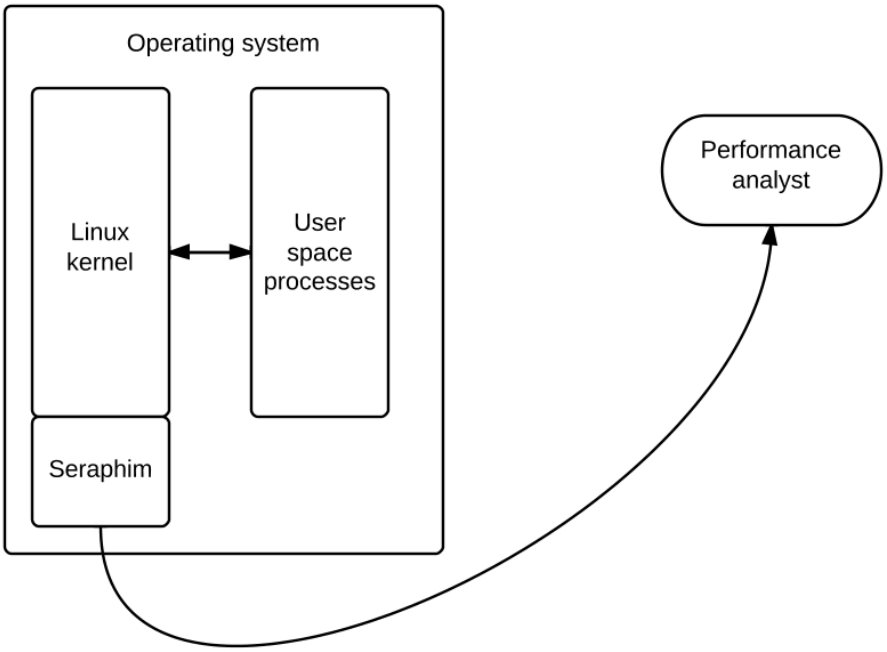

Figure 3: Usage of Seraphim as a resource monitoring tool by a performance analyst

4. EXISTING TOOLS

Currently, there is no adequate open-source tool on the market for Linux resource management and command execution via kernel module routines. Several years ago there were tools that fit the specification, but they were created for malicious purposes (Attack Sneaks Rootkits Into Linux Kernel, n.d.). Other tools, such as Nagios (Nagios, n.d.) and Tripwire (Tripwire, n.d.), which are proven solutions and industry standards, have become products with a large amount of legacy and archived code, considering they have been in use for more than a decade (Nagios History, n.d.). Some of them (like Knark (Intrusion Detection FAQ: Knark: Linux Kernel Subversion, n.d.)) which could have been implemented as tools without a

malicious purpose have been out of date for several years due to the advancement of the Linux kernel and the lack of development.

If implemented correctly into a target computer system, Nagios provides monitoring of computer resources and system metrics, including a powerful scripting API to modify Nagios to specific needs of the target computer system. Such integration allows the generation of detailed reports about security incidents, with the ability to extend the reporting system. (Nagios - Nagios Features, n.d.). Seraphim draws inspiration from several segments of Nagios, especially the extendable API and a report generating system.

Even though Knark hasn't been developed for several years, it still poses a threat to operating systems running the Linux 2.2 and Linux 2.4 kernel (Information about the Knark Rootkit, n.d.). Knark's attack vector is defined by the ability to hide TCP or UDP connections, perform system call injection, hide files, directories and processes and change the UID and GID of a process, just to name a few of its features (Intrusion Detection FAQ: Knark: Linux Kernel Subversion, n.d.). The distinguishing part of Knark is that it is implemented as a Linux kernel module, giving it automatically an advantage over other tools (such as Nagios and Tripwire) since it has access to the same resources as if it were the Linux kernel itself. Such design was a primary trigger for the development of Seraphim, considering that, as a Linux kernel module, it would have an amount of features not accessible if it were created as a regular, user space application.

Tripwire functions by defining policies, upon which are generated reference points of target computer resources (file systems, databases, virtual systems to name a few). Later ongoing integrity checks compare the current state of target computer resources with the reference points and, upon policy restrictions, can act if the modifications were unauthorized. (Tripwire Enterprise FAQs, n.d.). The predefined policy based system is a feature that was implemented in Seraphim as a set of commands defined in the application itself prior to compilation.

There are, in fact, tools that have adapted to the development of the Linux kernel and the need for adequate monitoring and system control (such as Nessus (Nessus Vulnerability Scanner, n.d.)), with the main drawback of price (Nessus: Tenable Store, Unified Security Monitoring, n.d.) and proprietary code.

5. SERAPHIM STRUCTURE

Seraphim consists of several subroutines, each providing a specific purpose. The main reason for making the features of the software atomic is the ability to easily extend it using a crude API.

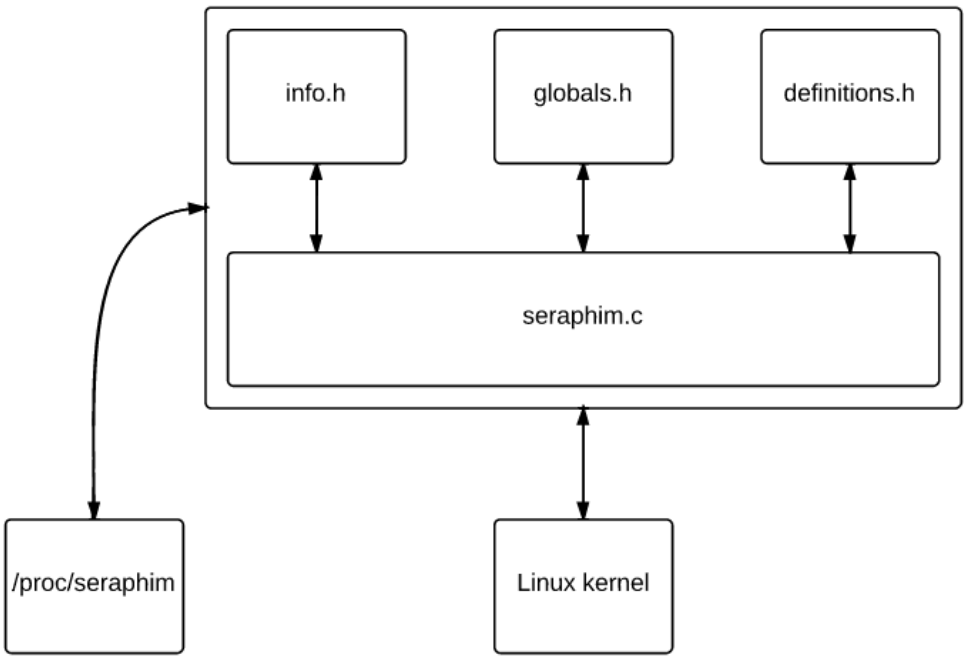

Figure 4: Block diagram of Seraphim structure and connections

To start the application, one must compile it on the target system (or a viable alternative) and then insert the kernel module into the Linux kernel using adequate system provided commands.

The entry point of the application is the file “seraphim.c” which is an aggregation of several files which provide adequate kernel communication and logging facilities. Kernel communication and logging facilities do not exist on their own, they are supplemented by several secondary subroutines which provide the actual interface into the Linux kernel. Secondary subroutines are defined in the file “globals.h”. Primary subroutines exist in the file “definitions.h”. The file “info.h” contains necessary author and licensing information.

Primary subroutines of Seraphim provide the implementation of secondary subroutines into forms that the Linux kernel can execute. The main part is the infinite loop that provides the execution of primary and secondary subroutines. Primary and secondary subroutines are duplicated at several places due to the fact that disk writing operations are categorized as slow operations, hence they were sometimes dropped from the Linux kernel process execution queue. After defining adequate primary and secondary subroutines, it is required of the programmer who is extending Seraphim to include the subroutine calls in the infinite loop so that they could be executed.

```
static void printString(char *string) {

    struct tty_struct *tty;

    tty = get_current_tty();

    if(tty != NULL) {

        (tty->driver->ops->write) (tty, string, strlen(string));

    }

    else
        printk(KERN_ALERT "TTY equals zero.\n");
}
```

Figure 5: Example of a secondary subroutine "printString" which prints the given string to the terminal console

Before the execution of the main loop, Seraphim registers itself to the kernel and provides an input/output interface under the /proc filesystem which allows an authorized user to manipulate the flow of the application.

6. KERNEL COMMUNICATION

Before each run, kernel modules must be loaded into the kernel. This is usually done with the command “insmod”. After they are loaded, kernel modules start their execution. The process of loading a kernel module implies that the kernel module is being added to the Linux kernel, forming an integrated entity between the raw kernel and the kernel module. Considering this, it is safe to conclude that Seraphim runs in the kernel space, a region in memory where the Linux kernel runs and provides defined services (Kernel Space Definition, 2005), unlike most other resource monitoring applications, which run in user space, a memory segment where user processes reside (User Space Definition, 2005).

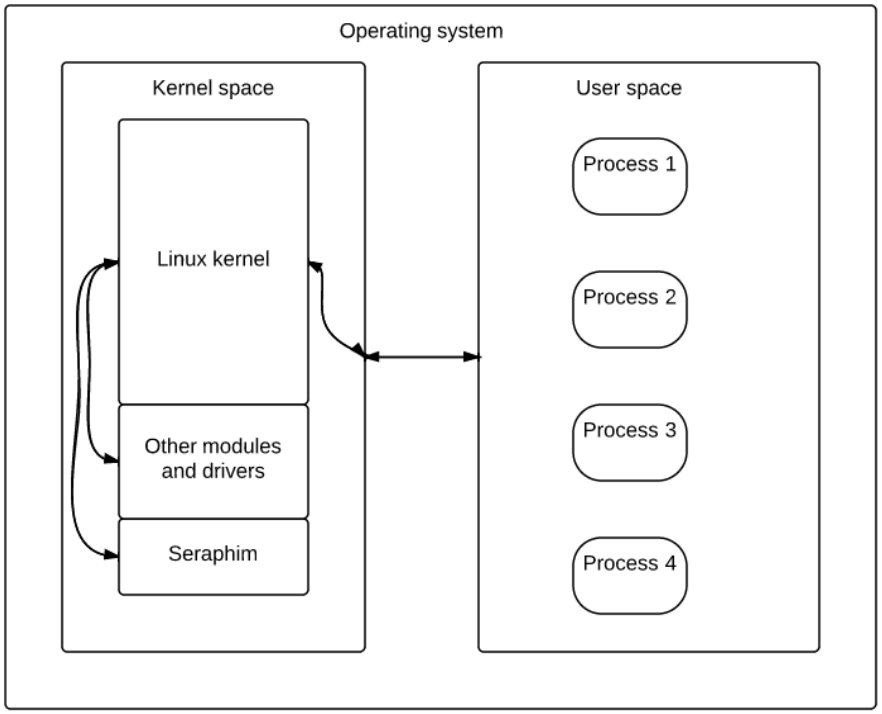

Figure 6: Seraphim integration within the operating system with four running processes; inter-process communication and communication with the user space kernel communication provider is abstracted

As defined earlier, the primary subroutines are defined in the file “definitions.h” and they are supplemented by secondary subroutines in the file “globals.h”. The main part of these subroutines, both primary and secondary, provide communication with the kernel. Kernel modules communicate with the kernel by having access to subroutines not normally available to user space applications due to the fact that kernel space applications (in this case kernel modules) are compiled against the Linux kernel itself, instead of compilation against the GNU Standard C library.

Communication with the kernel is defined on several fronts. One of them is the usage of existing teletype interfaces to provide the piping of data through the kernel to the end user, allowing real time monitoring from the teletype interface from which Seraphim was loaded into the kernel.

The most important part of Seraphim is the ability to execute system commands automatically as an administrator. That feature is provided by the “runner” subroutine which utilizes the kernel functions for string concatenation and memory management, creating a construct which is then called by the kernel and executed after passing the Linux process execution queue.

One of the other places where the kernel communication is extensively utilized is for the creation of adequate files under the /proc filesystem, providing a user interface for kernel communication, and the ability to log executed commands and the status of resources predefined before the compilation.

Commands used for communication with Seraphim are inspired by the BASIC programming language and consist of a single string which is then parsed inside of Seraphim to determine its meaning. Currently, the only implemented command is the command “STOP” which halts the execution of Seraphim.

7. LOGGING FACILITIES

The ability to log targeted resources and their states and also the results of executed commands from Seraphim is of vital importance to the security and integrity of the targeted system. Monitoring of resources is done several times per iteration of the main loop, providing redundancy in case of dropped statements from the Linux kernel process execution queue. Both the results of monitoring and command execution are logged in the messaging facilities of the kernel, from which they can be extracted for further analysis.

The process of monitoring and logging is done by executing a specially crafted command embedded inside a subroutine, which is modified before execution with the resource from the /proc filesystem that we wish to monitor. The location of the file where the log should be saved is predefined as a macro and can be changed prior to compilation and execution. Furthermore, the event of monitoring is logged in the kernel message device, along with a timestamp providing the system analyst with information at what time and which state was the system in when there was an unplanned event.

Each executed command is logged in the kernel message queue and in the adequate files on disk defined before the compilation of the kernel module. Furthermore, subsequent command executions are marked in the files on the disk. Timestamps of resource monitoring and command execution are written in the kernel message queue, allowing qualified persons to determine at which time since the start of the system has there been a breach of monitored resources or the execution of unauthorized commands.

8. COMMAND EXECUTION

As it was noted above, Seraphim provides the execution of commands under administrative privileges using the “runner” subroutine, providing a simple interface to execute additional commands to the system for maintenance and extended security monitoring which isn’t encompassed by Seraphim.

Similar to the logging facilities, command execution is encapsulated in a specific subroutine, which takes two parameters, first one being the command that is supposed to be executed and the second one which represents the location on the file system where the result of the execution will be written. The key component of this subroutine is “call_usermodehelper” (Linux Manual Documentation, n.d.), a subroutine which allows the calling of predefined commands as a superuser, having access to all components of the operating system. It is worth mentioning that both the logging facilities and command execution are based on the same principles and subroutines.

Using the ability that Seraphim can execute commands defined before compilation, one can theoretically infinitely extend and integrate Seraphim into the target system, using it as a hub for continuous monitoring and security activities, supplemented by its own integrated subroutines providing a low-level approach to the Linux kernel and operating system which applications running in userspace cannot achieve.

9. CONCLUSION

In these tempestuous times, the ability to have up to date logs of crucial data on your target systems is the primary concern, as is the execution of commands to mitigate attacks against the monitored system or simply the execution of commands to reinforce the system on which they are being run. A large number of solutions on the market simply do not provide the necessary features required for low level system monitoring or the management of computer resources and command execution.

Seraphim, at this current state, provides the answer to these problems by monitoring predefined files and executing predefined commands, without the need for external control. Furthermore, Seraphim is modularly built, allowing further expansion before compilation.

Further course of Seraphim development is porting the source code to the Microsoft Windows operating system, with the same or even greater features, and later, implementing additional features such as system call injection and scripting to the original Seraphim for the Linux kernel. Considering the alternate tools (Nagios, Tripwire and Nessus) and the man hours spent developing them, one can conclude that Seraphim, even though has a fraction of their possibilities, is a worthy contender, despite the fact that it was developed with a lot less man hours than its main competitors.

ACKNOWLEDGMENT

Abstract: *Identity management systems are used in different types of organizations. Most of them have remote users who access the organization's resources through the Internet. It is crucial to prevent frauds and unauthorized access to data. Techniques for authentication that are used in today's identity management systems are vulnerable when they are used over the Internet. Identity management systems integrated with multimodal biometric systems could build a more secure environment in which to perform critical operations. In this paper, we present the architecture of a prototype of an integrated system of identity management and multimodal biometrics. Special attention was given to how to integrate multimodal biometrics into existing identity management system.*

Keywords: identity management system, authentication, multimodal biometric, single sign-on, open source

1. INTRODUCTION

Modern information technologies have enabled information infrastructure to connect remote entities around the world by using large networks, relying on application level protocols and web services. The advantages of computing resources, which are available on the Internet via cloud computing and virtualization technologies, are being used by the companies to an increasing extent. Given that the number of online users is growing daily and approaching the actual total count of people, the issue of digital identity management arises in order to protect privacy and retain liabilities in transactions and interactions in accordance with the regulatory controls. Digital identity can be defined as the digital representation of information about a particular person or organization. Digital identity has a finite, but also an unlimited number of attributes. Digital identity may include attributes of a person such as: name and surname, personal identification number (PIN) or passport number. Additionally, it can obtain biometric data such as the iris of the eye or a fingerprint, as well as the information about the users' activities, including web searches and transactions during Internet purchase. Biometrics is a relatively new field, but today, in the process of verifying users' identity, multimodal biometrics is its greatest asset. In multimodal biometrics, different modalities are taken simultaneously in order to determine users' identity. Therefore, the probability of verifying an identity is high.

The identity management and access control involve several fundamental parts, such as: user identification, authentication and authorization. These three activities are strongly connected and, in fact, we can say that they form a chain of interdependence. Authorization depends on authentication, and the authentication itself is based on identification (Lynch, 2011). There are lots of other activities that are important for identity management, but particular emphasis is put on managing user accounts and monitoring of the system user activity.

In order to respond to current trends, a prototype system for identity management needs to be developed. It is necessary that this system fulfils requirements for identity management, policies and monitoring of the system user activities. In accordance with these requirements, a system has been designed for identity management based on FreeIPA solution for digital identity management and MMBio framework for multimodal biometrics.

2. IDENTITY MANAGEMENT

Identity management can be defined as the creation, management and use of digital identities. Identity management implies safe management of the entire digital identity's lifecycle, from its creation (registration of a digital identity), through maintenance (implementation of organizational policies with regard to the

access to electronic resources) and, eventually, the termination of digital identity. It allows efficient and safe access to data and applications.

Three key elements of identity management are: policies, processes and technology. Policies refer to limitations and standards that need to be followed in order to be in compliance with regulations and business practices, as FreeIPA allows by defining the policies. Processes describe the sequence of steps that lead to the completion of business tasks or functions. Technologies are automated tools that help achieve business goals more efficiently and accurately with regard to all limitations and guidelines outlined in the policy.

Identity management system of an organization does not remain stagnant over time. New technologies will be introduced into the system, new business models and limitations will change the processes and management type. Once one of the elements undergoes a change, a new balance needs to be established (Kong, 2011).

Three key elements of identity management are:
- Data access service
- Access control
- Identity life cycle management

Basic concepts of digital identity are:
- The subject, entity
- Resource
- Digital identity
- Authentication
- Authorization
- Federation
- Integrity
- Single sign-on (SSO)

The subject or an entity is a person, group of people, an organization, a virtual object (e.g., computer process, application, text file), tangible object (e.g., electrical appliances and computers) or any other entity that requires access to a particular resource.

A resource can be a specific data in the database, a remote server or a website, and what is common to all the resources is the access, i.e., the entity refers to its own digital identity when accessing the resource.

Digital identity, the very concept of it, represents an experience of one's' own identity, the identity of other people and things in the aspect of digital technologies (Prasad and Rajbhandari, 2011). The definition of digital identity consists of the following parts:
- Identifier
- Credentials
- Key attributes
- Context-specific attributes

The identifier or the key is a part of the information that uniquely identifies the object in a particular context. Examples of identifiers are email addresses, user names or the unique identification number that every person possesses.

Credentials are private or public data that could be used as proof of identity authentication.

Key attributes represent data that help describe identity. Key attributes can be used in a variety of different business and application contexts. For example, addresses and phone numbers are common attributes used in a variety of business application.

Context-specific attributes are data that help describe the identity, but these attributes are used only in specific contexts.

Authentication is a process of verifying the identity of the user, devices, or other entity in a computer system, which is often a prerequisite for gaining access to resources in the system.

Authorization is an approval given to the user, application program or a process to accesses a particular object or group of objects. Authorization is often resolved through the mechanism of roles. It is possible to

assign a specific role or group of roles to one user or a group of users. The role may consist of other roles, which together make up a set of privileges at the disposal of the authorized entity.

Federation enables secure sharing of information with external systems that need to manage the identities of foreign customers. Without this functionality, administrators would have to maintain a separate folder for all foreign users and manually update data about them (Williamson, Yip, Sharoni, and Spaulding, 2009). Identity Federation represents a circle of trust and allows users from one domain to access resources in another domain without any additional introduction.

Integrity is a guarantee that the content of the received message was not altered in respect to the content of the original message sent.

Single Sign-On (**SSO**) is a process of authentication that allows a user to access one or more resources within single security domain. SSO is a common procedure in Enterprises, where clients logs in once and gain access to different resources connected to a local area network (LAN), without the need to re-enter log-in credentials.

3. MULTIMODAL BIOMETRIC SYSTEMS

Problems that occur with previous methods of identification could be solved by recognition of a person based on something he or she is, by using biometric identification. In this way, issues with password memorization and safety of the object are resolved, and the identification of a person is enabled without external data or objects (Hermans and Valkenburg, 2009). This is particularly significant once we take into consideration the fact that distance communications are expanding. Throughout the Internet people use services such as electronic commerce and administration, they perform business transactions, study and maintain personal contacts. In all of the above mentioned situations it is crucial to establish the identity of the person performing a transaction, or the person with whom communication is maintained. This way frauds and unauthorized access to data are being prevented.

Similarly to the Internet technology, the first implementation of biometrics was for military purposes. Academic institutions have directed their efforts adequately with the more evident need for biometric technologies. Progress in the technology development, specifically in biometric sensors of affordable price, has enabled the implementation of biometric technology in new areas (O'Gorman, 2009). Now, even the smaller development teams with limited budget can afford the costs of procurement of appropriate equipment used for development and testing. This technology development trend has assisted the emergence of open source biometric solutions, developed by the open-source community. Systems that integrate multiple different biometric modalities, e.g., face and fingerprint, voice and the iris, are called multimodal biometric systems. Integral parts of multimodal biometric systems are methods for fusion of information concerning various modalities.

Multimodal biometric systems imply several processes:
- Acquisition of biometric data
- Biometric data processing
- Characteristics extraction
- Comparison and decision making

Each of these processes involves working with a multimedia database of multimodal biometric data. Depending on where the above processes are deployed, we can distinguish between distributed and centralized architecture of multimodal biometric system. In a centralized architecture all biometric processes are located on one host. Distributed architecture implicates the distribution process in several different places (machines), where they must have the ability to communicate through the network.

Potential users have at their disposal numerous commercial as well as open-source solutions. Commercial solutions often make up closed units, with all the advantages and disadvantages of this approach. Some of the open source solutions enable the development of flexible systems, which can have the same use value as commercial solutions in certain situations, but with much smaller financial investments. Also, the use of biometric authentication is not generally in the forefront and is offered as an optional possibility with some of the commercial producers' solutions (Bogicevic, Milenkovic and Simic, 2012).

The solution offered by Microsoft, Active Directory Services (ADS), includes an integrated identity management system. Ever since the Windows server 2003 R2, Active Directory Federation Service (AD FS) is an integral part of the ADS and is being used to create connections between organizations. This is

possible by user authentication through Active Directory which represents an identity provider. Moreover, AD FS issues tokens that are used in the authentication process. In addition to ADS, Microsoft has also developed MIIS-Microsoft Identity Integration Server, which has changed names, but in the year 2010 was presented as FIM – Forefront Identity Manager. FIM was developed in order to integrate with Active Directory and Microsoft Exchange solutions.

IBM offers an identity management system, which is a part of Tivoli and is called Tivoli Identity Manager, based on policies and roles. It provides a hierarchy of roles, web self-services, group management and synchronization of user data with different repositories. The advantage is in the possible synchronization of Tivoli with ERP systems. Furthermore, there is a possibility of using biometrics as an authentication method.

The imposed open source solution is the FreeIPA solution that allows creation of identity storages, centralized authentication, domain control for Kerberos and DNS services and authorization policies, and all this on Linux systems using the native Linux tools. Basically, the FreeIPA is a domain controller for Linux and Unix systems. FreeIPA defines the domains through control of the servers and reported client machines. That provides a centralized structure that was previously unavailable in Linux/Unix environments, and all this through the use of native Linux applications and protocols.

A suggested technical solution is based on FreeIPA and MMBio solutions. Identity management is done with the help of FreeIPA system, while MMBio framework for multimodal biometrics is responsible for working with biometric data. Data acquisition is done with the help of kerberized application for acquisition which uses functionalities of the FreeIPA solution.

A multimodal biometric application has been developed together with the use of framework. Within the application, three different open source solutions have been integrated and each of them works with different biometric modality. The modalities used are: fingerprint, face and voice. Although each of the open source solutions has lower accuracy than commercial solutions available on the market, when different modalities were combined, the accuracy of the system was at a considerably higher level than it was with any unimodal solution individually.

4. MMBIO – FRAMEWORK FOR MULTIMODAL BIOMETRICS

In order to build a multimodal biometric system from unimodal open-source solutions, several challenges have to be solved. It is necessary to establish communication between open-source unimodal solutions, acquisition sensors, biometric database and multimodal fusion algorithms. Also, this communication has to be implemented in accordance with the system distributed nature, as different system components can be deployed on various platforms. Moreover, biometric data management has to be implemented, with special focus on supplying data in accordance with unimodal biometric solutions specifications. Finally, framework has to support component reusability in new, different context.

MMBio framework for multimodal biometrics was developed to overcome these challenges (Milovanović, Minović and Starčević, 2012). Communication between different system parts is based on MMBio communication protocol. Communication protocol is used rather than object serialization because communication protocols are platform independent. However, unimodal solutions and acquisition sensors often support only nonstandard, solution specific communication methods. In such situation, it is necessary to develop a communication adapter in order to translate protocol commands to solution specific ones.

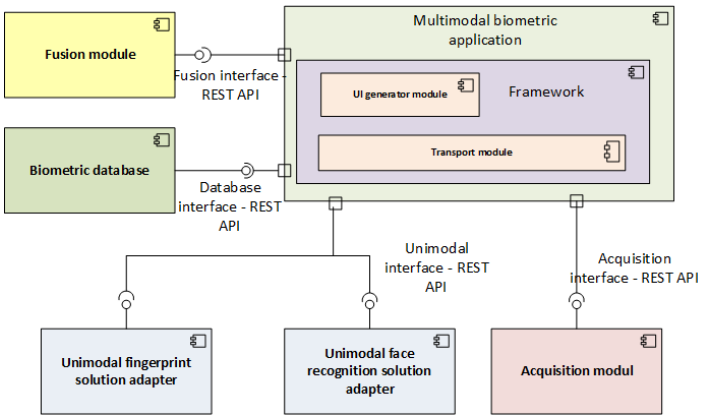

Figure 1: Multimodal biometric system architecture

MMBio framework supports different multimodal database work modes. It is possible to use either centralized or distributed database. Also, biometric data associated with an identity can significantly differ from one biometric system to another. In a multimodal biometric database, a person can have data about several different biometric modalities, and each modality may be represented by several data instances. Biometric data can be in raw form, or stored as biometric characteristics. Each type of biometric data can be stored in different file formats, and some file formats are solution specific. MMBio communication protocol has been designed to comply with different biometric database models, and supports different use case scenarios.
Figure 1 shows architecture of multimodal biometric system developed with MMBio framework. System components are biometric application, biometric database, acquisition module, and unimodal solutions (Milenković et all, 2013). Communication adapters are used for protocol message translation. Each component reports its functionalities to multimodal system during the initialization process. Communication between components is synchronized, based on request/response paradigm. In this use case, MMBio protocol is implemented by using REST (Representational State Transfer) services. Protocol messages are sent over HTTPS protocol. An example of protocol message is shown on Figure 2

```
POST /NBIS/resurs/match HTTPS/1.1
Content-Type: image/jpeg
User-Agent: Jersey/2.2 (HttpUrlConnection 1.7.0_25)
Host: 10.10.1.176:8080
Connection: keep-alive
ServiceName: NBISFingerprint
UserID: 1120
Timestamp:09.09.2013. 14:54:03
Modality:Fingerprint
Biometric-Sub-Type: index finger
Biometric-Sample-Type: raw image/bmp
Content-Length: 277921

PGh0bWw+CiAgPGhlYWQ+CiAgPC9oZWFkPgogIDxib2R5PgogICAgPHA+VGhpcyBpcyB0aGUg
 Ym9keSBvZiB0aGUgbWVzc2FnZS48L3A+CiAgPC9ib2R5Pgo8L2h0bWw+Cg==
.....................................................................
```

Figure 2: Protocol message example

HTTPS request line contains information about web service location. Example shows a biometric data match request which is being sent to a unimodal biometric solution. Header fields are used to describe request in detail. User ID, information about biometric modalities and sample types, content type are contained in the request header. Biometric-Sample-Type field describes whether biometric data is raw or processed. Payload contains extracted biometric characteristics that are to be verified. In the example, Jersey framework was used to implement REST web services.

5. FREEIPA

In theory, Identity management (IdM) describes the management of individual principals, their authentication, authorization, and privileges within or across some boundaries with goal of increasing security and productivity while decreasing cost, downtime and repetitive tasks. In practice, what this means? IdM manages over the following data, functions and processes:

- Identities (principals): users, machines, services and/or applications
- Authentication: password, biometry, 2 Factor Authentication (2FA)
- Authorization: Polices, ACLs, DAC, MAC

FreeIPA is built as a set of services over a single domain to achieve this goal. Its mission is to facilitate the management of the domain, the identity of the users, client machine, and configured services. Services used by FreeIPA are:

- Authentication: Kerberos KDC, Dogtag Certificate System
- Data Storage: 389 Directory Server
- Server/Client Discovery: DNS
- Management: NTP

FreeIPA itself defines a domain, a group of machines that have shared configuration, policies, and identity stores. This shared configuration allows the machines (and users) within the domain to be aware of each other and operate together.

Sharing configuration is done through a client-server paradigm. This means that FreeIPA have a client part. It must be installed on the machine before it can join to the domain.

For FreeIPA a client is simply any machine, which is configured to operate within the FreeIPA domain, using its Kerberos and DNS services, NTP settings, and certificate services. That is an important distinction: a client does not require a daemon or (necessarily) an installed product. It requires only system configurations that direct it to use FreeIPA services.

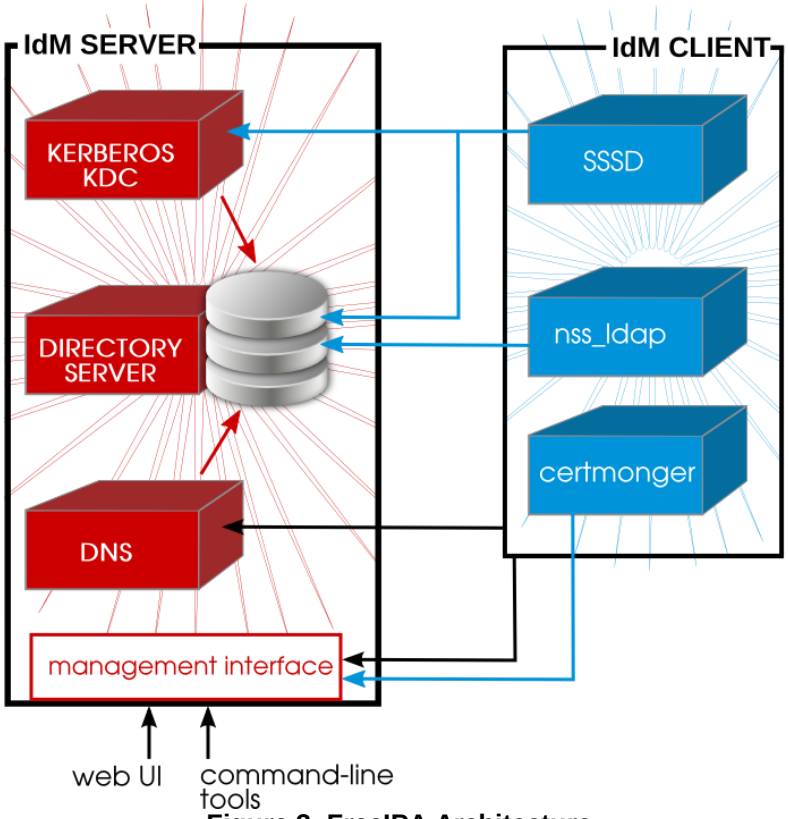

Figure 3: FreeIPA Architecture

IdM uses the local storage (cache) on a client to improve performance in a few ways:

- Store IdM information when the machine is offline.
- Keep information active beyond its normal timeout period if the client cannot access the central server. The cache is persistent even after rebooting the machine.
- Reduce the round-trip time of requests by checking information locally before looking at the server.

Information is stored either in an LDB database (similar to LDAP) or the local filesystem (as XML files), depending on the type of information. There is a two type of information: Identity information (about users, machines, and groups) and policies which are set globally on the server and then are propagated to the clients.

As Figure 3 shows that FreeIPA client uses two native daemons to interact with the IdM server:

- SSSD provides the user authentication for the machine and enforces host-based access control rules.
- Certmonger monitors and renews the certificates on the client. It can request new certificates for the services on the system, including virtual machines.

When a FreeIPA client is added to the domain (enrolled), its SSSD and certmonger are configured to connect to the IdM server and the required Kerberos keytab and host certificates are created. The host certificate is not used directly by IdM; it may be used by other services, such as a web server or any other local or remote applications.

6. ARCHITECTURE OF PROTOTYPE

Current operating systems use text password for user authentication. Almost everyone knows the weaknesses of this method of user authentication. The main objective of the proposed prototype is to extend the current one-component method of user authentication. As shown in Figure 4, a prototype extends FreeIPA authentication with a biometric sample of the user. During process of authentication it sends standard credentials of the current user together with biometric sample. Standard FreeIPA server does not know how to handle this request for authentication. Therefore, we added MMBIO server to FreeIPA services and diverted sending the request for authentication to it. MMBIO server extracts biometric sample from request and sends it to the MMBIO search engine (Multimodal Biometric Matcher). Also it must send standard request for authorization to the FreeIPA. Process of authorization can be counted as successful when both have got positive responses. MMBIO server sends back to the client consolidated response.

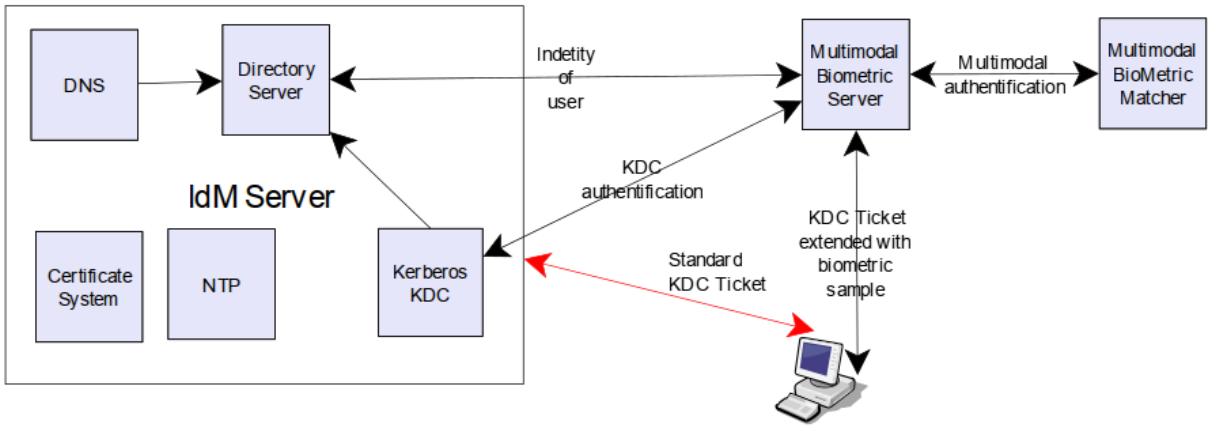

Figure 4: Prototype Architecture

It should be noted that it is necessary to pair the identities stored in the FreeIPA server and the MMBIO server due to different ways of storing user information. MMBIO server needs to know which identity from FreeIPA repository has biometric samples in its database and vice versa. In this way, communication between FreeIPA and mmbio server transmits a minimum set of data sufficient to unambiguously determine the identity of a user during authentication process.

MMBIO Matcher uses unique identifier MMBIOHashID to determine identity of the user. The process of adding users in MMBIO base is process of taking the biometric samples. Upon completion of the acquisition of samples it is necessary to bind MMBIOHashID to the identity of a user in FreeIPA storage.

On the other hand, the process of adding a new identity in FreeIPA environment includes creating a user profile and binding it to a MMBIOHashID. We have two scenarios:

- Newly created user does not have enrolled biometric samples in MMBIO database,
- Newly created user is already enrolled in MMBIO database

The second scenario is trivial. We need to bind the user identity with existing MMBIOHashID. In the first scenario we need to take biometric samples from the user and upload them to the MMBIO database.

During process of authorization, on the client side, key part is SSSD (System Security Services Daemon). It allows to any application, on the operating system which use NSS (Name Service Switch) for identity and PAM (Pluggable Authentication Module) for authorization, to use biometric sample along with standard password mechanism (shown in Figure 5.). An SSS Client Application is unaware that it is communicating with an SSS Client Library. It simply calls a standard NSS or PAM function, which is mapped by the NSS/PAM runtime to a module-specific function name, and which is then delivered to an SSS Client Library.

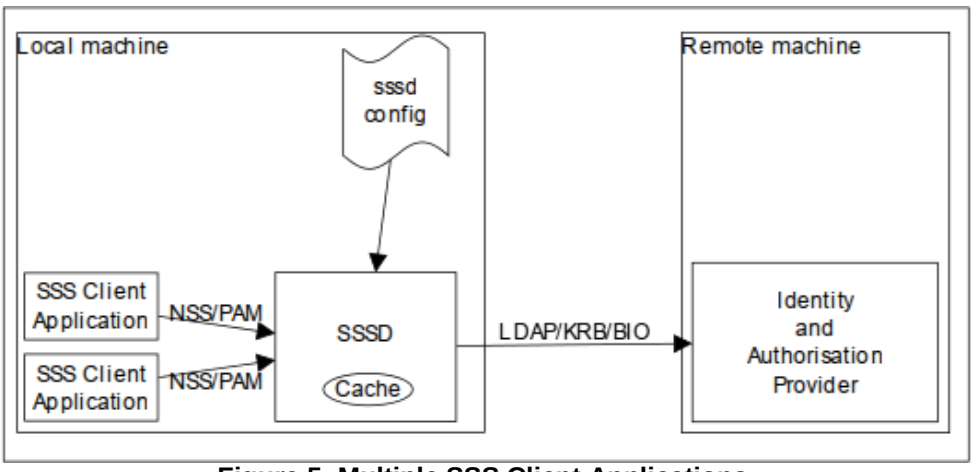

Figure 5: Multiple SSS Client Applications

Key features from SSSD are:

- NSS and PAM interface to the operating system
- Pluggable back-end system to connect to multiple different identity sources.
- Offline authentication

With SSSD it is possible to create multiple domains of the same, or of different types of identity provider. SSSD maintains a separate database file for each domain. This means that each domain has its own cache, and in the event that problems occur and maintenance is necessary, it is very easy to purge the cache for a single domain.

7. CONCLUSIONS

In this paper various important aspects of the Identity Management Systems and Multimodal Biometrics functionalities are revised. Most of Identity Management Systems allows Single Sign-on feature. With remote users and communications made through the Internet, the possibility of fraud and unauthorized access to data increased. Securing the authentication process is today's the biggest concern. Therefore, allowing the use of biometric data of one user in the process of authentication for access to critical data, it reduces the chance of fraud and unauthorized access.

Developed prototype confirms possible integration of identity management and multimodal biometric systems. During implementation of the prototype, some new issues concerning communication between client and server have risen, and they should be further investigated. Moreover, challenges connected to the acquisition of the biometric data and its upload to the MMBIO database are of great importance, and they are going to be an important part of future work on this topic.

ACKNOLEDGEMENT

This work is a part of the project Multimodal biometry in identity management, funded by Ministry of Education and Science of Serbia, contract number TR-32013.

Abstract: *Multimodal Biometric Systems in Identity Verification use statistical data on anatomical and physiological characteristics of humans and they always carry a dose of certain amount of uncertainty with regards to the accuracy of results. At some important social activities, like security, healthcare or finance, the accuracy of certain biometric systems becomes questionable as singular mismatches could cause irreparable damage harm to an individual person or the community. In recent years, in order to achieve a more reliable identification, there has been intensive application of multimodal biometrics systems, namely application of fusion of independent biometric data. Analyses that were conducted in recent years have shown numerous advantages in relation to the accuracy and the efficiency of implementation of biometric fusion. However, in order to accomplish this, attention must be paid to ways that data, in multimodal biometric systems, are connected.*

Keywords*: Biometric systems, methods for biometric data, biometric fusion, multimodal biometrics*

1. INTRODUCTION

The process of globalization is strongly connected to the issue of security and identity recognition and validation, due to which attention is paid to international connection of security mechanisms based on multimodal biometric systems. Biometric identification is becoming sophisticated because it combines different biometric modalities and techniques, and, in return, it gains higher accuracy or it notably reduces the effort of users in the process of identification. In recent years, there have been large amounts of data in literature about research in the field of multimodal biometrics, but the impact of certain combination of biometric modalities, the available methods of processing biometric data and the influence of the size of the biometric database on the system's overall performance hasn't been significantly analysed. This paper analyses multimodal biometric systems for identity verification that simultaneously use several biometric modalities i.e. a fusion of independent biometric characteristics. Special chapter of this paper refers to ways of connecting biometric data in multimodal biometric systems, because the method of data connection directly influences the overall system's performance in the realistic conditions of use.

2. MULTIMODAL BIOMETRIC SYSTEMS FOR DETERMINATION OF IDENTITY

When only one biometric characteristic is used for identification, or when several characteristics of a single mod are used, then some parts of the procedure for determining identity become critical with regards to the accuracy of the data for processing, i.e. their precision so errors occur more frequently in the work of the system compared to procedures that use a fusion of several independent biometric characteristics – specific mode of operation used for identification. Then we say that we are talking about multimodal biometrics i.e. multi-biometric system for identity recognition and verification with multiple biometric characteristics.

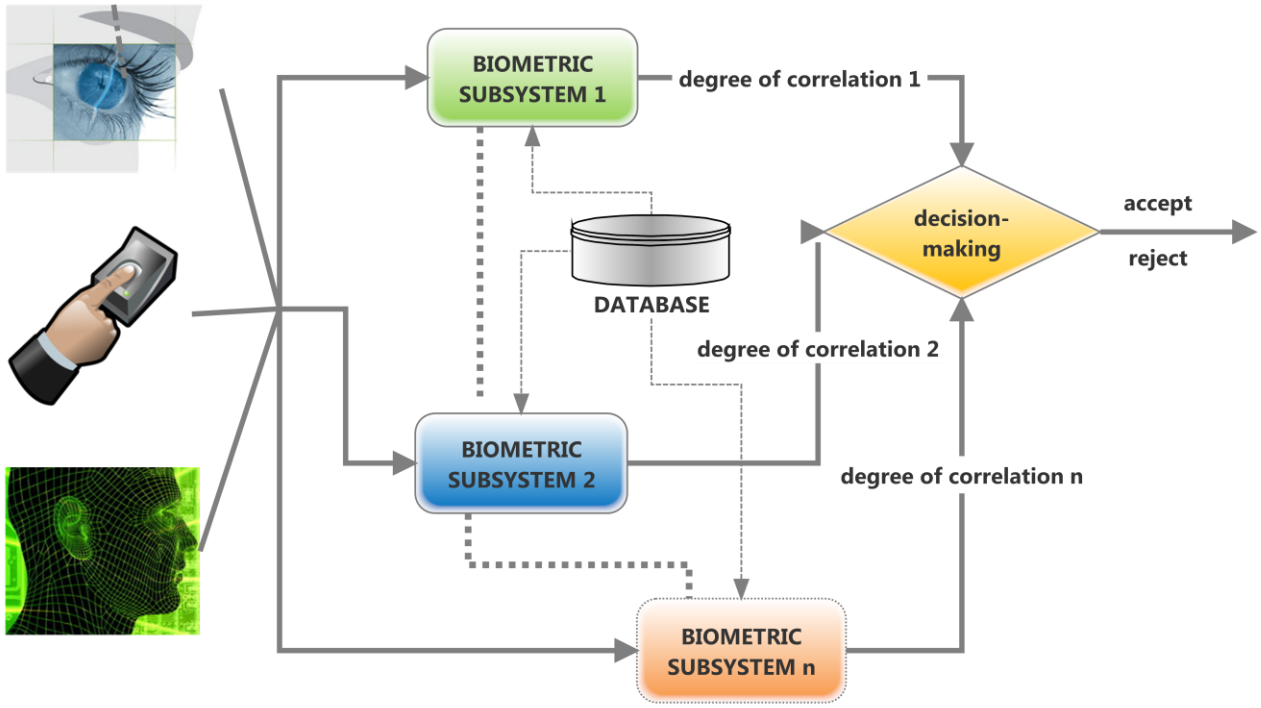
In order for multimodal systems to be more precise than unimodal, but also fast enough, it is important to find an efficient combination for the fusion of biometric characteristics. As mentioned, the first multimodal systems were those created by combining biometric characteristics of voice and face lines.[1] The aim of their application was to overcome the aforementioned limitations that appear in unimodal systems, which increased not only the precision of work but also the reliability of the process of identification, the overall number of implemented biometric systems as well as the number of different applications in the society[2]. Those multimodal biometric systems are showing significant advantage in prevention of abuse of biometric technologies because they provide a greater level of security of the system having in mind that they require a user to be physically present during data collection.

[1] A. Ross, K. Nandakumar, A. K. Jain, (2008).
[2] A. Nagar, K. Nandakumar, A. K. Jain, (2012). Technical report: Multibiometric Cryptosystems, vol. 7, NO.1.

The essence of multimodal systems is seen in the use of several independent procedures in a process of calculation of a degree to which the biometric data entered match to those stored in the database (Y.Xu, D.Zhang, J.Yang, 2010). This way, the number of components that in case of failure or malfunction could endanger the overall functioning of the system functioning is eliminated or significantly reduced. The collected intermediate results of independent system components are then adjusted for final process of decision making. The principle method of work of a multimodal system is illustrated in picture No.1.

By all means, the identification becomes more sophisticated and expensive as different techniques of biometric identification are combined, thereby gaining on reliability in precision and deduction while allowing the level of the requested effort on a side of a user in the process of identification to be influenced as well.

It should be emphasized that, in recent years, a more intensive application of multimodal systems is in use, so the results achieved in the field of testing the accuracy of certain multimodal combinations can be found in literature, but without data that refer to the performance of such systems. More importantly, the influence of the amount of data stored in database is in direct relationship with the system's performance.



Picture 1: The principle method of work of a multimodal system

According to the available sources, there is no simple way to choose biometric methods to be used in a multimodal system. However, we could still say that, in majority of different scenarios, the best results are achieved through a combination of biometric methods that, even in unimodal systems, offer a great level of accuracy, as expected, while satisfactory results are achieved by combining techniques that each, for itself, provides the average accuracy of the work of the system. The techniques most frequently used in multimodal biometrics include techniques that work with fingerprints, face lines and iris images.

A safer biometric system can be built if a larger number of the aforementioned methods are used. In practice, it is desirable to combine physical and behavioural characteristics, since it reduces the possibility of fraud of a biometric system in the process of the identification or verification. It is already mentioned that these methods are in use at border crossings to control passenger entry or exit, to control access to a certain area, the network protection etc.

Multimodal biometrics could also be used as a support to standard procedures of identity control when, from standard documents and papers, it is not possible to acquire a sufficient number of data that would describe a person... Therefore, due to the risk of abuse, it is recommended to use both standard protection mechanisms as well as biometric data. One of the examples is a fake fingerprint. If only one biometric technique is used, and the person possesses a fake fingerprint, which is used for authentication, on behalf of a person, it could result with abuse. However, if the verification is based on face recognition, or, better yet,

on iris detection or vein position check, it is possible to ascertain, with greater level of certainty, whether or not it is the person in question or it is an attempt of identity theft.

Multimodal systems have numerous advantages over unimodal ones. In case when one biometric characteristic is common to several persons, the presence of the other method prevents a scenario of wrong acceptance. System frauds are drastically limited by existence of larger number of methods that are used during identification.

3. METHODS FOR BIOMETRIC DATA CONNECTION IN MULTIMODAL SYSTEMS

Efficiency and precision of multimodal systems are greatly influenced by methods and means of interconnecting several biometric data and their respective fusion. The process of unification of biometric data itself can be accomplished using different logical processing levels. As the main task of biometric system is acquiring biometric samples, the first possible level at which the fusion could take place is the level where a process of acquiring samples is completed. The result of fusion, at this level, is an aggregated sample obtained by combining multiple samples acquired. For instance, aggregated sample is a combination or raw data obtained from several fingerprints of a single person.

In the second stage of processing, based on the acquired, raw biometric sample certain characteristics are derived and placed into a pattern, so fusion, at this level is conducted by unifying several formed patterns into a one unique pattern which is then recorded into the database. In the next, the third phase of processing, matching of the derived characteristic, with the existing one in the database, is tested where, in multimodal systems, matching is done among several derived characteristics or mods which are compared with equivalent recordings in the database, and results are, by fusion, combined in terms of similarity in order to get a unique result a scalar, as a measuring unit of similarity. Finally, in the last, the fourth stage of processing, a decision should be made whether or not the system determined or failed to determine the identity of the analysed person. The fusion of data, on a decision level, is made easy as decision is made for each tested biometric mod individually, and after that, the final decision is made by the means of majority selection (A. Hicklin, B. Ulery, C. Watson, 2006).

The most important preconditions for efficient and precise running of multimodal systems are related to the functioning of input sensors. Those sensors need to be designed in such a way that they are cost effective and able to rapidly collect biometric data and store them into the system, without an error. Apart from this, keeping in mind the possibilities of sensors and chosen combination of biometric characteristics, it is important to conduct the needed analyses of several possible levels of data fusion, in order to choose the level that is, under given conditions, the most precise and efficient. At present day, a large number of sensors as well as groups of acquired biometric data are available, therefore, it is necessary to find the best solution for each application.

Biometric fusion is used in processes of identification as well as in procedures of user verification. The task given to the system for identification is, of course, far more challenging than the one for the system of verification. Experiences in the application of such systems have shown that the best results are achieved by using biometric modality of fingerprint. The multibiometric systems which use combination of several fingerprints for identification, like AFIS does should be highlighted. Also, it is concluded that fusion on the level of characteristic comparison, so far produced the best results (A. Ross, A. K. Jain, 2004).

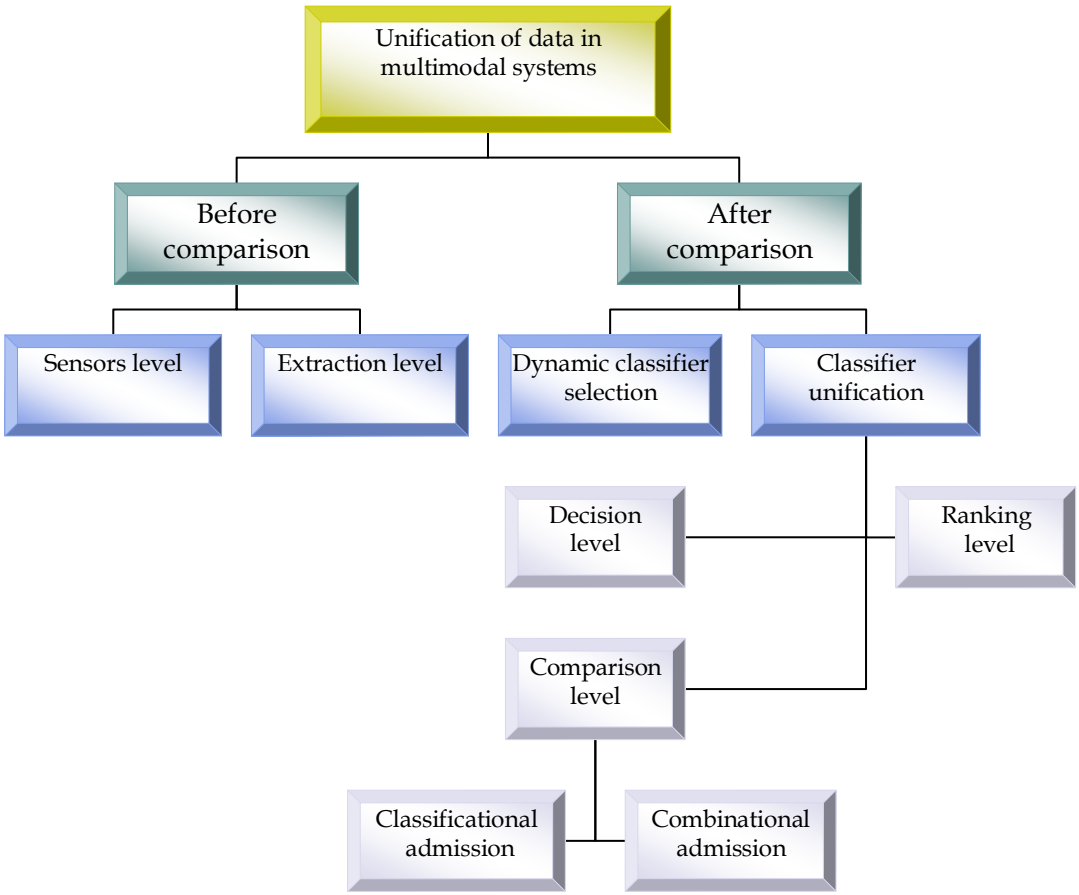
The analyses conducted in several cases, have shown that the two largest advantages that can be expected if biometric fusion is applied, are precision and efficiency. However, based on a fact that the fusion process is processing several aggregates of data, unlike in unimodal systems, it leads us towards demands for stronger computing systems and thereby higher expenses. Apart from this, more time is required to complete the task considering that more biometric data is being collected. Keeping in mind challenges that biometrics pose with regards to the right to privacy, we can say that the demand for collection of multiple data on a particular person does create a greater danger to violate one's privacy right.
Instead of a conventional approach to the location of potential combining of multimodal biometric data, Sanderson and Paliwal divided levels of fusion to two basic groups i.e. (A. Ross, K. Nandakumar, A. K. Jain, 2008): fusions prior to comparison and, fusions made after the comparison.

Approach to later fusions could be based on the concept of ranking of results or assigning points i.e. scores to comparison results. In terms of identification mode of work, the system's output result can be viewed as a ranking of identities entered into a database. In this case, the output result indicates a group of potential identities by sorting obtained matching scores, in a descending manner.

The goal of the method of fusion at this level is a consolidation of output rankings of singular biometric systems in order to obtain a common ranking for each identity. The ranking offers a better insight into a decision making process, but it reveals less information than the result represented in points, i.e. scores. Unlike scoring, ranking offers a possibility to compare the work of multiple biometric systems. Because of this, in this particular case, normalization of scores obtained is not needed (A. Ross, K. Nandakumar, A. K. Jain, 2008).

Normalization is an important phase with fusion technologies in multimodal biometrics. The goal of normalization is adjustment of parameters that refer to the location and scale of distribution of comparison results, scores, at the exit point of a separate module for comparison, in order to bring the results obtained from multiple modules, to the same level in order to allow further comparison (A. Ross, K. Nandakumar, A. K. Jain, 2008).

The picture No. 2 shows the taxonomy of possible techniques of unification of data in multimodal systems, according to *Sanderson* and *Paliwal*.



Picture 2: Taxonomy of possible techniques of unification of data in multimodal systems

The first group of techniques, prior to comparison, includes sensor and unification level fusions of the derived characteristics (a characteristic vector), while the second group includes match score and decision level fusions (A. Ross, K. Nandakumar, A. K. Jain, 2008).

4. CONCLUSION

Analysing the relationship between the group of techniques that belong to the model of earlier fusion, compared to those belonging to a later fusion, it can be concluded that techniques that belong to the model of earlier fusion, generally, have an advantage because the earlier fusion's algorithm does not include only biometric data, but their relationships, as well, which reduces the entropy of the system in question. As an

illustration of the expressed position, we can say that biometric characteristic contains more information on a concrete biometric modality than what we get at the exit of the comparison module (I. Milenković, D. Starčević, S. Paunović, 2011). The analysis of papers that deal with the problem of fusion, on all the aforementioned levels, indicate that the largest number of advantages is gained with unification at the level results of characteristic comparison because the previous results of processing of modalities within the system are relatively easily combined. The shortcoming of the fusion at the early stage of processing can be seen in the demand for compatibility of biometric data, which is not always easy to accomplish. As far as the fusion at a later stage is concerned, for example, decision making level, the research have indicated shortcomings of the fusion at this level because the possibilities for integration are very rigid as they possess a lesser number of information, unlike previous levels.

Abstract: *The increasing utilization of biometric technologies in a variety of institutions and organizations requires constant research and improvement of biometric systems performance and precision. In such circumstances, combining several biometric technologies (multimodal approach) stands out as a possible solution. Using different biometric modalities and different biometric sensors and solutions developed by various companies, reveals the interoperability problem in multimodal biometric systems. This paper describes the aforementioned issue and lists currently available standards that address this issue. Also, a set of biometric communication protocols implemented in MMBIO framework that try to solve this problem are briefly presented in the paper.*

Keywords*: biometric systems, multimodal biometrics, MMBIO framework, interoperability, communication protocols*

1. INTRODUCTION

Utilization of biometrics for identification purposes dates from 1858. when Sir William Herschel, who worked for the Civil Service of India, recorded a handprint on the back of a contract for each worker in the organization (Komarinski, 2005). He used the recorded samples to distinguish real from fake employees when payday arrived. This is thought to be the first systematic capture of hand and finger samples that have been used for identification purpose. Later, in 1965. North American Aviation developed the first signature recognition system (Mauceri, 1965). In 1994. The Immigration and Naturalization Service Passenger Accelerated Service System (INSPASS) biometric system has been implemented which allowed travellers to bypass immigration lines at selected airports in US. Authorized travellers received a card with their hand geometry information (Wayman, 2004). They presented their cards along with approaching their hand to a biometric sensor. Upon authentication, passenger could proceed, thus bypassing the long lines. This system was discontinued in 2004.

One of the milestones in application of biometrics in organizations and institutions was also the so-called PIV (Personal Identity Verification) of federal employees and contractors (United States Department of Veterans Affairs, 2004). In August 2004. USA President Bush issued Homeland Security Presidential Directive 12 (HSPD-12) for a mandatory, government-wide personal identification card that all federal government departments and agencies will issue to their employees and contractors requiring access to Federal facilities and systems. The PIV for federal employees and contractors, specifies the technical and operational requirements for the PIV system and card. Also, in the same year several USA states established state-wide palm print databases that allow law enforcement agencies in each state to submit unidentified palm print samples in order to be searched against each other's database of known offenders. Biometric passports (Wikipedia), which contain biometric data about the passport owner, are also a mentionable milestone in biometric systems application in organizations and institutions. The biometric data is stored on a special chip, which contains information needed for face, fingerprint and iris recognition. Many developed European countries, but also a vast number of other world countries have implemented biometric passports, including Norway (2005), Japan (2006), Australia, USA (2007), Serbia, Montenegro (2008) and also Bosnia and Herzegovina (2009) .

All of aforementioned milestones show that implementation of biometric systems can improve authentication, security and identity management inside an institution in general. However, besides obvious opportunities and advantages of using biometrics in organizational settings, existing limitations must also be taken into account. As standard biometric system is not effective on its own, it must be improved in some manner. Usually, it is combined with a smart card system, but the cost of implementing both systems is significantly large (Nadir Blog, 2008). Also, lack of reliability of standard unimodal biometric systems is a mentionable disadvantage. Biometric devices can be fooled; if fingerprints or some other physical modality are compromised, they can't just be replaced like passwords or smart cards.

A possible solution for presented disadvantages could be the usage of multimodal biometric system, that uses several biometric modalities and in that way has improved performance and reliability. Also, by using different biometric solutions or devices, including those that are open-source, the cost of implementing such system could be drastically lower. However, combining those components and making them work together in a reliable manner is an issue that needs to be addressed. This issue is known as multimodal biometric system interoperability problem.

In the next chapter, the term interoperability is defined and also the problem that this paper tries to solve is stated. Currently available biometric standards that solve the problem of interoperability in biometrics are listed in third chapter and also each of presented standards is briefly described. In the fourth chapter, the solution that is used in MMBIO framework in order to solve the interoperability problem is briefly described. Conclusions, shortcomings and future work regarding the presented biometric communication protocols are defined in the last chapter.

2. INTEROPERABILITY IN BIOMETRIC SYSTEMS

This chapter presents the interoperability problem in biometrics research area. Afterwards, different formal definitions of interoperability, that are currently available in literature, will be listed.

In the research area of biometrics, several definitions of interoperability are present. (Wikipedia) defines the interoperability as an "ability of making systems and organizations to work together (inter-operate)". In (Microsoft, 2012), Microsoft states that "interoperability allows disparate information systems from multiple vendors to readily work together and exchange data". As for the software, term interoperability is used to explain the ability of various programs to:

- exchange data using some of standard formats for data exchange
- read and write same file formats
- use same protocols.

Term interoperability is most frequently used to annotate functioning of different biometric sensors in a number of IT environments (Biometric Web Services, 2012). On the other hand, within the ISO/IEC 2382-1:1993 standard (International Standards Organization, 1993), term interoperability is defined as "The capability to communicate, execute programs, or transfer data among various functional units in a manner that requires the user to have little or no knowledge of the unique characteristics of those units".

The problem of interoperability in biometric systems can be divided into a number of specific tasks. It is necessary to provide a communication tool between biometric solutions (both, open source and proprietary), biometric sensors and biometric database. One of the fundamentally important tasks is enabling communication and standard way of data exchange between biometric system and various types of biometric sensors, as well as acquisition devices. In this way, problem of dependence on a single manufacturer, also known as "vendor lock-in" is being solved. Last, but not the least important task in solving the problem of interoperability in multimodal biometric systems is standardization. In order to provide a wider application field of multimodal biometric systems, standardizing each segment of the system, especially communication, is of great importance. Also, it is necessary to include existing standards and allow their use within the system.

3. STATE OF THE ART

In this chapter, currently available biometric standards that solve the problem of interoperability in biometrics are listed and several most significant institutions in this research area are presented. Also, each of presented standards is briefly described.

There are several important standards which deal with interoperability problem between different biometric solutions, such as:

- MBARK
- BioAPI
- CBEFF
- ISO/JTC1/SC37
- FBI Wavelet Scalar Quantization
- Web Services for Biometric Devices
- OASIS/BIAS

Most of listed standards are not public. However, one of major problems is that none of available standards fully defines communication protocols required for network communication between all parts of a multimodal biometric system. In addition, these standards are mainly dealing with only one part of biometric system, usually the acquisition or data storing processes. Some of most important institutions in the world engaged in biometrics research field are:

- National Institute of Standards and Technology (NIST)
- International Organization of Standardization (ISO)
- International Electrotechnical Commission (IEC)

Tool for multimodal biometric application development MBARK (Multimodal Biometric Application Resource Kit) (Biometric Clients Group, Image Group, Information Access Division, Information Technology Lab, 2009), developed by the National Institute of Standards and Technology (NIST) tends to reduce complexity in the development of biometric applications. MBARK is open source software and it is available to public. It has valuable features, such as: consistent user interface, flexible user configuration and sensor interoperability. MBARK uses plug-in mechanism that enables real sensor interoperability based on mutual API. This API is used for integrating camera, fingerprint and iris scanners.

BioAPI (BioAPI Consortium, 2008) is a complete biometric standard that defines two application programming interfaces: interface for application programming (API) and interface for service programming (SPI). API enables application to utilize BioAPI framework functionalities, while SPI enables the framework to use biometric functionalities. Main goal of BioAPI standard is to enable communication between the application and biometric technologies independently from the manufacturer.

CBEFF is a standard for exchanging biometric data between different systems and organizations. It is adopted by ISO. This standard describes a structure and set of metadata elements necessary to support exchange of biometric information in a common way (National Institute of Standards and Technology, 2004). Among other features, CBEFF promotes interoperability of biometric-based applications and simplifies software and hardware integration process.

NIST recognized the potential of web services and their application in biometrics research field. Thus, project WS-BD (Web Services for Biometric Devices) (Micheals & Kevin, 2012) was created as a mean of providing interoperability of biometric systems. Limitation of WS-BD is that it only applies to the acquisition process of biometric samples.

OASIS BIAS represents efforts of the International Committee for IT Standards (INCITS) to provide a documented, open framework for developing functionalities needed for biometrics based identity management, which can be easily and conveniently accessed through web services. This standard defines and describes methods and relationships through which the BIAS framework can be used within Web services based on XML technology, as well as on service-oriented architectures (OASIS Committee Specification, 2011).

4. BIOMETRICS COMMUNICATION PROTOCOLS

As part of the project "Multimodal biometry in identity management", Laboratory for multimedia communications at the Faculty of Organizational sciences, develops framework for multimodal biometric system development (MMBIO) (Milovanović, Minović, & Starčević, 2012) . One of the problems that needed to be addressed within MMBIO framework is the interoperability problem. It is necessary to design communication protocols and implement software classes required for the functioning of framework in network environment. This chapter describes the solution that is used in MMBIO framework in order to solve the already mentioned issue (Šošević, 2013).

Biometric communication protocols within the framework are divided as follows:

- acquisition
- unimodal
- database
- multimodal

Commands that belong to above mentioned protocols are categorized according to their purpose. Database commands and unimodal commands are further divided into subcategories.

Unimodal commands

The unimodal category consists of those commands that are used to manipulate biometric samples, as well as those commands which are used for authentication. Manipulation of biometric samples includes commands CheckQuality, TransformData and ClassifyBiometricSamples. CheckQuality command is the quality check of the sample after the sample has been captured by the sensor. Using the TransformData command, biometric sample is being processed and transformed to another form. More specifically, some of pre-processing algorithms are applied to the biometric sample. There is a also the possibility to classify biometric sample using a classification algorithm or class. Classification can be done by issuing the ClassifyBiometricSample command.

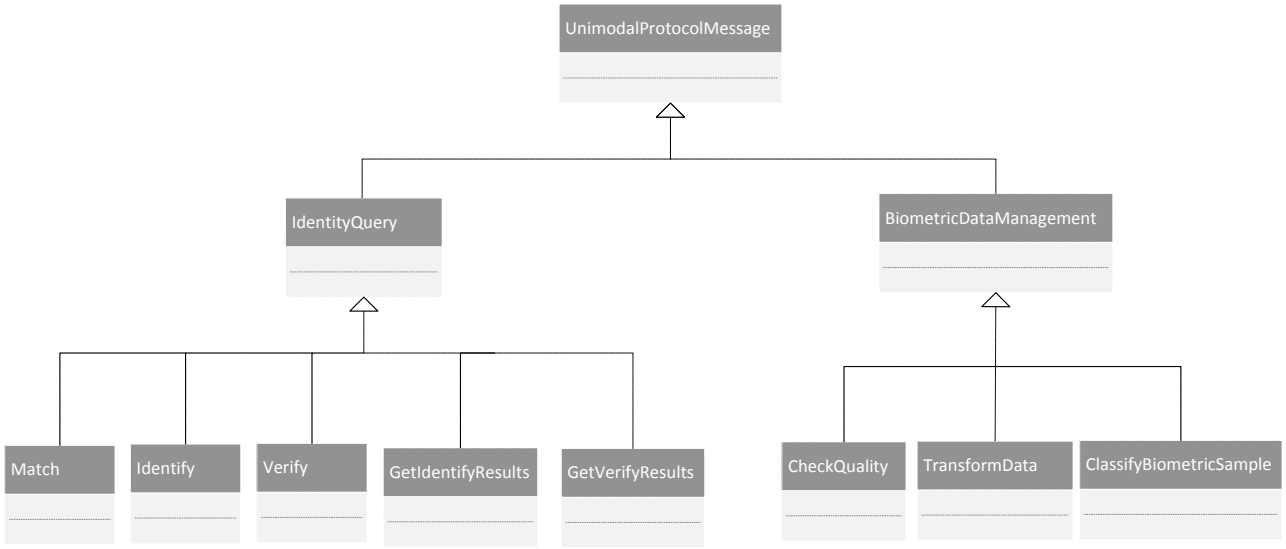

Figure 1: Unimodal commands class diagram

Authentication commands include the process of comparing biometric samples. Precisely, they include two main working modes of a biometric system - identification and verification. Match command initiates comparison of two biometric samples, resulting in a matching score. Besides this command, there are more complex commands - Identify, which executes identification process and Verify, which executes verification process. Two more commands are present in this category - GetIdentifyResults and GetVerifyResults, which are reserved for usage in case of asynchronous communication. Those commands are not yet defined in the current version of protocol specification, which is one of the issues that need to be solved.

Acquisition commands

Acquisition category consists of commands used for direct configuration and managing a biometric sensor. It includes commands SetConfiguration, GetConfiguration, TryLock, ReleaseLock and Capture. Settings to be used by the sensor during samples capture can be set by issuing the SetConfiguration command. There is also an option to view the current sensor configuration via the command GetConfiguration. TryLock and ReleaseLock commands are a part of the mechanism that enables concurrent access to each sensor. Before changing any settings, biometric system has to "take" the sensor by placing a lock (using the command TryLock). By issuing Capture command, the sensor is requested to perform a capture of biometric sample.

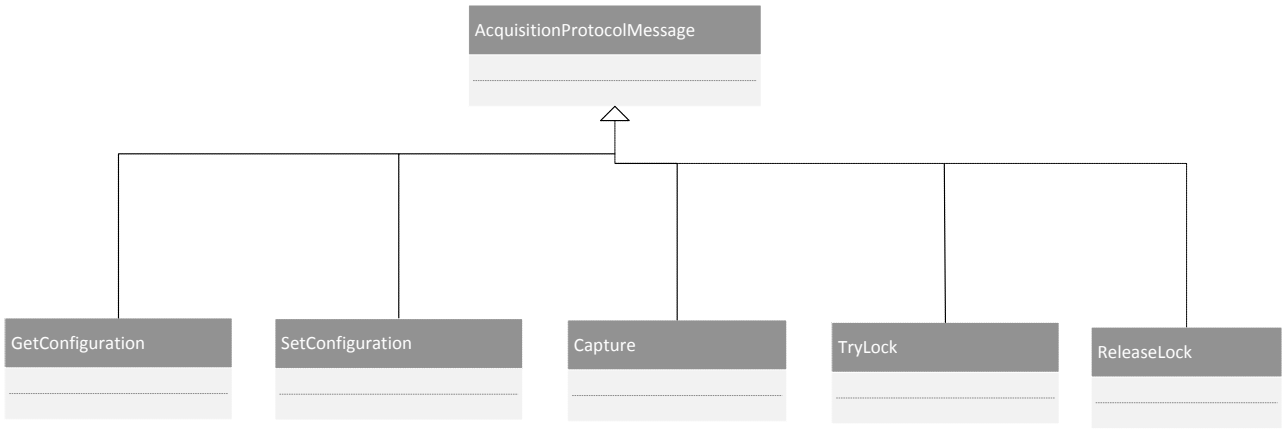

Figure 2: Acquisition commands class diagram

Database commands

Database commands are divided into two groups:

- metadata management commands
- biometric data management commands

Metadata management commands include CreateUser, AddUserToSubset, RemoveUserFromSubset, as well as commands for biographic data management - SetBiographicData, GetBiographicData, DeleteBiographicData and ListBiographicData. It is important to note that metadata also consists of users' biographical information. It is clear that in addition to storing multimodal biometric data in the database, it is also required to save information about users. New user in the database can be created using the CreateUser command. There is also an option to define user subsets in the database (i.e. users from Europe, America, Asia...). Users' belonging to a subset can be defined by issuing AddUserToSubset command. On the other hand, it is also possible to remove the user from the specified subset by using the RemoveUserFromSubset command.

Setting biographical information for the user can be done by calling the SetBiographicData command. Deleting biographical data from the database is done with DeleteBiographicData command. Proposed protocol also provides mechanism for viewing biographical data. Certain biographical data can be extracted from the database by issuing the GetBiographicData command. Also, ListBiographicData enables system user to list all biographical data for a targeted user.

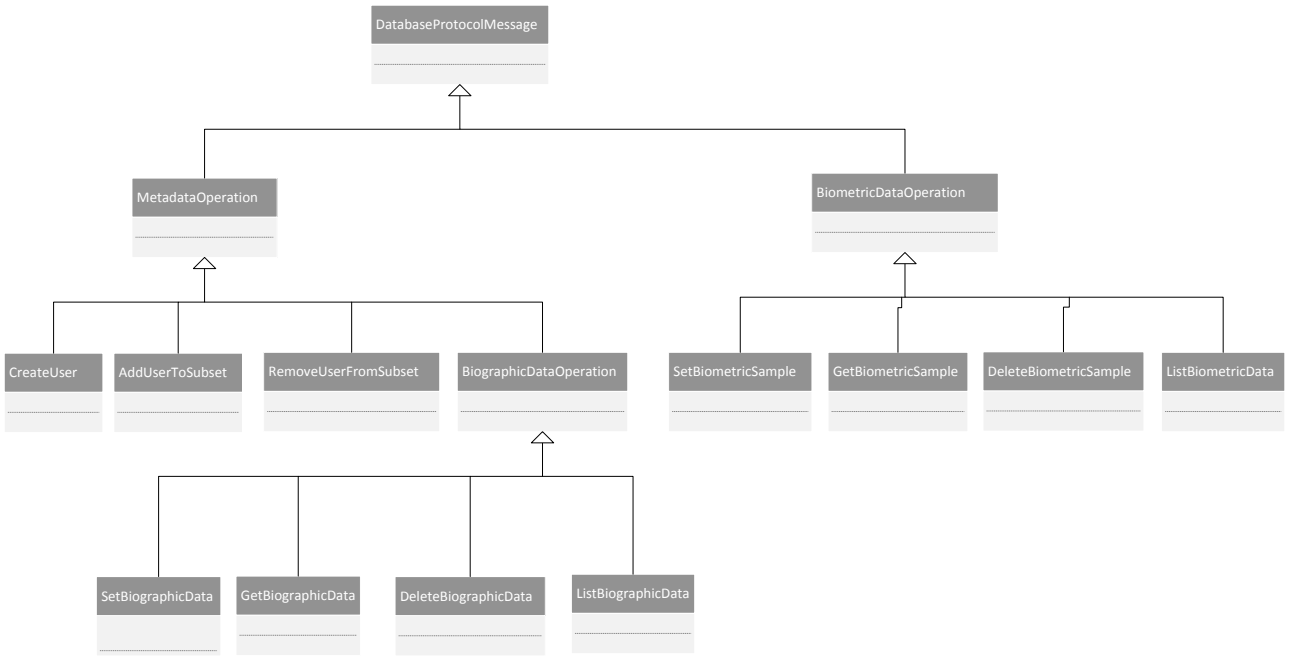

Figure 3: Database commands class diagram

Biometric data management includes similar commands as in biographical data management group. Those commands are SetBiometricSample, GetBiometricSample, DeleteBiometricSample and ListBiometricData. Using SetBiometricSample a biometric sample for a certain user is recorded in the database. If you need to retrieve biometric sample from the database, it can be done by issuing the GetBiometricSample command. To delete saved biometric sample of an user, DeleteBiometricSample command can be used. Also, it is possible to extract all biometric samples of desired user by using the ListBiometricData command.

Multimodal commands

Multimodal commands are those that are used to utilize the functionalities provided by a multimodal biometric system. FuseScores and FuseScoresList commands are members of this category. Using the FuseScores command, matching scores obtained by executing the verification process are fused. By issuing the FuseScoresList command, fusion of matching scores obtained by executing identification process is done. When using both of these commands it is required to define fusion algorithm that is desired to be applied in fusion process. The difference between verification scores fusion and identification scores fusion is that verification process returns only one matching score per modality, while identification process returns a list of matching scores. Thus, the result of FuseScores command is the score calculated by using selected

fusion algorithm. On the other hand, issuing FuseScoresList command results with a list of scores calculated by applying selected fusion algorithm on identification matching scores list.

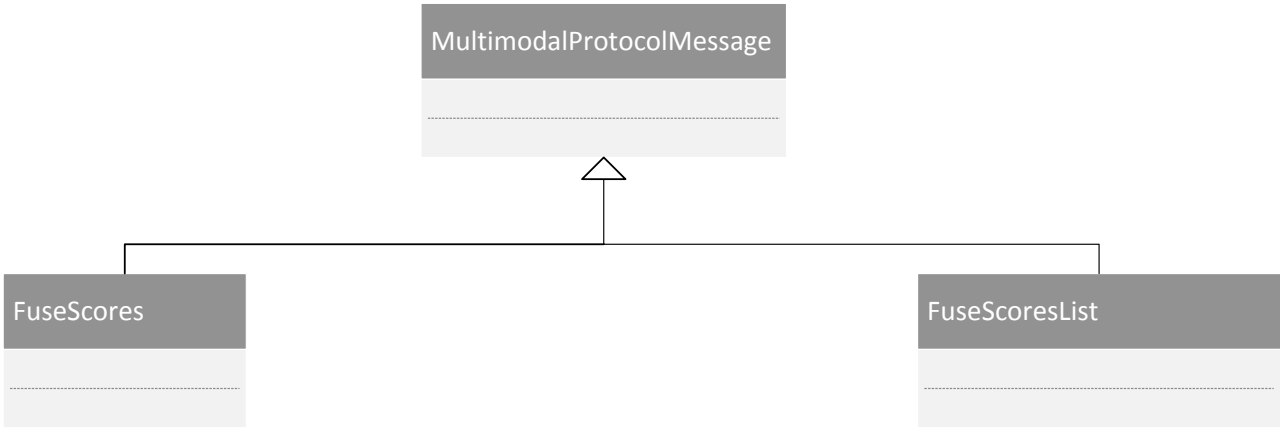

Figure 4: Multimodal commands class diagram

4. CONCLUSION

This paper describes the interoperability problem in multimodal biometric systems. First chapter provided an introduction to the application of biometric systems in institutions and organizations. Afterwards, the term interoperability has been defined and its meaning in the field of multimodal biometrics has been explained. Also, the biometric systems interoperability problem has been stated and current state of the problem has been presented by reviewing the existing relevant literature. In the final chapter, possible solution for the interoperability problem has been proposed in the form of biometric communication protocols and related commands.

Presented communication protocols are being used in MMBIO framework for multimodal biometric systems development. By implementing the defined protocols the interoperability problem in biometric systems is trying to be solved. Communication protocols must be sufficiently generic, but also they need to support all functionalities which are provided by integral parts of a multimodal biometric system. Throughout the paper, several communication protocols used in different segments of biometric system functioning have been presented. Those segments are acquisition, unimodal segment, database segment and segment related to the multimodal approach.

Of course, protocols presented in this paper have several shortcomings. Primarily, all protocol messages are designed in such way that they include synchronous communication. Asynchronous communication is not supported currently. Therefore, adaptation of protocols to asynchronous mode of communication is one of directions of further research. Also, it is necessary to define header fields and information transmitted via protocol messages. It should be considered adjusting developed protocols with existing standards such as CBEFF and/or BIAS.

ACKNOWLEDGEMENTS

This work is a part of the project Multimodal biometry in identity management, funded by Ministry of Education and Science of Serbia, contract number TR-32013.

THE IMPACT OF APPLYING INTERNATIONAL SPECIFICATIONS AND STANDARDS TO BIOMETRIC SYSTEMS

Milorad Milinković[1],
[1]Faculty of Organizational Sciences, milorad.milinkovic@mmklab.org

Abstract: *The rapid development of biometric systems and their wide application in practice have led to the emergence of the large number of hardware and software manufacturers on the international market. This phenomenon caused the problem of interoperability of biometric systems. This problem significantly affects the functioning and performance of biometric systems, with special emphasis on the security of biometric data to be exchanged. In this paper, the application of international specifications and standards is suggested as an important part of the solution to this problem. These specifications and standards, such as BioAPI and CBEFF specifications, registered and published as multistandards by ISO (International Organization for Standardization), propose the establishment of single plaform (BioAPI) and unique format for data exchange (CBEFF), to facilitate the functioning of the biometric systems regardless of hardware or software manufacturers.*

Keywords*: Biometrics, Standards, Specifications, BioAPI, CBEFF*

1. INTRODUCTION

First of all, the term of interoperability should be defined. Li and Jane (2009, p. 27) state that “interoperability in the field of ICT includes the use of the same format or protocol without disrupting the performances of the system”. This is related to the functioning and communication between parts of the same system, as well as cooperation and communication between various systems.

Since Biometrics is increasingly presented on the market (for example, access control, e-commerce, internet banking and other areas that require a high level of data security in authentication) and, as Li and Jane (2009, p. 18) point out, “Biometrics uses physical or behavioral characteristics of an individual to uniquely identify the user during authentication”, the security of information as well as communication between the parts of a biometric system must be at the highest level. Deravi (2008, p. 34) discusses that “due to the fact that the development of biometric technologies and devices, as well as software applications, gained the momentum, there was the problem of large number of manufacturers and the problem of communication between the softwares and devices from different manufacturers (so-called "vendor lock-in")”.

Considering those facts, leck of unique platform as well as unique format for information exchange between components of one biometric system or between different biometric systems has become the big problem. So, as it stands in The BioAPI Consortium report (“BioAPI Specification Version 1.1”, 2001), in 1998 BioAPI Consortium has been formed with the main aim to create BioAPI specification and define a unique platform for communication between applications and biometric technologies regardless of the manufacturer. Subsequently, BioAPI with the status of an international standard should accelerate the acceptance of biometric technologies and a large number of commercial applications at the international level.

On the other hand, as Deravi (2008) points out, since there was no single format that would facilitate the exchange of biometric information, cooperation between NIST Institute and BioAPI Consortium has formed CBEFF (Common Biometric Exchange Formats Framework) as an idea to establish a unique format for the exchange of biometric information between different systems with the emphasis on data security. Primarily, the format for the exchange of fingerprints was established, followed by NISTIR 6529 specification, which applies to all biometric modalities, today now known as CBEFF. The current version NISTIR 6529-A is an extended version of CBEFF which, unlike previous versions, may contain information of various biometric modalities at the same time or more information of a single modality.

In the following text, these specifications are described through examples in detail, emphasizing their role in improvement of the interoperability of biometric systems.

2. BIOAPI SPECIFICATION

In The BioAPI Consortium report (“BioAPI Specification Version 1.1”, 2001, p. 7) stands that “BioAPI is a standard that defines a simple biometric application interfaces, standardized modular approach to biometric

functions, algorithms and devices, standardized methods for distinguishing biometric data and device types, and support for biometric identification in distributed computer environments".

In the same report ("BioAPI Specification Version 1.1", 2001) stands that BioAPI provides the basic functions of biometric systems, such as Enrollment, Verification and Identification, and includes a database interface that allows to BSP, a software which communicates with the device for enrollment and verification, to manage the Identification of the population. Also, BioAPI defines an API (Application Program Interface) for the application developers and SPI (Service Provider Interface) for developers in the field of biometric technology. Those interfaces present the two basic levels of BioAPI platform.

3. STRUCTURE OF BIOAPI PLATFORM

The basic version, BioAPI v1.1, consists of two essential parts presented in Figure 1 ("BioAPI Specification Version 1.1, 2001", p.17): API, Biometric Application Programming Interface, or application level, and the SPI or Biometric Service Provider Interface. API is the highest level where the basic biometric functions, that each software application must contain in order to communicate with BioAPI platform, are implemented.

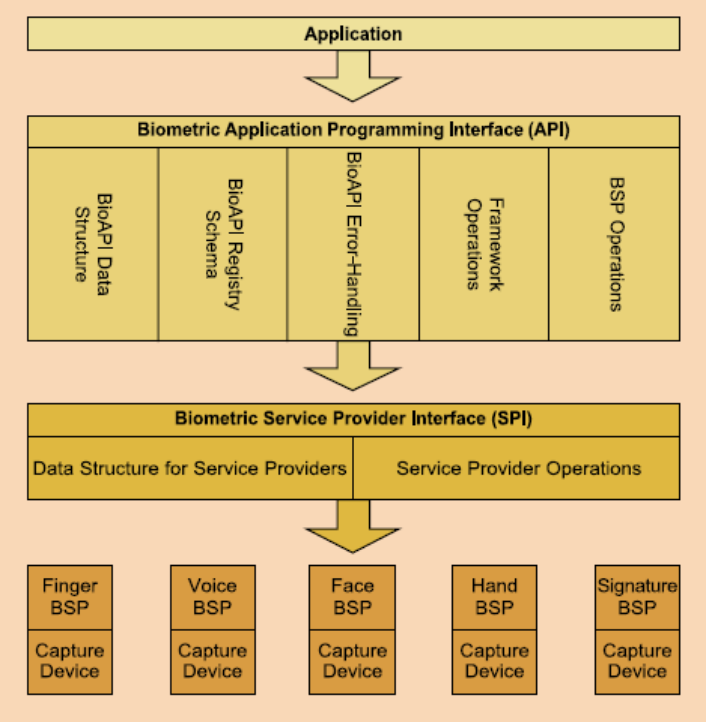

Figure 1: *Structure of BioAPI platform* ("BioAPI Specification Version 1.1, 2001", p.17)

In The BioAPI Consortium report ("BioAPI Specification Version 1.1", 2001) stands that API level is organized into five categories as shown in Figure 1. The first category is the Biometric Data Structure and defines all the data structures that are used in the application. BioAPI Regisity Schema is used to store information for each component within BioAPI. BioAPI Error Handling defines operations for error management within BioAPI. Framework Operations defines general operations for running and disabling applications. BSP Operations provides operations for data exchange and communication between the application and the BSP. All biometric operations Capture, Process, Enroll, Verify, Identify and so on, are defined by the BSP Operations. Among other things, BSP Operations provides operations that allow applications to access and manage biometric databases.

In the same report ("BioAPI Specification Version 1.1", 2001) stands that SPI consists of two categories: Data Structure for Service Providers and Service Provider Operations (BSP). SPI communicates 1-on-1 with the BSP. API calls are routed to the SPI. Every BSP is connected to the BioAPI via SPI. BSP (Biometric Service Provider), regardless of the manufacturer, is a software that communicates with the biometric device and must be compatible with SPI interface specification, because it is the only way to be engaged into the BioAPI working environment and to be used by all biometric applications compatible with BioAPI. BSP contains the unique aspects of individual biometric technologies, namely the products and devices of certain manufacturers (for example, there are BSP for face, hands, iris etc.). BSP can be local or distributed. Local BSP completely operates within a single platform, while distributed BSP can be instantiated and loaded as a separate client-server components with a client-server communication. For biometric applications, client-server architecture is usually applied because it is safer environment for the executive biometric algorithms,

and when it comes to the identification of a large population this architecture has enough power to run the biometric algorithm unlike local BSP. In addition, the database can be placed on a server, which makes client work easier.

4. BIOAPI COMPLIANT BIOMETRIC SYSTEM EXAMPLE

In the following text there is small example of a biometric system for face verification of the persons, which works within LAN (Local Area Network), and it is also compliant with BioAPI specification and based on a client-server architecture.

4.1 BSP FOR FACE VERIFICATION COMPLIANT WITH BIOAPI (SPI LEVEL)

In their paper, Yuan, Hui, Leung and Gao (2004) discuss the significance of compliance of biometric system with BioAPI explaining the small example of biometric system for face verification. Apart from the mandatory operations defined in the SPI, Yuan et al. (2004) explain that the four primitive biometric functions Capture, Process, CreateTemplate and VerifyMatch are implemented. LEM algorithm is used to compare face images due to recognizing a person. On a sample of 30 users LEM showed nearly a 100% accuracy in recognizing.

Capture is a function for taking a picture of an individual faces, when enrolling or verifying person. It provides a GUI or graphical user interface for taking a picture with the camera. Taking picture provides picture frame, face image and user information (such as Customer Identification Number).

Process function allows preprocessing and normalization of the face samples for verification. It takes the raw data after Capture function and output is processed biometric data.

CreateTemplate function processes the raw array of pictures (gallery) after the Capture function done working to create a template for enrolling. It involves three steps: pre-processing, normalization and LEM formatting. Array of nine images is generated from the raw data (in the form of a single data), which are standardized for LEM. After that, the image information is encoded and returned to the launched application and stored in the Application Database.

The last function VerifyMatch compares the processed biometric data after Process function and face templates from Application Database.

4.2 BIOAPI COMPATIBLE APPLICATION FOR FACE VERIFICATION (API LEVEL)

Yuan et al. (2004) in their paper explain the importance and performance of BioAPI compatible application, called FaceControl, for access control to the protected area. The application is implemented in a client-server architecture. The client makes a face image, while the server processes and verifies the raw image with the stored templates from the database. The client and the server communicate via LAN. Figure 2 (Yuan et al. 2004, p. 295) and Figure 3 (Yuan et al.,2004, p. 296) illustrate the client-server processing in FaceControl application by calling the primitive functions included within BSP.

Figure 2 (Yuan et al., 2004, p. 295) presents the process of enrollment. The client uses the Capture function to enroll. The output is an intermediate data in the form of image-array. It is sent to the server. Server calls CreateTemplate function from the BSP. After processing, template-array is created and recorded in the database.

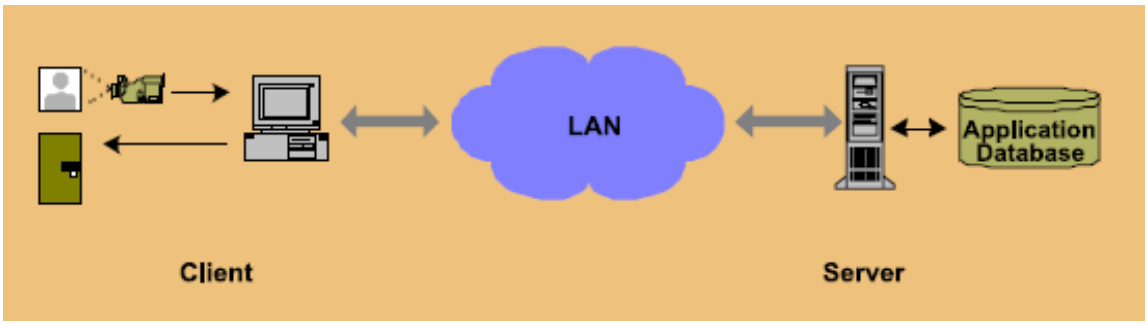

Figure 2: *Process of enrollment* (Yuan et al., 2004, p. 295)

Figure 3 (Yuan et al., 2004, p. 296) explains the verification process. On the client side, FaceControl calls Capture function for face verification. After taking picture output is intermediate biometric data that is sent to the server for verification. On the server side after Process function output is processed data and it will be compared using VerifyMatch function with template array called from the Application Database. The result is

returned to the application FaceControl on the the client side. The result of the verification implies whether person may approach to the protected area or not.

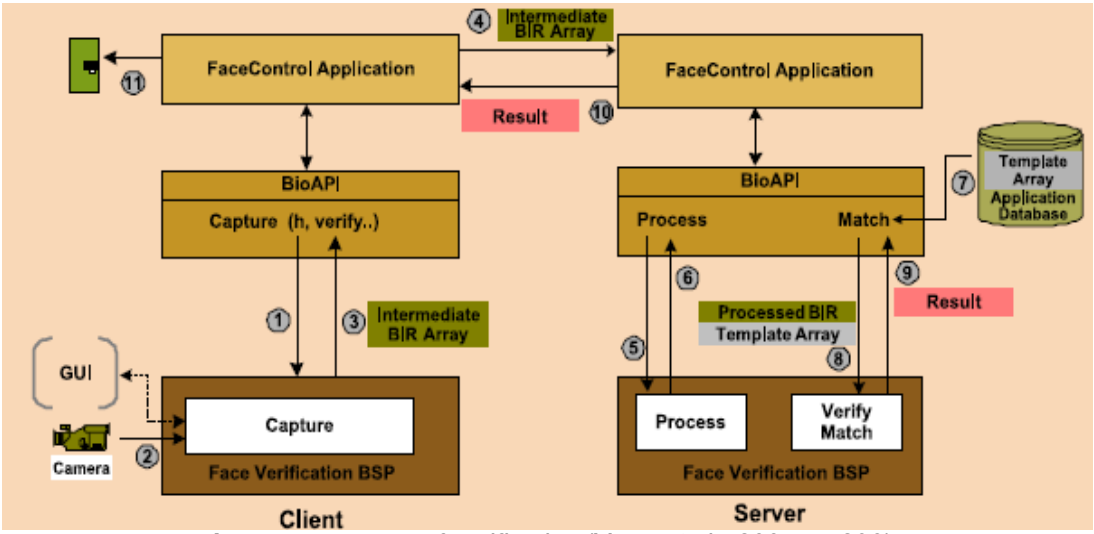

Figure 3: *Process of verification* (Yuan et al., 2004, p. 296)

5. CBEFF (COMMON BIOMETRIC EXCHANGE FORMATS FRAMEWORK)

Clarke (2011, p.57) defines CBEFF as "set of general guidelines for the establishment of standards or specifications compliant with standard, created by some of the so-called patron organizations like BioAPI Consortium, ISO, ANSI, NIST, etc.". Clarke (2011) state that CBEFF record comprises a set of elements of the biometric data used for biometric information exchange between the various components within one biometric system or between more biometric systems. CBEFF record is compliant with (patron) format defined by some of the standards. An essential part of CBEFF record is BDB defined by one of the client organizations that is registered with the IBIA association (International Biometric Industry Association).

Clarke (2011) points out that compatibility of biometric data with the standard or specification in the exchange of information enables smooth exchange of data regardless of the manufacturer or biometric technology. If two systems during data exchange use different standards or specifications that are consistent with CBEFF framework, there are standardized applications that transform CBEFF basic structure from one patron format to another patron format for easier communication, which improves system interoperability.

6. CBEFF DATA STRUCTURE

According to NIST report ("CBEFF", 2004) there are two CBEFF data structures: basic and nested. The basic CBEFF structure refers to one biometric modality such as face, iris, fingerprint, etc. The nested structure can be very complex and generally contains the data elements of two or more biometric modalities.

6.1 CBEFF BASIC DATA STRUCTURE

In the basic structure, CBEFF data elements are placed in the fields within CBEFF record (file). Fields are grouped into the three main sections: SBH, BDB and SB. Each section includes fields that are required or optional.

6.1.1 SBH (STANDARD BIOMETRIC HEADER)

In the NIST report ("CBEFF", 2004) stands that SBH is composed of the basic fields that may be required or optional, and carries a particular set of data necessary for the exchange within the system or between the different systems, as it is described in Table 1 (NIST report, "CBEFF", 2004, p.6). Each field is described and presented within Table 1.

Table 1: *SBH fields* (NIST report, "CBEFF", 2004, p.6)

Field Name	Required or Optional	Description
SBH Security Options	R	Defines data security
Integrity Options	R	This field defines which the integrity attribute goes with data. Signature or MAC.
CBEFF Header Version	O	-
Patron Header Version	O	Patron Format Specification or Standard version.
Biometric Type	O	Biometric type (e.g., fingerprint, voice, etc.).
Biometric Subtype	O	Additional specification within a biometric type.
Biometric Data Type	O	Level of processing applied to this data (e.g., raw, processed, etc.).
Biometric Purpose	O	Intended use of the data (e.g., enrolment, verification, etc.).
Biometric Data Quality	O	Quality of the biometric data.
Biometric Creation Date	O	Creation date and time of the biometric data.
Validity Period	O	Valid-From and Valid-Until Dates for this record.
Creator	O	Text identifier of the application's owner.
Index	O	Unique identifier for the biometric reference data within the record's application space.
Subheader/Basic Structure Count	O	Number of CBEFF Structures in the level below this header's level in a CBEFF nested structure.
BDB Format Owner	R	ID of the Group or Vendor which defined the BDB.
BDB Format Type	R	BDB Format Type as specified by the Format Owner.
Product Identifier (PID)	O	Unique (registered) identifier of the entity that created the biometric data.
Patron Format Identifier	O	Unique (registered) identifier of the patron format of the next lower nested level.
Biometric Data Block (BDB)	**R**	**Defined by the Format Owner. May be encrypted.**
Signature	**R**	**Signature or MAC. Only present if the SBH Security Options value is "Integ-rity-Only" or "Privacy-and-Integrity".**

It can be concluded that each biometric record with this kind of structure is standardized and ready to be exchanged with the component or system that uses the same CBEFF format, and used as well for different purpose such as enrollment, verification, etc.

6.1.2 BDB (BIOMETRIC DATA BLOCK)

This section according to NIST report ("CBEFF", 2004) contains the biometric data of a certain modality (iris, face, hand print, fingerprint, etc.). It represents a memory block specified by the owner of the data type (modality). It can be standardized and non-standardized, depending on whether it is adopted by an official body, working group or consortium. Manufacturer, the official body for standardization, working group or consortium may determine that this field contains only the biometric template. Also they can determine the structure of the data with additional parameters and information. Patron format specifications may require that BDB must be encrypted (specially defined encryption) or uncoded, which is an optional security measure.

6.1.3 SB (SIGNATURE BLOCK)

This field contains a unique digital signature (content was determined by the patron format specification) and it is a security measure.

6.2 CBEFF NESTED DATA STRUCTURE

In the NIST report ("CBEFF", 2004) stands that nested structure exists when it comes to exchange of more then one biometric modality (fingerprint, face, voice, iris, etc.) simultaneously and/or more biometric data of one modality. It contains root header and sub-headers. Each sub-header corresponds to a certain modality. In the Figure 4 (NIST report, "CBEFF", 2004, p.14) example of nested CBEFF structure is presented. This CBEFF record carries the data of two modalities: voice and fingerprints. BDB sections are standardized or non-standardized. The record is protected by the signature.

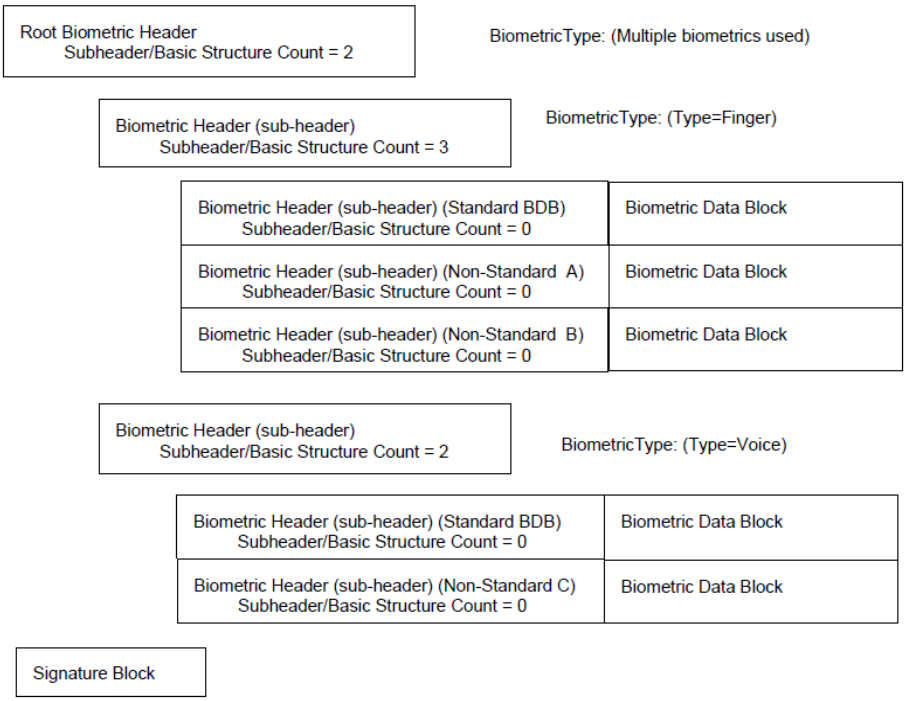

Figure 4: *CBEFF nested structure* (NIST report, "CBEFF", 2004, p.14)

7. CONCLUSION

Standardization of biometric systems is a key to their successful implementation and operation. The establishment of the unique working environment, unique working protocols, technical interfaces and everything else that makes a platform functionally independent such as BioAPI, implies that biometric systems gain two very important characteristics - interoperability and interchangeability (replacing system components without disturbing the operation of the system) that make them unique and allow system operating regardless of the origin of components. Components become changeable, systems become more functional and harmonized, communication within the system easier, and more important is that the costs of development and exploitation of components and systems are becoming lower.

On the other hand, several multiple standards published in U.S. (by ANSI, NIST) as well as worldwide (by ISO), based on CBEFF, proves the importance and the advantages of CBEFF framework in terms of improving system interoperability and security in exchanging data.

Simultaneous application of an independent platform and a unique format for the exchange of biometric information, solves the problem of interoperability of biometric systems as well as security of biometric data exchange, and elevates to a higher level the exploitation of existing biometric systems as well as development of modern and sophisticated biometric systems.

NOVEL APPROACH FOR TEXT PLAGIARISM DETECTION

Predrag Krstojević[1], Nikola Milikić[2]
[1]Faculty of Organizational Sciences, University of Belgrade, Serbia pkrstojevic@gmail.com
[2] Faculty of Organizational Sciences, University of Belgrade, Serbia nikola.milikic@gmail.com

Abstract: *With the widespread use of the Internet for educational and personal purposes, access to the online books and research papers have become much easier for everybody. But that has also resulted in making text plagiarism become much easier to perform and plague the research publishing industry. In this paper, we tackled the problem of computer-assisted text plagiarism detection. We have developed an algorithm for plagiarism detection based on the combination of string matching and bag of words techniques. The algorithm is language and topic agnostic and can be applied to different cases of text plagiarism problems. The evaluation has shown that algorithm gives good results in detecting text plagiarism in documents with different topics. Also, it gives almost the same results as a commercial tool it has been compared with. Future work would include more extensive evaluation and development of a full-fledged web application for plagiarism detection based on this algorithm*.

Keywords*: plagiarism detection, plagiarism detection systems, bag of words, string matching, algorithm*

1. INTRODUCTION

Problem of plagiarism of essays and thesis work in education is a growing nuisance. Omnipresence of the Web makes the process of finding similar works significantly easier and thus the opportunity for a student to copy/paste a paragraph, page or even a complete work of somebody else becomes trivial. Pew Research Centre has performed a study and reports that 89 percent of study participants credited the rise of plagiarism to the widespread use of computers and the Internet. In the same report, authors state that 55 percent of college presidents have seen increase of plagiarism in students' papers in the past 10 years, while only 2 percent declared plagiarism is on the decline (Parker et al, 2011). Proper procedure when re-using somebody else's work would be to properly reference the original paper and thus give the appropriate credits to the author. However, the problem arises in cases when other author's content is re-used without proper referencing, which arrogates his/her work and contribution.

The topic of this paper is to design a technique for plagiarism detection in texts. This technique should be language agnostic in order to avoid lexicological and morphological specificities of a language a text is written in. This would also enable wider use of the new technique. The technique for plagiarism detection is based on the algorithm for calculating text similarity of two text documents. The algorithm is described in this paper. It is assumed that if two documents have a high text similarity score, than one document is a plagiarism of the other. This paper also describes a reference implementation of the text plagiarism detection technique and it is written in the Java programming language. The reference implementation was used to test the technique and compare its results with other approaches and tools. Also, the reference application can be downloaded and used within other applications or as a separate program.

The following section (Sec. 2) will describe common methods of text plagiarism and approaches for their detection. Section 3 presents the new approach for calculating text similarity that we are introducing in this paper. After that, in Section 4, the algorithm for calculating text similarity score is described and is followed by an example of calculating text similarity score (Sec. 5). Section 6 presents the reference implementation software of the new algorithm that was used to perform the evaluation of the algorithm (Sec. 7). Finally, we conclude the paper and give outline of directions for the further research (Sec. 8).

2. STATE OF THE ART

By observing various examples of text plagiarism, commonly found methods for illegitimate text usage can be summarized as follows (Gipp et al, 2011):

- *Copy & Paste plagiarism* - the direct copying of an entire text or part without a quotation;
- *Disguised plagiarism* - includes addition or modification of some parts of a text in order to disguise the act of copying someone else's work;
- *Undue paraphrasing* - the intentional rewriting of other peoples' ideas;
- *Translated plagiarism* - the machine or human translation of paragraphs from other sources from one language to another without adding references;

- *Idea plagiarism* - the appropriation of research methods, experimental setups, argumentative structures, and background sources.

Clough (Clough, 2003) identifies similar forms of plagiarism methods and distinguishes between: Word-for-word plagiarism, Paraphrasing plagiarism, Plagiarism of secondary sources, Plagiarism of the form of a source, and Plagiarism of ideas.

Existing plagiarism detection systems (PDS) can be categorized into *extrinsic* and *intrinsic* plagiarism detection. Extrinsic PDS method is a comparison of a document with a corpus of reference documents. Intrinsic PDS method does not use a reference corpus for comparison, but uses methods that resembles human ability to spot potential cases of plagiarism just by reading the content and detect variations in writing style (Eiselt et al, 2009; Alzahrani et al, 2012; Seaward & Matwin, 2009).

There are many different approaches of plagiarism detection, as well as their variations. The most commonly used approaches are (Gipp et al, 2011; Gipp & Meuschke, 2011):

- *Fingerprinting* method is currently the most widely applied approach for plagiarism detection. Documents are represented as a digest composed of a set of substrings of original text. These sets are called fingerprints, and their elements are called minutiae. After the formation of fingerprints of two documents, matching of fingerprints and their minutiaes are performed;
- *String matching* involves searching for verbatim text overlaps between texts. If the matching string is longer than given threshold, then the text is considered as a plagiarism;
- *Bag of words* analysis assumes representing documents as one or multiple vectors, e.g. parts of the document, which are used to calculate text similarity.
- *Citation-based Plagiarism Detection* is intended for academic works that have a lot of references. This approach uses citations and references for determining similarities between documents in order to identify plagiarism;
- *Stylometry* is one of the most used methods for intrinsic plagiarism detection where linguistic features of a suspicious text are examined in order to detect variations in writing style.

3. DESCRIPTION OF A NOVEL ALGORITHM FOR CALCULATING TEXT SIMILARITY

The algorithm for calculating text similarity that is proposed in this paper receives as input two text documents whose contents are being compared. The result is a similarity score of these text documents that ranges between 0 and 1. The algorithm consists of the following steps:

1. Generating the list of the most frequent words in both documents separately. The number of the most frequent words the algorithm should find is configurable. All words that do not add to the context of the text content are ignored (prepositions, conjunctions, etc.). The most frequent words are sorted in descending order by the number of occurrences in the text.
2. Finding intersection of the most frequent words from both text documents.
3. In this step, occurrences of the most frequent words (from the intersection list generated in step 2) are looked up in both text documents. For each occurrence of the most frequent word, a context window is created. Context window is composed of the most frequent word and words that precedes and follows it. Context window enables detecting the same parts of sentences in two text documents as they preserve the context a frequent word has occurred in. That means if someone has copied someone else's text, context windows are going to be the same in both text documents.
4. Context windows for both text documents are compared and text similarity score is calculated according to the formula that is described in the following section.

Example of half context window

Listing 1 presents two examples of half context windows. Half context window consists of only one word that proceeds or one word follows the most frequent word. These two examples show context windows for the words *start* and *globalization*.

start: [
is ***start***,
start process,
its ***start***,
start corresponds,
one ***start***,
start is,
period ***start***,
start eight,
doesn't ***start***,
]

globalization: [
begin ***globalization***,
globalization reflected,
called ***globalization***,
globalization should,
is ***globalization***,
globalization occurs,
for ***globalization***,
globalization preceded,
is ***globalization***,
]

Listing 1: Example of half context window

Example of context window of length 1

Listing 2 presents examples of context windows of length 1 for words *start* and *globalization*. Context window of length 1 has one word preceding and one word following the most frequent word.

start: [
is ***start*** process,
its ***start*** corresponds,
one ***start*** is,
period ***start*** eight,
doesn't ***start*** training,
]

globalization: [
begin ***globalization*** reflected,
called ***globalization*** should,
is ***globalization*** occurs,
for ***globalization*** preceded,
is ***globalization*** made,
]

Listing 2: Example of context window length 1

4. CALCULATING TEXT SIMILARITY SCORE

First, for each of the most frequent words we calculate its context window matching score by using the formula (1).

$$cwm_l = \frac{ct}{st} \qquad (1)$$

where:

cwm (context window match score)	Score of the context window matching for the particular most frequent word
ct	Number of context windows that appear in both text documents for the particular most frequent word
st	Total number of unique context windows in both text documents for the particular most frequent word
l	Context window length

Word weight is obtained by the formula (2).

$$ww_i = \frac{cw_i}{\sum_{j=0}^{m} cw_j} \qquad (2)$$

where:

ww (word weight)	Word weight in relation to the whole set of the most frequent words
cw (context window)	Number of context windows for the i most frequent word
m	Number of the most frequent words in a document

The formula for calculating the text similarity score:

$$ss = \left(\sum_{i=0}^{k} ww_i \cdot cwm_i\right) \cdot \frac{k}{n} \qquad (3)$$

where:

ss (similarity score)	The similarity score of two text documents
ww (word weight)	Word weight of i in relation to whole set of the most frequent words
cwm_i (context window match)	The degree of matching of context windows for i the most frequent word
n	Number of the most frequent words
k	Number of words obtained by intersection of the most frequent words in two documents

5. EXAMPLE OF TEXT SIMILARITY CALCULATION

Figure 1 presents an example of calculating the text similarity score of two text documents. First, ten most frequent words are found in both texts (n = 10). In these two lists of the most frequent words, 7 words are the same (k=7). For example, the most frequent word “PHP” appears 20 times in the first text document, while it appears 30 times in the second text document. For each word from this intersection set, context windows are created and compared. For instance, for the word “PHP” the same context windows appear 15 times in both text documents (ct = 15), while there are 35 unique context windows in both text documents (st = 35). Context window match (cwm) score for this word is 15/35 = 0.43.

Word weight (ww) is the weight of a word in a document (from the set of the most frequent words). For example, the most frequent word “PHP” appears 20 times in the first document, while the total number of occurrences of all most frequent words is 142. When 20 is divided with 142, a calculated word weight for the word “PHP” is 0.14 (ww = 0.14).

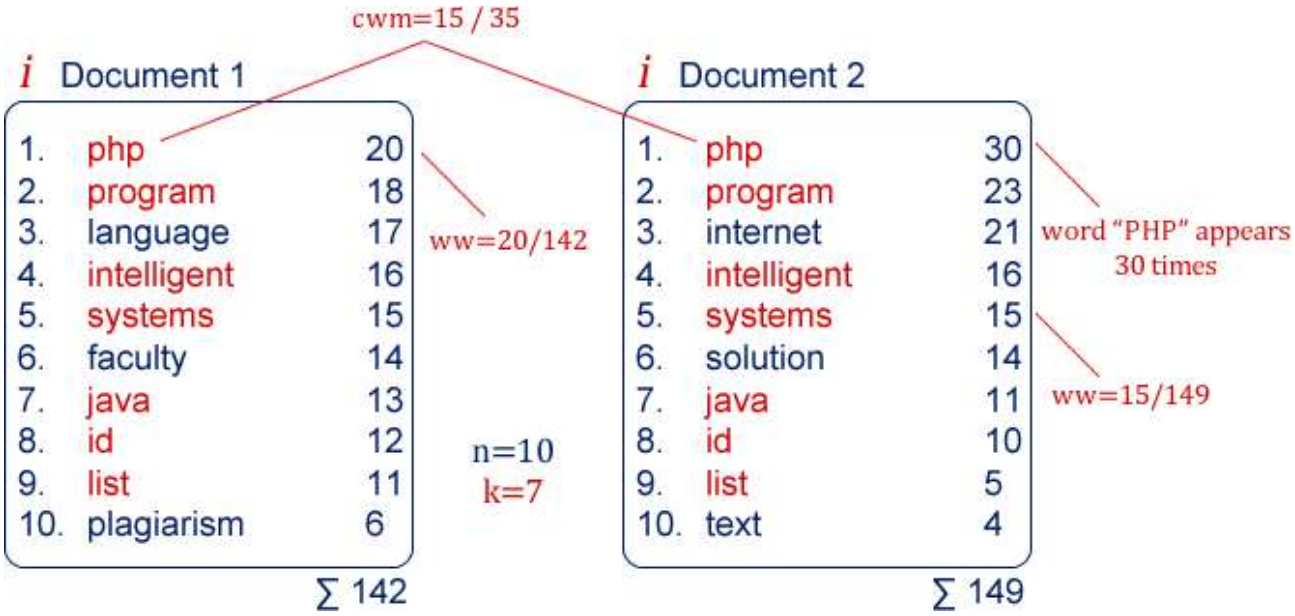

Figure 1: Example of computing the similarity score

For each of the most frequent words this process is repeated, and then these values are used for calculating the text similarity score. Values of context window match and word weight are multiplied and this value is summed for all of the most frequent words. In the end, the total sum of all final values is multiplied with a degree of matching of the most common words in both documents (k/n).

6. SOFTWARE DESCRIPTION

In order to evaluate this algorithm, we have created a prototype application in the Java programming language that implements the algorithm for calculating text similarity score (Fig. 2). The application allows loading original text document and several test documents that will be compared with the original. Also, the application supports loading content from .doc, .pdf and .txt files.

User can choose a number of the most frequent words to be looked for and the length of the context window, which can affect precision of calculating the text similarity score. When application finishes comparison of text documents, it displays the result of matching documents in the range of 0 to 100.

Also, after completion of documents comparison, application displays a report (Fig. 3) that contains all relevant information about the process of calculating text similarity score.

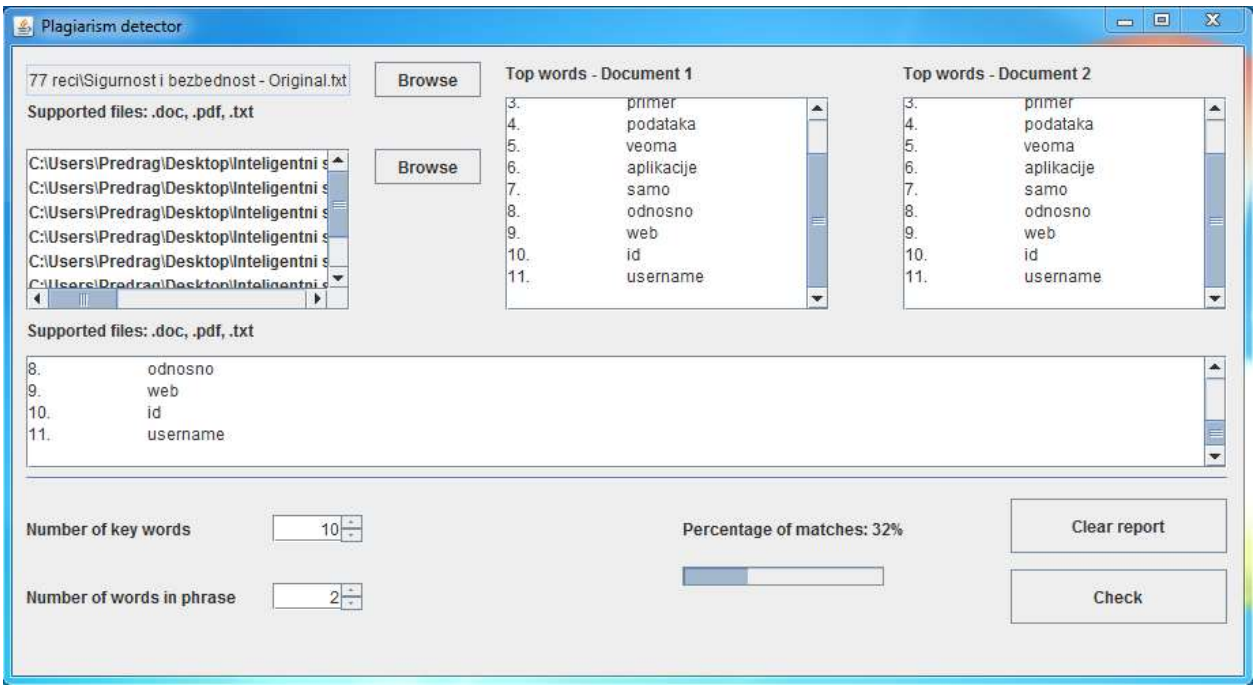

Figure 2: GUI of the plagiarism detection prototype application

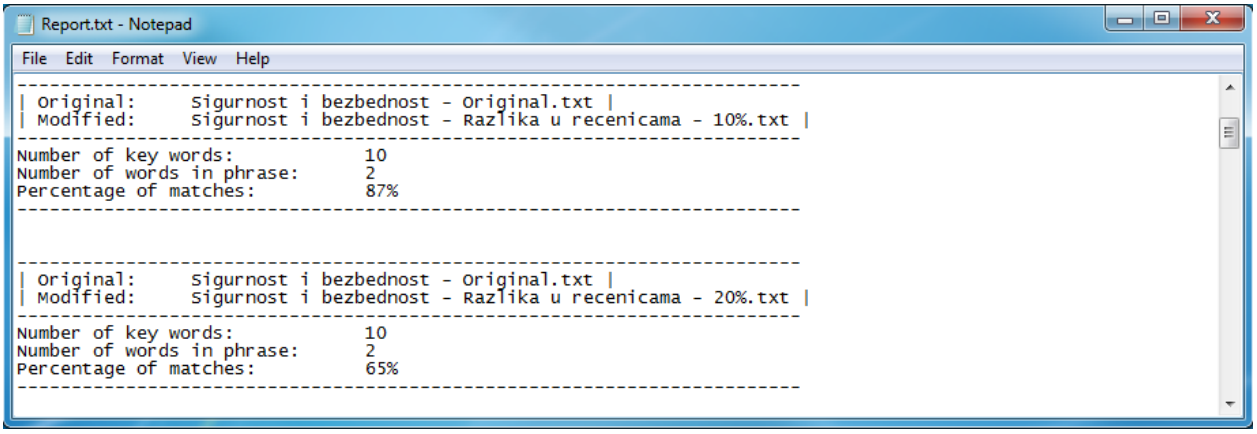

Figure 3: Report example

7. EVALUATION

Previously developed prototype application was used for the evaluation process. Six different text documents in Serbian language with different topics and number of words were selected. And for each of them we have created a comparison set consisting of the texts with the same content, but modified in a specific way. Modification was performed in two ways in order to get approximately realistic situation of re-using someone else's work. The first method, called *Random changed words*, consisted of randomly selecting words in a document and modifying it by adding several characters to the end of the word. The assumption behind this approach is that the potential plagiarist will modify only certain words in a document. In the second approach, called *Randomised sentence words*, a document was modified by randomly changing the order of words in a sentence. The assumption behind this approach is that a potential plagiarist will replace a sentence from the original document with another sentence that uses the same or similar words. In total, we have generated 84 different test documents to evaluate the algorithm with.

Table 1: Examples of modifications in test documents

Original text Globalization is the process of international integration arising from the interchange of world views, products, ideas, and other aspects of culture.
Random changed words Globalization is the <modified word> of international integration <modified word> from the interchange of world views, products, ideas, and <modified word> aspects of culture.
Randomized sentence words aspects integration is the world process products of international arising from the of views, ideas, interchange and other globalization of culture.

Using these two modification methods we have generated seven test versions of each original document, but with the content modified in 10, 20, 30, 40, 50, 60, and 70 percent.

Evaluation of the algorithm was performed by comparing content of each of the original text documents with respective versions of modified documents. We evaluated each test document with different configurations of the number of the most frequent words and different context widow lengths. The number of the most frequent words (*n*) was set to 10 and 30 words. And we have also tested the algorithm to compare different lengths of context windows (*cwl*), i.e. half context windows, context window of the length one and the length two. The algorithm was tested with these six combinations of configurations over the test documents generated by the two modification techniques. Configuration combinations are:

- C1 – n = 10, cwl = ½
- C2 – n = 30, cwl = ½
- C3 – n = 10, cwl = 1
- C4 – n = 30, cwl = 1
- C5 – n = 10, cwl = 2
- C6 – n = 30, cwl = 2

Also, with the same test dataset, we have tested the performance of the commercial plagiarism tool Plagiarism Checker X[1] in order to compare its results with the algorithm described in this paper.

Comparing document versions generated by the two modification methods, we can observe that the algorithm scored higher the documents modified with the *Randomised sentence words* approach. Out of 84 different versions of test documents, in 63 cases the algorithm gave the best results when configuration C2 was used. In 14 cases the best results were achieved with configuration C1 and in only 7 cases C4 gave the best results.

When observing the performance of the comercial tool Plagiarism Checker X, it gave slightly better results with documents generated with the *Randomised sentence words* modification method. But with documents generated with the *Random changed words* modification method, the comercial tool gave far worse results..

Tabelar presentation of the evaluation results can be found on the following page: http://is.fon.rs/node/29. Also, generated test documents used for the evaluation can be retrieved from the same page.

8. CONCLUSION AND FUTURE WORK

From the evaluation results, we can make a conclusion that the algorithm for plagiarism detection introduced in this paper has the best results when number of the most frequent words is set to 30 and half context window is used (configuration C2). This configuration gives the best results with test corpuses generated with both modification methods (*Random changed words* and *Randomised sentence words*). When compared with results of the commercial tool Plagiarism Checker X, the commercial tool gives slightly better results. But here, we should have in mind that this tool is commercial and closed source.

For the future work, we plan to further develop the algorithm. One of the improvements would be to combine this approach with the Citation-based Plagiarism Detection method. Also, we plan to perform evaluation of the algorithm with texts in other languages, first of all English. The prototype application developed for performing the evaluation will be documented in detail and published on the Web as an open-source library.

[1] Plagiarism Checker X is a commercial program for plagiarism detect with various functionalities, such as comparing two documents, compare multiple documents and online document search. link: http://plagiarismcheckerx.com/

The goal is to develop a full-fledged web application based on the new algorithm that can be used in educational institutions for plagiarism detection.

NEW PROCUREMENT MODEL

Dragan Manojlov[1], Viktor Nagy[2]
[1]Deloitte Central Europe, dmanojlov@deloittece.com
[2]University of Pecs, nviktore@gmail.com

Abstract: *The new procurement model would serve for improvements of procurement process in many companies which use an old purchasing model which covered only procure to pay process. The procure-to-pay cycle, including all activities from the procurement of fixed assets, goods and services to receiving invoices and paying vendors, is the basic business process. The companies, especially in public sector, do not have optimal control of risks in procurement process and face with late fees, wasted time, break in business process and with non-compliance issues such as fraud or overlooked incidents. In order to mitigate these risks and increase market competitiveness, the company must to develop and implement the modern procurement model. Having after developing of new purchasing model which including the whole cycle from sourcing to paying of obligation in procurement, it would be crucial for company to implement an adequate software solution in order to automatize all purchasing processes as much as possible. SAP and Oracle EBS as ERP systems earned more than 38% of total ERP software revenues in 2012 on world-wide basis (Pang, Dharmasthira, Eschinger, Motoyoshi and Brant, 2012), offer up-to-date solutions for procurement processes. The choice of the right solution for companies is the last, but the most important stage in order to close procurement model (Manojlov, Lutovac, 2012 SymOrg). This paper is taken into consideration all the facts and standing conclusions from previous procurement models as the source for developing new solution. In order to create new business model for procurement, we used comparative method for analysis of software solutions by using of external sources, survey to assess level of centralization of procurement in several companies where data are collected through interviews with CEO and Managers of these companies. Additionally, description method is used in order to establish link between relations and rules in old procurement model. In most companies, the change of business model for procurement is seen as a necessary step and focus is placed on that a change of business model is needed. In this paper, we elaborate the characteristics of old procurement models and define steps & guidelines as approach in implementation of new procurement model. The benefits of creating the right procurement model for the company are substantial, not only in terms of cost reduction, but also in the ability to better focus resources, enhance value from supplier collaboration and innovation, and more fully captured contractual promises.*

Keywords*: New procurement model, procure to pay, optimization in purchasing, ERP*

1. INTRODUCTION

The role of the procurement can be formulated on many ways depending of the specifics in the company. The connection between the company`s operation and procurement is very closed. The significance of procurement processes has strong relation with definition of final product of the company. If company is repetitive manufacturer with classic finished products included various raw materials plus external services in their BOM`s, the procurement department plays the critical role. In discrete manufacturing and service companies, the procurement model has the less influence on the whole business process. However, the procurement is basic process for trading companies. Many trading (distribution & retail) companies structure their business model on discount model with vendor who deliver strategic goods to them. The typical examples of these companies are Agroglobe d.o.o. (structure their Profitability Analysis model based on earning per vendor) and Phoenix (has the methodology of discounts related to rebates and early payments).

The cost of raw materials occupies the first position of all the other costs, so any deviations emerged during the links of purchasing have an effect on the realization of the company"s anticipated goal, and further will have an influence on the enterprise profit target. While abundant of potential risks and uncertainty exist in the whole process of purchasing in such a changeable environment of market economy.

The role of procurement in Serbia is still defined very differently than the rest of the developed world. The public companies in Serbia have the limitation of law who prescribed strict rules in Public procurement act (Ministry of finance Serbia, 2014). On the other hand, there is no clear approach related to procurement strategy in private sector. The main decision about procurements in private sectors for strategic materials, services or fixed assets are mainly based on friendly relationships between vendor and customer.

Till the middle of the 90`s due to the generally accepted view, the procurement department belonged to the production in production company and belonged to the sales in distribution company. According to this traditional approach, the objective of the procurement model has to follow settings in production process: Right Quality, the Right Quantity, at the Right Price, at the Right Place, at the Right Time (P. N. Mukherjee, 2006). It is not so far till the true from today`s practice in procurement. Instead of this, purchasing must become supply management. New approach of procurement must to be much wider, primarily the procurement serves to the sales and adversely the sales must to dictate procurement. Anyhow, new procurement model must to operate with many variables in order to obtain competitive advantage.

2. OLD PROCUREMENT MODELS

What procurement exactly means? According to Oxford English Dictionary, “procure” means to obtain some item, while “purchase” means also to obtain some item in exchange for payment. So, although sometimes these two words are used interchangeably, they have varied interpretations. Tony Colwell (Colwell 2011) referred to “procurement” in the public sector as “care and effort” in upstream activities – strategy, sourcing and negotiating – up to execution of a contract. The exact responsibility of the procurement division may vary across organizations, but often post-execution activities, like contract management, placement of orders for deliveries, the management of day-to-day supplies, and processing payments, are also included in its scope.

Considering level of centralization, there are 3 basic models for procurement, any others are hybrid models, a combination of these three (Colwell, 2011):

- Local, where all activity, decision making and control is managed locally and is autonomous.
- Central, where decision making and procurement activity is coordinated centrally. (There may be local activity and controls outside the scope of procurement, for example, calling off supply under a centrally negotiated contract.)
- Networked, where decision making is not independent, but is controlled in some way across local units, like node, or nodes, on the network.

The combinations of vertical and horizontal centralization in purchasing process divided procurement model on federal procurement and centrally led procurement model.

- At federal procurement, managed by the central governance, some items are controlled at local level, while others are controlled centrally. Usually the centre defines the autonomy degree of local level by mutual agreement or by mandate.
- At centrally-led network procurement, activity is managed across local unit, the control is performed by the nodes on the network where the centre acts as the primary node.

Generally, centralized procurement in mid and big companies often fails to live up to its promises. Apart from historically falling short on delivering to the bottom line, we are facing new issues such as sustainability. The size of the company is the most important variable for level of centralization of procurement in the companies.

For purpose of this work, we performed research with CEO and/or Procurement Managers in several companies during first quarter of 2014. The main point of this research was impact of level of centralization and planning on the size of the company. Some of the companies who participated in research are TENT d.o.o., Sintelon, Relja Junior, Computer Shop etc.). The results are in table below:

Table 1: Level on centralization on size of the company

	Annual level of sales	Planning	Centralization
Small company	Under 20k EUR	Annual	High
Mid company	From 20k-100k EUR	Monthly	Mid
Big company	Under 100k EUR	Daily based on MRP	Low

This research shows that level of centralization in procurement decreases in large companies and the planning is most complicated organized in large companies. Anyhow, this paper will count of all facts in old procurement model and generate the new one which focused on supply management.

Generally, the base for old procurement models lies in their centralization. Our research shows that centralization is valid in small and low organized companies. The crucial point of modern procurement model is considering many variables.

The top priority in putting together a powerful operating model is not the issue of overall centralization or decentralization; it is determining how best to structure procurement"s various roles in corporate, business unit, and functional-level purchasing. Should the procurement function own, control, and manage the entire process for every corporate stakeholder? Should it participate actively in the purchasing decisions and processes of the individual business units, functions, and geographic regions in which the company operates? Or should it merely carry out those purchasing decisions?

Additionally, some authors (G. Zakeri, D. Craigiey, A. Philpottz and M. Todd, 2013) used linear programming of demands in order to have optimal procurement. They proved that an efficient linear programming formulation for the demand response of a price taker, industrial or commercial user of electricity has some ability to self-generate. According to them, new procurement initiated new procurement. They established a monotonicity result that indicates fuel supply of S may be spent in successive steps adding to S in total.

There are many reasons that the operating models constructed to procure and pay for goods and services prove inadequate. They may not include the processes, tools, or resources needed to fully execute the sourcing strategy.

They may not be properly connected to organizational decision making or sufficiently integrated into key corporate planning processes. Decision making authority and accountability may not be clearly defined. Or the IT systems that enable them may be fragmented, impeding efficiency and clouding the visibility necessary to ensure compliance with overall purchasing policies and objectives.

3. SPEND ANALYSIS

One of the most powerful tools in procurement process is spend analysis. Any procurement analyst must to operate with some kind of spend analyze. It is the basic report in procurement cycle. Generally, spend analysis is the process of collecting, cleansing, classifying and analyzing expenditure data from all sources within the organization (i.e. purchasing card, eProcurement systems, etc.). The process analyzes the current, past and forecasted expenditures to allow visibility of data by vendor, by commodity or service, and by department within the organization. Spend analysis can be used to make future management decisions by providing answers to such questions as: what was bought; when was it bought; where was it purchased; how many vendors were used and how much was spent with each; how much was paid for the item.

Procurement should work to identify all spend data, internal and external, for the organization. Once spend data sources are identified, the data should be collected and automated. The second steps in spend analyze is cleansing. This process is necessary to insure accurate organization and correlation of spend data and to enable actionable analyses. The cleansing must to include the following activities:

- Grouping and categorizing spend data should be done by adopting an internal taxonomy or by adopting an industry-standard classification scheme.
- Higher-level classification of spend at the category or vendor level is the first step in grouping and categorizing spend data. Examples include: categorizing goods and services that are being acquired; determining how many vendors are being used for specific categories; and how much the organization is spending on specific categories, in total and with each vendor.
- Item-level detail of spend data enables a precise view of spending with each vendor and for each commodity on an organizational, departmental, project, and buyer basis.
- Additional enhancements should also be applied to the collected spend data. These include but are not limited to: contract terms, minority or women owned business status, alternative parts data, industry pricing indexes, average selling prices, vendor financial risk scores, performance information, lead times and inflation.

The third phase is automation of data extraction, classification, enhancement, and analysis and services that can streamline existing procedures and make spending analysis a repeatable process.

Last phase is analyzing of spend data. In this phase, the procurement analyst make must to assess whether the current procurement structure, processes, and roles are adequate to support a more strategic approach to acquiring goods and services (e.g. whether cross-functional commodity teams would provide more effective, coordinated management of high-dollar, high-volume categories of goods, services, and vendors on an on-going basis).

Ernst & Young, leading auditing & consulting company in USA, presented several benefits from spend analyze in procurement process on US markets in research from 2012.

Table 2: List of benefits for companies from spend analyse (EY publication, 2012)

Eliminate duplicate vendors (Reduction depends on previous efforts.)
Reduce material and service costs through informed strategic sourcing strategies based on the data
Improve contract compliance
Use contract pricing to create savings
Meet regulatory reporting rules
Improve inventory management by cutting excess stocks
Lower inventory costs
Reduce expediting costs
Improve product management by cutting unnecessary part introductions
Increase part reuse
Align design and supply strategies
Facilitate early vendor integration
Reduce spend analysis project cycles
Refocus procurement professionals on strategic tasks

Normally, the significance of certain benefit depends of various factors in the company. These results arisen from procurement models on US companies must be projected on other world-wide market.

As an example, we examined two companies with different size (one is more and other is large) and their management view of these benefits in Serbia. For small company such as Relja Junior d.o.o., the most important thing in the business is to have lower inventory costs and reduce expediting costs. On the other hand, expectations from spend analysis for energy Serbian giant EPS are much different. They expect elimination of duplicate vendors and reducing of material and service costs through informed strategic sourcing strategies based on the data.

Spend analysis begins with identifying internal and external sources for collecting spend related data for the organization. Once data is collected, it should be cleansed, grouped, categorized and analyzed.

Finally, the data should be updated regularly and the spend analysis process should be performed on a continual basis to support decisions on strategic sourcing and procurement management for the organization.

4. PROCUREMENT MODELS IN EPR SYSTEMS – SAP EPR AND ORACLE EBS

As previously mentioned, they are two main players on ERP market related to procurement, SAP and Oracle. Additionally, four major technology segments are recognized in analyze from Deloitte Central Europe from 2012 including: 1) Spend Visibility, 2) eSourcing/Decision Support, 3) eProcurement/EIPP, and 4) Information, Performance, and Risk Management. The marketplace is characterized by a dominance of „top tier" vendors such as Ariba, SAP, and Oracle with an array of niche vendors providing technology and services. According to the last news published by SAP in 2013, Ariba became the contained part of SAP, so Oracle and SAP are the main players.

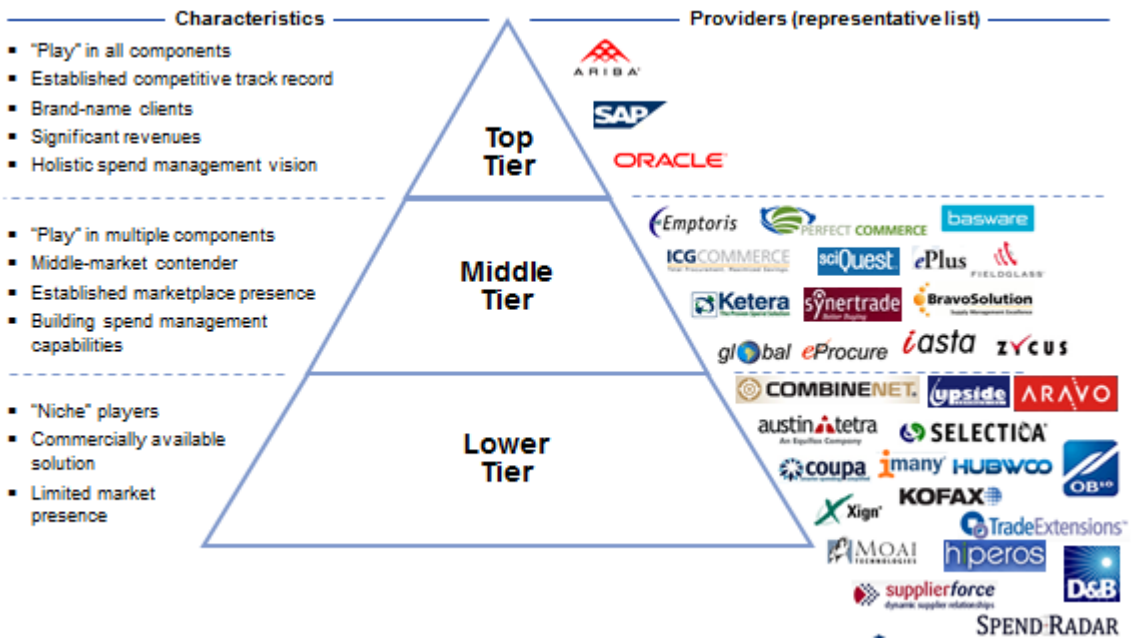

Figure 1: Sourcing & Procurement Technology Landscape

Anyhow, the both ERP systems offer the functionalities for procurement. In SAP, the procurement, also called Material Management module has two sub-modules: Purchasing and Inventory Management. Purchasing relies on master data such as Material Master, Vendor Master, and Info Records. An Inventory Management component handles all movements in inventory management process. Purchasing integrates tightly with other SAP modules such as Financial Accounting, Sales and Distribution, and Controlling. Purchasing causes commitments to be posted to Controlling; and when goods are received, posting can be made against cost centers. Also, when goods are received, SAP posts an Accounting document to Financial Accounting (FI) against a specified General Ledger account. Sales and Distribution passes requirements to Purchasing in the form of Procurement Proposals generated during MRP.

Oracle EBS has stand-alone application called Purchasing. Additionally, Oracle launched "Oracle Advanced Procurement Application". "Oracle Advanced Procurement" is the integrated suite of applications that dramatically cut all supply management costs. Oracle Advanced Procurement reduces spending on goods and services, streamlines procure-to-pay processes, and drives policy compliance.

Analyzing of SAP ERP 7.0 and Oracle EBS 12, the both solutions have the following advantages comparing to other software technology for automatization of procurement processes:

- Automated posting in General Ledger application
- Various field and consequently controls in purchasing master data
- MRP workflow process (some technical prerequisite must to be established for Oracle EBS)
- Integrated planning with production and sales
- Complete procure-to-pay automation
- Budget-based procurement (SAP solved this problem with Ariba and Oracle EBS with extension on Oracle Advanced Procurement)

The client that implements the ERP system has no usually internal expertise that is necessary for the implementation of complex software. Thus, the client engages an external consulting company to actively lead and participate in the implementation of the ERP project (Manojlov & Lutovac, 2012). The company must to pay attention of functionalities related to procurement processes, because it is the main point for integration on other separated modules.

5. NEW MODEL BASED ON COMBINING „SOURSE TO CONTRACT (S2C)" AND „PROCURE TO PAY (P2P)"

The new procurement model should be divided into two models. First is S2C and the second one is P2P. S2C covers all activities from sourcing to contracting and P2P covers all activities from purchasing to paying of vendors. Implementation of these two components is not "must", but desired. The company will have an optimal procurement optimization, only if implement the both components.

Generally, an old fashion companies had to have P2P concept without S2C component. Especially, S2C add value for the company in combination with well-structured P2P concept. Source to contract and procure to pay must to feed each other. In modern company, P2P co-exist with S2C and adversely. During an investigation an old procurement models, we defined several phase for P2P and S2C cycle. P2P are consisting from the following phases:

a) *Identify Need* as identification of requirement to purchase products and/or services, either planned or unplanned
b) *Create Requisition* as creation of a formal request for goods and/or services
c) *Approvals* which allows necessary company`s approver to review and sign-off on purchase requisition
d) *Create purchase order* as creation and issuance of an order to vendors, including acknowledgement, confirmation and any changes
e) *Receive* as formal receipt of goods and services, including quality inspection checks and appropriate escalation in case of errors
f) *Payment* in the form of efficient and accurate payment to vendor after verification of goods receipt and purchase order matching (2-way or 3-way matching) to ensure compliance
g) *Collect Performance Data* as measurement and collection of metrics (lead time variability, defect rate, etc.) used for continuous improvement of internal and vendor performance

The last phase called “Collect Performance Data” of P2P model should be starting point for analyze spend in S2C model. Therefore S2M model are consisting from:

a) *Analyze Spend* as systematic categorization, archival, retrieval and analysis of spend-related information
b) *Conduct Demand Management* as proactive management of demand
c) *Analyze the Supply Market* as active tracking of industry trends and relevant changes in the supplier base
d) *Define Sourcing Strategies* as application of the most relevant sourcing strategy and tactics for each spend category
e) *Tender Bid Process / Negotiate* in the way of standardized process to conduct bid process and vendor negotiations
f) *Finalize KPIs (Key Performance Indicators) & Contract* - key performance indices that track and measure the supplier performance and internal compliance to preferred vendor lists and contracts

Last phase “Defining of KPI & Contract” (f) initiate identification of needs as lighter for starting point in P2P model (a). Also, the company must to define the relevant persons in order to manage in each step of these two models. The most important thing is defining of leaders i.e. there should be two persons: Leader of P2P and Leader of S2C models.

Additionally, P2P and S2C should be treated as horizontal approach of procurement. S2C is upstream application and P2P is downstream application. However, the most important thing is to define a set of core principles guide “The Source-To-Contract” and “Procure-To-Pay” processes. These set of core principles must to be developed as a basic for implementation of procurement model in the company. Normally, adaption of this model has to follow and consider the company`s specifics. In table 3, the boundaries of new procurement model is set for each components.

Therefore, the source-to-contract capability is built on a dynamic, closed-loop process that has the ability to address and focus on both indirect and direct spend. On the other hand “procure-to-pay” capability is built on the above principles in a way that reduces transactional work to enable increased focus on value-added strategic activities.

The benefits of adopting the right procurement model for the company are substantial, not only in terms of cost reduction but also in the ability to better focus resources, enhance value from supplier collaboration and innovation, and more fully capture contractual promises.

Table 3: S2C (Upstream) and P2P (Downstream) instructions for implementation of model

SOURCE TO CONTRACT (UPSTREAM)	PROCURE TO PAY (DOWNSTREAM)
Spend Intelligence	**Automation & Intelligence**
Create automated "company-wide" spend analysis that generates periodic "canned" and ad-hoc reporting aligned with strategic sourcing goals and category requirements	Create a "lights out" automated transaction factory where cost effective to do so and capture data in a clean way that allows analysis that creates procurement intelligence
Organizational Planning	**Governance & Compliance**
Create a 2 to 3 year "calendar" prioritizing sourcing opportunities / events company-wide, which is updated annually and for market/contract events to manage ad-hoc needs	Create a common standard of company-wide policies, procedures, and approvals that are integrated into the P2P workflow and tie to other functional systems to drive compliance and individual adherence
Formalized Strategies & Management	**Strategic Management**
Create uniform category playbooks defining the driving forces behind price, market complexity, and business impact. The primary category value levers & tactics are defined with total cost of ownership (TCO) in mind and tied to operating guidelines	Create procurement and category strategies that minimize the need for ad-hoc /exception management and incorporates supplier scorecards, supplier management tools, and preferred supplier compliance reporting/monitoring
Governance & Compliance	**Self-Service & Connectivity**
Create defined policies, procedures, and roles & responsibilities that manage strategic sourcing and category management (e.g. mission, guiding principles, category span of control, category segmentation, etc.)	Create the system connectivity necessary to support user and supplier self-service; online catalogs, product/service master, supplier portal, electronic document exchange, etc.

Theoretical validation of the new procurement model will initiate the following facts:

- Globalization trend is the lighter for the company to drive of best pricing model / reduce of costs and have the process called "spend under management" during the S2C phase of the model.
- Improving of management of supplies, qualities, and cost risks in the step of spend analyze.
- Enabling of operational excellence and aligning to the needs of the business. Supply chain risks in term of increased regulatory, supply security, quality, and recall risks are forcing some companies to evaluate their risk mitigation strategies during the S2C phase of the model.
- Operate "As One". S2C and P2P phase must to be operated as one in order establish an optimal procurement organization and mitigation the risk of failures in whole business process.
- Proactively manage strategic supplier relationship in the step of analyzing of supply market in order to increase focus sustainability. Key trend for proactive procurement management is the fact that customers and governments become demanding companies which have plans to make their operations more sustainable.

6. CONCLUSION

The main strength of new procurement model is strong cooperation between P2P and S2C phases in procurement. An old procurement models take into consideration only P2P part of procurement. New procurement model, presented in last chapter of this paper, has holistic approach and P2P and S2C are strongly cooperated. It covers the processes from initiation of need to realization of procurement in P2P component which serving as input data in analysing of spend to finalization of key performance indicators in S2P component.

Additionally, the new procurement model must to provide the basic assumption for providing of robust supply-side information, metrics, and alerts that integrate with implementation of technology applications such as Oracle BI Applications or SAP Ariba. It delivers specific insight across the organization in order to increase the company"s performances in managing its customers, suppliers, and financial decisions.

Many authors tried to develop procurement model such as Tony Colwell (2011), G. Zakeri, D. Craigiey, A. Philpottz, M. Todd (2013), but nobody from them is not taking into considering all relevant facts in procurement process.

This model will be the starting point for many companies to define their procurement strategy and consequently redefine their position on the market. The next step will be practical validation of new procurement model through implementation of the model in real company.

WEARABLE COMPUTING IN EDUCATION

Barbara Petrovic[1],
[1]Student at Faculty of Organizational Sciences barbara.s.petrovic@gmail.com

Abstract: *This paper represents an overview of wearable computing technologies that have been applied in education. The focus of this paper is on the existing models of the application trough the method of analyzing different authors and their ideas. Purpose of this analysis is sublimation of knowledge and current practice trough analytical and deductive methods, as well as the proposal of wearable computing model in education. Utility of this model is primarily sublimation of previous knowledge and emphasis to its use in education. Most important finding is that wearable computing is still poorly used in education, therefore further study of its potential academic use is recommended. Consequently, this paper contains a proposal model for introducing wearable computing technologies and Google Glass in academic educational institutions.*

Keywords*: wearable computing, education, ubiquitous computing, blending learning, Smart Watches, Google Glass, NFC tags*

1. INTRODUCTION

New technologies are changing the way of the daily life. Education is just one of the aspects of the modern world that can not be imagined without use of technology. In the current academic education using desktop computing is quite common. Desktop environment (PC, Laptop, Mobile phones) involves the use of graphical interfaces and is based on work with icons, windows, folders, wallpapers, tool-bars and desktop widgets (Desktop environment). The use of technology in all aspects of life including education led to the creation of the following concepts: ubiquitous computing (ubiquitous computing), a hybrid learning (blending learning) and wearable computing (wearable computing). These concepts are interrelated. To understand the idea of wearable computing in education it is necessary to understand all three terms which will also be discussed in this paper.

The first part of the paper begins with brief description of the concept of wearable computing and its historical review. The second part is a review of literature and existing models as well as the review of commercializes wearable computing technologies that are used in medicine, sports or entertainment, and may represent a “milestone” for application in education. The third part of the paper contains a proposal of introducing these technologies in academic educational institutions as a learning tool. Through this paper will be shown that wearable computing technologies can be used in two ways: for learning technical science in specialized curses for students and as a tool for each individual which should facilitate communication among students and professors, provide better flow of information and knowledge and enable easier and more reproductive learning at any time. While the analytical part of this paper covers both scenarios, proposed model highlights the second approach. Thus, research direction focus on increasing communication between students and professors, increasing the efficiency of information distribution and increasing the quality of group assignments by using Google glasses in correlation with other wearable computer elements.

2. WEARABLE COMPUTING CONCEPT AND HISTORY

Wearable computing that use sensors, wireless communication and mobile phones is just one part of the ubiquitous computing concept. Contemporary concept of ubiquitous computing was set by Weiser (1988) and it is based on the interaction between man and computer, where the computer is integrated into everyday objects used by everyone. He predicted widespread use of computers and "omnipresence" in all aspects of life. Further, ubiquitous computing in education was initiated by the creation of ubiquitous learning paradigm which is a transition from traditional learning to e-learning. Mentioned paradigm implies to environment that enables learning anywhere and anytime, with the help of computers and computer-based technologies (Yahya et al., 2010). This type of learning completely disregards traditional teachings, which in practice has not yet occurred. Despite the application of technology for learning the traditional view is not completely replaced, which leads to the creation of blended learning concept. The so-called “hybrid learning” or blended learning is a learning system based on synergy of traditional and e-learning. Charles R Graham in

his work synthesizes different definitions for this term, and sets blended learning as: "a combination of online learning and face-to-face learning" (Bonk & Graham, 2006).
Blended learning uses web - based courses, collaboration software in real-time systems, knowledge management, combined with self-learning and face-to-face (Singh, 2003) and it can be use for tutoring through blended learning platform, which has proven more effective in "sharing information, for clarification of learning areas and planning activities" then traditional approach to tutoring (De Smet et al., 2008).
The next step in the development of learning models in higher education is the application of wearable computing technology. Wearable computing technology provides a higher level of synchronization with the user and their needs, and it does not requires from user to interrupts his task during process of collection and providing data. During last ten years it is being gradually introduced in education, which is the subject of this paper.

Historically, a wearable computing concept as an idea of a portable device that will provide useful information to a user is much older than it looks. The first mechanical inventions that can be carried by user are considered to be the beginning of the wearable computing idea. The precursor of the concept is a pocket watch founded in 1510. by Peter Henlein in Nuremberg ("The history of wearable Computing"). One of the next interesting steps towards today concept of wearable computing is Vannevar Bush "Memex" desribed in article "As We May Think " in 1945. Although it is not constitute as wearable technology, it is used to increase user's memory. Modern concept of wearable computing is also based on this idea. "Memex" is a private file or library that should contain the records, books, correspondence, and based on its flexibility provides easy content accessibility, and serves as a user memory supplement (Bush, 1945). In the modern sense, wearable computing has been used for the first time, for the prediction of the outcome of roulette, by Ed Thorp and Claude Shannon's in the year 1966. The wearable computing device made for this purpose was worn in a shoe (Miller, 2012 ; "Wearable Computing").
In the 21st century, the concept of wearable computing is far more complex. Since first pocket watch and "Memex", the wearable computing concept is being developed as a technology that should be able to swimmingly help user in fulfilling various tasks. It is not enough that the device is portable, easy to use and provides information on the complex demands placed by the user at any time. It is necessary that it simultaneously and continuously provides information to the user through the process of feedback without disturbing user during his task fulfillment. The emphasis is on a greater synchronization that in the future should be complete. In 1981. The Steve Mann designed a backpack based on wearable multimedia computing system. Part of this technology is the display, which is worn on the head and covers one eye. The display supports text, graphics and audio. The concept allows the user to work with variety of computer applications while on the move performing other activities. Later, 1999th Mann has created EyeTap digital eyeglasses that collect video data from the surrounding, then sends data to a computer which processes it and delivers back to the glasses in such a way that real picture is replaced with processed one. It is the beginning of creating so-called AR (augmentative reality) known as enlarged reality. Mann has continued to refine the prototype of the glasses with the help of sophisticated new technologies that have since become available ("Wearable computing"). In 2014. this idea is modified and commercialized under the name Google Glass.

Defining the wearable computing concept:
"Wearable computing is the study or practice of inventing, designing, building, or using miniature body-borne computational and sensory devices. Wearable computers may be worn under, over, or in clothing, or may also be themselves clothes" (Mann, 1996).

Mann later expands his definition of wearable computing, and binds it with concept humanistic intelligence. Humanistic Intelligence is an inseparable intertwining of computers and humans. Wearable computing is the embodiment of humanistic intelligence and comprises three components: stability, increase and mediation (Herzog & Witt, 2007). Further, one of the founders of the first International Conference of wearable computing called the International Symposium of Wearable Computing is Thad Starner also believes that wearable computing is a term to describe a system that is able to be at all times available to user with use of feedback loop. Specifically, he believes that wearable computing should be able to "observe and model the user's environment and the user's physical and mental condition (Herzog & Witt, 2007)". Definition of wearable computing is subjected to changes in accordance with the development of technology. To better understand the concept it is necessary to determine the elements that underlie this technology as follows (Herzog & Witt, 2007):

- **The operating system is constant**- system has a role of secondary support that is always available for providing useful functions to the user.
- **Seamless integration with environment**- system in not an obstacle and does not interfere with the user as he performs other physical tasks.
- **Context awareness**- system is sensitive to changes in the environment and the changes related to user.

- **Flexibility**- during application operation system can automatically adopt interaction style in order to reduce mental effort of the user.

3. REVIEW OF WEARABLE COMPUTING IN EDUCATION

Wearable computing technology is entering an era of commercialization, but still has not become an inseparable part of higher education. Wearable computing in education is mostly used in small temporary research groups. This technology is still away from the usual learning applications, such as desktop computing. According with specified, this part of the paper will provide a brief overview of the current wearable computing use in education. Use can be for learning about new technologies, manipulating campus environment or as a learning tool instead of classic learning materials like books and desktop computers. There are cases that can even be used as a aid for students with disabilities.

3.1 Wearable computing for learning technical sciences

Most famous example for learning new technologies is use of Lily Pad Arduino in education. Lily Pad Arduino is a wearable computing tool introduced into the market in the period of 2007-2009 year. It is based on microcontroller panel (ATmega168V ATmega328V I) which can be sewn to different textile materials. This tool was designed by Leach Beucheley and Spark Fun Electric. Range of products are wide: heat sensors, light sensors, MP3 , battery, LED White, accelerometer and more, and they can measure different variables. while connected with Arduino Software to a computer. This way, user gets all the information on collected data trough Lily Pad system (official Arduino Website). Leach Bulechley and colleagues conducted an experimental workshop based on Lily Pad tool. The idea was to implement a process of gaining knowledge of the electronic, programming and computer-based e-textile technology as part of wearable computing technology in workshop conducted at the high school population. Although, the authors believe that Lily Pad can be used in university education programs too. The paper disclosed the observation that the female population has lesser tendency to choose computer science programs. This kind of creative teaching in secondary schools can increase the number of women who will choose to study computer science at faculty (Buechley et al., 2008).

Similar example is Grace Nagai's work in 2010. Nagai and associates conducted a study where the wearable computing technologies are used for teaching robotics. Also, the practical work is carried out on the secondary school students, but the authors at the very beginning as well in the conclusion argues that this program is suitable for the use in higher education. Platform is named TeeBoard. As in the case of Lily Pad technology it represents a synergy of textiles and electronic components. The difference from the Lily Pad concept is in programming language, which is in this case adapted for users with no previous programming experience and knowledge of the C language. For that purpose Brick Layer graphical text-based program was created in Java Script that can be run by Web browser. The student do not types commands in C language, but use descriptive predefined structure called "blocks" or "bricks" that uses graphic text logical unit. User arranges "blocks" on a computer in that manner that they represents command path for wearable computer sensors on T-shirt (Nagai et al., 2010). Educational benefits from this program are the same as in the previous example.

3.2 Wearable computing for automatization of classrooms and campus environment

Another case of wearable computing application is done by Ho Park (2008) and associates from the Korean Institute for Advanced Science and Technology is development of advanced ubiquitous environment under the campus environment. This concept named U-TOPIA use different technologies: hardware/software, user interface, communication technology, and UFC wearable computer. The use is manipulation of environment like turn on/off devices and record scene. Interface called i-Trow was developed, which is based on the wireless device for recognizing gestures. In a separate control room devices that can be manipulated through this concept were set up. The idea is that individual can use wearable technology and wireless communication to assign commands to different intelligent devices. To make this idea come to life it has been developed an UFC wearable computer whose main characteristics are "modularity and sensitivity". UFC wearable computer designed to look like addition to clothes - buttons, necklaces, Zig Bee earrings (earrings with Zig Bee transceiver) was connected to the devices trough standard USB protocol. Another essential part of this platform is a wireless ring-shaped device for gesture and movement recognition.
This way students can use the wearable computing sensors to turn on and off music, amplified and mute music, turn off and on printer, watch pictures, send and delete files (Ho Park et al., 2008).

Cooter Willis and Sumi Helal are creators of model intended for blind users within the campus environment. This model does not cover learning process. It is merely a tool for the blind users in educational institutions.

The concept was created on the idea of the need to facilitate the movement of persons with visual impairments. The technology is based on RFID (Radio Frequency Identification) Information Grid in the framework of wearable computing model.
System used to notify the user about the location and distance of objects is RIFD tag placed on all larger objects in the environment as well as the doors and hallway so the better information could be transmitted to the user. NAVCOM belt containing Devantech SRF08 Range Finder was used as wearable computing element. This Range Finder can read the object distance from 3 cm to 6 m, with the ability to detect the distance of up to 16 objects. The above mentioned technologies can communicate with mobile phones over Bluetooth SPP connection. This concept should facilitate the mobility of blind students across campus (Willis & Helal).

3.3 Wearable computing as a learning tool

For the benefit of this paper, Wei Hsun Lee's and Chieh Kuo's work will be introduced as well. They propose the use NFC tags (Near Field Communication tags) as a ubiquitous platform for interactive learning. The platform supports NFC reading model, P2P (Peer-to-Peer) model and wireless communications. They are also supported by the NFC phones that can identify each NFC tag individually by its ID code. This model is proposed for use in education. Idea is providing simultaneous answers to questions from the professor at the end of the lecture, in order to determine how much students understand the lecture. The concept is programming NFC tags in responding manner A / B / C / D so students can gave answer to the professor questions using tags. Answers are given with click on tags, then sent via NFC phones and delivered with the help of Bluetooth to Notebook of professor. Thus, the results of the collected answers are given in real time by all students and they are shown up automatically on the professor Notebook screen. This way the teacher is very quickly able to assess how much students understand his lecture (Lee & Kuo, 2014).

Wearable computing can be used as well, for learning to play piano. PianoTouch system is Wearable Haptic Piano Instruction System that is used for passive learning. Wearable computing gloves with vibration motor on fingers can simulate movement needed for playing compositions. Laptop. MP3 player or mobile phone can communicate via Bluetooth with PianoTuch and control it by producing music output. Vibration on fingers that are coming from PianoTuch gloves indicate which finger is needed for playing note (Huang et al.,2008). The model proved to be very effective.

In order to a certain technology become an integral part of daily life it is necessary to become available for the masses, and easily applicable. As such wearable computing technology is not designed to be exclusively used at the university learning technology courses, but also to "serve the people and facilitate tasks (Duval et al., 2010)" in a much wider use. One of the conditions for its wide range of applications is to be accepted by users (Bergmann & McGregor, 2011). This is because it is expected from wearable computing technology to become an integral part of higher education in the future, as desktop computing is today. By far the greatest degree of commercialization this technology experienced is in medical and Fitness use.
The concept of wearable computing for the general population was successfully introduced by the company Nike. Product Nike Shoes Bluetooth, appeared on the market in 2012. Nike Shoes Bluetooth link Bluetooth technology with iPhone and iPhod Tuch trough applications to provide an overview of variables: such as strength, speed, number of exercises . ("Nike makes Bluetooth Smart sensors cool and fun"; "Nike Smart Shoes Communicate via Bluetooth"). Nike has introduced wearable computing technology to the general population and thus opens the possibility of using the same in the different segments of everyday life.
During last two years Smart Watches have been emerged on market. Smart Watches can use daily application such as weather forecast and news, remote applications like camera and thermostat, fitness applications, games and tools applications for measurements and calculations. Most of the watches allow viewing of messages, e-mail, and can be sync with Facebook and Twitter. The user can receive calls or dial the number for the remote connection and wireless technology associated with a mobile phone.
One more useful example of commercialization of wearable computing is application of wireless sensor networks ad wearable computing technology in medicine. Monitoring vital signs of patients using this technology becomes significant practice in medicine science. These examples point to the gradual commercialization of the latest technological achievements in different spheres of life. Education is only one of the segments in which these technologies with modification and adjustment may be applied.

4. APPLICATION MODEL FOR SMART GLASSES AND WATCHES IN E-LEARNING

Google Glass is currently the most interesting wearable computing technology available in the market and is designed for commercial purposes. It is the type of smart glasses which allows the user to input voice commands so glasses can capture what the user sees. Therefore they support commands without hands, and in real time share what the user sees. It has option to show the direction of movement if the user is lost, to answer questions and translate voice of user to foreign language (Google Glass website). The initial idea

is that the Google Glass can be use in educational institutions. In 2013. Forbes published an article in which Dr. Grossmann is proposing the application of Google Glass for medical student education.
The idea is based on consultations in real time where the student may request and receive instructions via glasses thanks to the transmission of visual and audio data. This can lead to serious consultation during surgery. To support his idea Dr. Grossmann made video footage showing the consultations with the student via Google Glass during the student surgical exercise on manikin (Nosta, 2013). Models that are proposed in this paper emphasize the usefulness of wearable computing smart glasses technology as a learning tool that should provide better and faster communication, exchange of data and knowledge in educational environment.

First model that is proposed in this paper is based on some features of Google Glass and possibilities for further modification. Some of the faculties such as Faculty of Biology, Faculty of Veterinary and Medicine, Department of Physical Teaching, Faculty of Pharmacy, Faculty of Medicine within their courses required field learning. At the Faculty of Biology and Faculty of Pharmacy, students do field collecting of plant samples. For them this model considers the possibility that smart glasses can provide in field learning process.. Google Glass allows connection with applications for mobile phones which are supported with GPS technologies. GPS and applications based on it can be used for its precision timing capability and position information. GPS option in conjunction with the transfer of data in real time with Google Glass should provide information about student's position on the field, so professor can easily form task groups for field learning. In accordance, it is possible for professor to simultaneously run multiple groups. GPS allows tracking of student's location and movement. Google Glass feature that supports text and audio setup further allow quick tasks and instructions providing. Mixing it with already mentioned idea of eye movement tracker it can easily provide readable information for student while he is moving. This model enables different groups setting at different locations at the same time. This would be feasible only if all the students and professor have Google Glass to work with. Each student would be capable to get instructions on his smart glasses and to ask additional questions if it is needed. This way real time communication allows the teacher to give useful advices while the student performs the collection of study materials from nature that are required for different works/tasks. With already mentioned option of asking questions and getting responses via glasses, thanks to the Internet and Wi-Fi, use of this model can further reduce the need for the professor presence on the field. Each time a student collect some materials from nature with the simple question asking can get basic information about the same material from the Internet on Google Glass. This way, instead sitting in a classroom and learning from books smart glasses allow students to learn in fare more interesting manner trough synergy of field learning, tutoring and text based information, all at the same time using modern technology. Another useful way of using Google Glass would be a simultaneous recording of certain material that the student sees and explanations given by the teacher regarding the same material. In this way the student is able to review the recorded lectures later, in order to better prepare for the exam.

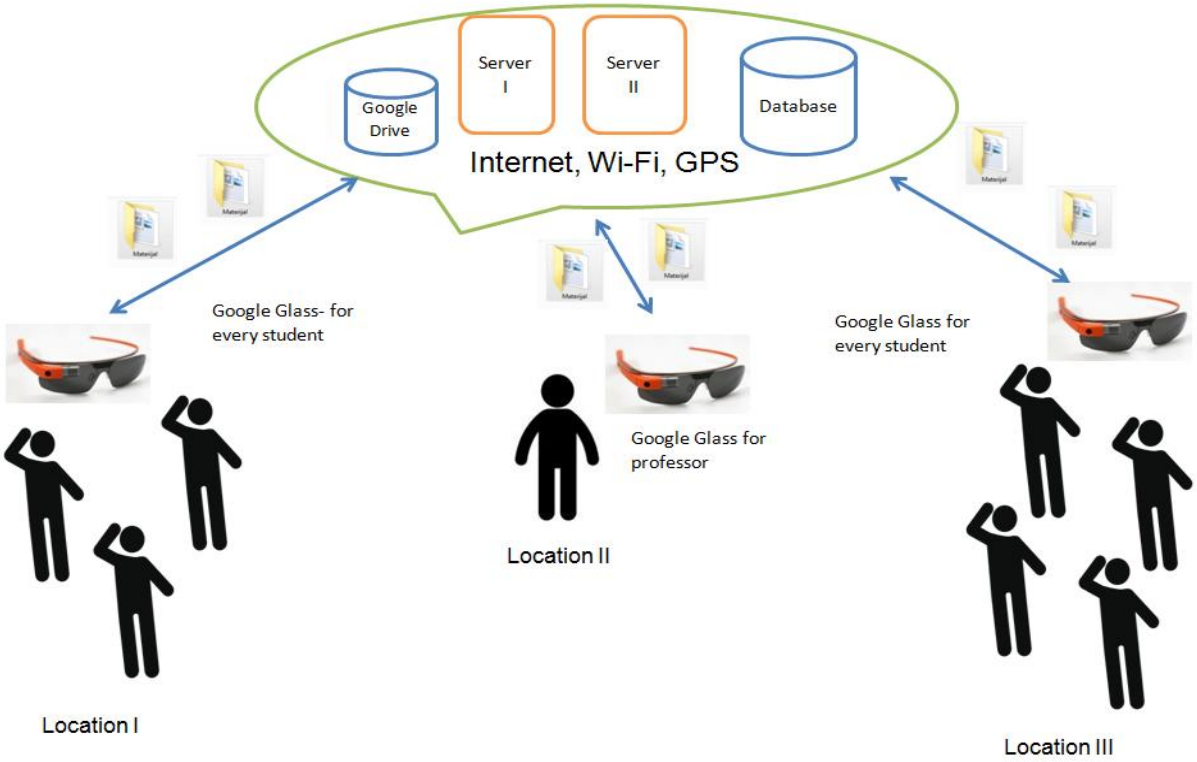

Figure 1: Communication between professor and students on various locations

Learning can be improved by fare trough motivating students to make their own scripts, from which they will later learn. Camera on Goggle Glass allows students to take pictures or record a particular material in real time. Information collected this way can be stored in a database that was created specifically for this purpose. Continue through questioning Google Glass (which has already been mentioned) a student can take information that considers most relevant, pare it with a particular image and store it in the script that is resembles to data storage. Student can manipulate collected information in the way that is most suited for him and for later learning. In the future it is expected that technology will recognize every material trough shapes and colors recognition programs. Today, recognition technology is primarily used to identify human faces (Hsu et al., 2002; Wang & Tan, 2002). These systems are expensive and complex. 2D Gabor, RBG color model SPD and other models that support this technology can be modified and applied in identification of plants and animals with smart glasses so that students would be able to see, take visual record and simultaneously recognize specific plants in real time, tanks to recognition program and Internet. Basically, students would get an answer about the plant/animal or some material trough recognition program and Internet on their smart glasses. If this application comes to life it would be indeed the application of augmented reality. As we can see Google Glass can be modified and used in a far more complex manner then they are used at the moment, and that applies even if we do not add any new features and performances.

Second model is based on the combination of Google Glass with Smart Watches and NFC tags used in classrooms. Faculty can allocate the necessary funding for certain courses and endure students with Smart Watches for personal use. These watches should facilitate communication with teachers so that students will be provided with working material and teaching schedule on the Smart Watches. Updating information on them will be enabled through NFC tag that is placed on all tables within the classroom or amphitheater where lectures and exercises are held. By leaning Smart Watch to a NFC tag automatically via Wi-Fi technology materials are updated as well as class schedules. NFC tag is associated with database of a certain course which holds and preserves data in the Cloud environment of the Faculty. Model diagram provides an example of Cloud environment of the Faculty that is base for communication with students. It provides all the necessary information and data for the teaching models of e-learning.

Communication with students can be improved with NFC tag and Smart Watch. All information would be provided to students using NFC tags and Wi - Fi technology for updating data on student's Smart Watches. The teaching team is the one who is responsible to create the necessary data and input it to the Cloud environment. It is understood that the Faculty has its own web site for sharing information as well. First, professors need to prepare the data for Interface from which website is going to be updated with fresh data. After passing the data into the appropriate form it is ready for downloading over the NFC tag. Idea is to allow all students with Smart Watches to easily and simply, in the shortest possible time interval come in possession with working material immediately after the lecture. NFC tag can be programmed to recognize the ID of each Smart Watch and thus can be used for the keeping evidence of student's presence at lectures and exercises. Data on keeping presence evidence can be storage also in Cloud space database of Faculty. Model also assumes that the students have a Google Glass that can be connected to their Smart Phones.

With modification of Google Glass and installing sensors to recognize the device ID similar as in NFC tag, it would be possible to achieve communication between the Smart Phone and Google Glass. Smart Watches have touchpad. After connecting the devices via Wi-Fi networks, using a touchpad screen student can issue a command to transfer the material from Smart Phone to Google Glasses. Also, in order not to interfere with another student task one can use touchpad on Smart Watch for commanding Google Glass what text student wants to follow up and read at any given moment on a screen of Google Glass. The final process of communication is between Google Glass and Google Drive in Cloud environment. Google Drive allows storage of documents in Cloud environment which reduces the memory usage of the Google Glass and the student is able to access recorded documents anytime and anywhere if there is a Wi-Fi network. This model must be supported by 3G and Wi-Fi communication.
Next graphic represent communication flow between students and professor using Google Glass.

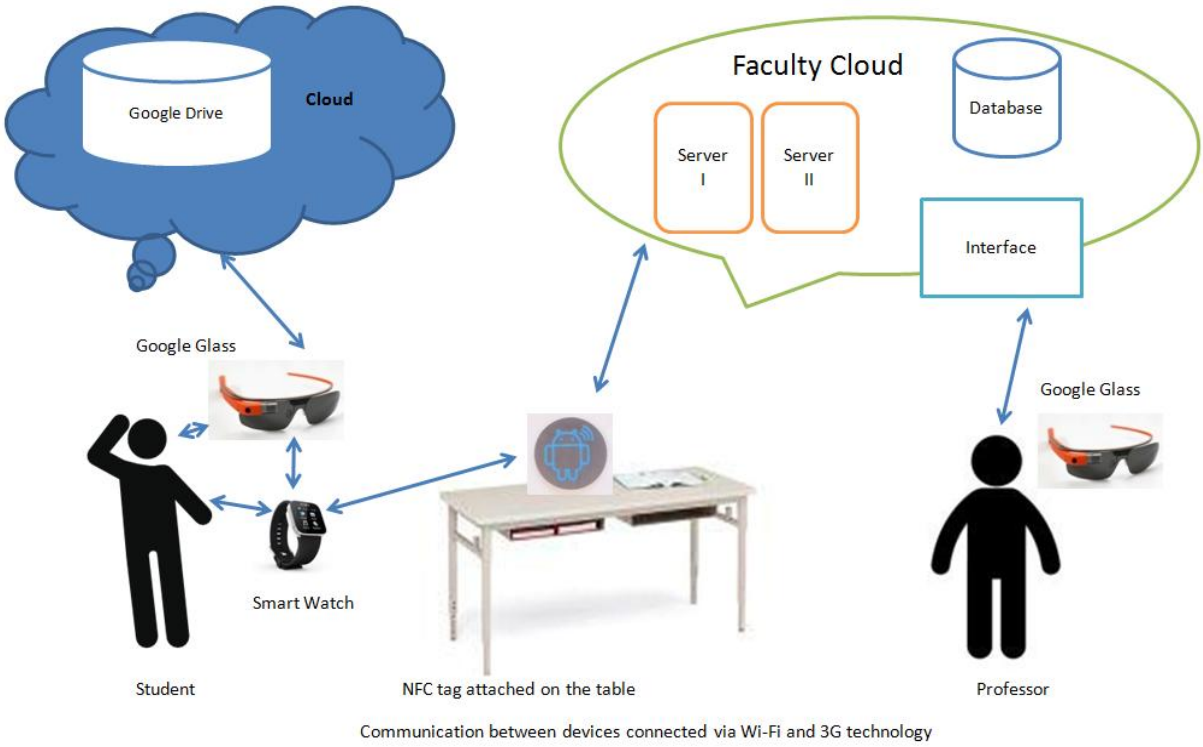

Figure 2: Information flow via Google Glass in classroom

6. CONCLUSION

Wearable computing technology is a concept that is not fully reached its potential in any segment and especially in education use. At this point some of the essential characteristics like context awareness, flexibility and Augmentative Reality are not fully met. As far as its use in education there in not enough papers with implementation models so in that field there is a lot of free space for research and for proposing something new. Models presented in this paper are not perfect but can be god “milestone” for future research. There are some good sides and bad sides of these models. First of all models we gave are intended to lower barrier between old educational systems and new technologies. Further, using wearable computing in education can really help to create even better communication among students and professors and it can be the key to create new successful generations. We live in the time of fast information so we need to provide adequate access to it in educational environment as well. The first model emphasize to applicability of the wearable computing at different locations at the same time. Second model more highlights the need for faster information flow. The good side of second model is uniformity of the process of obtaining information which can help students and professors because there is no much space for incomplete information awareness and communication loops. Represented models are based on idea of using wearable computing for all students not only for the one with technical knowledge and programs. Wearable computing should allow easier and faster communication both between teachers and students and among students as well.

Bad side of these models is time that is needed to make them work. Further, students and professors are needed to be trained to use wearable computing technology. From professors is expected to update their materials on time without delay. Face to face communication is minimized and it can be negative in psychological manner. In larger student groups there can be cheating with the registration of present students. Professors should after registration is done by students count number of students in classroom and number on registered Smart Phones and then compare obtained information. The good side of this model is idea of pushing wearable computing technologies in educational purpose so the information flaw is better and the productivity is higher in all faculty activities. Regarding to all, proposed models need to be further developed in accordance with the available technology and knowledge.

IMPROVING OF THE QUALITY AND RELIABILITY IN THE DEVELOPMENET OF THE SOFTWARE SOLUTIONS

Tatjana Davidov[1], Saša Bošnjak[2]
[1]tanja.davidov1@gmail.com
[2]sasabosnjak1996@gmail.com

Abstract: *The software engineering is aimed to finding renewable, anticipated processes or methodologies of the software solutions. The methodological proceedings improve the quality and the reliability level of software, whereat all quality factors are grouped in the unitary paradigm, which determine software solutions of the modern software development, and they are oriented to reusable assets.*

Keywords*: the quality and reliability of the software, object oriented programming, component programming, reusability assets.*

1. INTRODUCTION

Modern software engineering deals with the process of software development, with theoretical knowledge, practical procedures and proper conducting of development activities. Software engineering passes through a large number of researching and practical phases. The quality of a software product is evaluated and estimated many times, whereat the three most important aspects are: the quality of the software according to user's perception, the quality of the software process production and the quality in the frame of business environment where the software will be used, whereat the software products will be estimated, the maintenance and developing methods. Generally, the software quality is estimated only by mathematical models, which include defects measuring in the programmed code, the number of dismissals (termination of performance or program failures) the time required for software development, with reference to finding and fixing errors in the software code.

2. COMPONENT AS A BASIS OBJECT-ORIENTED (OO) PROGRAMMING

The object oriented approach to the development deals with objects as independent and autonomous units, in which the whole partially participate in making software. Formally the objects make components, which contain single solutions, in building up complex and demanding Software. The basic approach of this development is to select, configure, to specialize and to figure a new software program which is being built. The components are very dependant on their size, complexity, functional and technical possibilities. OO programming has raised the quality of software solutions on a higher level and it contributes to formalize the develop software for multiple purposes. OO software development is about methodological, modern and flexible technology that provides solutions to create a better quality of software solutions and software development too. Only the OO programming provides tools and techniques of multi-functional software solutions (Reusability assets-R) i e components that depend of precisely defined methodological activities: production methods, R management, infrastructure, placement and using of R values.

The quality criteria are numerous, but generally they are divided into: internal and external criteria. External criteria (speed of software performance, simplicity of appliance, interface and functionality of software solutions) are usually in the interest of the final users. The interest of professional programmers is based on internal quality criteria, such as procedures in the implementation and distribution (reusability, scalability and robustness of software components, which are independent software units). The quality of external criteria is based on the quality of internal criteria. ''The ability of an program unit (program, class, subprogram, method) to work out according to its specification, whereat the specification means the precise description of what the program unit needs to do, it's called ''the correctness''[A], which is the most important quality criterion of OO engineering.

3. IMPROVING OF SOFTWARE QUALITY

Improving of software quality (Software Quality Assurance SQA) is a multidimensional concept. It requires measurement of many parameters in determining of potential targets and limits of the software quality. It is particularly complex to specify which parameters have to be measured and to provide testing of software system according to the specified outputs of software quality all of processes during development or project documentationfor supporting. It is necessary to specify all the measurement parametersand provide testing of a software system according to the specified outputs of software quality.

The research quality range can be extended to different aspects of business skills, where the software is integral part. Accordingly, we assume that the technical improvement of business and working environment reflects automatically the business value.

In this respect, setting the software features standards, to follow it, analyze and specify the target to achieve the specified outputs, are part of the practice software standardization. Some of the standards in the frame of international defined(International Organization for Standardization-ISO) as ISO 9000[B](Information Technology) or JUS/ISO 12207[C](Software life cycle processes) then (International Electro Technical Commission-IEC[D]). ISO/IEC 9126 international standard of the software quality is divided into four parts (ISO-9126[E]) which analyzes and defines:

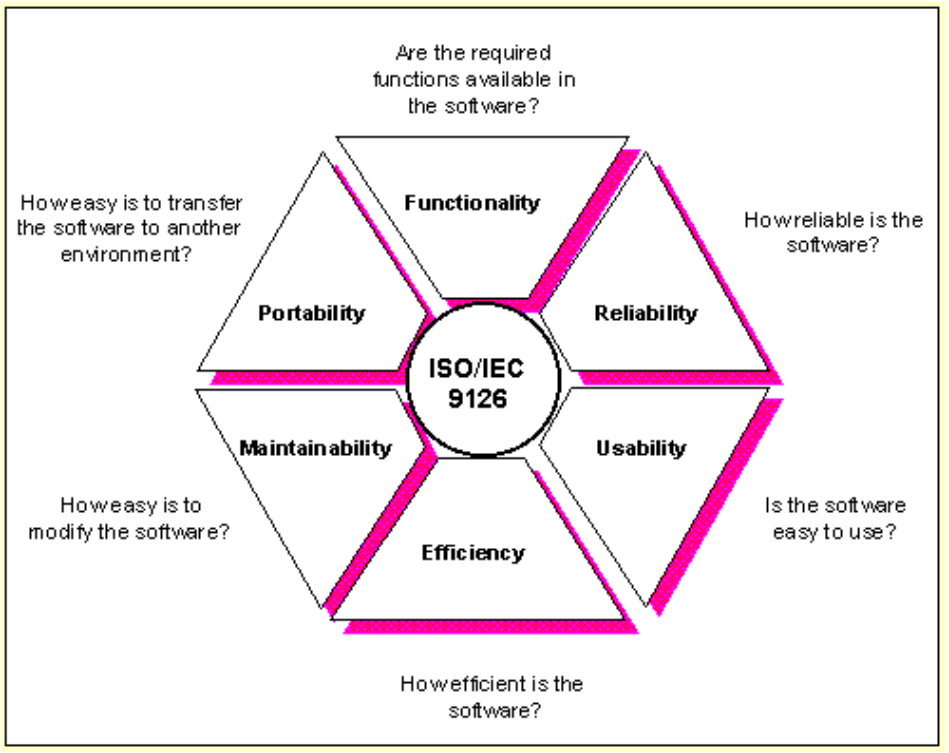

Figure 1:ISO9126software qualitymodel[F]

- ISO/IEC 9123 1 quality model
- ISO/IEC 9126 2 external software metrics
- ISO/IEC 9126 3 internal software metrics
- ISO/IEC 91264 quality in use metrics

According to the quality model ISO/IEC 9126[G] each subfeature affects on one basic feature on a higher level.

The evaluation of software quality should be specified on the standardized features, which ISO/IEC 9126-1 defines in the six most important attributes of a **good software system**:

1. Functionality
2. Reliability
3. Usability
4. Efficiency
5. Maintenance
6. Portability

Each attribute has a set of elements that can be measured using internal or external software metrics. To evaluate software products, primarily means to assess its reliability, which is reflected in the two most important factors: complexity and size of the program. The typical variables in which the values can be readout are:

- Total number of errors
- Length of program- thousands of code lines (KLOC)[H]
- Thousands of non comment source statements (KNCSS)
- Number of errors in the date inputs
- Number of different operators (keywords)
- Number of different operands (data inputs)

The complexity of programming task slows down its development and maintenance also. The natural complexity of the task may be very different from the evident complexity of developed program for this task. Software is a ''discrete'' system and it is essentially the cause of its complexity. The software product is measured in metrics from different aspects, and it precisespecific actions and realistic information in:

- Preparing of the specification of contract obligations
- Checking of software specifications
- Maintenance and costs checking
- Improving of productivity
- Improving the quality
- Reliability increase
- Basis defining for further predictions
- Requirements for new software tools and additional training.

The complexity and the ''discretion'' of the software system sometimes creates a confusing situation by using the terms software measurement and software measurement and software metrics. We would like to say that the software metrics involves quantitative measures derived from attributes in the software cycle, in mechanical or algorithmic way, so it doesn't depend on device which is measured on the quality of software, whereby it can be: a human, hardware, software or any similar combination. Measuring of software products provides:

- Objectivity, reliability, security, accuracy, suitability, uniformity, formulary process and process of logical thinking
- And not at all measuring by intuition.

The most prominent objective-formal attitude of software development is represented in ''Program-based components''. (Component-oriented programming-COP)[I]Components programming enables unified implementation, software development methodologies, but it is not always completely. The development of the internal part of components is similar to the development of other types of software (OO, structural etc). On the other side, the development of the external part of components is still relatively unexplored, and there are no excellent solutions for some component features:

- Define the connection between the components
- Distribution (clustering) components of the physical parts of the system and
- Time independence of running components (how to continue the performance of distributed applications if a component isn't available).

4. THE METHODOLOGICAL FRAMES WHICH JUSTIFY THE PROGRAM UTILITY BASED ON COMPONENTS

Building of methodological frames and models that prove the improvement of software solutions can be described as a difficult task, because it isn't included all of factors which can be measurable. Which tasks in development or maintenance will be planned, and how it will be implemented, it is estimated in costs and benefits analysis.(cost/benefitJ). This model takes into consideration the positive and negative factors that get into the analysis of total costs and benefits, and that indicates if the planned action is recommended. The costs/benefits analysis is carried out with financial support. If we want to include the intangible items in the analysis, then we have to give a valuation for the same, you will inevitably include the subjective factors in the measuring process. Yet, in accordance with all aspects of measurements and assessment, cost/benefit analysis is the best technique in the process of deciding if the R is deserved investment.

R metrics, define measurable categories, valuation software products, with its indicators are reflected in continues monitoring of cost/benefit connections, during the development and maintenance of software systems. The metrics assess the segments in which the R software shows a positive result, as evidenced by a group of 6 metrics:

- The quality, productivity and metrics of time-to-market
- R metrics economy
- R metric library
- R metric products
- Re-use of the metric values

The primary results such as quality, productivity and time coming out on market are used as input parameters for the economic model of software reuses. All other metrics contribute to the primary.

5. METRICS OF REUSED CURRENT VALUE

The reused software is proved by metrics of reused current value and R metrics. The formula realizations of R metrics define measuring of the following parameters:

A. Metric size: measuring the size of R values
   Measurement: KNCSS values R
   Benefits: provides useful measure of capacity in planning R
B. Number of R for each value:
   Metrics: Number R in relation to, the time until
   Benefits: Measuring the frequency of R values. The low frequency may indicate that the required re-engineering values and the efforts should be directed at the reusable R values, and the functions that they perform.
C. R Metrics:
   Metrics :Measurement of re-utilization of value based on fundamental R characteristics. Such marks can be subjective appraisals by user (excellent, good, average, meager, poor), while there is a way to get R metrics to be evaluated by automated tools.
   Benefits: The characteristics are identified which creator of R values in particular way emphasizes to fulfill the needs of users.

The measurements of the R size can be numerous. It is listed six models that define R metrics are sufficient to demonstrate the advantages of software built on R values. The methodology defines accurately and thoroughly all steps of a complex research of this type known by the name ''the goal questions-metrics''. This method is basically every metric and the research always begins and gradually leads to pre-approved methodology steps of this method.

$$\textbf{Quality R} = \frac{\text{(The number of errors and thefailureofthe program)}}{\text{(KNCSS thenew software) or (KNCSS inR-values)}}$$

R metrics defined measures the concentration of defects in the application program:

1. It is compared the concentration of errors in R values in the new software, whereat the better quality on a higher level of participation in the new software program.
2. It is determined the level of concentration errors before and after their integration of R values in the project of development, taking into account the errors appear additionally due to the integration of R values in the new product.

$$\textbf{Quality R=} \frac{\text{(The number of errors and thefailureofthe program)}}{\text{(KNCSS in softwarewithoutR) or the(in the software ofKNCSSR)}}$$

Figure 2: Formula of the new program quality with or without the R value[K]

Preponderance of errors significantly reduces the quality and reliability of software. The sharing of R values and its integration into new software products, from technical point of view, requires an analysis or other additional parameters through the following information:

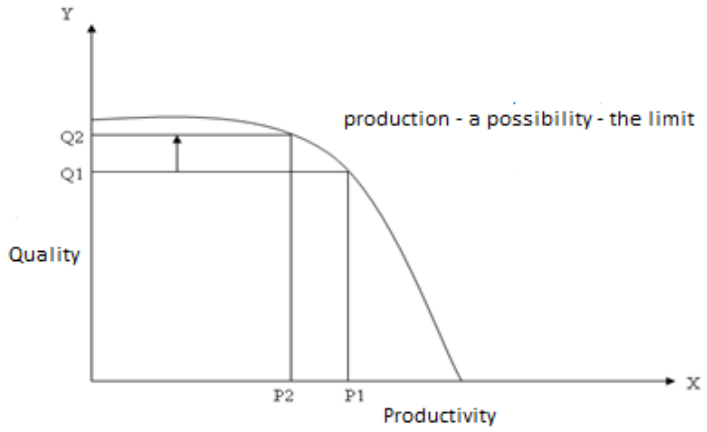

Figure 3: Mutual exclusionbetweenquality and productivity[L]

- Functionality- the area in which the program fulfills the user's requirements. R components can quickly create a prototype that will allow changes to the functionality of future decisions on the fly, during the current development.
- Accuracy- the level in which the software is released from extra efforts of designing and coding errors because it is constantly tested and reused.
- Reliability- the degree or reliability and accurate performance of certain functions with minimum glitches.
- Performance- the successful implementation of R program as an adequate response on time. The maintenance ability performance is under various conditions for a specified time.
- Usability- the application software is friendly to users, easy to use and learn, the user procedures are fast executed and it is easy to prepare and to interpret the input and output parameters.
- Localization- R values have the foreseen functionality for certain volume of business, but in the specific locations of application software emerging the requirements may be modified, where the necessity appears for regional users.
- Support- of maintainability R software. The engineers creators of R value takes over and the process of their maintenance. Under these conditions, the cost decreases per unit of product.
- Flexibility- R software provides the ability to modify the system requirements. Only changing parameters of the R component, is sufficient to modify the output values of R.
- Integrity- reflects controlled an authorized access to software or data.
- Testing- testing to fulfill the requirements of the program proves the achievement of the planned functionality.
- Portability- meet requirements of transfer programs from one hardware configuration or operating system to another or the ability to transfer between different working environments.
- Strong operational R software raises the level of interoperability of software, because the components of the re-handling routines are used by other systems. Therefore, the time and effort which are invested in the development and debugging of the original components of individual modules, which are used many times, und it is ultimately worth. The cost is amortized on a large number of component usages, which indicates the viability of the usage.

Comparison between quality and productivity provides a choice of outputs and inputs. The output is limited by comparison of these two parameters. The production graph is limited with labor, time, and capital, where input produces alternative exits. ''Curve- production-possibility-boundary'' as it is shown in the chart tells about the production, which gives a choice of thresholds of productivity or quality, which is mutually exclusive to a certain point. If we illustrate by the following picture, we can say that the effort involved in achieving the quality product Q1, entails a certain level of productivity P1. However if you would like to make some mistakes and weaknesses, and raise the level of quality in Q2, it requires the additional labor costs and time, which would otherwise bring down the level of productivity in P2. The company management according to offered parameters should decide which threshold wants to implement, higher productivity, lower productivity or vice versa R components dampen the benefits of raising productivity and quality of new software products but sometimes priorities need to be defined.

6. RELIAIBLITY IN SOFTWARE DEVELOPMENT

The methodology which estimates the **quality** of its **software** processes tries to raise the quality which also affects the raising of **reliability** of **software**.By analyzing the factors, it helps to improve the quality of the end-products usability. The equation measures these factors.

The semantic meanings of the terms are:

C_d - price debugging
t - estimated lifetime of the software product
f - relative frequency with which the components are executed
E - tf - number of repeating the code that will be executed
p - assumption that the component contains an error code
r – fp - reliability or assumption of errors causing product
c_f - price for code of broken code components
K- 1000 fold passage through software
(Note: all formulas are the references^{M})

It should be determine breaking points that represents the value of going through the lines of program code for debugging, is equal to the expected cost due to defects or errors or when the component code uses only one product:

$$C_d = Epc_f$$

If the component code is potentially multiple times in the N product, then the total number of performance components was:

$$E_{total} = \sum_{i=1}^{N} E_i$$

Thus, the breakpoint when the component code used in the N product is:

$$C_d N = E_{total}\ pc_f$$

Because the Etotal > E to be exactly Cd N ≥ Cd. More pieces of code are executed, the higher cost of lurking bugs in the code that can be justified, until they are amortized in a number of use. R cannot afford more debugging to reduce P ie assumption is that the component contains an error, which improves r ie reliability of a software product.

1. If we assume that we have a software component that is reusable, we can perform analysis of quality and reliability, according to the proposed methodology.

c_f = 80€.
E= 10.000 performance
P= 0,001 presumption that contains an error

Then C_d = Epc_f
= 10.000 x 0,001 x 80€
= **800€**
price debugging components

(Reliability) R =fp=10,000*0.001= 10is the number ofthe assumptionsthatthe component codecontains an errorafter10,000repetitions:

80 € /10possible numberof detectederrors=8 €, which is the pricefordebugginga single passthroughthe codecomponents.

If the cost of the development program lines of code is ie components that may contains an error, € 80, with 10.000 replications discover 10 possible errors, then the reliability is extremely high after the passage of 10.000 lines of code in the program. Price for each debugging is 8 €. The more debugging or going through lines of code, the less opportunity for error and greater reliability software solutions(R), which is seen in the following formula:

R = fp = 1.000 * 0.001 times passes assumption errors = 1
R = fp = 10,000 times passes * 0.0001 assumption errors= 1

2. On the basis of these analyzes, we make a conclusion, that the cost fo 8 € to pass through a single component should not be justified. On the other hand, if the software component of the real potential for R (re-use) of three products where a component is executed 10H, 20H and 30H times, recognizing that cf=80 € and P= 0.001 then:

Er = Epi = 10H + 20H + 30H = 60H
C_d (3) = 60H x 0,001 x 80€ = €4.8H
Epc_f = 60.000 x 0,001 x 80€= **4.800€**

Reliability R = fp = 60,000 * 0.001 = 60 is the number of assumptions, it is possible to detect an error in the code components after 60,000 repetitions, 80 € / 60 = 1,33 €, which is the price for debugging a single pass through the code.

The mathematical expression confirms that the 6-fold increase of debugging is a reasonable cost price, which is given 6 times repeatedly, passing through the component code, and it don't increase the reliability of software. If the € 80 cost component code is, and we assume that there are mistakes, and we have calculated that the assumptions of possible 10 errors in the code after 10.000 repetitions 8€ is a price for each pass through the code during debugging. However, if the same code is used in three organizations, and each has 10.000, 20.000, 30.000 passing through the same code, so debugging is 6 times increased, in which case the value of 1.33 €is an extremely low cost per debugging passing through the code.

5. CONCLUSION

The scope of the research quality of the software system business is the legal capacity, whereat the quality depends on the products and services which are provided by complex business systems, where software is an integral part. Therefore, improving the technical quality of software operating environment, reflects the business value of complex business systems.

With this methodology it is estimated the quality of software by their actions and it tries to raise not only the quality but also the level of reliability of the software. Analyzing the factors of improving the quality in the most rational and efficient war, it is amortized the R component, which participates in the development of software applications, which increases the quality and reliability of the final product of their used time and the effort in developing and debugging the original reusable components is shortened and it is multiplied in its use, since the manifold usage justifies the time spent for building, debugging and testing of components because the components are already prepared as a partial software solutions. The rational use of your time gives a space to perform quality, reliable and comprehensive analysis, which usually requires more resources and time and expert, which affect the proper development of the project tasks. The quality and reliability in the development of software solutions assimilated paradigm Reusable Assets-Component Software Development.

Abstract: *This paper presents the main elements of the development of a software solution for monitoring the quality of production during the execution of the production cycle. Controlling elements are based on the tracking malfunctions which can be seen at the assembly of the final product. The specificity of the present software solution represents the monitoring of workers and supervisors in the analysis of production quality. Monitoring the quality of production during the execution of the production cycle has a wide range of implications for the organizational elements of the company and production planning. Analysis of malfunctions during the assembly of the final product significantly improves the quality of production, shortening of the production cycle, as well as a more efficient choice of suppliers and elements for installation. The software solution presented in this paper is designed in such a way that it can be universally applicable to all forms of industrial production at the assembly of the final product.*

Keywords*: Software Development, Information Technology, Quality Control, Production Cycle, Production Analysis*

1. INTRODUCTION

Analysis of production quality is one of the most important elements of industrial production. Quality creates one of crucial factors in the placement of the final product. However, analysis of the actual quality and identified defects during production significantly affect other business segments. A large number of identified deficiencies in terms of poor installation inevitably implies a number of organizational and technical measures in terms of the improvement of the production process. Reduction of certain defects during production affects the shortening production cycles due to eliminating the need for subsequent finalization of the finished product. Also, the improvement in the production process results in adequate production planning, management of human and material resources, as well as achieving financial effects.

Considering the importance of achieving quality production, to this issue is given great importance. Mitra (2012) this issue of improves by a statistical approach to the analysis of quality. Modern methods of quality control include numerous methodologies (Wadsworth et al., 2002, Besterfield, 2004, Christensen et al., 2007).

The analysis of production quality a number of authors highlights with the different approaches, introducing new improvements in this area:

- Various quality techniques for manufacturing (Reece, 2007)
- Implementation of quality control stations (Shetwan et al., 2011)
- A modeling approach for quality control (Weiss, 2013)
- Quality control model based on danger theory (Zhang et al., 2009)
- Implementation of n-line quality control (Pan et al. 2009)
- Implementation of intelligent quality control system (Zhao et al. 2009)

An essential element of improving production quality control is the implementation of information technology. In this sense Demant et al. (2012) highlight opportunities of visual quality control in manufacturing. Chen et al. (2010) accent of consideration set to the application of data mining technology in the analysis of quality control. Certainly one of the most important elements of the application of information technology refers to the automation of certain segments of quality control in manufacturing (Maki & Teranishi, 2001).

Software solution which is presented in this paper is a computer support for monitoring and analysis of quality of products at their final assembly, as well as individual components of the installation. The specificity of this approach is based on recording of product quality and registration of certain defects during the manufacturing process. In addition to timely response, in terms of subsequent finalization of finished products and elimination of identified deficiencies, this approach also aims to analyze the production process and improve organizational and technological elements of production.

2. REVIEW OF THE SOFTWARE SOLUTION

The basic elements of a database of the considered software solution are based on records of individual malfunctions, control elements, as well as information about workers and supervisors who participate in the monitoring of the quality of production. Figure 1 shows the Codebook of workers and supervisors with their basic data, which is one of the original table for the analysis of the results of the monitoring of quality control application. The structure of the code list table is based only on basic data on workers and controls, directly relevant to the activity of monitoring the quality of installation. Through the relational model, these basic data can be linked to other tables in the database of integral information system and thus obtain other information about the workers and supervisors who participate in this activity. Registration number of workers is the unique identification number of workers or supervisors in the entire enterprise information system and the primary key of the table in the function of connecting with other database tables. Seal number of workers or supervisors means the identification number of workers at the check list in monitoring of quality. The table includes the number of working days for monitoring quality control as well as required field which defines the worker or supervisor.

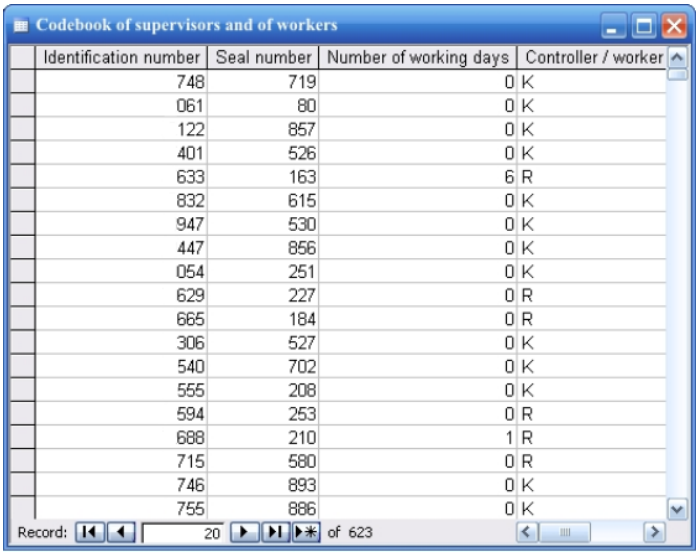

Figure 1: Codebook of supervisors and of workers

Table with control elements is a database table for quality analysis of installation. In addition to the primary key which uniquely marks individual pre-defined control elements. The specificity of records makes points of workers and supervisors for indicating the importance of individual malfunctions. The table contains predefined values for expressing the importance of identified eventual malfunctions over individual elements of the control. Figure 2 summarizes the structure of this table.

Figure 2: The table of control elements

The table Irregularities is the most important table in the database intended for monitoring the quality control of installation, Figure 3. In the table records are kept on concrete individual control elements which represent sub-assemblies in which the specific defect was observed. Basic data which constitute record of individual malfunctions are, in addition to the elements of control and identified malfunctions, the identification number of each product, the date of inspection and the number of seals of workers or supervisors. Data is automatically joined values of some important malfunctions in the Table of control elements.

Record: 20 of 294

Figure 3: The table of data on individually identified defects

Based on previously entered data, the software solutions enable creation of a number of reports, by which in different aspects can analyze required information on quality control. Figure 4 shows a report of improprieties with other related data, grouped for specific final products. This allows the analysis of all malfunctions identified over certain products. Additionally, of great importance are the reports by which the observed malfunctions are grouped according to individual elements of control. This analysis is carried out on certain sub-assemblies with the associated disadvantages. This analysis affects the selection of individual components and determination to a particular supplier in terms of quality. A large number of malfunctions, which indicate poor installation, implies different measures for improving individual operations of installing, to the structural and technological improvements.

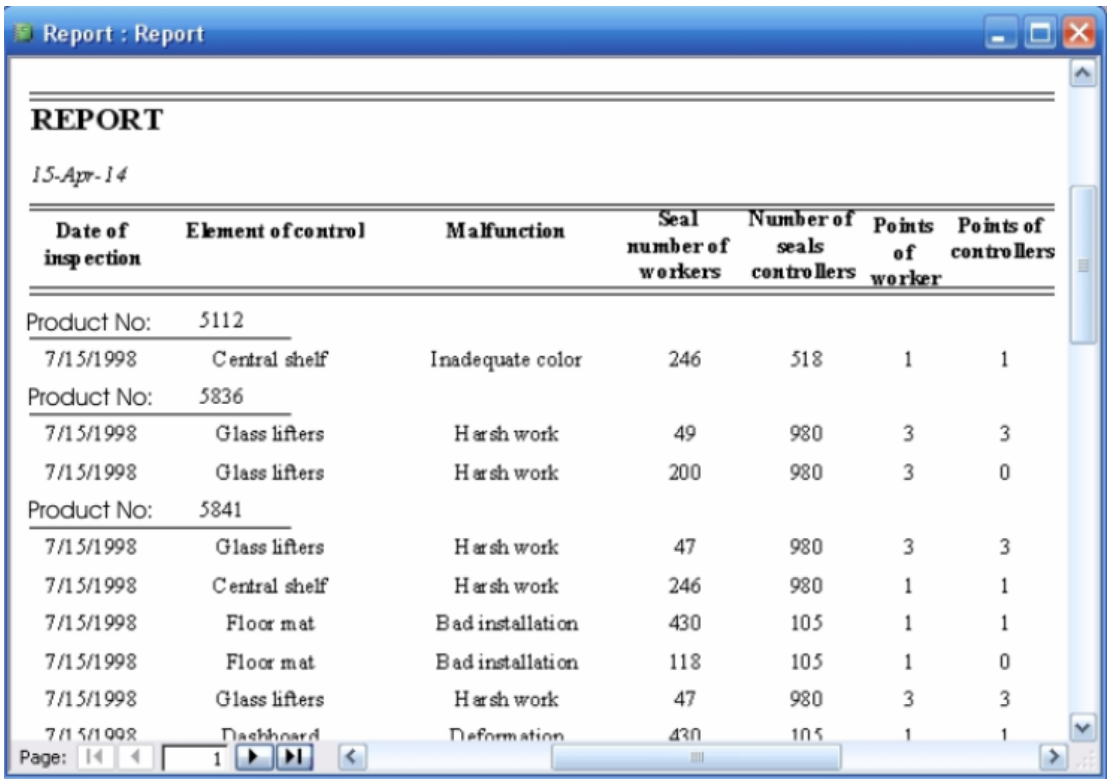

Figure 4: A report on irregularities grouped for specific final products

When considering the quality control of the presented software solution, accent is placed on the statements relating to the monitoring of work of the supervisors and workers in the process of monitoring and failure analysis. Figure 5 shows the data report only about the controls in this activity. Based on the number of seals, controllers obtained automatically, through the rest of the most important information, information about the controls, by establishing relational links with the table codebooks of controllers. Reports are formed grouped for individual controllers, where the information relates to a summary presentation of the acquired points of controllers, regarding the importance of identified malfunctions. In purpose of analysis the controller operation, an important information is a summary presented number of working days for control on this activity and achieved points in relation to the number of working days. In this way can be evaluated the work of controllers and their contribution to the detection of deficiencies in the quality control of production. Based on the displayed personal identification number of the controller, by establishing relational links to other tables of the integrated information system, it is possible to obtain all other necessary information about them. In the same way enables creating reports about the workers, by which can be evaluated their work in the quality control activities., Figure 6.

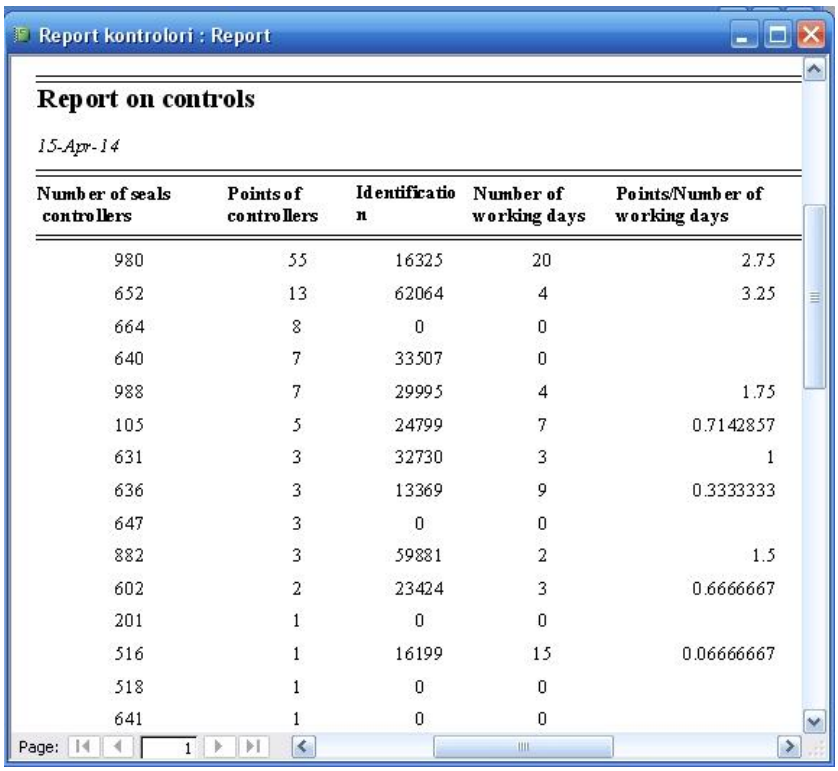

Figure 5: Report about the controls

Automatization of the report creation about the controls is performed by placing a query over tables of the relational database. The following listing is an appropriate program for the creation of this report, created with SQL (Structured Query Language) language, the universal language for accessing relational databases:

INSERT INTO [REPORT controllers] (NoSealController, SumOfPointsController) SELECT DISTINCTROW REPORT.NoSealController, Sum(REPORT.PointsController) AS SumOfPointsController FROM REPORT GROUP BY REPORT.NoSealController ORDER BY Sum(REPORT.PointsController) DESC;
UPDATE DISTINCTROW [REPORT controllers] INNER JOIN [CODEBOOKS CONTROLLER I WORKERS] ON [REPORT controllers].NoSealController = [CODEBOOKS CONTROLLER I WORKERS].NoSeal SET [REPORT controllers].IdentificationNo = [CODEBOOKS CONTROLLER I WORKERS]![IdentificationNo], [REPORT controllers].NoWorkingDays = [CODEBOOKS CONTROLLER I WORKERS]![NoWorkingDays]
WHERE ((([CODEBOOKS CONTROLLER I WORKERS].KontrolorWorker)="K"));

In addition to previous report which has a general character, one of the most important analysis refers to the work of supervisors or workers on a monthly basis or within a specified period, Figure 7. By this is perceived detailed and summary results of the work, in order to establish stimulating measures and rewards according to the effect of operation. In addition to data on observed irregularities in certain elements of control, in this sense are of importance and generated summary points that describe the overall significance of results. The programming code for creating this report is presented in the following listing:

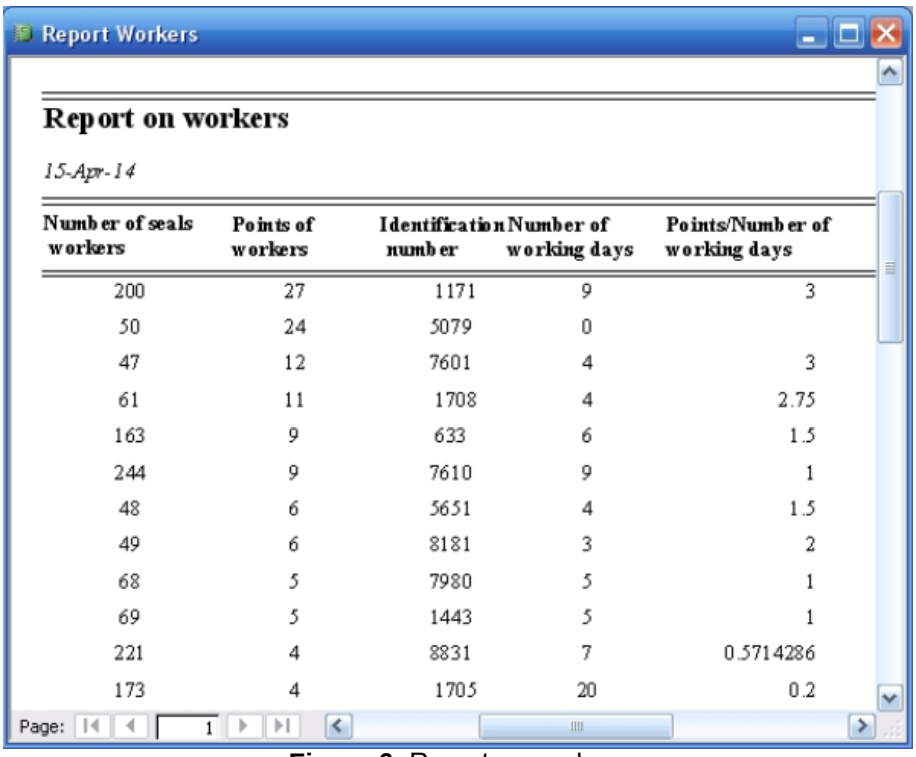

Figure 6: Report on workers

INSERT INTO REPORT (NoProduct, DateInspections, ElementControl, Malfunction, NoSealWORKERS, NoSealController, PointsWORKERS, PointsController)
SELECT DISTINCTROW MALFUNCTIONI.NoProduct, MALFUNCTIONI.DateInspections, MALFUNCTIONI.ElementControl, MALFUNCTIONI.Malfunction, MALFUNCTIONI.NoSealaWORKERS, MALFUNCTIONI.NoSealaController, MALFUNCTIONI.PointsWORKERS, MALFUNCTIONI.PointsController FROM MALFUNCTIONI WHERE (((MALFUNCTIONI.DateInspections)>=[SIGN INITIAL DATE] And (MALFUNCTIONI.DateInspections)<=[SIGN FINAL DATE]));

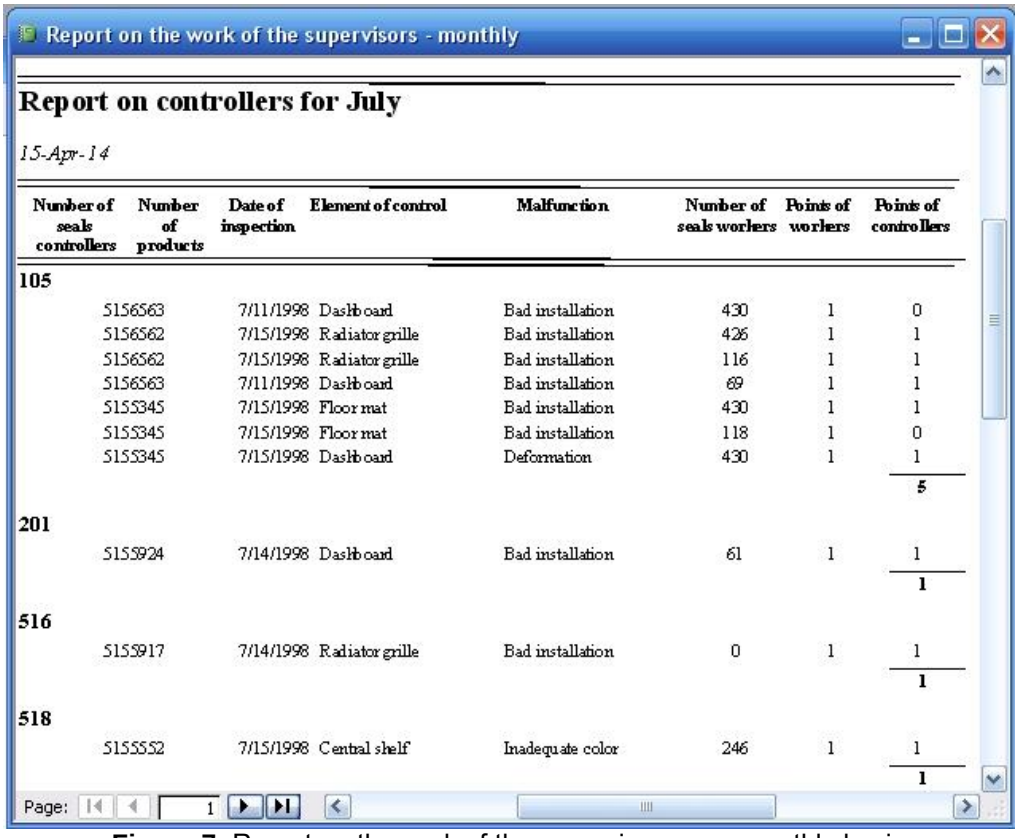

Figure 7: Report on the work of the supervisors on a monthly basis

3. CONCLUSION

In this paper are presented basic elements in the development of a software solution, which enables computer support for recording and analysis of malfunctions of finished products. The most important elements of the considered solution are presented . Discussed computer support is created using MS Access software tool, which is one of the most suitable tool for this purpose. The reasons for this can be seen in the speed of development of software support in all areas: creating a database, automation of calculation and analysis of data by setting the query, formation of different satisfactory reports for business purposes.

In addition to monitoring the quality of the product and identified malfunctions, the prezented software solution enables the analysis and evaluation of supervisors and workers in the quality control process. Evaluation of the work is provided in general terms and in a period of time, such as monthly. In this sense there is a possibility of evaluating and rewarding work by performance and by the importance of the identified irregularities in the quality control.

By predefined codebooks of supervisors and workers, as well as with a table of elements of control, it is enabled automatical creation of reports, with all necessary information, based on the entered elements of control and malfunctions, identified during the production process. Database tables, formed for the purpose of this software solutionis, is possible to link with other databases of the integral enterprise information system by a relational model, in order to obtain a large number of other reports. In this sense, the presented solution is not an isolated segment, but part of the overall information system.

An important feature of the displayed solution is a logical overall structure, in terms of its universal applicability in all industrial company, with the characteristic of the assembly of the final product. The greatest significance for the application of the considered software solution can have in case of execution of complex products with a large number of parts. In this sense, the solution may represent a conceptual basis for the development of own computer support in the individual industrial production.

Abstract: *Ideas on the theory of voting have been adopted in number of recent online applications. Web search engines and recommendation systems use various voting methods for ranking results. The paper addresses a problem of implementing different types of voting systems, along with their definition and history. It points out the necessity of comparing them in order to complement different types and to suggest their improvement. Special attention is dedicated to the comparative analysis of voting systems, and applying Single-winner system of voting to Joomla component. Joomla component "Music recommendation" is developed.*

Keywords*: Voting system, Single-winner, Joomla component, Music recommendation, Model-View Controller.*

1. INTRODUCTION

Ideas on the theory of voting have been adopted in number of recent online applications. Recommendation systems have proven to be valuable tool for online users to cope with the information overload and to provide useful suggestions related to various decision-making processes (Ricci et.al, 2011). Various voting methods for ranking results have been proposed and many of them have been successfully deployed in the business and academic applications.

However, there are a lot of concerns in regard to adaption and design of learning mechanisms and algorithms for review ranking. Therefore, this research will be addressing this issue. Paper goal is to provide an insight into different types of voting systems, along with their definition and history. Special attention is dedicated to the comparative analysis of voting systems, and applying Single-winner system of voting to Joomla component. The growing attention on modeling in software development has subsequently brought the design of components in forefront. The specification and design of the component is strongly related to its availability and usability. Model-View-Controller (MVC) software architecture is recognized as the most used and accepted approach for designing a component (Bose, 2010).

First, literature overview presents the scope of the work done in defining different types of voting systems and Component-based software development approach. UML class diagram and process workflow of "Music recommendation" voting is given in section 4. Section 5 examines existing voting systems in order to define appropriate voting mechanism for "Music recommendation" component. In conclusion, we discuss research outcomes and ideas for future work.

2. VOTING SYSTEMS

Voting system or electoral system represents the way by which voters choose between given options in elections or on political referendums. The system sets the rules for achieving valid voting credential, as well as rules for aggregating votes in final results.

Common voting systems are: majority rule, proportional representation or plurality voting with many variations, such as first past the post or preferential voting (Rivest and Shen, 2010). Social choice theory or theory of voting represents a mathematical theory for formal analysis of combining individual opinions, preferences and interests to reach collective decision. From a standpoint of majority rule voting system, those who aren't familiar with voting theory are usually surprised that another voting system exists and that there are differences in meaning to be supported by majority. Therefore, majority rule voting can sometimes get the results that majority does not support. If there were only two options on each election, a winner would be chosen only by majority rules voting. However, if there were three or more options, it might happen that none of them get the majority votes of most or least liked. A simple choice does not allow voters to express

their order of preference and their feelings towards certain options. Different voting systems may give very different results, particularly in situations where the majority does not clearly specify their preferences.
Voting system determines a form of voting ballot, a set of legal votes, counting method and an algorithm for determining the results. Based on an algorithm, voting systems are divided into two general types: Single-winner and Multiple-winner voting systems (Nurmi, 2010). Moreover, the voting system may also specify how voting power is distributed among voters and distribution of voters in the subgroup whose votes are counted independently.

Conduct of elections in practice is not considered as a part of the voting system. It does not specify whether the ballot is in the form of plain paper, cards ticking or on a computer screen. A voting system also does not determine whether and how votes are kept confidential, the way to check whether the votes were counted correctly or who is allowed to vote.

3. COMPARATIVE ANALYSIS OF VOTING SYSTEMS

According to the algorithms for determining the results, voting systems are divided into: Single-winner and Multiple-winner voting systems. Scope of our work is in Single-winner voting system and it is applied in developed Joomla component.

Based on the voting method, Single-winner voting systems are divided into:

1. One vote or Sequential voting systems

In these systems voters vote for only one candidate and it is distinguished from the voting system applied in Joomla component “Music recommendations”. In the game each participant must vote for all recommended songs, not just for one. The best known Sequential voting systems are: Majority, Approval, Runoff and Random ballot voting system (Johnson, 2005).

Under the Majority system, a candidate must receive an absolute majority of votes to be a winner. This system encourages tactical voting and voters are pressured to vote for one of the two candidates with the highest chance of winning, because a vote for any other candidate is most likely wasted vote with no impact on the final result. Its implementation would be very simple, but it is not appropriate for the application where wasted votes should not appear. Approving voting system is similar to a Majority system. Voters can vote for as many candidates as they wish and the candidate with the most votes wins. It is simple and more flexible for voters. However, it is not used for the application because voter must give points to each song. In a Runoff voting, a candidate wins in the first round if obtains an absolute majority of the votes. Otherwise, a second round is held between the two candidates with most first-round votes and the winner is the candidate with best score from the second round. The last type of Sequential voting system is a Random ballot. In this system, a winner is chosen by random selection of a ballot. The use of a random ballot voting wouldn‟t make any sense, because it wouldn‟t depend on voters‟ preferences.

2. Ranked voting systems

Ranked voting system allows voters to rank candidates in order of preference. Ranking voting systems are divided into: Borda count, Bucklin, Instant-runoff, Condorcet, Coombs, Supplementary and Position voting system. These systems are the most similar to the voting system of the component “Music recommendations”.

Under the Instant-runoff system, voters rank candidate by giving mark „1‟ to the most preferred candidate, mark „2‟ to the second-most preferred and so forth in ascending order, while the order in “Music recommendations” voting system depends on the total number of candidates. The ordering process in Instant-runoff system is simpler for voters and also for implementation. The winner is a candidate who receives over 50 percent of the first preference votes. Otherwise, the candidate with the fewest first preference votes is eliminated and the points of eliminated candidate are assigned to the remaining candidates, who are ranked next in order of preference. The process flow is repeated until one candidate wins by gaining more than half the votes (Gehring, 2007). The processes of eliminating the candidates and assigning their points to the remaining candidates are not suitable for “Music recommendations” voting system. In “Music recommendations” system, it is necessary to assign the total number of points by all participants to each song.

Borda count is the most similar voting system to the “Music recommendations” voting. Voters rank candidates in order of preference, by giving a certain number of points which depends on the number of candidates. The candidate with most points is the winner. The only difference between Borda count and “Music recommendations” voting is used series of points.

Condorcet methods use pairwise counting and compare candidates one-on-one. The winner is the candidate whom voters prefer to each other candidate (Johnson, 2005). This method is implemented in “Music recommendations” voting in case where two or more songs have the same total number of points. The final rank is determined by Condorcet method in the aggregate ranking. The pairwise counts can be displayed in matrix. Under the Supplementary voting system, voters express only a first and second choice of candidate. If no one receives an absolute majority of first choice votes, all candidates are eliminated except the two leading candidates. The system is not suitable for “Music recommendations” voting, because in the second round the votes of eliminated candidates are transferred to the candidate of voters‟ next preference. On the other hand, Bucklin voting allows ranking the candidates in order of preference. If one candidate has a majority of first preference votes, the candidate wins. Otherwise, the second choices are added and this cumulative method is not suitable for “Music recommendations” system, since the winner is the candidate with the most points added.

3. Rated voting systems

Under those systems, voters give grades to each candidate from specific series of points. They are divided into: Range voting systems and Majority judgment (LeDuc, 2002). In Range voting system, the ranking ballot is used and voters rank each candidate with a number from defined series. The candidate with the highest sum wins. This method increases the level of tactical voting. Majority judgment system allows voters to judge each candidate and method of six grading levels is suggest, from “excellent” to “rejected”. The median grade for each candidate is calculated and the candidate with the highest median grade wins. The difference between Range and Majority judgment voting is in calculation of highest score.

4. DEVELOPING A COMPONENT FOR JOOMLA CMS

Bose (2010) describes Component-based software development (CBD) as approach based on the idea to develop software systems by selecting appropriate off-the-shelf components and then to assemble them with a well-defined software architecture (p.2). Complex software systems are built efficiently using component based approach in a short period of time. It brings the design of the component to the forefront. Model-View-Controller (MVC) software architecture is recognized as the most used and accepted approach for designing a component. This approach divides the component into three functional parts: data access, data presentation and business logic. The changes made in one part do not affect others.

The Model is responsible for data management, i.e. extracting data from database or from other data sources. In developing a component there can be multiple models and each of them can be defined for different data sources. It includes methods of presenting, creating, updating data and others methods related to handling data. The Model is all business logic with no knowledge of the View.

The View is responsible for presenting the data pulled out from the database. In Joomla CMS, it renders a HTML page from data using the general scheme. The View never changes the state of a database and only shows its condition retrieved from the model. Requests for data change are issued by the Controller and the Model executes them. Modules are automatically associated with a view by the Controller. The Controller selects the appropriate model or multiple models based on user requests and forwards requests to the model. It creates the view and ties it to one or more models. The duty of the Controller is to create a view, not to present data.

In Joomla CMS, each part of MVC is represented by an abstract class: JModel, JView and JController (Whitepaper 2011). These classes are in library joomla.application.component. Figure 1 shows the relationship of these classes.

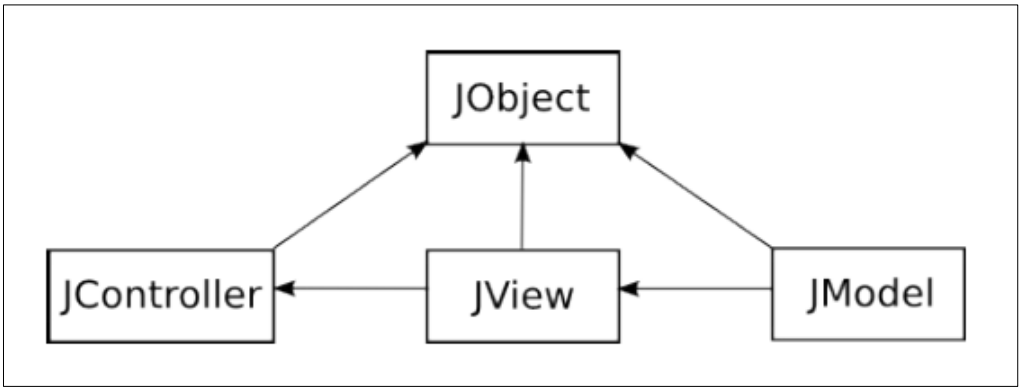

Figure 1: MVC – the relationship of abstract classes

5. DEVELOPING A JOOMLA COMPONENT "MUSIC RECOMMENDATIONS"

5.1 A problem statement

The progress and development trend of Internet communication and the popularization of music websites have encouraged the music fans to seek for more information about music tracks and artists. Music recommendations based on previous searches of every registered user are provided by specific sites, such as YouTube. However, the personal recommendations have significant influence on user online music tracks and artists choices. They affect users' perceptions of trustworthiness. Therefore, "Music recommendations" component was created in autumn 2008 and it reached over 1000 new songs.

In the absence of adequate methods, "Music recommendations" occurred in the form of separate sub form on the main forum. The game take place on a weekly basis and the week is divided into three phases: setting the songs, listening and voting. Two days, Sunday and Monday, are reserved for setting the songs. Each member has an opportunity to recommend a song within these two days on forums" topic created by the administrator. Songs are mostly described by attributes: name of the artist, title of the song, YouTube link and additional information, which is optional and represents members" comment on the song. Listening activity lasts for the rest of the week, accurately until Saturday, the day which is reserved for voting. Each member is required to send their ballots to last week"s winner on Saturday until midnight. Members are voting for each song except their own by specific scoring system, which depends on the number of participants and administrator publish it on the eve of voting. If member forgets to vote or for any other reason doesn"t send his votes, will be disqualified from the current week voting. When all participants vote, last week"s winner adds the points and publishes them on the same topic as song recommendations. In addition to this topic, there are topics on which is possible to comment on the results and the songs. There are also archives of all recommendations, winners and scored.

Increasing demand cause a need for reducing "the human factor" to the smallest possible level, i.e. to create an application for adding the points, creating and closing a voting week, etc. Moreover, number of participants expressed the wish for setting anonymous recommendations which is not allowed on forum. It reduces subjectivity to zero during the voting process.

Therefore, the Joomla component called "Music recommendations" is created as a part of the website with idea to make the game more interesting and user-friendly. Figure 2 illustrates the voting website page of "Music recommendations" component.

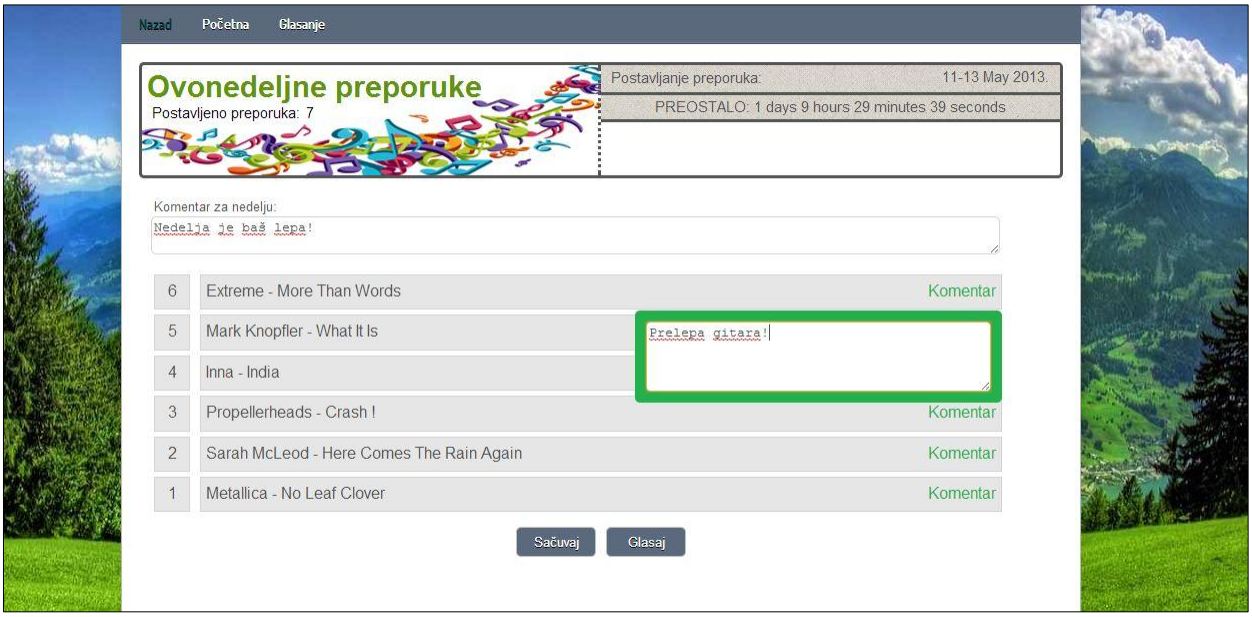

Figure 2: Page for voting

5.2 The component model structure

The organization structure of the model consists of four blocks: current settings, process, history and exit. The model is given in Table 1.

Table 1: The organization structure of the model for "Music recommendations"

Current settings (home) – recommendations set out in the current week
Process (settings, voting, results)
History – results from last week
Exit (back) – exit from "Music recommendations"

"Music recommendations" game takes place on a weekly basis, from Saturday (00:00) up to next Saturday (00:00) and each week represents a process. Two days, Sunday and Monday, are reserved for settings the songs and other days are for voting. Each process is divided into two parts: setting and voting. Thus the week can have two statuses: "setting" and "voting". In first part, participants set songs and review the songs set by other participants. The second part of voting allows the participants to vote for posted songs. If all participants voted before the time for voting expired, weeks" status would become "locked". In this period participants can't set songs. They can only watch the election results from the current week. Results from last weeks are always available in the "History". The process diagram is given in Figure 3.

t1= t3 - Monday (00:00), t2 - Saturday (00:00) (1)

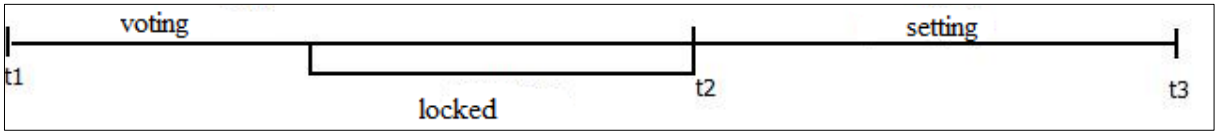

Figure 3: Time intervals of a process

The specification and design of the component is strongly related to its availability and usability. Object-oriented design of the component is illustrated through UML class diagram (Figure 4), as the most important structural model. The objects and information structures used by application, both internally and in communication with users, are described.

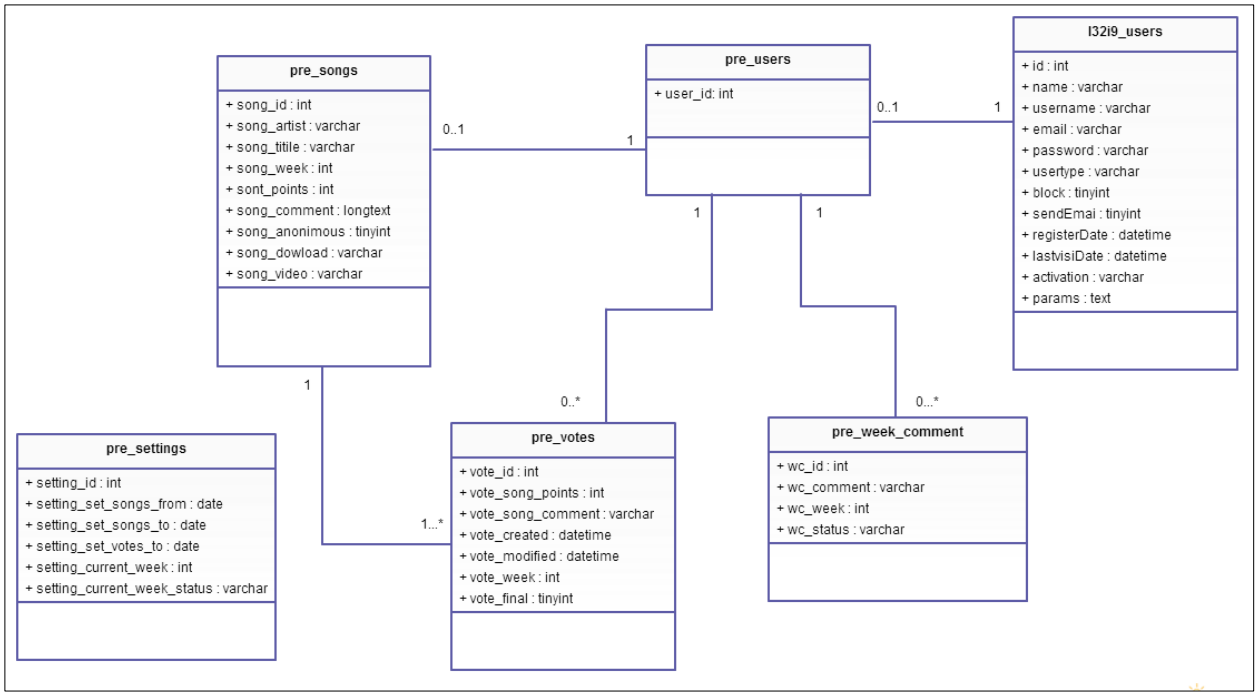

Figure 4: UML class diagram

5.3 Joomla component "Music recommendations" voting system

Creating ballot is the first step in implementing voting system of Joomla component "Music recommendations". The ballot includes all the candidates who are qualified to compete. If member recommends a song to others, member will be eligible to participate as a candidate in voting process. The voters are also the candidates on the ballot.

Moreover, each member who recommends a song can announce whether the previous set songs are known to member. If 30 percent of all participants know the song set by one of the participants, the song has to be replaced by a new one. Otherwise, the member will be disqualified not just as a candidate but also as a voter. The number of voter and candidates is equal, because a member who doesn't recommend a song has no rights to be a voter. After defining the number of candidates and voters, the voting process can be performed. Each voter ranks songs from other participants except their own. Ranking refers to giving points to each song that the other participants set in a particular order, so the most points are given to a song the voter has liked the most and so on. Voter must give points to each song in a way that one value from defined series of points can be applied to only one song. Ratings depend on the number of candidates, i.e. the number of songs that are posted. Rule by which the points are given is represented in Table 2.

Table 2: The ratio of the number of participants and points

Number of participants	Series of points
< 9	1, 2, 3, 4, 5, …
10	10, 8 ,7, 6, 5, 4, 3, 2, 1
11	12, 10, 8 ,7, 6, 5, 4, 3, 2, 1
12	14, 12, 10, 8 ,7, 6, 5, 4, 3, 2, 1
13	14, 12, 10, 9, 8 ,7, 6, 5, 4, 3, 2, 1
14	16, 14, 12, 10, 9, 8 ,7, 6, 5, 4, 3, 2, 1
15	16, 14, 12, 11, 10, 9, 8 ,7, 6, 5, 4, 3, 2, 1
16	18, 16, 14, 12, 11, 10, 9, 8 ,7, 6, 5, 4, 3, 2, 1
17	18, 16, 14, 13, 12, 11, 10, 9, 8 ,7, 6, 5, 4, 3, 2, 1

After the voting, the points that are given to each candidate are calculating. The points are added up and the candidate with highest total number of points wins. Other candidates get their ranking positions in the aggregate ranking list.

If two candidates have the same total number of points, they will be compered in terms of the position they hold in rankings by other voters. The candidate who holds better position in ranking list of one voter gets 1 point. The process continues until positions of candidates are compared in ranking list of all voters, not considering the ranking list of candidates who are compared. The candidate with highest number of points, i.e. who holds the better position in ranking list of other voters, is a winner.

If a voter doesn"t vote, voters" recommended song is automatically disqualified and the position of that song on the aggregate ranking list is taken by a song that was placed underneath.

6. CONCLUSION

There are numerous types of voting systems in use around the world. Different voting systems may give very different results based on rules which enforce how votes are collected, counted and added to get a final result. Moreover, the number of voters can have influence on counting method and an algorithm for determining the results. There is no single voting method that fits all cases. Many of existing voting systems are complementary, with strengths in different areas. It is necessary to understand in-depth the algorithms of different voting systems and choose the right one. Therefore, the special attention is dedicated to the comparative analysis of voting systems. The algorithms of assigning the grades are observed and process flow for determining the winner is briefly described for each best known voting system. Based on in-depth analysis and a problem statement, the appropriate voting system is select for “Music recommendations” website component. The advantages of Ranked voting systems are applied in developing Joomla component “Music recommendations”. Under defined voting system, participants rank the candidates in order of preference, by giving different grades from series of points to each candidate. The total score of each candidate is presented in the aggregate ranking list. In “Music recommendations” system a voter is also a candidate. Voters must rank songs if they want to stay in the game. In this way, system motivates voters to participate in the game.

It is important to emphasize that Single-winner voting system isn"t completely applied in developing Joomla component, only some elements. The main contribution of this work is reflecting through the creation of Joomla component based on Model-View-Controller software architecture with own voting method. UML class diagram of the component is presented. The resulting method and component can be widely accepted and future research intends to explore new improvements of the method and its further implementation.

Abstract: *This research model was developed through a multidisciplinary combinatory approach, theory of decision-making and project management. In the research, the study of influence of project management during the implementation of ERP solutions in Serbian companies is presented. The development of IS in companies is being researched, the metric of responsibilities on the project is presented, the role of project manager is identified, representing the percentage of companies with established ERP solutions by sector and size and the reasons for implementing SAP ERP solutions in Serbian companies is reviewed. The study systematically presented: a comparative analysis of IS before and after use of ERP solutions, a comparative overview of the new and old system in surveyed Serbian companies, the display module implemented in those companies, the percentage impact of SAP ERP solution implementation in Serbia, the total cost of ERP ownership as a percentage and the cost percentage in surveyed companies.*

Keywords: *ERP system, implementation, information system, enterprise*.

1 INTRODUCTION

In this research paper, based on the systematic study of the relevant literature and research performed in surveyed companies in Serbia, with different type of activities, production processes and the ownership structure, on a representative sample, using the questionnaire, the methodological aspects of the implementation process of ERP system have been researched and evaluated. Eminent authors, (Monk, EF& W Agner, BJ 2006) define ERP as the most important software in the company, which coordinates data / information in all areas of business. ERP solutions help manage business processes through the use of a database and shared management reporting tools. ERP solutions support the efficient functioning of business processes through business operations including sales, marketing, manufacturing, logistics, finance and human resources. Harwood, S. (2004) pointed out that ERP cannot be, in any way, classified as a database with pre-built software.

2 ERP FACTS

ERP solutions enable us to provide automated support for business processes and improved access to information and assistance in the implementation, including process modeling and documentation and tools that support the training and development of ERP solutions, (Denic et al., 2013).

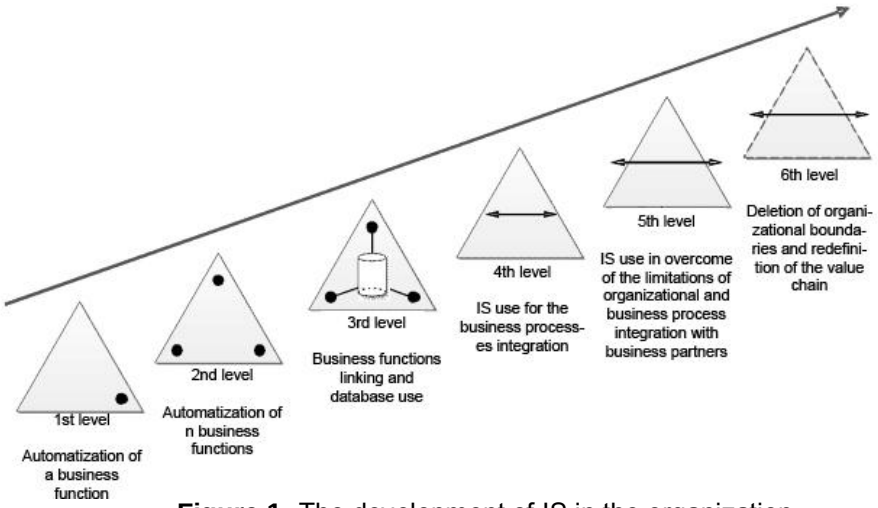

Figure 1: The development of IS in the organization

Source: Boddy D., Boonstra A. & Kennedy G. (2008). Managing information systems– strategy and organization. England etc.: Prentice Hall.

ERP solutions also allow the integration of business processes within and outside the organization, so that the boundaries between organizations disappear by changing their business value. Such systems are called Integrated IS or ERP solutions and their development is presented in the figure 1.

If there is a need to describe the ERP solution from the standpoint of the user, the following can be done: (Hamilton S. 2002).

- the way of making every product and service shall be defined
- the requirements of specific products or specific customer requirements shall be set
- the realistic business plans and proper time delivery of products and services shall be defined
- in order to coordinate activities in the supply chain the schedule shall be used
- the accurate calculation of product costs providing useful information for managers is allowed.

2 PROJECT MANAGEMENT AND ACCOUNTABILITY DURING PROJECT IMPLEMENTATION

The following Table 1 presents Serbian companies, with various types of activities, the production processes and the ownership structure (representative sample), where ERP system was implemented and which participated in the survey and also, the results of research.

Table 1 Companies that participated in the survey

Company Name	Activities of the company	Years In Business	Number of Employees	Web site
Srpska fabrika stakla A.D.	Glass industry	105	870	www.srpskafabrikastakla.com
Swisslion Takovo	Confectionery	17	2762	www.swisslion-takovo.com
Holcim Srbija	Manufacture of cement, aggregates and ready-mixed concrete	135	334	www.holcim.rs
JP PTT Srbija	Postal services, e-commerce, Internet	174	15336	www.posta.rs
Dijamant Zrenjenin	Food industry	76	585	www.dijamant.rs

Source: Research conducted in enterprises in Serbia, 2014.

The following Table 2 presents the results of research related to the review of the reasons for implementing SAP ERP solutions in the above mentioned Serbian companies, which show that every company has its priority reason for the introduction of modern ERP solution, which can be summarized in improving operations and creating positive effects of operations, increase of company value by creating competitive advantage, as well as the survival of the companies in the increasingly open global market in terms of the current global economic crisis. (Denic et al., 2014).

Table 2 Reasons for implementing SAP ERP solutions to enterprises in Serbia

Company name	Reasons for implementing SAP ERP solutions to enterprises
Srpska fabrika stakla A.D.	Improving the business, increasing the company's value.
Swisslion Takovo	Greater efficiency and productivity of operations.
Holcim Srbija	Within its own corporate SAP ERP.
JP PTT Srbija	The current system has unorganized data system. SAP ERP offers the lowest business risk.
Dijamant Zrenjenin	Effective business management and replacement of existing information systems.

Source: Research conducted in enterprises in Serbia, 2014.

In the analyzed companies it is predicted that they shall, together and individually, determine the respective roles and responsibilities in the project implementation of ERP solutions. The appropriate personnel working on a project is of the utmost importance therefore, the personnel have to be carefully selected. The teams working on the project plan development and implementation of appropriate ERP solution are typically diverse teams made from staff belonging to the solution makers and solution purchasers. (Denic N., Zivic N.,

Siljkovic B., 2013). It is important that in the team are, from both sides, adequate interlocutors, who recognize the problems which can occur.

During implementation, the staff was changing mostly in the team of solution makers. The project leader failed to suggest new staff members, and the people from other projects have been spontaneously hired, which had significant influence on the team motivation. In that respect, the project manager performed most of the work alone, and this fact suggested that the Purchaser had no professional leadership. From the Purchaser side, the team included two computer experts who were, more or less, coordinating the project in terms of connecting applications to support production of a new ERP solution. The project included eleven people in total from which six were engaged directly from the purchasing company and five from solution makers company. Also, project manager was chosen from the purchasing company and the other five representatives were from various areas of ERP solution knowledge. The role of information transfer and the inclusion of end-users in a new information system were assigned to them.
Prerequisite for participation in the project was that they were well introduced to the procedures for operating in the old information system. The solution makers offered one person to be appointed as the leader of the project, while the other four had the advisory role, each in specifically defined area. That is how they performed necessary programming work, because they had the role of the creator, more or less. They were even more motivated to work on the project, since it was shown that successful project is in the interest of all participants in the project, although there was very little time to perform. In that respect, the overtime was not an obstacle. From our point of view, regarding the success of the above projects, the prevailing opinion is that some companies can be observed as unsuccessful in ERP solution implementation, and that some companies, from the project management point, can be presented as an example of a successful project implementation and reconstruction of the existing information system. Due to the short period of implementation, the success of such project is more the exception than the rule.
Key users were additionally motivated to work on the project. Top level management, project team leaders and department leaders, had working meetings at which they discussed the progress of the project, as well as the problems and solutions. Despite the very short time for the project realization (three months) and the complexity of the project, it was realized in due time. At the end, the users accepted the implemented ERP solution.

The following Table 3 shows the metrics of responsibility on the project implementation of ERP solutions for companies.

Table 3: Metrics responsibilities on the project

	PM	PMC	PS	FSP
Definition of the target	P		C	
The requirements of a new information system	CO	PA	C	CO
Preparation of the draft document	P	P	C	C
Establishing the project organization	PA	P	C	
Determination of resources, team leader, motivation of participants in the project	PA	P	CO

The management that manages changes in a company shall consist of well educated and high quality individuals, who have authority in the company, and enjoy the respect of subordinate staff, who must be able to understand the technical support of people in the company, which are implementing the ERP system and to have the trust at all levels of the business of the company,(Denic N., Zivic N., Siljkovic B., 2013). In this way, the company spreads good atmosphere and mood and desire for change, which is one of the most powerful advocates of change in a viewpoint. Most project managers are preparing very detailed reports on the cost parameters and they spent time in the implementation of ERP systems, and often, at the same time, they inform about the benefits and savings of ERP systems implementation. It is necessary to obtain data regarding the time which IT staff, in the company, is spending each month in order to prepare different orders or in fixing the errors associated with the Management orders and also, how much time is consumed in planning and control of the business system. However, this can be easily overcome with different tools, which allows the management to solely, and very simple, create their own orders. The ERP solution works more efficient if employees and IT staff work as a homogenous group.

Previous evaluations showed the importance of the project manager during implementation of ERP solutions in the company. Detailed presentation on the review of relevant scientific literature is presented in the table 4 while Figure 2 shows the percentage of companies with established ERP solutions across sectors and size, for year 2007.

Table 4 Some champion definitions found in the literature

Authors	Definition
Beath (1991, p. 355)	"Information technology champions are managers who actively and vigorously promote their personal vision for using information technology, pushing the project over or around approval and implementation hurdles."
Chakrabarti and Hauschildt (1989, p. 166)	"The Champion (process promoter) acts as a linkage. He has the knowledge of the organization and knows who should be concerned with the innovation, thus connecting the sponsor with the expert. His strength is the ability to translate the technical language of the innovation into one which is commonly used in the organization. By becoming a salesman of the new idea, the champion is able to develop a plan of action. His diplomatic talents provide access to different people within the organization".
Day (1994, p.149)	"The agent who helps the venture navigates the socio-political environment inside the corporation".
Ettlie et al. (1984, p.687)	"A person advocating" for the project.
Fischer et al. (1986, p. 13)	"The key characteristic of the product champion is the tension between the individual and what the organization wants".
Howell and Higgins (1990, p. 40)	Champions "make a decisive contribution to the innovation process by actively and enthusiastically promoting the innovation, building support, overcoming resistance and ensuring that the innovation is implemented".
Rothwell et al. (1974, p. 291)	"Any individual who made a decisive contribution to the innovation by actively and enthusiastically promoting its progress through critical stages".
Maidique (1980, p. 64)	"A member of an organization who creates, defines or adopts an idea for a new technological innovation and who is willing to risk his or her position and prestige to make possible the innovation's successful implementation".
Markham et al. (1991, p. 219)	"A role where individuals are strong advocates for a project and generate positive behavioral support for an innovation during its development or work on behalf of the project in the face of organizational neutrality or opposition".
Smith et al. (1984, p. 25)	"Sells idea to obtain resources. The major salesman to management for accelerating progress toward commercialization".
Shane (1994, p. 29)	"An advocate whose goal is to promote the innovation".
Roberts and Fusfeld (1981, p. 186)	"Recognizing, proposing, pushing and demonstrating a new (his or her own or someone else's) technical idea, approach or procedure for formal management approval".
Schon (1963, p. 84)	"Essentially the champion must be a man willing to put himself on the line for an idea of doubtful success. He is willing to fail. But he is capable of using any and every means of informal sales and pressure in order to succeed".

Legend: The core of these industries is (100%) represented by the companies from seven EU Member States (Germany, France, Italy, Spain, Poland, Sweden, United Kingdom) and 811 companies from the chemical industry, 349 companies from the steel industry, 661 companies from the furniture industry, 1026 companies in the retail and transport activities 997 companies have been included.

3 REVIEW AFTER IMPLEMENTATION

Table 5: Comparison of IS before and after ERP solutions

	Before using ERP solutions	**With the help of ERP solutions**
Information Systems	Unconnected systems.	Integration system.
Coordination	Lack of coordination between business functions (e.g. production and sales)	Supports coordination between business functions.
Databases	Unconnected data. The data have different meanings. Inconsistent data definitions.	Linking data. The data has the same meaning in all business functions
Maintenance	Maintenance of individual IS. Inconsistent results. Expensive to maintain separate IS.	Uniform maintenance. Changes affecting several systems.
Interfaces	Impossible exchange interfaces between systems.	Unified interface between systems.
Information	Repetition, inconsistency.	Information is available in real time (e.g. customers, suppliers)
Architecture system	Is not uniform.	Based on a client / server.
Processes	Incompatible processes.	The integrated business processes based on business models
Applications	Various applications (e.g. several different systems for acquisition).	Uniform application - modules (e.g. common data acquisition)

Source: Sumner M. (2004). Enterprise resource planning. New Yersey: Pearson, Prentice Hall.

As shown in the above Table 5 Sumner, M. (2004) amongst other, claims that the greatest success of the ERP solutions is to ensure the availability, visibility and consistency of data across the enterprise.The respondents' opinion, after the implementation of the new SAP ERP solution, in comparison to the old software solutions, was positive, and 80% were satisfied with the new solution and new user interface.

Figure 3 shows a comparative overview of the new and old software solutions.

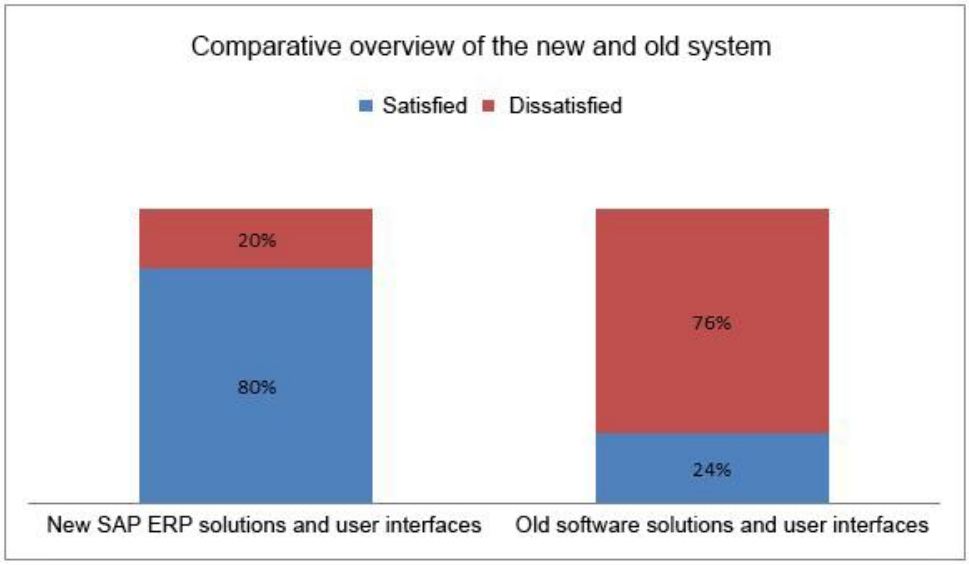

Figure 3 Comparative overview of the new and old system in chosen companies in Serbia
Source: Research conducted in enterprises in Serbia, 2014.

Table 6 presents an outline of the implemented modules in these companies.

Table 6 Display module implemented in companies

Company name	Implemented modules in chosen companies
Srpska fabrika stakla A.D.	FI, CO, MM, SD, PP
Swisslion Takovo	FI, CO, MM, SD, PP, BC
Holcim Srbija	FI, CO, MM, SD, PP, PM
JP PTT Srbija	FI, FI-AA, CO, MM, IM, HR, BC
Dijamant Zrenjenin	FI, CO, MM, SD, HR, PS, BC

Source: Research conducted in enterprises in Serbia, 2014.

Figure 4 shows the percentage of the implementation impact of SAP ERP solutions in Serbia. Implementation of SAP ERP solutions resulted in lower operating costs (80%) and it facilitated the management of the company with the maximum percentage. From a sample of implemented SAP ERP solution, implementation is completed in 60% of the sample, according to the planned time, while 40% is completed within the planned budget. The participant`s expectations from SAP ERP solution implementation were 60% while the quality of knowledge, adopted by the participants, is increased to the maximum.

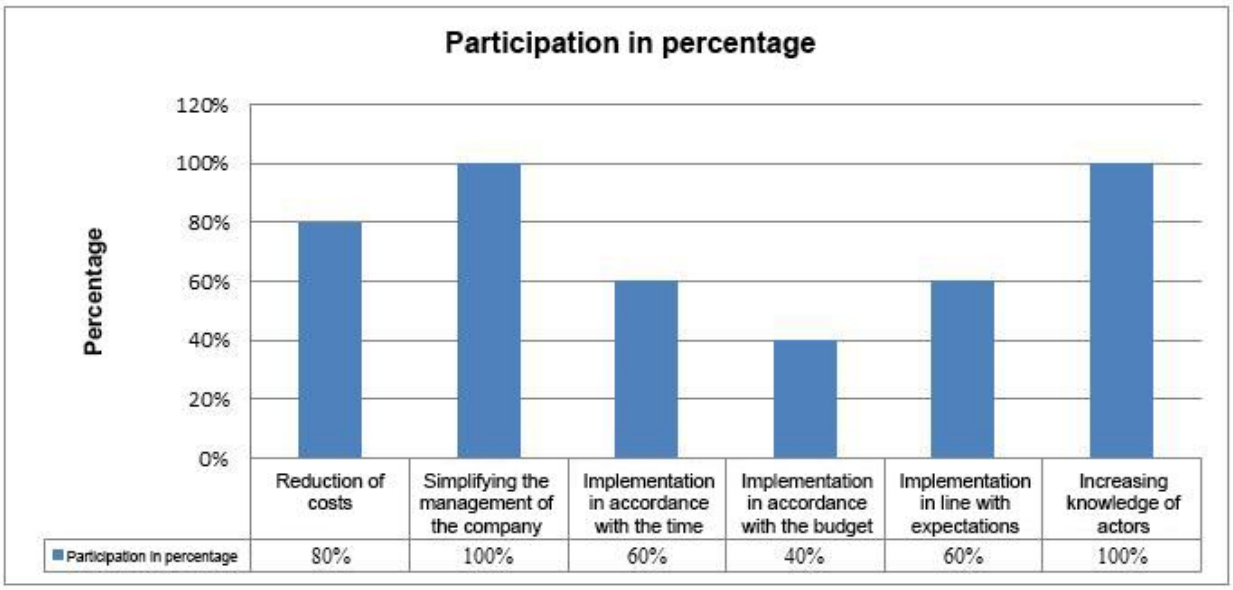

Figure 4 The percentage impact of implementing SAP ERP solutions in Serbia
Source: Research conducted in enterprises in Serbia, 2014.

A very important category in the process of introducing and implementing ERP solutions are costs. Most of the cost can be measured, i.e. they can be easily identified and evaluated in terms of the amount, while the advantages (benefits) of ERP solution implementation are difficult to estimate in that manner. They can be divided into two categories: (Cotterell M. & Hughes B. (1995).

- Direct benefits of ERP solutions are those that can be evaluated in terms of the amount, such as (Bodde et al., 2008) direct cost savings (reduction in costs due to automation of processes, such as reducing paper invoices), quality improvement (e.g. reduction of errors), avoiding the increase of costs (e.g. lower maintenance costs due to less damage), increased revenue (e.g. sales increase through new services), the survival of the business (e.g. if an organization wants to stay in business, it must provide certain services).
- Intangible benefits are usually long-term benefits of the project and they are immeasurable in terms of the amount, and very difficult to estimate. Olson (2004) states that they include the expected increase in the market share, improve customer`s service and image of the company. In addition, these benefits include satisfaction (dissatisfaction) of employees, supply chain integration and the ability to support e-commerce. Intangible benefits often lead to real competitive advantage, although the economic impact is often difficult or impossible to be accurately estimated.

Table 7: Total Cost of Ownership of ERP as a percentage

Costs	Disposable	Recurring
Direct costs:		
Hardware	5 -1 0%	
Software	2 5-30%	
Maintaining ERP Provider		2 0-30%
Programming	5%	
Training	1 0%	
Consulting	1 5-20%	
Indirect costs:		
Employees	10%	5%

Source: Harwood S. (2004). ERP: the implementation cycle. Oxford [etc.]: Butter worth Heinemann.

In the previous table 7 the total cost of ownership of ERP is presented, as a percentage, while in the following figure 5 the percentage of the cost of SAP ERP implementations in companies in Serbia is presented. The largest percentage of costs requires the involvement of consultants. The procurement and purchase of new equipment represents 13% of the total project cost.

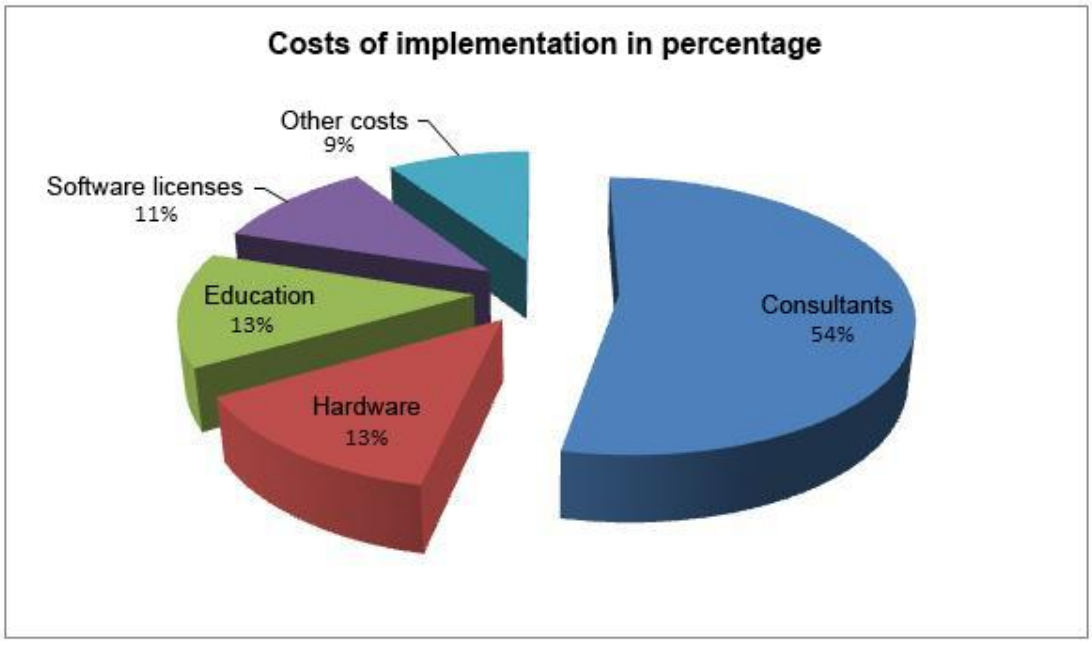

Figure 5 The percentage of the cost of the sample surveyed companies in Serbia
Source: Research conducted in enterprises in Serbia, 2014.

Given that ERP is a new information technology, and as such is constant, it is shown that the structure and goals of employees in the organization are changing, organizational structure, working values, information and knowledge are also changing, company goals are causing the change and that naturally create resistance,(Denic N.,2010). Usually, there are three types of planned changes in the organization of the company due to the implementation of ERP systems: structural changes, technological changes and changes focused on people (employees). Success is multidimensional and it refers to time and goals. Today`s success, does not have to be considered as such in two years (or 6 months). EPR systems which today provide a competitive advantage will provide such advantage if (or when) the competition reaches that competitive advantage (the advantage can become only a business expense). Success is sometimes evaluated depending on the company's unique goals in connection with the system.

The advantages of the implementation are:(Denic N., Zivic N., Dasic B., 2013)

- Real time Information across all functional areas,
- Standardization and accuracy of data, integrated information,
- Inclusion of "best practice" in the application,
- Standardization and acceleration of the business processes.

4 CONCLUSION

Given that ERP systems are new theme on this market and that relevant literature regarding the implementation of the ERP system exists only in developed countries, and that countries in the developing and third-world countries do not have the necessary knowledge and experience in the field of ERP systems implementation, this research paper provides a modest contribution to an improvement of research of above mentioned issues. Enterprise Resource Planning (ERP) systems are currently highly demanded in companies in Serbia and the region, especially for companies in the manufacturing and services based on industrial production, because they provide an effective management system that leads to significant improvement of productivity. What is presented in this paper is a comprehensive study to identify critical success factors and key benefits of ERP systems implementation using the responses from the concrete, chosen companies. The importance of these factors is examined in Serbian companies through the poll questionnaire. The results of the study provided practical guidance for business owners, management and ERP consultants in order to be more effective in managing the implementation of ERP solutions with its increasingly limited resources. In this paper, we were engaged in the research framework of the adoption and use of ERP systems, and we payed attention to the following questions: What are the factors and how much they influence on the adoption and use of ERP solutions by the company users. All previous studies have emphasized a small number of factors, so that none of them gives clear answers to the questions asked. In the introduction, the ERP system was presented, actually in order to be more precise, we have presented various definitions of ERP solutions and implemented an overview of the development of ERP solutions. In addition, we explained the advantages and limitations of ERP solutions, as well as trends in ERP solutions. Afterwards, the life cycle of ERP solutions is presented, and it was divided into four phases: identification of needs, selection of suppliers, the introduction and use,(Anderegg T.2000). If all of these phases are not being implemented during the life cycle of implementation, then their impact is significant in respect to the next phase of the life cycle and, directly or indirectly, to the adoption of ERP solutions by the users. The main contribution of this meticulously research is a comprehensive review of ERP solutions and its lifecycle.

Results of systematic research of the relevant literature and research conducted in different companies by type of activity and ownership structure clearly showed the following problems in project management of ERP solutions implementation in Serbian companies:

- Vague scope of the project,
- Under-definition of requirements,
- Bad assessment of deadlines
- There's no application of project management methods
- Frequent changes in management or project team members,
- Inadequate or insufficient training of end-users,
- Project does not provide solutions to interact with other systems.
- Lack of documentation of the system and the project as a whole.

Research has shown and confirmed that the benefits for the company which implemented the ERP system can be seen in perspective. It is also shown that, the most companies, do not assess the benefits and

impacts of the implemented ERP system to the organization and its operations. It is also indicative that the largest number of companies would not accept the research which will be conducted outside the company in respect to the effectiveness of the implemented ERP systems and their impact on the company.

As further directions of development and trends in ERP system implementation, the appropriate analytical methodology Hierarchy Process (AHP) can be used, and it can be used to determine the weight of the key success factors of ERP system implementation instead of, as up to now, the citations number of the key success factors, which were being used by some authors. Hestermann with co-authors (2009), in their research points, also emphasizes that in recent years the following trends were affecting ERP systems (especially for medium-sized enterprises):

- Verticalization system
- Modernization through the use of service-oriented architecture (SOA),
- Globalization, which is not only a characteristic of large companies,
- Consolidation of the market with a large number of mergers and acquisitions of ERP manufacturers.

MANAGING THE RISKS IN INFORMATION TECHNOLOGY (IT) AND ROLE OF INTERNAL AUDITING

Marina Gavrilović [1]
Company for Auditing and Accounting services Co. " AUDITING " doo , 9, Goranska Street, Vrnjačka Banja

Abstract: *Information technologies provide new business opportunities and increase the economic effectiveness of the organization. With the increased application of information technology there occur new potential risks that must be identified and controlled. The paper emphasizes the importance of internal audit in risk management of information technology. Audit of Information Technology is considered an activity of crucial importance in achieving the expected efficiency of information technology. This paper describes the methods of risk assessment, control activities, objectives and contribution of internal auditing in the process of risk management of information technologies.*

Keywords: *organization, information technologies, management, risk management, control and internal auditing.*

1. INTRODUCTION

Rapid technological progress affects all areas of human activity, including the objectives, strategies, methodologies, techniques, practices and criteria for evaluating the efficiency of control functioning in the risk management process. Innovations and changes in information technologies are relatively frequent, providing new opportunities, but they also carry numerous risks to be managed, which is a new challenge for the management. New computerized systems that are being introduced to meet the goals must be under control, and any events that may prevent the fulfillment of the objectives must be identified and risks assessed. Information technologies (IT) are of capital i.e. of strategic importance to business, and therefore, require a proper organization, management and control. Information is controlled by the information system, which in that way, become the basis of modern business. The success of the entire business depends largely on the operation of its information system, for which reason it is necessary to pay due attention to issues relating to the introduction of effective control of information technology. Otherwise, the survival of the entire organization business can be questionable.

Organization management has the task to establish a convenient system for risk management in information technology, primarily to assess the fulfillment of the planned development objectives, identifying, eliminating or reducing the risk to a minimum. It is therefore necessary that the process of risk management implements the internal auditing, as a professional, independent and advisory function, which is a new challenge for the internal auditing. When defining the risk management strategy in IT, the function of internal audit is also included. It justifies a range of control activities in order to identify and assess the risks, it is focused on the areas of higher risk and on the probability that the risky situation will occur, as well as on the potential negative effects on the business, which that risky situation might cause.

2. INTERNAL AUDIT AS A COMPONENT OF RISK MANAGEMENT PROCESS in IT

The audit of information systems (information systems auditing) is most frequently referred to as auditing of information technology, Weber (1999) pointing out that the auditing the information technologies “is the process of gathering and assessing evidence based on which it can be determined whether the information system operates in the function of property preservation and integrity of data, whether it allows the efficient realization of business objectives, and whether the business resources are used in an efficient manner."
Internal audit provides independent and objective test functions, objectives and activities of an information system as to gather evidence that can be independently analyzed or be a good basis for the revision of other business areas of the organization. Internal audit collects sufficient and competent evidence on:

- the efficiency, effectiveness and cost-effectiveness of the information system (the three "E"),
- the preservation of the integrity of information systems and data, and
- whether the information system meets the requirements of legislation, policies and rules on generally accepted business practices of the organization.

Information technology innovations are always important. They provide new business opportunities and increase economic efficiency In addition, by its operation, the internal audit helps in establishing the control

environment, that must be established by an organization, as a part of the policy of compliance with certain standards. Activities of auditing system in information technology must be focused towards the creation of an effective control environment that ensures the identification, evaluation and prevention of risks and provides transparency of the internal control processes, (Sobel, 2007). Therefore, the internal audit function within the organization plays an important role in the risk management of information technology.

3. RISK ASSESSMENT AND OBJECTIVES OF GENERAL CONTROL ACTIVITIES IN AUDIT OF IT

It is almost impossible to imagine the flow of business processes of the organization and provision of timely and reliable information needed to make different business decisions without the use of information technology. Therefore, it is not necessary to emphasize the impact of information technology on the overall business process of the organization. Reliable information system allows a prompt transmission of accurate information to management and employees, coming from internal and external sources, which are of importance to them to carry out tasks under their responsibility. The erroneous risk assessments in information systems are not rare done by the management, which business organizations can present as huge losses. According to McNamee (2008) the most common examples of such estimates include:

1) The minimum investments in IT because there are leaders who believe that IT investments will not yield the expected results, as being unprofitable and
2) Lack of or inadequate supervision upon the information system.

Internal auditing carries out the evaluating procedures of the selected internal controls of information system to determine its compliance with the objectives of the organization or with the appropriate adopted internal control procedures. According to James (1999) the task of internal audit is that continuously checks how the system of internal control of electronic data processing. These methods usually comprise individual programs and procedures, as well as the environment in which processing of such data takes place.

3.1. THE PROCEDURE OF RISK ASSESSMENT IN IT

The success of risk management is to assess when and how to minimize risk, eliminate or accept a certain extent. The basic assumption of the risk assessment is preliminary familiarization with the organization's goals and risk exposure to achieve the set goals. Risk assessment is an important activity of internal audit in risk management of information technology. It involves performing procedures to identify and analyze risks.
Identification and analysis of risk instruments of modern risk management IT. Risk assessment up includes the identification and ranking of all relevant internal and external factors that could prevent the realization of the goals of the organization. At the stage of IT risk assessment, the internal audit function assesses the adequacy of internal control system. To achieve implement the following activities:

1) Determine the scope of the business processes of the organization that are subject to risks and the most important elements of organizational and business processes and the system of internal controls;
2) Assess the control framework and established controls in relation to the objectives, risks, and past experience;
3) Checks whether the system of internal control is of the appropriate nature and whether it operates successfully, primarily for protection against risks.

After learning about the organizational structure, business organization and system of internal controls, the internal audit determines the methods and techniques for risk identification, and then for its analysis and assessment. The risk assessment includes identification of the dangers followed by the gaps of information systems. According to Sawyer (2005), IT risk can be classified into two groups: (1) random and (2) intentional. One of the biggest dangers of random data processing is the threat of equipment destruction, the destruction of a folder, deleting data, assigning the wrong commands, force major (fire, floods and earthquakes), explosions , or acts of terrorism, loss of management personnel, improper installation of equipment etc. Intentional dangers (threats) are generally pre-designed frauds, such as data stealing, the use of prohibited programs, the abuse of certain data, hackers, various acts of sabotage, viruses etc.

When internal audit identifies potential risks, the next step to take is to identify the property that is most exposed to hazards listed, and then follows the risk assessment process. It often deals with forecasts of potential losses. It is therefore a very important task of auditing to, after the completion of the task, deliver the report to the management which will present and document any deficiencies in the control system, if noticed. The report will present their opinion on the possible consequences of deficiencies in control procedures, as well as suggestions for taking the possible preventive and corrective actions and measures to improve such controls, and implement process control of corrective actions and measures. Thus, the internal audit established in the risk management process is organized as a permanent activity.

3.2. CRITICAL AREAS AND OBJECTIVES OF GENERAL CONTROL ACTIVITIES IN IT

Control audit activities related to risk management of information technology, nowadays, are almost unavoidable. Internal Audit of Information technologies has a supervisory role and is the holder of various control activities, in cases where it is estimated that the main risks are those associated with information technology. Management is responsible for: (1) the establishment of an adequate system of internal controls and information technology to ensure that all critical areas and key business processes are covered by the control; (2) to design appropriate procedures to inform the employees of the policies and procedures of the organization, as well as of all changes. Employees are required to apply establish the control policies and procedures. According to Sawyer (2005), the general control of the internal audit is a set of policies and procedures that are meaningful in the risk management process, in order to achieve the following objectives:

1) *Provision of information*. Internal audit helps the management to provide accurate, timely and complete information, including accounting information for planning and monitoring the performance and reports on business operations;
2) *Ensuring the compliances*. Internal audit helps to ensure compliance policies and procedures of the organization with the legal requirements applicable to the business of the organization;
3) *To promote efficiency and efficiency of business operations*. Internal audit provides an environment in which the managers and employees can increase their efficiency and effectiveness;
4) *Realization of planned goals*. Internal auditing provides a mechanism for monitoring the achievement of pre-set objectives and tasks of the organization.

According to Moeller (2007), internal audit can adequately protect the information system, only if it is informed of all the threats that can attack and endanger it. This includes identifying of areas where the threat is greatest-the threat of the existence of errors or loss. To be effective, internal audit pays the greatest attention to potentially risky areas. Audit of Information Technology is considered an activity of crucial importance in achieving the expected efficiency of information technology, for several reasons, according to Weber (1999) the most common are:

1) To preserve the integrity of data
2) Preservation of tangible and intangible assets and
3) Protection of privacy.

Preserving the integrity of data. Data are a sensitive resource of organization, as they enable the analysis of business in the past, current and future periods. Data integrity implies to completeness, clarity and truthfulness. Data are complete when all business events are covered. Clarity means that the data can be interpreted in only one way and the user of the data must be in a dilemma regarding its meaning. Data are true when they faithfully reflect the events to which they refer. In view of the above facts, data integrity is a very important activity of the audit. It aims to verify whether the internal controls of information system are established, and if so, whether they work adequately.

By the proper processing the data are converted into information that is the basis of so-called information economy. Bringing the quality decisions, long and short term ones, mainly depends on the quality of data or information on which decisions are made. If an image is created of an organization on the basis of exact information data, the organization will have greater opportunities to adapt its operations to constant changes. But if the image is created on the basis of incorrect information, the organization will inevitably suffer significant losses, which are difficult to be compensated. This may be due to the lack of appropriate IT controls carried out by the internal audit.

Preservation of the assets of the information system of an organization. It is undisputed that data are very important resource of an organization, but it is equally true for other IT assets (hardware, software, staff). As a consequence of the influence of supply and demand, the prices of IT equipment are decreased, the total value of the equipment with software grows, and increasing is the price of labor experts in the field of IT. There are few experts in the field of computer science as compared to the needs of the organization, especially when it comes to e-business mode, which, from the global point of view, plays a dominant role. Even the most developed countries in the world have problems to adjust the rate of technological progress to the number of necessary experts. They resolve this issue by hiring experts who come from less developed countries, like our country, and these, on the other hand, have a problem because of the emigration of such experts. Any loss of IT resource, either data or property being in question, results in large financial problems in the organization. If, for example, there comes to a loss of a program (software), the confidential information could come into the hands of competitors, leading to large losses.

Activities carried out by internal audits for the purpose of protecting these assets are difficult because of the nature of property, and therefore, they are to be carried out with special due diligence of auditors. The

reasons why the traditional methods of managing IT assets must be replaced with new modern methods are: (1) a large value of intangible IT assets (2) big volume of this the assets (a large number of software codes), (3) infrastructure network of information system is located in different geographical areas, and (4) Internet work, presented at present, means the work in cyberspace. Possibility of any loss of these assets should be prevented by appropriate actions and measures, the significant role of which is the internal audit.

Protection of privacy In the information system, among other things, the data of the staff are collected and preserved, which can even be of personal nature. These are, for example, the data on the health status of employees, their culture, economic status, qualifications, family situation, education, political and religious orientation, etc. If the data of the privacy of the staff are not protected adequately, it may happen that they come into the hands of malicious persons. As privacy is one of the basic human rights, the organization needs to work on passing legislation and measures to protect and preserve the privacy of persons employed (business software solutions in Serbia, Belgrade (2011). Each organization, with its internal acts determines it's the issues of individual privacy and the necessary measures of protection, thus building up its information system. By control and auditing of information system will be established whether these rules are respected and conducted in the organization, to what extent and what results are achieved.

4. CONCLUSION

Information system is the basic infrastructure of business in an economy and the holder of the information resources of business, so any improvement of their efficiency, effectiveness, and cost-efficiency, as well as improving the preservation of assets and the integrity of data, will greatly affect the business strategy and business results of the organization. Any technology, including information technology itself, is neutral and can be of use to individuals or organizations and to the human community in general, but it can also be misused. The problem lies in its implementation. Appropriate risk management system in IT means the establishment of a number of procedures and criteria for the identification of rapid technological change, in order to fulfill the tasks and set the criteria for risk tolerance for the purpose of taking the necessary actions and measures for proper management of IT risks. Key events of rapid technological changes shall be subject to the identification and assessment of risks throughout the entire business process at all levels of management.

The main objective of the organization in managing the risks in information technology is to determine the procedures and scope of practice of the top-level management and executive management bodies, when making strategic decisions about the cost-effectiveness of IT investments, as well as when bringing the decisions, by which the business risks of extensive use of information system are managed.

Integrated internal audit in risk management system of information technology helps the organization establish an adequate system of internal control of IT, leading to the achievement of defined strategic objectives of the organization. It contributes to assuring quality, relevant and reliable information base for decision-making and management, which gives a positive reflection of the organization and increases its value, which is the basic concept of successful management.

THE INTRODUCTION OF THE EFFECTIVE METHOD OF GIS TECHNOLOGY IN WATER SUPPLY SYSTEMS

Dejan Stajčić[1], Branko Ćebić[2] , Bojan Stojčetović[3]
[1] JKP „Vodovod Valjevo" dstajcic@verat.net
[2] branko.cebic@vipos.edu.rs
[3]High technical school of vocational education Zvečan, [3]bstojcetovic@yahoo.com

Abstract: *This document presents the created effective method of introducing Geographic Information System into Water Supply Systems. The main aim of this paper is to analyse the project on the introduction of GIS Technology in Water Supply Systems in Serbia. The result of the thorough analysis and research is the introduction of the effective method of GIS Technology. This method is developed and successfully implemented in Water Utility Service 'Vodovod Valjevo'. The main purpose of this method is the effective introduction of Geographic Information System with the maximization of the major effects. The created method can be used for the educational purposes but also as a starting point for the implementation of the project on the introduction of GIS Technology in other organizations which deal with water supply systems, only with the written consent of Water Utility Service 'Vodovod Valjevo'. The method consists of thirteen introductory phases. Five of these phases are the basic structural phases whereas eight other phases represent the phases of assessment, measurements and control. When the decision about introducing GIS Technology has been made, the main motivating factor for the introduction and implementation of the project is the enhancement of the whole organization's efficiency. The major expected effects of the implementation and introduction of GIS Technology in Water Supply Systems are: the increase in the economy, the development of the information system, the enhancement of employees' professional competences, and much better organization of the water supply system as well as the introduction of the strategy for ecologically sustainable development. This paper also presents the basic GIS software packages which are used in Water Supply Systems in Serbia and their functional analysis.*

Keywords: *geographic information system, efficiency, method, organization, water supply system*

1. INTRODUCTION

Following the development of information and communication technology management of PUC "Water Valjevo" in association withthe service of development is defined as a priority increasing of organizational effectiveness by information systems development.

„An information system can be defined as a set of interrelated components that collect, manipulate, store and disseminate data and information and provide a feedback mechanism to meet an objective" (Vavpotič., 2012). The introducing of geographic information system and its full integration with business information systems imposed as a priority in modern organizations including the PUC "Water Valjevo. Developed geographic information system will be used as a basis for reducing losses in water supply network,increasing efficiency, reducing negative impacts on the environment, the development of information system, increasing professional competence of employees and raising the level of organization.

2. COMPOSITION

Observing the effectiveness of water supply systems in Serbia can be easy to spot weaknesses in terms of ratio of the quantity of produced water for drinking and the amount of water which is invoiced to the direct customers. For the calculation of organizational effectiveness, we used the formula E(X), which place in relation precisely this type of loss and the goal of research is to reduce this kind of loss and increasing organizational effectiveness in this way.

$$E(X) = \frac{X}{Y^{!}} * 100\ \%$$

E(X) – coefficient of organizational effectiveness of water supply system
X- the quantity of water billed to the direct customers
$Y^{!-}$ the quantity of water produced

To make GIS system to be effective it is necessary to introduce GIS by the created model and to observe the phases of introduction. In this way, the GIS will achieve maximum results. Text that follows shows the phases of GIS technology introduction, created by effective method.

The introduction of GIS technology by an effective method consists of the following phases:

- The decision on implementation of GIS technology;
- Measuring justifiability of decisions;
- Forming the team;
- Review of the decision of all team positions;
- Hardware-technical structure;
- Review of the hardware-technical structure justification;
- Software solution;
- Rating of software solutions;
- Organizational procedures;
- Rating of defined organizational procedures;
- Evaluation of the first phase of the introduction of GIS technology;
- Rating the second phase of the introduction of GIS technology;
- Quarterly evaluation and control (include a review and re-consideration of the first 10 points.

The decision on implementation of GIS technology

The decision on the implementation of GIS technology represents the initial stage in the process of raising organizational effectiveness of water supply systems. This decision has to be made by top management that has a clear vision of the main objective of implementing GIS technology, the effects of the introduction of GIS, the cost of the project and the time schedule of the implementation.

The decision must be presented in clear, concise, formal, written document which must be verified by all relevant institutions in the organization. In case of PUC "Water Valjevo" it is supervisory board, the general manager, director of production and technical department and director of economic, legal and general affairs. Such written decision shall be submitted, in addition to the signatories themselves, and all managers of work units, department managers, heads of services, to all employees information system tasks that are expected full involvement in the implementation of future projects.

Measuring justifiability of decisions

As all other decisions, if we want to be relevant, timely, effective and supported by as many employees it is necessary to be periodically reviewed and examine justification. In the PUC "Vodovod Valjevo" justifiability of decisions is measured in such a way that to each of employee sent a questionnaire with the question "Do you think that is in the PUC" Water Valjevo "required the introduction of GIS technology?" If the answer is affirmative to all employee shall be given the opportunity to present on the same form their opinions, proposals, suggestions regarding the implementation of the project. Thus the completed questionnaire each employee sign and submitted to a central database.

Forming the team

Since the decision has been made by the top management in the next phase should form a team. Engineer of organizational sciences defines organizational roles, tasks and responsibilities of team members. The company's management elected among the staff members of the project team and the immediate supervisor of the team. As with any team, goal is full implementation of project by defined term plans and budgets. Members of the GIS team must achieve a synergistic effect. In addition, to staff from the organization team, can join and external consultants with relevant competent knowledge in this field.

Review of the decision of all team positions

For the successful execution of all activities of the project each team member must possess adequate knowledge or ability to learn and acquire new knowledge. Phase of the review is carried out on the way that team members in a closed questionnaire listed the name of a member who they feel most competent as a team leader. Thus obtained results is compared with already done choices and manager should make the decision reviewed. Also, team manager once again considers all positions in team and makes a proposal to the director of production and technical department makes the final decision on the selection of team members.

Hardware infrastructure

The basic elements of hardware infrastructure are: server, personal computers, tablet computers, portable computers, computer networks, storage devices, plotters, printers, GPS devices, total station, permanent

stations, orthophoto base, cadastral maps, transportation equipment, and in some cases, unmanned aircraft for orthophoto record.

Review of the hardware infrastructure justification
Selection of the basic elements of hardware infrastructure is choice of the management of each organization and the final decision is made by the manager of the project team within the available budget.

Software solution
To software selection must be given maximum attention because the market faced a number of software solutions that are more or less compatible with the needs of the organization. The most important software that GIS team should have can be classified into two major groups. The first group consists of software to run on the field and they are: software for independent GPS devices, software for GPS receivers, software for portable field computers and software for total station. The second group consists of software to work in an office and are software that are used to transfer and convert the data from the GPS device to the database server, the basic GIS software for data entry and processing on desktop computers, designed primarily for use in the office, reporting software and the database itself. For decision making of the choice of software may be used different.
"The decision-making model developed and implemented by Utility Service Department Vodovod in Valjevo consists of three phases. In the first stage, the employee, who is responsible for the Information System, decided upon the alternatives which will be the case of the furher analysis and decision-making process based on the Additional questionnaire" (Stajčić., 2012).

The main requirements that GIS software in water supply systems must meet are:

- The possibility that the same descriptive class feature keeps the lines, points and polygons;
- The ability to display the results of input on an unlimited number workstations without additional licensing and with its own software solution;
- The possibility that the visual appearance of each element on the layer folder changes independent of the pre-defined layout for the same;
- Integrated module for calibration, refinement and georeferencing of scanned maps;
- Support for raster files size up to A0;
- Nativna / Built-in support for connection without any additional application layer / attachment to all common RDBMS systems that can run on Linux and Microsoft operating systems;
- Built-in "CAD like" drawingoptions with the GUI and the principles of work similar to AutoCAD;
- During digitization, software must be able that element that is digitalised use already delineated geometry and takes her vertex coordinates;
- Defining a virtual column over the attribute tables that are dependent on the attributes that exist in the attribute table;
- Conversion in the multilayer PDF document with coordinates;
- Built-in support for Bing Maps without additional licensing;
- Built-in functionality to connect to the Google Earth service;
- Built-in ability to export data for Google Earth model;
- The possibility of developing additional modules and applications using its own development environment with its own editor, programming languages and compilers optimized for desktop GIS platform;
- Minimum of five developed own tools used in water supply systems;
- The supplier shall present a document certifying that he is authorized by the manufacturer, to sell the software in the Republic of Serbia.

All software for data entry and data processing can be divided into two major group. The first group consists of commercial solutions, and other non-commercial open source solutions:

1. Commercial solutions:
   - *ESRI ArcGis;*
   - *AutoCAD® Raster Design, AutoCAD Map 3D;*
   - *MapInfo;*
   - *MapSoft.*

   - "The software solution of ESRI company, ArcGIS is a synonym for reliable software for data entry and processing." (Esri., 2014). ESRI solutions are reliable and suitable for large water supply systems as a comprehensive solution. It includes 3D terrain modeling, ArcGIS Server, ArcGIS Web. All these modules are required water supply systems in later stages of the GIS. ArcGIS price, if supplied with all functionalities, is beyond the capabilities of small water supply systems the size of

the PUC "Vodovod Valjevo" so that the solution to price criterion is not acceptable. Large water systems, such as the water system Novi Sad, successfully implement this software solution. Analysis of software solutions for the model PUC "Water Valjevo" - Symorg 2012, this software solution is denoted as unacceptable because of the high cost of implementation and after the first round vote.

- AutoCAD ® Raster Design, AutoCAD Map 3D, are solutions that the PUC "Vodovod Valjevo" successfully implement and use since 2014. This solution comes in a package AutoDesk Suite. This solution comes in a package with other CAD functionalities but does not include all the basic requirements placed in GIS software. Since the PUC "Vodovod Valjevo" already owns the GIS solution and in view that does not meet all the software requirements, this solution is not considered as a solution that will be used as the basic GIS tools. The main representative of this software for our market is Autodesk.
- MapInfo is a basic GIS software solution of U.S. company Pitney Bowes Software, which has all the basic requirements of the GIS solution should have. "Its have the possibility of further development using its own compiler and programming language" (Lama., 2014). Modules such as WebGIS, 3D modeling are modules that this software includes with additional licensing. These functionalities are not required in the initial phase of the introduction of GIS technology, so this solution is acceptable because the cost is totally suited for smaller water supply systems. Water supply system of Uzice and Nis use this software solution. The main representative of this software for our market is firm Lama.
- MapSoft solution of Chinese company is the main GIS solution that recently appeared on the our market. This solution has not yet been implemented in any water supply system in Serbia. Therefore, this software solution is not acceptable for the water supply systems which as a condition placed delivery of the reference list. "This software solution has the possibility of additional software development" (Docus., 2014). Additional tools for water supply systems are still in the development stage, therefore, does not yet have the opportunity to present all the functionalities of the developed modules, thus the reliability of the further development of this tool is hard to measure. The main representative of this software for our market is firm Docus Cacak.

2. Non-commercial open source solutions are:
    - *Grass*
    - *Chameleon*
    - *Geonetwork opensource*
    - *Geotools*
    - *Gvsig*
    - *Ilwis*
    - *Jump gis*
    - *Openlayers*
    - *Postgis*
    - *Quantum gis*
    - *Terraview.*

These software solutions are suitable for minimum water supply systems and water supply systems which are not able to devote the funds and want to start with the implementation of GIS. In larger water supply systems, these software tools can be used as an additional solution. According to their functional characteristics these solutions do not meet all the basic requirements. The PUC "Vodovod Valjevo" successfully used Quantum GIS. This software is used to upload georeferenced cadastral plans and orthophoto basis. Given that the GIS department needed sophisticated software tools, this non-commercial solutions are seen as complementary and can be used in work places where entry is required and reading spatial data and where it is not planned expenditure and financial investment.

Rating of software solutions

According to the turbulent and dynamic software development, organizations that want to effectively use new technologies must review the decision of a chosen software. Once selected software solution will not be a permanent solution, it is justified at one time and one time interval. This period can not be defined in advance, but must be continuously performed evaluation of available software to help organizations always have the kind of software which is most appropriate at a given moment. Check and reviews of software in water supply systems should be carried out once half-yearly.

Organizational procedures

Organizational proceduras are a necessary prerequisite for effective GIS. Applying and defining redesigned and brand new procedures enable achieving a higher level of management. Organizational procedures must cover all aspects of the GIS team work, and the work of all departments which own data entries in a single

database. In PUC "Vodovod Valjevo" case were redesigned management procedures for defining the consumer, measuring points and measuring devices. Completely new organizational procedures created for entry of digitized projects, with all the objects and associated attributes, they are set as a prerequisite in creating.

Rating of defined organizational procedures
It is necessary to observe organizational procedures and re-review them, also and pre-defined stages. This procedure is necessary to carry out semi-annually. If determine the need for change then should redesign organizational procedures and defines an entirely new organizational procedures.

Evaluation of the first phase of the introduction of GIS technology
Represents a phase of measurement and control of the results achieved in increasing organizational effectiveness . GIS technology as a basis for raising organizational effectiveness has a purpose only if the coefficient of efficiency of the water supply system is stagnant or has grow. In the event of an unexpected fall of the coefficient, estimate of the first phase of introducing GIS is not positive, and expected results are not satisfactory. If this ratio declined it is necessary to determine the cause and to define strategies for proactive action. In the PUC "Vodovod Valjevo" the expected increase of this ratio for the first phase is only 1-2%. The low level of increase of organizational effectiveness is due to the fact that this is the introduction of new technologies whose implementation takes time to train all staff and work on the application of the use of GIS database can not go completely synchronized, but about using can speak only after 0,5-1% of the base is formed. Evaluation of the first phase should be carried out after the formation of 2,5% of the total base.

Rating the second phase of the introduction of GIS technology represents the second phase of the measurement and control of the results achieved in increasing organizational effectiveness. In the PUC "Vodovod Valjevo" the expected increase of this ratio for the second stage is only 2.5-5%. At this stage it is expected a significant increase of organizational effectiveness. It is assumed that the staff have sufficient training, the technology is fully integrated and therefore the coefficient can not be dramatically lower than expected. The second phase of the evaluation should be carried out after the forming up to 5% of the total base.

Quarterly evaluation and control (include a review and re-consideration of the first 10 points). Period of introducing GIS project in the water supply system should be divide into smaller cycles of time. These cycles should not be less than 4 months. After the end of each cycle should determine the coefficient of organizational effectiveness. This ratio can vary according to the number of available personnel involved in the operation, their training level, the type of used technology and method of application. This phase is presented by activity number 16 on the Gantt chart 1 (Figure 1).

	Task Name	Duration	Start	Finish
1	**PROJECT of GIS introduction**	**130 days**	**Fri 1.11.13**	**Thu 1.5.14**
2	The decision on implementation of GIS technology	5 days	Fri 1.11.13	Thu 7.11.13
3	Measuring justifiability of decisions	2 days	Fri 8.11.13	Mon 11.11.13
4	Forming the team	11 days	Tue 12.11.13	Tue 26.11.13
5	Review of the decision of all team positions	3 days	Wed 27.11.13	Fri 29.11.13
6	Hardware-technical structure	12 days	Mon 2.12.13	Tue 17.12.13
7	Review of the hardware-technical structure justification	3 days	Wed 18.12.13	Fri 20.12.13
8	Software solution	11 days	Mon 23.12.13	Mon 6.1.14
9	Rating of software solutions	3 days	Tue 7.1.14	Thu 9.1.14
10	Organizational procedures	15 days	Fri 10.1.14	Thu 30.1.14
11	Rating of defined organizational procedures	2 days	Fri 31.1.14	Mon 3.2.14
12	Evaluation of the first phase of the introduction of GIS	4 days	Tue 4.2.14	Fri 7.2.14
13	Data collection	22 days	Mon 10.2.14	Tue 11.3.14
14	Evaluation of the second phase of the introduction of GIS	4 days	Wed 12.3.14	Mon 17.3.14
15	Data collection 2	23 days	Tue 18.3.14	Thu 17.4.14
16	Quarterly evaluation and control (include a review and re-consideration of the first 10 points.	10 days	Fri 18.4.14	Thu 1.5.14

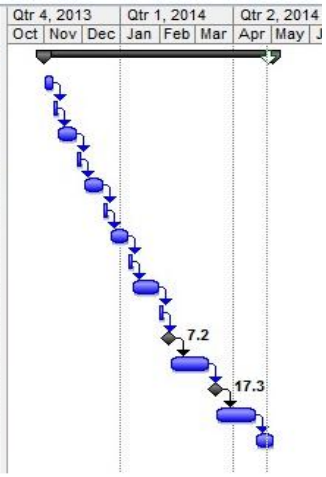

Figure 1: Gantt chart activities of GIS technology introduction

3. THE MAIN EFFECT OF INTRODUCING GIS TECHNOLOGY AT AFOREMENTIONED METHOD

The most significant direct effects of implementation are:

- the impact on the effectiveness;
- ecologically sustainable development;
- impact on the development of information systems;
- raising the professional competence of employees and

- a higher level of organization.

The impact on economy increasing
Large losses in water supply systems is the losses of water that is not invoiced to final consumers, but it is distributed in the system. The loss of water that is not billed to the final consumers, measured by the percentage is moving at about 50%. In water systems that are more economical, this percentage is much lower leads to a level below 10%. The aim of the PUC "Vodovod Valjevo" is phase shift implementation of GIS as a basis for measuring losses in the network. In this way in phases will be revealed and losses in the network. By detecting network losses and their elimination we will increase economy of the water supply system. In case of PUC "Vodovod Valjevo" long term goal is phased shift reduction of losses and bringing to the desired level of about 10%. The expected level of economy increasing is about 5% by looking at each phase of the implementation of GIS respectively.

The introduction of GIS technology in water supply systems form the basis of respecting principles of environmental management and the basic application of ecological strategies in their business. In fact, since water supply systems encompass a large amount of water they greatly affect the environment. Along with the increased environmental awareness and the need to introduce sustainable development there is and the growing need to introduce all forms of technology that will contribute to environmental protection. GIS technology has been used in water supply systems as a basis for the analysis of water losses in the network is a necessary condition for the respect of the principles of environmental management. The basic principle of environmental management that will be accepted is the principle of change in consumption patterns. The water in the system will be distributed with respect to this principle as the water system to be operated in this manner classified as environmentally responsible system.

The impact on the development of information systems,
Geographic information system viewed as part of the information system of organization aims to increase the effectiveness of water suplly systems. In fact, in a common base of information system enter data collected by GIS technology. These data is available to all users of the information system. In this way, the impact of GIS on the overall information system is very large. The most significant benefit of this way of linking is the availability of spatial data. PUC "Vodovod Valjevo" is in the process of integration of geographic information system.

A higher level of organization.
Geographic information system is not goal in itself, but should be seen as a means to achieve the strategy of raising the effectiveness of the organization. In water supply systems, GIS should be implemented in a way to raise the level of organization of the system. Introducing of GIS must follow, redesigning the organizational structure, defining organizational roles and tasks. The introduction of GIS has to follow the definition of completely new procedures that have not existed. In this way, occurs complexity of the organizational structure but only In this way GIS contribute to the development of the entire organizational structure and then we can talk about a higher level of organization. Procedures must cover all aspects of work with GIS in order to avoid situations that GIS remains an isolated part of the system.

Raising the professional competence of employees
All employees can be divided into two groups. The first group consists of persons who will use the information from the database, these employees expand their knowledge in the use of spatial data. The number of this employees will be equal to the number of personal computer users within the information system, which means that practically all users of the information system have access to information collected by GIS technology.The second group of employees are members of the GIS team. These members will be able to use themselves all the software and all the GIS hardware. Also, they will expand knowledge and gain new experience in organization, environmental management and information system. Their knowledge and experience will expand by the seminars, forums and direct benchmarking with organizations that have adopted GIS.

4. CONCLUSION

Geographic information systems in water supply systems is the basis for increasing organizational effectiveness . Geographic information system should be considered as part of the overall information system within the organization and as such it needs to be fully integrated with business information system. Only in this way, from information system can be expected maximization of results . All water supply systems are required to define as one of the goals of their business implementation of geographic information system. This objective is necessary to set, but and begin its implementation . The realization of this project does not always and in every case must be limited in terms of the water supply system is not able

to allocate some funds. Water supply systems can start this business with minimal financial investment,by engaging human potential. Water supply systems that do not have these resources can hire external consultants.

With the introduction of geographical information systems in water supply systems will achieve the expected raise of organizational effectiveness. The introduction of GIS technology we expect realization of direct effects: increase of economy, environmentally sustainable development, impact on the development of an information system, raising the professional competence of employees and higher level of organization . All direct effects are already achieved in the PUC "Vodovod Valjevo ."

Abstract: *The main objective of this paper is to present a software system developed to provide access to data of public interest related to Serbian healthcare system. The focus will be on pharmaceutical institutions and information regarding medicines and their availability in pharmacies. The software integrates and centralize all relevant information from all healthcare institutions in Serbia. As a result, the system provides benefits to all stakeholders: citizens, healthcare institutions and National Health Insurance Fund (NHIF). Citizens can find the nearest pharmacies that has medicines they need at the time. Healthcare institutions integrates data from all organization units - pharmacies, enabling efficient medicines stock management. For the first time NHIF have access to accurate stock level for all medicines in all pharmacies in Serbia. NHIF uses the system to analyze the data in order to make decisions concerning procurements, rationalization, control raising performances and cutting costs of healthcare system. Software system is consisted of four integrated modules. Medicines search is provided in the form of web application at NHIF official website, and on Healthcare institutions websites, and also in the form of Android application for smart phones. Besides the system contains data integration module and analysis and reporting module.*

Keywords*: data of public interest, Serbian National Health Insurance Fund, Find a medicine, Medicines stock level, Software*

1. INTRODUCTION

The economic situation in the Republic of Serbia and inefficient management of the healthcare system has led to major problems in the functioning of almost all of its parts. This situation affected the healthcare institutions at almost all levels of healthcare system. Frequent shortages of medicines and medical supplies, increasing waiting lists, insufficient capacity to provide healthcare services are just some of the key issues facing the healthcare system.

NHIF has recognized these problems and set up a high priority level to resolve them. NHIF has performed a detailed analysis of the state of the healthcare system in order to determine the precise steps that will help to solve each of these problems. During the analysis it was determined that many health care institutions, and consequently the NHIF does not have information that are the indicators of the success of performing their activities. On the other hand, there are institutions that have well-maintained information systems and the necessary information, but this information in different institutions vary in content and structure. This situation did not meet the requirements of the users of the healthcare system. They did not have access to the necessary information related to healthcare. Also, due to incomplete and different data structures any attempt to aggregate data analysis by NHIF at the republic level was very difficult. That is the reason why increasing access to data of public interest have been identified as one of the preconditions in solving pressing problems. Yasnoff et al (2000) point out that "development of effective public health information systems requires understanding public health informatics (PHI), the systematic application of information and computer science and technology to public health practice, research, and learning".

The focus of this paper will be on pharmaceutical institutions and information regarding medicines and their availability in pharmacies. Frequent shortages and unbalanced distribution of medicines in healthcare institutions resulted with serious threats to the health condition of the insured persons. Also, it happens that old people and people with serious medical conditions visit several pharmacies in order to find a required medicines. Many pharmacies did not implemented any kind of searching of medicines stock level, while searching the medicines stock level at the republic level was out of the question.

The subject of this paper is the importance of transparency and functional integration of pharmacies data of public interest on a daily basis in order to improve the functioning of the healthcare system as a whole. Leape et al. (2009) proposed to increase the level of transparency as one of the measures to increase the level of organization of the healthcare system. In this way it can be ensured:

- uploading the medicines stock level on a daily basis in order to perform procurement of necessary medicines,
- perform their uniform distribution by pharmacies as it would not happen that in the a city or part of the city there is no required medicine, and in other has more than necessary. This leads to accumulation of inventories and hence unnecessary costs,
- provide a stable supply of medicines which would prevent possible shortages and
- simplifies the way users of healthcare services find required medicines

2. DATA OF PUBLIC INTEREST

The most important step toward better healthcare system was to identify the data of public importance which health care institutions have to make accessible on a daily basis. Primarily, it was necessary to define the unique structure of the data in order to enable adequate integration and analysis.

NHIF management board made a decision on data which will be mandatory as a content of a website of every health care institution and forced them to operate in accordance to this act. This act was published in Official Gazette no. 52 and was applicable from 14th of June, 2013.

NHIF made detailed specification of the data which every type of health care institution have to make public. This specification divided data to set of categories for every type of health care institution. So we have:

- Primary health care level
- Secondary and tertiary health care level
- **Pharmaceutical institutions**
- **Pharmaceutical institutions founded by means of private property that have signed contract with NHIF**
- Rehabilitation facilities
- Department of Public Health and the Institute

This paper is focused to pharmacy institutions, and relevant information identified are:

- Medicines - part regarding data of medicines that are financed from obligatory health insurance. This provides insured persons, health care institutions, medicine manufacturers and public in general to have insight to the information of the medicine
- Medicines stock level - related to the stock level of medicines, implant materials and medicine devices based on information provided by health care institutions.

This way NHIF standardized and simplified gathering of information from all pharmaceutical institutions and enabled centralized data analysis, better stock optimization and easier medicine search. Leape et al (2009) argues that all this leads to cost reduction and increasing satisfaction and trust of insured persons in the health care system.

It is very important to point out that along with the public pharmaceutical institutions which consists NHIF pharmacy network, this system includes pharmaceutical institutions founded by means of private property that have signed contract with NHIF to issue the prescription medication. This doubled the number of pharmacies and made medicine search easier and much more useful. On the other hand pharmaceutical institutions founded by means of private property that have signed contract with NHIF have opportunity to promote themselves and increase the sale.

3. FIND A MEDICINE

The software system that is the result of this project provides accessibility of data regarding the level of stock of medicines and medical devices as the information of public interest for each pharmaceutical institution and all associated pharmacies, as well as the centralization of these data for the purpose of business analysis.

This project was implemented as a Content Management System (CMS) which, in addition to functionalities related to input and display of data enables the functionalities related to the processing and analyzing the collected data.

The project has been realized through the implementation of three web applications and one android application which together constitute content management system. One web application is designed for employees of health care facilities and provides data entry concerning stocks of medicines in a pharmaceutical institution. Data entry is enabled by using web forms that are an integral part of the Content Management System. Users can upload the XML file which reduces the work load of employees. Another web application is meant to employees in NHIF and enables data analysis in order to improve control and

business operations. The third web application and Android application allows all citizens to access information of public interest and enables them to search of medicines they need.

Figure 1 shows the designed software applications. All business logic is located on the application server at NHIF, and communicates with a database server. The following applications has been developed, targeted to different user categories:

- The citizens - have the opportunity to view and search information of healthcare institutions. The ability to search the data is provided in two different ways:
  - Using a web application, which requires a web browser. It is available at http://rfzo.rs/index.php/component/content/article/16-infolekovi/2012-10-29-12-35-11/501-pronadji-lek,
  - Using the mobile application, which requires Android mobile phone. Application is free and available for download at https://play.google.com/store/apps/details?id=rs.rfzo.apoteke&hl=en. Pan et al. (2007) point out that mobile devices are getting smaller, smarter, and more connected, any time and any access to any information while on the move. According to Noordam et al. (2011) mobile devices are widely used within the health system.
- The pharmaceutical institution - responsible for entering and updating the data. This information is available to citizens and the NHIF.
- The National Health Insurance Fund - have the possibility of analyzing the data and creating business reports

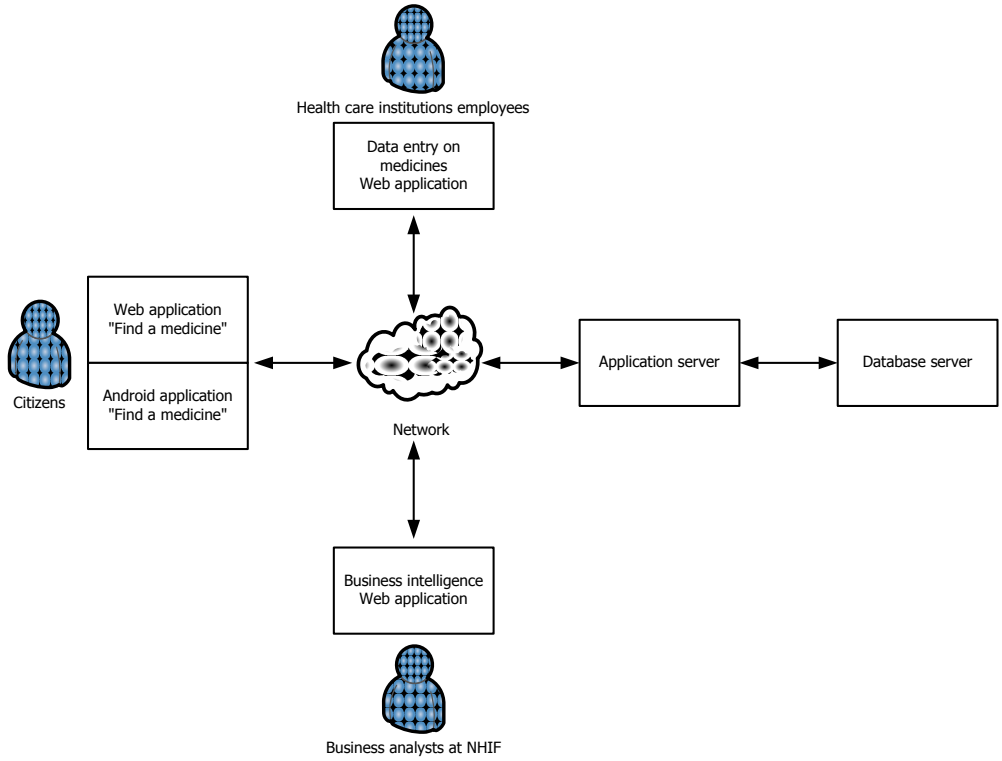

Figure 1: Designed software applications

The system enables all citizens to search the stock levels for all medicines and to find the pharmacy that is closest to the users location, and have the searched medicines on the stock at the moment of search. In addition, citizens are able to report all observed problems in system operation, especially in case the pharmacy refuses to issue a medicine while the stock level the pharmacy reported for requested medicine shows positive value. In this way, NHIF got another controlling mechanism and the ability to quickly react so to prevent these situations in future.

Table 1 represents the number of pharmacies in each branch office of NHIF. Numbers includes the public pharmacies and also the pharmacies founded by means of private property that have signed contract with NHIF.

Table 1: Number of pharmacies included in the system

Branch	Number of pharmacies

Užice branch	39
Čačak branch	40
Šabac branch	107
TOTAL:	**2328**

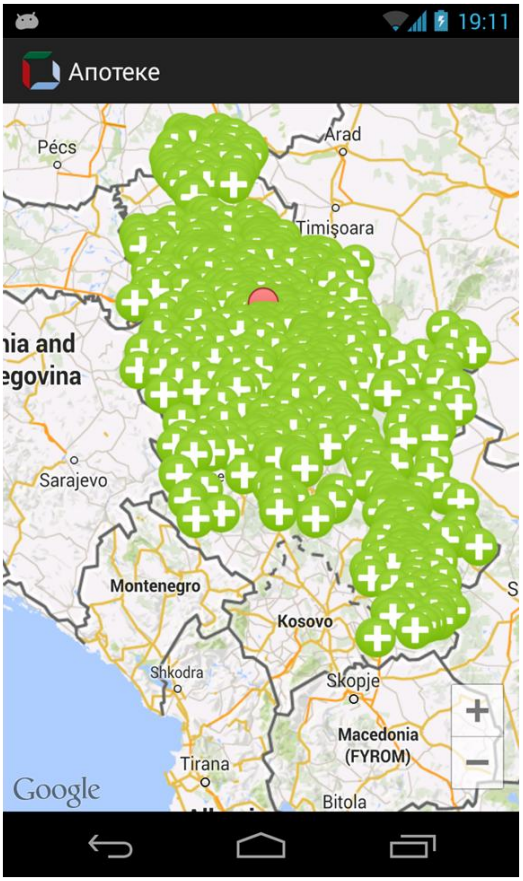

Figure 2: Each "+" sign represents a pharmacy that uploaded accurate medicines stock level

Information about the current medicines stock level at pharmaceutical institution can be submitted in the form of XML (Extendable Markup Language) document. It should be noted that the institution may submit an XML document that applies to all pharmacies in its network, but also any pharmacy can separately submit their medicines stock level. This way the flexibility is achieved because pharmaceutical institution at its sole discretion choose how to submit the data.

XML has become the standard for data exchange between systems. Based on the current medicines stock level in pharmaceutical institution the information system generates the XML document. The generated XML document must be well-formed and valid. For validation of XML documents it is necessary to use pre-defined XML schema. According to Varlamis & Vazirgiannis (2001), the schema can be used to validate the structure of the XML document automatically. An example of the generated XML document is shown in Figure 3.

Figure 3: "Medicines stock level" XML document

As presented, the "Medicines stock level" XML document contains following elements:

- **Pharmacy** - represents the identification number of pharmaceutical institution. The identification number must be in accordance with unified health institution registry at NHIF.
- **OrganizationUnits** - a complex element consisted of the list of all organizational units - pharmacies, and medicines stock level for a date for all organizational units.
- **OrganizationUnit** - represents the identification number of the concrete organizational unit - pharmacy. The identification number must be in accordance with unified health institution organizational units registry at NHIF.
- **Dates** - represents a complex element consisted of medicines stock levels for specified dates for a concrete organizational unit - pharmacy.
- **Date** - represents an element that contains attribute Date of medicines stock level.
- **JKL** - represents the identification code of medicine. This code must be in accordance with unified medicines registry at NHIF.
- **Quantity** - represents the available quantity of the concrete medicine at specified date at the specified organizational unit, at the specified pharmaceutical institution.
- In **Date** element, elements **JKL** and **Quantity** is repeated, and **Quantity** is given for each **JKL**.

The information system of pharmaceutical institution or pharmacy must provide the validation mechanism because only valid documents can be uploaded and integrated in the system. Figure 4 shows the algorithm for creation and uploading the Medicine stock level XML document at the system.

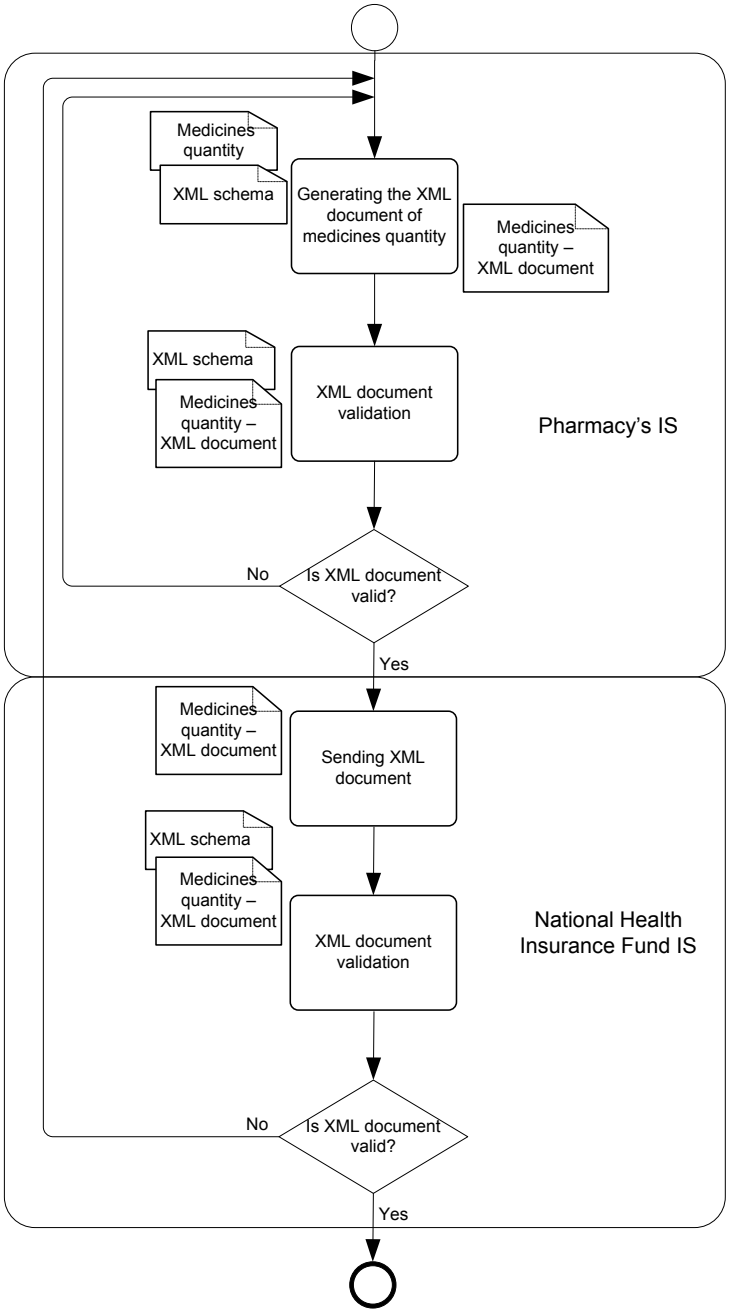

Figure 4: The algorithm for creation and uploading the Medicine stock level XML document

As a development platform of this system the JavaEE (Java Enterprise Edition) has been used:

- Java Server Faces - JSF as user interface of the web application. According to Mann (2005), JSF includes a set of web-based HTML controls and mechanisms for event processing. For each pharmacy is being displayed the position on a map, working hours, phone number and available quantities of required medicines in order to provide all necessary information so the user can get his medicine quickly. Web application user interface is shown in Figure 5.
- Enterprise Java Beans - EJB as business logic of the system, running on the GlassFish application server.
- Android SDK - used as the user interface of the application running on the Android operating system. Whipple et al (2009) point out that Android allows the development of innovative applications that can fully take advantage of the device's hardware (e.g. access to location services based on GPS system). Using location service applications become aware of the environment (position of user) of the execution. For each pharmacy is being displayed the position on a map, working hours, phone number and available quantities of required medicines. Android user interface is shown in Figure 6.
- Microsoft SQL Server 2012 database server as relational database. Madsen (2010) argues that relational data modelling presents power and most-popular database design method.

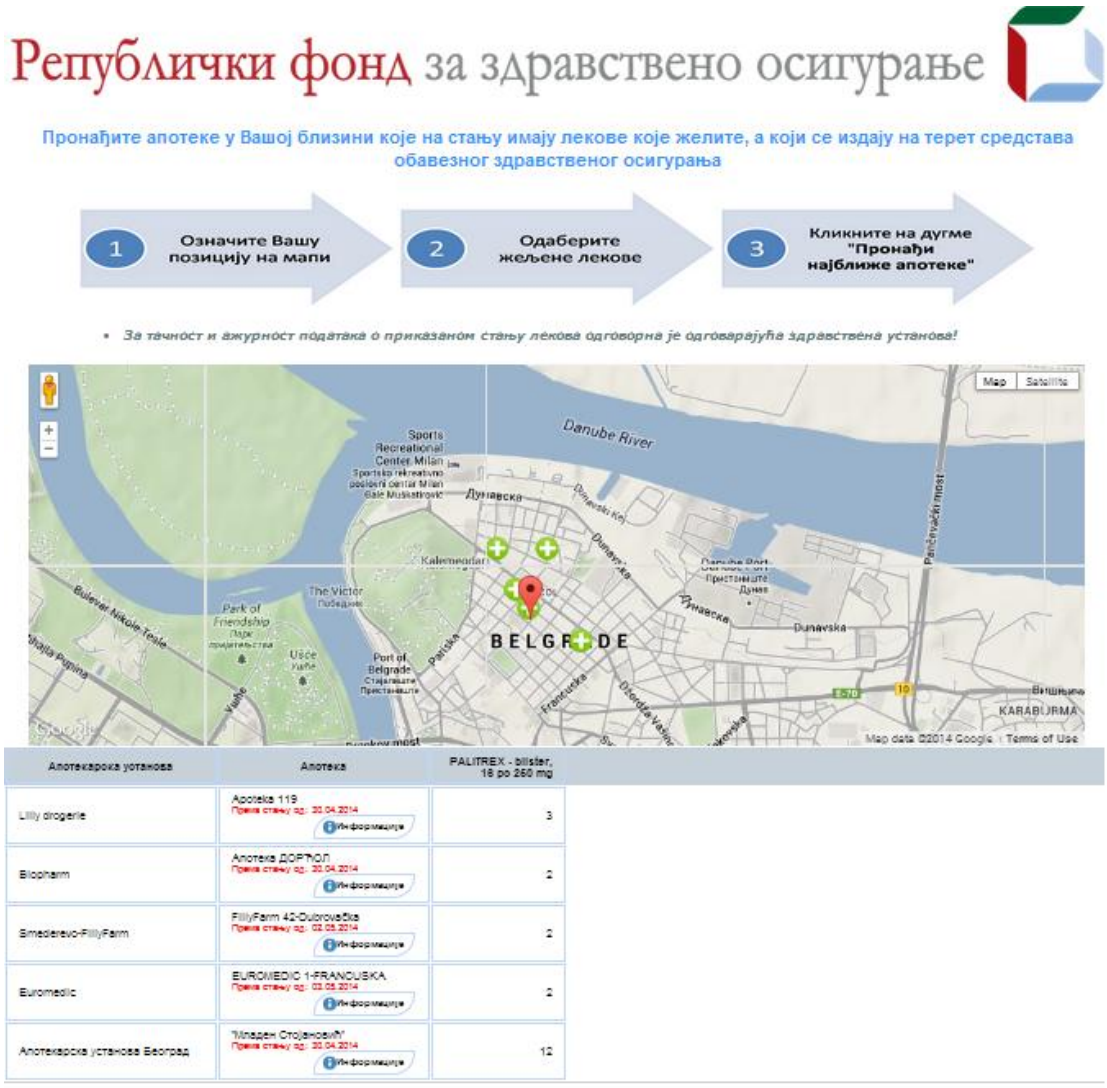

Figure 5: User interface of the "Find a medicine" web application

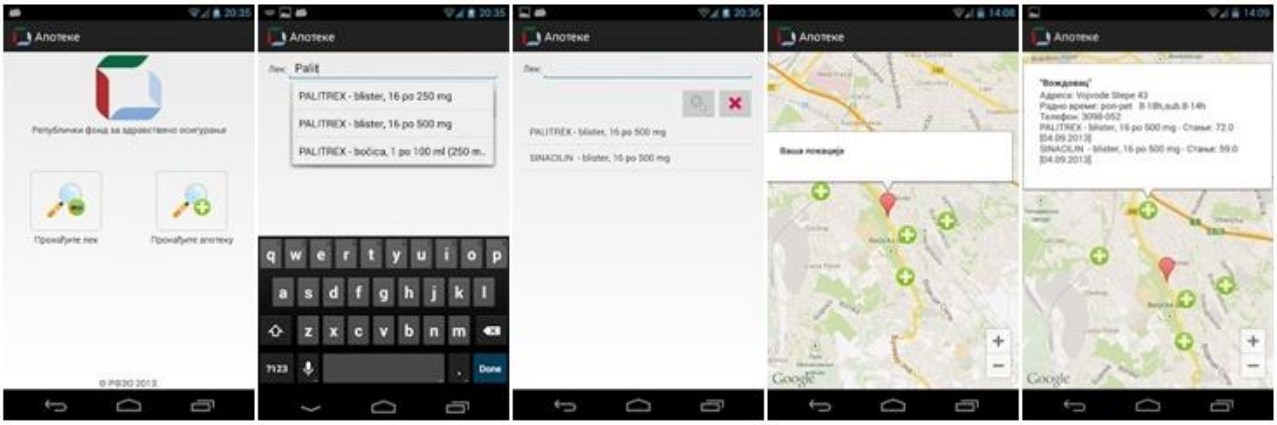

Figure 6: User interface of the "Find a medicine" Android application

These technologies are stable and supported by the largest software companies. In this way, applications which have been created are scalable and easy to maintain. These technologies are widely accepted and have strong support in the open-source community.

4. CONCLUSION

This paper presented software system which supports availability of pharmaceutical institution's public data, their integration and centralized collection. This data were identified as very important for both: users of health care insurance and NHIF.

One of the goals of this system was to provide centralized data analysis and better medicine stock control. In order to do that NHIF standardized the data of pharmaceutical institutions relevant for medicine stock management. Health care institutions have to send medicine stock level information in requested XML format on daily basis. This data are checked and saved in NHIF central data storage. As stated before, this enables centralized analysis, stock level optimization and provides possibility to find nearest pharmacies that have requested medicines. System also offers a possibility to make an irregularity report (inconsistency of medicine stock data provided on the website with real stock level in the pharmacy) which can be used as an additional measure of control.

As a result, the system provides benefits to all stakeholders: citizens, healthcare institutions and NHIF. Citizens can find the nearest pharmacies that has medicines they need at the time. Healthcare institutions integrates data from all organization units - pharmacies, enabling efficient medicines stock management. For the first time NHIF have access to accurate stock level for all medicines in all pharmacies in Serbia. NHIF uses the system to analyze the data in order to make decisions concerning procurements, rationalization, control raising performances and cutting costs of healthcare system.

Abstract: *This paper analyses business-related Service Level Agreement (SLA) lifecycle phases. Focus is on SLA negotiation phase from user's perspective, where user may be end user or another service provider. Analytical Hierarchy Process (AHP) is chosen as a method for multi criteria decision making analysis. Goal is set to be SLA election among all offered SLA templates. Relevant criteria are defined by user's preference. Alternatives are SLA templates offered by service providers.*

Keywords*: service provider, user, SLA, lifecycle, negotiating, AHP*

1. INTRODUCTION

Service Level Agreement (SLA) is a contract between the service provider and the user which defines all technical, financial and legal aspects related to a particular service (Hasselmeyer, Merschr, Koller, Quyen, Schubert, Wieder, 2007). The term "user" can be regarded to an end-user, or another provider. The negotiation between service provider and user is based on a SLA template, which defines parameter ranges of service characteristics supported by the service provider. SLAs contain Quality of Service (QoS) properties that must be maintained by a provider during service provisioning. These properties, defined as a set of Service Level Objectives (SLOs), should be measured and monitored during the time period of provisioning the particular service that has been agreed in the SLA. The SLA must also contain a set of penalty clauses which could be applied in cases when service providers do not meet the agreed conditions of SLA. Specification, monitoring and identification of how SLOs may be impacted by the choice of specific penalty clauses are not straightforward. The participation of a trusted mediator may be necessary in order to solve conflicts between involved parties. Automating this conflict resolution process may provide substantial benefits. There are several possible outcomes. These include monetary penalties, impact on potential future agreements between the involved parties and the enforced rerunning of the agreed service. There are a number of concerns when issuing penalties for SLA noncompliance (determining whether the service provider is the only party that should be penalized, or determining the type of penalties that are applied to each party). Usage of monetary penalties requires certain payment system. Knowing the provider"s reputation, user can make decisions regarding the best service provider for a specific task. Reputation, based on the previous behaviour of the provider, can be represented as a numerical value quantifying compliance to one or more SLAs. This value can be used by other users to determine whether or not to negotiate with specific provider. In this paper, we focus on user perspective of SLA negotiation phase where user must evaluate all offered SLA templates and finally choose service provider to sign an agreement with.
The paper is organized as follows. After introductory remarks, second part of this paper analyses all stages of SLA lifecycle: planning and development, negotiation and sales, implementation, operation and maintenance, periodic assessment of the Quality of Service (QoS). Third part represents analysis of negotiation phase from user"s perspective. Several criteria and parameter ranges are defined according to user preferences. AHP is chosen as the most appropriate multi criteria decision making method. Concluding remarks are given at the end of the paper.

2. SLA LIFECYCLE

SLA lifecycle consists of at least five phases, as shown in Figure 1, (Stojanovic, Bostjancic-Rakas, 2009):

- Planning and development – considers a number of QoS and SLA aspects. It defines generic parameters and technology-specific parameters; design and development of SLA template that ensures that offered QoS guarantees are realistic;

[1]This work is partially supported by Ministry of Education, Science and Technological Development of the Republic of Serbia under No. 32025.

- Negotiation and sales – a service provider must negotiate and agree with the user about technical details of a service, where QoS parameters may be customized or the same as those offered in the standard template;
- Implementation – configuration and activation of the service, beginning of operation;
- Operation and maintenance –monitoring and operation, real-time QoS reporting and service quality validation and real-time SLA violation handling;
- Periodic assessment of the QoS and whether it meets the SLA –scheduled during a single user SLA agreement period where the assessment is related to the delivered QoS against the SLA parameter values and limits, and the levels of user satisfaction with the service product.
-

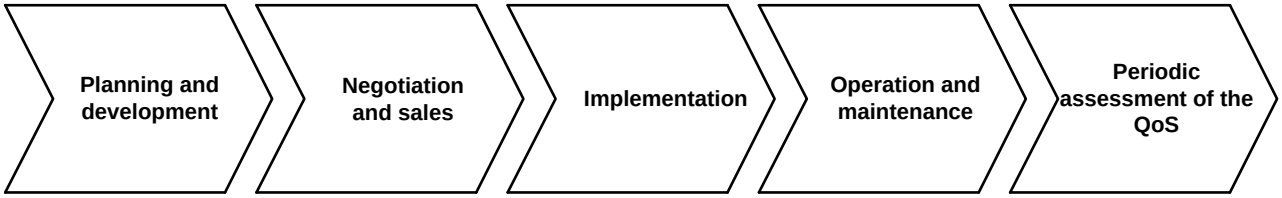

Figure 1. SLA lifecycle

SLA contains, among others, a service description and a list of guarantee terms that describe the duties of the involved parties, i.e. guarantees given by the provider and obligations to be observed by the user. The provider guarantees the fulfilment of specific service level objectives on well-defined metrics, and the payment of penalties - compensation in case of violating a service level objective (Schulz, 2011).The SLOs may include service availability, user response time, service response time, service outage resolution time etc.(Raju, Dhivya, Saranya, Abbinaya, 2013).
The negotiation between service provider and user is usually based on a SLA template. A template defines parameter ranges of certain service characteristics which are supported by the service provider. In the simplest case, there are no parameter options for the user. User can either accept the given offer or reject it. More complex negotiations are also possible (Andrieux, Czajkowski, Dan, Keahey, Ludwig, Nakata, Pruyne, Rofrano, Tuecke, Xu, 2006).

2.1 Template specification

Business practice in specification of SLA templates is not often economically efficient and present obstacle to successful business operation (Taylor & Tofts, 2006). A particular challenge for the specification of SLA templates is to obtain an understanding of the dependency between technical and business aspects. Definition of an evaluation function that maps each possible SLA template to a scalar scoring value that can be interpreted economically may address before mentioned challenges. The function is based on technical characteristics of the service provider, and gives a business-relevant evaluation of the SLA template. Thus, the evaluation function combines technical and business parameters from each SLA template into a single scoring value. Usually, many SLA templates result in the same score and a landscape of scoring values is formed. This landscape and its visualization provide a useful decision support for the selection of SLA templates that are actually offered to potential users. The final decision of the service provider is based on additional information like market situation and analysis of competitors (Schulz, 2011).
The approach for designing SLA templates by defining a scoring function on the space of all possible SLA templates is proposed in (Schulz, 2011). This methodology is depicted in Figure 2.

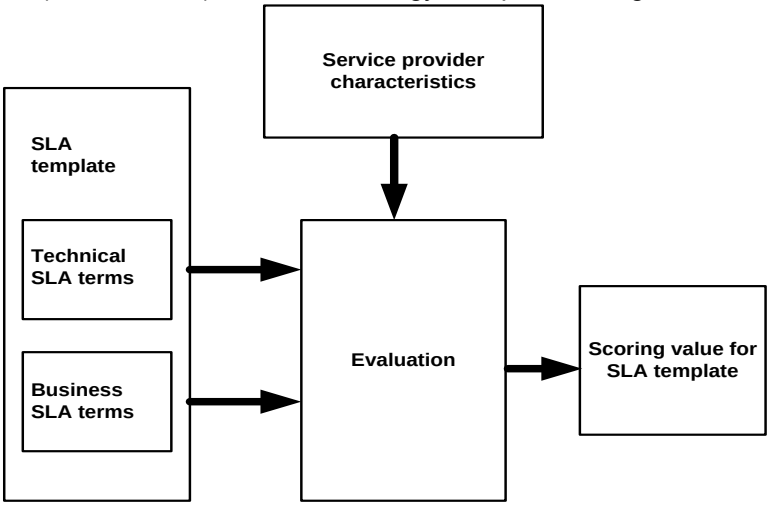

Figure 2. Designing SLA templates (Schulz, 2011)

The guarantee terms in a SLA specify allowed ranges for quality metrics and business value parameters like price and penalties. The technical terms express service level objectives by defining thresholds on the quality metrics. The fulfilment of objectives is evaluated over a defined time period. If the objectives are not met, an agreed penalty has to be paid by the provider. This can be a monetary payment or a period of free service usage, or some other form of compensation. The amount and calculation rule for the determination of penalty is defined in the business terms of the SLA.
Another input for the evaluation function is the service provider characteristic. This is a probability model for the quality metrics, based on empirical data of the service provider during past service operation (Dingle, Knottenbelt, Wang, L, 2008).
Metrics that can be observed are availability, response times, resource utilisations, throughputs and system productivity. Availability of the service is the ratio of time during which service is provided to users depending on the Mean – time – to Failure (MTTF) and Mean – time – to – Repair (MTTR). It can be represented as:

$$A = MMTF / (MTTF + MTTR) \quad (1)$$

Response time is the time from a user sending a request to receiving a response. SLAs are often concerned with means, variances, and percentiles of response times. Resource utilisation is the ratio of time for which a given resource is used by a given service. For example, it may be required that a service does not utilise more than 10% of available network bandwidth. Throughput is the average rate at which a given set of activities occurs. Productivity is a weighted sum of the throughput of a number of activities, where the weights are user specified rewards associated with completion of each activity. If the unit of the reward is financial, this measures a system"s profitability.
If the metrics depend on external parameters like varying user workload, the effect of external factors can be reduced by defining user obligations in the SLA and hence narrowing the range of external parameters. Combining the probability model for SLO metrics and the penalty model, an expected penalty can be derived. For each pair (target value, violation penalty) defined in the SLA template, the amount of expected penalty is calculated and represents the desired scoring value.

2.2 SLA negotiation

Many of the negotiation techniques can be applied for SLA such as game theory, time based decision making functions, machine learning, genetic algorithm, intelligent agents etc. Service negotiation is primarily based on decision making. In order to achieve rapid, effortless, and useful negotiation service, Analytic Hierarchy Process (AHP) might be used. AHP deals with many large, dynamic and complex problems. The advantages of AHP over other multi criteria methods are flexibility and ability to check the inconsistencies.

2.3 Monitoring

Monitoring of SLA begins once an SLA has been defined. A copy of the SLA must be maintained by all involved parties. It is necessary to distinguish between an „agreement date" (agreeing of an SLA) and an „effective date" (subsequently providing a service based on the SLOs that have been agreed) since a request to provide a service based on the SLOs may be undertaken at a time much later than when the SLOs were agreed. The monitoring infrastructure is used to identify the difference between the agreed upon SLO and the value that was actually delivered during service. It is necessary to define what constitutes a violation. Monitoring plays an important role in determining whether an SLA has been violated, and thereby determine which penalty clause should be applied as a consequence.
Providers" reputation and users" trust are largely based on the provided monitoring infrastructure. In the context of SLAs three monitoring modules can be distinguished: a trusted third party (TTP), a trusted module at the service provider, and a module on the user side. The trusted third party provides an independent module that can monitor all communication between users and service providers. After successfully completing the SLA all involved parties receive a signed ticket from the TTP that can be used for reputation building of the service provider. Trusted modules can also monitor communication between user and service provider and can similarly provide tickets after successful completion of an SLA. The main difference between TTP and trusted module is that the trusted module is integrated into the service provider. Thus, the internal state of the service provider can also be observed. However, their implementation is difficult. Usage of a module on the user side requires a user to determine if metrics diverge from the predicted behaviour of the service provider. In situations that require a high level of assurance, these monitoring modules can be combined. It is essential to monitor all relevant metrics and to provide all involved parties to retrieve such data in appropriate format.
Usually, a TTP module satisfies all required functionality for a monitoring service. Once a user and a service provider (SP) have created an SLA, the service provision is monitored by a TTP. This TTP can be a trusted module executing on the service provider"s system, or a server that is physically separated from the service provider. In all cases, the service provider must not have any access to the TTP, outside of the interactions that are properly defined. Built-in module and separate server are conceptually identical. However, the attacks on a built-in module can potentially be more difficult to detect. At the same time, user should have access to the TTP monitoring mediator for audit purposes, but without possibility to modify the data recorded

by the TTP. Messages are exchanged between the User (U), Service Provider (SP) and Trusted Third Party (TTP), as depicted on Figure 3. The TTP maintains a database of reputations (RDB), updating it whenever a provisioning takes place. The RDB is useful to import the reputation score at the beginning of a service provision and export it back at the end of the service provision so it can be used by other possible users. A user may also hold a local reputation value associated with a provider – based on monitoring the SLAs that it holds with a provider.

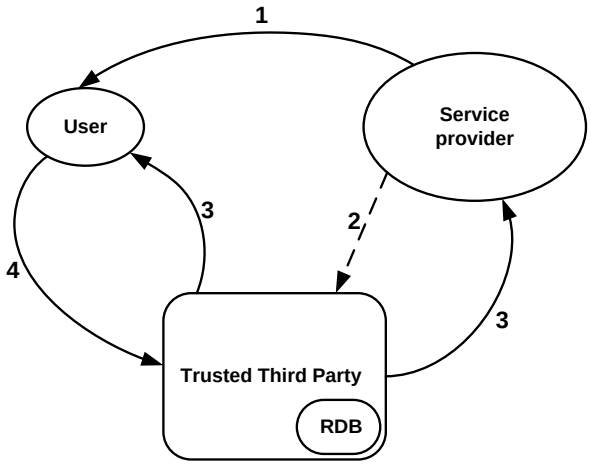

Figure 3. Messages exchange between the user, service provider and trusted third party

Whenever a service provider provides a service to a user (1), it is monitored by the TTP (2). This causes the TTP to update the reputation of the involved SP. The TTP sends a message to both the SP and the user notifying them about the update (3). User then sends a message containing its response (R) to the transaction. This response is used by the TTP to update the reputation of the service provider. Once the user sends its response, the TTP generates the new reputation of the service provider.

2.4 Types of violation

One of the main issues that the provider and the user have to agree during the SLA negotiation is the penalty scheme. Both the service provider and the user are free to decide what penalty to associate to the various types of SLA violations, in accordance with the weight of the parameter that was not fulfilled. Non-fulfilment comprises defective performance (parameter monitored at lower level), late performance (service provided at the appropriate level but with unjustified delays), and no performance (service not provided at all).

Based on these descriptions the following categories could be defined:

- All–or–nothing provisioning: provisioning of a service meets all the SLOs –i.e., all of the SLO constraints must be satisfied for a successful delivery of a service;
- Partial provisioning: provisioning of a service meets some of the SLOs – i.e., some of the SLO constraints must be satisfied for a successful delivery of a service;
- Weighted partial provisioning: provision of a service meets SLOs that have a weighting greater than a threshold.

Monitoring can be used for detection whether an SLA has been violated. Typically such violations result in a complete failure – making SLA violations an all-or-nothing provisioning process. In that situation a completely new SLA needs to be negotiated, possibly with another service provider, which requires additional effort on both the user and the service provider. Based on this all-or-nothing approach, it is preferable for the provider to satisfy all of the SLOs. An SLA typically contains several SLOs, where some SLOs may have higher priority than others. The importance of the different SLOs may be established during the SLA negotiation phase. Both user and service provider can then react differently according to the importance of the violated SLO. Weighted metrics can also be used to ensure a flexible and fair penalty mechanism in case an SLA violation occurs. Thus instead of terminating the SLA altogether it might be possible to renegotiate the violated part of the SLA. The more important the violated SLO is, the more difficult it will be to renegotiate the SLA.

2.5 Penalty clauses

Using penalty clauses in SLAs can lead to two questions that need to be answered: what types of penalty clauses can be used and how they can be included in SLAs. The focus is on penalty clauses for service providers. Behind the imposition of any contractual sanctions lies the idea that faulty behaviour of a provider should be deterred.

A penalty clause in an SLA may consist of the following:

- A decrease in the agreed payment for using the service – a direct financial sanction;
- A reduction in price along with additional compensation for subsequent interaction;
- A reduction in usage of service from the provider;
- A decrease of the reputation of the provider.

All parties involved in SLA negotiation can agree on a direct financial sanction for SLA violation. Usually, the amount to be paid depends on the value of the loss suffered by the user through the violation. Due to the difficulties in proving and recording the financial value of the loss, during the negotiation phase the parties may choose an agreed payment for non-performance that is a fixed monetary value that will have to be paid upon non-performance, regardless of the fact that no financial loss was suffered by the user. The service provider can deposit the negotiated penalty at a TTP that acts as a mediator, before the service provision commences. On successful completion of the service provision, based on the SLA, the TTP returns the deposit to the service provider; otherwise the user receives the deposit as compensation for the SLA violation. In this case, a trusted monitoring mediator is required since a user can never prove by itself that an SLA was violated. Another possibility is that a user reduces its usage of services from a provider that violated an SLA. A third kind of penalty clause can lead to a change in the reputation of a provider. In such a system the reputation of service providers that violate SLAs will decrease. Correct determination of the service provider"s reputation is necessary. In the SLA negotiation phase service provider and user can agree on which reputation mechanism to use.

2.6 Quantifying Reputation

Formally, an SLA consists of a collection of metrics $m=\{m_1, m_2, \ldots, m_n\}$ and time interval δt representing the period over which the SLA is valid. For each metric in an SLA its success or violation can be determined. Thus, success (m) takes value of 1 if metric m is fulfilled and value of 0 if metric m is failed.
The success rate φ of an SLA can be defined as the number of successful metrics relative to the total number of metrics n:

$$\varphi = \sum_{i=1}^{n} \frac{success(m_i)}{n} \tag{2}$$

Each metric can be weighted according to its relative importance for the user. Each weight, ω, can have a value between 0 and 1, where 1 means very important and 0 represents no importance to the user.
This gives the weighted success rate, τ:

$$\tau = \sum_{i=1}^{n} \frac{success(m_i)}{n} \times \omega_i \tag{3}$$

The weighted success rate, τ, of an SLA objectively quantifies how satisfied a user is with it. The weighted satisfaction rate, ψ, of a collection of SLAs can similarly be calculated:

$$\psi = \sum_{j=1}^{k} \frac{\tau_j}{k} \times \rho_j \tag{4}$$

where ρ represents a weighting factor that corresponds to the importance of each individual SLA, and k is a number of SLA contained in a given collection. Finally, the reputation, R, of a service provider can then be quantified by:

$$R = \sum_{l=1}^{p} \frac{\psi_l}{p} \tag{5}$$

where p represents number of all SLA collections. Initially, a service provider will obtain some default value for its reputation and as the number of agreements served increases its reputation will more accurately be reflected by R (Omer, Warnier, Quillinan, Brazier, Cojocarasu, 2008).

2.7 Termination

An SLA may be terminated in the following situations:

- when the service being defined in the SLA has completed;
- when the time period over which the SLA has been agreed upon has expired;
- when the provider is no-longer available after an SLA has been agreed (for instance, the provider is under liquidation).

In all three cases, it is necessary for the SLA to be removed from both the user and the provider. Where an SLA was used to provision a service, it is necessary to determine whether any violations had occurred during provisioning. As indicated above, penalty clauses are also part of the SLA, and need to be agreed between the user and the provider.

3. USER PERSPECTIVE OF SLA NEGOTIATION BASED ON ANALYTICAL HIERARCHY PROCESS

In this part of our paper, we analyse which SLA agreement user will choose among all possible SLA templates offered by the service providers. The decision is made using AHP. As mentioned above, AHP is very valuable decision making support. We suppose that user can either sign or reject offered SLA template, i.e. there are no parameter options for the user. Also, service provider offers one SLA template to one user. Various criteria along with alternatives for a particular problem can be implemented for SLA election. One example of possible criteria and alternatives are shown in Figure 4.

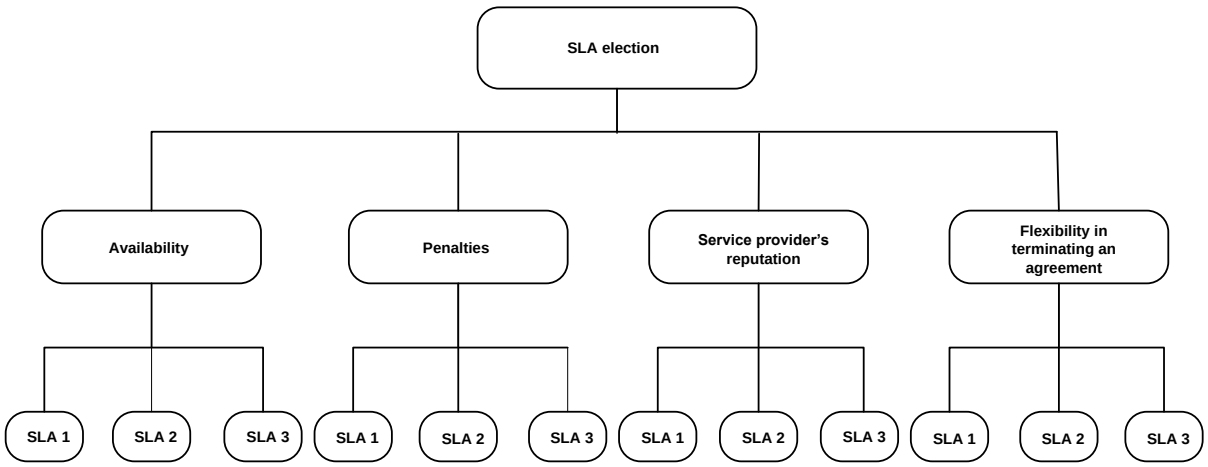

Figure 4. Structure of AHP decision making model

The user is choosing a service provider among three possible to sign an agreement with. Chosen criteria are availability, reputation of the service providers, penalty and flexibility in terminating an agreement. Availability is calculated using Eq. (1). We suppose that user prefers high availability, above 0.95. Reputation of service providers is monitored during previous service provisioning, and calculated using Eq. (5). We suppose that recorded data are available by TTP. Penalty clauses are defined in SLA negotiating phase. User has some flexibility in terminating an agreement on request under certain circumstances defined during negotiation. Relevant parameters in each SLA template are given in Table 1.

Table 1. Offered SLA templates

Relevant parameters	Service provider 1	Service provider 2	Service provider 3
Availability	0.967	0.941	0.982
Reputation	0.526	0.761	0.837
Penalty	20% price decrease	a month free of charge	30% price decrease
Flexibility in termination	compensation of all remaining financial obligations by user	compensation of 75% of all remaining financial obligations by user	compensation of all remaining financial obligations by user

We observe the two possible cases, regarding user preferences: (1) user is more sensitive in terms of availability and penalty clauses, and (2) user is more sensitive in terms of service provider"s reputation and penalty clauses. Obtained results are presented in Figure 5 and Figure 6, respectively.

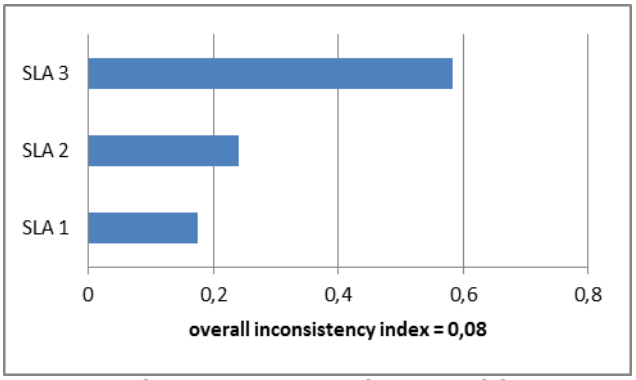

Figure 5. AHP results, case (1)

In the first case, both service provider 1 and service provider 3 offer high availability, above 0.95. Thus, an availability criterion is satisfied. From user"s perspective, penalties are also essential. Suppose that user prefers a certain time period of free service provisioning. Hence, service provider 2 is in advantage compared to service providers 1 and 3. Reputation of service providers is not essential in this case, but it is preferable to take higher values. Flexibility in terminating an agreement is also not essential, but user always prefers lower amount to be paid in the case of terminating an agreement before agreed SLA has expired. According to AHP, service provider 3 offers the best conditions and user will sign this agreement.

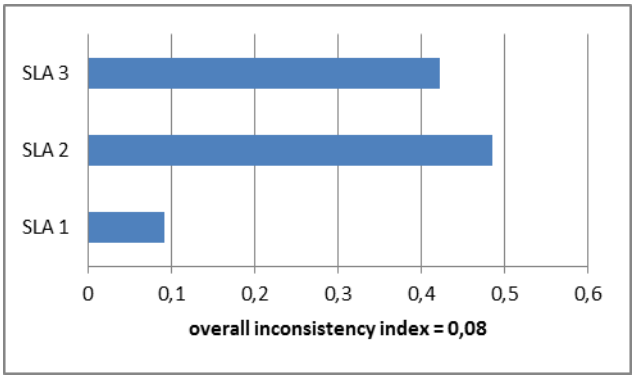

Figure 6.AHP results, case (2)

Case (2) presents the situation where user is more sensitive in terms of provider"s reputation based on previous service provisioning and penalty for SLA violation. As mentioned before, reputation is provided by TTP and it is preferable to be as high as possible. Penalties are also of great importance. Again, service provider 2 has advantage in comparison with other service providers, since user prefers a period of free service usage. Service availability and flexibility in terminating an agreement are not crucial. However, availability should be above 0.95 and it is preferable that user has possibility to terminate an SLA with the lowest financial compensation. Considering all criteria, service provider 2 best matches user"s requests. Thus, AHP suggests user to sign an SLA with service provider 2.

4. CONCLUSION

This paper presents business-related aspect of SLA through all lifecycle phases, from template design, through negotiation, implementation, operation, maintenance and monitoring to termination of an agreement. The focus is on SLA negotiation phase based on SLA templates. Essential challenge for the specification of SLA templates is to achieve understanding of the dependency between technical and business aspects. The proposed methodology for establishing a quantitative relationship between technical and economical parameters, which maps each SLA template to economical scoring value, is described. Monitored data in previous service provisioning are provided by mediator between service provider and user, Trusted Third Party. Service provider"s reputation is than calculated according to available recorded monitoring data. AHP is chosen as the most appropriate multi criteria method for decision support. Relevant criteria are set by user. Two cases are observed. The first one, when user is more sensitive in terms of availability and penalty clauses defined in SLA template, and the second one, when user is more sensitive in terms of service provider"s reputation and penalty clauses. In both cases, user obtains precise results with very low inconsistency index thus increasing a possibility of making satisfactory decision.

INNOVATIVE ORGANIZATION AND MANAGEMENT

MILITARY TRANSFORMATION PROCESS AND DISBANDING OF MILITARY UNITS

Nebojsa Nikolic [1]
[1]Strategic Research Institute, Ministry of Defense, Serbia, nidzan@ptt.rs

Abstract: *Reductions in military personnel, material and financial resources are the most obvious effects in contemporary undertakens known as the military transformations. Reductions generates disbanding of military units, and that processes are not less complex than vice versa -forces generation. Disbanding process generate reverse logistics supply chains for huge amounts of military material. Parts of that material are weapons, vehicles, various equipment, ammunition, mines and other explosive items. Those are highly dangerous items which need special and specific care. Normally, logistics lines are not designed for altered flow direction of large amounts of war material. Large scale reverse logistics of explosive ordnance is unusual task and needs to be planed and realized on the project management basis. Another sensitive issue of disbanding process, is dealing with sufficient military personnel. For a number of reasons, solving the problem of military human resources surplus is expected also to be successful. All implications of disbanding of military units are complex and needs to be carefully planned and executed, which leave enough room for application of various methods of System Analysis, Project management, Operational Research and Management Science. Lessons Learned approach, that is, analyses of available experiences of former and current military transformation events, is precondition for success in the future.*

Keywords*: Military transformation, System analyses, Supply management, Human Resource Management*

1. INTRODUCTION

Military transformation is a complex process of changes of one military organization, undertaken to meet current and future challenges for national security. There are many subjects of change: size, organization, deployment, doctrine, training, equipment, organizational culture and values. There are many limitations and imperatives like: budget, time, law, visions of strategic decision maker, capacity for change, current obligations and engagements, etc.

At this moment, military transformation in case of many countries means next: downsizing of military personnel, units, garrisons and supplies; new organizational patterns of military units; technical modernization (new weapons and equipment); doctrinal changes (urban warfare, counter-insurgent operations, multinational engagement, peace missions); new profile of the military man, etc.

Collateral product of military transformation is disbanding of military units. Disbanding generate surplus of personnel, equipment, weapons and explosive ordnance. Those have to be processed somehow. Material flow direction has to be altered: dispose, collect and somehow terminate military material from end users (military units) to some point where it will be terminated in a safe and appropriate way.

Disbanding of military units means and comprises next activities:

- Dismissing a military unit from its obligations, tasks, duties, zone of responsibility, and cetera.
- Discharging of military personnel from theirs positions, duties, responsibilities, etc.
- Dislocations of material items that belong to a military unit which is a subject of disbanding process: main items (vehicles, armaments, etc), unit's supplies (ammunition, fuel, spare parts, food, etc); and other equipment, from current physical location of the unit into logistical bases of higher command or other predefined places.
- Dispatching a documentation of military units towards the Military Archive.
- Deserting the military facilities and infrastructures (release real estate form the presence of military units).

2. DISBANDING OF MILITARY UNITS

Military transformation is a process that takes time, money and good realistic plan. Part of transformation is change of the structure: number and composition of military units. At this moment, the change means downsizing or in other words: disbanding of military units. That is complex task which should be perceived as

project management problem. A number of different but connected and interrelated problems should be resolved in parallel, inside a specified time period, and with a restricted budget.

One of a large scale military transformation process in a near past, started in a time around a dissolution of former state (Serbia and Montenegro in June 2006). Serbian General Staff started with huge transformation of subordinate commands and military units (without administration of Ministry of Defense and its subordinate organizations). According to a former Chief of General Staff, general Ponos, in a period of one year (from June 2006, to June 2007) a number of garrisons was reduced for 47%, a number of brigade-size units decreased for 55%, and separate battalions cut down for 70% approximately; personnel reduction was planned at the level of about 30% (Ponos, 2007).

Figure 1 presents entities that should be processed (terminated in a proper manner) in disbanding of military units. General disbanding process presented at Figure 1, offers a lot of opportunities for creative application of the System Analysis, Project Management and methods of Operational Research and Management Science. The most challenging entities at Figure 1 are explosive ordnance reverse logistics and resolving a problem of personnel coming from disbanding military units.

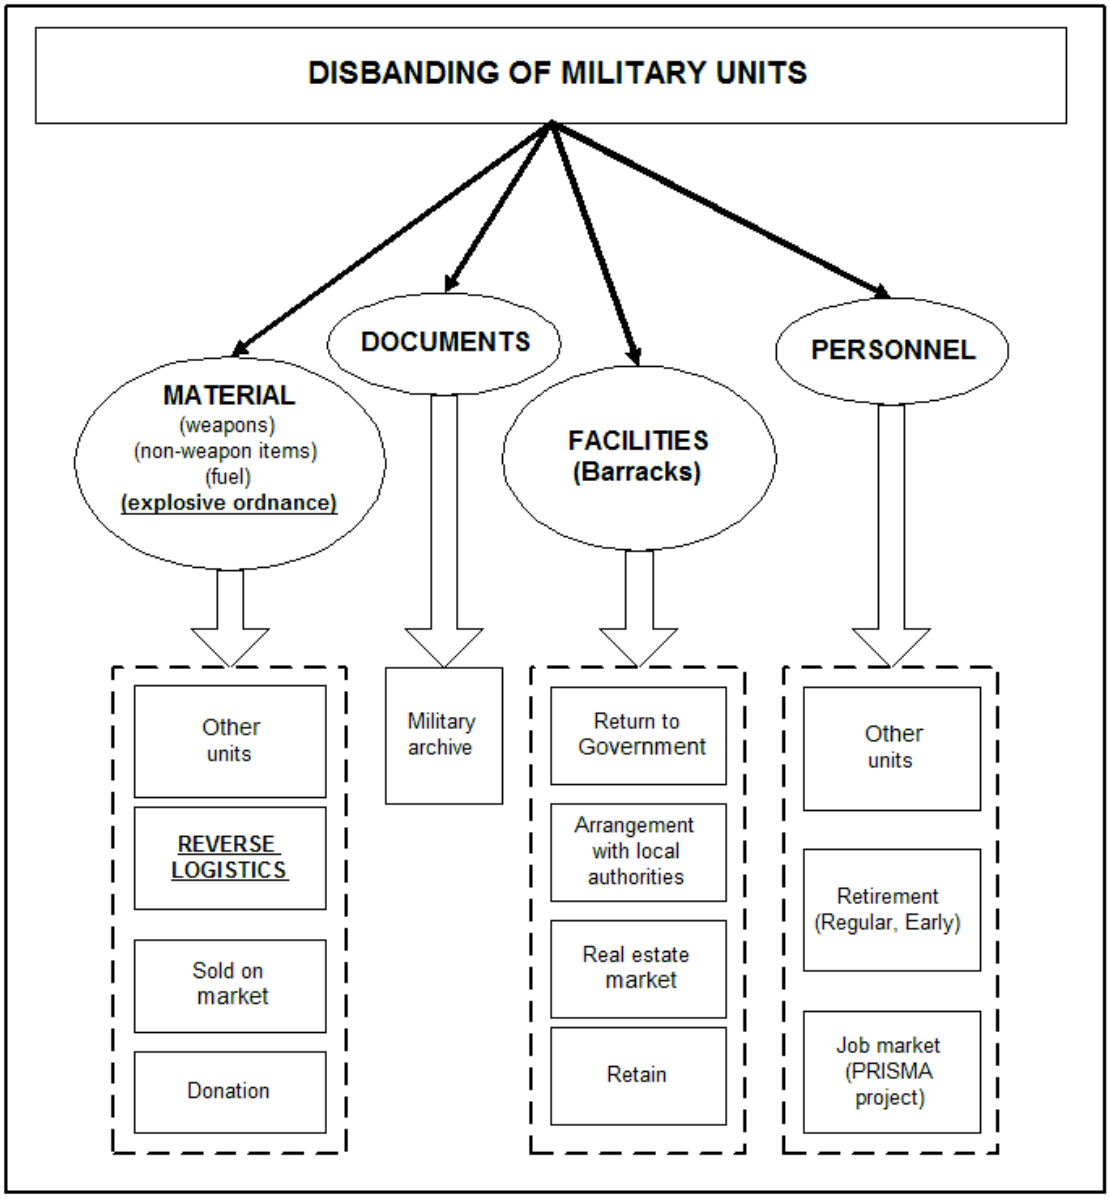

Figure 1. Disbanding of military units

3. DISCHARGING MILITARY PERSONNEL

Dealing with military personnel of disbanded military units is highly sensitive issue in many aspects and due to a specific character of military profession. Also, it is an organizational challenge for a human resources management.

There are different solutions for this challenge. Some of military professionals will be retired (regular or early retirement), some of them will be additionally trained and directed to civilian labor market. The rest will be distributed in other military units. In any case, many professional will make a career transitions inside or outside military organization.

Mechanisms for a Selective Early Retirement (SER) of military personnel exist in many countries, but in different forms that do not change the main two-fold idea. First, SER obtains care of military personnel after respective time period of military service (usually at least 20 years of service for full pension). And second, SER allows effective tool for military organization to transform itself (in this context to reduce its size) in a predefined time.

Ministry of Defence, jointly with some international organizations dedicated to the problem of security and demilitarization, developed the Program for Resettlement of military personnel (known as program PRISMA), in order to find one of possible solutions to the problem (Pietz, 2005). PRISMA was established and run in cooperation with some civilian faculties (Faculty of Organizational Sciences in Belgrade, in example), and with strong financial support from some partner states (Denmark, Norway, Sweden and Finland). Project PRISMA has lasted about six years, on more locations (regional centers) in Serbia, and costs near 10 millions of euros, encompassing around 7500 potential users.

On the other side, one vital organization should try to keep in active service better personnel. To make decision “who is better military professional” some criteria and some methodology are needed. Decision making theory and Multiple-criteria analysis could help here. Nikolic (2009), presented some problems and possible approach towards solution for better criteria for ranking of military officers. In fact, problem of ranking military officers (and other categories of personnel) belongs to wider area of the Human Resources Management (HRM). Various problems appears in the HRM due to the organizational dynamic, changes at the strategic level of organizational management, altering stakeholders preferences, changes in the wider organizational environment, an so on. In various periods, different problems can arise as dominant and place more care on human resources recruiting and development, or retaining or discharging. However, high quality and reliable system of ranking criteria, is always welcomed.

4. DESERTING MILITARY FACILITIES/INSTALATIONS

Problems with military facilities and installations (real estate), which remains empty in a disbanding process of military units, is logically simple but cumbersome for practical realization due to complicated laws, many stakeholders with different interests, etc.

In case of Serbia, Ministry of Defence, made a document known as “Master plan for military real estate”. The main idea behind that plan was expectation that many of buildings in former military bases will be sold on the real estate market. Huge amount of money was expected from that undertaken, and planned to be reinvested in some other urgent needs (like technical modernization).

However, that was too optimistic and many of those building are still in status quo. Some of main reasons for this were very complicated procedures, real estate’s documentation, valid and clear property proofs, differences in approaches to starting price level determination (market prices were very high, but potential buyers expected different treatment), problematic situation at real estate market, and of course negative influence of world economic crises in period after 2008.

5. DISPATCHING MILITARY UNIT’S DOCUMENTATION

Documents of military units usually go to the Military Archive and there is no special problem with this, except of heavy workload for the Military Archive services. This process assumes not only a physical relocation from military units to the Military Archive, but also accomplishment of some administrative procedures for classification, collecting and packing of unit’s documents, which is time consuming effort.

Military Archive is an organization in Ministry of Defence, whose mission is to collects, process and keeps documents that have been created in an army from its early days until today. In case of Serbia, that is the Military Archive who takes care of military documentation, starting from 1847 until today (www.isi.mod.gov.rs/vojni_arhiv02 , retrieved on March 24, 2014.). At the moment, there are more than 36 million pages of various documents generated in armed forces during the wars and peace intervals from 1847 up to now.

Documentation allocated in the Military Archive is valuable source for domestic and international historians, academics, courts, lawyers, and similar subjects, but also for common people who wants to get information about their relatives who served in military units in the past. Military Archive works according clear procedures and respects Republic of Serbia's law related to the archival material and archival service.

6. DISLOCATION AND PROCESSING OF MILITARY UNIT'S MATERIELS

Part of the disbanding process is the reverse logistics of all material of a military unit. First method for dealing with material surplus, coming from disbanding military unit, is relocation of material and equipment to other military units that will survive transformation. Second approach assume recycling of weapons, and it is relatively simple and benignly process besides it could be expensive due to cutting of high quality steel and generating transportation cost. Other methods for releasing the units from military equipment is selling it, or even donating it to some other (friends, partners,…) countries. Sometimes, donating material to the third subject/country may create mutual benefits (economic or political). Fuel can be "processed" through normal use or easily sold on market, so there is no problem with it besides it is a kind of dangerous and explosive items.

However, the situation is completely different in a case of explosive ordnance. Explosive ordnance is common term for all kinds of ammunitions, mines, missiles, rockets, and other explosive devices. There are many kinds of explosive ordnanace. They are very sensitivity and dangerous. Conseuently, they need special care, safety and security measures. Explosive ordnance are enery of war and have to be available to the military units in right amounts, at right time, on right place, and in right conditions. Explosive ordnance are very speciffic products with speciffic market. Consumption is not predictable enough: there is almost zero consumption in peace time, but within war demands increase drastically. Usually, all armies have some level of explosive ordnance supplies, which are calculated on the base of many factors.

There are many factors which make that explosive ordnance supplies become obsolete or surplus: changes in the strategic environment (peace dividend, change of adversaries, new security challenges and international agreements); technical innovations (new weapons); change of military doctrines; and end of life cycle of explosive items.

Military logistics system worked under heavy conditions in order to met hard lines of military transformation process. However, material flow was altered from its original design: all material from many disbanding military units flowed to a few depots. Disbanding of military units and, consequently, reverse logistics chain of explosive ordnance (EO), could be seen as important projects in the wider framework of military transformation process, because (according to set of definition of "project", Nokes and Kelly, 2007):

- It is "a temporary endeavor undertaken to create a unique result" (PMI definition of the project). Disbanding of military units and reverse supply chain of EO are discrete, almost unique events in life cycle of a military organization.
- It is "a set of coordinated activities, with a specific start and finish, pursuing a specific goal with constraints on time, cost and resources" (ISO 8402). Disbanding of military units and reverse supply chain of EO are complex endeavor usually forced with hard time-limits placed by strategic decision makers and constrained with prescribed procedures, laws and resources.

Besides a security sector reform, military transformation and disbanding of military units as a consequence, there could be more other reasons for ammunition disposals:

- International treaty obligations (bans of\n some kinds of ammunition or mines; weapons controls; CSBM – confidence and security building measures).
- DREAM (Disarmament, Demobilization, Reintegration and Arms Management).
- Decommissioning (the removal of weapons from active service induce removal of ammunition for that weapons).
- Return of military units from missions or wars.

"Normal" military logistics supply chains are well studied due to its primary importance, including new research trends and innovative concepts (in example: Wang, 2000; Dumond and others, 2001; Robbins at all, 2004). Main problem with reverse logistics supply chain for explosive ordnance in the case of disbanding of military units is a quantity of material which has to be processed in a short time with limited resources. In simple words, it is not designed for such level of reverse material flow.

In terms of the queueing theory, we have overloading of service channels, or at least heavy traffic conditions. Under pressure to finish task in a limited time, elements of supply system (depots) which receive material from a number of disbanding units, have to accelerate servicing (receiving, sorting, packing, stocking, securing). However, that could leads to a harassment of appropriate procedures and prescribed standards for safe stockpile management. The result is higher safety risk. Additional danger comes in situation with declared "non-perspective" ammunition. It is in a human nature to pay lower attention on items which are declared for disposition and destruction ("non-perspective" items).

7. CONCLUSION

Military transformation is a complex process that could be initiated on the basses of different events: political decision, international obligations, security environment, economical issues, societal changes, technological advancement, and so on. Military transformation assumes the change in its essence. There are many subjects of change: size, organization, deployment, doctrine, training, equipment, organizational culture and values. There are many limitations and imperatives like: budget, time, law, visions of strategic decision maker, capacity for change, current obligations and engagements, etc.

Military transformation in case of many countries means next: downsizing of military personnel, units, garrisons and supplies; new organizational patterns of military units; technical modernization (new weapons and equipment); doctrinal changes (urban warfare, counter-insurgent operations, multinational engagement, peace missions); new profile of the military man, etc. In this paper we identify and elaborate few main flows in a disbanding process of military units, as its main implications, which are: discharging of military personnel; dislocations and processing of material items that belong to a military unit which is a subject of disbanding process; dispatching a documentation of military units towards documentation warehouse (the Military Archive); and deserting the military real estate.

POSSIBILITY OF ORGANIZATIONAL CONSULTING AS A PROCESS IN IMPROVING THE PERFORMANCE OF ORGANIZATIONS AND INSTITUTIONS

Marija Jevtic[1], Marina Mojovic[2]
[1]University of Novi Sad, Medical Faculty, MD, PhD, public health specialist, group analyst
[2]Consulting art / Psychiatrist at MD private practice, psychiatrist, group analyst, psychoanalytic psychotherapist and organizational consultant

***Abstract**: The paper deals with a problem of changes in external environment which influence and require organizational changes in organizations and institutions, in public sector above all. The process of continual organizational changes and role of consulting in the process of changes and implementation of proposed changes are analyzed in the second part of the paper. Organizations today recognize changes within themselves, in society and in the environment in general. They monitor changes that occur in all three segments in order to develop mechanisms which would enable them to cope with the inherent risks mainly relating to lenience of organizational boundaries, disintegration of internal hierarchical structures and crisis of trust. Organizations in which people work and provide livelihood ceased to be perceived as a safe place, which also relates to public sector, health organizations, educational sector and others. Changes and transformations, as well as increased permeability of institutions bring some benefits, but also evident risks and damages that can be seen in hindering the fulfillment of the primary task. These changes can have particularly serious consequences certain sectors such as public health and education. There is a trend of increased monitoring of the performance of the public sectors, but it is accompanied with pronounced requirements to achieve results with limited economic resources, which leads to dissatisfaction among staff. A group of professionals from different sectors and different roles in organizations are interested in the process of further education in organizational consulting within the Section of psychodynamic and group analytic approach to understand the psychodynamics of institutions, organizations and society. They are studying the possibility of "curing" institutions. By studying psychodynamics of institutions in the sensitive time of transition and changes and by using different techniques and process organizational consulting, a positive contribution to the individual goals within the organization, as well as to group and overall goals of the organization may be provided. Psychodynamic approach is a significant step in improving the work and it contributes to the improvement of the matrix of the organization.*

***Key words**:*
Organizations and Institutions, Process of Transition, Organizational Consulting, Psychodynamics of Institutions, Matrix Organizations

1. CONTEXT

The paper deals with a problem of changes in external environment which influence and require organizational changes in organizations and institutions, in public sector above all. Organizations today recognize changes within themselves, in society and in the environment in general. Organizational boundaries are more lenient, more fluid, more flexible, but also unpredictable.

Network communication, influence and partnerships within and among organizations are more developed. Partnerships between organizations are developing rapidly, but this merging changed the conventional boundaries of the organization and the field. Outsourcing or obtaining services needed for its work from outside the organization, change the structure, procedures, methods of work, and also contribute to the openness of the system, transformations and changes.

Hierarchy in organizations today are not "straight" and clear, but complex, overlapping and fluid. Individual authorities of some roles in the organization are continuously the subject of negotiation in

relation to the short term task and goal, which is a risk for individual management roles, as well as danger for the whole organization. Permanent teams of rigid structure are changed by the teams formed by the project task, of long or short duration, but limited time frame.

It seems that where once a boundary (of the organization) used to be, there is a network now. The good side of this phenomenon is the diversification and expansion, and the accompanying, negative side is certainly the risk of dislocation, disintegration, degradation. It is therefore important that consultants knowledgeable in this area discuss the topics of great importance:

- sociological and psychological characteristics of a new organizational system,
- opportunities to work in new organizational circumstances,
- characteristics of the consultations of the new organizational groups and possible dilemmas,
- impact of gained experiences on the theory and practice here and now.

Public sector, as well as health sector and educational sector are important sectors in all countries (Crnjanski V 2012, NHIS 2014). They have many employees, represent a large system of special sensitivity to outcomes that are expected of it and these organizations are in line with the changes, less rigid than before, and the boundaries of organizations are more lenient. Professional and commercial networks of impact are more developed; availability and flow of information are more present, as well as partnership and cooperation, but also mechanisms of disintegration, which are more and more evident in the organizations.

Organizations monitor changes that occur in wide work environment and in the region in general. It is necessary, therefore, to develop an awareness of risk and knowledge of risk management of modern organizations, both with managers and workers, i.e. members of the organization, in order to overcome disintegration and crisis of trust to the best extent possible (Cooper and Darlington 2004).

The group matrix as a secure base was investigated by Liza Glenn and nature of matrix is most consistently described as a network and not easy to understand (Glenn L 1987). Galbraith Jay wrote in her book that organization structure does not fail, but management fails at implementing them correctly (Galbraith J 2014).

Considering the importance of the public sector, it is necessary in the analysis to take into account that this sector is inseparable from other sectors of society, and that our societies are becoming increasingly structured around bipolar opposition, between the net and the self (Castells 2000). State of instability is present in all organizations, and it is necessary to get used to this situation and to seek ways of functioning outside the state of stability. Society and its main organizational units and sectors are in the continuing process of transformation, and new states of stability, it is completely obvious, cannot be expected in the near future (Schon D 1973).

As large institutions and organizations are especially vulnerable and instability is more visible, it is obvious that the age of anxiety did not bypass the public, health and educational sector and did not remain within the limits of one country, political system or economic level of development. Lack of trust in managers and implementation of their solutions is deeply rooted in the health sector, and managerial roles can often be associated with the post of the scapegoat. Being powerful does not mean having a job well done, but it seems more often being good in a complex game of avoiding pitfalls, winners and losers (Cooper and Darlington 2004).

There is a trend of increased monitoring of the performance of the public sectors, especially those of health and education. The control system of performance is becoming more complex. The question is how to work in the new organizational environment in light of the many new negative occurrences and more pronounced requirements to achieve results with limited economic resources. The perspective that funding will be more and more complicated and difficult is clear and therefore there will be growing dissatisfaction of individuals in health sector organizations.

The question is how to work in the new organizational environment in light of the numerous adverse events, challenges of changes and demands for achieving better results, with limited economic resources. Resistance, uncertainty and control dominate the atmosphere in institutions and organizations. Trust and positive economic outcomes in the present circumstances, are difficult goals

to achieve, which often threatens the realization of the primary task, for example treatment of patients and improving the health of the population in health sector.

Public sector, health organizations and educational sector as well as individuals are exposed to all the influences of the present age. Consequently not only tradition and history but also an organization's vision and mission are exposed to the influence of various external factors. The relations within the health organizations are a consequence of both the external factors and the internal norms developed within the same organization. Human resources, equipment and facilities are basic elements of an organization. Further structuring depends upon the vision, mission aims, type, purpose, possibility, legal frame but there are some organizational segments that are not easy to formulate or analyze. This part of an institution's organizational capacity makes a matrix which does not follow any technical, legal or other strict procedural aspect of the organization. It significantly influences the feelings of an individual within the organization as well as the image that the organization sends to the outer world.

2. METHODS

Bearing in mind the overall general situation which monitors public sector and health organizations, the aim of this paper is, among other things, to show the possibility of using psychoanalytic and group analytic approach in work with organizations of the public sector and health organizations.

The attempt is made to improve the working results of the health system using the method of the psychoanalytical and group-analytical approach to understanding the psychodynamics within the work process of institutions, organizations and society.

For this purpose, a systematic approach to the education of experts interested in contribution in this area, who are basically of different educational backgrounds but share ambition of focusing their work in the future on the improvement of the work in organizations, has been designed.

The education is organized by the Section for psychoanalytic and group-analytic approach to understanding the psychodynamics of institutions, organizations and society, which is a part of the Group Analytic Society Belgrade (GASB), and in cooperation with the Society for consulting and education 'Consulting-Art' (Jevtic M et al 2013).

The entrance interview is obligatory and the education consists of: theory, supervision, experience in working in a small group-analytic semi-open group, social dreaming experience, experience in working in medium group-analytic group as a facultative activity, as well as a facultative participation in two international educative workshops in this field. Theory and supervision are organized in 14 modules (12 regular and 2 facultative modules). Reporting on an organizational situation from the point of view of a leader, manager or HR representative or any other view or reporting on some other social group situation in which a trainee has participated in is discussed and linked to the theory and practice of this field.

By acquiring theoretical knowledge, presenting and showing examples from the practice, by practicing through the role of the client, observer, supervisor, as well as a consultant, course attendant acquires the knowledge and ability to conduct process consulting in health and other organizations.

3. RESULTS

The complex relations within groups and organizations as well as the effects of external factors are especially important to all sectors and institutions. They are not only affecting the efficiency and quality of the provided services but also the mental health of both health professionals and clients and patients. The organization's matrix is of great importance for its efficiency, especially in the public sector and health system.

Over 30 experts from the health system are being additionally educated in the field of organizational consulting organized by the Section for psychoanalytic and group-analytic approach to understanding the psychodynamics of institutions, organizations and society. The significant capacity for "healing" of organizations and institutions is gained in such a way. For example, today the network of public health institutions in Serbia consists of over 150 primary health care institutions, over 40 hospitals, 30 specialized hospitals, 16 institutes and 4 clinical centers. Clinical centers as the most complex

organizations with several thousand employees are undergoing organizational transition, which economically represents a difficult situation, and have extremely complex system of relations among individuals and groups.

The result of the work is the realization of two levels of the Course of organizational consulting, with two generations of attendants and gradual establishment of a network of the people interested in working in the public sector, different institutions and health system, with the appropriate capacities and acquired skills and knowledge that can benefit the organization, whether that work is carried out in the form of external or internal process of consulting. The emphasis is on process, not the expert consulting, which is also important note, because it requires the development of partnership between the consultant and the client (clients).

4. DISCUSSION

All organizations are nowadays more networked than before, and hierarchies are not "straight" and clear, but complex, overlapping and fluid. Individual authorities of individual roles in the organization are continually subject to negotiation in relation to the current task. This leads to the inexorable uncertainty among managers, endangered status in relation to others and in relation to the own self.

Andrew Cooper and Tim Darlington (2004) primarily studied public sector organizations, in which the boundaries of autonomy and control are dissolved, and which are at the same time followed by instability and complexity, as accompanying features. They compared the contrast of a new organizational order and orthodox psychoanalytic theory of functionality and dysfunctionality, wondering to which extent fitting into the current reality of people's experiences in organizations goes. The prerequisite of human psychological and social health at work are processes of containment as a common practice of thinking and, in a way, a new kind of phenomenal form in the organization. Thinking leads to the discussion of the disappearing organization, i.e. organizational containment in a networked world.

Linda Hoyle points out that the change is an additional potential for creativity. Reactions to changes are, however, very different, and it is important to explore the psychoanalytic theories of unconscious resistance to a change (Hoyle L 2004). Elliot Jaques (1955) and Isabel Menzies (1989) who have also dealt with these works, point out that people use social systems (organizations) to ward off anxiety. Stress and anxiety in the system of hospital personnel cannot, for example, only be attributed to the task and to the fact that the social defense system is insufficient to reduce anxiety because it also produces it. Change in the organization conducted by the management faces different reactions from sycophant (absolute followership) to sabotage and reactions of positive support with constructive comments, or negative and contradicting, with the stated reasons for such an attitude can be found among them. On the basis of this study the possibility of using the model of process consulting, by helping people in the organization to move from the extreme roles of saboteurs or sycophants, to contemplating and constructive positions in which they would give a better contribution to the work of the organization, with the aim of contributing to the realization of the primary task in the public sector and health sector, has been open (Menzies I L 1989, Jaques E 1955).

It is also important to emphasize that the understanding of individual existential primary task, which is a source of resistance to a change, is using a process of bringing the existential task into conscious awareness with the aim of understanding one's own anxiety and the perception of resistance as a non-compliance with the organizational normative primary task.

The standpoint of Sarah Vaughan on the impact of organizational culture in dealing with conflicts in the workplace is interesting one. Conflict is natural and useful in solving problems in the organization, but it can also be devastating and lead to destructive and negative behaviors in the workplace, including physical and verbal aggression, intimidation and victimization, leading to the development of negative consequences, both for the employee and organization as a whole. Because of the severity and magnitude of the problem in health systems and their importance to society as a whole, the study of culture, ethics and the relationship between national culture and organizational culture in the function of the realization of the primary task in health care organizations is important (Vaughan 2011).

Due to the significance which all institutions and organizations represent to individuals, for its size, capacity and aim, it can be said that:

- It is necessary to constantly search for new approaches in order to find a new possibility to improve the organization
- Today, more than ever before, organizations represent a challenge when studying processes and dynamics within them is concerned
- Group analytic therapy can be further developed to research the psychodynamics of institutions, organizations and societies
- There is a significant interest among group analysts and other professionals as well for education in this segment in order to improve the relations in the organizations, different groups and society in general.

5. CONCLUSION

Interdependence in modern organizations and systems increases; this also applies to the public sector, health and educational organizations, which is important for intergroup relations.

In order to achieve the progress a step toward cultural fluidity and flexibility is needed, as well as the work of the containment, and in its absence the risk of instability, destruction, unpredictability is high and the chances for promotion of solidarity, creativity, and sense of security, are smaller.

Naturally, the question of psychoanalytical theory and practice persists, as well as this function, it can become real, applicable and with satisfactory results. Until we make effort, invest time, knowledge and creativity, it cannot be known. One thing is certain, that every kind of such and similar work in organizations, the use of the psychodynamic approach, brings small or large steps in advancing the work of the organization and contributes to the improvement of the matrix.

Groups within health organizations have different levels of cohesiveness which mainly depends on the common aim and a motive deriving from it. Therefore, the research of group and subgroup characteristics within organizations is an important topic whose aim is to improve the management of all institutions which nowadays can be candidates for the work improvement through the group-analytic organizational consulting.

MANAGEMENT OF INNOVATIVE ACTIVITIES OF COMPANIES IN THE FUNCTION OF ACQUIRING AND MAINTAINING A COMPETITIVE ADVANTAGE

Nenad Lalić[1], Miladin Jovičić[2], Ognjen Zupur[3]
[1] Faculty of Business Economics Bijeljina, University of East Sarajevo and AD "The Eagle" Bijeljina
[2] Faculty of Business Economics Bijeljina, University of East Sarajevo
[3] Faculty of Business Economics Bijeljina, University of East Sarajevo

***Abstract**: The study shows how innovation activities combine the dimension of management and innovation activities, and whether the appropriate intensity of their use may affect the competitiveness of enterprises. The research had been conducted in order to explore an impact of management innovation activities on the competitiveness of small, medium and large enterprises in Bosnia and Herzegovina. Survey has been used as a methodology and sample has been made of respondents from companies. Based on the identified barriers in the management of innovative activities, the model of innovation activities that would escalate innovative activities on daily basis has been proposed. Within the model it has been proposed framework and criteria for investment flow and measure the results of innovative activities. The model is applicable to all companies, regardless of their size.*

Keywords: *management, innovative activities, competition, enterprise model.*

EXORDIUM:

Uncertainty business, innovation activities and competitiveness do not represent a new theme in the business environment, but its perseverance promote that the only certainty of surrounding is the fact that tomorrow will be the same as uncertain as today. It is precisely in the fact that the environment changes are constantly monitored and it that lies the greatest problem related to the management. And it is very clear that even today many trends change, creating the conditions under which it will be in due time to change the rules in the existing industries. The path of development is based on change and flexibility, due to the fact that positive changes in the long term will contribute to greater wealth, higher levels of employment and freedom of the individual (Jovicic, 2006). Nevertheless, talking about the constantly changing environment and a high degree of uncertainty, the basic principles of good management, if necessary, adapt and configure compared to the changed circumstances.

Good management is essentially what has always been a challenge to make the accumulation and use of all available resources, especially knowledge. The ability of management is a key moment in response to external changes and trends (*Preston, Kerr and Cawley 2009; Hotho and Champion, 2011; Cunningham, Cutler, Hearn, Ryan, and Keane, 2004*), and on the cooperation with educational institutions in designing relevant innovative plans and programs (*Bauer, Viola and Strauss, 2011; Haukka, 2011; Bridgstock 2011*). In practice, every manager has to deal with the problem of changes, challenges and new opportunities that must react to innovative activities (*Jaksic-Levi, 2001*). In today's turbulent environment, the question is pointed on survival, the survival of enterprises and even entire countries to the global market. It is necessary for management to adapt to changes in the environment, and to maintain the strength in the innovation activities of enterprises continuity to maintain in the business, and in order to survive. If you are not able to follow the changes, to initiate change, to be innovative, to change their own organization, products, methods, technology, etc., it is inevitably that it will befall crisis. The aim of the study is to review the existing practices of innovative activity management in companies in Bosnia and Herzegovina (B'n'H) and its effect on strengthening the competitiveness of enterprises caused by the same.

1. REVIEW OF THE LITERATURE

For the management of the last century it can be said that it is an activity of coordinate tasks that they perform more efficiently and effectively. Management evaluates started and expected changes in the environment that will inevitably impact on the overall strategic position of the company. These changes are often subtle, inaudible and should been seen, heard, identified and assessed much earlier than do competing companies (SehiC, 2002). This, above all, a skill that is focused on finding such measures and actions to improve the implementation of certain activities and enterprise, and the functioning of the economic and social system makes it more efficient, today it's called management, and it took its place among the modern scientific disciplines *(Jovanovic, 2009*). However, management theorists of twentieth

century have made the management of most companies to have a similar hierarchy pyramid structure, so it's hard to find the best practical examples of management who are really good enough. Even for those companies that are set to be an example, are not sufficiently flexible as they should be, and not innovative as they could be. It is clear that what limits the innovation company is not operational, but its business model management. Theorists innovative management, management of the XXI century, are trying to change the principles of management of the last century (*Hatunić, Kuc, Hatunić, Mesic, Kuc, 2011*).

Previous studies, some more than 80 years in the field of innovation management have pointed to two conclusions. Innovation is primarily a process, not just a single event, and in accordance with this innovation should be managed. The second conclusion relates to the fact that the result of the process of innovation can influence by influencing the process of innovation (*Tidd, Bessant and Pavitt, 2005*). The main challenge today is the fact that the level on which is placed the management of innovative activities is expanded significantly. Globalization moves the competition from the level of prices and technical innovation to the knowledge management and innovation management (*Djordjevic, Cockalo & Bogetić, 2010)*. Accordingly specified words, it comes to mass innovative phenomena in organizing and managing work in companies, and recent research has focused on the management associated with cognitive management doctrine (*Avolio, Walumbwa and Weber, 2009).* As a result, management takes an innovative-creative character, and companies that successfully implement innovative activities become more innovative companies. The introduction of innovation in the enterprise cannot be realized without good governance same. American professor of management Tide (Tide, 2009), suggests four stages in the process of innovative activities that would lead to their accelerating, namely:

1. Management scanning and searching internal and external environment;
2. Managing strategic selection of ideas;
3. Manage the allocation of resources for the development of knowledge and the use of selected and collected signal;
4. Management implementation innovation.

From ability of management depends on innovation enterprises, improving operations, risk management, working effectively with employees, improving employees' knowledge, adequate organizational culture and climate, etc., all of which leads to the effectiveness of investments. Efficient management is an important success factor (*Mumford, Scott, Gaddis, and Strange 2002*). Evidence suggests that management plays an important role in the production of creative thinking and innovation (*Rickards and Moger, 2006*). Bigliardi (*Bigliardi, 2013*) emphasizes the importance of managing the development of innovative activities to meet the needs of customers, and the end result would be the improvement of financial results and distancing himself from the competition. Empirical results (Ibid, 2013) confirms that by increasing the level of innovative activity has improved financial results of the company. Today, managers are viewed primarily as professionals who possess effective knowledge, skills and abilities, and who know that it successfully applied to other employees in order to strengthen the innovative activities, produce results and achieve corporate objectives. So young and avant-garde company usually seeks managers who are able to make quick, intuitive decisions, without hesitation of applying innovative approaches to problem solving (*Lalic, 2010*).

According Rejnert (*Rejnert, 2010*) from the profile manager largely depends in what extent the company will overcome the inherited problems and accept market rules because the challenges are much greater than they were before 20 years or more, and the reasons are that:

1. Modern enterprises focus on the provision of services;
2. Modern enterprises are enterprises in the sphere of knowledge economy;
3. Modified form of techno-economic causes major changes;
4. The amount of allowable defects is much smaller than in the past;
5. It is impossible to choose the winners;

With regard to management of enterprises of B'n'H, attention was not paid to management, probably because of leadership, which is the legacy of socialist planning, but also because of the fall of consciousness during and after the war. The strategic course of B'n'H is integration into the European Union and the placement of domestic enterprises and the economy into the European and world market, which can only be achieved by their competitiveness. In front of the management companies from Bosnia and Herzegovina lies a complex task that requires awareness of the importance of innovative activities of enterprises, competent management, good choice of strategy, business flexibility, elasticity organizational structure, etc. (*Hatunić et*

al, 2011). Therefore, the motive of the research was to investigate the influence of management companies in B'n'H on encouraging innovative activities in enterprises and the importance of same ones, to the competitiveness of enterprises.

2. RESEARCH METHOD

After briefly looking at the characteristics of management and innovative postulates, the focus of the next phase of the research was to identify the connection of innovative activities and the competitiveness of enterprises. Data collection for the study of relation of innovative activities and the competitiveness of enterprises in B'n'H was made by constructed questionnaire. The final sample size is 100 companies, of which 69 SMEs (small and medium enterprise)s, and 31 great companies from all parts of Bosnia and Herzegovina. Study was initiated on December 6, 2012., sending online questionnaires to address of the enterprise and it was completed on 7th April 2013th year, which analysis and synthesis of data were collected. Questionnaire was designed for the management of the companies.

The closest relationship with the aim of research, and the research hypothesis, which states: "*Raising the level of innovative activity in enterprises is the basic prerequisite for gaining and maintaining competitive advantage*".

3. RESULTS OF RESEARCH

The results of empirical research on the management of innovation activities in SMEs and large enterprises in B'n'H, for the most part, indicates the opinions and attitudes from the theoretical part of the study. In this regard specific obstacles were identified in the management of innovative activities which are reflected in the following:

- Outdated internal structure of knowledge, technology and other tangible and intangible assets (61% of respondents);
- Most managers of companies from BiH was not well versed in innovative activities in which areas to apply them (56% of respondents);
- Low-frequency in the development or innovative projects of enterprises (44% of respondents);
- Lack and limitation of financial resources (74% of respondents);
- Low-level monitoring innovation, managerial skills and writing projects (46% of respondents);
- Weak links of the economy, public sector and educational institutions (69% of respondents);
- Interaction between management and employees is at a low level (58%);
- Awareness of the importance of the development of innovative activities and changes in companies is low (66% of respondents);

For claims from another part of the questionnaire, which were available for therespondents ,there was offered a Likert scale. Engineered Likert scale, with 5 answers indicates the attitude of respondents from SMEs and large enterprises in B'n'H on innovative activities in enterprises, as well as their competitiveness. Within these statements, on which the respondents tried to identified themselves, offered answers were: (1) No (2) A very small part of the case, (3) Partially so, (4) For the most part it is true, (5) Yes, completely so. Replies of respondents were ranked the scores 1, 2, 3, 4 and 5 replies under 1 and 2 are the negative attitude of the respondents in relation to the fact assertion, grade 3 represents a neutral stance, while customer 4 and 5 imply a positive attitude of respondents from SMEs and large enterprises in Bosnia and Herzegovina.

Certainly that is one of the most interesting results obtained from the first statement of the questionnaire exactly the number of newspapers that the company has introduced in the last three years (Figure 1).

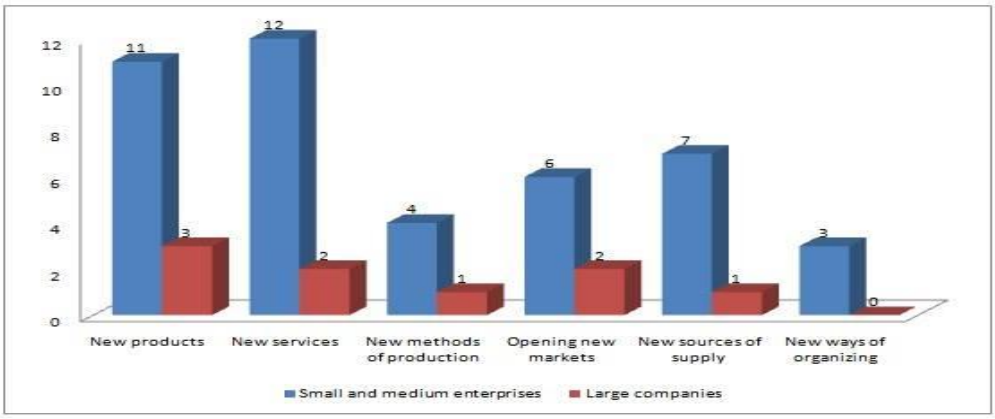

Figure 1. Innovation companies

As you see in the Figure 1, in the last three years, SMEs and large enterprises introduced a total of 52 **recent additions** that were completely new to the company. Of these 34 innovations that have already been used by other companies, and 18 recent additions are full innovations in the branch of the company. Also, it was found that some companies introduced more novelty, so that the number of companies that are actually have introduced some of the 41 innovations (34 *SMEs and large enterprises 7)*, while 59 companies did not have any innovations in the last three years. On the other hand, the European Union, according to official data of the European Commission (*European Commission: Enterprise and Industry, 2013)*, more than half of the companies have reported that they had to put up some of the innovations in the last two years, the undisputed leader of Germany whose even 79 % of companies had some of the innovative activity in the last two years. Therefore, it can be concluded that companies from B'n'H are largely behind, not only from the leader as Germany is, but also from the European average. Their views on the remaining five offered statements are presented in the Figure 2.

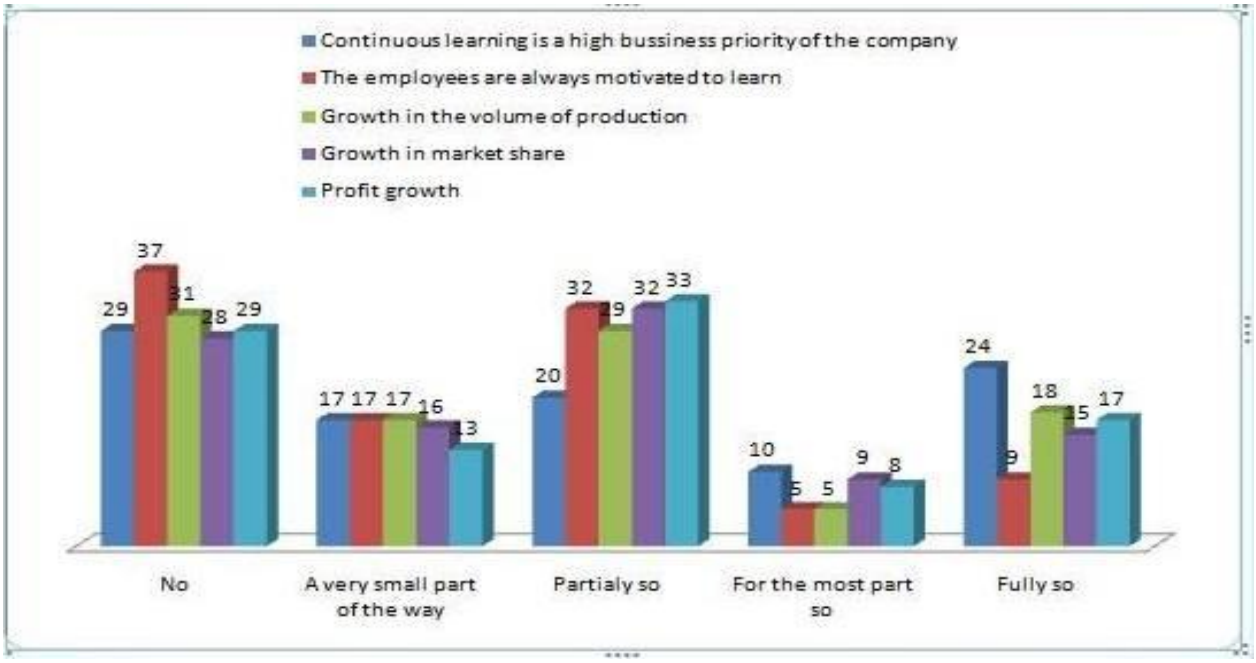

Figure 2. Answers given to the allegations set

Based on data collected from the questionnaire for respondents, it has been possible to test hypotheses through a program for statistical analysis of the data, "IBM SPSS 21." Approach was made by formation of two variables, and innovative activities and competitiveness, which contained claims which respondents could express their disagreement or agreement.

First step in data processing was the formation of scale on the basis of statements and analyzes internal homogeneity statements based on the value of Cronbach's alpha coefficient. Table B1 shows the value of Cronbach's alpha coefficient used measurement scale for variable innovation activities and competitiveness.

Table 1. The value of Cronbach's alpha coefficient (α) for the applied measurement scales

Scales	N	α	Total α
Innovation activities	100	0,826	0,899
Competitiveness of enterprises	100	0,791	

Based on the values of Cronbach's alpha coefficient it is possible to conclude that the applied measurement scales possess a satisfactory level of homogeneity (Table 1). In addition, values are displayed and Cronbach's alpha coefficient for each scale separately.

Table 2. Effect of claims on the Cronbach alpha coefficient (α) of the scale for innovative variable activities.

Claims	N	α	Total α
Innovations	100	0,728	0,826
Motivation	100	0,846	
Continuous learning	100	0,678	

Based on the values of Cronbach's alpha coefficient it is possible to make a conclusion that the applied measurement scale (innovations, motivation, continuous learning) have a satisfactory level of homogeneity of the variable innovation activities (Table 2).

Table 3. Effect of claims on the Cronbach alpha coefficient (α) of the scale for the variable competitiveness.

Claims	N	α	Total α
Volume of production	100	0,810	0,791
Market share	100	0,704	
Profit	100	0,618	

Based on the values of Cronbach's alpha coefficient it is possible to make a conclusion that the applied measurement scale (production volume, market share, profit) have a satisfactory level of homogeneity of competitiveness variable (Table 3). Therefore, it can be concluded that the odds of internal homogeneity for all of dimensions is satisfying, and based on these dimensions it can form two variables: innovation activities and competitiveness variable.

In order to understand the connection established variables the method of correlation analysis is used to determine the connection type of innovative activities and the competitiveness of enterprises. This method is a bivariate correlation analysis, and is thereby used Spearman 's correlation coefficient. With this method will identify functional connections established variables which will confirm or reject, respecting the existence between the established variables. The value of Spearman 's correlation coefficient ranges in the interval from -1.00 to +1.00. Direction of correlation, indicating that the (- / +) sign, will determine the direction between the variables that may indicate a negative or positive correlation. A values of 0 indicates that no relationship (correlation) does not exist (Pallant, 2010).

To accept the hypothesis of work requires to meet the following:

1. The correlation coefficient is statistically significant at $p < 0.05$;
2. Correlation coefficient is predicted direction.

The obtained Spearman correlation coefficient is 0.840 and indicates a high correlation between the variables, indicating that the strengthening of innovative activities and strengthen the competitiveness of enterprises. In addition, it is measured the correlation between the dimensions of innovative activities and competitiveness.

Table 4. The value of Spearman 's correlation coefficient

		Innovative Actions	Competitiveness
Innovative Actions	Spearman's Correlation Sig. (2-tailed)	1	,840**
Competitiveness	Spearman's Correlation Sig. (2-tailed)		1

**. p <0.05

The obtained Spearman correlation coefficient is 0.840 and indicates a high correlation between the variables, indicating that the strengthening of innovative activities and strengthen the competitiveness of enterprises. In addition, it is measured the correlation between the dimensions of innovative activities and competitiveness.

Table 5. Value Spearman 's correlation coefficient measuring innovative activity and competitiveness.

	Innovation	Continuous learning	Motivation	The volume of production	Market share	Profit
Innovation	1	.770**	.559**	.434**	.532**	.799**
Continuous learning		1	.597**	.487**	.651**	.847**
Motivation			1	.475**	.596**	.628**
Volume of production				1	.395**	.519**
Market share					1	.647**
Profit						1

**. p <0.05

Shaded fields are fields significant correlation values, while others are obtained values are also statistically significant, but fall into the category of medium and low correlations (Table 5).

4. PROPOSED MODEL FOR FACILITATION OF INNOVATIVE ACTIVITIES OF ENTERPRISES

The aim of the study was related to the perception of obstacles managing innovative activities in companies, and the impact of innovative activities on the competitiveness of enterprises. Research has shown that there is a difference in the management of the companies that are innovative-active, and those which are not, and that good governance must have innovative activities for strengthen of competitiveness enterprises. Based on the identified obstacles to managing innovation activities in enterprises, it is necessary to focus on management issues, such as:

How to create conditions for innovative activities which must be continuous process in the company and how it is supported by all employees?

How to develop a behavioral model that defines the behavior of the company in the management of innovative activities on everyday level?

In this regard, it has been proposed a modified model of management innovation activities (Skarzinski and Gibson, 2009) that would motivate employees and contributed the innovative activities on daily basis.

In order to build and maintain the ability for innovative activities, the company should be carefully managed in innovative activities. Under the proposed management model innovation activities it is necessary to strengthen the innovative offer in order to reach as many creative ideas by employees in order to strengthen the innovative offers.

Strengthen innovative demand in a way that older managers were interested to demand creation of employment, improving the innovative demand.

Establish a zone pressure in a way that managers do innovative activities as a priority in their business. As one of the solutions, there is some pressure on managers in terms of: the number of new ideas and the speed with which they come, the master income level of innovative activity, how much time the manager is paid to supporting innovative activities etc.

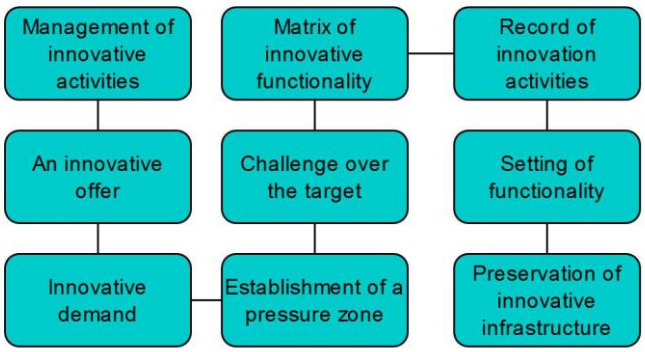

Figure 3. Model Management in innovative activities

To put a challenge above objectives in terms of focusing on unrealized need or solve a consumer of today's global problems, such as pollution or poverty, which can act very inspiring. When employees understand that they are part of the company that wants to create history, not just profits, it can create energy and enthusiasm on employees, and to voluntarily engage in innovative activities.

Establish matrix innovative functionality that is, an efficient system for the measurement of innovative activities and their effectiveness. In this connection it may be proposed modified framework benchmarks for investment flow and measure the results of innovative activities (Table 6) successful company "Whirlpool" (*Skarzinski and Gibson, 2009*).

Table 6. Criteria innovative activities

	Invested assets	Flow	Result
Process	The range of communication networks	The number of new ideas, and pace which progress	The number of innovations in phase experimentation
Management and employees	Percentage of time dedicated to innovative activities	Percentage of employees dedicated to innovative activities	Percentage of trained employees
Efficiency and financing	The percentage of the budget that is allocated for innovative activities	Assessing quality in against targets	Total income from innovative activities

For matrix to be completely functional, process, management and employees, efficiency and financing, must be measurable through invested and realized, that the end result would be to measure the number of innovations in the phase of experimentation, the percentage of skilled workers and the total revenue generated from innovative activities.

Creating record of innovative activities, or database. When company do better and faster to develop a database it makes it better to be able to monitor and evaluate their own innovative capability.

Adjust the functionality of innovative activity in the case: that the company has not sufficiently innovative ideas; to come to "jam" the idea in the midst of the company, or channels, etc. If the above comes to management may decide to:

1. Increasing the number of ideas that arrives through the channel;
2. Increasing the budget for innovative activities;
3. Mild lowering the criteria for passage of ideas, etc.

Preserving innovative infrastructure is priority management. To preserve its innovative enterprise infrastructure should not be compacted innovation in some corner of the company, but to incorporate innovation into every corner of the enterprise, and that innovation is equal to the operational efficiency (*Skarzinski and Gibson, 2009)* ..

Therefore, the present model would be applicable to all companies, regardless of their size. Presented model, which would be developed over time and through experience, it could be a good prerequisite for the successful management of innovative activities.

5. CONCLUSION:

Summarizing all the above it can be concluded that BiH is one of the few countries on whose territory, despite the significant changes that have occurred in the transition countries and global processes that affected the whole world, the management has not taken hold and is completely left out of practice. It is not significantly altered inefficient management system and has not obtained a new quality or new productive forces, similar to that of the management system in enterprises market economy countries. The management have been made only formal innovations, only new institutional control bodies such as the assembly of the shareholders and board of directors. Management companies in BiH is addicted to bureaucratic management employees and the existence of the bureaucratic enterprise. Generally speaking, the companies in B'n'H has not developed an awareness of the importance of the development of innovative activities, which points to the fact that the management company is not a strategic partner with the employees of the company, and does not affect the awareness of employees about the importance of innovative activities. Theoretical and empirical exploring it has been determined, and it is particularly devastating fact that in most enterprises in B'n'H is still present consciousness that creates a successful competitive position by introducing novelty. One way to gain and maintain a competitive advantage must be sought in an appropriate management model of innovative activities and the proposed model in this study may have been a one of the solutions. The model is applicable to all companies that strive to be innovative, regardless of their size. This model, whose development is taught through time and experience, he could be a good prerequisite for the successful management of innovative activities, especially in companies in transition countries such as Bosnia and Herzegovina.

INTERNATIONAL MANAGEMENT

THE IMPORTANCE OF ASIAN CONGLOMERATE BUSINESS MODELS IN INTERNATIONAL MANAGEMENT

Abstract: *This paper analyzes the prominent Asian conglomerate business models in terms of contemporary international management. The paper examines their specific characteristics and contribution to increasing the competitiveness and export performance. It also reviews current and future importance of business networking in practice, with special reference to the conditions of discontinuity. The emphasis is on the significance of the implications of the Asian management in the development of conglomerates and independent business entities within them. It has been shown that important business models in the Asian market with its existence shape the conditions of profit making and the course of regional integrations. The paper displays the results of studies of Asian management and its importance for the improvement of the position of Asian conglomerates in the global market. The innovativeness of Asian management is also important as it contributes to companies' success in international business with its specific knowledge and methods. The focus is on the management of international activities and prospects of the global success of Asian business groups. Practical examples provide insight into the most important advantages that characterize the Asian conglomerate business models in the context of comparative management.*

Key words: *Asian conglomerate business models, International management, Business groups, Export, Competitiveness*.

1. INTRODUCTION

The complex business environment in Asia requires timely optimal business decision making in order to achieve planned economic results of operations. The current environment demands a flexible adaptation to new international markets, due to the existence of different quality and quantity of important resources, such as knowledge, capital and technology. Management of these resources is the key to the future and sustainable development of Asian companies. Bearing in mind that the given conditions are followed by increasing fluctuations within the aggregate supply and demand, and the different needs of consumers, Asian markets require a modified approach to the creation of the business model. Based on this, it can be concluded that the modelling of business ventures has to be founded primarilly on innovation. New business models in Asia can be viewed as parts of the business system, consisting of a series of interdependent links, thus creating an advantage and making competitive business viable (Mayo & Brown, 1999).

Models of modern business networking in Asia realistically reflect the growing economic prosperity of the Asian economies. The use of business opportunities to create value for consumers is visible in applying specific management skills in practice. There is a trend of business process improvement, with the aim of generating profits with the help of synergistic effects of knowledge, capital and information.

The analysis of specific characteristics of conglomerates and business groups in Asia requires exploration of the entire social and economic environment of enterprises, which is reflected in the decision making processes of managers. The impact of cultural heritage and its consequences for the management structure provide a broader picture of the reasons for the creation of innovative approaches to business. A distinctive holistic approach is featuring along with the connections with traditional values of society on the one hand and focus on future business success at the international level on the other. Multidisciplinary nature points to the continuous need of Asian management for improvement and enhancement of business processes, while achieving efficiency and developing knowledge management. The existence of business groups contributes to the success of regional integrations and acts as an important factor of achieved macroeconomic performance and enhanced competitiveness.

[2] This paper includes the research results of the author realized on Project No. 179081 financed by the Ministry of Education, Science and Technology development of the Republic of Serbia

2. CHARACTERISTICS OF ASIAN CONGLOMERATE BUSINESS MODELS

Business groups in Asia start from a competitive performance in the market, with the development of strong business relationships with multinational corporations abroad. Their essential characteristics are diversification of production and centralized control. In the modern international management, they are associated with the specifics of the Asian management and the centuries-old tradition of culture that ultimately resulted in the formation of hierarchical structures largely based on the age and experience of managers.

Some authors (Almeida & Wolfenzon, 2006) emphasize the family management of firms in business groups as a major difference compared to other conglomerate companies in the world. Business groups are characterized by the operation of separate business entities that are under the same ownership and work with the unique control. The high degree of independence and domestic market imperfections promote economies of scale and incremental growth of innovation, contributing to long-term success in international business.

The achieved results are largely attributed to specific managerial skills, unique, original business models and development of new methods of management. For our analysis, especially important business groups in terms of the specifics of doing business in the modern practice of international management are *chaebol* groups in the Republic of Korea, conglomerate companies *qiye jituan* in the People's Republic of China, the *business houses* in India and *keiretsu* in Japan.

The sales of *chaebol* business groups are equal to about 75% of Korea's GDP (gross domestic product) (Colpan, Hikino, & Lincoln, 2010). These groups are the main drivers of innovation in Korea, significant in terms of international competitiveness, as well as a great strength of the economic prosperity of the state. Their characteristics are management of companies in accordance with paternalism, and in some cases a lack of transparency of information. Development of *chaebol* groups has a crucial impact on total exports and future course of economic development of Korea. Continuous changes in the external business environment impose detailed analyses of the functioning of the *chaebol*, as a factor of shaping the social, economic, cultural, and technological components of the entire Korean society. The challenge of testing the responsibility delegation functions and the creation of new management processes in the business of *chaebol* consists of defining the modified business paradigm that will serve the next generation of managers as a basis for decision making.

By applying the reformed regulations and rules, transparent operations and increasing the number of specific skills, the management of *chaebol* calls for the harmonization of the existing system and the new model of international business. The mechanism of the high degree of state intervention, present since 1950s of the twentieth century, involves a hybrid form of close cooperation between the public and private sectors in the Republic of Korea. The impact of modern business models of companies in *chaebol* groups depends precisely on the market deregulation and mutual cooperation with major international corporations. The liberalization of markets, the increased level of competitiveness of enterprises and generating new business strategies affect the need for a smaller share of the instruments of state action, with an increasing emphasis on the sustainability of the business model of *chaebol*. Sustainable management integration has increased by 25% over the period of 2007-2012, as a result of a better distribution of responsibilities, increased investment in research & development and investments in sustainable business opportunities (Solability, 2013). Internal management strategy called New Venture Units (NVU) focuses on the replication ideas of start-ups business model in context of existing firms (Kim, Bae, & Bruton, 2012). The growing interest of *chaebol* managers for innovative solutions arising from the internal business environment makes NVU a new foothold of innovation development, as the main reason for the huge success of these business groups in international business.

According to the (International Chamber of Commerce, 2013**)**, based on the Open Markets Index, the Republic of Korea is ranked at the 45th place out of 75 countries, with a score of 3.6 (on a scale of 1 to 6). Notwithstanding its rank, according to the market openness, among the G20 countries, the intensity of local competition, according to which the Republic of Korea takes the eighth place out of 189 countries, indicates the negotiating power of the *chaebol* management and competitive strength they possess and in foreign markets (Schwab & World Economic Forum, 2013). Outsourcing in the stage of interorganizational actions of the company has an increased participation, where *chaebol* groups position their production processes in the countries of the region. Capital capabilities and effective human resources management provide an impressive level of absorptive capacity of the *chaebol* in the case of the global economic crisis. Continuous

improvement of cohesive business policy, which respects the principles of successful corporate governance, contributes to the preservation of the economic power of *chaebol* in global terms.

Paternalistic, authoritarian management style is associated with a high degree of nepotism in the *chaebol*, which proved to be economically efficient, given the presented work ethic, with respecting traditional and family values. The family is the initial reason for the existence of these groups, which is suggested by the term *chaebol*, which is a specific combination of two words "wealth (*chae*) and family (*bol*)." In the long run, vertical integration and operation within the internal market reduces transaction costs and promotes a more efficient allocation of resources between two associated enterprises (Murillo & Sung, 2013). The emphasis is on the synergy of specific knowledge, diversification of investment and attitude to business risk.

"Top 30" *chaebol* groups have an obvious role of a leading force in the economy of the Republic of Korea. (Moskalev & Park, 2010). Sustainability of business with own financial and technical resources contributes to *chaebol* groups competitiveness in international business. Solutions for global challenges faced by top management are found in the redistribution of equity, more efficient monitoring by the banks, a greater share of external markets in their business, with the aim of greater placement of the final products (Choe & Pattnaik, 2007). Equal distribution of wealth and the internationalization of business of small *chaebol* group members (*kyeyol* companies) are cited as key future strategic orientation, due to the increased geographic dispersion of distribution, growth of foreign competition and the importance of price competitiveness.

Internal monitoring and operation on the principle of holding companies is gradually adapting to the growing demands for a holistic, institutional management system in accordance with moral norms and beliefs of individuals. Reorientation of business towards technologically advanced products strengthens the interaction between managers and communication, given that the top management has the authority but not all of the relevant information, while the middle and lower management has the necessary information, but not the authority to implement them. The emphasis is on improving the management through changes of the existing business model in order to achieve the desired success and future economic prosperity of the Republic of Korea (Park, Shin, & Suh, 2008).

Building on the model of the future challenges of *chaebol* business groups, comparable to them are the basic principles of management of *qiye jituan* conglomerate companies in the People's Republic of China, that in the mid-1990s became an important form of doing business. *Jituan* business groups emerged from many state regulations and laws adapted to the creation of new conglomerates, which was expected to comprehensively incite the whole Chinese economy. Business ventures of Chinese *jituan* are mainly centralized, primarily stemming from the parent company to the subsidiary companies ("children" companies), in which the mother company owns a majority share in the property (Lu & Yao, 2006). With this multilayered management structure *jituan* is able to control a large number of partner companies, which is why diversification is a popular strategy aiming to achieve progressive development. Specific approach to managing complex *jituan* groups stems from deep-rooted Chinese cultural norms, based on which the business associations are achieved primarily through a personal relationship of managers (*guanxi management*). According to Chinese business customs, security of basic resources necessary for existence should be consolidated with a large network of *renqing* (exchange of private services among employees, manager empathy) and *mianzi* (face, reputation and honor of the individual) (Su, Mitchell, & Sirgy, 2007). The given principles are largely responsible for the extensive system of loans within the Chinese business groups, which continue to operate externally and shape other economic activities in the country. Quantitative analyses showed that the higher the interaction of managers within *guanxi*, the greater the rate of profitability and productivity of a company (Keister, 2000). On the downside, it is noted that the connections between *guanxi* managements hinders the implementation of acquisitions and spin-off of the business group members.

Intervention of the authorities and direct participation in decision-making arises, due to the implementation of the objectives of international management, the need for the division of Chinese business groups in terms of public and private property, in order to choose an adequate strategic approach to business. These two groups of companies primarily differ in the degree of diversification in the later stages of the life cycle of the company, where private Chinese business group are highly diversified, thus becoming a key factor in organizational mosaic of management in East Asia (Carney & Gedajlovic, 2003). The size of conglomerate Chinese companies gives them an advantage in the process of financing, and there are common examples of business groups establishing their own financial institutions, similar to those around which the processes are organized in the Japanese *keiretsu* groups (He, Mao, Rui, & Zha, 2013). National business groups in China are particularly effective in the sector of control of the group capital and distributing the final products. Increasingly present and incremental is the transformation into hybrid forms of business of conglomerates, connecting public and private sector and taking advantage of bilateral dependence in terms of economic

transition (Nee, 1992). Inefficiency can arise in case of frequent attempts of the state to use microinterventions to affect the decision-making of the management (Nee, 1992).

There is a tendency to reduce the influence of the state over *jituan* to a less extensive administration and partial control of the parent company of the conglomerate, which is considered to be a major step towards market economy and liberalization of trade in goods and services. According to (Keister, 2000), special attention should be directed towards analysis of the interdependence of government regulations and economic performance of conglomerate companies in China.

Dynamic collectivism, as a consequence of the philosophical values of Confucianism, contributes to the accumulation of firm specific knowledge within the Chinese business groups. Power of the Chinese management, resulting from the egalitarian collectivism and consensus-based decision-making, makes the model of business groups in China adequate for fast-changing markets in Eastern Asia. Vertical collectivism, as a still prevalent form of governance, shows a degree of inefficiency, which is indicated by the ranking of the People's Republic of China at the 60th position out of 189 countries included in the analysis, according to the willingness to delegate authority (Schwab & World Economic Forum, 2013). However, in the long run, both horizontal and vertical collectivism create a relationship of trust between companies and customers (Romar, 2004) and form the basis for moral reasoning of managers. Rule of law (*fa zhi*) serves as a framework for the design of structural change of groups and their strategic orientation of business relationships (Wang, Wang, Ruona, & Rojewski, 2005). Competitiveness of member companies of Chinese *jituan* pertains to the specific management initiatives, creativity and interpersonal cooperation of which improve the model of Chinese business groups. In the context of sustainable development in contemporary Chinese management, special attention is paid to corporate social responsibility (Milicevic, Lovric, & Markovic, 2012).

The emergence of complex business systems in India called *business houses*, as insufficiently tested models in the practice of international management, implies the importance of business networking in Asia. The diversity of the business portfolio and focus of financial resources to conglomerate core business support the expansion of the *business houses* in the restrictive business environment of India (Manikutty, 2000). Structure of business houses model, in a way similar to *chaebol* groups in the Republic of Korea, can set conceptual obstacles in improving management and timely implementation of business plans and make it difficult to allocate industry-specific resources, mainly inflexible and nonfungible (Colpan, Hikino, & Lincoln, 2010).

“Persons Acting in Concert” (PACs) represents individuals, companies or other legal entities through which the controlling shareholders may indirectly control affiliate companies (Colpan, Hikino, & Lincoln, 2010). The importance of the PACs for business is visible in the fact that the direct ownership of the family members of the owner of the *business houses* in India is very small, so in the company Reliance Industries it is only 0.75%, while in the Tata group it is not registered (Colpan, Hikino, & Lincoln, 2010).

Some authors (Khanna & Palepu, 2000) find that *business houses* in India by focusing on the strategy of unrelated diversification can fill institutional gaps and use their own capacity to play a key role in business ventures. However, while unrelated diversification would be an adequate response of optimal development in regulated market conditions, the Indian market deregulation allows groups to choose a route based on the use of the current opportunities, with the help of the core competences. When the capacities limit is reached, *business houses* expand their activities by signing license agreements with companies from industrial sectors that are not related to their primary group business (Nayyar, 2008). In the period after the implementation of the so-called "Second Wave" reforms, investments of Indian *business houses* largely turned to developed countries, promoting global competitiveness by geographical refocusing and changing the sector composition. Due to the saturation of demand and globalization of business trends, *business houses* are more concentrated on the production of technologically advanced products and marketing opportunities, with the possible neglect of generic resources within the group (Guillen, 2000). Effective management of international activities and turning towards capital-intensive industries make Indian business houses important global competitors. They also become a leader among developing countries in the number of mergers and acquisitions executed annually (Nayyar, 2008).

A comparative analysis conducted in 2006 shows that the company, members of business groups in India, were six times larger in terms of sales profits than stand-alone firms, and four times larger in terms of their overall assets (Colpan, Hikino, & Lincoln, 2010). Data analysis suggests taking advantage of economies of scale. Efficiency is reflected in the high turnover ratio of stocks, lower production costs and a higher rate of return, giving a strong negotiating power to management in India. Managers of business houses have a parental role, for which the Indian term is *mai- baap* (mother - father) business management (Goyal, 2012).

Thus, the top management also has a high reputation in international activities, where it implements important decisions based on competence and social equality of employees, which is particularly highlighted in the Indian conglomerate. A pragmatic approach to solving problems gives them the freedom resulting from the control of the business processes of the group, thus initiating the growth and indirectly influencing the improvement of the market mechanism.

Japanese *keiretsu* conglomerate groups consist of technologically superior companies in the Asian market. Business-oriented and financially concentrated around the major Japanese banks, *keiretsu* use the advantage of the positioning of its production facilities in the markets of neighboring countries, as indicated by the fact that they accounted for about 40% of all foreign direct investment of Japan in Asia (Peng, Lee, & Tan, 2001). *Keiretsu* systems are divided into horizontal and vertical, suggesting great heterogeneity of the organizational structure of Japanese conglomerates. Vertical *keiretsu* consists mainly of manufacturing companies and their subcontractors, where upstream suppliers and downstream distributors share the total costs of joint ventures (Lin, 2005). Common equity and close relationships among suppliers reduce transaction costs, promote better coordination and create long-term relationships of cooperation (Matsuura, Pollitt, Takada, & Tanaka, 2003). The combination of autocracy at the conglomerate level and a high degree of autonomy within the company strengthens the ability to create information and transition efficiency of the vertical *keiretsu* in the planning process and reciprocal monitoring of companies, during business internationalization process (Aoki, 1990). Intra-group information spillovers enhance innovation in member companies, and thereby enhance their business success (Lincoln, 2009).

Horizontal *keiretsu*, on the other hand, is based on a lesser degree of hierarchical structures, frequent informal bottom-up management interactions and the formation of the business core, generally of a bank or trading company, which provides financial support to conglomerate (Peng, Lee, & Tan, 2001). It is composed of companies from various industrial sectors, whose management makes independent decisions and shapes the policies *keiretsu* by equal rights (Lai, 1999).

The management of *keiretsu* conglomerates is characterized by the decision to establish long-term, flexible contracts with employees, frequent communication, reducing information asymmetry and specialized investments. The main source of competitiveness of *keiretsu* is its capability to generate extremely high profit margins through joint contributions of the member companies individually specialized for a particular business segment in the chain of production (McGuire & Dow, 2009). The power of *keiretsu* groups establishes the basis for secure business environment, promotes research and development and prevents destabilization of the economic development of the country, resulting in the generation of technological fusion in the Japanese market. Significant competitive advantage derives from the possession of rare, valuable and hard to imitate assets, which have the power to create great added value for the company during the initial stages of entering the foreign market (Peng, Lee, & Tan, 2001). The prominent internal control of *keiretsu* companies, one of the main features of their management, significantly increases productivity by using specific mechanisms and skills, which in practice proved to be very successful (Lai, 1999).

Total commitment to achieving the goal of reducing inventory costs and operating in accordance with the principle of zero inventory is what makes business management techniques of *keiretsu* one of the most efficient in the framework of international management. Special attention is devoted to teamwork, lateral communication and cyclic distribution of labor, according to which employees are trained to perform several different tasks (Wireman, 2004). *Anshin* management concept, which is literally translated as "peace of mind", is based on the establishment of trust between suppliers and manufacturers and a large investment of time and effort in establishing long-term business partnerships (Aoki & Lennerfors, 2013). Applying homogenization of management activities and promoting cooperation between companies, *keiretsu* groups skillfully combine traditional business values and the demanding requirements of the international aspects of business, thus positioning itself as a leader in cost- efficiency and productivity in the Asian market. Impact of the success of *keiretsu* companies in the Japanese economy is unambiguous. Thus, according to (International Chamber of Commerce, 2013), Japan is ranked as number 1 in the enhancement of production processes and the intensity of local competition, in the analysis that included 189 countries.

3. ASIAN CONGLOMERATES IN CONTEMPORARY INTERNATIONAL MANAGEMENT

Haier Group, a Chinese conglomerate group *jituan*, succeeded in a relatively short period of time since its establishment in 1984 to create a reputation of a highly efficient manufacturer of quality consumer electronics and home appliances. The strategy of internationalization of Haier Group is comprised primarily of the operation on the principle of Uppsala model, by successive greater physic distance and expansion of

products range in the early stage of export of products in developing countries, by forming a joint venture with local business partners. The goal of the management is to market the products whose brand is recognized worldwide, but with adaptation to the specific needs of consumers. In the markets of developed countries, business is started with low-end items by applying extender strategy of penetration pricing and then, by gradually building trust with users, the aim is to ensure competitiveness in the high-end consumer products sector (Duysters, Jacob, Lemmens, & Jintian, 2009). By emplying Dodger strategy of transfer of international competitive assets back to the domestic market, Haier Group avoids direct confrontation with immediate competitors and establishes technology alliances with the competition, as well as with global conglomerates in other industrial sectors. By "rural" and "green" strategies Haier Group has developed a large network of energy-efficient operations in rural areas of China, becoming a leader in this field since 2009 till today, which is a great foundation for testing different market segments (Chan, 2011).

Samsung Group, a globally renowned Korean conglomerate group, consists of more than 60 affiliate companies, the largest being Samsung Engineering, Samsung Heavy Industries, Samsung Medical Center and Samsung Electronics. Parental role of Samsung's headquarters is very present. An example of a particularly successful company within this conglomerate group is Samsung Electronics, which has made great progress in manufacturing technology components, which to them are cash-cow products (Rim, 2007). The strategy of expansion by extensions of partnerships and conquest of peripheral markets has allowed Samsung to become the leader in the memory chip industry, already after the first 10 years of operation (Mathews, 2006). Investment in research and development as a key to achieving sustainable competitiveness are substantial. The Samsung Advanced Institute of Technology as Samsung Group's R&D Hub has been established.

LG Group is characterized by an extremely complex network of business and dominance in emerging markets such as India, Indonesia and Brazil. Fields of activity of this conglomerate are primarily electronic industry (LG Electronics), chemical industry (LG Chem) and telecommunication industry (LG Uplus). Out of the total investment, significant funds are allocated to research & development, which is the main reason for its rising dominance in the sector of LED (Light- emiting diode) technology as a key innovation in the group. By increasing production capacity as a survival strategy, LG Group maximize economies of scale. Applying the tactic of aggressive internationalization through mergers and joint ventures, LG has become one of the world's most competitive business groups. By increasing the quality of the final product, LG becomes the best "value for money" competitor (Choe & Pattnaik, 2007). "Top - tier" strategy of sustainable competitive advantages enables LG Group to set the market standards in understanding what really needs to be done in order to create a balance between cost-efficiency and meeting the specific needs of the user (Choe & Pattnaik, 2007).

Reliance Industries Limited business house is the second company by income level in India. Business model of this business group gives a realistic picture of the advantages of the complex structure of a company and the benefits of intra - industry trade in goods, reducing transportation costs and inventory turnover ratio, as two important factors in the business sector of the petroleum industry. By backward vertical integrated management strategy of procurement of raw materials within the group, Reliance reduces costs for the amount of import duties and creates a sustainable business model, which is indicated by the fact that 2012 export of this business house had a share of even 14% of the overall exports of India (Reliance Industries Limited, 2013). The resiliance of the business model in the period of uncertainty and rapid changes results from the leadership in innovation and turning towards renewable energy sources, especially *jatropha curcas* biofuel production model, including sources of competitiveness, such as reducing greenhouse gas emissions and longer productive life of installed production plants (Pandey, Singh, Singh, Kumar, Singh, & Singh, 2012).

Tata Group has a long business tradition. Today, this renowned Indian business house is operating with more than 100 global affiliate companies in various sectors, including the sector of information and communication technologies, engineering, energy, automotive, chemical and other industries. Large companies that make up the Tata Group are: Tata Steel, Tata Motors, Tata Consultancy Services, Tata Power, Tata Chemicals, Tata Communications and Tata Beverages. The impetus of creative ideas and innovative solutions has resulted in the emergence of Business Excellence Model, where Tata Group views each subsidiary as a center of excellence, which decentralizes responsibility and accelerates the process of generating new business plans (Tata Group, 2013). Managerial competence within the group requires the formation of teams of experts, who continue to manage demanding operations abroad. Purchasing luxury brands such as Jaguar and Land Rover, Tata Group acquires significant market share in developed countries and know-how. A large part of its business activities is turned to the internationalization of business, with a strong focus on branding all product lines. Orientation towards business philanthropy is prominent.

An example of a successful horizontal *keiretsu* is a Mitsubishi Group, a part of which is also one of the six major banks of Japan, The Bank of Tokyo - Mitsubishi UFJ, Ltd., around which the operations of many other *keiretsu* groups are centred. Mitsubishi Group operates on the principle of management without a parental company, applying flexible strategy of high degree of unrelated diversification. Code of conduct and review of the development of individual management skills arising from collectivism puts the work ethic to the forefront of management. Respect for cultural heritage and a specific business model contributed to the international competitiveness of the Mitsubishi Group. The *"Shoki Hoko"* concept of corporate social responsibility, *"Shoji Komei"* concept of integrity and honesty, *"Ritsugyo Boeki"* the concept of expanding the business internationally represent the three basic principles of business philosophy that are the mainstay of integrated business chain of continuous customer satisfaction (Mitsubishi Corporation, 2012).

4. CONCLUSION

Analysis indicated the specificity of Asian conglomerate business models and confirmed the importance of effective management in terms of increasing competitiveness of the conglomerates in global business, the actions of which reflect the macroeconomic situation of individual countries. A prominent feature is the strategic orientation to stable operation and long-term development, with the implementation of sustainable growth components. Results and achievements on the level of business groups are reflected in the further development of the Asian economies. The conglomerates are expected to continue in the future to improve competitiveness at the global level through effective implementation of specific management models and techniques, as distinguishing features of Asian management.

Reform and harmonization of the decision making process with international trends represent a challenge and an opportunity for Asian conglomerates to expand their operations in highly developed countries, starting with the benefits of development of production processes in technologically advanced economies of Asia. The close connection between business, social and economic environment in Asia foregrounds the importance of strategic management decisions. The degree of government intervention, control and financial support must be seen from the aspect of increasing the business performance of networked companies.

Business trends in the global environment show that the business of conglomerates has a positive effect on the course of development of the Asian economies. In the international management particularly prominent are the achievements of the presented Asian companies in many sectors. Future role of Asian conglomerates is important from the perspective of sustainable competitiveness in a global context.

Abstract: *In the global economy there are movements of capital from one to other countries. For the countries which carry out economic reforms, inflows of foreign direct investments (FDI) are important for achieving better economic performances. There are various research papers about the influence of FDI on the economic growth. The aim of this paper is to analyze the influence of FDI on gross domestic product (GDP), exports and unemployment in the Republic of Serbia from 2000 to 2012. The method used is linear regression applied on the World Bank data and the Statistical Office of the Republic of Serbia data. For the period of 2000-2012, the results show that there is no linear correlation between FDI and GDP per capita, exports and unemployment. The economic crisis has worsened the already poor economic situation in Serbia. For the period before the global economic crisis (2000-2007) the obtained results show that there is a strong positive correlation between FDI and GDP per capita, FDI and exports, FDI and unemployment.*

Keywords*: foreign direct investments, economic growth, gross domestic product, exports, unemployment, the Republic of Serbia*

1. INTRODUCTION

When trends of capital exports are analyzed, it is necessary to take into consideration the global economy, global markets and global competition. Exportation of capital from one to another country represents the investment of capital into the economic development of another country. The process of exportation of capital is carried out in order to realize higher profits from such investments than the profits gained from investing into domestic market. The capital moves to the regions where higher profits are expected. Investors invest in lucrative opportunities and possibilities for avoiding risks. Natural resources, large domestic markets and lower production costs are a few attractive factors for investment. The movements of capital from one country to another could be observed from various aspects. The main and the most important classification implies two forms of capital exports: investments and loans. When deciding on investment of capital according to the above given classification, the basic criteria is the difference in profits or dividends if the capital is used for investing, i.e. the amount of interest if the capital is used for giving loans.

Of all types of capital flows, foreign direct investment is generally considered to be the most desirable. Capital inflows such as bank loans and bond funds tend to crowd out domestic investment; however FDI tends to increase the national investment in the equal amount. In today's globally competitive environment, attracting foreign direct investments is one of the top issues for most countries, and especially for the countries which carry out economic reforms. FDI has the potential to generate employment, raise productivity, transfer technology, increase exports and contribute to the overall economic development. Due to that fact, all countries try to improve many factors and policies that have influence on attracting foreign investors. There are different studies that show FDI has a positive effect on the economy (Borensztein et al., 1998; Campos and Kinoshita, 2002; Makki and Somwaru, 2004; Alguacil et al., 2011; Giroud et al., 2012) while also there are researches whose standpoint is that FDI has a negative effect on the economic growth and other economic variables (Hermes and Lensink, 2003; Stanisic, 2008; Doytch and Uctum, 2011).

The aim of this paper is to analyze the impact of foreign direct investment on the economic growth of the Republic of Serbia. The research has been conducted as an analysis of the influence of FDI on GDP, exports and unemployment in Serbia from 2000 to 2012. The method which was used is linear correlation conducted on the World Bank data and the Statistical Office of the Republic of Serbia data.

The paper is structured in five chapters. After the introduction, the second chapter offers an overview of the Serbian economy. The third chapter delivers applied methodology which describes the influence of FDI on the economic growth in the Republic the Serbia from 2000 to 2012. The next chapter gives an overview of the research results, while the last chapter reserved for the conclusion.

2. OVERVIEW OF THE SERBIAN ECONOMY (2000-2012)

Year 2000 is determined as the real beginning of economic reforms in Serbia and at the very start economic growth was present. Production growth in Serbia has been explained by the following factors: a) before 2000 Serbia already had a market-based economy, b) there was macroeconomic stability present, which improved business environment and helped achieve economic growth, c) the country received foreign support and donations (at the end of October 2000), and d) the UN sanctions had been lifted (Begovic et al., 2005). The reforms were implemented quickly. The expansionary fiscal policy and tight monetary policy were the main tools for developing better economic environment. A large number of enterprise privatizations was performed. The banking system, as a sector with a large inflow of foreign capital, was reformed as well. In addition, Serbia received numerous foreign grants and aid. The lack of savings and domestic capital slowed down further reforms and the ability to finance consumption and investment. In that situation, the solution was the inflow of foreign capital, especially foreign direct investments. Foreign capital had a role in achieving Serbian economic growth. Since then, FDI is considered an essential factor in starting production and realizing economic growth.

According to the Development Report of Serbia 2010 (2011), the economic growth of Serbia is based on domestic demand, import and the need for foreign funds. In the period 2001-2008 the average rate of economic growth was 4.9%. The achieved economic growth was a consequence of the process of undergoing economic and social policy changes, institutional reforms and the favorable environment in the international capital market (Đorđević and Veselinović, 2010). However, Serbia established a new model of growth. The new growth model was changed to pro-investment strategy and export-oriented economic growth. The new growth is based on the reform of the public sector, restructuring and infrastructure development. The main objectives of this model are correlated with the EU's goals – decrease of unemployment, human capital improvement, investing in knowledge and technology, export-based growth, rational energy use and poverty reduction. Accomplishing such objectives depends on – fixed investment increase, reducing the share of public consumption in GDP, raising the share of exports in GDP and reducing the current account deficit (Jednak et al., 2013). Although Serbia implemented the new model of economic growth, the rise in production output was not achieved. The possible reasons could be the lack of domestic capital, less foreign investments in comparison with the 2000s due to the global economic crisis, previous unstable political and business environment, insufficiently developed institutions, small domestic market or the distance from investing countries (Erstin and Uvalic, 2013). Further on, the exports are not high enough because the most investments are made the service sector which does not have a large share in the Serbian exports. During the time period 2000 – 2012, the FDI in Serbia had a different volume and trend. The most inflows of FDI were through the privatization and acquisitions in the banking sector, while the greenfield investments were very low.

Merlevede and Schoors (2009) analyzed the FDI inflow in 10 transitional economies and found that the FDI inflow in those countries is primarily affected by the used models of enterprise privatization. The study demonstrated that the countries which mainly used models of internal privatization and free distribution of stock to their citizens, attracted significantly less investments than the countries whose privatization was largely based on the external model.

The highest inflows of FDI were at the beginning of the analyzed period and in 2006 (mostly due to FDI in the telecommunications sector), while the declines of FDI were in 2004, 2008 and 2009. Total net FDI during the entire period amounted to about €15.1 billion (2001-2011). Foreign investors invested in Serbia in the following sectors - services sector (trade, banking, telecommunications, distribution of petroleum products, tourism) and production sector (beer, beverage, tobacco, food and metal and non-metals industry). The highest inflows of FDI came from Austria, Norway, Germany, Luxemburg, Greece, the Netherlands, Italy, Russia, Slovenia and Hungary. The highest foreign investments in Serbia (2001-2011) are Telenor (€ 1602 EUR mil), Gazprom Neft – NIS (€ 947 mil), Fiat Serbia (€940 mil), Delhaize (€933 mil), Philip Morris DIN (€733 mil), Stada – Hemofarm (€650 mil), Mobilkom – VIP Mobile (€633 mil), Agrokor (€614 mil), Banca Intesa (€508 mil), Salford Investment Fund (€500 mil), Eurobank EFG (€500 mil), Raiffeisen bank (€500 mil), Mercator (€500 mil) and StarBev – Apatin Brewery (€487 mil) (Business info group, 2012). Even though the inflows of foreign capital have been present in Serbia, the country's economy has not always had good economic performance. FDI had a direct and an indirect impact on economic activities in Serbia. Moreover, various investments had a different time of realization and influence on the output increase. Due to this fact, there is some difference between FDI and GDP. Based on this overview, the correlations between FDI and GDP, exports and unemployment will be analyzed in the following sections of the paper.

3. METHODOLOGY AND DATA

This paper is based on applied methodology and research carried out in the previous period in the Republic of Serbia (Šabić et al., 2012; Jaćimović et al., 2013). A survey conducted in 2012 (Šabić et al., 2012) found a high correlation between FDI inflows and GDP and between GDP inflows and exports, while the linear correlation between FDI inflows and the unemployment rate was very low for the time period of 2000 to 2010.

Jaćimović et al. (2013) conducted a linear regression analysis of the dependence of imports and exports of goods and services and the growth of GDP per capita from FDI inflows. Time period taken into consideration by this research is from 1995 and ends with 2011. The inflow of FDI was the independent variable, while the dependent variables were the import and export of goods and services and GDP per capita. This study led to several conclusions: 1) There is a strong linear correlation between these variables; 2) Albania has the highest influence of FDI on the dependent variables; 3) Bosnia and Herzegovina has the lowest degree of correlation between variables; 4) The impact of FDI inflow on GDP per capita is the lowest in Macedonia. However, the shortcoming of the research lies in the low statistical reliability of the used method. This is due to the fact that the only reliable correlation between the variables is identified in the case of Albania, where we can see that €1 million of FDI inflow leads to an increase in exports of €3.56 million, the growth of imports of €5.73 million and the growth of GDP per capita by $4.3. In all other cases, R^2 is lower than 0.5 which makes it impossible to analyze the remaining SEE countries. The authors distance themselves from the results and suggest different effects of the global economic crisis on the analyzed countries as the reason for these results.

In this paper, the Inward FDI Performance Index was calculated for the period from 2000 to 2012. Subsequently, the linear correlation between FDI inflow and GDP per capita, FDI inflow and exports of goods and services and FDI inflow and the unemployment rate for the same time period were analyzed.

Inward FDI Performance Index ranks countries according to FDI inflows based on their economic strength (measured by GDP level). The index is calculated using Equation 1:

$$\frac{FDI_i / FDI_w}{GDP_i / GDP_w}$$

where FDI_i represents the FDI inflow for the observed country, FDI_w represents the total amount of FDI in the world, GDP_i represents the GDP of the country observed and GDP_w the total world GDP.

If the index value is greater than one, it indicates that the country attracted more FDI than it contributed to the total global production (measured by GDP) and vice versa in the case when the index is lower than one. The Inward FDI Performance Index measures the country's attractiveness for foreign direct investment according to its market size, while other factors are considered to be of equal importance. Other factors may be various: political and economic stability, the presence of natural resources, development of infrastructure, business environment, opportunities for participation within the privatization process and similar (Bandura, 2005).

Pearson's coefficient of simple linear correlation will be used for measuring the degree of concurrence between: (1) FDI (x) and GDP per capita (y); (2) FDI (x) and exports of goods and services (y), and (3) FDI (x) and the unemployment rate (y) in Serbia for the time period 2000-2012. The standard formula for calculating Pearson's coefficient is used:

$$\frac{\sum_{i=1}^{n}(x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{n}(x_i - \bar{x})^2}\sqrt{\sum_{i=1}^{n}(y_i - \bar{y})^2}}$$

To simplify the interpretation, the coefficient of determination R^2, which represents the squared value of Pearson's coefficient, will also be used. The determination coefficient measures the degree of the variance of the two variables which is common, in other words, we examine the common part of the FDI variance and a) GDP per capita, b) exports of goods and services, and c) the unemployment rate in Serbia for the observed period of 2000-2012.

Data on FDI and unemployment rates are downloaded from the database of the World Bank, while data on GDP, GDP per capita and exports of goods and services was obtained from the sources of the Statistical Office of the Republic of Serbia. The data was analyzed using statistical software package IBM SPSS

Statistics 22. It was used to calculate the previously explained Pearson's coefficient of linear dependence. The Inward FDI Performance Index for Serbia for the period 2000-2012 was calculated based on the data obtained from the World Bank.

4. RESULTS AND DISCUSSION

The Inward FDI Performance Index for the observed period demonstrates different values by years (Table 1), so it can't be claimed that a trend in FDI inflows exists. The index has the minimum value in the first (2000), as well as in the last analyzed year (2012). The index value is also lower than 1 in 2001. In all other observed years, the index exceeds the value 1, indicating that Serbia attracted more FDI in relation to its economic strength in global terms, measured by domestic GDP share in world GDP. The highest value of the index is realized in 2006 (5,00) and 2003 (4,78).

Table 1: Inward FDI Performance Index for the Republic of Serbia (2000-2012)

Year	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012
Inward FDI Performance Index	0.06	0.70	2.02	4.78	2.58	2.72	5.00	2.01	1.77	2.42	1.69	2.54	0.60

Based on the data, Pearson's correlation coefficient was calculated and the results are shown in Table 2.

Table 2: Correlations between FDI net inflow and exports of goods and services, GDP per capita, unemployment rate (2000-2012)

		FDI net inflow	Exports of goods and services	GDP per capita	Unemployment rate
FDI net inflow	Pearson Correlation	1	.446	.492	.488
	Sig. (2-tailed)		.127	.088	.091
	N	13	13	13	13

Based on the obtained results, it can be concluded that there is no statistically significant correlation between FDI and exports of goods and services (R^2=0,199); FDI and GDP per capita (R^2=0,242) and FDI and the unemployment rate (R^2=0,238). These results imply that there is no influence of FDI on the basic macroeconomic indicators and the economic growth in Serbia. The reasons for this can be found in the impact of the global economic crisis on the Serbian economy and the significant decline of all macroeconomic indicators.

To comprehend whether the global economic crisis had an impact on the relationship between FDI and economic growth in Serbia, the analyzed period of 2000-2012 was divided into two sub-periods: the period before the global economic crisis from 2000 to 2007 and the period after the global economic crisis from 2008 to 2012.

The obtained results for the first sub-period are shown in Table 3. The results are considerably different from the results for the whole given period.

Table 3: Correlations between FDI net inflow and exports of goods and services, GDP per capita and unemployment rate (2000-2007)

		FDI net inflow 2000-2007	Exports of goods and services 2000-	GDP per capita 2000-	Unemployment rate 2000-2007
FDI net inflow 2000-2007	Pearson Correlation	1	.870**	.743*	.792*
	Sig. (2-tailed)		.005	.035	.019
	N	8	8	8	8

**. Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed).

The correlation between FDI and exports of goods and services is statistically significant at $p<0.01$, while the linear correlation between FDI and GDP per capita and FDI and the unemployment rate is statistically significant at $p<0.05$. At the same time, FDI and exports of goods and services share 75,69% common variance (R^2=0,757); FDI and GDP per capita share 55,20% common variance (R^2=0,552) and FDI and the unemployment rate share 62,73 of explained common variance (R^2=0,627). It is evident that in the period of 2000 to 2007, the highest linear correlation is present between FDI and exports of goods and services, which may indicate that the FDI were mainly export-oriented.

However, there is a positive correlation between FDI and the unemployment rate, which confirms that the increase in FDI inflow raises the unemployment rate. This can be explained by the fact that FDI were mainly the result of the privatization process, which implied rationalization of business operations, which in this way found a new owner.

The obtained results for the sub-period of 2008 to 2012 are presented in Table 4.

Table 4: Correlations between FDI net inflow and exports of goods and services, GDP per capita and unemployment rate (2008-2012)

		FDI net inflow 2008-2012	Exports of goods and services 2008-2012	GDP per capita 2008-2012	Unemployment rate 2008-2012
FDI net inflow 2008-2012	Pearson Correlation	1	.090	.862	-.666
	Sig. (2-tailed)		.885	.060	.220
	N	5	5	5	5

It is visible that there is no linear correlation between FDI and exports of goods and services. Pearson's correlation coefficient for the relationship between FDI and GDP per capita is 0.862, while the coefficient of determination is 0.743, which indicates a strong connection between FDI and GDP per capita for the period of 2008-2012. However, due to the shortcoming of Pearson's coefficient and its sensitivity to the size of the sample, this relationship is not statistically significant, i.e. it can't be confirmed with how much trust the obtained results can be accepted. There is a moderate inverse linear correlation between FDI and the unemployment rate (Pearson's coefficient equals -0.666), while R^2 equals 0.444, which confirms that there isn't a statistically significant correlation between these variables. The inverse correlation between FDI and the unemployment rate can be explained by the creation of new jobs by the inflow of investments by slowing down the privatization process in the period of 2008 to 2012.

4. CONCLUSION

Based on the analysis of the economic state of the transition countries which carry out economic reforms, it can be concluded that the macroeconomic stability, economic growth and development, political climate, legal certainty, tax policy and other factors have the biggest influence on FDI inflows. The development of a market based economy, opening of the economies to the world, strengthening of the private sector, stability, and above all political stability, legal system reforms and its adaptation to the European legislation, as well as the consistent implementation of adopted laws and tax harmonization with the ones existing primarily in the European Union, are the internal factors which directly influence the decisions of foreign investors to put their money into the developing countries. Some of those factors have a negative impact on a potentially higher FDI in the SEE region. First of all, this refers to the slow implementation of legal system reforms, the slow economic restructuring, the problems in the privatization process, slow and weak growth of the private sector, as well as the unstable political situation in the recent years that had its culmination in war activities.

For the developing countries, the transition economies and the countries which carry out economic reforms, foreign direct investments are the key factor for achieving better economic performances. Those countries have a lack of domestic capital. Thus, their model of the economic growth is based on the foreign capital. However, some of the countries could not obtain output increase. Various research explore correlation between foreign direct investment and GDP. Some of the studies show a positive correlation between those two variables (Borensztein et al., 1998; Campos and Kinoshita, 2002; Makki and Somwaru, 2004; Alguacil et al., 2011; Giroud et al., 2012), while others show a negative correlation (Hermes and Lensink, 2003; Stanisic, 2008; Doytch and Uctum, 2011).

This paper analyzes the Serbian economy and the role and impact of FDI on the economic performances - GDP, exports and unemployment for the period of 2000-2012. The results show that in the analyzed period of 2000-2012, there was no statistically significant correlation between FDI and macroeconomic indicators (GDP per capita, exports of goods and services, and the unemployment rate). Surely that the global economic crisis affected the economy of Serbia and made the already bad economic situation even worse. In order to comprehend the effects of the economic crisis, the analysis was divided into two sub-periods: the period before the economic crisis, from 2000 to 2007 and the period after the financial crisis, from 2008 to 2012. In the first sub-period, the results showed that there is a strong linear connection between FDI inflows and macroeconomic indicators. The most important is the relationship between FDI inflows and the exports of goods and services. This may indicate that investments increase the export potential of Serbia, which is very important given the constant balance of trade deficit. There is also a high correlation between FDI and the unemployment rate, which is primarily the consequence of the fact that FDI was attracted through the privatization process, which included restructuring and downsizing in order to increase efficiency and a small number of greenfield investments. The period of 2008-2012 was characterized by a high correlation between FDI inflows and the exports of goods and services, while there is no significant linear correlation between FDI inflows and GDP per capita and FDI inflow and the unemployment rate. The results for the second sub-period can be explained by the effects of the global crisis on the Serbian economy and the deterioration of all macroeconomic indicators in the given period.

Based on the research on the impact of FDI in the process of transforming the economies of numerous world countries, and especially the former Eastern Bloc, into the modern market economies, attracting foreign capital has become the priority of the economic policy of the Republic of Serbia. Given the fact that Serbia is one of the last European countries to enter the transition process, it has the advantage of the experiences of other countries at its disposal in terms of FDI inflow.

Abstract: *Paper presents analysis of international competitiveness as a result of entrepreneurial initiatives. Business model is introduced as a tool suitable for such analysis and details of contemporary business model theory are presented in order to build a solid basis for analyzing competitiveness of companies. Another conceptual prerequisite for such analysis is considered in form of tools needed to grapple with competitiveness concept. Building on these an analysis is provided where the individual traits of the entrepreneur are pinpointed as an element of utmost importance for international competitiveness of entrepreneurial activities in contemporary business. The paper also presents the variety of entrepreneurial initiatives in the international environment.*

Keywords*: International Competitiveness, Business Model, Entrepreneurial Initiatives, International Business, Internet, Born Global Entrepreneurs.*

1. INTRODUCTION

The analysis of international competitiveness, so highly important for planning the new business venture or any other kind of international entrepreneurial business activity, is almost impossible without looking at the business model proposed for such an activity. Recent discussions and dilemmas regarding the business models related to some of the biggest entrepreneurial activities in ICT (Information and communication technologies) area such as IPOs (Initial Public Offering) of Twitter and Facebook companies and acquisition of WhatsApp firm illustrate this issue very clearly. To achieve international competitiveness is an ultimate business aim for any entrepreneur in a globalized and highly dynamic contemporary business environment. In order to achieve this clear cut business vision is needed along with the first class leadership skills. Although entrepreneurship by its definition involves risk taking and involving with activities regardless of resources on hand one must consider thorough planning when embarking on international business venture. Therefore the core importance of analyzing business plan related to it.

2. INTERNATIONAL PERSPECTIVES OF BUSINESS MODEL

There are many preconditions for the success of international entrepreneurial activity. Sometimes these fail in spite of the existence of resources and opportunities and many times the failure is due to inadequacy of the underlying business model. In order to avoid such failures, business model needs to be examined, looked at in detail and planned carefully in advance of an international entrepreneurial activity. Difficulty of this task is partly due to unexacting consensus on definition or the nature of business model concept among scholars and practitioners. Therefore we will have to look at different approaches in order to present more clearly this concept that bears such an importance for international entrepreneurial activities.

Dilemmas regarding the conceptualization of the business model are best illustrated by variety of synonyms used in place of the word model such as design, pattern, architecture or plan. Often we find in both practitioners notes and scientific papers instead of business model terms such as business concept, economic model or revenue model describing various aspects or the unity of the same phenomena. As business model describes very different aspects of an organization at different levels of comprehension of the inner workings of an organization such as economic, strategic and operational levels at which an organization functions. In order to bridge this gap an integrative definition of a business model has been proposed as: a concise representation of how an interrelated set of decision variables in the areas of venture strategy, architecture, and economics are addressed to create sustainable competitive advantage (Morris,

[1] This paper includes the research results of the author realized on Project No. 179081 financed by the Ministry of Education, Science and Technology Development of the Republic of Serbia

Schindehutte & Allen, 2005). Entrepreneurs need to consider six groups of factors related to their business activities in order to get a hold on overall picture of business perspective in a certain market that is best described and defined by the business model.

The first group of factors relate to the offering of the organization, its primary product or service, the way in which the product or service can be accessed by customers, the means of production or provision of services. Business model often fits into business deliberations of technology based spin-off companies and one such example is coming from Xerox company breeding grounds and the success they achieved based on the differences in their respective business models and pondering entrepreneurs did when envisioning the offerings of these spin-offs (Chesbrough & Rosenbaum, 2002).

The second group of factors defines market elements and the intended user groups defining those for whom the product or service has been planned for. Organization driving the entrepreneurial business may be B2B or B2C oriented and the intended market may be local or national or international. Also position of the customers in the value chain needs to be defined. The analysis and planning of the approach to user groups when defining the business model is of high importance, especially in the entrepreneurial activates related to ICT where the long tail principle drives most of the contemporary markets (Gordijn & Akkermans, 2001).

The third group of factors deals with internal capabilities of an organization and the factors driving it. These factors include all elements of the business from production and selling to R&D and supply chain management. According to (Viscio & Pasternack, 1996) the core competences of a company are of crucial importance for the business model and it is of utmost importance how this competence or competences if there are more then one in play fall in with other elements of the business model. If their importance is underplayed, then the organization most likely won't be able to exploit the full capacity it can derive from such a competence. On the other hand, if it is a sole object of the business model and if other elements are ignored and removed from the business planning process, then there is a danger of sudden and astonishing market or other occurrences disrupting entrepreneurial business activities.

The fourth group of factors important for a business model of entrepreneurial venture deals with competitive strategy issues such as innovation leadership, customer relationships, product quality and its features, overall operational excellence and dependability. It is often that a business model represents the design of content, structure, and governance and allow for creation of value through the exploitation of business opportunities (Amit & Zott, 2001). All the described elements playing into competitive strategy of an organization constitute important factors within the business model concept and that entrepreneur with intentions towards the international activities have to consider these important factors within the business model framework.

The fifth group of factors involves those relating to economic side of entrepreneurial activities such as pricing, revenue sources, and volume of production or service provision, revenues and profits. These factors although seemingly very well researched and known, still comprise many different aspects, such as influence of venture capital availability on entrepreneurial activity (Samila & Sorenson, 2011). If there is ample venture capital available, then it is more likely that an entrepreneurial activity will occur, obviously for reasons of financial resources at entrepreneurs' disposal, but also and perhaps equally important for reasons of increased overall entrepreneurial experience available related to the source of the venture capital and that inevitably follows this kind of capital.

The final group of factors that will be described and analyzed within the framework of a business model viable for international entrepreneurs comprise factors influencing the entrepreneur individually such as time available to him personally for entrepreneurial activities, scope and size of planned or intended entrepreneurial activities. These factors encompass many important considerations such as personal motivation and the aim one has when embarks upon any kind of entrepreneurial activity (Fairlie, 2013). This is especially true for international entrepreneur activities, since the stakes for the entrepreneur are usually much higher in such activities than in the one with predominant local features. Having in mind that the volume of activity, financial interest and time invested are much larger than in local or national business framework, all kind of different personal issues specific for international entrepreneurs, such as reputation in certain markets and in general, networking and experience, may arise.

By having a deliberate business model description involving so many factors is advantageous for analyzing entrepreneurial activities because of the complexities involved in conducting business in the international

environment that is nowadays characterized by globalization processes and cultural influences that demand innovative and creative business solutions. Business model is closely related to various concepts coming

from the field of strategic management that make analysis of international business ventures and other international entrepreneurial activities more accurate. One important concept is defined as strategy, which is the creation of a unique and valuable position, involving a different set of activities (Porter, 1996). Another one, similar, but very distinctive and different, is defined by the same author as operational effectiveness. This concept encompasses the notion of performing activities better, with fewer inputs and defects than competition (Porter, 1996). It is important to note that business model as defined previously contains elements of both strategy and operational effectiveness proving to be a powerful tool for analysis of international entrepreneurial activities.

Finally we will discuss the concept of entrepreneurial activities as an important addition to business model framework which we will use in next sections to analyze international competitiveness and entrepreneurial business initiatives. Business is conducted through implementation of various activities and thus inherently a business model builds framework that groups, describes and organizes the business activates and provide relationships among them in order to describe a meaningful overall picture or map of the business. Such grouping of activities provides good basis for describing elements of a business model and therefore an entrepreneurial business activity may be considered as a founding element for the business model describing overall entrepreneurial activity (Siggelkow, 2002).

Having this in mind we will examine once more the role of the business model and its usefulness for the entrepreneur as it is inextricably related to building successful international business venture and international competitiveness related to it. Advantages an entrepreneur can find in pondering over his business model are numerous, and four major incentives for this can be defined as: conceptualization of the business through set of strategic choices that are interrelated; seeking relationships that may be complementary, primarily these may be some of the elements that posses unique combinations; developing sets of activities around a framework that is logical in the given business environment; ensuring consistency of strategy, architecture, economics, growth, and exit intentions (Morris, Schindehutte & Allen, 2005). Interrelation between concepts of business model, strategy, operational effectiveness and business activities can provide an overall framework for efficient analysis of international competitiveness, so important for success of any entrepreneurial activity in contemporary business.

3. THE SIGNIFICANCE OF INTERNATIONAL COMPETITIVENESS FOR ENTREPRENEURS

When international competitiveness is mentioned the first thought that comes to one's mind is international competitiveness of countries. With readily available instruments that measure this phenomena on a yearly basis, such as The Global Competitiveness Report of World Economic Forum (Schwab & World Economic Forum, 2013) it is no wonder that such inspiration is probable. International competitiveness is of utmost importance for entrepreneurs and the prospect their enterprises have in an international market. There is of course relation between the two and some research provide data describing international competitiveness of countries supplemented by data describing dynamic trends of companies (Dosi, Grazzim & Moschella, 2013).

Country competitiveness is defined as the set of institutions, policies, and factors that determine the level of productivity of a country. Productivity determines rates of return and consequently investments in economy of a country, thus making a more productive economy, the one that grows faster over time (Schwab & World Economic Forum, 2013). According to same source twelve groups of factors are underlying for competitiveness.

Institutions' features make the first group of factors that determine competitiveness of an economy. By providing legal and administrative framework for entrepreneurs and their activities institutions largely define what is possible for organizations and in which timeframe.

Infrastructure available to the economy provides another important framework that determines what is possible and when for entrepreneurs. Transport infrastructure such as roads, ports and information infrastructure such as availability of the broad bend Internet defines the rate of flow of business and the rate of flow of information, which often is crucial for successful international entrepreneurial activity.

Macroeconomic environment and health and primary education make the third and the fourth group of factors that determine competitiveness of an economy by providing yet another layer of environment defining context for activities of entrepreneurs. Thus, macroeconomic environment provides possibilities for long term

planning if it is stable and predictable. Basic features of demographics that are important for many decisions in business are determined by health and primary education.

Higher education and training define fifth group of determinants explaining competitiveness of an economy. These determinants are very important in contemporary business that is mostly driven by innovation and managed by creative drive of the leaders. A knowledge economy and innovative, knowledge related business operation that are the goal of economies and of particular companies are standing on the shoulders of higher education and vocational training that mostly define the quality and the scope of skills that human resources may provide to businesses.

Efficiency of markets, the one of goods, the one of labor and the financial one are next three determining groups of factors for competitiveness of an economy. Efficient markets allow for flow of goods, experts and capital thus providing resources and inputs for entrepreneurial activities and means of distributing the outputs of these activities.

Ninth group of factors encompass technological readiness of companies to adopt and implement modern technologies with an emphasis on ICT that has become general purpose technology (GPT) of our times. Many times foreign direct investments determine the level of available technologies in an economy, thus the separation of this group of factors describing technology availability and the readiness to implement it from innovation.

Market size determines with great effect competitiveness of an economy in that the growth have been found to be related to trade openness i.e. market size. The inclusion of domestic and foreign market in overall market description and measurement provides for the unique measurement tool that can be applied for both developing and transitional economies and those more developed. It is also of utmost importance for international entrepreneurial activities to consider the size of the markets available worldwide.

Eleventh group of factors involve business sophistication that encompasses the quality of a country's overall business networks and the quality of individual firms' operations and strategies (Schwab & World Economic Forum, 2013). Both of these are especially important in very developed economies where more simple production improvements have been exhausted as a driver for productivity increase. Business network quality is also very important for an entrepreneur because of the cluster phenomena that is so influential in contemporary business.

The final, twelfth group of factors is related to innovation. It is very clear that this group of factors is the most important one since it alone can in a long run improve standards of living and productivity. It is especially true for developed economies that have existed means of improving productivity by application of existing technological solutions. As for the developing and transitional countries the globalization effects and dynamics of change in contemporary business environment make the innovation a must even for the companies in those economies that have ambitions to compete in world markets. The importance of innovation for international entrepreneurship activities is tremendous and usually such activities are depending heavily if not completely on an innovative service or a product.

In order to provide for better understanding of the described factors that determine the competitiveness of an economy, they have been grouped into three groups relating to the stage of economic development that each of these groups decisively influence. Thus, the first four groups determine predominantly the competitiveness and development of so called factor driven economies. These economies compete based on their factor endowments of which most important are unskilled labor and natural resources. Consequently the companies and entrepreneurs of these economies base their competitiveness on the price and are involved in activities such as sell of basic commodities and services. As an economy develops it becomes the efficiency – driven economy. The name comes from the fact that since the wages have risen in these economies they also have to maintain the increase in efficiency of production and quality of products and services in order to be able to increase their prices. In such economies factor groups five to ten are mostly responsible for determining competitiveness of an economy. Finally, when wages go even higher, the only way to sustain this is by having innovative and cutting edge products and services that are new and unique and are based on innovations. Such economies are labelled as innovation – driven economies and factor

groups eleven and twelve determine predominantly their competitiveness. As an illustration we will provide rankings of some economies according to (Schwab & World Economic Forum, 2013, 11, Table 2). Factor driven economies are mostly those of countries of Africa, South and Central Americas and Asia, such as Ethiopia, Nicaragua, India and Pakistan. Some of economies that are in transitional phase from factor driven towards efficiency driven are Azerbaijan, Iran, Saudi Arabia, and Venezuela. Efficiency driven economies encompass those of Bulgaria, China, Montenegro, Serbia and Romania. Transitioning towards innovation

driven stage are among others economies of Hungary, Brazil, Poland, Russian Federation and Turkey. And finally some of the innovation driven economies are Austria, Czech Republic, Germany, Israel, Italy, Slovenia, Taiwan, UK and USA. Having this in mind one can assess the important competitive factors for companies and entrepreneurs willing to compete and start entrepreneurial activities aiming at international markets coming from certain economies and thus focus the attention of both theoretical analysis and practical efforts at these factors.

International entrepreneurial activities are dependent on Internet in variety of ways, from information gathering to product delivery and customer relations building. If Internet related entrepreneurial activities are analysed their success is positively related with three characteristics: Internet or online reputation, technological competitiveness related to Internet technologies and finally existence of Internet communities related to entrepreneurial activity, entrepreneur or the brand. The life cycle of an organisation that relates its business activities to Internet is shorter in general. Only 37% organisations with less than 20 employees reach the fourth year of the existence and 9% endures more than ten years in business ventures. All of these aspects have to be grappled with and pondered over by entrepreneurs planning to start international business activities that are nowadays almost exclusively Internet related.

4. THE VARIATY OF ENTREPRENEURIAL BUSINESS INITIATIVES

The importance of entrepreneurship in economy was very well researched and defined (Drucker, 1985), (Schumpeter, 1934). Many different theories and a well sized body of research exist on different features of entrepreneurship in an effort to get a better understanding of this complex phenomenon and find ways to foster it, all in line with its enormous importance for contemporary societies and economies. The role of individual entrepreneur has been also looked into and it seems to be one of the crucial factors influencing competitiveness of an entrepreneurial activity, especially if it is aiming for more complex and knowledge intensive international markets. High importance of entrepreneurs has been often related to their ability to advance innovative business operations, thus innovativeness and entrepreneurship are related in many ways some being straight forward, and some being more complex. Although this fact may be almost self-evident it has been for years that researchers have treated these two fields as almost separate and data have been collected through unique research dealing with either of these two topics and seldom with both as noticed in (Sandberg, Hurmerinta & Zettinig, 2013). In this paper researchers define some individual traits of those prone to innovate and those prone to entrepreneurial activities and then look at what traits are common for these two groups. Innovators have these unique traits according to this research: willingness to change and curiosity and interest in problem solving. Entrepreneurs have the following unique traits: high need for achievement, internal locus of control. Both group share traits of: risk-taking propensity, high tolerance of ambiguity, persistence and self-efficacy. Having these traits in mind, it is important for fostering competitiveness in e.g. efficiency driven economies to focus efforts in higher education and vocational training to individuals with such traits since they are highly likely to be the ones to engage in entrepreneurial activities. In order to create competitiveness in international entrepreneurial ventures such individuals should be educated to a highest degree practicable having in mind their field of interest and character traits that have been described, in order to maximize the competitiveness of the companies they might be establishing and running in the future. A fine example of importance of education for entrepreneurial individuals is depicted in biography of Steve Jobs, founder and CEO of Apple Inc, nowadays a very successful company started exclusively by entrepreneurial activities of Jobs. He has always underlined how crucial for his individual development has been the educational experience from elementary school where a teacher who made a difference made an enormous impact on him, to the college that he never graduated from, but where he learned many useful thing, not obviously related to ICT, such as calligraphy, that made a lasting impact not only on ICT industry, but on the whole Western civilization and its culture (Isaacson, 2011).

The personal story of Steve Jobs is indicative for another phenomena regarding entrepreneurship. It is a relationship between start-up entrepreneurship and the one that is exercised in later phases of a company life-cycle. This phenomenon called strategic entrepreneurship plays a key role for entrepreneurs that are

searching, combining and trying out new resource combinations in the pursuit of profits under uncertainty (Bjornskov & Foss, 2013). The idea of combining research of early phase of activities of an entrepreneur when his company is called a start-up and later phases in which he is wheeling an established company, but still is driven by same entrepreneurial drivers and same individual traits, taking risks, trying out new ideas, etc. brings to life a holistic approach to role of entrepreneurship in defining the comprehensive output of an economy and competitiveness of both economy and individual companies. Therefore this approach must be considered when discussing international entrepreneurship and its competitiveness especially in the future,

since rise in body of research and knowledge in this area is expected along with its importance as an even greater number of economies will move towards innovation driven economic model.

Having discussed different personal traits of entrepreneurs and their importance for establishing international competitiveness of companies and economies, primarily their personal traits and their performance throughout the whole lifecycle of companies they are leading, it is not hard to come to understanding of the concept of the born global entrepreneurs. Those are the ones who start their entrepreneurial activities right in the middle of an international competition game, aiming for the global market right from the start-up phase of their companies. There are four propositions important for the born global entrepreneurs (Persinger, Civi & Vostina, 2007). The first deals with fact that the entrepreneurs with high need for achievement in the global arena will start globally oriented companies. If he is thinking in terms of international competition and thus international competitiveness, then it is likely that a company started will plan and execute its business operations in these relations. Next the entrepreneurs who decided to run as start-up that is aiming for the global or international market will not perceive their own behaviour as bearing special or higher risks. Again one is to consider the mind frame of the global born entrepreneur who thinks, informs himself, plans the business activities in global and not in local or national terms and therefore when it comes to acting on those thoughts information and plans it is not perceived as something very unusual or that bears a special risk. The third proposition deals with proactive attitude of an entrepreneur and such entrepreneurs will be more persistent in overcoming challenges in international markets (Persinger, Civi & Vostina, 2007). This is related to the final proposition of the authors, the one that makes relationship between strong global orientation of an entrepreneur and the high chance he will start a born global company. Again we see how important is the mind set of an entrepreneur in both overcoming challenges in new markets and for embarking on international or global entrepreneurial venture.

Having all this in mind, it seems like a good idea to provide a fuzzy comprehensive evaluation method for evaluating international competitiveness of entrepreneurial activities which is exactly what (Yanrong, Yu & Kang, 2011) propose in area of high-tech entrepreneurial enterprises. Their competitiveness evaluation index system comprise six indexes that deal with R&D ability, entrepreneurial ability, financing ability, marketing ability, profitability ability and growth ability. We have discussed in some length entrepreneurial ability driving mostly from personality of the entrepreneur and have concluded that it is a complex area influenced by many factors, an area that is very good suited for fuzzy logic solution. Therefore, further research building on proposed method is needed that will encompass additional elements and factors that influence entrepreneurs individual traits that are so important for competitiveness of international entrepreneurial ventures.

Finally, we will look into some of the activities of Internet entrepreneurship in Serbia that are international in their scope of activities as analysed in (Sofronijevic, Milicevic & Ilic, 2012). The good example for this is company Nordeus. It embarked on international business venture by launching Top Eleven software game through Facebook and Internet app stores for Android and iOS devices. By reaching global markets Nordeus established an international brand that brought it one of the prestigious The Europas awards for the best start-up in computer games in Europe 2011 (www.nordeus.com).

5. CONCLUSION

When contemplating business model as a basis for the analysis of international competitiveness of entrepreneurial activities in contemporary business, one have to bear in mind the broadness and complexity of business model concept. There are several emerging areas of interest related to business model concept such as business model being a new unit of analysis, its holistic approach to describing of how companies do business, relationship between business activities of the company and the underlying business model and explanation of how value has been created departing from the idea of explaining just how value is captured in a certain business model (Zott, Amit & Massa, 2011). Ideas as such present great expansion and

broadening of conceptual base of business model concept that allow for broader and more complex and all encompassing analysis of the entrepreneurial business. On the other hand, one always have to include the institutional context in the analysis of entrepreneurial activities, for especially in contemporary business there is no such a thing as a intervention free market or total freedom of capital, labor or product flow. A good example of such tendencies is presented by analysis of 2.854 life histories of entrepreneurs from twenty Chinese cities in order to conclude that the institutional background plays a very important role in defining entrepreneurial activities in China (Lu & Tao, 2010). The level of institutional influence is not the same all over the world, one may say that in China it plays a more important role than in some other markets and economies, but when one is envisioning an international entrepreneurial activity and analyze related

competitiveness of the company involved, one has to factor in the important role of institutions in the economy. In order to do it, entrepreneur has to be very well informed and interested in international and global envisioning of his business.

International competitiveness of entrepreneurial activities is highly related to traits of the entrepreneur, but other factors influence this important business feature. In order to understand well and use it to one's own advantage, international competitiveness needs to be analyzed and business model lends itself as one comprehensive and practical, though complex tool for this purpose. Therefore those looking into area of international competitiveness of entrepreneurial companies and entrepreneurs need to grapple with and make best use of business model concept if they are to analyze, envision, plan or research this complex phenomena.

***Abstract**: This paper describes the special evolution of debt of Romania and Serbia, during and after the recently completed global recession, with a focus on public debt. After a brief theoretical introduction and an equally short review of the recent literature devoted to the subject, the authors stress both the common elements and the particular aspects of the upward trends of borrowing in the two economies, concluding with some final remarks and a tentative anticipation of short-term and medium-term evolution.*

***Keywords:** external or foreign debt (ED), public debt (PD), governmental debt (GD), Gross Domestic Product (GDP), export (X).*

1. INTRODUCTION

Debt issues dominate economic history, and the economic history of the last three decades has dilated it in point of volume and impact, up to limits that are hard to accept and not in the least anticipated. Two concepts prevail in the language of this significant economic chapter: external/foreign debt and public debt, and in particular the last one has caught the attention of recent research.

External Debt (ED) means an amount in foreign currency payable, at a given point in time, by an economy to other economies and/or international financial institutions, in keeping with the loans received by the government and private companies, under the government's guarantee, and is to be paid over a period longer than one year. This sense is used in international statistics, and is understood as external public debt, not including loans with maturities under one year, which were contracted without the government's guarantee. Foreign debt can be gross or net, after deduction, from the gross external debt, of its own claims in relation to non-residents. In determining net foreign debt, only claims (rights) are taken into account, or those that can be easily mobilized (for which there is the perspective of collecting it from foreign debtors is clear).

Public Debt (PD) represents all the obligations that the state (government) assumes when contracting internal and/or external loans to finance public economy. Public debt is related to the financial intervention of the state (government) in the economy, which aims at forming public capital, stimulating investment, increasing employment. In its broadest sense, public debt also includes visible debt, resulting from cash deposits in public vaults, which is payable at any time by the depositors. In terms of material content, it can be of goods and values, in terms of its destination it may be of consumption and of production, and in terms of duration it may be long-term, short-term, etc. *Encyclopaedia Britannica* definition shows that "*public debt represents the obligations of governments, particularly those evidenced by securities, to pay certain sums to the holders at some future time, being distinguished from private debt, which consists of the obligations of individuals, business firms, and nongovernmental organizations.*"

The debt owed by national governments is usually referred to as the national debt and is thus distinguished from the public debt of state and local government bodies (http://www.britannica.com/).

Much of the literature on the topic of debt produced in recent years has tried, and it is still trying, to provide and present original solutions and new methods of reassessment of those phenomena and thresholds, and especially of forecasting external and public debt (Knedlik, Von Schweinitz, 2012), or even extends the analyses related to the same range of problems in geographic behavior areas (Hrvoje, 2013), considered similar in point of behaviour.

Contemporary theory continually redefines the essential role of foreign and public debt and the financial development of an economy, while delimiting a number of debt sustainability problems that are increasingly acute, so the tendency always appears of expanding the universe of financial research and enrich it with new instrumental or cross-disciplinary solutions – crossdisciplinarity being accepted today as the *application of field-specific methods and their recognized use in fields that are altogether different from the original ones*,

with special effects and an increased relevance in understanding the phenomena in question (Săvoiu, 2014). In this regard we can mention the identification and statistical quantification of certain limits through indicators having the nature of restricting debt by the budget, going as far as the maintenance, through close monitoring, low thresholds for reference interest rates, a phenomenon of quantification of incipient "financial repressions", through statistical indicators (Reinhart, 2012; Prabha and Savard, 2013), continually assessing and predicting a phenomena which is hard to achieve in practice, suggestively called *liquidation of public debt*, particularly aimed at *government debt* (Reinhart and Sbrancia, 2011).

A new approach to adjusting the level of public debt in a more sustainable manner is more clearly distinguishable, based on a slightly more stable fiscal measures, or on measures with no temporary character, there being constant monitoring and the analysis of results being conducted at an ever shorter time intervals, noting that tax recovery and reducing debt, however, require a long time, as process management activities (the current Eurostat indicators system operates, during the recession, and especially after recession, with quarterly periodicity). The attempt to scale, through innovative indicators, "the hidden areas of public debt" (IMF Survey, 2013) is another original solution for analyzing debt, stratified in keeping with the level of development of the economies.

Kenneth Rogoff and Carmen Reinhart, who analyzed and quantified the phenomenon of debt over nearly eight decades, between the two great historical recessions (starting in 1929, and in 2007), noting that, after more than three years of financial crisis of the system, plus another three years of recovery (basically, over a period of about six years, i.e. the duration of the latest recession in the Balkans), the debt of a country tends to increase, on average in the first three years, with 86 percent of its original level, and after six years it tends to double in relation to the volume of exports, because of these very hidden areas of the debt; the delimitation of the hidden area especially regards commitments for future budgetary payments related to the pension scheme, which is under the pressure of an aging population; thus, those thresholds or limits of debt are set, where its effects turn from positive to negative, and the debt itself becomes *unsustainable*. (Cecchetti, Mohanty, Zampolli, 2011).

In the European community the preference is maintained related to primarily evaluate public debt, and more especially government debt, whose theoretical limit amounts, in general terms, within the European Union (EU) and European Monetary Union (EMU), to 60% of GDP. In Romania, secular studies (Reinhart, Rogoff, 2010) place the alarm threshold even lower (at about 41%), while for Serbia, which has a much higher per capita income and a higher degree of development, the general alarm level remains that proposed in pre-accession (EU) and (EMU), i.e. the same 60%.

The intention and the originality of the present paper is to exploit the method of confronting, in statistical terms, the phenomenon of borrowing and the statistical indicators in the two Balkan economies (that of Romania, a member of the EU, and of Serbia, which is currently in the pre-accession phase), behaving in a relatively similar ways in their modern history of nearly one and a half centuries.

2. A BRIEF STATISTICAL ANALYSIS OF THE ALARMING UPWARD EVOLUTION OF PUBLIC DEBT IN SERBIA AND ROMANIA

Due to a series of social and geopolitical discontinuities in Serbia, analysis of public debt in the period before the year 2000 are not suitable. After that, the public debt of the Republic of Serbia shows two distinctly different trends:

- decreasing trend between the years 2000 and 2009, and
- increasing trend since 2009 until today.

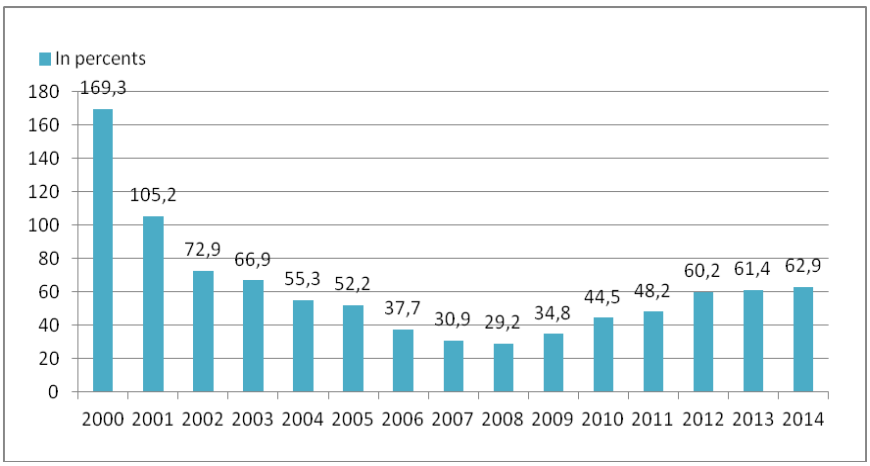

Figure 1: Public debt of the central government share of GDP%
Source: Uprava za javni dug, February 2014, page 9

If we analyze trend and base for the decrease of the public debt share of GDP in the period up to year 2008, we can carry out important conclusions. The most significant debt reduction occurred by the year 2004, based on agreements on writing off debts (66% of the debt to the Paris Club, 62% of the debt to the London Club of Creditors (until 2003)). Further reduction is a result of repaying a debt of 1.3 billion euros on the basis of old foreign currency savings and domestic debts based on delays. Since 2004, the acceleration of the privatization process and the use of privatization revenues to cover the budget deficit made it possible to achieve the low amount of new loans, and in 2008 Serbia was in the group of low-debt countries.

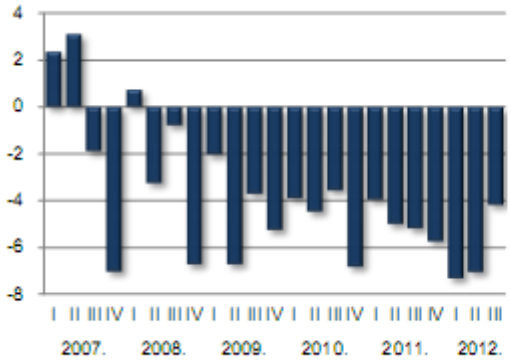

Figure 2: Fiscal budget deficit/suficit share of GDP% for Serbia, 2007-2012.
Source: Šljivić, S.,Jevtić, B., Šljivić, S. 2013. page 508

Since 2009, with the first effects of the global economic crisis, public debt starts to grow both in absolute figures, as well as a share of GDP. The main causes for this increase were: primary fiscal deficit which was financed by the loans, as well as the activated government guarantees for debts of public enterprises, but also a remarkable decline in net foreign direct investments. Correlation between budget deficits and public debt points to the key motive for borrowing, and that is maintaining the budget stability, while the relationship between the public debt trends and economic activity is negative.

For example, Romania can be extrapolated, as lying relatively close to the average trend of the South-Eastern European area, and especially the Balkans. Romania makes a relatively common instance for the two areas in point of overall trends in the phenomenon of borrowing. We exploit three waveforms that cyclically dismantle (in a Kondratiev manner) three similar historical periods in the two economies, defined by upward-downward repeatability, based on the visual support of the graph for a logical statistical thinking, the quality of which is recognized for the phenomenological approach to temporal variation (Figure 3)

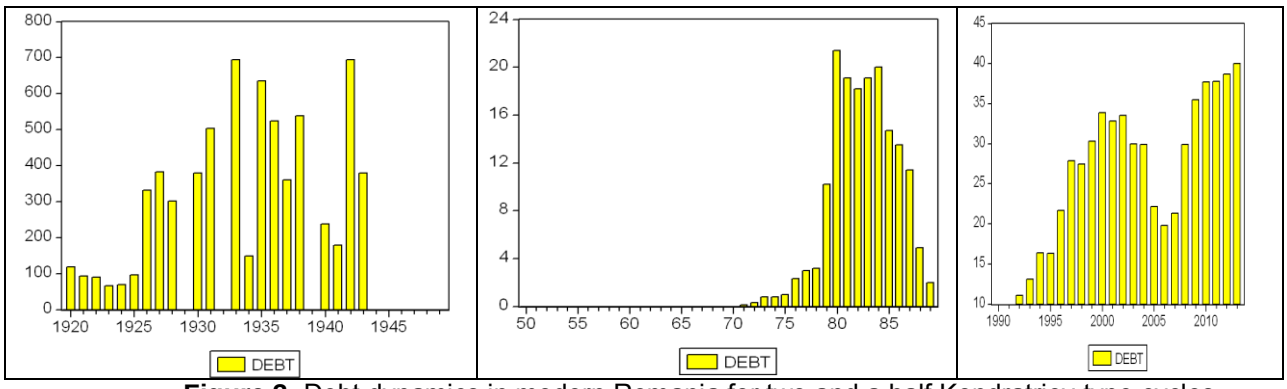

Figure 3: Debt dynamics in modern Romania for two and a half Kondratriev type cycles
Source: Săvoiu, G., (2014), figures 5-7 pages 5-7.

The main statistical indicators of public debt are the indicators of public indebtedness (PD, PD/GDP, PD/inhabitant and total annual change of PD in %), and, in separation, the indicators of public debt service or the annual financial burden of public debt repayment (PDS, PDS/GDP, and PDS/inhabitant) (Săvoiu, Apostol, 2013). A breakdown of the values of these indicators in the first category shows rising levels developments, and especially increasingly alarming dynamics.

Table 1: Major statistical indicators of the level of public debt of Romania and Serbia, during and after the crises

	Romania						Serbia					
	2007	2008	2009	2010	2011	2012	2007	2008	2009	2010	2011	2012
Public debt - PD – mil. USD	24863	33906	39704	45280	48645	55293	12526	12901	12908	14539	16105	18667
PD/GDP (%)	17.1	19.6	22.3	26.8	29.3	31.9	35.8	30.4	30.8	37.1	43.5	48.5
PD/Population - USD/inhabitant	1152	1576	1849	2108	2268	2580	1695	1748	1754	1985	2205	2567
Total annual PD change (%)	47.3	36.4	17.1	14.0	7.4	13.7	2.4	3.0	0.1	12.6	10.8	15.9

Source: *Economist Intelligence Unit,* available on-line at: http://www.economist.com/content/global_debt_clock.

Public debt in early 2013 was, according to World Bank data, 172.5% of Romanian exports, and 182.2% for Serbia, as the general theoretical limit accepted for PD/X is 200%. Much more serious, however, is the debt level reached after six years of analysis, i.e. multiplied by 2,224 times for Romania, and only 1.49 times for Serbia. At the same time, the negative legacy of debt (i.e. the debt inherited) rises from the parents to their children 2.24 times in Romania, and 1.52 times in Serbia. The GDP/inhabitant indicator in the two economies is totally different at the beginning, which appeared to require separate analysis thresholds, but is strikingly close at the end of the period analyzed. The most serious evolution remains the structural one: the share of public debt in GDP in Romania increased from 17.1% to 31.9%, and 35.8% to 48.5% in Serbia, in about six years of recession and post-recession, and the outlook becomes really alarming, asking for immediate concrete policies with major financial impact.

Table 2: Short-term and medium-term outlook for public debt indicators in Romania and Serbia

	Romania			Serbia		
	2013	**2014**	**2015**	2013	**2014**	**2015**
Public debt - PD – mil. USD	59481	**63670**	**67859**	21359	**24052**	**26745**
PD/GDP (%)	34.4	**36.9**	**39.4**	60.3	**72.2**	**84.1**

Total annual PD change (%)	7.6	**7.0**	**6.6**	14.4	**12.6**	**11.2**

Source: *Economist Intelligence Unit* for public debt* (http://www.economist.com/content/global_debt_clock).

The question whether there is a statistical association between public debt and economic growth, or, to put it differently, if public debt is justified as a factor of development and, especially, as infrastructure investment support intended to change the economy, has a disappointing answer.

Table 3: Associable or correlated potential indicators characterizing public debt and economic growth

Year	Romania				Serbia			
	GDP growth (%)	PD(%)	GDP/ capita	PD/ capita	GDP growth (%)	PD(%)	GDP/ capita	PD/ capita
2007	6.3	47.3	8170	1152	5.4	2.4	5277	1695

A correlation matrix, even considered for a very small number of terms, delimits both similar and different behaviours in the two economies according to the values of the determination coefficient in Table 4 (which contains the values of the correlation ratio, or of simple R resulting from the classic R squared):

The analysis of the correlation between GDP growth (%) and PD (%) identifies an average connection between *public debt and economic growth*, visible and relevant in Romania, which has now a much more open economy under the impact of the crisis and the recession, and also under the impact economic of restarting growth, as a EU member, and a negative relationship, or almost a non-existent one, meaning at the limit of statistical testing, in Serbia (R= - *0.209301*).

Large inflows of foreign capital through credits, privatization and foreign direct investment (FDI) has been a major source for financing high consumption in Serbia in the period between 2005 and the middle of 2008 (Popovic, N. Jaško, O, 2012), which had the influence on economic activity, with the GDP growth rate greater than 5%. However, the economic crisis has refocused the use of these sources to cover the budget deficit, in which was observed, opposite of the required, permanent reduction of spending on infrastructure projects and the economy (up to 5% of the national budget), while the allocation for salaries in the public sector and pensions grants remained at the same level (about 55% of the national budget). On the other hand, FDI were almost stopped, given that many companies performed operations contractions during the crisis in order to fit these new circumstances.

Reduction or stabilization of the public debt is possible on the basis of reductions in public spending or through tax increases (budget inflows). In the short term, reforms in public sector in order to reduce budget expenditures may be sufficient to stabilize the debt of Serbia, while the long-term debt reduction needs tax policy that is associated with the stimulation of investments in the real sector and individual demand. Particulary acceptable operations are those that operate in both directions, especially Public Private Partnership (PPP), which do not increase public debt, and substitute public sector investment and increase demand.

On the other hand, after statistical confrontation between the two countries, the values of R highlight a strong positive relationship (having an evolving nature) between the dynamics of economic growth in Romania and Serbia, and between the debt dynamics per inhabitant, as well as a contradictory reversed, or staggered (R= *- 0.628160*) relation between the temporal trends of indebtedness of the two countries, according to their financial and monetary policies, which are distinctly separate at the moment, but are probably likely to be common in the near future, as EU member states. From this emerges an important remark, highlighting the advantages of EU integration, i.e. synchronicity and integration into the EU economic cycle can bring about, through "contagion", in addition to other advantages, some optimization in debt policies: public debt is much better correlated with economic growth and much more appropriate in times of recession in Romania, compared to Serbia; the remaining trends are similar for the two economies.

A tentative econometric modelling could only be achieved for the Romanian economy (Săvoiu, Apostol, 2013), where comparative data are available for a longer period of time (minimum 15 years or items in the model).

Table 5 summarizes two specified econometric models for Romania, parameterized and validated, with public debt as endogenous variable (a unifactorial and multfactorial model as possible examples).

Table 5: Two econometric models of public debt (PD) in Romania between 1997 and 2012

Dependent Variable: PD Method: Least Squares Specified models for the 16 – term series	R-squared	F-statistic
$PD_i = 31.90 + (- 2.41) \times FDI/GDP_i + \varepsilon_i$	0.621825	23.01993
$PD_i = 111.70 + (- 1.55) \times FDI/GDP_i + (-3.56) \times EUFCF_i + (-0.669) \times$ Savings in $EU_i + \varepsilon_i$	0.802784	16.28232

Software used Eviews. Source: (Săvoiu, Apostol, 2013a, page 25-26)
Note: Foreign Direct Investment as % of GDP = FDI/GDP_i; European Union Fixed Capital Formation as % of EU GDP = EU FCF_i.

The major conclusion of this analysis shows that econometric models can be made to simulate and estimate or predict the dynamics of public debt, as well as some aspects of the most important exogenous variables that contribute to an optimized and efficient debt service applied to various periods or horizons.

3. SOME FINAL REMARKS

The present paper started from the idea to emphasize the importance of public debt, of statistical confrontation on this issue between the economy of Romania and Serbia in general, and also the assessments and modelling which are possible, but did not limit tiself to the public debt, which requires a special, detailed treatment, exceeding the space of a midsize paper. The significance of public debt issues goes beyond many other important economic policy issues relating to accession and convergence processes, because of its effect on major economic equilibria, and especially on economic growth, optimizing the ability to consistently and sustainably manage the public debt process, turning it into a process of investment and development impact, in parallel with a process of inflation control.

Of course external debt is also important (i.e. at the beginning of 2013, Romania's foreign debt already exceeded the alarm level of 100 million, i.e. about ¾ of the official GDP), but the monitoring tools to do that are much more improved, and the solutions are much more efficient, and the experience of both economies is already relevant from the periods prior to transition, through the balance of payments and balance of trade analyses.

The aggravating prospects of global public debt, which is likely to exceed USD 55.802 billion no later than at the end of 2015, and the prospects of Romania's and Serbia's public debt, which at the end of the same year 2015 will be around USD 67.9 billion, and 26.75 billion respectively, require statistical analyses based on innovation both instrumentally and methodologically, foresight solutions and policies focusing on new econometric modelling and simulations. In the past six years, public debt has followed an upward trajectory

aggravating through its consequences speeding up, and even defining, a globalizing process. Public debt has relevant advantages and disadvantages. The first category includes help to the National Bank in the monetary policy, the ability to avoid the negative effects of taxes against incentives and increased government spending, finally managing to develop the economy of any country, but leaving an unsustainable legacy for next generations. However, when public debt exceeds the theoretically admissible limit, more and more long-term economic difficulties are generated, and this is what really happens in the case of Romania and Serbia.

If for the economy of Serbia, which is on the eve of EU accession, there are no previous secular studies, which induces the threshold of 60% of GDP as the natural limit of the moment, for the Romanian economy there are international researches. Thus, in a famous 2003 paper, which examined debt carefully in relation to GDP, a threshold of 41% of GDP was established, upwards of which the effects of debt start inducing not the economic growth required of an EU economy towards the EU-28 average, but rather to the diminishing of its economic growth (Reinhart, Rogoff and Savastano, 2003).

The analysis in that paper highlights, among other things, that both Serbia and Romania have exceeded it in the short and medium term, that is rapidly and dangerously approaching the *sustainability* limit the of public debt, i.e. 60% and 41% of GDP respectively, or the maximum level accepted by investors for these countries. The paper mentioned insistently emphasizes the importance of the phenomenon, and generating new economic policies that do not *neglect the signals provided by the general public debt indicators, and by internal debt, especially*, first, because "*internal debt is already nearly two-thirds of the public debt*" (Reinhart and Rogoff, 2011), and secondly, because the indicators are becoming ever more explicit and turning into increasingly lower warning thresholds, and thirdly, because the domestic market needs to be increasingly investigated and monitored, confronted with similar markets and simialr effective solutions, largely ignored in the literature on the complex phenomenon of public debt.

Abstract: *This paper analyzes economic convergence of economies of Romania and Serbia. First part of the paper is dedicated to theoretical description of knowledge and its relation with other evolutionary concepts such as transition, convergence, teleonomy, semiconvergence, accession and integration. After that three hypothesis of convergence are analyzed and described in short. Economies of Romania and Serbia are descibed using convergence criteria, namely: price stability, sound public finances or a sustainable fiscal position, exchange rate stability and low long-term interest rates. Similarities are observed between those economies, and trends and characteristics are described. Paper concludes with evaluation of future prospects for sustainable convergence or economic divergence on the other side.*

Keywords: *Economic convergence, transition, EMU, public debt, budget deficit*

1. INTRODUCTION

This paper describes several evolutionary concepts (transition, convergence, emergence, teleonomy, semiconvergence, accession, integration), which are specific to the economies of Romania and Serbia, from the transition to a market economy to convergence, emergence, etc., focusing on real convergence of countries in Europe. After an introductory overview of the major concepts, from emerging convergence to teleonomy, devoted to the subject, the authors highlight and detail the concrete criteria for evaluation economies of Romania‟s and Serbia‟s according to the convergence criteria, ending with a few conclusions regarding semiconvergence rather than complete convergence.

An open economic system, analyzed as a specific structure, either static or dynamic, as in the national economies of Romania and Serbia interpreted in keeping with the systems theory, can become unstable and generate a new structure, through processes of self-organization, which reinstates, in a broad sense, the subsystems of the respective economies, through an adaptive evolution focused on survival and change, being also characterized by evolving complexity and non-linearity, and generating, in terms of the same systems theory, *order out of chaos* (Holland, 1998).

Convergence is: a) a circumstantial concept, defined by a state of similarity, either structural or complete, and also partial or incomplete, or limited, of a small number of parameters of level, which an economy, seen as a complex open system, must reach in over a certain period or range of time; b) a mainly process significance, containing at the same time components of the concept of similarity, and also complementary elements, finally generating a broader concept of harmonization; c) a term having a forecasting nature, which implies reaching a level or target, to which an economic phenomenon is converging, which is approached both spatially and temporally, as a gap or recuperation period (a time interval of development in advance, or a period of lag recovery); d) an instrumental concept of financial economics and financial statistics, intended to confront or compare, watching the coherent economic fusion of economic subsystems, or even economies, into a larger system or an economic union, by constant identification and ranking of developments and by dealing with a number of performance benchmarks, or values considered mid-level of a standard subsystem (an economy parameter, the average level of the aggregate, a modal or median value of a normalization phenomenon, etc.); e) an integrative phenomenon of a dynamic and systemic nature, involving pooling in order to achieve economic and social objectives that are assessed and updated regularly based on historical requirements.

Convergence systemically implies other phenomena as well, or at least some aspects of them, generally having a biological origin, such as *emergence* (Chalmers, 2006) and *teleonomy*. The former concept, *emergence*, defines *a complex phenomenon, part of a cycle of change* (Holman, 2010), *the result of a simple*

combination between low level mechanisms in simple ways, being an intrinsic property of open complex systems of any kind, or describes the appearance of a new organ, of new structures or some new properties of higher order, a form of change, and from that angle it is regarded as actual birth of something entirely new in an open environment (it is easier to illustrate it physically by radiations, bodies escaping an environment after travelling through it).

Emerging phenomena are related to meta-equilibrium, even if at the level of subsystems everything may seem unbalanced, from a global perspective the system can remain stable and orderly (hence *the theory of emerging evolution in the process of development* argues that the emergence of new qualities is absolutely spontaneous and unpredictable. Theoretical systems purely emerging as complex adaptive systems generate *novelty*, are *unpredictable*, ensure *consistency* and *integrity*, determine *self-maintenance* or relative stability against environmental variations and any changes that occur in their internal structure, also being *asymmetrically causal* – the newly acquired properties are determined only in the "bottom-to-top" direction, never the other way around).

The emergence of such systems takes the form of *weak emergence*, or emergence *explained in a deterministic sense* (a complex statistical causality that is measurable as direction and intensity), or *strong or indeterministic emergence* (Osberg, Biesta, 2007) based on a high degree of risk and uncertainty (the probabilities and their dynamics or their historicity outlining emergence scenarios, or scenarized emerging trajectories of an evolutionary type).

Convergence is not identifiable to transition, in terms of its significance, although apparently, or purposefully, it can be confused with that concept. The example raised for nearly half a century in the national economies of Romania and Serbia (1945-1990) was that of transition from capitalism to socialism, which was in fact *nothing more than the emergence of a system or regime of state capitalism under the leadership of a single communist party*, followed, for nearly a decade and a half or two decades, by the transition to a market economy in both Romania and Serbia, a post-communist transition inspired by (neo-) liberalism, in search of a structural, procedural and organizational end superior in economic efficiency.

Transition is in itself a transitory, temporary or transient phenomenon or process, a transformation phased as a *stage* or period, a transformation or a change in the economy, but *a radical and temporally limited one* (Dăianu 1997; Dinu, 2000). On organizational level, changes are dominantly implemented by interweaving periods of incremental changes with periods of radical transformation (Lewin, 1951; Dulanović&Jaško 2007). In the history of any economy there coexist a larger or smaller number of transitions and several ways to express these "sudden changes" or "paths of accelerated development" from one type of economic and social structure (form of government, economic organization, etc.) to another, which "accelerate" the natural phases, as are styled economic transitions in dictionaries or in an economic literature generating a genuine theory and various distinct patterns or models of transition (for example, writing about the transition in Romania, Joseph Stiglitz identified the main factors of a predominantly negative role as being the too restrictive fiscal policy, the legislation that kept changing, and the absence of programmes meant to create opportunities for business,).
A recent signification of convergence has dominated the last decade and a half, being in a visible expansion, both in frequency of terminology usage, and intensity and depth of statistical determinations; it is narrowing to the scope of the European Union, and conceptually characterizes the time course of a number of processes related to the conditions of pre-accession, accession and post-accession to this interstate union focused on regional componency, as well as and phenomena generated by ensuring economic and monetary stability concerning the criteria for accessing the Euro region, as a natural and constitutional consequence of state membership, derived from intra-community evolution towards higher stages of the integration process.

In this particular manner, and referring the vast and complex phenomenon that brings together both joining and integration into the EU, *economic convergence* grounds, in the new millennium, the macro-financial architecture of the countries or economies that are to become members of the euro area, and globally it concerns the very globalization process. The birth EU was conducted around three main axes, or three pillars: a) the pillar of the European Communities; b) the pillar of common security policies; c) the pillar of judicial cooperation in criminal and police matters. Later the concept of European citizenship was introduced, and the European Parliament"s powers were strengthened, to shape, as early as 1999, with the advent of the euro, an original economic and monetary union, within which the economic convergence of the component countries or states became the fundamental issue. The meanings of economic convergence multiplied suddenly: a) a phenomenon of transition and integration of economies within a common monetary area with internationalization trends, through economic stability-oriented processes (the euro currency is illustrative in parallel with the requirements of the Maastricht treaty, which became gradually financial criteria expressed in a rigorously statistical manner, maintained and subsequently consolidated at Amsterdam in 1997, institutionalized in Nice in 2001, legally customized in Lisbon in 2007, etc.); b) synchronization of business

cycles against asymmetric shocks (Frankel, 2004), felt integratively or community-wise, and anticipated and eased as impact limiting thresholds); c) the generally valid assumption that income per capita (GDP per inhabitant or national income available per capita, etc.) of the developing economies tend to grow faster and with higher rates than in developed economies, to finally find that all economies show a clear trend of convergence concerning income per capita (Le Gallo, Dall'Erba, 2006), due to the effect of recovery, in time and space, of the gap between economies, which is called the *catch-up effect*); d) similarity by gradual harmonization of the level of productivity and export share of non-tradables, in an aggregate context of trade integration of national economies (but also taking into account the Balassa-Samuelson effect, revealing faster productivity growth in tradable sectors than in the non-tradable sectors, in the economies of less developed countries)[1]; e) similarity of economic structures, which become synonymous with complementarity and harmonization of economies in an aggregate or intra-community space (the usual example starts from the shares of agriculture, industry and services in GDP), as pointed out in a recent study, in which a deeper analysis is conducted by another author (Dinga, 2008);

Extended economic convergence holds in practice as many as four dimensions: a) *nominal* or strictly monetary convergence, targeting economic stability and the transition to the single European currency; b) *actual* convergence, which is intended to diminish disparities (especially felt by income and productivity); c) *institutional* convergence, i.e. ensuring compatibility of institutions; d) *structural* or *complete* convergence (Iancu, 2006). There coexists, in the theoretical field, still other classification of convergence, one of an instrumental and parameter type: **β** (conditional on the initial state), **σ** (similarity GDP/capita), **γ** (business cycle synchronization), **δ** (similarity of convergence factors), **α** (similarity of the economy structure), etc., a classification which is frequently used in the structuring of the phenomenon and its distinct modelling instances. In essence, the neoclassical theory of economic growth postulates that all economies that are characterized by formal similarity of the basic parameters (of the production function) will achieve the same level of development, regardless of their initial position.

Based on these findings, three hypotheses of convergence were formulated in the convergence theory: a) *the absolute* (or unconditional) *convergence hypothesis*, according to which the level of income per capita across countries converge in the long term, regardless of their initial conditions b) the *conditional convergence hypothesis*, according to which the level of income per capita in countries having fundamentally identical structures converges in the long term, independently of the initial conditions; c) the *club or group convergence hypothesis* (Baumol, 1986), in which the GDP per capita in countries that have the same fundamental structure, converges in the long term either by an increase in GDP per capita, leading to clubs (groups) of nations with very high incomes, or by a decrease in GDP per capita, generating clubs (groups) of nations with very low incomes, assuming that the initial conditions are similar. Testing those hypothesis has led to the initial definition of several types of convergence:
a) *type* **β** *or "beta" convergence*, arguing that, in the long term, in the context of the absolute convergence hypothesis, according to its own regression equation and its own *regression coefficient* (Sala-i-Martin, 1996), developing economies tend to grow faster than developed ones, and in the context of the conditional convergence hypothesis, there is the same phenomenon, but with some altered parameters, depending on a number of determinants (focused on the link between classic convergence of the quantitative type, and contemporary convergence, which also includes qualitative aspects, also reflecting reducing disparities or processes of deletion of the *gaps* (whether *dimensional gaps* or gaps of macroeconomic correlation, gaps *of dynamics* in the real economic variables, and *simple structural* gaps, or structural differences that exist between two entities segmented methodologically), rather than the *catching-up* ones, defined as dynamic recovery, at different rates, on short and medium term, for the less developed economies and developing economies relative to developed economies (generating economic paradoxes or dilemmas, such as the Lucas type of paradox or the Tosovski dilemma);
b) *type σ or "sigma" convergence*, indicating a decreasing variation of income per capita in a group of countries; this type of convergence is expressed by the statistical indicator of the *coefficient of variation of GDP per capita*, and is fairly commonly exploited in analyses of convergence or economic studies, through the mathematical expression based on an indicator resulting from the classical statistical algorithm of the coefficient of variation (σ_t); its interpretation is quite straightforward when σ^2 or the dispersion of the phenomenon considered is decreasing over a certain period of time, or a transverse process (or in a certain

[1] In a study conducted on a total of 111 countries, and implicitly as many national economies, during the two decades between 1970 and 1989, Jeffrey Sachs and Andrew Warner (1997) concluded that the economies of the developed countries had increased by only 2.3% / year per capita, while developing countries had a 4.5% increase, and isolated countries or closed economies similar to an apparently closed system barely reached 2%.

spatial delimitation) of national economies (and even parts of these), or when the value of the coefficient of variance **σ** decreases, then a convergence process ($\sigma_{t+1} < \sigma_t$) is identified;
c) *type* **γ***, or "gamma" convergence* (quasi-real convergence), which can be described as synchronization of business cycles, is valid even in conditions in which, structurally, there are notable differences between the economies analyzed as open system or ensemble of open phenomena (synchronization of business cycles may have positive effects in terms of eliminating asymmetric shocks by making them symmetrical shocks, as exemplified by the general monetary policy in the euro area);
d) *type* **δ***, or "delta" convergence* (Dinga, 2008), which requires *similar levels of real convergence factors for two or more economies*, or at least an identical "list" of convergence factors, yet not necessarily also similar levels of these (once the convergence factors become similar in two economies, the convergence process would be an already completed one);
e) *convergence of type α or "alpha"*, which involves "the final target or ultimate destination type" of any economic development, and is emphasized by *a similar structure of the economies compared, although permanently raises important issues of methodology and dimensions that are hard to solve* (once solved, the idea of a process of convergence disappears as well).

2. CRITERIA, LIMITS OR THRESHOLDS OF CONVERGENCE, AND ILLUSTRATIONS FOR ROMANIA AND SERBIA

According to the Protocol and Article 109j.1 of the *Maastricht Treaty* (the original article was later renumbered to become Article 121.1 of the *Treaty of Amsterdam*, and later again renumbered as Article 140 of the Treaty on the Functioning of the EU), the criteria of nominal convergence and the explanatory elements, thresholds, limits and normal bands of variation (fluctuation) in the European Union refer to: a) *price stability* (the average inflation rate recorded during one year before the euro zone access must not exceed by more than 1.5 percentage points the inflation rate of three member states scoring the best results in terms of price stability); b) *sound public finances or a sustainable fiscal position* (limiting public debt below 60% of GDP; limiting budget deficit below 3% of GDP); c) *exchange rate stability* (respecting the ± 15% band as the normal band of variation (fluctuation) provided by the exchange rate mechanism for at least the last two years before the country‟s access to the EMU, and the absence of action of devaluation of the national currency against the euro during the same period); d) *low long-term interest rates* (achieving a level of long-term interest rates that does not exceed by more than 2 p.p. the average of the interest in the three countries with the lowest interest) Note: p.p. = percentage points.

In international economic literature, among the numerous opinions, an increasing clear conceptual similarity is identified between *the properties of optimum currency areas (points 1-5)* and the *real convergence criteria*, but other additional criteria are requisite, which have an increasing spreading and frequency of occurrence (6-10): 1) *high degree of economic openness*; 2) *synchronization of business cycles*; 3) *labour mobility*; 4) *flexibility of prices and wages*; 5) *high level of financial development*; 6) *high levels of foreign direct investment*; 7) *high rates of saving*; 8) *improving competitiveness*; 9) *high standards of education*; 10) *the flexibility of the economy as a whole*. The more flexible a national economy is, the easier real convergence is – and this criterion is rather an aggregate of the other nine previous criteria (Traşcă, 2007).

The international financial crisis has revealed *significant asymmetries* between the EU and EMU member states and the three candidate countries, and also *the need to review* and rethink them, starting from *their asymmetry* and the fact that *their standards are too ambitious* (Darvas, Pisani, 2009). In conclusion, the essential criterion of real convergence remains reducing the gap between incomes per capita, a real process conditioned by significant gains in productivity and relative price convergence. If all nominal convergence criteria relate to a set of financial, monetary, foreign exchange, tax policies, indicators are also more efficiently systematized compared with the same major typology of (actual, nominal, institutional) convergence, obviously following the same policies, from Moritz Schularick‟s original manner, presented as early as 2002 (Table no. 1).

The updated 2013 version stipulates six EU indicators of convergence for the Maastricht Treaty, structured according to Table 2: a) three based on money criteria, i.e. inflation (≤ IM3 + 1,5 p.p., where IM3 is the average inflation of the three EU member states that have the lowest inflation), *the nominal interest rate on long-term bonds* (≤ D3 + 2 p.p., where D3 is the average of nominal long-term interest of the three EU member states having the lowest inflation), and *nominal exchange rate* (keeping the nominal exchange rate within the band ±15% of the pilot); b) two having to do with taxation and the budget: *total public debt* (percentage of GDP ≤ 60%) and the *general government deficit* (percentage of GDP ≤ 3%); c) one of a legislative nature: *national financial legislation* (including the legislation for the national central bank – with emphasis on the status of the central bank).

Table 1: Baseline variables, turned into 16 official indicators, structured in the EU by convergence classes (Schularick, 2002), pp. 16-22.

CONVERGENCE		
Nominal= 6 variables	**Real** = 6 variables	**Institutional** = 4 variables
I. Degree of monetary and fiscal stability (3 variables): inflation, (3 variables) inflation, budget deficit and external government debt *II. External economic relations* (3 variables): current account balance, foreign direct investment and trade integration with the EU	*I. Level of economic development* (4 variables): GDP/capita, unemployment rate, share of agriculture in GDP and share of private sector in GDP *II. Dynamics of the real economy* (2 variables): GDP growth rate, growth rate of productivity	*I. Institutions and economic policies* (4 variables): legislative reform, competition policy, financial sector liberalization and liberalization of trade and foreign exchange markets

Table 2: Concrete monitoring of meeting the Maastricht criteria for Romania in 2011

Criterion	**Thresholds, limits and bands of variation, and level of fulfilment**		
Public debts	Maximum 60% of GDP	Fulfilled (33,4%)	**YES**
Budget deficit	Maximum 3% of GDP	**Shortfall (-4,9%)**	NO
Inflation rate	1,8%+1,5%=3,3%	**Shortfall (5,8%)**	NO
Nominale long-term interest rates (10 years)	2,4%+2% = 4,4%	**Shortfall (7,0%)**	NO
Exchange rate	2 years without devaluation of ERM* II	**Shortfall**	NO

Source: *** (2012), Academic Society of Romania (SAR), *Euro, mai devreme sau mai târziu?* (*Euro, sooner or later?*), accessible online http://www.romaniacurata.ro/spaw2/uploads/files/SAR-13-24.pdf. *Note: ERM II stands for Exchange Rate Mechanism. By 1999, the exchange rate (as an important element of the European Monetary System) was a multilateral system of parities which allowed each currency to fluctuate within a band limited in relation to each of the currencies included in the system, establishing also central parity rate in ECU. This was the first exchange rate mechanism (ERM I). When the single currency, the euro, was adopted in 1999, a new exchange rate mechanism, called ERM II, was adopted. Through this mechanism, the multilateral system was replaced by the bilateral one, whereby each participating national currency has a defined central parity rate expressed in euro.

Table 3: Analysis of the fulfillment of convergence criteria for Romania and Serbia, as of 31 March 2013

Country	Average inflation rate (in last 12 months)	Budget deficit as % of GDP	**Public debt as % of GDP**	Member country ERM II	Long-term interest rate (last 12 months)
Annual limits (thresholds / limits)	up to 2,5% (31 March 2013)	up to 3,0% (fiscal year 2012)	**up to 60% or fall (fiscal year 2012)**	minimum 2 years (31 March 2013)	up to 4,81% (31 March 2013)
Romania	**3.9**	**2.9**	**37.8**	**Not a member**	**6.43**
Serbia	**7.3**	**6.4**	**59.2**	**Not a member**	**No data available**

As can be noted, the above variables cover the combined criteria, but only partly explain the factors of convergence, whose spectrum is very broad, as they appear in the econometric modelling dedicated to this phenomenon. To be sustainable, the European Monetary Union is structured based on a fiscal union, and this in turn implies the existence of a political union, as suggested by the so diverse convergence factors, such as: stability or economic balance, mobility of production factors, similarities in inflation and interest rates, comparable productivity, relatively equivalent economic structure, price flexibility within acceptable parameters, integrability of financial markets, comparable degree of economic openness, diversification in production and consumption, fiscal integration, and especially political integration.

3. CONCLUSION

The integration of the new states in the European economy involves, amomg other things, attaining socio-economic convergence targets, which are defined and updated periodically, in keeping with the imperatives of the historical moment, as the topic still holds an important place in the theory of economic growth. If the neoclassical theory of economic growth postulated that all economies characterized by uniqueness of their basic parameters can achieve the same level of development in time, regardless of their initial position, detailing the three major hypotheses of real convergence (absolute or unconditional, conditional and club), testing these hypotheses empirically confirms, with an acceptable error level, the quantitative definition of real convergence of the **β** type, which shows that, in the long term, in the context of the absolute convergence hypothesis, poor economies tend to grow faster than richer ones, and of real convergence of type **σ**, which stresses a decreasing variation of income per capita in a group of countries, and also convergence of type **γ**, which is aimed at synchronizing the business, **δ** – the similarity of the convergence factors, **α** – similarity of economy structure, etc.

In the context of the last global financial crisis, the European Union considered inappropriate to review the criteria stipulated by the Maastricht Treaty, but this is required from practical considerations, along three new dimensions (Darvas, 2010): a) anchoring the average EU criteria in order to avoid that the performance of small economies in the euro area affect the target level of criteria, and reducing disparities; b) criteria of inflation, interest rate and budget deficit should be covered within a variation interval as to the average euro area, provinding a wider decision-making solution for anti-cyclical fiscal policy; c) government debt to GDP should be limited to the same average of the euro area, or it should follow a downward course, decreasing at a satisfactory pace and reaching below the threshold.

Accelerating Serbia"s EU accession and Romania"s convergence to the European Union (EU), as a member state ranking in one of the last two positions in most indicators, are regarded both from the nominal angle, when time seems to be contracting, but also the real angle, when, quite on the contrary, time is much longer. From the first sight, two approach horizons co-exist and subsist, one nominal or short-term, obviously, and one real, i.e. longer. Finally, joining the EU and EMU, respectively an initial convergence and a final convergence, complete or of the structural type, involve a *favourable compromise* between real and nominal convergence, given that Serbia must fulfill the conditions of accession, and Romania, after two years of ERM II, must meet the Maastricht criteria in full. In reality, the current state of both economies certainly describes stages of real and criterial semiconvergence rather than full convergence.
