Figure 1: Questionnaire on the application of educational games in teaching logistics and SCM at faculties in the Republic of Serbia **(one part)**

In the sixth phase, the Questionnaire was activated and then the personalized invitations for participation in questioning were sent from the author' personalized e-mail address. The invitations were sent only one time because of the potential disturbance of respondents. During this process, sending of one invitation was unsuccessful, even after multiple attempts. Included in the invitation was a brief explanation of the study and a statement that participants in questioning will get a database of 55 logistics and SCM educational games as a prize. The Questionnaire was active 25 days, and during this time, the completed questionnaires were automatically collected.

In the seventh phase, the analysis of results was done. In doing so, the questions with multiple responses were analyzed by Multiple Response Analysis (MRA), and more precisely with the Multiple-Dichotomy Method because of the type of the used questions. Also, non-parametric statistical tests were used because of a small number of respondents (and consequently – inadequacy to testing the normality of the distributions of the used variables). The analyzes are all done by the help of tools MS Excel and SPSS Statistics 17.0.

4. RESULTS OF STUDY

The population of teaching staff in the field of logistics and SCM at faculties in the Republic of Serbia consisted of 70 teachers and teaching assistants who work within 26 accredited faculties. The invitations for participation in questioning are successfully sent to 69 teachers and teaching assistants. The total of 32 completed questionnaires is collected from teaching staff of 17 different faculties. Therefore, the response rate of teaching staff is 46.38%, and is considered acceptable. It is interesting to mention that the response rate of teachers (51.16%) is higher than the response rate of teaching assistants (38.46%).

More than half of teaching staff that participates in the survey (54.55%) have experience between 3 and 8 years in teaching logistics and SCM courses. About 10% of teachers from state faculties who teach logistics courses for more than 20 years, as well as about 10% of teachers from private faculties who teach in this field less than 3 years were among respondents.

All respondents use traditional teaching methods such as lectures and discussions, as it was expected; and 15.63% of them use only this method. Then, 68.75% of respondents use case studies; 43.75% of respondents use simulations; and exactly half of the respondents (50%) use simulations and/or educational games in combination with other teaching methods. In addition to the offered teaching methods, the respondents mentioned tutorials and mentoring work with students, visits to the Free zone and relevant companies.

Only about one-fifth of the respondents (18.75%) stated that they used educational games, and thus, it can be generally concluded that educational games are not used to a great extent in teaching logistics and SCM at faculties in the Republic of Serbia. The respondents who use games work at 5 different state and private faculties. There was no statistically significant difference between the game users of state and private faculties (Fisher's exact test: $p(2\text{-sided})=0.063$), i.e. games are equally used both at the state and private faculties.

The respondents-non-users of games cited during the questioning several reasons why they do not use educational games in teaching logistics and SCM. These are:

1. lack of familiarity with educational games;
2. lack of required material and financial resources for games introduction into teaching;
3. lack of time for game introduction into teaching;
4. the little interest of students, in the sense that most students are only interested how to "arrive" at the desired grade;
5. lack of motivation for applying educational games;
6. lack of agreement between teachers and teaching assistants in relation to using games, wherein the problem is participation scoring;
7. a view that learning should be a hard and serious job, so there is no need for games introduction; and
8. An insufficient number of teaching assistants.

The four of these reasons were offered, and the other four were identified based on respondents' responses. Respondents gave a total of 41 reasons, which indicates that more than half of the respondents stated more than 1 reason.

The two most common reasons why respondents do not use educational games in teaching logistics and SCM are:

1. lack of familiarity with educational games according to 61.54% of respondents; and
2. lack of required material and financial resources for games introduction into teaching according to 42.31% of respondents.

The reason of lack of familiarity with educational games was given by 57.90% of teachers and 71.43% of teaching assistants (no statistically significant difference was found, Fisher's exact test: *p(2-sided)*=0.668), (see Table 2). This same reason was stated by 65.22% of respondents from state faculties and 33.33% of respondents from private faculties (also, no statistically significant difference was found, Fisher's exact test: *p(2-sided)*=0.538).

The reason of lack of required material and financial resources for games introduction into teaching was stated by 47.37% of teachers and 28.57% teaching assistants (no statistically significant difference was found, Fisher's exact test: *p(2-sided)*=0.658). Also, this reason was stated by 43.48% respondents from state faculties and 33.33% respondents from private faculties (no statistically significant difference was found, Fisher's exact test: *p(2-sided)*=1.000), see Table 2.

Table 2: The two most common reasons why respondents do not use games

	The two most common reasons why respondents do not use educational games in teaching logistics and SCM at faculties in the Republic of Serbia (*N*=26)		
	N	Lack of familiarity with educational games	Lack of required material and financial resources
Teaching staff			
Teachers	19	11	9
Teaching assistants	7	5	2
Fisher's exact test		0.668	0.658
Faculties			
State faculties	23	15	10
Private faculties	3	1	1
Fisher's exact test		0.538	1.000

*significant for $p<0.05$; **significant for $p<0.01$

It is interesting that all respondents who do not use educational games in teaching logistics and SCM stated that they would like to introduce educational games in teaching in this field in future, except one respondent who did not want to answer this question.

A small number of respondents uses games in teaching logistics and SCM at faculties in the Republic of Serbia (*N*=6), as we previously concluded. They use 2 games in average (*N*=6; mean *M*=2.33; standard deviation *SD*=1.21). From the answers, it can be seen that both manual and computer versions of games are in use; mostly free games, but also games that cost more than 450 Euros; most games are already developed by others, as well as new games developed according to their own needs. All respondents-users of games in teaching indicated that the games positively influence on the interest in courses. Furthermore, these respondents were asked to rate how much it is easy or difficult to improve certain fundamental competences of students by using games on a five-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). In that sense, they evaluated the following competences: solving problems, decision making, planning and organizing of tasks, communication, and team-work. The selected results are presented in the form of radar chart in Figure 2. These results show that the observed teachers are satisfied with the possibilities of improving students' competences with the use of games.

A half of respondents (*N*=16) gave additional comments on the application of games in teaching logistics and SCM. Their comments are divided into three groups:

- positive comments – that point out the advantages of using games in teaching;
- constructive comments – that give useful suggestions in relation to the use of games in teaching; and
- comments of non-supporters of the games – that observe the use of games as unnecessary and/or useless activity.

Thus, ten comments are classified in the group of positive comments (62.50%), five in the group of constructive comments (31.25%), and one in the group of comments of non-supporters of the games (6.25%).

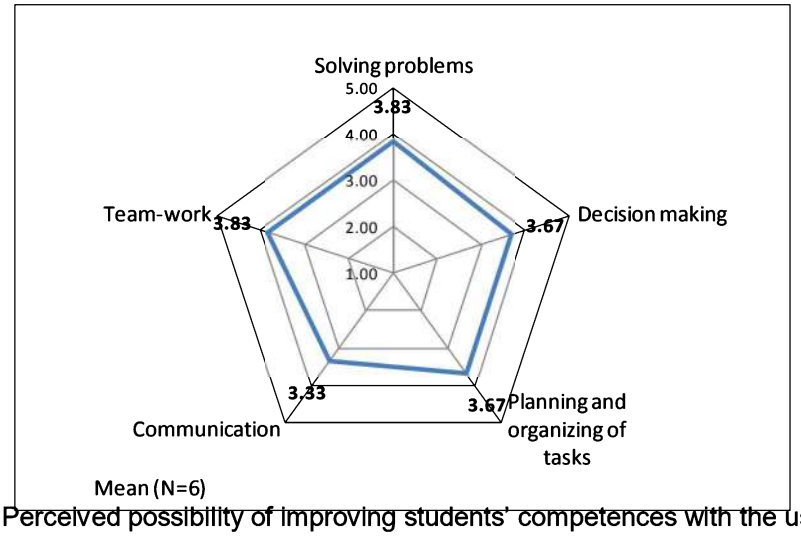

Figure 2: Perceived possibility of improving students' competences with the use of games

Finally, 84.38% of participants were interested in getting a database of 55 logistics and SCM games.

5. DISCUSSION OF RESULTS

In this study on the application of the logistics and SCM games, 46.38% of competent teaching staff from the higher education institutions in the Republic of Serbia participated. The obtained response rate is considered acceptable based on specifics of populations, which can be justified by considerations and data given in Neuman (1997), Chang (2003), Faria and Wellington (2004), Lean et al. (2006), and Zoroja (2013). Thus, according to Neuman (1997), p. 247, the adequate response rate presents the assessment which depends on population, practical limitations, topics and answers with which researchers feel comfortable so that the response rates less than 50% can be accepted. Moreover, in some of the previous studies on using simulations and/or games in teaching (such as Chang, 2003; Faria and Wellington, 2004; Lean et al., 2006; and Zoroja, 2013), the adequate response rates were less than 25%. Hence, it can be generally concluded that the teaching staff is a specific population not much interested in participating in studies of this type.

The results of this study confirm that educational games are not used to a great extent in teaching logistics and SCM at faculties in the Republic of Serbia. Only around one-fifth of the respondents (18.75%) actually use games in teaching in this field. Additionally, an interesting fact is that exactly half of the respondents (50%) use simulations and/or educational games in combination with other teaching methods. This data is very different from the conclusion expressed in Johnson and Pyke (2000) – that most teachers use at least one game, simulation and/or interactive exercise in addition to other teaching methods for teaching logistics and SCM. However, this conclusion was derived based on analysis of courses from the several leading institutions of higher education in the US. On the other hand, if the data was considered from the wider context i.e. compared to users of business simulation games (studies like Faria and Wellington, 2004; Zoroja, 2013), they could be positively interpreted. Thus, according to Faria and Wellington (2004), 30.6% of teaching staff from the higher education business schools in the US use business simulation games (study conducted in 2003). The study from Croatia conducted in 2012 shows that 26.32% of teaching staff from the business and economics departments of higher education institutions in this country are users of business simulation games (Zoroja, 2013).

The results show that the teachers who use games in teaching are satisfied with the possibilities of improving students' competences with the use of games. Here, it should be acknowledged that this conclusion is derived based on a small number of respondents who use games. The aforementioned reason also limits the consideration of using manual vs. computer versions of games, free games vs. commercial games, and similar comparisons.

The results of the study confirm that teaching staff is not sufficiently familiar with the logistics and SCM games. This reason was stated by more than half of respondents (61.54%). Of course, this can be closely connected with the small number of respondents-users of games, as Faria and Wellington (2004), p. 198, pointed out that it is difficult to be a game user if one is not familiar with games. The other reasons of non-users of games were: a lack of required material and financial resources for games introduction into

teaching, a lack of time for game introduction into teaching, a perceived little interest of students, etc. We believe that the identification and understanding of these reasons are important for future activities in the sense of their mitigation/overcoming. At the same time, the findings show the ubiquitous interest of the teaching staff for games introduction into the teaching of logistics and SCM at faculties in the Republic of Serbia. The analysis of comments confirms that teaching staff has positive attitudes to the use of games in the teaching process.

While the data for this study is derived from a population-based questioning, it is important to note obvious limitations to the generalizability of the findings. The population of teaching staff from the field of logistics and SCM in the Republic of Serbia was small. Additionally, the response rate to the questionnare was 46.38% and the group of respondents-users of logistics and SCM games were under-represented.

6. CONCLUSION

This is one of the first empirical studies of the application of educational games in teaching logistics and supply chain management which has been conducted in the Republic of Serbia. The study answers the following questions: "What is the level of application of the logistics and SCM games at faculties in the Republic of Serbia?", "Are the teaching staff satisfied with the effects of using the games?", "What are the reasons for not using the games in teaching?", "Is the teaching staff interested in introducing games in teaching logistics and SCM?", and some other issues that are not covered in this paper. One of the main findings of this study that there is a large number of teaching scholars who not use logistics and SCM games in the Republic of Serbia, probably most of all due to a lack of familiarity with these games and of course the other reasons, is not surprising. This suggests a need for further investigation of the effectiveness of using games in logistics and SCM courses. We believe that more empirical studies about the effects of employing games in addition to the other teaching methods could stimulate an interest in games amongst teaching staff currently not familiar with them. Additionally, the development of methods of the selection of games and tools like DST SLSCMG (Decision Support Tool for the Selection of Logistics and Supply Chain Management Games) (see Cvetić et al., 2013), then development and application of a new frameworks or models of learning logistics and SCM based on games (such as those presented in Lewis and Maylor, 2007; Huang et al., 2008), can be useful to current and potential logistics and SCM game users.

PROJECT MANAGEMENT

COMPETENCES OF THE PROJECT MANAGERS IN RELATION TO THE TYPE OF PROJECT

Dejan Petrović*, Marko Mihić, Vladimir Obradović
Faculty of Organizational Sciences, Belgrade
*Corresponding author, e-mail: dejan.petrovic@fon.bg.ac.rs

Abstract: *The paper considers competencies of contemporary project manager in relation to the type of project. The paper starts with an analysis of project types and their influence on project management approach. Competent factors of a project manager are divided and considered in the three separate groups: factors of technical competences, factors of behavioral competences, and factors of contextual competences. The importance of the project manager competencies is connected to the type of the project. The last part of the paper analyses competencies of project manager and project types. The assessment of contemporary project manager competencies should show us directions of further improvement of project manager.*

Keywords*: project manager, project type, technical, behavioral and contextual competencies*

1. INTRODUCTION

Presently, a great variety of different approaches to project management exist. All of these have been developed with the intention of using the previous experiences in project management and applying adequate procedures, methods, and techniques so that the project is implemented in line with the desired objectives. Among the world renowned organizations involved in the development of project management approaches and gathering numerous professionals in the area are IPMA – International Project Management Association and PMI – Project Management Institute. A special feature of the contemporary project management is the use of specialized software tools for project management (Microsoft Office Project, Primavera Professional Project Management …) which are practically indispensable for management of any complex projects.

The role and the position of a project manager are of special significance for the functioning of a project. The project manager is fully responsible for ensuring that the project is implemented in line with the schedule, budget, and quality. But the competencies of the project managers depend on the type of project.

2. ORGANIZATION AND PROJECT TYPE

From the project point of view, organizations can generally be divided into two groups relative to their attitude towards projects:

- Project oriented organizations,
- Organizations which are not project oriented.

Project oriented organizations carry out each of their operations in line with the principles of project organization. This group of organizations includes: construction companies, project design organizations, contracting companies, scientific and research organizations, consultancy companies, aircraft manufacturers, shipbuilding companies, manufacturers of large equipment and plants, marketing agencies, software companies, design centers, military industry and many others.

Organizations which are not project oriented do not perform all of their tasks in line with project management principles, but can nevertheless organize a number of their activities as projects: marketing of new products, research and development of new products and services, construction of new capacities, introduction of new information technology systems, reorganization of the company, capacity building, organization of annual shareholder meeting, moving of the offices, production for a known buyer, and quite a number of other operations. Some researches indicate that up to 50% of the operations of such companies are carried out as projects.

One of the easiest ways to categorize projects in an organization is to group them along the lines of two perspectives: significance of the project and project client. From the point of view of significance, a project can be strategic or operational, whereas from the perspective of the client it may be internal or external.

Using these parameters all projects in an organization may be classified into four groups, as shown in Figure 1.

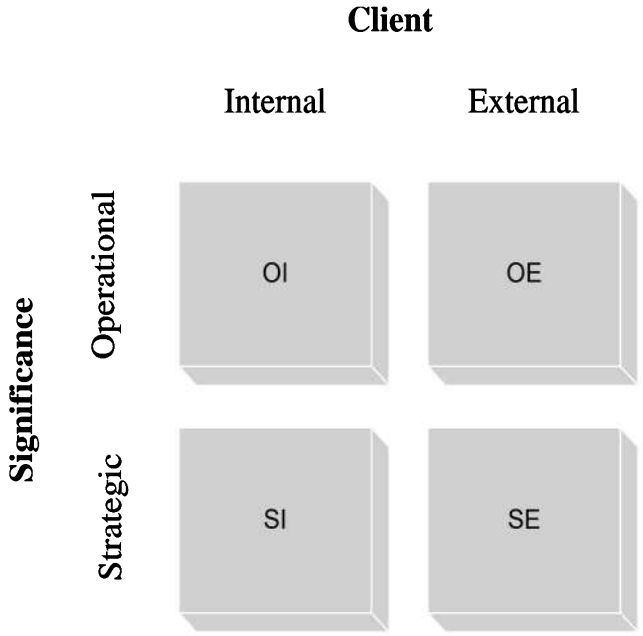

Figure 1: Categorization of projects relative to its significance and client

Project categorization system in organizations may be very complex. A research of literature conducted by Lynn Crawford, Brian Hobbs and Rodney Turner (Crawford et al. 2005) points towards a total of 37 distinctive characteristics that can be used for categorization of the projects. Table 1 shows the most commonly used ones, as well as the characteristics which were considered to be of greatest significance for categorization of projects.

Numerous types of projects are distinguished with respect to the industry in which they are implemented; their purpose; technical structure and other attributes. Each of the types of projects has its distinct attributes which help set them apart from others and define the style of management of their implementation.

Table 1: Comparison of most frequently used and most important attributes of project categorization (Crawford et al. 2005)

Most frequently used characteristics	Most important characteristics
Application area or product	Organizational benefit
Nature of work	Costs
Customer	Customer
Complexity	Application area or product
Costs	Complexity
Scope	Strategic importance
Strategic importance	Risk
Risk	Nature of work
Organizational benefit	Resources
Results	Scope

3. COMPETENCIES OF THE PROJECT MANAGER

The project manager is a person in charge of accomplishment of project objectives. He/she plans, organizes, leads and controls the work of the project team or the organizational unit in charge of project implementation. In smaller size projects, the project manager can also perform some of the project activities. The project team comprises people who are in charge of performing individual tasks or groups of tasks in line with the project manager's instructions. The members of the project team rely on one another and affect each other's work, and together, they work towards achieving the project goals (Jovanović et al. 2009).

To analyze and evaluate the competencies of the project managers, factors for evaluation of those competencies must be identified. It is believed that the successful project management requires a mix of skills, including interpersonal skills, technical competence, and behavioral skills along with the ability to understand the situation and people and to comply the appropriate leadership behavior (Strang, 2003). Research conducted on a series of seminars in project management by Barry Posner's (Meredith, Posner & Mantel, 1995) gave testimony that 1400 different skills are needed a project manager. 1400 of these positions are grouped in 6 field skills of project managers:

- Communication skills (listening, persuasion) - 84% of respondents believe that being a good communicator is the most important skills of project manager,
- Organizational skills (planning, goal setting, analysis) - 75%
- team building skills (empathy, motivation, a sense of loyalty and pride) - 72%
- Leadership skills (showing on the case, energy, vision, delegating, positive attitude) - 68%
- Ability to solve problems and tasks (flexibility, creativity, patience, perseverance) - 59%
- Technological skills (experience, knowledge of the project) - 46%.

El-Sabaa (2001) is, in his research, divided project manager's competencies into three categories:

1. The ability to work with people (mobilization, communication, problem solving situations, delegation of authority, political sensitivity, self-assessment, and enthusiasm);
2. Conceptual and organizational skills (planning, organizing, target orientation, the ability to see the project as a whole, ability to visualize the connection of the project with economic and non-economic subjects, problem orientation);
3. Technical skills (specific skills in the use of methods and techniques, project knowledge, understanding the methods, processes and procedures, technology requirements, the ability to use a computer).

A survey has shown that the relative importance of the ability to work with people estimated by project managers in the field of agriculture is 85.6%, while by the project manager in the field of electro-energy projects amounted to 84.4%, and project managers in the field of information systems 85.9%. The relative importance of conceptual and organizational skills is 77% (project managers in the field of agriculture), 82.9% (project managers in the field of electro-energy projects) and 78.9% (project managers in the field of information systems). Technical skills are, for all tested areas, received the least relative importance by project managers: agriculture - 48.4%, electrical energy - 50.5% and information systems - 52.5%.

The following text will provide a detailed overview of the competency factors based on ICP IPMA Competence Baseline, version 3.0 (IPMA, 2006). IPMA Competence Baseline is a common framework for assessment and certification of project managers promoted by the International Project Management Association – IPMA. IPMA Competence Baseline breaks down professional project management competencies in three broad ranges: technical competences, behavioral competences, and contextual competences. These ranges represent the integration of all elements of project management, together they describe a particular function and are independent for the most part. Each of the areas consists of competence elements which cover the key aspects necessary for successful project management.

The first range is that of technical competences consisting of competence elements that deal directly with the project management matter. In the 'Technical' range the competence elements described are needed to initiate and start, to manage the execution of, and to close and analyze a project. Depending on the kind, size and complexity of the endeavor being carried out, technical competences may apply to management of a project, program or portfolio.

In the technical range, the competence elements of a project manager include the so called "solid" elements of project management. The technical competences consist of the following twenty competence elements:

- **Project Management Success.** Achieving the project, program or portfolio objectives within the agreed constraints is a result of the competence of the project manager to integrate and balance among the requirements, activities and project results. This element also entails the capacity of project managers to analyze the effort underway, define the plan and procedures, implement the plan and bring the project to successful closure.
- **Interested Parties (Stakeholders).** This competence element refers to the capacity of the project manager to identify and analyze the interested parties, develop a strategy, define a plan and ensure that they are satisfied in each of the project phases.
- **Project Requirements and Objectives.** The project manager should be able to clearly identify project requirements, develop a business case, define objectives, validate requirements at key points in the project lifecycle and constantly assess compliance with the project objectives and implement the project in line with the previously defined requirements and agreed objectives.
- **Risks and Opportunities.** This element includes the competences of the project manager to identify risks and opportunities in the project, analyze possible consequences, develop a risk and opportunity response plan and regularly control and update the risk and opportunity response plan.
- **Quality.** The project manager is supposed to ensure that the project requirements are met in line with the main purpose for which the project is developed. This process entails development of the quality plan, quality assurance, and quality control.
- **Project organization.** Project organization covers the competence of the project manager to design appropriate organizational structure, identify the necessary resources and define the appropriate roles, levels of responsibility, procedures and means of communication.
- **Teamwork.** This competence element covers the competence of the project manager to build a team, develop a common sense of purpose, belonging and commitment and constantly improve the quality of work performed.
- **Problem Resolution.** This competence includes defining procedures for detecting problems, analyzing problems and identifying their root causes, capturing ideas to solve a problem and selection of possible solutions and implementation of the selected solution.
- **Project Structures.** A project manager should possess the appropriate knowledge to analyze and define different project structures by using methods such as WBS, PBS, OBS, etc.
- **Scope and Deliverables.** The purpose is to assess what needs to be done and what is covered by the project scope that has to be carried out for the project to finish successfully and produce the desired results.
- **Time and Project Phases.** This covers the project manager competences to implement the project within the approved schedule. It includes structuring, sequencing, estimating the duration and scheduling of the activities, including the monitoring and control of timely execution of the project activities.
- **Resources.** This is the capacity of a project manager to identify the necessary resources, develop a resource plan, optimize the use of resources, and monitor and control the use of resources.
- **Costs and Finance.** A project manager must have the capacity to adequately perform all activities related to planning, monitoring and control of the costs in the phases of project preparation and implementation.
- **Procurement and Contract.** This is the capacity of a project manager to obtain the best value for money of goods and services from project vendors and suppliers.
- **Changes.** A project manager should have the capacity to identify all proposed changes, analyze their consequences to the project, get the changes accepted or rejected, as well as to plan, execute and control the approved changes.
- **Control and Reports.** Includes the capacity to measure the actual progress and project performance, compare them with the plan, provide information to all project participants and stakeholders and undertake appropriate corrective actions.
- **Information and documentation.** This entails the capacity of a project manager to manage information and documentation by establishing appropriate information systems and defining documentation management procedures.

- **Communication.** A project manager should have the capacity to effectively manage project communications by developing communication plans, disseminating information and developing comprehensive reports.
- **Start-up.** Start up competence element entails the process steps such as initiating start up process, developing a detailed project management plan, securing resources and formal agreements to start the project.
- **Close-out.** Close-out refers to the competences to plan and carry out activities related to the completion of a project, handing over of the operational documents, agree on a process to resolve open issues, complete all financial transactions and update the final costs, conduct a comprehensive review of the project and record the lessons learned.

Behavioral competence range covers competence elements such as personal behavior and project management related behavior. This range also covers opinions and skills of the project manager. This is a set of different competency elements, which are relevant to the project manager, and project manager's competences in managing relations with the people in the project and the project stakeholders:

- **Leadership.** Leadership involves the capacity of a project manager to provide direction and motivate others in their role or task to fulfil the project objectives. Leadership is particularly important when a project encounters problems, where change is required or where there is uncertainty about the course of action.
- **Engagement and motivation.** Is the personal buy in from the project manager and from the people inside and associated with the project.
- **Self-control.** This is a systematic and disciplined approach of the project manager to coping with the daily work, changing requirements and stressful situations.
- **Assertiveness.** This is the ability of the project manager to his/her views clearly, persuasively and authoritatively.
- **Relaxation.** It Is the ability of a project manager to relax, recuperate and regroup after stressful events and react and make decisions in the light of the new circumstances.
- **Openness.** Openness is the ability of the project manager to make others feel they are welcome to express their suggestions, worries and concerns that the project can benefit from. Openness is an important competence and is a means to use knowledge and expertise of others.
- **Creativity.** Creativity is the capacity of the project manager to think and act in an original and innovative way. The project manager should exploit and encourage the creativity of individuals and the collective creativity of the project team, to obtain better results in the project.
- **Results Orientation.** This means the capacity of the project manager to focus the attention and attention of the project team on key objectives to obtain the optimum outcome for all the parties involved, so that the project results satisfy the interested parties.
- **Efficiency.** This is the ability of the project manager to use the time and resources in a cost effective manner in order to produce the agreed deliverables with as little investment as possible.
- **Consultation.** This is the competence of the project manager to reason, present solid arguments, to listen to other points of view, to negotiate and to find solutions.
- **Negotiations.** Negotiations are the means by which the project manager can resolve disagreements concerned with the project or programme to arrive at a mutually satisfactory solution. A well developed ability to negotiate can help the project manager to avoid real conflicts.
- **Conflict and crisis.** This competence element covers ways that the project manager handles conflicts and crises that can arise between different individuals and parties involved in a project or programme.
- **Reliability.** A reliable project manager builds trust with others by delivering on the promises made. Reliability covers responsibility, correct behaviour, robustness, and confidence.
- **Values appreciation.** This is the ability to perceive intrinsic qualities in other people and understand their point of view. It also covers the ability to communicate with them and be receptive to their opinions, value judgements, and ethical standards.
- **Ethics.** This competence element embraces the morally accepted conduct or behavior of the project manager.

Contextual competence elements describe the competence of the project manager to manage relations with the parent company and the competence to operate in a project focused organization. Contextual competences may be divided as project management in permanent organizations, and links between managing a project and managing a work of the organization. Contextual competence elements include elements that describe the concepts of projects, programs and portfolios and represent a connection between these concepts and the organization or between organizations, which are involved in the project. Understanding these concepts for project implementation is one of the most critical elements of the effective work of a project manager.

- **Project Orientation.** Project managers should have sufficient knowledge about managing project-oriented organizations.
- **Program Orientation.** This is the element of competence covers the competence of a project manager to develop and apply project management related knowledge.
- **Portfolio Orientation.** This is the capacity of the project manager to prioritize organization's projects and/or programs and optimize business improvement initiatives of the projects and programs to the organizational objectives.
- **Project, program and portfolio orientation.** This covers the processes of introduction and continuous improvement of the project, program and portfolio management in organizations.
- **Permanent Organization.** This competence element covers the relationship between the project organizations that are temporary and the permanent entities of the line managed organization contributing to or interfacing with the project work.
- **Business.** In order to be fully effective and efficient, project manager needs to fit into the business environment. Project, programme and portfolio management are linked to the organization's strategy.
- **Systems, products and technology.** This competence element covers the linkage between a project/programme and the organization regarding systems, products and/or technology.
- **Personnel Management.** This element covers aspects of project manager's competences related to projects and/or programmes including planning, recruitment, selection, training, retention, performance assessment, and motivation.
- **Health, security, safety and environment.** This element covers the activities of project manager that help ensure the organization, i.e. implementation project results, behaves appropriately in the context of health, security, safety and the environment.
- **Finance.** This element covers the financial context within which the organization operates. The project manager must provide information to the financial management of the organisation about the financial requirements of the project and co-operate in accessing the funds, checking payments and controlling the use of such funds.
- **Legal.** The project manager must operate within the legal boundaries and recognize the aspects of law applicable to the particular project or programme and which derive from the project or programme itself.

4. COMPETENCIES OF PROJECT MANAGER AND PROJECT TYPE

The project manager does not have to have specialized skills and knowledge for all tasks carried out in the project. The work of the project manager does not entail narrow specialization in a particular subject matter within the project scope. In order to efficiently perform the job, it is essential for the project manager to undergo appropriate training to acquire adequate knowledge and skills of project management and thus properly coordinate and direct the activities and stakeholders to achieve the desired project goals (Muller & Turner, 2010). The project manager must possess knowledge and understanding of economic and technical characteristics of the project activities to manage them adequately and make appropriate decisions (Oehmen, 2012).

The organizational structure of small size projects involving a small number of people is relatively simple. In these projects, the project manager can fairly easily and directly manage all individuals in the project. However, as the project expands so does the system of management, and the scope of control that one project manager may have over the activities is becoming restricted.

Technical expertise is one of the oldest skills that are required by the project manager. Most organizations today believes that a successful project manager requires a good knowledge of the area where the project is implemented (Levin, 2014). This attitude is related to the view that the project manager cannot be recognized

by the team if it is not a technical expert if it is unable to plan an elegant technical solutions, solve technical problems and identify possible technical problems regardless of the type of project (Muller & Turner, 2007).

It is certain that a particular expertise in the area where the project is implemented necessary for successful project management, but the question is what the level of knowledge necessary for the success of the project is. There is no universal answer to this question, but mostly depends on the type of the project and individual approach. Individuals who focus on the word "project" think that a perfect knowledge of the area where the project is implemented is critical, while on the other hand, individuals who emphasize the word "manager" believe in the expertise of its project team. The above mentioned research shows that knowledge of the area where the project is implemented is not a necessary factor for the successful conduct of the project, but some knowledge of the area in which it is implemented is necessary. Most of the problems in project implementation, which occur due to the project manager, are related to ineffective project management, but not for a lack of technical expertise.

Ability to work with the client / user can bind to the modern project manager for all types of projects. This ability has evolved from demands for basic communication and the need to see the project from the perspective of the client or user.

One of the most important characteristics of the modern project manager is the ability to plan the project into line with the impact of the project on business and adjust the implementation of the project so as to obtain relevant business results for the organization.

Ability to use appropriate methods and techniques of project management also falls into the classic skills of project managers. Today's project managers the ability to be more reflected in adapting the methodology of project management in accordance with different characteristics and type of the project. A successful project manager is also reflected in the ability to use methods and techniques of project management in order to recognize problems early enough and predicted solutions before problems have a significant impact on the results of the project.

The strategic ability of project managers is also a feature of the modern project manager (Levin, Ward, 2011). Due to the need for agility of organization, project manager no longer has the luxury of implementing the project out of close coordination with the strategic guidelines of the organization. The project manager must understand the strategy of the organization and customer/client and for each type of project has to review whether it is in accordance with the strategic goals of the organization. The project manager needs to fine-tune the project in accordance with changes in business strategy so that the project continues to be relevant to the organization or client. The project manager must be prepared for rapid changes in the priorities of the contracting authority of the project.

The ability to build a team and motivate the project team is now accepted as a necessary ability for all type of projects because technical knowledge of the project manager is not enough to motivate the project team members. Project managers usually borrow people from the functional units and therefore they need additional knowledge how to develop project team. The project manager should allocate tasks so as to keep the project team clearly focused on results and to encourage members of the project team so that they feel responsible for the achievement of project results.

Ability to solve problems has always been a desirable ability to project managers by the organization. This is often linked with the view that a project manager needs to be an expert in the area where the project is carried out. Today, however, the complexity of the project is much higher than before (and continues to grow) and the number of areas in the project for which the project manager needs to be an expert. Instead to expand the ability of problem solving, the contemporary project manager should have the ability to build the capacity of the team to effectively solve problems.

One of the capabilities of the modern project manager is possession of cultural intelligence. In a globally connected world, projects are no longer limited to one location nor are the users only at one location. Today, the resources and users are globally located, and the project manager should be able to accept the knowledge and skills as well as the specificities of cultures that individuals bring with them.

Capabilities that distinguish successful project managers at small projects are not also the skills that are essential in large projects. Desirable skills of project managers are changing in relation to the size of the team, as well as in relation to how the project includes various functional units or exceeds the boundaries of the organization, and whether the project is strategic or more operationally oriented.

The stronger expertise of project managers will lead small projects to success because personal knowledge and personal skills allow the project manager to successfully solve problems. But this approach has no meaning when the number of members of the project team is bigger. If the project takes place within a single functional entity conflicts and potential problems is much smaller. But if the scope of the project includes a larger and more functional units, then by the project manager requires different skills. If the project has to improve the existing functionality, then the focus is not on the ability of the strategic vision of the project managers. But if the project aims to achieve strategic results for the client's business, then the project manager should have the ability to see through the technical aspects of the project and to run the project according to the desired business results.

5. CONCLUSION

The paper presents the most important competencies of project manager in relation to the type of project. Organizations have to assess existing skills of project managers and check how they comply with the current requirements of the relevant organizations in the field of project management and trends in this area. Evaluation of project manager's competencies should allow defining directions of their further development.

When the number of projects increases in the organization (usually when the organization grows) the performance of project managers no longer depends only on his abilities and ways of implementation of the role, but also the willingness of the organization to adapt appropriate approach for projects execution. In this case it is necessary to reduce the so-called "feudal" relationship and hierarchy among organizational units and give project managers the authority to directly allocate resources and rewards individuals from the functional units. This is often a great change, but without it, there is little possibility that they will ever have a good track record on projects that include several functional units. Also, the introduction of the multiproject management principles into the organization will help project managers about assigning priorities and resource allocation.

Many things have influence that someone become a successful project manager. But project success comes from the ability of project managers to justify himself with the needs of each project. Project managers who are improving their skills in accordance with the requirements of modern project management can expect to be successful in the future regardless of the type of project.

Abstract: *This paper presents discuss the topic of knowledge sharing in project environment.There is an awareness of the fact that knowledge sharing between projects increases organizational knowledge and add value to future project and the performing organization. On the other hand, literature and a number of researces showed that there are different mechanisms that can be used to share knowledge, depending of project characteristics. This papers analysis literature on knowledge sharing in project environment, relying on knowledge acquisition and creation of new knowledge. Paper also present the results of empirical research conducted in Serbia to reveal what are the most frequently used mechanisams to share knowledge between project – formal or informal.*

Keywords*: project, knowledge, project environment*

1. INTRODUCTION

Knowledge sharing between projects increases organizational knowledge. Each project has different plans, results, problems and the level of performances which gives plenty of opportunities for learning. By integrating and sharing of such experiences between projects a company can create the significant base of organizational knowledge for future endeavors. The existence and development of the knowledge base in the organization has a significant effect on the strategic development of an organization (Szulanski, 1996; Nagarajan & Mitchell, 1998).

Cooper et al. (2002) present a dynamic process of learning between projects, which can be used by managers to test ideas, see impacts and capture best practices. The conclusion is that the procedures for the acquisition of knowledge and dissemination of lessons learned should be organized. However, learning within the project does not happen naturally, it is a complex process which needs to be managed (Todorovic et al., 2015). The learning process can not exist in isolation from other processes, and organizational learning is impossible unless it is seen as a supplement to other processes. Sense (2007) highlights the following five factors that influence the creation of a learning environment: cognitive style, the relationship between the participants in the learning process, the hierarchical scale, knowledge management and situational context. Arthur, DeFillippi i Jones (2001) also emphasize the foundation of the project success on learning, classifying the success of the project in terms of performances and aspects of learning. Knowledge generated by learning from the projects could lead to far-reaching changes in the strategic focus of the organization (Brady & Davies, 2004). One of the most recent papers in the field of knowledge management between projects confirms the hypothesis that an appropriate environment, including social and technological aspects, enable knowledge management process and has a significantly positive impact on documenting of project knowledge (Reich et al., 2012).

2. KNOWLEDGE ACQUISITION IN PROJECT ENVIRONMENT

The ways of acquiring of organizational knowledge include: the usage of knowledge that already exists in the organization or gathering knowledge that exists outside the organization, instructions or direct transmission of knowledge from the people who own it, observation and notification of problem solving, brainstorming, protocol analysis e.g. experts are required to express their thoughts in solving problems aloud, nominal group technique, Delphi technique, etc. To acquire knowledge in project environment following steps need to be implemented: use of certain assets in order to collect information from people involved in the project; interpretation of information and draw conclusions based on the of experts knowledge and their judgment; the usage of those interpretations to form policies that represent the thinking of people who have experience of working on projects.

3. KNOWLEDGE SHARING IN PROJECT ENVIRONMENT

Acquired knowledge becomes information and the process of sharing knowledge should enable not just a simple transfer of such information but transfer of knowledge to new users in their context and then move into knowledge. The process, which involves the adoption of new information and linking them with existing

knowledge and experience, is a learning process. Learning and knowledge are separate but related processes in terms of learning to create knowledge, and expertise to influence the future of learning (Lyles & Easterby-Smith, 2003).

The process of knowledge sharing is in the literature often treated as a black box (Berends, 2005). The knowledge gained is not always completely and without any changes useful to the project. It can be either to extensive or too specific. In other words, it is necessary to adapt the requirements of a particular project. The process that enables this is the process of *knowledge creation*, based on existing knowledge gathered within and outside the organization, adapting it to the needs of the project.

The knowledge sharing can be seen as a process of reconstruction of knowledge, not as a simple act of sending and receiving of organizational knowledge (Abou-Zeid, 2005). In other words, when we talk about the knowledge transfer, but without the creation of new knowledge without an existing organization, then we can talk just about information transfer (Boder, 2006).

Knowledge creation can be accessed through a variety of ways such as training, hiring external resources, recruiting people of different profiles in order to create fresh knowledge base. This is a question of innovation - effectively turning ideas into action. The challenge is not to lose creative ideas and allow them to flow wherever they can be used. Most often the difference between the old and new knowledge is not always clear. Innovation can often be drawn from the lessons of the past. The application of old knowledge almost always involves some adaptation and in the process creates new knowledge. In the end, the quality of knowledge does not depend on the fact whether it is old or new, but whether it is relevant. The following text of this paper is focused more on the process of knowledge creation, the process of integration of project knowledge.

4. KNOWLEDGE INTEGRATION IN PROJECT ENVIRONMENT

Integrating knowledge present the set of activities of team members that share individual knowledge and combine them to create new knowledge (Okhuysen & Eisenhardt, 2002). The core activities of any project-oriented organization is a coordination which is achieved through the active participation of individual specialists and managers. Such coordination can not be achieved without access to an adequate knowledge.

In many project there are multifunctional teams reither than functional teams. Multifunctional teams are formed under the assumption that they will combine specialized knowledge in different organizational units. However the way in which knowledge will be integrated remains often poorly explained. Multifunctional teams are typical for the following three situations: when the focus is on creativity and innovation, when you need to reach a consensus through community input, negotiation, or investigation and when it is necessary to manage strategic change.

The integration of knowledge collected from various projects has its economic value, because the organizational competitiveness is affected by diversity and strategic value of specialized knowledge and also the organization's ability to integrate knowledge effectively. An organization's ability to integrate knowledge depends on the mode of communication and working procedures (routines) and the way in which implicit knowledge into explicit codified rules. On the efficiency of the process of integration of knowledge affects the existence and developed knowledge among the participants, coordination and organizational structure (Papke-Sields, Beise, & Quan, 2010).

Despite the existence of knowledge that should be integrated, one of the necessary preconditions is the common basis between users of this knowledge. E.g. in the case of sharing knowledge for the development of a new trade system between technicians and sales managers, the key point is that sales have basic knowledge about the technology to be applied, a technician basic knowledge about the process of trade. Coordination is a process that must be constantly improved. In addition, the very organizational structure affects efficiency and effectiveness through the integration of knowledge way to connect the activities and tasks that are running.

The greater scope of knowledge that should be integrated, the lower is the efficiency of knowledge integration. The greater the volume of knowledge requires better coordination, and organizations that do not have a lot of experience in this process becoming less efficient in this process. On the other hand, a larger scope of knowledge strengthens the competitiveness of organizations and reduces the chance for copying from other organization. Flexibility of the process of integration of knowledge depends on the organization's ability to reconfigure existing knowledge by promoting innovation (Love et al., 2005).

The above theoretical assumptions are tested on four projects: the introduction of ERP systems, the development of new banking services, business process redesign, introduction of management systems they know (Love et al., 2005) The first conclusion is that the formation of common knowledge in multifunctional teams depends on the perception the value of the project by the stakeholders (of their support); the second thing is the previous experience of the organization in the implementation of complex projects.

Further, knowledge sharing is associated with the existence of objective measures, that explain the purpose of the project results. The way of communication among team members, sharing "narrative story," was significantly conditioned by the organizational structure in all four projects. However, it was noted that the exchange of knowledge in an informal way the project is affected by culture, or accepted the values and principles of conduct by members of the team. In this part of the practice is different from theory. According to this study, the level of efficiency in the context of multifunctional projects depends precisely on the communication process, how to manage social capital and how organizational structure contributes to the development of social capital.

Prencipe (2001) based on the collection of data through interviews and questionnaires with projects from six organizations developed a schematic view of learning as an attempt to create a pattern for learning process between projects. First, the organization is divided into three kategoije: social projects where prevailing social processes and work with people; technical projects with clearly articulated processes and ICT projects. For each of the three project's categories the author developed a matrix that shows the mechanism for the accumulation of experience, knowledge articulation and codification of knowledge.

Table 1. Social projects

	Learning process		
Level of the analysis	*Acumulation of experience*	*Knowledge articulation*	*Knowledge codification*
Individual level	• On-the-job training • Job rotation • Specialization	• Figurative thinking • Thinking aloud • Notes	• Diary • Reporting system • Individual system design
Project level	• Reuse of experts • Developed group thinking • Face-to-face communication • Informal encounters • Imitation	• Brainstorming • Formal project reviews • Debriefing meetengs • Ad hoc meetings • Lessons/learned/post-mortem meetings • Intraproject correspondence	• Project plan • Milestones • Meeting minutes • Project history files • Intraproject lessons learned database
Organizational level	• Informal organizational rutines, rules and selection processes • Departmentalization and specialization • Communities of practice	• Project manager camps • Knowledge rereats • Professional network • Knowledge facilitators and managers • Interprojet correspondence • Interproject meeting	• Drawings • Process maps • Project management process • Lessons learned data base

Table 1 present "L" form, that has a social approach. The emphasis is on creating and sharing tacit knowledge, based on experience through joint work on the project. Contacts face to face and via social media have great significance. Learning between projects has more informal character and involves sedimentation of new practices in the form of routine.

Table 2. Techical projects

Level of the analysis	*Learning process*		
	Acumulation of experience	*Knowledge articulation*	*Knowledge codification*
Individual level	• On-the-job training • Job rotation • Specialization	• Figurative thinking • Thinking aloud • Notes	• Diary • Reporting system • Individual system design
Project level	• Reuse of experts • Developed group thinking • Face-to-face communication • Informal encounters • Imitation	• Brainstorming • Formal project reviews • Debriefing meetengs • Ad hoc meetings • Lessons/learned/post-mortem meetings • Intraproject correspondence	• Project plan • Milestones • Meeting minutes • Project history files • Intraproject lessons learned database
Organizational level	• Informal organizational rutines, rules and selection processes • Departmentalization and specialization • Communities of practice	• Project manager camps • Knowledge rereats • Professional network • Knowledge facilitators and managers • Interprojet correspondence • Interproject meeting	• Drawings • Process maps • Project management process • Lessons learned data base

Table 2 present "T" shape that has a technical approach and is characteristic of the organization attach importance to the articulation process at all levels. Meetings are often organized in order to improve communication and knowledge transfer.

Form "steps" (shown in Table 3) refers to organizations with developed advanced ICT tools to support learning between projects. Their efforts are focused on the codification and storage of knowledge developed during the execution of the project and its documentation in order to be used on other projects. These processes are aimed at creating and renewing formal procedures.

This approach is presented by Prencipe (2001) and have been modified by Love et al (2005) who state that is arguably how an extremely dynamic process of learning between projects can be presented by static matrix. In addition, looking at the phases and types of projects can be concluded that in relation to them a learning mechanism can be more acceptable than another.

For example. face to face communication and meetings are appropriate for the activities of problem solving and creative activities that are present usually at the beginning and end of the project, while the processes based mechanisms are more appropriate in the phases of the project in which the plans are already in place.

However, the above scheme represents a good starting point for presenting similarities in learning styles between projects in different organizations.

Table 3. ICT projects

Level of the analysis	*Learning process*		
	Acumulation of experience	*Knowledge articulation*	*Knowledge codification*
Individual level	• On-the-job training • Job rotation • Specialization	• Figurative thinking • Thinking aloud • Notes	• Diary • Reporting system • Individual system design
Project level	• Reuse of experts • Developed group thinking • Face-to-face communication • Informal encounters • Imitation	• Brainstorming • Formal project reviews • Debriefing meetings • Ad hoc meetings • Lessons/learned/post-mortem meetings • Intraproject correspondence	• Project plan • Milestones • Meeting minutes • Project history files • Intraproject lessons learned database
Organizational level	• Informal organizational rutines, rules and selection processes • Departmentalization and specialization • Communities of practice	• Project manager camps • Knowledge rereats • Professional network • Knowledge facilitators and managers • Interprojet correspondence • Interproject meeting	• Drawings • Process maps • Project management process • Lessons learned data base

5. KNOWLEDGE SHARING IN PROJECT ENVIRONMENT IN SERBIA

In order to investigate what are the most frequently used mechanisms for knowledge sharing, a reserch was conducted. The questions were design to find out do the respondents use more formal (documented) or informal ways to acquire and share knowledge in project environment. More than 100 questionnaires were collected from participants on project from different industries (construction, processing industry, metal industry, wood industry, trade, public sector, healthcare, architecture, design, etc.)

Research results show that 72% of respondents answerd that they have some documented procedure for project management in their organizations. On question what area of project management are regulated the most, the results show that project planing, monitoring, control and reporting are regulated in a very high level, hence project initiation and selection are in the most of partially or even not regulated.

Since the purpose of this research was to discover wherther team members use a systematic approach to acquire and share knowledge between project the question were oriented on how they treat the problems, risk and changes on their project/is there any documented file on those issuess; do they always create a final report on competed project or this action is not a common practice; and what are the most frequently used mechanism for knowledge sharing: project files/reports or less formal communication.

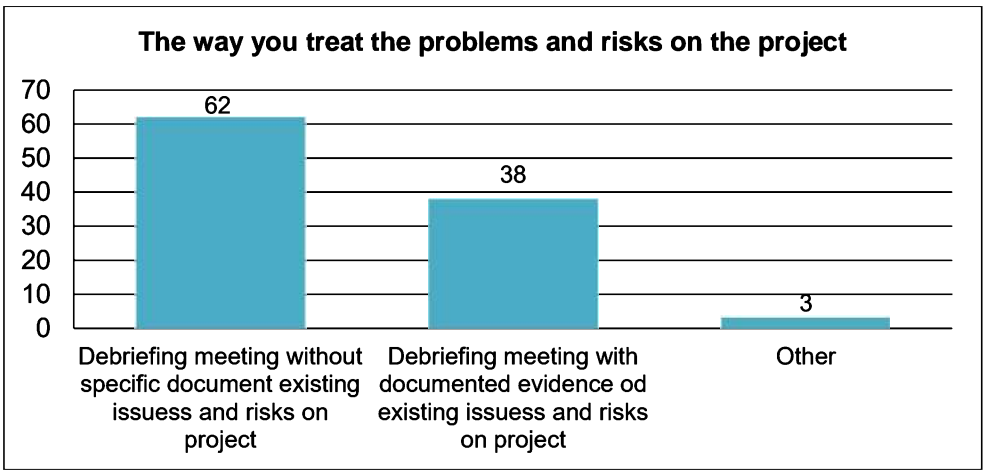

Figure 1. The way you treat the problems and risks on the project

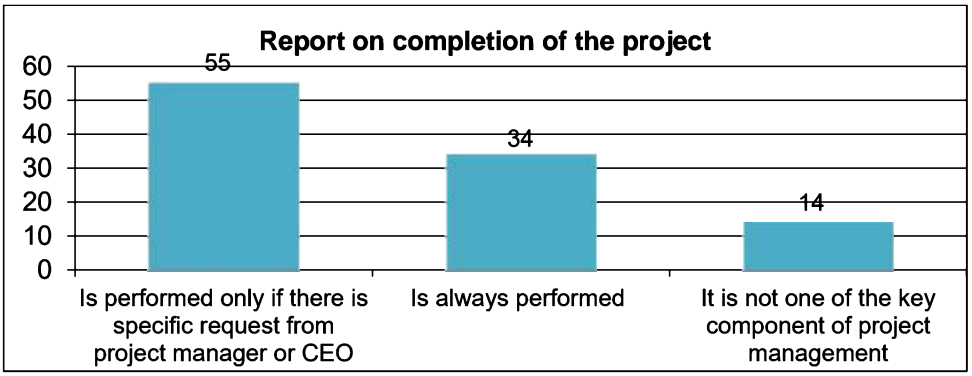

Figure 2. Report on compleation of the project

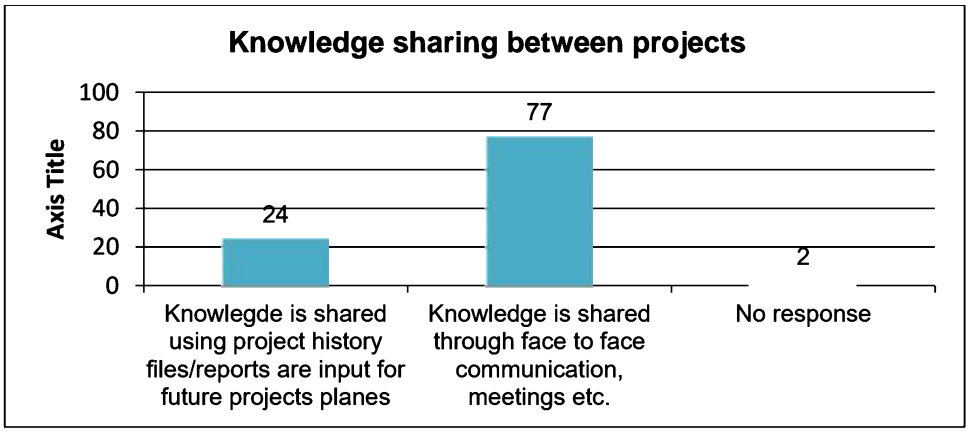

Figure 3. Knowledge sharing between projects

Results showed that respondants use mostly unformal mechsnisms to share knowledge between projects. Around 60% of respondants answer that discuss project risks and problems but that they don't have a procedure to document those issues. Only 38% answered that they document all project problems and risks. Final report on compliteted project is always performed in only 34%, in more than 50% final report is performed only if CEO or project manager request it.

From the perception of the respondants knowledge between project is shared mostly using informal communication, meetings, experts reusage. Only 24% of them said that they use files/reports from preveuos projects to acquire information and knowledge.

6. CONCLUSION

Through literature review it can be concluded that the key factors of influence on knowledge sharing process in project environment are: organizational culture, organizactional structure, stakeholder support, and the level of coordination of this process along with other procesess in project. Literature points on significance of

knowledge sharing between projects for organizational knowledge. Literature also shows that there are different mechanisms to acquire, articulate and codify knowledge beetwen projects in accordance to project characteristics. However, in the practice there is an evidence of knowledge sharing using mostly informal ways instead of formal processes. It is not doubtfull that knowledge can and should be shared using informal ways and that benefits of tacit knowledge can be achieved, but the question is how much informations and knowledge are passed if there is no formal evidence of project realization (problems, risks, changes and other issues, compliation etc.) and the usage of project history files for future projects.

MATURITY MODEL COMPARATIVE ANALYSIS: OPM3 VS. IPMA DELTA MODEL

Dragan Bjelica*, Zorica Mitrović, Marija Todorović
Faculty of Organizational Sciences, University of Belgrade
*Corresponding author, e-mail: bjelicad@fon.bg.ac.rs

Abstract: *The purpose of the paper is reflected in the comparative analysis of the maturity models, specifically in relevant aspects of the IPMA Delta and OPM3 maturity model. The comparative analysis includes general and specific observation' characteristics from individual, project and organizational point of view. General characteristics include maturity model levels, maturity development, maturity assessment. Specific characteristics of each model are the essence of the model as well as what they clearly emphasize in maturity development – procedures, best practices, assessors' approach, etc. A maturity model assumed that progress according to goal and expected results' achievement comes in stages. Therefore, this analysis identifies potential issues for maturity implementation: "how to fulfill certain requirements", "how to quantify qualitative aspects of evaluation" and maturity model perceived as a "promotional tool". Theoretical and practical implications are discussed.*

Keywords*: maturity, assessment, project management, model, IPMA Delta, OPM3*

1. INTRODUCTION

In psychology, maturity has been perceived as a willingness to respond appropriately to external influences. This reaction is generally less instinctive. "Being mature" means to know how to behave in a given place and at the appropriate time in accordance with a specific circumstances and culture. Human being development theories include the purpose of life concept, which highlights the maturity of a clear purpose in life, direction and intention, which contributes that life has meaning. Maturity has different definitions across the legal, social, religious, political, emotional and intellectual context. According to the mentioned aspects, the concept and definition of maturity and immaturity, usually is explained very subjective.

Generally speaking, there are two main reasons for maturity models implementation in organizations. The first reason is reflected that suggested maturity model will help in verification process – comparing results with best practices in industry and categorization according to maturity level. The second reason for the maturity model implementation is an assessment of its current capabilities and goals to achieve the desired level. Organization gets an insight into their strengths and weaknesses and clearly observed actions and areas in which improvements are needed. In addition to the above, maturity model implementation also raises awareness in the context of possible improvements within the organization.

2. PROJECT MANAGEMENT MATURITY DEVELOPMENT

Maturity model development begins with the development of the first maturity model, known as maturity model based on the capabilities (Capability Maturity Model), created by the Institute for Software Engineering (Software Engineering Institute, SEI), with the support of the Ministry of Defense - United States. The model was developed and upgraded in the period from 1986 to 1997, and got his real successor in 2002, a model that is now known as Integrated model-based capabilities, (The Capability Maturity Model Integration, CMMI). Although primarily intended for the software industry has found its application in other business areas and serve as a basis for making the most famous models today.

Since the current stream of maturity analysis dedicated to the assessment of project management maturity is still in its early phases, there are many important aspects that remain unclear and, should be addressed by future research. Articles within scientific area maturity model development have the main objective of developing or creating a new maturity model. This may contain conceptual as well as design oriented models or descriptions of models, if the purpose is the introduction of a new model. Scientific articles within scientific area maturity model application aim principally at the maturity models' implementation in several

aspects or specific domains. They also include maturity appraisal and model implementation. Articles within scientific area maturity model validation have the main purpose of validating existing maturity models. This includes empirical as well as conceptual validation, maturity models comparisons, simulations, best practices, case studies, and so on. The main objective of articles within this topic area meta-articles is maturity models characteristics. These are, for instance, literature reviews, process models for the development of maturity models, or other theoretical perspectives (Wendler, 2012).

One important topic would be to assess and compare project management maturity in different strategic aspects for organization. Evaluation of maturity in project management company depends on the person carrying out the assessment and its ability to obtain important information about project management, as well as intelligent evaluation of data in order to show meaningful conclusions. In most situations, the auditors were hired consultants which are not connected with the organization, hired for their experience and expertise. This contributes to the impartiality and objectivity in the evaluation. Future research could analyze and compare project management maturity between organizations that largely rely upon internal projects, and organizations that generally contract for external project support. Future research could also analyze project management maturity in terms of the strategic importance of project management phases and activities. One of the most important aspects that future research should address is to emphasize a clear relationship between project management maturity and successful project delivery. The value of project management maturity assessments clearly establish this vital link (Grant & Pennypacker, 2006). The implementation of an adequate project success analysis can contribute to knowledge management in project environment (Todorović, Petrović, Mihić, Obradović, & Bushuyev, 2015).

Table 1: Overview of the maturity model

Model	**Organization**
Capability Maturity Model Integration – CMMI model	Carnegie Mellon University
Information Technology Capability Maturity Framework – IT CMF model	Innovation Value Institute
Portfolio, Programme and Project Management Maturity Model – P3M3 model	OGC i Axelos
IPMA Delta model	International Project Management Association - IPMA
Organizational Project Management Maturity Model – OPM3 model	Project Management Institute - PMI
COBIT Maturity Model	IT Governance Institute - ITGI
Project Maturity Model – PM^2 model	Interthink
PRINCE 2 Maturity Model - P2MM model	APMG International
Gartner Maturity Model for Project and Portfolio management	Gartner
Project Management Maturity Model – PMMM model	PM Solutions

3. PERFORMANCE EVALUATION AND MATURITY LEVELS

Performance evaluation and analysis of organizational maturity has become popular in the last decade, where the area of IT projects stand out as the primary area for the maturity model implementation. The concept of maturity for most people is associated with complete development. The same principle is applied in the project management context. There are different definitions in project management scientific field for project maturity. Different maturity concept analysis showed that the repeated project success and organizational strategic objectives are commonly associated with maturity in project management, and is generally perceived as:

- implementation of project management methodology and related processes, that they repeat with higher probability of success (Kerzner, 2001)

- the organization's ability to repeat the success in the successors' projects (Dooley, Subra, & Anderson, 2001)
- the overall ability of the organization to select and manage projects in a way that they support the organizational strategic objectives (Hermarij, 2013)

The basic concept of maturity models characterize the levels and the path of maturity. Each phase has a corresponding features, which include business improvements.

Table1: Maturity levels - characteristics

	Processes	Documentation	Management	Metrics
Level 1	There is no established practices and standards	There is no collected documentation – ad hoc approach	Management understands and is aware of the project management approach.	Collected informally on an ad hoc basis
Level 2	Processes exist, but there are not considered as organizational standards	Documentation exists only for the basic processes	Management supports the project management approach, but understanding and involvement is not consistently applied to all projects. Large projects are implemented in a systematic manner, and management is involved in such projects.	There are basic metrics to track costs, time, and technical specifications.
Level 3	All the project management processes are established as organizational standards. These processes include customers as part of the project team. Almost all projects using these standards.	Documentation exists for all projects.	Management is involved in key decisions related to the inputs and approvals.	Metrics formally collected and each project is evaluated and managed in the context of other projects.
Level 4	Processes, standards and systems support project management approach.	The processes are documented and support metrics' usage in the decision making process.	Management understands its role in the project management processes. There are different management styles and different project management requirements for various projects.	Effectiveness and efficiency are used as metrics. All projects, changes and issues are evaluated against the metrics of cost estimates, the planned assessment and calculation methods according to earned value.
Level 5	The established processes are actively used to improve project management activities.	Lessons learned are constantly reviewed and used to improve the standard processes and documentation in project management.	Management is focused on continuous improvement.	Metrics collected during the project implementation are used to analyze the project performance and to improve organizational decision-making process in the future.

The purpose of the maturity model implementation refers to the following aspects:

- Descriptive: Capability Maturity Model was created to describe the process whereby the current competencies of the organization evaluated according to preset criteria and therefore be used as a diagnostic tool. After organizational maturity assessment, it is necessary to inform internal and external stakeholders.
- Providing guidelines: Maturity models provide guidelines for performance improvements.
- Comparative aspects: Maturity paths are used for comparative purposes in order to provide benchmarking for internal and external stakeholders. The organization is compared with the prior therein based on historical data, then compared with industry norms and averages from the industry, competitors and set objectives in achieving the appropriate level of maturity.

4. IPMA DELTA MODEL

IPMA Delta model integrates the latest aspects of knowledge management and project management competences called "360^0 assessment of competencies". It was created by the International Project Management Association - IPMA. IPMA Delta model basically defines three aspects of observation and based on them integrate evaluation system: Individual level estimates (based on the IPMA Competence Baseline 3.0 - ICB), project level assessment (based on the IPMA Project Excellence Model) and organizational level estimates (based on IPMA Competence Baseline Organisational - OCB).

Certification system in organization provides confirmation that the organization has implemented a system with all relevant aspects and in accordance with company policy. Organizations based on an assessment of their position and status, can establish and ipmrove systems for project management. Top management decide about the organizational strategic directions and needs for improvement and therefore set goals for maturity improvements.

4.1. Individual level assessment

Individual certification level is based on an estimate of technical, behavioral and contextual competencies in project management. Each level of certification (A to D) carries the appropriate knowledge, skills and experience required. This system can be described as a "career focused on certification." Within three areas of competence there are 54 elements of competences (International Project Management Association, 2006).

4.2. Project level assessment

IPMA Project Excellence model (IPMA Project Excellence Model - PE) is modified for the purposes of self-evaluation for organizational projects and programs. It is based on the EFQM model (European Foundation of Quality Management) and principles of total quality management. IPMA Project Excellence model has been applied in many national and international associations for the reward system within the IPMA networks. This benchmarking tool has been used to measure project excellence. This model consists of segments that concern employees, resources, processes, leadership, project goals (Backlund, Chronéer, & Sundqvist, 2014).

4.3. Organizational level assessment

IPMA Organizational Competence Baseline defines organizational competence in project management, program and portfolio management. This standard defines organizational competences as the ability to integrate the people, resources, processes, structure and culture in projects, programs, and portfolio system. Organizational competence in project management should be specifically aligned with the mission, vision, organizational strategy, and should be focused in order to achieve results to ensure continuous organizational development. (International Project Management Association, 2013).

4.4. Delta effect

IPMA Delta model provides information based on the Delta, where the effect of competence ipmrovements show the maturity path to a higher class. Based on the analysis of individual, project and organizational competencies, the organization has insight into the strengths and weaknesses of competences for project management. The organization independently determines which category of competencies wants to certify. Also, the IPMA Delta shows the "delta effect" between existing and desired competencies in project management (International Project Management Association, 2014).

5. OPM3 MODEL

Model OPM3 (Organizational Project Management Maturity Model) is one of the most recognized standards in the world for assessing organizational maturity published by the Project Management Institute (PMI). The model was designed in 1998. He was preceded by the release PMI - Special Report of ethics, standards and accreditation, published in 1983, followed by PMBOK standards published in 1987 and the PMBOK Guide in 1996 and framework for development of project manager competencies OPM3 in 2002 (designed to translate the strategy into successful results - consistent and predictable).

Organizational Project Management presents systematic management of projects, programs and portfolios that are consistent with the strategic objectives of the organization. The concept of organizational project management is based on the idea that there is a correlation between the ability in the management of projects, programs and portfolios and its effectiveness in strategy implementing. The degree to which the organization implemented this system for project management called organizational maturity in project management.
OPM 3 was initially designed without an overall system related to the maturity levels. Establishing the specific maturity level would mean that the maturity analysis is one-dimensional. From the other hand, OPM3 is multidimensional. OPM3 also categorizes capabilities within the five process groups of project management (initiation, planning, implementation, control and closing) providing the possibility of evaluation through the four levels of maturity (Project Management Institute, 2003).

OPM3 standard has three key elements:

1. Knowledge - describes the organizational project management and organizational maturity in project management, explaining why they need it and how maturity in project management can be identified in the organization. PMBOK 5 is a key connection with maturity assessment.
2. Assessment - presents the methods, processes and procedures that an organization can use to realize self-assessment. Evaluation is done using the interactive tools of best practice that suggests further detailed consideration competencies required for project/program/portfolio implementation.
3. Improvement - provides processes, the skills' list they need to improve from lowest maturity level to higher levels of maturity.

6. COMPARATIVE ANALYSIS BETWEEN MODELS

Maturity models can be used as a short-term tool for assessing the maturity of enterprise, program or portfolio organization (currently determining the maturity) or as a long term asset for constantly improving the business processes of the organization or projects, programs and portfolios (continuous development process). One of the general characteristics, immanent to considered models, is that the assessment is determined on the basis of questionnaires and / or interviews. Usually it is pre-defined set of questions. The negative aspects for IPMA Delta and OPM3 model implementation are:

- Models describe "what it takes to be fulfilled in order to reach a certain level", but do not say anything about "how to fulfill certain requirements"
- There are not sufficient quantitative indicators for all aspect of maturity assessment
- The maturity assessment has been perceived as a "promotional tool"

Following table (Table 3.) characterize IPMA Delta model and OPM 3 model constraints and main components:

Table 3. Comparison between IPMA Delta model and OPM3 model constraints and components

Model	Constraints	Components
IPMA Delta	• Limitations on the quantification of maturity • Qualitative assessments of project and organizational components • Subjectivity of assessors (gives appropriate level of organizational maturity)	• Individual competence analysis (based on the IPMA Competence Baseline) • Project analysis of competences (based on EFQ model) • Organizational analysis of competences (based on IPMA Competence Baseline Organizational)
OPM3	• The framework should be accepted by top management • Highlighting the time, cost and less value being delivered • Insufficient emphasis on complexity, continuous learning, social processes, creating value, broad conceptualization	• Knowledge (organizational project management maturity and best practices based on the PMBOK processes • Evaluation (methods for the evaluation of best practices) • Improving (the order to develop the ability aggregating them into best practices)

7. CONCLUSION

Research shows that organizations have increased the level of maturity in project management with cost savings, increased ability to predict a time and schedule for the project and increase the level of quality. This implies that increasing maturity in project management positively affects the performance improvement in project. IPMA Delta defines five classes of organizational competencies in project management, emphasizing the current state of the organization with the areas where improvements are needed. Also, IPMA Delta Model is based on competences, while the OPM3 is based on knowledge and best practices. IPMA Delta and OPM3 model show the evolutionary trends in the project evaluation and appraisal, and create excellence aspects in project management field.

This paper is a result of the Project No. 179081 funded by Ministry of Education and Science of the Republic of Serbia: Researching Contemporary Tendencies of Strategic Management Using Specialized Management Disciplines in Function of Competitiveness of Serbian Economy.

SUSTAINABILITY AND PROJECT MANAGEMENT – WHERE IS THE LINKAGE?

Danijela Toljaga-Nikolić*, Marija Todorović, Dragan Bjelica
Faculty of Organizational Sciences, University of Belgrade
*Corresponding author, e-mail: toljagad@fon.bg.ac.rs

Abstract: *The paper is aiming at providing the insight in one challenging issue that organizations and managers are facing with – linking sustainability with project management concept. Nowadays, managers attempting to integrate the concept of sustainability into organizational strategies, programs and projects, and it becomes a real challenge. How to embed environmental and societal issues in a way that project delivers expected outcomes? The paper presents different aspects of sustainability in a project management, including four-dimensional conceptual framework for managing sustainable projects. Since the traditional project management concept is mainly focused on time, budget and scope (regarding quality), now it becomes challenging how to consider equally and involve three aspects of the sustainability concept: social, environmental and economic aspects.*

Keywords*: sustainability, project, project sustainability, project management*

1. INTRODUCTION

Sustainability is a challenge for companies and managers today. This phenomenon is recognized as an organizational goal that companies integrate into their strategies, plans and actions. Managers are trying to include ideas of sustainability in different business areas, and project management is no exception. It could be said that every tendency to integrate sustainability into project management actually involves the entire project management process which indicates how complex this idea is. What is expected to happen as a consequence of sustainability concept integration into the project management process? Generally speaking, companies seek for increased market share and increased profits.

Today it is important to do business as a socially responsible company and, at the same time, companies are faced with growing clients and government demands. Under these circumstances, managers are searching for the best way to satisfy every stakeholder and responsibility for customers' needs satisfaction is also a quite important step. Sustainability in a project management can be seen as the project ability to maintain its operations, services and benefits during its life cycle (Khan, 2000). To meet sustainability goals, companies should be able to make sustainability as a required and measured part of project management process. By managing this process, added-value for all project stakeholders could be ensured.

2. LITERATURE REVIEW

Sustainability concept is analyzed globally and as a widely dispersed one (Lozano et al., 2015). UN World Commission on Environment and Development defined sustainability as "a form of progress that meets the needs of the present without compromising the ability of future generations to meet their needs" (UN World Commission on Environment and Development, 1987). According to this definition, an element of sustainability is the aspect of future orientation and concern for future implications. Also, the same report includes statements of both social and environmental perspectives, and states that "in its broadest sense, sustainable development strategy aims at promoting harmony among human beings and between humanity and nature".

(Silvius & Schipper, 2014) completed a structured review of 164 books, book chapters and papers, and identified areas of impact which provide base for project sustainability consideration, e.g. project stakeholder management, project risk management, project portfolio management, etc. The authors concluded there are a growing number of publications that relate sustainability to project management. The importance of this burning issue is recognized by leading professionals and researchers in the project management field as well. The relationship between sustainability and project management is considered as one of the important developments in project management (Labuschagne & Brent, 2006). At the 22nd IPMA World Congress in 2008, IPMA Vice-President Mary McKinlay stated in the opening keynote speech that "the further development of the project management profession requires project managers to take responsibility for

sustainability". It indicates the importance of taking responsibility for the project results which includes the sustainability aspects of that results.

Definition of project management suggested by the Project Management Institute is widely accepted and, it refers to applying knowledge, skills, tools and techniques to project activities to meet the project requirements (Project Management Institute, 2008). Since sustainability includes multi-dimensional perspectives, such as economics, social and environmental aspects, sustainability should be included in all these aspects of project management (Marcelino-Sadaba et al., 2015).

Project deliverables can have social, economic and environmental impacts with longer lasting than projects themselves (Sanchez, 2015). Aligning portfolio selection and monitoring with the principles of sustainable development requires procedure (selection based on project cost and contribution to organizational goals). According to (Fernandez-Sanchez et al., 2010), a project is sustainable when three dimensions of sustainable development are improved, maintaining time, cost, quality and effort within an acceptable range. The sustainability principles are reflected in the definition or perception of project success. There is a strong link between sustainability in project management and project success. Todorović et al. (2014) stated about importance of measuring and analysing the project success, where success factors must be transferred to the operational level and become measurable.

Boswell et al. (2005) stated that it is difficult to achieve conditions for sustainable development and also not so easy to demonstrate that achievement. To achieve strategic sustainability objectives, project managers have to transform them into specific actions for projects. The necessity to move project management from the traditional approach toward a sustainable management is marked as a challenge and managing projects often requires dealing with organization factor that is sometimes beyond project manager`s control. Also, it is important to ensure that an organization is implementing projects that will reach stakeholders demands and its strategic goals by resolving portfolio selection problem. (Sanchez, 2015) recommends project portfolio selection based on the eco-impacts simultaneous analysis and analysis of the contribution to organizational goals.

An important phase in involving sustainable issues into project management is a clear understanding of the project life cycle and its phases (Sanchez, 2015). Different life cycles involved in a project interact mutually. Project life cycle is the life cycle where an idea is generated, developed and implemented. Asset/Process life cycle includes design, development, construction, implementation and removal of the service. And product life cycle recognizes the project deliverable as an idea that generates income for the company (Labuschagne et al., 2005) (Labuschagne & Brent, 2008). If we consider sustainability involvement in project management, then project life cycle should be taken into account (Labuschagne & Brent, 2006).

Maletic et al. (2014) pointed out that project management standards define several important management areas (products/services, stakeholders, processes) and they are, at the same time, aspects required for sustainable management. That makes project management as a good path for introducing sustainability in an organization (Bocken et al., 2014). Involving sustainability within strategic goals requires introducing innovation and learning from experience. Innovation can be considered as an important step for both business success and connect sustainability with project management (Amini & Bienstock, 2014).

3. DIFFERENT ASPECTS OF SUSTAINABILITY IN A PROJECT MANAGEMENT

The way of how society today is living, producing, consuming, etc. indicates that it might have negative effects on the life of future generations. This is why society today concerns about sustainability more than ever in every possible aspect. The traditional way of doing business cannot be called sustainable. Therefore, managers in organizations think about changes. The linkage between sustainability and project was established in 1987 by UN World Commission on Environment and Development, but today it could be said that sustainable society is seeking for projects since many changes in organizations are organized as projects (Sivius et al., 2012).

Based on the sustainability concepts, (Silvius et al., 2012) developed a working definition of sustainable project management: "Sustainable project management is the management of project-organized change in policies, assets or organizations, with consideration of the economic, social and environmental impact of the project, its result and its effect, for now, and future generations". The authors proposed project management processes, performance indicators, and competencies as areas in which project management has to develop in the future to capture the influence of sustainability.

Projects have an important role in the implementation of sustainable business processes and practices in organizations and therefore, project managers have a strong impact on the sustainability of organizations. According to (Silvius & Schipper, 2014), the project management standards failed to indicate the importance of the project managers' role in implementing sustainable development, and there is a certain competence gap of project managers concerning sustainability. To successfully introduce sustainability in organizations, (Silvius & Schipper, 2014) stated how crucial is to close this competence gap by the standards of project management competencies. The authors put the focus on five key-competences for sustainability: systems thinking competences, anticipatory competences, normative competences, strategic competences and interpersonal competences. By recognizing the importance of these competences, project managers will be well prepared for their crucial role in realizing sustainability of organizations.

According to Silvius and Schipper (2014), there are several differences in the characteristics of sustainable development and project management concepts.

Table 1: The differences between a sustainable development and a project management concepts

Sustainable development	Project management
Long term + short term oriented	Short term oriented
In the interest of this generation and future generations	In the interest of Sponsor / Stakeholders
Life-cycle oriented	Deliverable/result oriented
People, Planet, Profit	Scope, Time, Budget
Increasing complexity	Reduced complexity

The traditional concept of projects management and the concept of sustainable project management might be somehow in contrast. This is because in traditional concept, managers concern for time, budget and scopes (regarding quality), while now there are three elements that should be considered carefully: social, environmental and economic aspects (Daneshpour, 2015). (Marcelino-Sadaba et al., 2015) proposed a new conceptual framework that helps project managers in dealing with sustainability in projects (Figure 1). This framework is based on the assumption that following four dimensions are crucial for accomplishing sustainable project: *products* designed by using sustainability criteria, sustainable project *processes*, *organizations* committed to sustainability that carry out projects and *project managers* trained in sustainability.

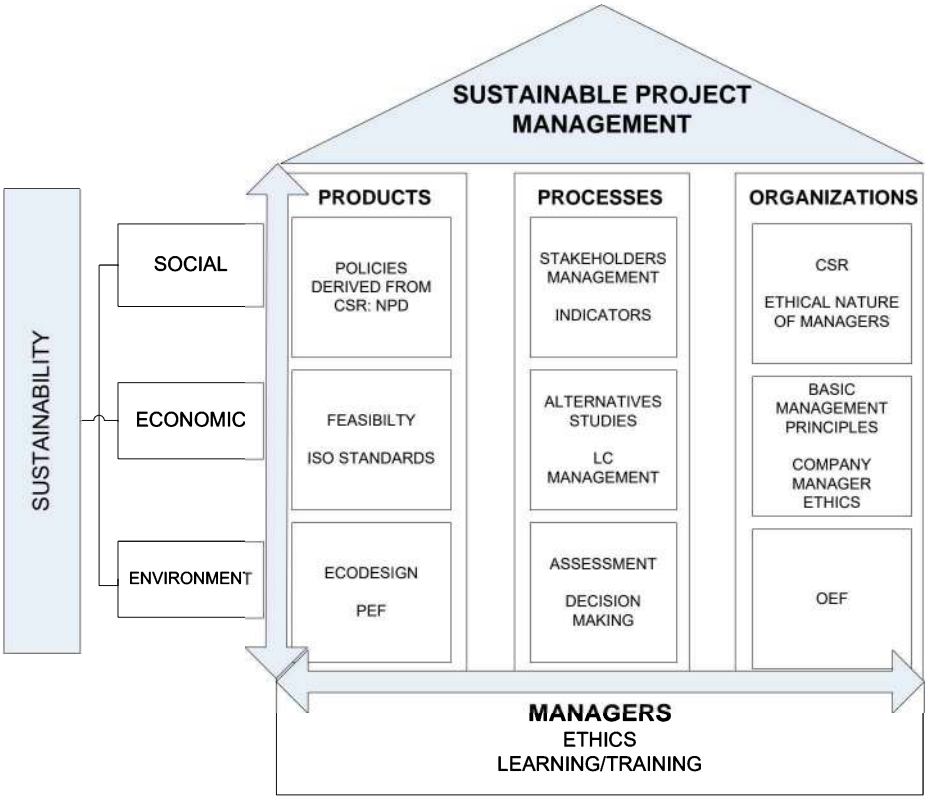

Figure 1: Four-dimensional conceptual framework for managing sustainable projects (adapted from (Marcelino-Sadaba et al., 2015)**)**

Figure 1. represents the conceptual model of the four dimensions of the sustainable project. Each dimension (products, processes, organization and managers) includes principles related to the three pillars of sustainability: social, economic and environment. The first dimension put focus on sustainable project products and the second one on the processes that help to include sustainability in the project. The third dimension relates to organizations that managing projects committed to sustainability and the fourth refers to project managers who are actually key players in linking sustainability and project management (Marcelino-Sadaba et al., 2015).

4. DIMENSIONS OF PROJECT SUSTAINABILITY

Project managers are seeking for ideas on how to make their projects more sustainable. Different authors, (Schieg, 2009) and (Goedknegt, 2012), pointed out that project managers have to take responsibility for sustainability. (Russel, 2008) stated that project manager`s position is excellent to influence operations within the organization to obtain greater sustainability. To include sustainability considerations in project management, project managers need to know dimensions of project sustainability. By knowing that, project managers increase the chances of project success. These dimensions have the potential to influence project sustainability and therefore has to be considered to ensure project sustainability. If any of these dimensions shows weakness, the sustainability of the entire project might be ruined. Dimensions of project sustainability are:

- Logistics dimension
- Economic dimension
- Community dimension
- Equity dimension
- Institutional dimension
- Environmental dimension (Khan, 2000)

Logistics dimension refers to the continued operation and the maintenance of project facilities. The question that can be asked is as following: Has the project received necessary support (both budgetary and institutional) to enable it to maintain required level of facilities?

Economic dimension refers to the continued flow of net benefits (for economic sector projects). Questions that can be asked are as following: Has all the cost and benefits under varying conditions weighted properly and does the project guarantee an acceptable level of financial and economic return?

Community dimension refers to the continued community participation (in projects where active community participation is crucial for both fostering new actions as well as for cost recovery). Questions that can be asked are as following: Has the project involved the community? Has it succeeded in maintaining a desirable level of participation of the community in the project activities?

Equity dimension refers to the equitable sharing and the distribution of project benefits. Questions that can be asked are as following: Has the project incorporated mechanisms that guarantee equitable access to and distribution of project benefits on a continuous basis?

Institutional dimension refers to the institutional stability. Questions that can be asked are as following: Has the project considered the institutional requirements and thus made provisions so that management support to project operations continue, during the life of the project?

Environmental dimension refers to the maintenance of environmental stability. Questions that can be asked are as following: Has the project considered environmental implications so that negative impacts on the environment are either avoided or mitigated during the life of the project? (Khan, 2000)

5. CONCLUSION

Sustainability and project management are two disciplines that are closely linked. Nowadays, organizations are searching for the more sustainable approach on project management. Organizations need change, and that change is organized in projects because these projects are likely to make a contribution to the organization sustainable development. To meet sustainability goals, managers should be able to make sustainability as a required and measured part of project management process. And, in order to define, implement and measure sustainability in the project, project managers should establish project management processes and procedures that could help in meeting sustainability goals. Also, project life cycle should be taken into account as a cycle where an idea is generated, developed and implemented.

The concept of project sustainability includes several dimensions that managers need to know to increase the chances of project success. Four-dimensional conceptual framework for managing sustainable projects can be used as a model where each dimension: products, processes, organization, and managers, includes principles related to the three pillars of sustainability: social, economic and environment. Still, there is a lot of effort that has to be involved in implementation of the sustainability concept in the management of projects.

MANAGEMENT

THE PROCESS OF DECISION MAKING AT LOCAL LEVEL; BASED ON THE MODEL OF THE CITY MUNICIPALITY OBRENOVAC

Bojana Ašković
City Municipality Obrenovac
Corresponding author, e-mail: askbojana@gmail.com

Abstract: *The article deals with determination of the concept of direct citizen participation and analyze its main features. The primary goal of this research is to determine the key characteristics and the actual development rate of the four levels of direct citizen participation at local level: informing, consulting, proposing and participating in decision making; based on the model of the City Municipality Obrenovac.*

Keywords*: citizen participation, mechanisms of citizen participation, decision making, city municipality Obrenovac*

1. INTRODUCTION

Citizen participation in the public affairs of a community is considered to be one of the basic conditions to introduce democracy completely. It is also a crucial characteristic of life quality. Local policy is the corner-stone of democracy since it provides participation at the highest level possible. Citizen participation in the public affairs of a community creates new forms of social relations and represents engagement of each individual in decision making with reference to them and their immediate community (Vukelić, 2009).

This project has two primary goals. The first one is to determine the key characteristics of the concept of direct citizen participation at local level and the second one is the analysis of the actual development rate of the four levels of direct citizen participation at local level: informing, consulting, proposing and participating in decision making; based on the model of the City Municipality Obrenovac.

Depending on the author, citizen participation can refer to a wide range of similar but different issues. With reference to the concept of devided power and decision making, civil participation could be defined as a process in which society members, who are not engaged either in politics or establishment, devide power with public employees when it comes to making crucial decisions and carrying out activities with reference to community (Milosavljević et al., 2006). In conclusion, citizen participation represents all the activities of citizens aimed at having influence on making political decisions.

Direct citizen participation can be manifested at all the levels of government, but it is the most feasible at local level. First and foremost, the reason is the size of the departments. It is common within the following sectors: education, health service, social service, ecology, economy and communal service development, etc. Citizens can also take part in analysis, initiation, formulating, carrying out and evaluation of different decisions. Methods of direct participation are numerous and various, therefore citizens have a variety of possibilities for participation at their disposal. The most important are the following ones: referendums, assemblies of all the citizens, national or civil initiative, citizens meetings, panel discussions and other forms of colective political consulting, communication by eletronic media and the Internet, participating in polls, passing information on local government initiatives to citizens and obtaining information from the part of the citizens, submitting petitions, suggestions, requests and complaints from the part of citizens, addressing local authorities with public criticism, taking part in activities organised by interest groups, local media or citizens associations, nongovernment, humanitarian, professional and other citizens associations, informal colective activities, neighbours initiatives, neighbours" councils, protests, peacefull gatherings, demonstrations, school boards and other consulting authorities, individual forms of participation such as charitable and philanthropic work, organised funds raising for mutual interests e.g. local voluntary tax, etc.

City Municipality Obrenovac is one of 17 Belgrade municipalities. According to Law on local self-management and Law on capital city, the City of Belgrade, as the unit of local government, is entitled to define in its statute the following issues: territory organisation, responsibilities, organisation and responsibilities of the authorities, forms of direct decision making on the part of the citizen and other vital matters important for implementing rights and duties of the city. Constitution of the Republic of Serbia and the above mentioned laws do not define "city municipality" as a unit of local self-management. Therefore they cannot be directly implemented on city municipalities. For the same reason, the City of Belgrade is given an explicit authority to define position of city municipalities within its statute.

2. FORMS OF CITIZEN CONTRIBUTION- CLASSIFICATION

There are different forms of citizen" participation and decision making at local level of government. Typology given by Bogoljub Milosavljević has been chosen for the purposes of this project because it is, on one hand thorough and systematic, and on the other one relevant to concrete conditions in Serbia, i.e. legally stipulated forms of direct citizen" participation in the country. In this sense, there is a difference among the following forms of citizen" participation: (a) *informing* – which refers to passing information on work, plans and intentions of representative authorities to citizen and providing them with other sorts of information of public interest; (b) *consulting* – which includes different forms of citizen participation referring to deciding on priorities for the local community, such as panel discussions, public discussions, consulting by electronic media and the Internet, participating in the consulting sector; (c) *proposing* – which includes various forms of citizen participation in making proposals and expressing criticism on the part of work of representative authorities, such as citizen" meetings, petitions, individual proposals, complaints, forms of public criticism, protests, peaceful gatherings, demonstrations, etc.; (d) *decision making* – which refers to the forms of direct democracy, i.e. direct citizen" participation in decission making. It includes assemblies of all the citizen, referendums, citizen" initiatives and forms of local self-management (Milosavljević et al., 2006).

2.1 Informing

Passing information on work of municipal authorities and their plans is the basic condition for equal rights of citizen" participation in decision making. An individual, who is not informed, is not in a position to take part in managing the activities of the local community accordingly, nor to influence or control the work of the authorities. Therefore, passing information on the work of all the authorities in public is the principle confirmed by all the relevant international and local legal documents. The process can be made difficult if some of the potential problems arise, such as one-way direction in passing information – from municipal authorities to citizen – and directions to provide the flow of feedback information are not developed enough. News in the media, pamphlets, brochures, etc. are the most often used means in one-way communication between the authorities and the citizens. There is a danger of making public only basic data about meetings held, regulations and reports, while many of the important notices are not presented in public. Citizens are deprived from their right to participate in municipality management. Under the conditions mentioned, especially when citizens are informed at the late phase of planning or decision making, citizen are not in a position to influence the programmes made for „their own well being".

The Statute of the City Municipality Obrenovac defines that making work public can be done in the following ways: publishing bulletin and informative booklets, cooperation with the media, presenting decisions and other acts in public, designing web presentations, organising public discussions and in other situations according to the statute and other acts of the city municipality authorities (The Statute of the City Municipality of Obrenovac). City Municipality Obrenovac shows the initiative to inform the citizens on its activities and future plans. There is a tendency to make it easier for citizens to realise their rights and provide them with timely, precise and high quality information on the work of the city municipality. In order to improve passing information to citizens, Municipality of Obrenovac has created and developed methods which provide greater rate of being informed on the part of citizens, openness and transparency of work of the local government and easily and timely information availability, especially concerning current municipal acts to all the citizens (in printed or electronic form). Methods of passing information used by the Municipality of Obrenovac are the following: web site of the municipality (only last year, on the municipality web site is published 813 articles); e-mail (on official e-mail municipality receives about 150 e-mails per year and sends the same number of answers; municipality also uses mailing lists for passing information); social networks profiles (on daily level Facebook and Twitter accounts have several posts or links. Official Facebook account has 9063 likes and Twitter account has 1408 followers); public announcements of municipal representatives in the media (public announcements, statements and taking part in talk shows, press conferences); publishing and distribution of occasional publications, brochures, informative booklets (during the year Municipality Obrenovac publishing and distribution from five to ten publications, brochures or informative booklets); public meetings with citizens in local community centres (more than 20 meetings per year); council and assembly meetings which are open to public and representatives of the media (60 meetings are year average).

There is more space to introduce greater transparency into functioning of the city municipality, especially within the range of the following: public decision making process (announcing agenda for assembly and council meetings); availability of information on the work of city municipality – each citizen should be provided with access to information (by organising public database, using information technology, simplifying administrative procedures); adequate passing information to the public on administrative authorities and their organisational structure; as well as passing information to citizens whose interests are influenced by a current procedure, sending them a report on the development of the procedure and contact details of the person in charge.

2.2 Consulting

Consulting is the form of participation in decision making which gives citizens the opportunity to decide on the priorities of local community in cooperation with municipal authorities. Consulting citizens, collecting their proposals and complaints includes two-way process in which the authorities ask for and receive citizens" opinion on certain issues which are of mutual interest for both parties involved. With difference to informative process in which citizens are the consumers of information, in consulting process authorities are the user of information provided by citizens. Legally stipulated methods for this form of participation are the following: panel and other forms of political consultations, public discussions, consulting by electronic media and the Internet, taking part in different consulting teams, etc (Milosavljević et al., 2006).

Public discussions are one of the important forms of citizen participation. Public discussions offer each individual opportunity to consider every single local issue and reconsider critically in order to come to adequate solutions. However, realising a public discussion can include serious disadvantages: inadequate announcement of the date and place of the discussion to be held, choosing the time for discussion that could be inadequate for certain groups to attend meetings, choosing the venue that could be inadequate in terms that its capacity is limited and can provide place for a small number of interested citizens, etc. Besides, it is often the case that public discussions are only used for providing legitimacy for already made decisions and therefore, they are not intended to active cooperation and decision making. It is usually done through consultation with selected experts, and the final proposal is passed to the public as information, which can be talked about, but which cannot be changed. If there is no openness and readiness on the part of politicians and administration to respect contribution of all the participants in discussion, public discussion is only a screen to provide legitimacy for already accepted aims, and citizen do not consider their contribution is worth it.

In the Municipality of Obrenovac it is a common practice to have an annual public discussion during the procedure of municipal budget verification. Citizens are invited to fill in a questionnaire in local community centres, municipality building hall or online and to make their proposals for creating budget for the coming year. The same citizens are invited to attend public discussion where received proposals are discussed about. Discussion is also attended by municipal representatives and managers of public companies. Experiences so far indicate that citizens are not interested in this form of participation, although the number of received proposals based on the questionnaire is always considerable. Lack of interest for public discussions is probably consequence of bad experience, lack of time, inadequate time of the event and apathy.

Consulting citizens by the Internet – in technologically advanced countries the Internet has become important means of communication between citizens and different levels of authorities and place where citizens gather to discuss different issues. It has greatly influenced relationship between authorities and citizens and made it more complex and diverse.

Municipality Obrenovac uses the following forms of communication between citizens and authorities: municipal web site – with option which offers asking questions and making comments under the news announced (these kind of questions and comments are not common); citizen service “Answer in two days” (more than 200 requests per year); profiles on social networks (Facebook and Twitter) are actively used for consulting on different priorities of local community. Several times a year municipality organises online campaigns for collecting proposals for different purposes (most often for infrastructure improvement, taking care of the place and surrounding public area). According to Population, household and flat register in Republic of Serbia in 2011, 54 % of citizen in Obrenovac aged 15 and over are computer illiterate (they do not use computers). It could be concluded that communication between authorities and citizens on the Internet is at the developing stage. The reason is lack of knowledge and use of modern communication technologies. Therefore it is necessary to develop and promote off line tools for consulting as well.

Participation in the work of various advisory bodies – taking part in dealings through councils of assembly and municipal consulting councils is the right of citizens. It is an opportunity to express opinions of professionals and distinguished citizens, no matter what their political attitudes are.

Unfortunately, in the Municipality Obrenovac members of the working bodies of the Assembly and of the commissions of the Council are delegated by political parties, so participation in the work of these bodies is the opportunity to implement the party goals and target target groups, not to present ideas for the improvement of life in the local community. Municipality Obrenovac has 5 working bodies of the Assembly with a total of 25 members and 12 commissions of the Council with a total of 84 members. However, the Youth Council of Obrenovac is an example of good practice of this form of citizen involvement. Council members were elected after a public invitation for nomination of candidates for members was announced. The Council of Youth comprises three representatives from public services and institutions, one

representative of student parliaments, two representatives of two largest parliamentary groups, one representative of youth organizations and informal groups. In the municipality of Obrenovac the following forms of consultation are also used: public forums, expert meetings with representatives of the institutions, thematic discussions with citizens' associations, surveys, boxes for complaints and suggestions, books of impressions, chatting with citizens which is realized through "open door" method, collection of comments and suggestions regarding some topics in a particular period.

The strongest recommendation for the improvement of this form of civic participation is a wider introduction of various methods for consulting citizens.

2.3 Proposing

Proposing, as a form of participation, involves putting proposals forward and criticism of the work of the authorities. Compared to the level of information and consultation, proposing involves a higher degree of citizens' influence on decisions taken by local authorities. It can occur in many different forms of collective (public meetings, petitions, peaceful protests, gatherings, demonstrations) or individual (individual suggestions, complaints, petitions) character.

Citizens' meetings are gatherings organized in closed areas of the municipality intended for discussions and suggestions on matters within the competence of the municipality. The Statute of the municipality of Obrenovac defines the mode of convening such meetings, how they work and state their attitudes. The bodies of the city municipality or local community are obliged, within 60 days from the date of the citizens' meeting, to consider citizens' requests and suggestions, to take a stand on them, make an appropriate decision or measure, and inform the citizens.

Petition and public criticism include citizens' right to put forward proposals, suggestions, requests and criticism to the authorities. In Serbia, there is no precise legislation on petition, so petition is viewed as a non-binding citizens' appeal. Accordingly, the deadlines for replying are largely extended, which creates a sense among the citizens that this means is inefficient (Milosavljević et al, 2006). Consequently, citizens do not initiate or sign petitions to the extent they would if there were more confidence in the positive outcome of these activities. The Statute of the Municipality of Obrenovac contains no provisions on the right to petition.

In the past five years there were not organizing citizens' meetings, but there were two petitions. One of them was against refinery near the river and the second one was for dog playground in the town. Both of them were successful. However, in the Municipality of Obrenovac the practice of organizing citizens' meetings, and filing of petitions and public criticism has not been recorded.. The main initial recommendations for improving this aspect of civic participation is that it should be positioned and defined. The Statute and the decision of the Municipal Assembly should define and regulate it as a flexible form of citizen participation, which will provide an opportunity for groups and individuals to, as simply as possible, express their opinions and proposals on matters within the competence of the local government bodies.

2.4 Decision making

Direct (participatory) democracy is based on direct and continuous participation of citizens in government. Citizens can be directly involved in the process of making important political decisions at the local level in different ways. Referendum and Citizens' Initiative are the most common form of decision-making today, that is, of the implementation of direct democracy at the local level (Civic Initiatives, 2009).

The Statute of the Municipality of Obrenovac also provides for referendum and citizen initiative (in addition to citizens' meeting) as forms of direct citizen participation in the performance of urban municipalities. However, it should be noted that only a referendum is a form of decision-making, while the citizens' initiative is a form of previous plea in which citizens propose to the Assembly and other municipal bodies to solve an issue using their decisions. The above-mentioned forms of direct participation of citizens provide protection in cases where elected representatives do not make decisions that are in the interest of all.

Referendum is a form of participation that allows for direct voting at the polls on various issues that are of importance to the community. The Statute of the Municipality of Obrenovac allows a referendum to be announced on the own initiative of the Municipal Assembly or at the request of citizens. However, the statute does not precisely define a range of issues that can be decided by referendum, nor the times when it must be carried out. It is generally considered that the referendum should be organized on the occasion of "big things" such as the mayor or a shift of defining priorities for capital investment in the municipality.

Citizens' initiative gives citizens an active role in the management of municipal policy and represents the right to propose solutions to certain questions or bring in certain acts. The Statute of the Municipality of Obrenovac defines it that citizens, through the Citizens' Initiative, propose to the Assembly of the City

Municipality, within which a particular issue within the jurisdiction of the municipality of the city will be regulated, change of the Statute or other acts and call a referendum. The Assembly of the City Municipality is obliged to hold a hearing on the proposal from the citizens' initiative and to submit a detailed reply to citizens within 60 days of the receipt of the proposal.

Citizens in the Municipality of Obrenovac do not use referendum or citizen initiative as a mechanism for citizen participation although they represent two fundamental forms of direct citizen participation in decision-making. Encouraging this form of direct citizen participation is possible by the introduction of new, or, if necessary, by improvement of the existing legislation that allow: citizen initiatives seeking the elected bodies of local government to resolve the issue raised in the citizen initiative, or to initiate a procedure for calling a referendum; advisory referendum or referendum in which decisions are made on issues of interest to the local community, which local authorities are carrying out on its own initiative or at the request of the local community.

When analyzing the lack of public participation in decision-making we should not neglect research results (Zdenka Milivojević) which indicate that the majority of Serbian population, accustomed to strong and (all) powerful state, still does not see themselves as citizens responsible for their own rights and obligations, but still view themselves as (subordinate) inhabitants whose life is in the hands of the state and whose problems are a matter of state institutions' concern. Such attitudes narrow the space for civil initiatives. In addition, citizens are insufficiently informed about both the existence of decision-making mechanisms, as well as about the method and the reasons for their application.

3. LOCAL COMMUNITIES

The Statute of the Municipality of Obrenovac provides that, in order to meet the needs and interests of direct relevance to citizens from a certain area, local communities be established in the city municipality. The local community is established for one or more villages and, as a rule, covers an area with approximately the same population. The local community considers issues related to the creation of better conditions of life in the local community. The work of the local community and the real participation of citizens in exercising their right to local governance largely depends on the determination of funding for the implementation of programs and tasks of the local community. In the Municipality of Obrenovac there are 29 local communities, out of which 25 are villages. In the elections for local communities of 2012 the members of local community councils were elected by direct citizen votes and this was the first time that members of local community councils had been elected in this way. This practice, however, has not been continued. Local community councils play an important role in decision making, especially those related to the creation of better conditions of life in the local community. Communication between the authorities and citizens of the local community is better in rural local communities, because citizens of the village rely more on the local community than those living in the town.

4. CONCLUSION

Most citizens do not feel participant in the decision-making process in their local community and they are insufficiently informed about the developments and plans of the local authorities. Many are not aware at all that direct forms of participation exists in their municipality. Generally speaking, citizens are poorly informed and are rarely willing to use the existing mechanisms to contribute criticism of the government or make proposals. Launching initiatives to solve certain issues and improve life in the community, is rather the exception than the rule. Also, rare attendance to meetings where proposals or decisions of the authorities are discussed further alienates citizens from the decision-making process (SCCM, 2006). While Obrenovac Municipality is making efforts to improve citizen information and consultation, it is noted that proposals and decisions are not present, nor is anything done regarding the mechanisms for their encouragement. The efforts of municipalities are merely a single - action practice, but not a systematic and continuous approach to strengthening and fostering civic participation. Recommendations for greater citizen participation are openness of the local authority, stronger dialogue between local authorities and the citizens and sharing responsibilities in local public life.

Openness of the local authority to citizens is the first step towards greater citizen participation and the achievement of a democratic society. Informing citizens, their right of access to documents of the local government and timely and adequate information are indisputable prerequisite for deeper direct involvement of citizens. Transparency, public disclosure of the minutes and decisions of local authorities, organization of modern information services, live communication with the citizens and creation of cities' and municipalities' web domains are some of the recommended forms of active information.

Dialogue between local authorities and the citizens is the second part of the process of citizen direct participation in public life at the local level. Citizens' right to petition and public criticism or public debate are

some of the forms through which dialogue between citizens and local authorities may occur. Better and more accurate organization of dialogue with citizens, specification of mandatory issues that citizens must be consulted about, establishment of the obligation of local authorities to respond to the suggestions, remarks or criticisms of citizens, participation of citizens in working and advisory bodies, better and more frequent organization of public hearings or the introduction of innovative forms of consultation, are the guidelines proposed.

Sharing responsibilities is a key part of citizen direct participation in local public life. Developing their awareness of belonging to the community and encouraging citizens to undertake the responsibility to contribute to public life, are aimed at improving the dialogue between citizens and their elected representatives and the exercise of citizen right to participate directly in decisions making important for the future of their community (SCCM, 2006).

Organization and promotion of citizen direct participation can and should be focused on the formal and informal forms and methods of involving citizens in local public life. The system should work to raise awareness and responsibility for democratic participation of citizens in public life and decision-making. Finally, openness, dialogue and sharing responsibilities for build up a long-term partnership between citizens and local authorities. The goal of each local government should be building of a community of competent and aware citizens who will be ready to fully assume their role in society.

PUBLIC SERVICE INTERFACE SOLUTION BASED ON BACK OFFICE INTERCONECTION FOR E-GOVERNMENT DEVELOPMENT: A MACEDONIAN CASE STUDY

Mimoza Bogdanoska Jovanovska[1], Natasa Blazevska-Tabakovska[1], Elena Vlahu-Gjorgievska[1]
[1]Faculty of information and communication technologies, Bitola, R.Macedonia
*Corresponding author, e-mail: mimoza.jovanovska@fikt.edu.mk

Abstract: *The core of e-government efforts is focusing on citizen-centric orientation with more user-friendly interfaces for the citizens. This paper has a purpose to present user-friendly interface solution for one public service for citizen in the e-government framework that takes part in smart city development. The proposed interface solution is based on back-office connections of whole stakeholders included in the process of public service issuing that belongs to the "life events" category. The offered solution is based on deep research in the area of Civil Registration in Macedonia, with focus on back-office connections in this public service delivery.*

Keywords*: e-government, back office, public services, interface, smart city*

1. INTRODUCTION

Cities are the future of humankind. In the last two century is noticed fast enlarging of the population that live in the cities: if in the 18th century less than 5% of the global population lived in a cities (Harrison and Donnelly, 2011), now, in the 21st century, in general at least 53% of the humankind lives in the cities (data related to 2014, http://kff.org/global-indicator/urban-population/) what is 10 times more than in the past. In the developed countries in the world as USA, United Kingdom, Japony, Russia, Germany, France, Spain, and many others, this number is between 75% and 91%, what point out that living in the big cities in the developed countries is bigger trend. Macedonia is no exception even belongs to the group of undeveloped countries – in 2014 arround 65% of the population in the country live in the cities.

The challenges that are emergence as a consequence of this trend within the cities caused problems like: lack of places to live, contamination, damaged or inadequate infrastructure, lack of effective health and education, poverty, low transparency of government, etc. Public administration institutions usually are located on different locations in the cities and very often there are long distances between them, what is also a part of the challenges of the smart city.

The revolutionary discovers of the last century that marks the way and style of life of this century (information and communication technologies (ICT), Internet and digital technology) are seen as the tools that offer possibilities for solving those above mention problems. The emergence and development of "Internet of things" opportunity arose much of everyday objects and processes to be controlled automatically by the Internet. Those tools enable the cities evoluation from traditional to smart city where the improving of the quality and efficiency of citizens lifes is highlight of the efforts.

E-government as an interdisciplinary scientific field that is on the intersection of computer, information, administrative, and political sciences (Bogdanoska Jovanovska et al.,2012), is a predecessor of smart city concept. Its focus on identifying opportunities and developing solutions based on ICT used in public administration domain by interconnection of the whole stakeholders involved in the public services delivery, have a great contribution to the process of facilitating the lives of the citizens in the big cities, where long distance between institutions are one of the biggest problem.

Based on the research of Bogdanoska Jovanovska et al. (2012): document analysis on relevant laws, procedures; survey on web-sites of public administration institutions; and interviews with servants included in the process of life events service delivery, related to Civil Registration area in Macedonia, qualitative information relevant for back office interconnection between relevant stakeholders involved in life events public services that belongs in this area were collected. Drawing of information flow network between all relevant institutions (public or business) included in the process of this life event realization was used as base for creating front office solution for one public service in this area: issuing Marriage Certificate. The final goal of this paper is creating the most user-friendly interface for front-end service realization of this e-service, based on well defined back office database connections between all involved stakeholders in the service delivery.

Further on the paper is organized as follows: next section gives the description of the civil registration area in RM, after that back office database connection by using information flow network is discussed Interface

solution public service – issuing Marriage Certificate is presented as fourth section. The conclusion with directions for further work concludes the paper.

2. DESCRIPTION OF CIVIL REGISTRATION AREA IN REPUBLIC OF MACEDONIA

The Civil Registration Area is a segment of the public administration in the Republic of Macedonia that utilizes the recording of crucial events related to citizens, i.e., changes in citizens" personal status from birth to death. More specifically, the Civil Registry records births, marriages (and all modifications) and deaths. In the Republic of Macedonia, birth, marriage and death certificates are commonly required and used for performing numerous distinct public services. The activities of the Civil Registry are within the sphere of competence of the Registrar Office, a legal entity within the Ministry of Justice of the Republic of Macedonia, established in 2010. The Registrar Office functions on the local level, through its 8 regional offices, 26 local offices of the departments for register operations and 239 local offices in rural settlements. The traditionally service delivery in this area - issuing the certificates for all events means realization of few steps: (1) citizens obligatory need to visit local offices that belongs to the city/municipality where the event happen (birth place, marriage place or death place); (2) fulfilling application for the certificate that the citizen needs, (3) completed all need documentations as support (personal identification card, identification card of the parents, prove of payment realization for that certain service issuing, etc.); and (4) when the certificate is ready, citizen needs to visit office again to take the certificate.
Currently, there isn"t any offered on-line public service organized as front-end in Republic of Macedonia. The information for public services mainly is available at one general web portal of e-government services in RM (www.uslugi.gov.mk) and specifically, the information related to issuing Marital Certificate is given at an official web site of the Registrar Office of RM (www.uvmk.gov.mk). At the general web site citizen can takes information for all public administration institutions in RM (ministries, biros, or other institutions) as well as the documents that the citizens need for issuing any of the public services that those public institutions offer. Registrar Office is part of this web page with all information also related to the issuing Marriage Certificate. The way of finding this information is quite complicated because the citizen needs to know which public institution issue this document. Additionally complications exist because up to 2010 this document was issued by the Ministry of Justice in the premises of Ministry of Interiors, and now this is duty of the new institution named as Registrar Office. Further on, as was already mention above, citizens can use second possible web site http://uvmk.gov.mk/?q=taxonomy/term/13 where he/she can see the form of the document in two versions: in Macedonian and in two languages form. If citizen click at given option (on left side) “documents” all document that Registrar Office issue are listed. The citizen does not have option to start procedure electronically for getting the document – Marriage Certificate.

3. BACK OFFICE CONNECTION IN THE PROCESS OF MARRIAGE CERTIFICATE ISSUING

For the purpose of presenting back-office interconnection between institutions (public and/or business) in the process of Issuing Marriage Certificate, i.e. for a visualization of the network, we use the Pajek software package (Batagelj and Mrvar, 2007) for social network analysis.
The network on the Figure 1 corresponds to the situation at the field, traditional realization of the process after the reform that took place in 2010 and involved establishment of the Registrar Office.

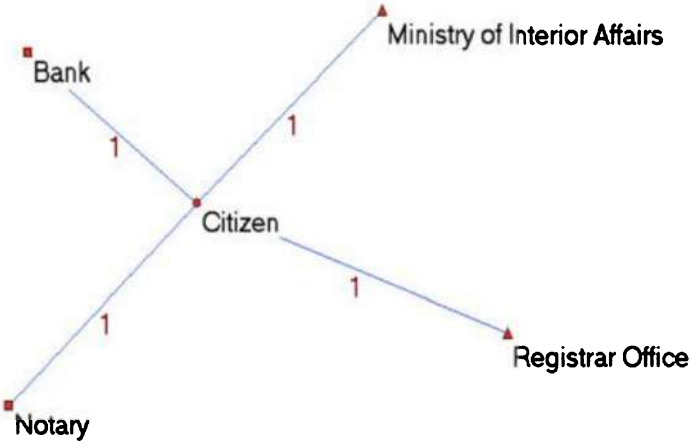

Figure 1: Information-flow network for the service "Issuance of marital status certificate”

The inter-organizational network presented at the Figure 1 is related to the information and document flows between public administration bodies and other stakeholders involved in the process of certain service

delivery: issuing of Marriage Certification. It is the traditional way of this certificate issuing where „the citizen" is in the center of the network – he/she has a role to connect the different stakeholders in the process of issuing public service.
According to the analyses that specifically focus on qualitative evaluation of e-services and European Commission DG Information Society (2001), four-stage model for the assessment of public-services online sophistication (EC1 model) is proposed:

1) information: the information necessary to start the procedure to obtain the public service is available online;
2) one-way interaction: the form (for printing or downloading) to start the procedure to obtain this service is available online;
3) two-way interaction: electronic intake with an electronic form to start the procedure to obtain the service including a form of physical or juridical authentication is possible;
4) transaction: covers full electronic case handling so that no other formal procedure is necessary for the applicant via paperwork; complete treatment of the public service is possible via the website, including decision, delivery and payment if required.

Above described public service delivery indicates that realization of this public service-issuing Marriage Certificate in Macedonia belongs to the first level of e-government development.
Electronically realization of this public services in the scope of e-government means back office connection of mention institutions, „behind the scene" documents interchange and information between public administration institutions as well as other stakeholders, and issuing document to the citizen without leaving its home, only by using some ICT device (computer, smart phone, credit card for payment, etc.). With other word saying: instead citizen to be in-line (traditional) he/she will realize this service on-line (e-government).
It is worth to mention Vintar et al. (2004) work on this problem, where the authors establish two dimensions of service maturity: sophistication and integration. The sophistication level according to them is defined according to the EC1 model, while the integration level according to the authors refers to "the degree of integration of service and corresponding processes required to solve a particular life-event problem:

1) dispersion: services needed to solve particular life-event are dispersed over different websites of different institutions;
2) coordination: services in the life-event are accessible through single entry point on the internet, but essentially services and corresponding processes remain unchanged;
3) integration: services and corresponding processes are integrated into one single process to solve the particular life-event in the whole."

Other very important thing for realization of this as well as any other public service on-line is interfaces that government institution offers to the citizen during the process of applying for public service realization i.e. submitting of the application. This part is important for two aspects: one – easy to use for every one even for those that have not high level of digital literacy, and second one (most important for us) solution that offer the best interconnections with all stakeholders involved in the process of that certain public service delivery, with all levels of controlling and cross-checking of the data that the citizen put in the process of application.
The process of electronically provision of public services includes two main parts: front office (portals, web sides) and back office (interconnections mainly between public administration institutions). Taking this in consideration "The provision of public services should be customer-oriented, taking their point-of-view: what the customers (citizens, business or even non-profit organizations) perceive in their relationships with public bureaucracy" (Vintar et al. 2004). So, motivation of the citizens to use portals/web sites depends of the user friendly interface of the portal as basic for easy managing of the services, as one side of the coin, and back office integration between public institutions, as other side on the coin, what is even more important, for functioning of the front office.

4. INTERFACES OF THE E-SERVICES

The crucial part of information system for using a smart government service is the user interface. Taking into consideration, many country governments take care about interface of the smart government services. For example, although the Singapore eCitizen portal had been assessed as the best of all analyzed portals already in the first measurement, it has improved from very good to excellent in the one-year period, which indicates that developers of the portal still take care of development of high-quality user-friendly public services (Leben et al., 2004).
The government services are used from beginners to experts (in term of using information system) and that is the main concern for interface designer. Most of the system users preferred an interface with small density (less than 50 percent of the interface to be filled with information). The experienced computer users preferred interface with higher density (sometimes approaching 90 percent occupancy of interface information). The designers are concern to offer interface that is easy to use or interface that allows quick access to necessary action/information. Sometimes these requirements are complementary but sometimes they lead to a completely different design decision. Beginners, for example, often prefer menus that show all the available

features of the system because they enable easy navigation and access. Experts, on the other hand, want menus organized around the most frequently used functions. The designers need to offer appropriate interface for all users, so they should try to balance between simple to use interface and interface with quick access.
Further, the user interface designed for public services, despite of principles for designing, should incorporate specific standards or document formats.

5. INTERFACE SOLUTION FOR ISSUING MARRIAGE CERTIFICATE

In the proposed case study, Issuance of Marriage Certificate (MSC), the user interface (UI) is created by using the official document as background for data entering (Figure 2).

Figure 2: User interface for issuing marriage certificate

The user should not enter all fields, but only those that contain the basic information needed for issuing marital status certificate. Elements which facilitate the entry (Figure 3) are used in the created UI:

a) Dropdown lists are used for choosing a city, municipality and place for delivering the certificate (e.g. the place where the marriage is concluded);
b) Entering dates is supported with datepickers (e.g. date of birth for each of the spouse, date of marriage, etc.);
c) Entering text - certain fields for text input are limited in length (e.g. identification number must be 13 characters), while some other fields are not limited (e.g. Entering mail address of the applicant).

By entering all necessary information, button for sending and processing the request is allowed. After the user sends the request for issuing the marital status certificate:

a) The information inserted by the user are checked within two institutions. When the information are validated the request is processed;
b) User receives an email with account and amount that need to be paid (costs for issuing the certificate);
c) After the validation of electronic payment, user receives an email with notifications for completed certificate and information about the delivering of the certificate (as shown in the request form - in the branch Registrar office or on home address).

If there are inconsistencies in the information entered by the user, he/she receives an email with further information that are needed for completion of the request.

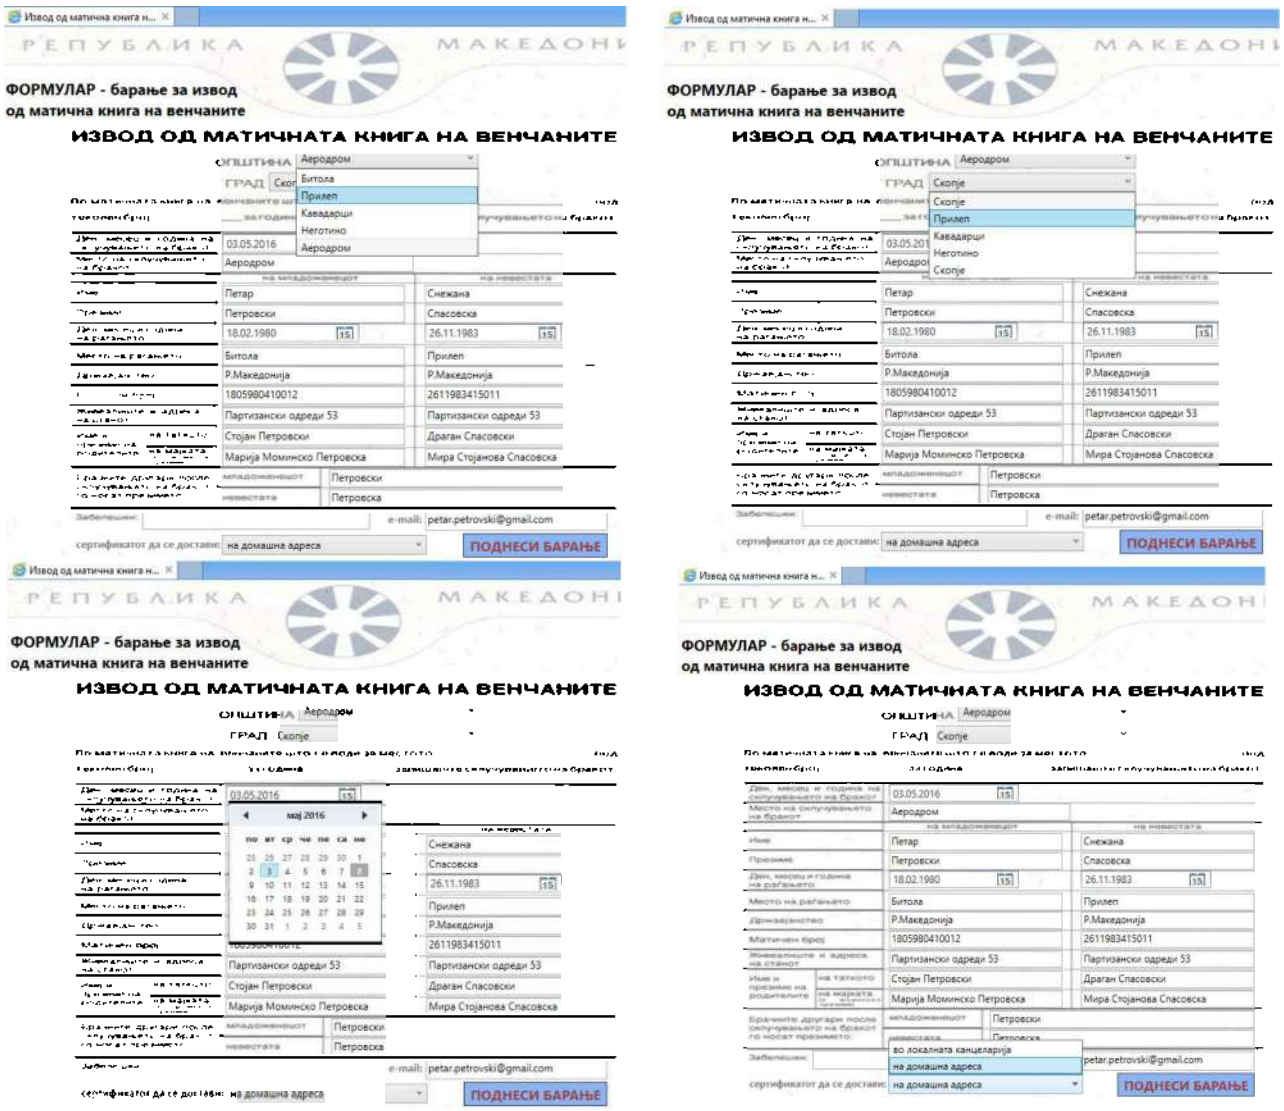

Figure 3: UI elements for facilitating the information entries

6. CONCLUSION

In this paper, based on dedicated research on front and back office situation in Republic of Macedonia related to issuing public service of Marriage Certificate, we propose interface solution for on-line realization of this service in context of e-government in direction with smart city development.

Having in mind that mainly websites and portals are examined from the governmental point of view and assessed upon the governmental offers for the customers (which is not always user friendly) we are offering solution that will be more suitable for people with low level of digital literacy. Furthermore, our interface solution (front office) is based on high level of back office development solution.

The advantage of the presented interface is not only the simplicity – intuitive data entry and reduced chances for errors. But more important, saving time and money, which is general attribute of e-services, and ability for the citizen to receive the certificate by mail on his/her home address or in local branch office by his/her choice (not in the municipality where the marriage is concluded).

The proposed interface solution has several characteristics that are important for citizen-oriented user-friendly e-government: usability, customization, openness and transparency. The advantage/strength offered by this interface solution reduces the burden of citizen (going from one to other institution for gathering need documentation necessary for getting Marriage Certification) and enabling the citizen from his/her home, at own PC starts/end procedure for getting this document.

The main purpose of this interface solution is actually the integration of various public and business institutions into a unified well coordinated back office system. We expected that the proposed interface will give successful results not only in increasing the citizen"s satisfaction, but also in improving of the overall effectiveness of service delivery process and public administration functionality.

It is essentially to emphasize that the approach of replacing the traditional e-services should be based on an analysis of back office and then creating the interface, which is not practice so far. Analyzes of back offices for different certificates on local and republic level, as well as adding new public on-line services can be done as further work.

INSTITUTIONALISM AND ORGANISATIONAL LEARNING IN THE PUBLIC PROCUREMENT MARKET

Ondrej Jaško[1], Mladen Čudanov[2*], Gheorghe Savoiu[3]
[1, 2] University of Belgrade, Faculty of Organizational Sciences [3]University of Pitesti
*Corresponding author, e-mail: mladenc@fon.bg.ac.rs

Abstract: *Transaction costs represent one the most important elements of institutional economics. Their importance in studying current regulations and practice in public procurement domain is constantly growing due to the fact that production costs of bidders converge. Differences in regulations (institutions) and procedures related to public procurement create atmosphere that can significantly change negotiation outcomes. Bounded rationality, opportunism and imperfect information are identified as the key factors that generate transaction costs in public procurement. Organisational learning can influence a decrease in direct costs of closing a transaction, but cannot influence fundamental sources of transaction costs, such as uncertainty and risks.*

Key words: *transaction costs, public sector, organizational learning, bounded rationality, imperfect information, opportunism*

1. INTRODUCTION

Public expenditure in the Republic of Serbia accounts for 45.5% of GDP, which is similar to the Czech Republic and Poland, but more than Bulgaria, Romania, Croatia and Turkey (Veselinović, 2014). Most part of public expenditure (for many years it has covered over 50 per cent of Serbian budget) has been directed towards salaries in the sector, pensions and social benefits. The topic of this paper draws our attention towards the expenditures related to procurement of goods and services. Since the enforcement of the Public Procurement Law in Serbia, the share of public procurement costs in GDP has been monitored through reports of the competent state agency (according to official reports of Public Procurement Office), and it is found that public procurement accounts for 8 per cent of GDP. On the other hand, in reference countries (EU members above all), the value of public procurement (EU Commission, 2011) is about 3.5 per cent of GDP. Nevertheless, there are only few scientific studies that give attention to the analysis and conditions for improving efficiency and effectiveness of public procurement, particularly from the aspect of economic and organisational theory (Jaško et al, 2015). The aim of this paper, from the aspect of institutional economics, is to analyse the procedures and practices of public procurement and their influence on the efficiency of spending public funds (bearing in mind the possibility that the key factors of transaction cost levels can change), by applying the concept of organisational learning in public sector.

2. INSTITUTIONALISM THEORY AND PUBLIC PROCUREMENT

Today, transaction costs are inevitable part of public sector economy analysis and have their place in research papers and works of numerous theoreticians. On the other hand, it seems that there is no field with clearer reflection of this concept on practice than the field of public procurement. Numerous authors made their main contributions trying to connect the two research subject matters. Some of the most commonly mentioned relations between these two research subject matters are the issues of public choice (always related to decision-making in public administration) that were discussed by Brown and Potoski (2003) , Wals and Davis (1988). Mana, Matějková, Jurčík, Heidu (2014) expanded research on the issues of transparency, while Domberger and Jensen (1997), Reeves (2008) and many others researched into market-based public procurement. However, in this paper as well, it seems fair to give full credit to those whose contributions are in the basis of consistency and applicability of transaction cost concept, including a number of authors that are now considered to be the creators and developers of institutional perspective on economics.

Institutionalism is much older than its most significant result – transaction costs. Institutionalism was established on the works of those who followed the statement of Veblen that humans do not act exclusively

rationally and in accordance to their own interests, since their choices and decisions depend on tradition, customs, habits and other kinds of rules (e.g. laws, author's remark), so their natural surroundings, where they make their decisions, is social, i.e. institutional—(Veblen, 1899). North (1991) defines institutions as "humanly devised constraints that structure political, economic and social interactions". Constraints, as North describes, are devised as formal rules (constitutions, laws, property rights) and informal restraints (sanctions, taboos, customs, traditions, codes of conduct), which usually contribute to the perpetuation of order and safety within a market or society.

For example, let us observe the role of public policy makers. The first dilemma they have to face while deciding on which values to set upon their citizens is whether to offer a certain public service internally, through public services and enterprises, or externally, through private providers. Such dilemma is recognized in management of private companies as the question whether to ~~-m~~make or buy~~-~~. There are various factors, both in public administration institutions and public enterprises that can influence this decision, but Levin and Tadelis (2005) divide them into two separate groups – economic and political, while Brown and Potoski (2004) introduce a wide range of different factors. Some of the factors include city size, financial situation, i.e. indebtedness, specificities of procured goods or services, their susceptibility to quality changes, the possibility to measure the volume of provided services, etc. It is obvious that the answers to these questions are strongly related to the model of public sector, where there are examples of wide and narrow volume of public offices in different countries, and only partly to the economic effects achieved by different choices. Therefore, a decision is not only the result of choosing a good as such, but also of choosing the model of how to procure it and why that is useful, so the purpose of the good itself is sometimes disregarded, and attention is only given to the purpose of its procurement. Sometimes it seems that it is more important to procure goods and services in accordance to ´rules´, than to procure them under best economic conditions. Most commonly used public procurement rules are the ones that enable equal access and equal treatment in procedures, and transparency (Truchet, 2012).

A significant methodological difference between neoclassicism and institutionalism lies in the institutionalism concept that humans limit maximization preferences, which neoclassical economics built into the foundation of its microeconomic analysis that always takes into account the market participant, homoeconomicus' (Zabieglik, 2002). The economy based on homoeconomicus' can be seriously questioned if decision-making context is broadened, and if it is taken into account that humans always make decisions in social context , especially if they hold public positions, when from the level of individual interest, they move to a higher, common, general , or more specifically – public interest.

Neoclassical economics has been criticized because of its inability to deal with important and deep questions such as happiness and welfare, laws and justice (Gilboa, 2010). Rational choice is not always the one that maximizes the gain of the participants in transaction. It is usually considered in a broader context, including other people who are related to the transaction, but do not participate in it, and those who can have a future opportunity to make such transaction. These very consequences were first discussed by Pigue, who used them to establish his view on externalia, and then by Coase (1960), who called this effect - social cost transactions. Pigue's solution rests on taxation, which has to be conducted by the third party (the government) that does not participate in making the transaction, in order to reimburse the expenses to damaged parties on one hand, or to reduce undeserved advantages on the other. Coase's solution rests on direct negotiation between the parties, while the third party needs to create necessary conditions, so that the negotiation costs (transaction costs) tend towards zero (Coase 1960). Obviously, the costs of this kind of transactions will grow when there are lots of transactions (for instance, a lot of people living near a thermal power plant) and therefore most authors claim that the efficiency of Pigue's taxes will win over the low cost of Coase's transactions, which may result in transaction blockade. Apparently, inefficient contracting is one of very important aspects of institutionalism. If institutions are inefficient, they will not be used, or participants will tend to avoid them. Such examples of institutional inefficiency can lead towards improving institutional economy.

3. PUBLIC SECTOR AND PUBLIC PROCUREMENT INSTITUTION

Public procurement refers to the process by which authorities purchase goods and services intended to meet the needs of community, or that are necessary for proper functioning of public administration. It is clear that public procurement serves as means to obtain the goods that public sector cannot produce itself, or if it is not justified by economic or other reasons. The rules of public procurement, as compared to private sector procurement are not fully compatible to one of the key postulates that have been developed thanks to Coase (1937) and Williamson (1975). They noticed that a company or public sector in this case, will be developed

by vertical integration of transactions if that is the way to reduce total business expenses, which along with production costs include transaction costs, i.e. the costs of transaction realization. However, since the number of transactions is getting larger, it may not be possible to achieve the goal of reproducing market conditions within an organization, and the decision-making within an organization may become even less credible. So, these authors set the foundations for establishing company (public sector) limits in a cost-oriented way (Williamson & Winter 1991), but it is clear that the creators of public policies are not consistent in applying these rules when making decisions about public sector limits. That is how the demands for reducing public sector due to unsustainable accumulation of authorizations (Claus, 1984), neoliberal demands for introducing market mechanisms in public sector (Pierson, 1994), and demands of New Public Management representatives to transfer public authorizations to independent public agencies , all can be relevant at the same.

The number of people employed in public sector or public services that are conducted in public sector organization can be taken as a measure of changes of the rules applied in making decisions on how big public sector should be. Some relevant studies show that ~~"~~we separate evidence that downsizes work from evidence that does not (or equivalently here, that upsize work)" (Lee & Strang, 2006). Institutional approach provides several optimal solutions, which is one of its specific features as compared to neoliberal approaches in economy, and the forces that work towards applying one of the solutions are known as coercive, mimetic and normative pressures (Dimaggio & Powell 1983). As for the rules that are applied in public procurement domain in Serbia, it seems that all three sources had their respective roles in creating institutions.

Commons (1931) was the first to introduce the term ~~"~~working rules ~~"~~as a significant decision-making instrument, while Hamilton (1919) used the same explanation to introduce the term ~~"~~institutional economy— while trying to prove that development of economic principles has to overcome a passive position where economy is reduced to buyer-seller relationship. That relationship depends heavily on the rules that are being used between buyers and sellers, and that is the basis of institutional economics. Commons believed that economic problems which cannot be solved in market conditions can be solved in the conditions of institutional reforms, whereby he clearly pointed to strong relation between economy and law, which was in part, his key standpoint while being involved in establishing ~~"~~state of wealth" where he participated while taking part in numerous committees and forums in the USA. (Such commitment contributed to the fact that institutionalism is viewed as pre-interventionism).

One of the oldest regulations concerning public procurement refers to regulatory provisions that public procurement contracts between the state or its representatives and suppliers, have to be the result of tender procedure (Truchet, 2012) (public offers and competition), which has been mandatory in French legislation system since 1786, and on municipal levels since 1837.

4. APPROACHES TO INSTITUTIONAL CHANGES BASED ON ORGANISATIONAL LEARNING

Commons was also the first to introduce the term ~~"~~reasonable price" that referred rather to the procedure needed to get it, than to its amount. Namely, he points out that transaction price can be reached in negotiation process by gradually adjusting viewpoints, rather than by a discrete market mechanism with one price matching one type of goods. A price can vary depending on who sells, and who buys, but when ~~"~~a transaction has been contracted following a regular procedure, its value is guaranteed by the highest court of justice in the country—(Commons, 1931). The procedure is regular if it is transparent, if all the interested parties have access to it and if the same rules apply for all the parties.

One of institutionalism concepts is that both rules and institutions are historically changeable (Veben, 1899), not only because of the passage of time, which affects changes in social rules, but primarily because of technological progress. In the conditions of general application of ICT and orientation towards better efficiency and better results (Čudanov&Jaško, 2012), public procurement rules have been integrated into the procedures of electronic public procurement. Not only that public procurement procedures are now based on using electronic communication between the contracting authorities and bidders, but growing usage of electronic auctions emerges as the highest level of electronic procurement development.

A specific characteristic of electronic auctions in public procurement is that buyers, not sellers, initiate them. This characteristic causes another – the prices are getting lower, not higher, since the main goal is to obtain goods at the lowest possible price, while other conditions remain the same (quality, life cycle, payment terms, etc). Moreover, certain kinds of auctions enable bidders to change their bids several times, since they are familiar to the bids of other participants in the auction. Several auction procedures have been developed

and the most familiar type is called English auction (Abulaban & Qadah, 2006). The procedure is as follows: Contracting authorities determine reservation price (the highest they are ready to pay); bidders are not familiar with the reservation price; auction expiration time is determined; bidders are given chance to make their bids; after all the changes have been done in the given bids, the one with the lowest value will be chosen. In some cases, it is possible to limit the changes that can be done in the initial bid, which serves as a protective mechanism against speculative behaviour of the participants. Dutch auctions that are considered to have the most efficient procedure, from the perspective of buyer can begin with a symbolic price for the demanded good, which represents an offer to contracting authorities to accept the terms. Then the price gradually gets higher, and the first one who accepts the offered price wins the auction (Vicrey, 1961).

A thorough explanation of the effects such auctions have on the efficiency of public procurement was provided by William Vickrey, back in the 1960s, and many others since then. Today, they are integral parts of standard applications (SAP 2007) for procurement management not only in public, but also in most private companies. Except the mentioned ones, there are types of electronic procurement with elements of classical tender procedure and auction. *First-price sealed bid* is electronic procurement where no changes can be made to the initial bids, so it is the most similar to classic form of bidding, except that it is made electronically. *Second-price sealed bid* also does not let a bidder see other participants' bids. Bidders provide not only the price, but also the information on quantities they are ready to offer. What is particularly interesting is that tender winner will not pay the price he has offered, but the price offered by the participant who came second, which contributes to even greater price reducing (Abulaban & Qadah, 2006). Since the described rules can change the way bidders behave, several8 more options for auction procedures have been developed, especially for the English auctions, where 8bidders cannot see the value of other participants' bids, but only the sequence of bids, or they can only see their own and the leading bid, or the leading bid and/or the sequence of bids, without the values (Pridavok, 2011), etc.

Empirical inductive method has been used in developing institutionalism, as compared to neoclassical economics where abstract deductive method has been used for research and deduction (Bresser-Pereira, 2003). For example, the mentioned auction practice has become a rule that is now included into regulations in the field of public procurement, since it has been proved that such practice can improve both transparency and competitiveness of the procedure (Kumar & Chang, 2007). Nowadays, there are regulatory provisions about when and how auctions can be conducted in the public procurement process, which is an obvious example that institutions can also appear as results of experiments.

Institutions appear and change as the result of a long-lasting and incremental process of learning (Groenewegen, Spithoven & van den Berg 2010). Learning is recognised as:

- Improvement of performances and achievements.
- Memorising, or using the information from experience.
- Evaluation of knowledge, where learning means making changes in knowledge stock, its characteristics or distribution to units.

Knowledge obtained by improving processes and performances is at the very core of learning as presented by Nelson and Winter (1982), and it is achieved by codification of knowledge according to routines performed by individuals. That is ~~–~~learning by doing~~–~~access to learning. Routines are the result of a balance that appears between the forces that support changes and those that believe in the efficiency of current situations or processes. Routines are considered to be a form of organizational control that does not engage resources, and therefore reduce transactional costs, which makes them even more efficient.

Organizational learning is a synthesis of two processes: learning and dissemination of knowledge. Learning demands the existence of certain mechanisms that enable members of an organization to collect, analyze, distribute and apply knowledge, which can be done in classical manner, with technology enhanced learning (Čudanov et al 2012) or in blended learning approach (Mijatović et al, 2013; Horvat et al, 2015). Some of the mechanisms of knowledge dissemination in the field of public procurement have also been turned into rules, and what is more – into formal rules. For example, professionalization of clerks working in public procurement field is decidedly required by legislation through since each contracting authority is obliged to have at least one licensed clerk for the job. Certain exams have to be taken in order to get the license, and the acquired knowledge has to be improved by constant training throughout the year. The subjects to learn about are regulations, routines and procedures in public procurement.

Natural sequel, or special kind of evolutionary approach to establishing institutions is Path dependence theory. It was introduced by Nelson and Winter (1982) and was in accordance to North's understanding of how institutions are created. Institutions also appear as incremental connection between the past and the

future (North, 1991), being the result of collective learning that evolves from informal into formal institution, which again proves that the inductive method lies at the heart of institutionalism. Evolutionary process has to be understood as transformation process of cumulative changes, where the result of each modification or transformation, at a certain moment makes the conditions where future reproduction and transformation can take place (Martins, 2009). That is why the mentioned electronic procurement and electronic auctions in the bidding process are not an innovation, but a technologically advanced replica of the procedures that have been occurring in trade, or even procurement for decades, or even centuries. Electronic procurement is an example of adaptive learning (Argyris & Schön, 1978) because the basic set of postulates on how routines should look like is not reconsidered, but the changes in technology used to conduct them.

It has to be noticed that certain differences still exist in degrees of innovation and transformation in evolution processes (Tsang & Zahra, 2008), on the basis of which continuous and discontinuous changes can be distinguished. A continuous change is less intensely different from the previous situation or procedure. It is introduced as a continuous change of cumulative character, which means that it contains larger or smaller share of the previous situation and is conducted by continual updating of the existing organizational routines. Discontinuous change is discrete, caused by a decision or action of the participants in a process. It is much more intensely different from the previous situation or procedure. Discontinuous changes are usually conducted to make important strategic shifts, when the crisis is fully developed and is often followed by deposition of managers. Discontinuous change comes as a result of generative learning, or double-loop learning (Argyris & Schön, 1978), because it affects basic postulates of previously developed routines. As regards public procurement, centralization and decentralization can be the examples of such changes.

5. AMOUNT OF TRANSACTION COSTS AS A CRITERION OF PUBLIC PROCUREMENT EFFICIENCY

Transaction costs can be defined as costs related to the activity that needs be conducted, so that a certain product or service can be transferred from one organizational system to another (Jaško, Čudanov, Jevtić & Krivokapić 2013). More operative definitions of transaction costs, which describe their contents, point out that all costs except the costs of production (providing services) are transaction costs. Some authors explain the structure of transaction costs as a process, which makes it easier to identify them within the procedures of public procurement. They claim that transaction costs are the costs related to the process of connecting to markets, and specifically, they include ~~-c~~osts of negotiation and writing contingent contracts; costs of monitoring contractual performance; costs of enforcing contractual promises; and costs associated with breaches of contractual promises" (Rahman & Kumaraswamy, 20026).

While searching for operatively usable identification of transaction cost contents in order to conduct a research about transaction costs in the area of public procurement, it has been found that they can be divided into four categories: 1) research costs, 2) contract costs, 3) monitoring costs and 4) conduction costs (Williamson 1981; North 1991; Hennart 1993). Research costs include the costs of collecting market information related to supply, competition, etc. Contract costs include the costs of procedure to draw up and conclude a contract. Monitoring costs include the costs of monitoring whether each party fulfils obligations prescribed by the contract, while conduction costs include the costs of litigation and sanctioning contract parties which fail to fulfil their obligations (Dyer 1997).

What is it that generates transaction costs, what is it that influeces the level of costs, and vice versa, how is it possible to put them under control?

After Williamson (1975) identified the fact that the amount of transaction costs is heavily influenced by imperfect information, i.e. the fact that market decisions are made with incomplete information induced further search for finding answers to the given question. Next level of insight is that bounded rationality and opportunistic behaviour of market participants cause imperfect markets. Both bounded rationality and opportunism influence the amount of costs before and after a transaction, i.e. they can be *ex ante* and *ex post (Williamson 1975). Ex ante* bounded rationality is the result of inability to fully determine all specific qualities of a procurement subject, and to envisage all the circumstances that may appear during the procurement process. The more complex procurement object is, more time and recourses are needed to reduce or even eliminate this uncertainty. On the other hand, bidders need more time and resources to formulate their offer. *Ex post* bounded rationality generates costs of monitoring the contract execution and costs of making and accepting consumer complaints. On the other hand, bidders hedge against counterparty risk, currency swings, inadequate procedures on the side of contracting authorities while planning procurement, unjustified consumer complaints, etc.

Opportunism, which is defined as a tendency to gain personal interest by legal, but often morally unacceptable behaviour before or after closing a transaction, can also cause transaction costs (Williamson 1975). Information asymmetry suits opportunistic behaviour, since one party has more information on the subject matter of contract agreement, the conditions needed to conduct a transaction or the outcomes that will ensue (e.g. insurance holders hide risks (ex ante opportunism), or true facts about causes and amounts of damage (ex post opportunism)).

Competition level in the market is an important factor of the amount of transaction costs. If both bidders and contraction authorities can close a transaction with numerous participants in the market, opportunism risk is very low and thus the opportunism-based transaction cost. This observation is related to Williamson´s statement that bounded rationality and opportunism gain more influence by using asset specificity to conduct a transaction, by measuring service scope and frequency of transactions (Williamson, 1981). An asset is more specific if its use is limited to a smaller number of goods or services where it can actively participate in their reproduction. In this case, this specificity category does not include only funds, but also people needed to produce transaction subject. The greater number of specialists needed to realize transaction subject, the greater are transaction costs related to it.

If transaction subject is not easily measurable, both parties are burdened by measuring transaction efficiency, which can put pressure on them to show opportunistic behaviour in the process of creating and performing a contract.

Table 1: Classification of public services by specificity of investment and measureability of output

Specificity of investment / Output measurability	Low	High
Easy	Measurable market services • towing service • disposal of solid waste TrC: +	Measurable monopolistic services electric energy, gas and water supplying TrC: ++
Difficult	Non-measurable market services • public health services • social services TrC: ++	Non-measurable monopolistic services • Firefighters • Police TrC: +++

Key: TrC =total transaction cost

The expected number of transaction repetition also affects the outcome of negotiation. The easier it is to determine frequency and number of repetition, the lower is uncertainty, and thereby the cost calculated due to specific qualities of resources to be engaged. This is connected to the calculation influenced by the experience curve (Sallenare, 1985) in all the processes determined by certain routine.

While determining transaction costs contracting authorities and bidders do not calculate with the same values concerning specificity, measurability and frequency of procurement. A bidder can be a specialist for certain type of production, having economies of scale, while contracting authority may have this single purchase of that good. Contracting authorities and bidders may have different ideas about quantity of services or intensity of engagement in contract performance, which is not so relevant when it refers to products. Contracting authorities may intend to conduct a procurement every year, but a bidder assumes that it is going to be performed only this time. The consequence of such behaviour may be that transaction cost is not equally perceived by both parties. Since the price obtained in public procurement procedure is a result of negotiation, regardless of how it has been conducted, it can be assumed that the price will equal the sum of production and transaction costs of the party with bigger sum. The variation in price that can be achieved still needs to be determined by conducting research that will take into consideration not only negotiation results, but also negotiation processes, price convergence of both buyers and bidders.

6. CONCLUSION

Institutionalism introduced into economic analysis some new categories and perspectives on market relations and organizational dynamics within a system. Some fundamental categories of neoclassical economics have been challenged by introducing new approaches that include transaction costs, reasonable instead of market prices, negotiation as a procedure for obtaining a price, as opposed to supply and demand relations and prices that depend on negotiation methods. Institutionalism offers economic perspective on the

world that highly corresponds to organization of public procurement market and the degree of behavioural dependability on that market under the influence of regulatory institutions. Institutions make it possible to decrease transaction costs, since knowledge of transaction costs can decrease market imperfection, growing opportunism of the participants and can also increase efficiency in the entire public sector. In that market, institutions are viewed as dynamic categories that undergo changes under the influence of market participants´ learning, but due to progress in technology that is being used, as well. Knowledge improvement related to transaction costs that are generated by current institutions is a cornerstone for making changes in behaviour of both participants and institutions.

EMBRACING THE OPEN DATA INITIATIVE IN REPUBLIC OF SERBIA

Branislav Vidojević, Marija Milčić
Faculty of Organizational Sciences, Faculty of Organizational Sciences
branislav.vidojevic@outlook.com, marija.milcic@fonis.com

Abstract: *Open data as a term is being used more often than ever before. It is an initiative which represents the idea that some data should be available to everyone, without any restrictions. In this paper we described several formats for representing open data and we discuss which format should be used for data of specific nature. Also, we gave an example of open data based application, Serbian Parliament Open Data REST API. Finally, we describe legislation in Serbia concerning Open Data, in contrast to the laws of other more developed countries which could be considered as mature Open Data practitioners.*

Keywords: *OpenData, OpenParliament, GovernmentData, StartUp, entrepreneurship, SymOrg*

1. INTRODUCTION

Many companies and governments collect tremendous amounts of data in their regular work activities. Often, those data have only one purpose, and, after being used, those data are stored and probably never used again. The thing is that companies and governments maybe are not using those data, but someone could benefit of that kind of information. The concept behind open data is that some data should be available to everyone to use it, build upon it, make money of it and modify it and all that without any restrictions (http://opendefinition.org/od/2.1/en/). Open data initiative is becoming stronger and stronger as the time is passing by. The reason of such a trend is that more institutions are starting to see benefits of opening their data.

Why should someone put a lot of effort and time into releasing data to someone who just might use those data and benefit from it?

Several reasons to open data have been described by the authors of (Janssen et al, 2012), which can be summarized as follows:

- The first reason is that most of the data that should be opened is the data that is already publicly available. For example, governments must provide their citizens with certain information, but only when citizens request that information. That process is usually slow, not very effective, and it discourages people to ask for new information. In addition to that problem, format of the data that governments usually provide is not standardized, and it is in physical form, as paper, pictures etc.

- The second reason is that sometimes, companies and governments don't have enough resources to start a project and create a new value based on their data, but they know that it could be done. So, their motive could be to open their data to everyone, give example of usage, and wait for someone to do that work, or even to do a better job.

- The third reason is that there are lots of people that are great in their field of expertise who are eager to create new value from which they, or even the community, could benefit. By opening the data, companies and governments will give a push to the entrepreneurship spirit of that kind of people. More entrepreneurs lead to smaller degree of unemployment, which again lead us to better life quality, higher standards and better developed economy.

2. DATA QUALITY OF OPEN DATA

It is difficult to define data quality, because the perceived data quality differs from the one use case to another. A definition which is commonly used is that data is considered to be of high quality in correlation to fitness of use of that data (Zaveri et al, 2013). To be able to provide high quality data is of the utmost importance to understand the perception of the data consumer, who assess data quality based on several factors as accuracy, completeness, relevancy, consistency, availability, verifiability and timeliness. (Wang & Strong, 1996).

Tim Berners-Lee, the inventor of the Web, developed a 5-star deployment scheme for Open Data, which is widely used for determining the openness of the data (Berners-Lee, 2012):

- *1-star data*: To achieve one star on Tim Berners-Lee's scale, you have to make your data available on the Web, in any format, under an open license. It is the lowest score because the data is available on the Web, but it is difficult to process it, by hand or by machine. It can be said that data is locked-up in a document.

- *2-star data*: To achieve two stars, data has to be available as structured data which is structured using some proprietary software as Excel. Difficulty lies in data processability, because data consumer has to use same proprietary software as the data publisher, which represents an obstacle in open data context.

- *3-star data*: To achieve three stars, data has to be available on the Web in open format as CSV (Comma Separated Values). Now, everyone can find free tools to process those data. It is possible to publish data with ease. The problem is that data is not embedded into Web. Consumer has to search for new data to be able to use it and process it again, whenever he or she has a need for it.

- *4-star data*: To achieve four stars, data has to be linked to the specific URI (Uniform Resource Identifier). This means that others can pinpoint data using specific URI, bookmark data, reuse at will. It takes some time to organize data in the right way and to implement services, but it can produce great benefits to the publisher and consumers, such as better control over data, possibility to link data to other locations on the Web, and promoting it in that manner.

- *5-star data*: To achieve five stars, all it has to be done is to link existing four stars data to the other data on the Web. In that way, you can move through world of data, discover new data, interact with it, use it and reuse it whenever you wish to.

Quality and openness of data in Serbia is around three stars data. In year of 2015, official Serbia Open Data portal has been established (http://data.gov.rs/). In a moment of writing this paper, that portal had links to websites of other institutions in Serbia, like Ministry of interior, Ministry of Education, Science and Technological Development and several others. They have uploaded some of their data on their websites and data is mostly in CSV format. Their data is rather badly structured and difficult to find. Large number of databases and connections between those databases, without any open data regulatory entity, makes the task of opening the data quite difficult.

2.1 Open Data formats

In order to increase data quality, existing and widely used data formats should be used. Choosing the right file format depends on the nature of information data contains.

If data is published only once, without any need to change it afterwards, CSV, JSON (JavaScript Object Notation) XML, or any similar structured data format should be used. Chosen format must be machine processable, which means that file formats like PDF, Word documents, pictures or similar are not suitable for this purpose.

Comma Separated Values (CSV) format is used when dataset is relatively easy to represent in a flat structure. Tabular data in some proprietary format is not a good choice for opening the dataset and CSV file format should be used. There is no official definition of CSV file format, but RFC4180

(https://tools.ietf.org/html/rfc4180) gives a most standard recommendations how to use it (Tennison et al, 2015).

Example:

```
Marco,Polo,United States
```

Comma is used as a delimiter which delimits values of different properties. In this case, Marco is a name, Polo is a surname, and United States is an origin country of some person. Different persons are described in a separate rows.

JavaScript Object Notation (JSON) format is a lightweight textual format for data representation (http://www.json.org/). It can be used to represent even complex datasets. It is not dependent on any programming language, and it is easy to process it, even for humans. Nowadays, it is often used to replace XML format. Same data described in JSON format has smaller footprint (less bytes) than in XML format.

Example:

```
{
        “name” : “Marco”,
        “surname” : “Polo”,
        “country” : “United States”
}
```

JSON is a key-value structure. For every key, a value should be provided. A value can be a number, string, null value, boolean value (true/false), other JSON or array of JSONs.

Extensible Markup Language (XML) is widely used as a data-representation format. It is a reliable format, because there are a lot of XML Schemas which are used to represent the data structure of some XML document. If it is necessary to be sure that data are in right format, XML file format should be used. Each XML document has logical and physical structure (Bray et al, 2008). It is relatively easy to create validation schemas to be sure that document has a valid structure. Existence of many tools for processing and creating XML format documents represents great advantage of XML format.

Example:

```
<person>
        <name>Marco</name>
        <surname>Polo</surname>
        <country>United States</country>
</person>
```

We can see that same information has more text in XML format than in JSON format.

If data is being published regularly, creating an API (Application Programming Interface) should be considered. By creating an API, it would be possible to look up for data over HTTP protocol (Bizer et al, 2011). It would be easier to add new data through creating new URIs. In addition, updating the data would not be a problem because data would be available using same URI. Through API, different formats of data could be served, like JSON, JSON-LD (JSON Linked Data), XML, RDF (Resource Description Framework) etc.

3. EXAMPLE OF AN OPEN DATA APPLICATION

3.1 Purpose of the application

Open Parliament Data is a project with a purpose of opening data from the Parliament of the Republic of Serbia about its members, political parties, sessions and speeches to the public (http://147.91.128.71:9090/parlament/). In order to make the data from the Serbian Parliament available to the wider audience, we have developed, under supervision of Laboratory for Artificial Intelligence (http://ai.fon.bg.ac.rs/), an API that can be utilized by everyone without any limit. This API enables any programmer, data analyst, news reporter or any other interested party to easily access the data that was previously stored in databases, documents and internal records of the Serbian Parliament.

3.2 Data provider

Data was originally created by Serbian Parliament. Non-profit organization "Otvoreni Parlament" (http://www.otvoreniparlament.rs/) requested and got this data from Serbian Parliament. The same non-profit organization has created a MySQL relational database, has structured and siloed data in it and gave us the access to it in order to create REST API.

Database consists of data of more than 1100 parliament members, 160 thousands speeches, more than 1200 sessions and more than 70 parties from year of 2002 to year of 2012.

3.3 REST application development

REST is an architectural style which is based on web-standards and the HTTP protocol (Li & Chou, 2011). Open Parliament REST API was built using Java programming language. We used Hibernate framework to "map" the database. Mapping database tables enables transformation from relational to object model. So we represented every object with URI (Uniform Resource Identifier) in order to be able to get specific data record by specific HTTP GET request. For building REST API we have used Jersey framework. Jersey is an open source, production quality, serving as JAX-RS (JSR 311 & JSR 339) Reference Implementation for building RESTful Web services. Jersey provides a well-formed API so that developers may extend Jersey API to suit their needs. Our architecture is designed by well-known design principles, and it is easy to explore the opened dataset (Massé, 2012).

3.3.1 URI specification of the REST services

Every parliament member can be accessed by sending an HTTP GET request which follows the next pattern:

{domain name}/members/:id

Example: http://147.91.128.71:9090/parlament/api/members/12411

where :id represents specific identifier of every member.

To be able to get speeches of a specific member, URI has to be built in the following pattern:

{domain name}/members/:id/speeches

Example: http://147.91.128.71:9090/parlament/api/members/12411/speeches

where :id represents specific identifier of every member.

In order to access data of some specific political party, URI has to be built in the following pattern:

{domain name}/parties/:id

Example: http://147.91.128.71:9090/parlament/api/parties/476

where :id represents a specific identifier of every party.

In order to access data of members of a specific party, URI has to be built in the following pattern:

{domain name}/parties/:id/members

Example: http://147.91.128.71:9090/parlament/api/members/12411/members

where :id represents a specific identifier of every party.

In order to access data of a specific session, URI has to be built in the following pattern:

{domain name}/sessions/:id

Example: http://147.91.128.71:9090/parlament/api/sessions/889

where :id represents a specific identifier of every session.

To be able to get speeches from a specific session, URI has to be built in the following pattern:

{domain name}/sessions/:id/speeches

Example: http://147.91.128.71:9090/parlament/api/sessions/889/speeches

where :id represents a specific identifier of every session.

Also, it is possible to get data of a specific speech by building URI following pattern:

{domain name}/speeches/:id

Example: http://147.91.128.71:9090/parlament/api/speeches/409344

where :id represents a specific identifier of every speech.

There are possibilities to control number of results (limit, page), ordering (sort), date range (from, to) by setting values of the specific query parameters. It is also possible to search data for specific keyword by setting specific parameter (query).

3.4 Results and benefits of the application

This API has been developed to support Open Government Data initiative. This initiative in Serbia is just starting, so this kind of application can contribute to popularization of Open Data. In addition, this API was designed by Open Data design principles (Massé, 2012; Government service design manual, n.d.). That means that API is scalable, and learning curve of API usage is not steep. API is well documented, so others can use it with ease. Also, data and API are licensed under the Creative Commons license (https://creativecommons.org/licenses/by-sa/4.0/) so everyone can use, modify and redistribute the data for any purpose. Besides API, we have provided several examples to show usage of the created API (http://147.91.128.71:9090/parlament/). That will help others to quickly grasp principles of API usage.

Currently, application is in testing phase. Eventually it will be used by non-profit organization “Otvoreni Parlament” to provide application on their website to explore the given data (http://www.otvoreniparlament.rs/).

Source code of the application is stored at GitHub, with detailed manual how to start the project, to test it and even how to contribute (https://github.com/faculty-of-organizational-sciences/open-parliament-api).

3.5 Comparison with other similar applications

Open Data at the Scottish Parliament has the same RESTful architecture style, and provides information about core parliamentary business, informal work at the parliament such as cross party groups and awareness raising events and details about members including their contact details and their Register of Interests. While both applications have complete documentation, complex HTTP request and response examples and the same architecture style, the difference is in volume of the available datasets. Significantly larger amount of available data in Scottish open parliament makes conducting of complex statistic possible, which is currently not the case in our application (The Scottish Parliament, n.d.).

4. OPPORTUNITIES

Local and state governments around the world are becoming more aware that smart data management helps to create new opportunities for economic development, to increase the efficiency of service delivery, to improve citizens' outcomes and to increase citizens' participation in decision-making processes. Opening Data is globally recognized as a process that will significantly contribute to achieving the objective of sustainable development after year of 2015 (Cerović, 2016).

In Serbia there are several groups that are initiating opening of data sets from Serbian administration sphere. UNDP (United Nations Development Programme) has significant influence on data opening. They published Estimation of the readiness to open data, organized first competition for developing applications which use different data sets and organized conference "Open data: open possibilities'' (Cerović, 2016). ,,CRTA" (Center for research, transparency and accountability) (http://www.crta.rs/) is a group of activists and journalists, which influenced on institutions and public officials through monitoring and control of their work to increase their transparency of their regular work by opening their data. Their work resulted in providing several applications on the "Otvoreni Parlament'' (http://www.otvoreniparlament.rs/) website and "Prati pare" application. "Prati pare" application name translated in English means "Follow money" and the purpose of the application is to provide conditions for the responsible management of public funds and to increase the transparency of work of local authorities (http://www.pratipare.rs/).

The data value is in possibility of data usage. It is important to put pressure on the government services to open their data. In that way, they will recognize Open Data as a need they have to fulfill to be able to achieve economic prosperity by implementing socially important services for citizens. Socially important data has to be open by default, not open by request. Opening data can be initiated by civil society, the private sector, international organizations, donors and individuals, and even the state's administration.

According to the McKinsey Global Institute survey, open-data can be used as a significant factor of unlocking great economic value by minimizing the gap between different industries where traditional intuition based decision making would be replaced by data-driven decision making (Manyika et al, 2013).

Serbia has joined a partnership for open government in year of 2014 (http://www.opengovpartnership.org/how-it-works/dates-and-deadlines). Since then, more and more organizations have worked on open data initiative. As a result of three years of putting pressure on the government, UNDP in cooperation with SEE ITC and Norwegian Embassy organized a competition "Open Data Hackathon" (http://hakaton.rs/; Zrnić, 2015). The competition was 48 hours hackathon where programmers have been working on applications based on open data provided by several Serbian institutions. As a result of the competition, several socially useful applications have been made.

Organizations could use open data to improve their decision-making process. Analysis of open data enables companies to discover what users prefer, e.g. what are their desires and habits, in order to improve products and services and detect potential anomalies. By investing in technology for gathering, sharing and analysis of data, as well as standards for comparison using data from multiple sources improves the business models and production processes. Also, the meta-data (data about the data itself) further contribute to the usefulness of open data, because they help to acquire better insights into the characteristics and quality of the data.

Progress of some companies are based only on open data. Authors of this survey (PSI_Open data in business, n.d.) provided us with several examples:

Mobile App for events in Vienna helps Tourist Organization to promote events, and this application is only based on the open data from the catalogue data of the City of Vienna (http://itunes.apple.com/de/app/viennaevents/id442891364?mt=8&ls=1/).

Belgian company, Graydon Belgium, helps you to correctly assess and control the health of your business relations. You obtain all relevant and up-to-date information enabling you to evaluate financial situation of your possible business partners. A thorough financial analysis will help you make the right credit decisions. This application was developed thanks to open data of Belgium (http://data.gov.be/en).

5. LEGAL REGULATIONS

The first successful step towards to the opening of the data in Serbia is The Law on Access to Public Information, which describes procedure how to gain access into official documents, however, the law did not include open data as information of public importance. The most important contribution of this Act is the introduction of the Commissioner for Information of Public Importance and Personal Data Protection (United Nations Development Programme, 2013).

It is defined by the law (The law on Free Access to Information of Public Importance, 2007) that citizens have rights to require public information. In the Constitution (Republic of Serbia Constitution, 2006), it is clearly defined which information should be publicly available. Also, it is clearly defined which information must not be provided to public.

This question is regulated in accordance to the standards of The European Union, relating to the protection of personal data.

Serbia has signed the Convention on the protection of individuals with regards to automatic processing of personal data in September 2005, which was ratified by the Law on Ratification and which was passed in 2008. This helps us to make a distinction between which data we are able to request for and which we are not.

The regulations of this law which are associated with the opening of data are:

- In the section "Measures to improve public work of government authority" (The Law on Personal Data Protection, 2009) there is an Article "The obligation to publish a directory" in which is stated that state authorities are obliged, at least once a year, to create a data report such as descriptions of authority and organizational structures, information about the budget and means of work, types of services and other information in addition to the main data about its work.

- In the section "Measures to improve public work of government authority" (The Law on Personal Data Protection, 2009) there is an Article "Damage compensation" in which is stated that if the public information is not provided to a person who requested that information, public authorities have to compensate for damage if they had unreasonably denied to provide the requested information.

- Laws, decrees, regulations, official materials of state bodies and persons working at publicly important positions, as well as all official translations of these documents, are not considered as work of an author, but as public domain documents (The Law on Copyright and Related Rights, 2009).

When requesting for certain information to become publicly available, certain law regulations could be used (United Nations Development Programme, 2013):

- Law about state administration stipulates that work of public administration bodies is considered to be public. That means that they are obliged to inform public about their work, using medias or other appropriate way to inform public.

- Resolution of legislative policy stipulates that is necessary to ensure full transparency and openness throughout the process of passing the law.

- The National Assembly, the President and the Government have the right to disclose annulling the obligation of secrecy.

- Upon written request, the Department of Statistics and other authorities authorized to process statistical data can provide some information without identifying scientific and research institutions. The institution requesting the information must clearly indicate the usage purpose of these data.

- Different agencies have regulations governing their duties regarding the collection and storage of data.

The largest contribution to the opening of the data would be to establish a format in which information is reported, as well as licensing and further use of open data.

Legal regulation is very important and there are lots of governments that have published their Open Data laws. For example, Dubai Open Data Law, which allows sharing of non-confidential data between government entities and other stakeholders (WAM, 2015). United Kingdom Government has created the Open Government License (http://www.nationalarchives.gov.uk/doc/open-government-licence/version/3/) and public bodies now can publish their Crown Copyright material under this license.

6. CONCLUSION AND FUTURE WORK

Information is power, but only when it's on time and when it's available. Data can provide a lot of information but we can use it only if it is given in the right format. Power of open data can be used for fast development of small businesses. It will result in more employed people, a lot of different applications from which society can benefit greatly.

As a matter of future work, we will continue to maintain Open Parliament REST service. Also, we will implement new solutions like JSON-LD (JSON Linked Data) response format. We will try to popularize Open Data by giving open data workshops and passing our Open Parliament open source project to the community to help others to engage easier into Open Data projects.

DEVELOPMENT OF SYSTEM FOR COORDINATE AND EFFICIENT RESPONSE TO CYBER INCIDENTS

Svetlana Jovanovic[1], Mirjana Drakulic[1], Tamara Vucenovic*[2]
[1]University of Belgrade, Faculty of Organizational Sciences
[2]University of Belgrade, Faculty of Philology
* Corresponding author, e-mail: tamaravucenovic@yahoo.com

Abstract: *Traditionally, the main responsibility for safety of the society lies with the state. The particularities of cyber space, however, require the necessity of full cooperation of all segments of society since they can all be and are constant targets of cyber attacks. Many nongovernmental actors have more resources for cyber defence compared to the state: dominant resources are in the hands of private sector - telecommunications companies and providers, hardware and software manufacturers and large enterprises. Likewise, nongovernmental and academic communities often possess specific skills, analytic and research capacities, and international contacts in this field, as well as the potential to draw attention to possible violations of human rights. Therefore, it is of utmost importance to completely and actively include both private and nongovernmental sector, as well as academic communities, into strategic and operational activities at the state level and to establish multipartner cooperation based on mutual trust.*

Keywords*: CSIRT, CERCI System, cyber incident, cyber defence, cyber security*

1. INTRODUCTION

The safety of cyber space is one of the key topics and implies protection against damage, unauthorised use, and Internet, cyber space and user abuse. Therefore, network management is brought into focus of state and global policies due to the geo-strategic importance of network infrastructure, digital data flow and control, as well as due to its influence on new standards that will define the functioning of society in the near future.

EU policies, international experiences and national strategies of developed countries identify several strategic key issues to be analysed for the purpose of forming cyber security framework at the national level:

1. **Cyber threats:** cyber crime, cyber wars and cyber terrorism. Cyber threats target the infrastructure, individuals, businesses and governments, both nationally and internationally. Critical infrastructure servers and controllers that are connected to the network are vulnerable to attacks which can result in disruption of services and remote takeover. The development of information and communication technologies placed many pieces of information about individuals on the Internet, which left them exposed and vulnerable. Enterprises, especially small and medium ones, increasingly base their business on technology, and new approaches and models. Governments turned to new paradigms, authorisations and types of functioning, diplomacy, democracy, defence, and protection. At the centre of everything is trust which is compromised by each threat. The effects of the attack can have serious impact on society, national and international community, and the costs and weight of consequences increase through time unless there is a quick response system. The rate of new technologies and crime development requires continuous improvement of the crime-fighting system, knowledge and levels of cooperation. International cooperation through existing mechanisms, such as the Council of Europe Convention on Cybercrime, Europol and Interpol, is still facing obstacles due to incompatible policies and bureaucracy, and lack of capacities at national levels. Cyber attacks will be increasingly used in contemporary hybrid warfare and conflicts, a fact confirmed by the *Munich Security Report 2015* (Munich Security Report, 2013). At the same time, the necessary knowledge and resources the attackers are investing are minimal, the effects are great and the risk is mainly small.
2. **Protection:** technical, organisational, legal, diplomatic, political, and societal measures and mechanisms. Cyber attacks and incidents occur daily and their number grows at an increasing rate. It is imperative to develop an efficient mechanism for effective defence against current and future threats, decision making, and early warning systems. Taken measures can be preventive or reactive, aimed at early threat identification, target “resistance” enhancement (infrastructure, individuals, businesses, governments, international community) and efficient cyber risk reduction. Technical measures are hardware and software solutions meant to provide mainly physical protection (Poonia et

al., 2011). As for the organisational measures, crisis management, cooperation and communication of subjects, development of human resources equipped to perform that, as well as the promotion of all protection measures, are particularly important. Legal measures comprise the appropriate legal mechanisms (national, international, self-regulatory) to protect the data, information and communication technologies, and processes related to it, as well as subjects (Warren, 2011). For the purpose of maintaining cyber space security, it is necessary to set a strong flexible legal and institutional framework, but the cooperation based on mutual trust and sharing of common resources is just as important since the legal and institutional framework makes no sense without it. Due to the geo-strategic importance of the Internet, important new questions have been included in diplomatic agenda, such as: digital policies synchronisation on national, regional and global level;, critical resource and standard management; maintaining Internet security and openness; protection of the public and citizens" interest; protection of personal and national data, human rights and freedoms; children and marginalised groups rights and safety; cooperation among stakeholders through a comprehensive multipartner model; institutional capacity building, etc. Political and societal measures comprise measures to protect the society from unauthorised use and abuse of data, information and communication technologies, and infrastructure. The aim is to eliminate and reduce the cause of system "vulnerability" that could affect the society as a whole, the state, and/or individuals. These measures are realised through outlining protection and security policy, as well as development plan and programmes, both nationally and internationally (ENISA, 2013).

3. **Cyber security:** priorities, principles, institutionalisation, cyber security management, capacity-building with ***C**omputer **S**ecurity **I**ncident **R**esponse **T**eams* (***CSIRT**s*), national and international cooperation in cyber space – cyber peace, peaceful coexistence, coherency, climate of trust, mutual cooperation, collaboration (Christou, 2014). Regarding EU Cyber Security Strategy and *International Code of Conduct for Information Security* of General Assembly UN, as well as national needs and documents in the development of the Information society, special attention is given to the global culture of cyber security in Serbia. Currently, a public hearing is being held on the proposed Law on Information Safety which should institutionally establish a national CSIRT[1] (Proposal, 2013) and the jurisdiction should be assigned to the Regulatory Agency for Electronic Communications and Postal Services (RATEL). The primary mission of a CSIRT is to help other organisations handle incidents occurring in computer networks, as well as provide a wider set of services (Munich Security Report, 2015). National CSIRT will be responsible for coordination of individual CSIRTs in Serbia (Ministry of the Interior – MoI, Ministry of Foreign Affairs – MFA, Administration for Joint Services of the Republic Bodies – UZZPRO) with other relevant institutions: Ministry of Trade, Tourism and Telecommunications (MTTT), Special Prosecutor"s Office for High-Tech Crime (PTVTK), and private sector CSIRTs (Serbian National Internet Domain Registry – RNIDS, Internet Service Providers – ISPs, mobile telephone operators, etc.). In order to enable such networking, it is necessary to develop tools and techniques which will provide standardised and efficient communication. By defining/forming this mechanism, a framework would be set for undertaking long-term activities which would connect all stakeholders, enable national critical infrastructure protection and joining international 24/7 network (Javaid, 2013).

2. OBJECTIVES OF THE PROJECT

The main goal of this project is to improve information processing, information analysis and information-sharing infrastructure so as to allow for the exchange of sensitive and confidential data among the competent authorities. Other goals that will be achieved in this project: open, reliable and free digital society; safe and reliable business environment; safety of citizens; the development of economy and critical infrastructure; fight against crime and improved defence; creating of safe environment for institutions, economy and citizens; greater use of modern technologies; raising end-user awareness. That will be achieved by effective decision making, early warning systems and cyber security management - ***System** for **C**oordinate and **E**fficient **R**esponse to **C**yber **I**ncidents* (***CERCI System***)[2].

The objective of the project is to explore how the responsiveness of individual CSIRTs supported by CERCI System can be radically enhanced by advanced technology, exploiting, in an innovative way, sharing of information among different national authorities and sector-specific CSIRTs in private sector.

---

1 That coordinates and facilitates the handling of incidents for a particular country

2 Proposal of *Directive of the European Parliament and of the Council concerning measures to ensure a high common level of network and information security across the Union* specifies the necessity to improve cooperation on network and information system security at EU level with a view to counter cross-border incidents and threats effectively. http://eur-lex.europa.eu/legal-content/EN/TXT/?uri=celex:52013PC0048

That will be achieved through the development of two key services in **CERCI System**:

(a) service for efficient management of collaborative CSIRTs activities and access to and supply of shared content (event, threat, incident, etc.) - **Security Information and Event Management (SIEM) Services** and
(b) improved information processing, data analytics and visualisation - **Cyber Incident Data Analytics Tool (CIDAT)**.

Numerous international experiences show that the practical and operational cooperation platform, such as CERT (Computer Emergency Response Team) or CSIRT, is essential as a hub for collaborative multipartner model. Information about worldwide risks, omissions and incidents are distributed and available in many global analytic sources and shared among national CSIRTs. It is also of great importance for Serbia to form such a national operational body as soon as possible, so as to be able to access the networks of CSIRTs, exchange information about risks, process information about reported and identified incidents in Serbia, prepare reports on the state of the Serbian cyber space and regularly act to eliminate incidents in the country (Urosevic et al., 2014).

It is also important to emphasise the necessity of cooperation between CSIRTs and European institutions for cyber security. The expected adoption of *Directive of the European Parliament and of the Council concerning measures to ensure a high common level of network and information security across the Union* will demand that the member states develop a network, information security strategy and a national cooperation plan, as well as define competent authorities and establish CSIRTs. Due to the delay in adoption of this Directive, building of a secure infrastructure has not begun yet.

National centres and teams for combating cyber crime have been formed by most European countries. Apart from Bosnia and Herzegovina and the Republic of Macedonia, the Republic of Serbia is the only country in the Balkans that does not have an established centre of this type. This provides the opportunity to review experiences and shortcomings of national solutions in the EU countries and establish state-of-the-art cyber security solutions.

The process of harmonisation of the legal framework of the Republic of Serbia with the EU acquis within the Negotiation Chapter 10 - Information Society and Media, encompasses EU documents that refer to cyber security and impose an obligation of forming an adequate national institution for combating cyber incidents, i.e. cyber crime. For years, all relevant Serbian institutions have been exchanging experiences through trainings, instructions or study visits with European professional and government bodies. Considering the fact that the realisation of this project primarily requires connecting all national stakeholders, a decision has been made to develop solutions (CERCI System) in-house in the first phase by the representatives of executive authority, academic and professional Serbian community. This project would meet some specific requests stated in the proposed Directive.

In order to achieve high level of cyber space safety, all potential weak links must be secured, including military and civilian sectors, government authorities, critical infrastructure, organisations, small and medium-sized enterprises and the end-users themselves (Haller et al., 2011). CERCI System actively includes all societal sectors as partners into national cyber security framework and utilises the existing resources in those sectors.

3. CONCEPT AND APPROACH

To explore validity of the stated viewpoints, CERCI System will address the government and private sector as the most critical. The project viewpoints and new services will be, therefore, validated within Business Cases all involving cyber security information transfer and objectives harmonisation between different organisations.

Current situation analysis will be conducted based on the data obtained by various methods and using the experiences (European Police Office, 2014) from *the **I**nternet **O**rganised **C**rime **T**hreat **A**ssessment* (iOCTA) within EMPACT (*The **E**uropean **M**ultidisciplinary **P**latform **A**gainst **C**riminal **T**hreats),* and also *SOCTA (**S**erious and **O**rganized **C**rime **T**hreat **A**ssessments) UNODC (**U**nited **N**ations **O**ffice on **D**rugs and **C**rime),* as well as other methods used for data collection and environmental scanning, such as *PESTEL* (***P**olitical, **E**conomic, **S**ocial, **T**echnological, **E**nvironmental and **L**egislation*), i.e. *PESTLE* (***P**olitical, **E**conomic, **S**ocial, **T**echnological, **L**egislation and **E**nvironmental*) that affect crime and the application of law[3].

[3] UNODC, *Guidance on the preparation and use of serious and organized crime threat assessments*, http://www.unodc.org/documents/afghanistan/Organized_Crime/SOCTA_Manual_2010.pdf

Among numerous services (see Table 1) needed to support collaborative SCIRT activities in a CERCI System, this project has selected the most critical ones to explore and demonstrate the validity of the stated viewpoints. The services will be highly flexible and scalable, easy to integrate within different digital environments of different actors within a CERCI System. The services will be applicable in a combination with existing Portfolio Software Solutions (***PSS***) and Cyber Security Management Systems (***CSMS***) to allow easy usage of the results in different environments. It is likely that such services will have a high impact on new ways of collaboration between public and private sector. The intention is to develop services to fit the Collaborative Reference Architecture (CRA) relevant for the national or sector-specific Cyber Security Centres or similar organisations. The objective is to allow for an effective combination of these new services with the existing or emerging services for collaborative work, which in turn will allow better integration of CSIRT activities with the everyday work.

The main issue is to enable an effective measurement of the synergistic effects between the services from the perspective of CERCI System responsiveness. As responsiveness is defined through increased motivation to proactively learn and construct cyber security data exchange in CERCI System, the measurement of system functioning as a synergetic system has to be evaluated against specified responsiveness criteria for effective decision making. Since the CERCI System model is quite new, no such criteria for responsiveness have been elaborated so far, but these will be developed as part of the project.

The European Commission[4] has presented the requirements and tasks of a CSIRT.

Table 1*:* CSIRT Services list from CERT/CC[5]

I Reactive Services	II Proactive Services	III Security Quality Management
1. Alerts and Warnings 2. Incident Analysis 3. Incident Response Coordination 4. Vulnerability Analysis 5. Vulnerability Response Coordination	1. Announcements 2. Security Audits or Assessments 3. Security Related Information 4. Dissemination	1. Risk analysis 2. Security Consulting 3. Awareness Building 4. Training

Networking through CERCI System will provide a new concept of early warning systems, effective detection and activity identification, develop mitigation and response strategy, establish trusted communication channels, effect a coordinated response, share data and information about the activity, track and monitor this information to determine trends and long-term remediation strategies, improve coordination and standardise procedures among national or sector-specific Cyber Security Centres.

CERCI System fulfils all the requirements of a CSIRT through: developing an infrastructure for coordinating response, developing a capability to support incident reporting, conducting incident, vulnerability and artifact analysis[6].

These services will include:

I **Security Information and Event Management (SIEM) Services** consisting of:

- Services for **M**anagement of **C**omputer **S**ecurity **I**ncident **R**esponse **T**eam (MCSIRT) that serve to:
  a) identify partners (from public, private and academic sector), include them in collaborative CSIRT activities, in accordance with their responsibilities, within a complex CERCI System environment;
  b) standardise policy and procedures in accordance with the report of European Union Agency for Network and Information Security (ENISA, 2012) on harmonisation in terminology, definitions, validation processes or requirements for National/governmental CSIRTs and standards published by International Organization for Standardization/International Electrotechnical Commission (ENISA, 2006);
  c) support CSIRT"s objectives and different levels of expertise in an organisation, as well as different collaboration patterns that depend on jurisdiction and organisational structure; these will include so-called feedback provision services.
- Discovery/Provision of internal and external expert sources, including accessing, managing and monitoring content available within a CERCI System, to determine trends and patterns in incident activity.

[4] European Commission, 2013 http://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=COM:2013:0048:FIN:EN:PDF

[5] Adapted CSIRT Services list from CERT/CC: http://www.cert.org/csirts/services.html, There are other services not included in the project, which shall be developed within the Centre after the establishment of CERCI System.

[6] ENISA"s recommendations define the activities every SCIRT should fulfil

II Cyber Incident Data Analytics Tool (CIDAT):

- Provision of the most appropriate SIEM path for CSIRT-based software solution, taking into account different models of early warning systems for vulnerability discovery, initial triage, reproducing, evaluation, distribution and notification, using machine learning[7] techniques – **N**eural **N**etworks (NN)[8] – which will be deployed to study the types of incidents, vulnerabilities and weaknesses, the types of attackers, the patterns of incident content, etc.
- Improvement of the decision-making process of teams inside CERCI System using a rule-based system (RBS)[9] and in accordance with different organisation objectives and policy within the SIEM activities.

The analysis of internal complexity of organisations' ICT systems and the external threat environment, institutional and legal framework, roles and purpose of the existing human and technical capacities, services provided by CSIRTs in the Republic of Serbia, as well as comparative analysis of CSIRTs in EU, Serbia and countries in the region, will show best practice of CSIRT functionality and give parameters for the efficient model for coordinate and efficient response to cyber incidents - CERCI System. The testing of the developed System will be performed in a specially defined environment within the academic network of Serbia (which already has academic AMRES - CSIRT). The pilot project will be realised with teams from MoI and RNIDS since these institutions are going to form CSIRTs in the next year. MoI, throughout the implementation of new e-government services, must additionally take care of the security of information systems and data stored in their databases.

RNIDS manages the register of national Internet domains (TLD and IDN) assigned by ICANN, maintains the main DNS server for ccTLD and IDN, manages publicly available WHOIS server for national domains, establishes the principles of operation and procedures for the operation of accredited registrars and is therefore crucial for CERCI System implementation. After the measurement, analysis and improvement of CERCI System, training courses will be organised and realised for the representatives of all institutions" CSIRTs in the project. When the quality assessment is finished, CERCI System will be handed over to RATEL. Gradually, CSIRTs of other institutions will be included, i.e. secure information systems of state administration will be integrated. Centre will provide technical support until the conditions are created for the official institutions to completely take over the CERCI System management. Also, studies will be conducted and training courses will be organised in order to continuously raise police and judicial capacities and give suggestions for legal improvements in cyber security. Alumni group will be formed and occasional meetings will be organised with training course graduates for knowledge innovation. During the project, numerous communication activities will be carried out with the media and other target publics both through Press page on project"s website and other places in coordination with all PR offices within the institutions and organisations that are partners on the project. Centre will regularly follow the latest trends, develop new modules and improve CERCI System in accordance with structural and functional changes.

Therefore, this project intends to simultaneously address two tightly connected critical problems:

- How to provide effective means for collaborative teams within CERCI System, with geographically distributed partners (Diplo, 2015)? How to improve knowledge and experience sharing and the opportunity to exchange not only technical solutions and procedures but also actual software (Cichonski et al., 2012)? Although all stakeholders possess different levels of expertise, CIDAT will form a common-knowledge database for all actors and therefore improve the decision making process and efficiency.

---

[7] Machine learning has evolved from the study of pattern recognition and computational learning theory in artificial intelligence. It explores the construction and study of algorithms that can learn from and make predictions on data. Such algorithms operate by building a model from example inputs in order to make data-driven predictions or decisions, rather than following strictly static program instructions.

[8] Neural network (NN) is a machine learning technique, inspired by the way the human brain works. It consists of interconnected processing units - artificial neurons - that are able to learn from data by using specialised learning algorithms. NNs are typically used for resolving ill-defined problems, when the underlying model is unknown, when the data are error prone, and/or when generalisation ability is required.

[9] A rule-based system is a program that uses rules to do some specific task: derive an expert-like conclusion, make a recommendation, constrain a business process, implement a policy, etc. Nowadays, RBSs are widespread and can be found under different names: expert systems, automated monitoring systems, business rule management systems, business rule engines, etc. Rules in RBSs are simple IF-THEN statements that capture domain heuristics. These can be regular rules (e.g., "IF the tire is flat THEN first try to re-inflate it") but, if the knowledge is uncertain or fuzzy, uncertain rules (with numeric certainty factors used in a rule"s IF and/or THEN part) or fuzzy rules (i.e., rules with fuzzy expressions such as "IF the service is good THEN the tip is large") can be employed. Conclusions are made by using inference algorithms which associate facts with rules to derive new facts. Finally, RBSs can have explanation facilities that explain "HOW" the RBS has reached its conclusions, "WHY" it has asked some question or what problem-solving strategy ("STRATEGY") has been employed. The goal is to give users an insight into the reasoning process, thus alleviating their confidence in the system"s findings.

- How to harmonise different ways of recognising incidents, classification, prioritisation, marking and handling threats by employees in CSIRTs? Deviation can be in scope (for example, cooperation with significantly more other groups or groups with special requirements such as law enforcement, government, or Intelligence agencies), technical details (for example, new technology), or novelty (for example, a new type of incident). The project responds to this question by developing a CIDAT approach between CSIRTs and CERCI System. To be efficient and provide adequate response to incidents, this approach should be implemented by deploying a regulation mechanism which facilitates harmonisation and establishment of a common ground upon different CSIRTs. The project suggests that such an approach can be considerably enhanced by effectively exploiting the experience between CSIRTs and CIDAT. Exchanging these data in a secure way, reacting and providing information improve the quality of the incident handling process (ENISA, 2006).

In order to exploit the synergy between collaborative SIEM and comply with public and private objectives within dynamic, flexible CERCI Systems, efficient technology for early warning systems and cyber security management in CERCI System is essential. The project, therefore, focuses on these two problems, aiming to provide organisational and technical solutions for effective defence against current and future threats, which requires the addition of a balancing, outward focused approach on understanding the adversary"s behaviour, capability, and intent.

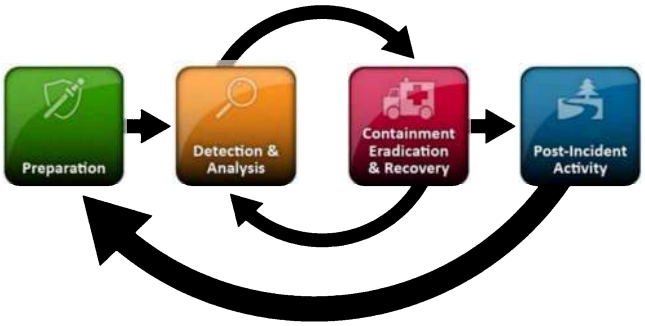

Figure 1: Incident response cycle

According to some international experiences, such as the recommendations of the American National Institute of Standards and Technology, the incident response cycle comprises four phases: Preparation; Detection and Analysis (reports, assessments, classification and triage – rejection, redirection or processing); Containment, Eradication and Recovery (inquiry, collecting data, incident response recommendations, providing assistance); Post-Incident Recovery, as shown in Figure 1[10].

Theoretical models of CSIRTs consider four core principles for effective CSIRTs: technical excellence, trust, resource efficiency and cooperation (Haller et al, 2011). However, the lack of automated intelligent platforms for activities and processes in CSIRTs is evident, and the means of achieving responsiveness are still in the phase of intensive development and investigation. By investigating the assumed increase of CERCI System"s responsiveness resulting from the synergy of the various services, the project will actually explore how technology creates conditions for effective CERCI System. It will also show the role of different services in practical application of this model.

This concept of CERCI System requires technologies to support sharing, harmonisation, building, and dissemination of information/warnings among law enforcement, government, or Intelligence agencies and universities, and effective combination of content and organisational information exchange systems (at both universities and organisations). The management of content and cyber security information exchange has a key role for both collaborative SIEM and harmonisation of public and private objectives. Thus the experiences between different CSIRTs must be fully exploited for the benefit of CERCI System. It is important to develop cyber security risk management tools and techniques within a CERCI System and use data from as many CSIRTs as possible.

While many CSIRTs effectively support collaboration, the existing solutions mainly do not meet specific needs regarding different collaboration patterns demanded in industry, often due to, e.g. „lack of people and resources" for processing all incidents (Chen et al., 2014). The CERCI System project will explore, for the first time, how collaborative CSIRTs can be improved by exploiting synergy of these two services (SIEM and CIDAT Services).

Such cyber incident knowledge and experience “chunking” model is typically implemented as an overlay model, a stereotype model, or a combination of the two. CERCI System is not only a coordinated and synergy model, but also a knowledge-sharing model (as shown in Figure 2) since it is based on knowledge and experience of all CSIRTs so that every individual CSIRT will be able to learn what any other CSIRT already knows, if it is related to protection from cyber attacks, incidents and threats.

[10] NIST Special Publication 800-61 Revision 2, Computer Security Incident Handling Guide, U.S. Department of Commerce - National Institute of Standards and Technology (August 2012) http://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-61r2.pdf

Within CERCI System, an individual CSIRT can use CIDAT for information exchange in a standardised way by using different applications. CIDAT primarily includes sharing of reports which will be precisely formatted, concise, transparent, and with data visualisation, in order to create a basis for faster and easier decision-making. Thusly built trust among CSIRTs can even lead to cooperation on levels not only related to cyber threats and incidents, which is implied by nature.

An innovative approach of CERCI System in this project will cover two issues:

a) how to use independent knowledge and experience of individual CSIRTs in order to find the most effective model for creating „joint knowledge and experience“;
b) how to most effectively adjust that joint knowledge to best match the needs of specific cyber security requirements.

Part of the CERCI System that relates to joint knowledge-sharing does not imply joint training courses and seminars but synergy of knowledge-building and duty-performing with a common goal to create a safer cyber space and protect users.

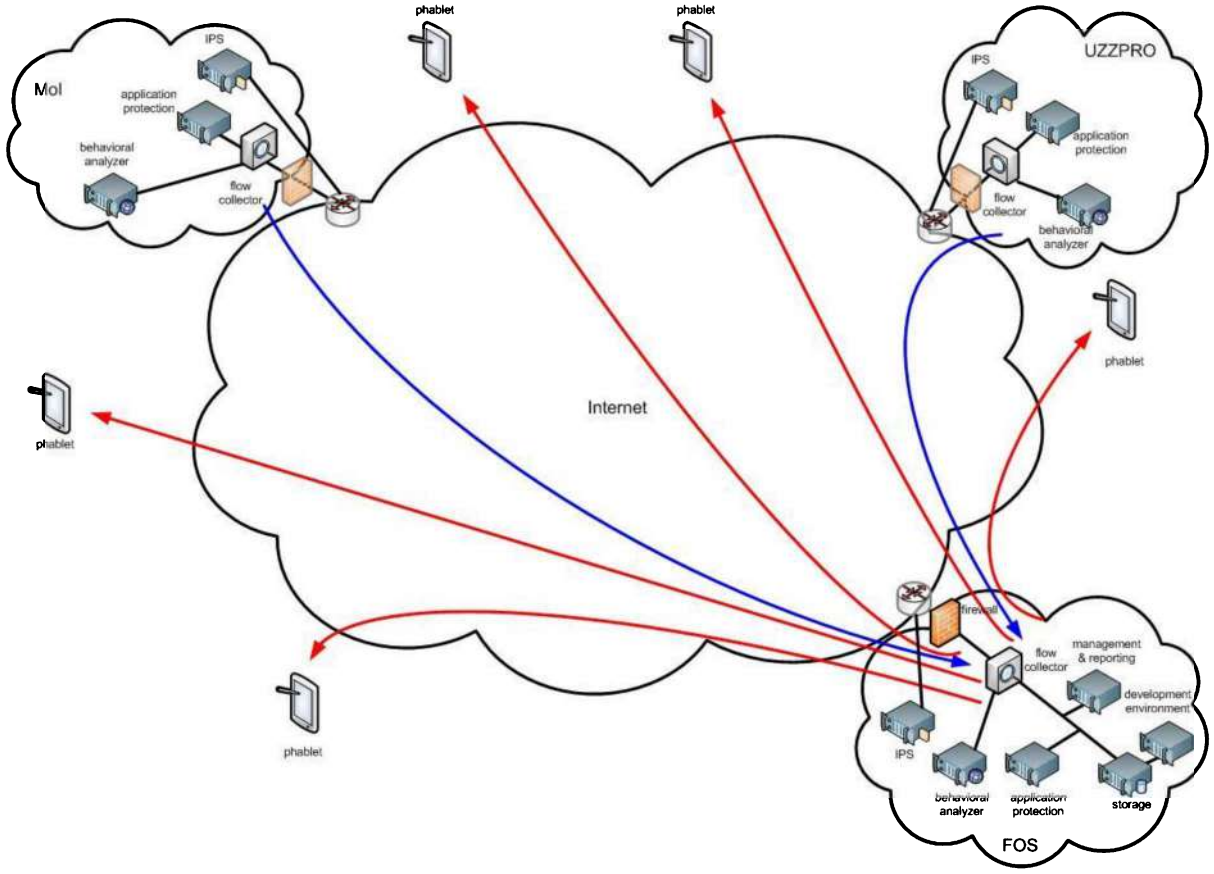

Figure 2: Scheme of CERCI System

The key part of CIDAT is quick identification and very quick classification of detected incidents using NN – it recognises typical patterns of incidents, classifies new threats according to the patterns it has learned. Software will be used by all parties according to a standardised procedure, but not all parties will be given the same authorisation, i.e. not all parties will be using the software for the same purpose, but in accordance with their individual competency, needs and interests.

4. CONCLUSION

The protection of vital societal functions through cooperation between official institutions, corporate, NGO and academic sector, and citizens will be implemented through CERCI System. Multipartner model is essential for the gathering of distributed information about safety risks, coordinated prevention and incident response, awareness and institutional capacities building, and the use of international contacts network for cooperation and support. This type of model, primarily a public–private partnership, is based on trust and cooperation, common interest and needs, all within the frame of a legally regulated system and the existing

jurisdiction of state authorities. For RATEL, the national contact point which integrates different organisations in combating cyber threats through CERCI System, communication with similar centres worldwide will be facilitated, as well as operational activities in case of incidents.

Through CERCI System, mechanisms and procedures will be developed for risk management, early warning systems and malware analysis (viruses, worms, and Trojan horse programs) – SIEM Service will harmonise and standardise communication procedures between individual SCIRTs and public and private sector (ISPs, hardware and software manufacturers). Also, data analytics tools and techniques (CIDAT) will be developed and they will provide, in an innovative way, automated and high-performance classification of events, threats, and risk data to provide strong security intelligence. That will create the basis for effective decision-making, faster response to incidents and extensible compliance reporting.

RESEARCH IN THE FUNCTION OF IMPROVEMENT OF PUBLIC PROCUREMENT LAW

Jovanka Vukmirović*[1], Predrag Jovanović[1], Dragan Vukmirović[1]
[1]Faculty of Organizational Sciences University of Belgrade
*Corresponding author, e-mail:vukmirovic.jovanka@fon.bg.ac.rs

Abstract: *Key findings of researching the positions of enterprises concerning public procurement, conducted in June 2015, were endorsed in the course of drafting the Amendments to the PPL, and that relevant measures have yielded the first positive results in the last quarter of 2015. as registered in the quarterly reports that contracted authorities are required to submit to the Public Procurement Office, on the basis of which this Office compiles its annual reports on public procurements. This case may serve as a model for all future amendments of the laws in Serbia in the sense that sound researches and analyses should precede regulatory changes. Findings of a comprehensive research of the effects of a law implementation coming from practitioners are irreplaceable inputs to the process of designing measures for upgrading the regulation.*

Keywords*: public procurement, amendments and supplements, research of attitudes of participants*

1. INTRODUCTION – RESEARCHINGTHE FUNCTION OF REDUCING UNCERTAINTY IN THE DECISION MAKING PROCESS

The public opinion poll and market research in the broadest context are the collection, analysis and control, or respectively the data exchange from the environment, under strictly controlled methodological rules (Vukmirović & Vukmirović, 2016). The result which follows represent information that is the basis for making responsible operational, tactical and strategic decisions. Research in the function of Management is a direct support for decision-making and information obtained in the process of research are aimed to decrease uncertainty in decision-making (Kochenderfer, 2015).

Decision making without relying on the information seconded from a research source represents a high-risk way of management and thus, in contemporary practice almost ceased to exist (Lacobucci & Churchill, 2015). Selection, processing and distribution of data is carried out through the use of modern information and communication technologies (ICT), all in the purpose of converting those data into knowledge starting from lower to higher decision making levels. Therefore, a user interface and the quality (accuracy, timeliness and coverage) of available information are very important for managers. Wrong decisions can still be made, but the probability is drastically reduced if decision makers have relevant information that serve as a basis for critical judgment.

2. THE PUBLIC PROCUREMENT LAW

Law on Public Procurement was adopted in 2008 after six years of applying the first Public Procurement Law ("Official Gazette of Republic of Serbia", No. 39/02, 43/03, 55/04 and 101/05), and after the adoption of the EU directives in this area (Directive 2004/18 / EC, Directive 2004/17 / EC, Directive 2007/66 / EC). According to the opinion the proposers, the law did not only fail to improve the public procurement system, in some segments it also represented a step backwards. In December 2012, third Law on Public Procurement was adopted ("Official Gazette of Republic of Serbia", no. 124/2012). The Law from 2012 was a very significant step forward when considering conditions for efficient use of public funds, in prevention of corruption and conflicts of interest, and it also was important for the establishment of a single market in public procurement and ensuring competition. The key innovations of this Law were:

- alignment with the European Union;
- more complete and simpler definition of the contracting authority;
- a clearer determination of the subject of public works contracts;
- reduce the number exemptions from the application of the law;
- tightening the conditions for the application of exemptions;
- a mechanism control prior of application of negotiated procedures that are commonly used;
- mechanisms for preventing conflicts of interest and corruption in public procurements;
- the partial centralization of public procurement;

- encouragement and in certain conditions obligation to perform electronic procurement;
- introduction of a new procedure - the competitive dialogue and regulation of two new forms of existing procedures - dynamic system of procurement and a framework agreement;
- Public procurement of small value is regulated in a way that enables process transparency and competition;
- planned mandatory publication of tender documentation, efficient publication and prescribed mandatory content of ads on public procurement;
- introduced environmental standards, and standards of energy efficiency as potential parts of the technical specifications;
- specifies the method of calculating appraised value;
- clearly stipulated manner in the decision to award the contract, procedures and deadlines for the conclusion of the contract;
- clearly and restrictively prescribed the possibility of changing the contract;
- for the first time regulated procurement in the defense and security domain;
- increased the responsibilities and powers Public Procurement Administration;
- changed the composition and operation of the Republic Commission for protection of rights where the Commission granted new powers, such as fines for non-compliance procedure itself to protect rights and the non-implementation of decisions, control of implementation of decisions of the Commission, annulment of the contract, conducting misdemeanor procedure at first instance and the submission of proposal for dismissal;
- system of protecting the rights has been made more efficient on the one hand by simplifying the procedure, and on the other through the introduction of new features such as proposing and imposition of temporary injunctions;
- misdemeanors are provided for all serious violations of laws and criminal sanctions are tightened with on the one hand, and on the other are ranked according to the severity of the offenses;
- statute of limitations for the offenses has been increased to three years;
- it is envisaged for the final decisions issued in misdemeanor proceedings to become published publicly

3. PREPARATIONS FOR THE ADOPTION OF AMENDMENTS AND SUPPLEMENTS TO THE LAW ON PUBLIC PROCUREMENT

Given that the State today represents the largest employer in Serbia, the Provisions of the Public Procurement Law were and remain the theme of national importance, and therefore are subject to permanent professional and media analysis, criticism and suggestions. On the eve of all stakeholders in the public procurement procedures, first of all the Bidders and Contracting authorities, the Public Procurement Office in cooperation with the of UNDP and support of the Kingdom of Sweden, two years after the application of the Law from 2012 has joined the preparations for the audit of the Law on PPL.

The first step was to identify major weaknesses in Public Procurement Law (PPL) implementation during past two years. In direct communications with their clients (contracting authorities and bidders), the Public Procurement Office (PPO) detected broader fields where improvements were needed: reducing unnecessary administrative burden on bidders, particularly small and medium sized enterprises (SMEs), increasing efficiency of public procurement procedure and reducing the rate of tenders annulled due to purely formal reasons (Cook & Semple, 2015). However, more detailed and comprehensive research was required in order to detect concrete obstacles and problems that have to be addressed in the planned amendments of the PPL. For that reason.

The Public Procurement Office in cooperation with the of UNDP and support of the Kingdom of Sweden has initiated an extensive research public opinion polls and market research, which included relevant categories of participants (bidders) in public procurement procedures.

The main aim of the research referred to perception of attitudes and value judgments of the participants (bidders) in the public procurement procedures and of their positive and negative experiences, as well as their attitudes about the Law on Public Procurement. In addition to the above mentioned objectives, the research had some specific objectives, such as:

1. Did Law from 2012 contributed the fight against corruption?
2. To what extent did regulatory and control measures of the Law of 2012, whose main objective was to Suppression of Corruption, hinder prolong and impede the public procurement procedures?
3. To what extent did additional administrative measures increase the costs and prolong the procedure, at the expense of suppliers as well as at the expense of clients and taxpayers?
4. To what extent is the complexity of the procedures, and the presence of corruption discouraged enterprises from participating in public procurement procedures?

5. To what extent did legal solutions increase overall transparency and how the establishment of the Public Procurement Portal contributed to this?
6. Should the Public Procurement Law regulate the procedure of public procurement so that it becomes a fast, efficient and easy to implement, and whether the Criminal Code and the Law on Misdemeanors should deal with issues of corruption and punishment?

4. METHODOLOGICAL FRAMEWORK FOR THE RESEARCH OF ATTITUDES OF PARTICIPANTS (BIDDERS) IN THE PUBLIC PROCUREMENT PROCEDURES

In Serbia, at the end of 2014, there were 331.059 of business entities operating under the status of "active." Of the total number registered, there were 115.692 active Companies, while the number of registered Entrepreneurs amounted to 215,367. Sample comprises only of active companies (excluding entrepreneurs). The study used a stratified, two-stage pattern. The strata consist form small and medium-sized enterprises (SMEs), up to 10 employees and of "large enterprises" - with more than 10 employees. Units of the first stage consisted of the active companies, while in the second stage it was selected according to business of companies (positive, negative, or “zero") in the previous year (2013).

Sample framework was the Register of companies of the Agency for Business Registers (www.apr.gov.rs). Size of the sample amounted to 1,009 enterprises and companies (companies). The sample is representative at the level of small and medium-sized enterprises up to 10 employees and companies with more than 10 employees. The target group of respondents in companies were owners / directors, then the middle management level (familiar and have a personal experience with the participation of enterprises in public procurement) as well as employees who are engaged in public procurement (searching the portal, documentation preparation, etc.). All the participants had Higher education. Data were collected by field survey in June 2015. Selection of companies was performed by software, based on a table of random numbers (Thompson, 2012). Supervisors urged companies and by telephone interview scheduling, while the interviewers were given information when and where to go and who in the enterprise / company to talk to.

5. THE RESULTS OF RESEARCH ON THE ATTITUDES OF PARTICIPANTS (BIDDERS) IN PUBLIC PROCUREMENT

Nearly three-quarters of surveyed companies (72%) participated in 2014 and 2015 in public procurement, which means that the survey gathered views not only of those who participate, but also of those which do not participate, which could indicate the reasons for non-participation. The bidders which participated in public procurement procedures were asked to say how many times they participated in during 2014 and 2015 and how many job did they get. Most of the companies that participated were positive financial (41 times on average), while businesses engaged "zero" or negative participated two and a half times less: 18, or 16 times.

From 38 participations in tenders in average for all surveyed companies, 13 cases were successful, which means that the success rate was 34%. Broken down by company size, micro enterprises (up to 9 employees), which are the most numerous in Serbia, were the rarest to participate in the tenders, while the number of occurrence (as well as the number of won tenders) increases with company size.

When asked what the first thought when it says "public procurement", the three most common associations were: tenders, state, public companies (32%), the possibility of getting a job (11.4%) and a bunch of papers and documents (10.7%).As the main source of information on public procurement, companies have stated Portal of public procurement. Reviews of the Portal in terms of its usefulness, transparency, inclusiveness and transparency were mostly good.

Of the four properties that have been evaluated a minimum was given the positive assessment of transparency (67% of best estimate). In two thirds of cases (65%), bidders do not believe that the public procurement procedures are „fixed" in advance. Tenders that are "fixed" in advance are recognized mostly on the basis of too demanding technical specifications and tight deadlines (57%) or when the price is much lower than the real (11%). Almost a third of respondents (32%) "know" that everything is pre-arranged.

Most providers (70%) believe that the law is "on their side". When this is added the fact that the Republic Commission for Protection of the rights in Public Procurement, in almost two thirds of the cases ruled in favor of the bidder, i.e. adopt their complaints, it seems that the legal solutions and institutions efficiently protected the rights of bidders. Third of bidder who were surveyed said that they use available opportunities to protect their rights so they complained to the Commission for protection of rights in public procurement procedures.

There is a significant difference in the number of complaints from the smallest (micro) company and the largest, more than 100 employees: micro-enterprises have complained, on average, in 23% of cases, a large almost twice as many (43%).

A similar situation is bound to pointing out the omissions of contracting authorities in the tender documentation which, on average, was 42%: the lowest enterprises indicated to the contracting authorities irregularities in the tender documentation in 30% of cases, and large companies in nearly twice as many cases (53.idders have pointed out that they had the great gain of the use of the Registry of the bidders which frees them to collect evidence for each procedure in order to fulfill four conditions required for participating in procedures. It is enough to put them once in the Registry and enroll. 71% of them are enrolled in the Registry which clearly demonstrates the utility of the Register for bidders, particularly in the sense that they reduce wasted time and money. When asked how much it costs them participate in the procurement process, bidders are given the following responses.

In most cases (45%) the cost of public procurement procedure ranged between 10 and 50,000 dinars, while in 42% of cases were less than 10,000 dinars. In proceedings with the lowest cost (5,000 pounds) has the smallest companies (up to 19 employees), while larger companies were more involved in tenders with higher costs. That indicates that the assessment of the amount of the costs for the participation is one of the factors on which the tenderer assesses whether to participate in the proceedings or not. Another factor is assessment of the potential cost effectiveness of the transaction. Reducing the cost of participation would lead to greater participation of companies, especially smaller ones, so that this factor must be taken into account in the preparation of bidding documents, all in order to encourage the participation of small and medium enterprises and strengthening competition in public procurement. Another important factor that the bidders pointed attention, like the one that reduces the competition is agreement two or more bidders to "dictate the rules" and thus virtually excludes other bidders. In 30% of cases, respondents have reported that bidders have met with such onset.

When asked about the negative experiences with contracting authorities most common was delay in the payment of contractual obligations by contracting authorities in 40% of cases. This is a serious problem, especially for smaller companies, which usually borrow from banks to acquiring the necessary raw material. The delay in the payment of the contracting authority leads bidder in the situation that it must repay the loan from its own resources, which are usually very scarce.

In addition to the problem of delay in payment, the bidders pointed out as a problem using criteria of the lowest price (20%) and unrealistically short deadlines to perform the services (14%). Asked whether is it necessary to have more active involvement of the police and judicial authorities in order to combat abuse and corruption, most respondents (83%) gave an affirmative response.

Third of suppliers have a good or very good knowledge of the Law on Public Procurement (35%), while a somewhat smaller number considered their knowledge of the Law as average (31%). Finally, the general assessment is that bidders have a neutral or positive attitude towards public procurement (total 63%), with 48% neutral and 15% positive. 35% of them have a negative attitude, while others did not declare themselves.

6. THE MAIN FINDINGS OF THE SURVEY AND THE GUIDELINES FOR THE REVISION OF THE LAW ON PUBLIC PROCUREMENT IN 2012

The main objective of the amendments to Law were improvements in the planning of public procurement, the conditions, manner and procedure of public procurement. The Law also regulates the centralization of public procurements and determines the method of recording data relevant to a public procurement procedure (Emmett & Wrigh 2012). The law determines the jurisdiction, operation and forms of organization of the Public Procurement Office and the Republic Commission for protection of the rights in public procurement procedures, as well as of ways for protecting the rights in public procurement procedures. Based on the results of research on attitudes and value judgments of participants (bidders) in the public procurement procedures, of their positive and negative experiences as well as of attitudes of the Public Procurement Law, there were presented the following conclusions and guidelines for drafting the new Law on Public Procurement, which entered into force in August 2015.

How to simplify, accelerate and reduce costs when participating in public procurement procedures
Based on collected data, it can be concluded that the central phase - selecting the best offer, well decorated law referred to 2012, noting that improvements are needed in terms of upgrading transparency and search of procurement in Public Procurement Portal, publication of procurement plans and reducing excessive

formalism. At the same time, at the stage of preparation and planning of the public procurement is necessary to improve the lot of the functions in market survey and planning, while at the stage of execution of the contract it is necessary to introduce systematic monitoring and control of the contract conduction.

How to encourage the participation of SMEs in public procurement procedures
Negative experiences in public procurement processes primarily relate to the inability to collect or delays of several months which may take the suppliers into bankruptcy. It is important to devise mechanisms to monitor and sanction non-performance of contractual obligations, i.e. the realization of the agreement, which is an area that is not in the domain of the Public Procurement Law, but Law of contractual relations and other regulations. Given that in many companies' employees do not know enough about the law on public procurement is necessary to give through the Public Procurement Office to give special attention to the training of micro-enterprises, in order to increase their participation. Incentives for participation SMEs in Public Procurement is given special attention in the new EU directives, as well as in the Development Strategy of public procurement in Serbia.

In addition, it is necessary that the Public Procurement further encourages contracting authorities to share the procurement by the parties whenever it is economically justified in order to create an opportunity for greater participation of small and medium-sized enterprises.

How to boost competition
An important prerequisite for competition is to reduce the number of negotiation procedures without prior publication. The Public Procurement Office is estimating the merits of this procedure, pointed out that the requirements of the contracting authorities were established only in a minority of cases which reduced participation of non-competitive procedures with 17% in 2013 to just 5% in 2014 which is the average in EU countries. It may be noted that, in the context of public procurement two key preconditions for strengthening transparency and competition were created:
a) Portal of for public procurement and
b) Limitation of to the representation in a negotiated procedure without a prior notice.

How to prevent corruption
In almost one third of cases (32%), a factor that discouraged bidders from participating in public procurement procedures had not been specific, but this was a perception („it is known, it can be seen, heard"). This points to the fact that the participation of bidders could increase significantly if the contracting authorities have taken measures to increase the credibility of their public procurement in the eyes of suppliers. In order to overcome the problem of "fixed agreement of bidders," it is necessary that the Competition Commission effectively sanction such occurrences.

Market research involves contracting authorities have communicated with potential bidders, which has not been the case in Serbia. The Public Procurement Office should prepare guidelines for contracting authorities on how to communicate with suppliers in order to conduct market research and also how to avoid the risk of undue influence of suppliers.

Criteria of lowest tender price and unrealistic short deadlines for execution of work requires the development of a system of internal control and audit which would include monitoring whether the bidder who offered the lowest got the job only on the basis of price and whether the bidder delivered the ordering party what was agreed in the contract (in terms of quality, quantity and characteristics). Surveyed enterprises indicated that the problem with most contracting authorities is that they do not have these types of controls, allowing the abuse. Therefore, the strengthening of controls at the stage of execution of the contract by the Public Procurement Office and other control authorities and services is very necessary.

Strengthening the role of the police and judiciary
One of the key issues to overcome weaknesses in the public procurement process pointed out by bidders, is to determine to what extent it is possible to eliminate the deficiencies stated by amending the Law on Public Procurement. Disadvantages such as: a) the inadequate definition of the needs of contracting authorities in the tender documents that do not match the offer in the market, in the sense that it is not clear what is wanted from the bidder, b) the lack of discipline in paying bidders and c) control of fulfillment of contractual obligations, are not possible to solve only with the Amendments to Law on public procurement, but it is also necessary to strengthen the mechanisms of checks and balances.

Then, it is necessary to establish a process for monitoring contract execution and to control the public procurement contracting authority. Internal Audit Unit have an important role in this process, or reviews and approvals of the State Audit Institution (SAI) is also of great importance. In the case of suspected corruption in public procurement, regulatory bodies such as the Public Procurement Office, the Commission and SAI

should inform the investigative authorities (police and prosecutors), in order to effectively conduct sanction by using the courts.

It can be concluded that it is important to clearly delineate what should be edited by the Law on Public Procurement- which is the process of selecting the most favorable bid so this happens in a prompt and efficient manner and that the contracting authority gets what they need, under the most favorable terms and in a timely manner. At the same time, sanctions for violations of the law needs to be conducted by specialized and competent institutions on the basis of the regulations under which they work.

In cases where these other institutions do not do their job as expected, the solution should be sought in the direction of taking measures to increase the effectiveness of their work and more efficient sanctioning of irregularities, which is the best barrier and prevention, instead of transferring responsibilities and tasks in the sphere of public procurement, thus burdening and it makes public procurement processes becoming unnecessarily complicated and expensive measured by expenditure of time and money.

7. IMPACT OF THE RESEARCH

The research had a significant impact on amendments of the PPL. Key findings of the research concerning transparency, efficiency and cost-effectiveness of the procedure, together with the administrative burdening of bidders, were acknowledged as vital issues to be resolved by means of amendments to the Public Procurement Law in order to improve the functioning of the public procurement system. Amendments to the PPL were finalized in July 2015 and entered into force on August 6 of the same year.

With a view to upgrading the transparency in public procurement procedures, the relevant recommendation of small and medium enterprises was adopted by means of introducing duty to publish procurement plans, decisions on awarding contracts, and decisions on cancelling the procedures on the Portal. This increased the number of documents to be published on the Portal, thus improving the informing of bidders and making it easier for them to take part in public procurement procedures.

A measure under the Amendments to the PPL intended to increase the efficiency in public procurement procedure, expressed by the decreased length of the procedure, was the introducing of duty to publish decisions on awarding contracts or on cancelling the procedures on the Portal, instead of delivering those by mail. In this way, the deadlines in the procedure are counted from the moment of publishing on the Portal, which significantly affects the shortening of time between the making of relevant decision and concluding the contract. Under the former practice, there were instances where bidders deliberately avoided to receive decision on awarding contract or decision on cancelling the procedure, thus causing substantial and unnecessary prolonging of the procedure. In addition, the statutory deadlines in the procedures got harmonized with the deadlines under the new Directives and, at the same time, shortened in comparison to the previous legal provisions, which has additionally contributed to expediting the public procurement procedures.

The effect achieved in the last quarter of 2015 was that the average duration of an open public procurement procedure (counting from the date of publishing the invitation to bid on the Portal, up to the day of concluding the contract) was reduced to 61 days, as opposed to 77 days it took to complete this procedure in 2014. In low-value public procurements, the length of the procedure was reduced from 37 to 29 days.

The second set of measures designed to increase the efficiency in public procurement procedures was aimed at reducing the number of cancelled procedures. Data from the Annual Report on Public Procurements for 2014 revealed that the most frequent reason for cancelling the procedure was that all received bids were unacceptable. Quite often, bidders would omit to provide one or another evidence out of numerous proofs of fulfilling mandatory and additional eligibility requirements (which they do fulfil), ending up with the bid being rejected on that grounds. The solution introduced by the Amendments to the PPL whereby all bidders only submit a statement declaring they meet mandatory and additional eligibility requirements whereas only the winning bidder is obliged to submit proofs on meeting all eligibility requirements, has significantly reduced the risk of a bid ending up rejected due to a formal oversight on the part of bidders who omitted to provide a certain proof although they do fulfil such requirement.

The next measure, designed to reduce the number of cancelled and repeated procedures, was to allow contracting authorities to award contract to the bidder whose price exceeded the estimated value in all types of procedures, rather than in open procedures only, and this was done by the Amendments to the PPL. Before these Amendments, contracting authorities would, at times, misestimate the value so that, consequently, all submitted bids would exceed the set value. In such cases, pertinent public procurement

procedure had to be repeated (except in the case of an open procedure), even if the new procedure could not be expected to garner the bids within the limits of the estimated value that had not been properly set in the first place. This was particularly the case with low-value procurements, and especially with the ones formed in lots. According to data from the quarterly reports, in 28% of cancelled low-value public procurements in 2015, the reason for cancellation was that the entire received bid had exceeded the estimated value.

It is worth emphasizing that prices offered in all other appropriate bids must be above the estimated value and that this price is a comparable market price, under the general limitation that contracting authority cannot assume an obligation in the amount exceeding the one allocated beforehand under its relevant financial instrument for this particular procurement. In this way, the new legislation created a precondition for decreasing the number of cancelled procedures and for increasing the number of successfully completed public procurement procedures, which resulted in decrease of the share of cancelled procedures in 2015 to 11% from 13% as it stood in 2014.

The key measure aimed at reducing the administrative burden for bidders (which was one of key findings of the research) was the option to prove fulfilment of all eligibility criteria for public procurement procedure (mandatory and additional ones) by means of a statement. The measure relieving the bidders from duty to submit proofs on fulfilment of mandatory and additional eligibility criteria in each individual public procurement procedure has substantially saved bidders time and money in their taking part in public procurement procedures and, thus, stimulated them to submit bids more readily and partake in public procurement procedures more willingly. This in particular refers to small and medium-sized enterprises (with up to 50 employees) which account for the majority of bidders in public procurement procedures, and which comprise ¾ of the total number of respondents in this research.

The reduction of administrative burden for bidders resulted in their greater readiness to take part in public procurement procedures and, consequently, in the strengthening of competition. For example, the average number of bids per concluded contact in 2015. was 2.9, more than in 2014, when it stood at 2.6 bids; this has effectively discontinued the four-year trend of decline in the average number of bids (and of weakening competition), as identified since 2012.

8. CONCLUSION

In June 2015 was conducted a research in the form of an opinion survey among the small and medium enterprises on the topic of public procurement, with a sample of 1009 enterprises, which produced the following findings. Concerning the transparency of public procurement procedures, most respondents underlined the necessity to publish the procurement plans and the estimated procurement values on the Public Procurement Portal.

The second important finding of this research was that enterprises were hesitant to take part in public procurement procedures where their estimates indicated they would have to spend too much time, or where the required “administration” would be too cumbersome. On the same note, the research also revealed general attitude of bidders that “each paper costs”, and their belief that the reduction of administrative costs would produce positive effects on bidder’ participation in public procurement procedures. As the result of a previous substantial administrative burdening, the participation of bidders in public procurement procedures has decreased, so that the average number of bids per concluded contract in 2014 was mere 2.6.

Another finding of the research was the need to improve the efficiency of public procurement procedure. Greater efficiency in public procurement can be achieved by decreasing the length of the procedure, and by reducing the number of cancelled procedures, which then had to be repeated and caused additional spending of time and money both for contracting authorities and bidders participating in such procedures.

One can conclude that the key findings of researching the positions of enterprises concerning public procurement, conducted in June 2015, were endorsed in the course of drafting the Amendments to the PPL, and that relevant measures have yielded the first positive results in the last quarter of 2015 as registered in the quarterly reports that contracted authorities are required to submit to the Public Procurement Office, on the basis of which this Office compiles its annual reports on public procurements.

Efficiency in public procurement procedures aimed at reducing the number of cancelled procedures was increased by provision that all bidders only submit a statement declaring they meet mandatory and additional eligibility requirements whereas only the winning bidder is obliged to submit proofs on meeting all eligibility requirements. In addition, second measure, designed to reduce the number of cancelled and repeated

procedures, was to allow contracting authorities to award contract to the bidder whose price exceeded the estimated value in all types of procedures, rather than in open procedures only.

The key measure aimed at reducing the administrative burden for bidders (which was one of key findings of the research) was the option to prove fulfilment of all eligibility criteria for public procurement procedure (mandatory and additional ones) by means of a statement.

At the end, it could be concluded that this case may serve as a model for all future amendments of the laws in Serbia in the sense that sound researches and analyses should precede regulatory changes. In many cases in past, amendments of the laws were prepared by relatively small groups of experts and clerks while the "voice of the practitioners" was silent. The outcomes were problems in implementation.

This case proved that a comprehensive research of the effects of the Law implementation with focus on weaknesses in practice coming from practitioners provided precious inputs to the process of designing measures for upgrading the regulation. The first results of the amended law implementation proved the approach was proper.

Abstract: *ISO 9001, the world's leading quality management standard, has recently been revised. The new version follows a new, higher level structure to make it easier to use in conjunction with other management system standards. With over 1.1 million certificates issued worldwide, ISO 9001 helps organizations demonstrate to customers that they can offer products and services of consistently good quality. It also acts as a tool to streamline their processes and make them more efficient. Focus of the paper is on the technical specification ISO/TS 9002 that is currently under development to help organizations easier application of ISO 9001. Based on a research performed using simple questionnaire among various organizations in Serbia, study presents the results on the awareness of the revision of ISO 9001:2015, expected benefits of quality management system implementation as well awareness on possible need and benefits of the guidelines given in the ISO/TS 9002.*

Keywords*: ISO/TS 9002, ISO 9001, quality management, revision, guidelines, benefits, improvement*

1. INTRODUCTION

International Organization for Standardization is an independent, non-governmental international organization with a membership of numerous national standards bodies. Through its members, it brings together experts to share knowledge and develop voluntary, consensus-based, market relevant international standards that support innovation and provide solutions to global challenges. International standards give world-class specifications for products, services and systems, to ensure quality, safety and efficiency. They are instrumental in facilitating international trade. Standards are developed by the people that need them, through a consensus process. Experts from all over the world develop the standards that are required by their sector. This means they reflect a wealth of international experience and knowledge as explained by International Organization for Standardization (2016).

Taking into account that the ISO 9001 is the internationally most popular standard for quality management systems based on ISO Survey (2014), it is crucial to pay adequate attention to recent revision of the requirements given in the standard. In addition, it can be useful to give some overview of importance of technical specification ISO/TS 9002 that is currently under development as guidance on effective implementation of ISO 9001:2015 among organizations in Serbia. Led by these drivers, survey presented in the paper is based on the following hypothesis that will be concluded in the final chapter of the paper:

- H0: Organizations in Serbia are aware of the benefits in their quality management system implemented according to the requirements of ISO 9001:2015.
- H1: Organizations in Serbia are aware of the development of the new technical specification ISO/TS 9002 and its possible practical usage.
- H2: Guidance given in the ISO/TS 9002 will be applied in organizations in Serbia to assist in the implementation of management systems based on ISO 9001:2015 requirements.

Latest available survey from the International Organization for Standardization (2014) is showing of the information that was used for the survey analysis, on the number of certificates for quality management systems according to the standard ISO 9001 issued for the organizations in Serbia, in the previous years are shown in the Table 1. Assumption is that overall number of ISO 9001 certificates exceed the numbers shown in this survey. For the purpose of this paper official available data will be used.

Table 1: Total number of ISO 9001 certificates in Serbia ISO Survey (2014)

Country	2010	2011	2012	2013	2014
Serbia	1790	3228	2750	2366	2637

In the same survey from the International Organization for Standardization (2014), considered data were related to the industrial sectors in Serbia and number of certificates in each one of them:

Table 2: Number of ISO 9001 certificates in Serbia by industrial sector ISO Survey (ISO, 2014)

Sector	Number of certificates
Agriculture, fishing and forestry	17
Mining and quarrying	20
Food products, beverage and tobacco	207
Textiles and textile products	28
Leather and leather products	4

Health and social work	43
Other social services	30

2. SHORT HISTORY OF THE ISO 9000 FAMILY OF THE STANDARDS

In the early days of developing first standards to this topics, according to the presentation from the working group 23, from the committee for management systems standardization ISO/TC176 (2012), a new work item proposal for three quality assurance “requirements” standards (ISO 9001, ISO 9002, and ISO 9003) was submitted to International Organization for Standardization in 1979. International Organization for

Standardization established its first committee for management systems standardization - ISO/TC 176. While the Deming Award Prize already existed in Japan, the Malcolm Baldrige Prize was just starting in the USA and soon afterwards the EFQM Business Excellence model in Europe, so it was decided to develop an additional standard giving extended guidance on the topic of quality, referred to as ISO 9004. During the development of these initial standards, it was decided that it would be better to place all the technical terminology in a separate glossary, ISO 8402, rather than repeating it in each standard. With five standards under development, feedback was received indicating that there was a need to explain the relationship between the different standards. Consequently, work was started on ISO 9000 "Selection and Use". ISO 8402 was published in 1986, with ISO 9000, ISO 9001, ISO 9002, ISO 9003 and ISO 9004 being published in 1987. Further feedback indicated that there was a need to provide users with application guidance for implementing ISO 9001, ISO 9002 and ISO 9003. It was then agreed to re-number ISO 9000 as ISO 9000-1, and to develop ISO 9000-2 as the desired application guidelines. While the initial editions of the ISO 9001, ISO 9002 and ISO 9003 standards had a distinctly "manufacturing" feel to them, there was growing recognition of the need to improve software quality. So it was decided to create a standard specifically giving guidance on quality for software, ISO 9000-3. There was also an historic association between the fields of quality, statistics, and maintenance and reliability. This led to the development of ISO 9000-4 on Dependability Management.

By the early 1990s, TC 176 was beginning to realize that it needed to consider the future revision and development of its standards, and so it produced a critical document called "Vision 2000" setting out a proposed path forward. One feature of Vision 2000 was to emphasize the difference between the basic introductory standards in the series, as compared to the requirements standards, and then the guidance standards going beyond the basic requirements standards. More feedback from the market emphasized the need to provide guidance on quality to the Services sector, but noting the recommendations in Vision 2000, it was decided to develop this as a part to ISO 9004, rather than as a part to ISO 9000. Consequently, ISO 9004 was renumbered as ISO 9004-1, and the very successful ISO 9004-2 on services was published.

ISO 9001:1987 and later ISO 9001:1994, contained 20 sub-clauses under clause 4, each addressing a different issue about quality. Feedback from the market suggested that there was a need for more detailed guidance on some of these topics, than was being provided through the generic application guidance in ISO 9000-2.

By the late 1990s, the ISO 9000 "family" of standards had grown to some 21 different standards as well as a number of supporting guidance notes and informative brochures.

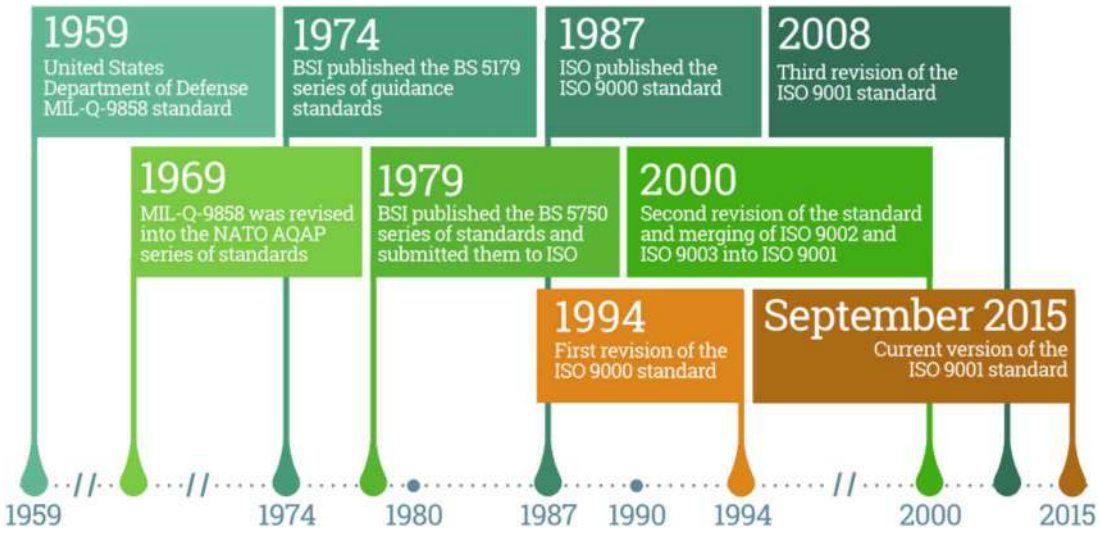

Figure 1: The history of quality management system standards by Advisera (2016)

Today, as presented by the International Organization for Standardization (2016) "*The ISO 9000 family addresses various aspects of quality management and contains some of ISO's best known standards. The standards provide guidance and tools for companies and organizations who want to ensure that their products and services consistently meet customer's requirements, and that quality is consistently improved*."

Standards in the ISO 9000 family include following basic set of the most important requirements or guidelines that can help various organization in not only implementing but also sustainably improving their quality management systems:

- ISO 9001:2015 - Quality management systems - Requirements.
- ISO 9000:2015 - Quality management systems - Fundamentals and vocabulary.
- *ISO/DTS 9002 - Quality management systems - Guidelines for the application of ISO 9001:2015*
- ISO 9004:2009 - Managing for the sustained success of an organization - A quality management approach
- ISO 19011:2011 - Guidelines for auditing management systems

2.1. Considerations on the revised ISO 9001:2015

ISO 9001 is the international standard that specifies requirements for a quality management system. Organizations use the standard to demonstrate the ability to consistently provide products and services that meet customer and regulatory requirements. It is the most popular standard in the ISO 9000 series and the only standard in the series to which organizations can certify. The current version of ISO 9001 was released in September 2015. The new version follows a new, higher level structure to make it easier to use in conjunction with other management system standards, with increased importance given to risk.

As explained by the American Society for Quality (2016), "*organizations of all types and sizes find that using the ISO 9001 standard helps them:*

- *Organize processes*
- *Improve the efficiency of processes*
- *Continually improve*

All organizations that use ISO 9001 are encouraged to transition to ISO 9001:2015 as soon as possible. This includes not only organizations that are certified to ISO 9001:2008, but also any organizations involved in training or certifying others.

Changes introduced in the 2015 revision are intended to ensure that ISO 9001 continues to adapt to the changing environments in which organizations operate. Some of the key updates in ISO 9001:2015 include the introduction of new terminology, restructuring some of the information, an emphasis on risk-based thinking to enhance the application of the process approach, improved applicability for services, and increased leadership requirements.

Organizations and individuals that use ISO 9001 are encouraged to transition to the 2015 revision as soon as possible. However, the International Accreditation Forum (IAF) and the ISO Committee on Conformity Assessment (CASCO) have agreed to a three-year transition period from the publication date of ISO 9001:2015."

Strategic objectives of the performed revision of the standard ISO 9001 were:

- Taking into account of changes in quality management systems practices and technology since its last major revision that took place back in 2010,
- To provide a stable core set of requirements for the next 10 years or more,
- To ensure the reflection of changes in the increasingly complex, demanding and dynamic environments in which organizations operate and
- To ensure the facilitation of effective implementation and effective conformity assessment.

Short overview of the content in the current version of the standard ISO 9001:2015 is given as follows:

Figure 2: ISO 9001:2015 Preview of content by ISO (2016)

In the text prepared by Lazarte (2015), acting ISO Secretary-General Kevin McKinley explains: "*ISO 9001 allows organizations to adapt to a changing world. It enhances an organization's ability to satisfy its customers and provides a coherent foundation for growth and sustained success.*"

The 2015 edition features important changes, which Nigel Croft, Chair of the ISO subcommittee that developed and revised the standard, refers to as an "*evolutionary rather than a revolutionary*" process. "*We are just bringing ISO 9001 firmly into the 21st century. The earlier versions of ISO 9001 were quite prescriptive, with many requirements for documented procedures and records. In the 2000 and 2008 editions, we focused more on managing processes, and less on documentation. We have now gone a step further, and ISO 9001:2015 is even less prescriptive than its predecessor, focusing instead on performance. We have achieved this by combining the process approach with risk-based thinking, and employing the Plan-Do-Check-Act cycle at all levels in the organization. Knowing that today's organizations will have several management standards in place, we have designed the 2015 version to be easily integrated with other management systems. The new version also provides a solid base for sector-quality standards (automotive, aerospace, medical industries, etc.), and takes into account the needs of regulators.*"

As the much anticipated standard comes into being, Kevin McKinley concludes, "*The world has changed, and this revision was needed to reflect this. Technology is driving increased expectations from customers and businesses. Barriers to trade have dropped due to lower tariffs, but also because of strategic instruments like International Standards. We are seeing a trend towards more complex global supply chains that demand integrated action. So organizations need to perform in new ways, and our quality management standards need to keep up with these expectations. I am confident that the 2015 edition of ISO 9001 can help them achieve this.*"

2.2. Purpose of the new ISO/TS 9002

Based on the International Organization for Standardization (2016) announcements technical specification ISO/TS 9002 is under development to assist users in the implementation of a quality management system based on ISO 9001:2015. It will provide guidance on the requirements in ISO 9001:2015, with a clause by clause correlation to clauses from 4 to 10 as shown in Figure 2 for ISO 9001.

Technical specification of ISO/TS 9002 (2016) will give examples of what an organization can do, but it does not add new requirements to ISO 9001:2015. The examples in technical specification are not definitive and only represent possibilities, not all of which are necessarily suitable for every organization.

ISO 9001:2015 contains requirements that can be objectively audited or assessed. ISO/TS 9002 will include examples, descriptions and options that aid both in the implementation of a quality management system and in strengthening its relation to the overall management of an organization.

While the guidelines will be consistent with the ISO 9001:2015 quality management system model, they will not be intended to provide interpretations of the requirements of ISO 9001:2015 or be used for audit or assessment purposes.

ISO/TS 9002 (2016) will be used by different organizations and implementation can vary based on types, sizes, levels of maturity and sectors and geographic locations. Based on these facts main purpose of survey presented in this paper was to present expectations of organizations in Serbia on this matter.

3. RESULTS OF THE RESEARCH AMONG ORGANIZATIONS IN SERBIA

In order to have factual data as a basis for objective conclusions on the hypothesis, comprehensive but simple survey was performed among 101 organizations from public and private sectors in Serbia. Survey had consisted of 11 questions towards locations, size, scope and similar data about companies as well on questions related to existing quality management system, perceived benefits of revised ISO 9001:2015 and awareness of developing of the technical specification ISO/TS 9002 and related guidance on implementing ISO 9001:2015. Results of the survey are given in the following figures and tables.

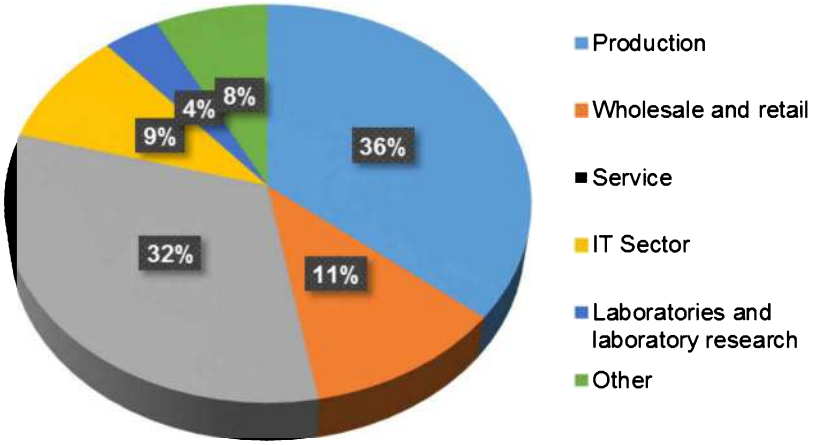

Figure 3: Industry sector of an organization

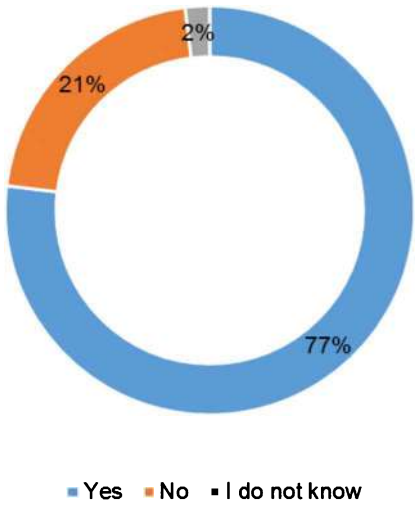

Figure 4: Did your organization implement Quality Management System - ISO 9001?

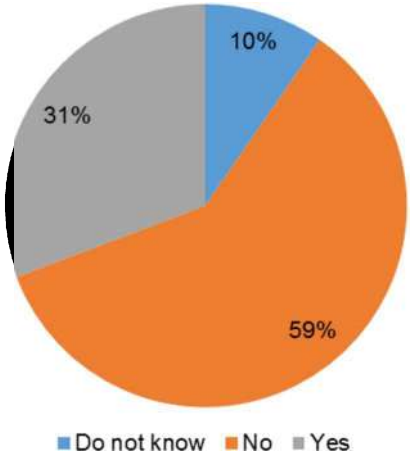

Figure 5: If your organization has been implemented a quality management system before, is it performed transition to the ISO 9001:2015?

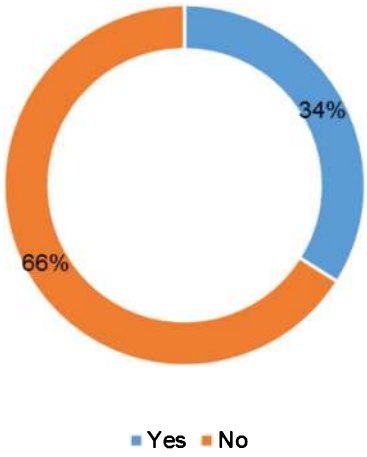

Figure 6: Do you know what technical specification ISO/TS 9002 is?

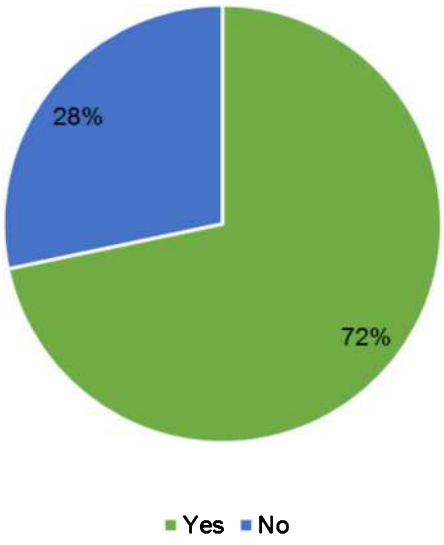

Figure 7: Do you believe that you need additional guidance on the interpretation and application of ISO 9001: 2015?

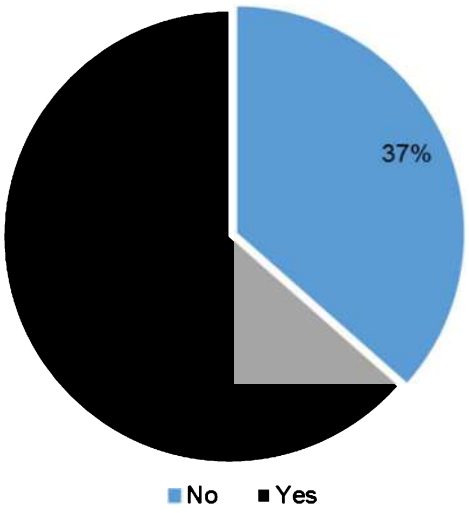

Figure 8: Do you think there is a need to adopt ISO/TS 9002 or ISO 9001:2015 is sufficient to implement the requirements for quality management system?

Conclusions of this survey are that organizations in Serbia are not familiar with existence of ISO/TS 9002 and their possibilities for better implementation of ISO 9001:2015 requirements and improving of business processes. Also, there is big demand for more assistance and information regarding interpretation of ISO 9001:2015 requirements.

The most useful information to give some additional conclusions is given in the Table 3 which consist of the answers given by the representatives from the organizations. They have been given different explanations on possible benefits from implementing revised version of the standard ISO 9001:2015 requirements:

Table 3: What are the benefits from implementing ISO 9001:2015?

Benefits (in %)	Companies ≤ 100 employees	Companies > 100 employees
Less paperwork	72	85
Winning tenders	61	78
Better risk and control management	53	60
The improvement of supply chain	39	67
Better clients' satisfaction	29	53
Easier implementing of EMS & OHS	21	47
Other	18	27

4. CONCLUSION

Considering results of the presented survey and the experts' opinion on the importance and methods of implementing concepts and principles of quality management in the various organizations, following conclusions can be related to the initial hypothesis:

- H0: Organizations in Serbia are aware of the benefits in their quality management system implemented according to the requirements of ISO 9001:2015. - C0: Most of the organizations are aware of the benefits they are pursue by effective quality management system although, on the other side, most of them still perceive the greatest benefit in two areas of easier participation on the tenders and less administrative bureaucracy related to control of paper documentation. There is still room for trying to express more benefits related to some other, more quantitative performance indicators like examples from the study on "Economic benefits of standards" explained by Gerundino, Weissinger, Grosfort and Damond (2014).
- H1: Organizations in Serbia are aware of the development of the new technical specification ISO/TS 9002 and its possible practical usage. - C1: Most of the organizations are not aware of the current development of the neither technical specification nor what it is the planned purpose of it.
- H2: Guidance given in the ISO/TS 9002 will be applied in organizations in Serbia to assist in the implementation of management systems based on ISO 9001:2015 requirements. - C2: Unless experts from the quality management system, representatives of institutes and universities as well top managers of the organizations themselves do not use maximum effort in spreading information on the importance and usefulness of the future technical specification ISO/TS 9002, there is a short chance that organizations

themselves nor different kind of consultants in this area will use ISO/TS 9002 on a big scale as a support to implementation of the ISO 9001:2015 requirements in Serbia.

Inputs for the future researching on the topics presented in the paper can indicate some of the following thesis in order to prepare beneficial results and practical guidance to the interested professionals and organizations that have implemented quality management system based on the ISO 9001 and possible guidance given in the future ISO/TS 9002:

- There is a great need of using additional methods of getting closer to current developments in the field of quality management relevant to the representatives of the organizations in Serbia based on the presented survey results from April 2016 in this paper.
- Internal and external trainings and workshops for the quality management representatives are essential for creating knowledge database that can be systematically explored in the various organizations as discussed by Schachner (2015) and emphasized by Smida (2015). It will be significant to research what level of improvement in organization can be generated through development of knowledge management system.
- If organizations on the worldwide scale and also it applies to Serbia as well, are aware of the risk based approach and using some of the simple risk assessment techniques to perceive strengths and weaknesses of their quality management system and processes they can be able to use more effective strategy and decision making models in order to maximize benefits of their management systems as also indicated by Bauer (2015) and Garscha (2015).

As changes in internal and external context of the organization are immanence to all kind of organizations it can be useful to organizations in Serbia to use more tools or guidelines, like given in the ISO/TS 9002, in order to be prepared to adequately react on time in the ever-changing conditions for existence of the successful business. Otherwise they can suffer from the shortage of information present and available but not used by the organizations as a lack of systematic approach to concepts like change management and analysis of internal and external issues using strength/weaknesses and threats/opportunities analysis or consideration of the political, economic, social and technological factors used to assess the market for a business or organizational unit as concluded by Pelzmann and Koubek (2015) as well as Pölz (2015).

PARADIGM EVOLUTION: FROM LINEARITY TO COMPLEXITY IN THE WORLD OF QUALITY MANAGEMENT

Miloš Borisavljević[1], Miloš Nedeljković*[1], Mladen Đurić[1]
[1]University of Belgrade, Faculty of Organizational Sciences
*Corresponding author, e-mail: milos1994nedeljkovic@gmail.com

Abstract: *The latest management concepts, which are based on nonlinear dynamical models, differ significantly from the traditional concepts intertwined by linearity, which are created for the world that seized to exist a long time ago. Such concepts, that include adaptability, nonlinearity and holistic approach, can provide a broader picture of the organization and the space in which it exists, which is a prerequisite for the creation of more adequate quality management mechanisms and solutions. This paper presents specific concepts and phenomena that were previously observed in some natural sciences and whose applicability can be found in different processes of organizational systems. The discussion on complex adaptive systems should lead to a better understanding of the organizational processes. The reason for the inclusion of the complex adaptive systems and the complexity theory in the management and quality management approaches lies primarily in a desire to create a more resilient and more flexible organizational system that learns and evolves, which is also a requirement of the lastest version of ISO 9001 standard. As is written in the new ISO 9000:2015 that „an organization's QMS model recognizes that not all systems, processes and activities can be predetermined; therefore it needs to be flexible and adaptable within the complexities of the organizational context", we recognize complex adaptive systems theory as an appropriate framework for making these concpets live in operational practices of organizations' quality maanagement systems.*

Keywords*: organization, quality management, complexity, complex adaptive systems, ISO 9000*

1. INTRODUCTION

The beginning of the XX century was marked by the development of management as a scientific discipline. Frederic Taylor, the creator of the scientific management theory, based his work on the need to increase productivity, i.e. industrial efficiency. Productivity was the most important factor of success in this era, so the entire focus was on manufacturing. The basic assumption was that only increasing the efficiency of the process would increase productivity as well. Further research of Taylor and his contemporaries came to the conclusion that the processes must be carefully designed and that the most suitable man should be selected for them. Even a linear approach like this one gave good results at that time and represented a major progress. However, nowadays it is simply impossible to manage the organization as a linear system.

Numerous management concepts that were created later have increasingly estranged from understanding the organization as a linear system. The latest concepts observe the organization as a highly nonlinear dynamic system that exists in a nonlinear, even chaotic, dynamic environment.

Variable, turbulent, often unpredictable business environment requires a greater level of adaptability from the organization. A long-time trend that shows great instability of the global world market, which is very susceptible primarily to economic and political influence, imposes organizational leaders to apply different management approaches to make their organizations more flexible. The challenges that organizations are dealing with have become more complex and traditional management approaches and the way that they are designed have not given the necessary flexibility. In an era characterized by nonlinearity and complexity, leaders primarily need to change the way they conceptualize solutions for the problems they face in managing organizations.

Today, people care about different things, they are better informed, more educated, but also better connected than in the past. Their expectations from the company, whether they take the role of customer/consumer, suppliers, investors or members of the community, are changing rapidly. Unfortunately, most companies have not evolved enough to keep up with all these changes and continue to operate by using the way of thinking and practice that was suitable for a very different world. (Mackey & Sisodia, 2013)

The system approach to management represents the basis and the starting point for analyzing the environment, changes and creating a solution for management systems. Taking into account the concepts of the systems theory, we can come to a better understanding of the problems and the mechanisms by which they can be solved.

The complexity theory as part of the systems theory provides a number of aspects through whose prism the organizational systems can be studied. The subject of studying in complexity theory is a nonlinear dynamic system, and since the organizations are nonlinear dynamic systems they fulfill this assumption. Through the prism of the complexity theory and the theory of complex adaptive systems, which are based on a systematic approach, observation and study of the management system of the organization can bring a completely new management approaches and concepts.

The basic concepts taken from the theory of complex adaptive systems and the complexity theory, which are increasingly present in the world of management, will be presented by the literature review.

2. FUNDAMENTALS OF THE COMPLEX ADAPTIVE SYSTEMS THEORY

Complex adaptive systems (CAS) are systems composed of a large number of interdependent components and agents with mutual interactions (Sammut-Bonnici, 2014; Doyle, Watz, & Portrey, 2015). Sammut-Bonnici (2014) notes that all components of CAS work as a whole and have the ability to learn through experience so they can adapt to changes that occur in the environment. Doyle, et al. (2014) observe agents as autonomous system components that are able to observe, analyze, decide and act taking into account information obtained from the environment and set goals.

Similar to the authors Domingues et al. (2015), Palmberg (2009) Bonabeuau & Meyer (2001), Rouse (2008) he defines some of the main characteristics of CAS:

- They represent the non-linear dynamic systems whose behavior and actions can become chaotic or random, depending on the nature of the system.
- They are composed of independent agents (or partially dependent) whose behavior is based on the physical, psychological or social rules.
- Because the needs and desires of agents (which are stated in their rules) are not homogeneous, their goals and behavior are often in conflict. In response to these conflicts and competitiveness, agents tend to adapt the behavior of each other.
- The agents' intelligence is limited. When they experiment and gain experience, they learn and change their behavior accordingly.
- Adaptation and learning tend to be only the outcome of the organization. The patterns of behavior arise before than being designed into the system.
- There is no central point of control. The behavior of the system is usually unpredictable and uncontrollable and no one is "the boss".

The model of the complex adaptive systems, except the inputs and outputs in the form of information, substance and energy, contains a system of simple rules, which defines the rules by which the system agents respond to the impacts detected by the system, whether they come from the system or from the environment. It is important to note that feedback allows adaptive learning which has a direct effect on the evolutionary mechanism of the system. Neikam (2015) mentions the importance of designing an organizational system model according to CAS because of the benefits in the form of co-evolution, which means that the system reacts in the same way to the environment aiming to create a suitable climate.

Sammut-Bonnici (2014) suggests that it would be extremely risky to transform organizational models into those which only involve self-organization, primarily because there is a possibility of the occurrence of chaos and the inability to predict any results of the system because he is not guided, i.e. it is not directed towards a determined direction, but should transform only those processes and parts of the system, according to the CAS, which in practice appear sustainable and efficient. CAS theory contributes more holistic view of the organizational system (Dooley, 1997).

2.1. Swarm intelligence

A large number of the world's leading organization accepts new concepts of management resulting from the theory of complex adaptive systems in order to maintain a competitive advantage through innovation. One of the new concepts that is based on complexity is swarm intelligence. Many companies like "Unilever", "Southwest Airlains" and others have adopted this approach to solve some of their problems. Primarily, the

approach is based on optimization of different business operations and provides greater flexibility, robustness and self-organization (Bonabeau & Meyer, 2001).

The swarm intelligence is a specific pattern of behavior of certain chaotic systems composed of a large number of individual agents that are manifested through their association to solve the problem by putting efforts toward a common goal.

The term is taken from the natural sciences, and it is best illustrated through the natural phenomena on which they were named, whether they are swarms of bees, a school of fish or a colony of ants. There are so many scientific programs about animals which are studying only the form of their behavior in a group. A flock of killer whales who use well-coordinated tactics and clear communication to surround the seal, a herd of wolves who are trying to isolate the buffalo calves from the herd by using an excellent coordination and strategy or a colony of ants that join forces to defend their habitat from attack or self-organize the shipment of food into their colony, are some examples of united intelligence of individual agents who represent on a higher level an intelligence of the group.

3. ORGANIZATIONAL AND QUALITY MANAGEMENT SYSTEM FROM THE ASPECT OF THE COMPLEX ADAPTIVE SYSTEMS THEORY

Mechanisms of early management concepts show a high degree of linearity, but as management theory and practice evolved more and more of these concepts carried nonlinearity in them. The concepts of today such as knowledge management, but also the management of complexity, base their mechanisms on forms that are adaptive and variable in space and time.

During XX century, the development of production technology has fundamentally influenced not only the society but also the logic of business and organization. Similarly, the dominance of the development of information technology at the turn of the XXI century affects not only the way of communication between people but also the organization. These trends require organizations that can combine efficiency with flexibility and innovation. (Palmberg, 2009)

Traditional quality management systems are based on hierarchy and centralization which means that information flows are directed from top to bottom and they are precisely defined. Contrary to them, quality management based on the complexity theory enables consideration of an organization as a decentralized system where information flows in all directions and where the level of bureaucracy is on a very low level. (Olmedo, Sancho, Meteos, & Valderas, 2002). Rouse (2008) provides a comparison table (Table 1) of differently oriented organizational models, i.e. traditional and complex adaptive organizational systems.

Table 1: A comparison of the characteristics of organizational systems (Rouse, 2008)

Criterion	Traditional	Complex adaptive
The role of top management	Management	Leadership
Methods	Command and control	Initiative and inhibition
Measurements	Activities	Results
Focus	Efficiency	Agility
Relations	Contractual and specified	According to personal discretion
Network	Hierarchical	Heterachical
Design	Organizational design	Self-organization

Setting the organization in the context which implies that it is a part of an environment that actually represents the system at a higher level of decomposition and taking into account factors that may affect the system, which is one of the most important changes in new ISO 9001:2015, can contribute to more efficient management and increase resilience of an organizational system. It should be noted that the model that defines the context must be adequate to the situation. Olmedo et al. (2002) note that linear models of dynamic systems can facilitate understanding of the basis and functioning of the system but such models contain a very simplified picture of the real situation with a known and determined environment, which in reality is not the case. Also, behaviour patterns that occur are well-known so that such a model does not imply evolution, learning and adaptability.

Although the organizations as open systems are exposed to the influence of environment, also the environment is exposed to its impacts, to a greater or lesser extent. Dulanovic and Jasko (2008) note that organizations need to adapt to the environment but also depending on how much power they have, they can

adapt the environment to their needs. The progressive growth in the number of organizations has led to the increased complexity of global environment in which they exist.

It is generally accepted (Wheatley, 1993; Domingues, Sampalo, Arezes, 2015; and others) that organizations and theit management systems are dynamic systems with a large number of nonlinear interactions both within its system and also with the dynamic but turbulent environment.

As for any other management system, we can say for a quality management system that „under certain circumstances, regularly behave in a predictable way. Under other conditions they exhibit a behavior in which the regularity and predictability are disappearing. Almost invisible differences in the initial conditions lead to the gradual divergence of systemic reactions compared to the normal state until the behavior of the system becomes very different (Rosenhead, 1998)."

Certain characteristics recognized by many authors (Domingues, Sampalo, Arezes, 2015; Palmberg, 2009; Bonabeuau & Meyer, 2001; and others) define the organization as a complex adaptive system, and some of them are especially important from the angle of the quality management system:

- A large number of different agents, with their interactions, make the system "alive" such as employees and other stakeholders and interested parties, as well as equipment, structure, organization, etc.
- The learning, which is increasingly represented as a management concept, also appears in the ISO standards for quality management systems (ISO, 2015b), involves the generation of knowledge upon which the organizational systems form patterns of their behavior. It is certainly a very important characteristic that gives the adaptability to the system.
- The co-evolution – as already mentioned, the organization is an open system that is subject to influences, but also the environment is a subject to influences that are coming from the organization, so this feature provides a space-time dimension to the changes that occur and represent an evolutionary trait of all participating systems.
- The complexity – numerous nonlinear interactions between agents of the system from which arises indeterminate behavior patterns.
- Emergence – because of its complexity and the imposed requirements, an organization creates certain patterns and mechanisms: the ISO 9000 family should be percieved as a set of solutions aggregated from the good practice, given the management practices and technologies utilized throughout the world.
- Self-organization as a mechanism that initiates the formation of specific patterns of behavior and it contains a system of simple rules by which it functions.
- Organizational systems are assembled from parts, sectors and departments that can be changed, abolished and/or added which is usually achieved by reengineering of business processes, so the principle of modularity is contained in the assumption that organizations possess this characteristic. Modularity is very important when it comes to adaptability because it gives more flexibility.

4. LEARNING AND AUTOPOIESIS THEORY AS A POTENTIAL BASES FOR SUCCESSFUL IMPLEMENTATION OF ISO 9001:2015 IN COMPLEX ENVIRONMENTS

In terms of the new ISO 9000 series, we are guided to understand that „organizations share many characteristics with humans as a living and learning social organism. Both are adaptive and comprise interacting systems, processes and activities." (ISO, 2015a). Also, the same document states that organizational QMS „needs to be flexible and adaptable within the complexities of the organizational context", with the following requirements which imply that appropriate learning and knowledge management processes are vital in achieving this. We here present the autopoiesis theory as one potential way of understanding how this set of requirements may be fulfilled in a complex enviroment.

"The concept of 'autopoiesis' essentially is the system, which is organized as a network of production processes components which continue to produce components that are using their mutual interactions and transformations that continually regenerate and realize the network of processes that produces them. Components in some way constitute the system as a unit in the area, in which they (the components) exist by specifying their implementation in such a network topology." (Varela, 1979)

In "autopoiesis" theory, the organization can be seen as a transfer or flow of knowledge whose characteristics change - new ones are created and old ones are abandoned. Knowledge is flexible, available to members of the organization and linked to the organizational history. (Von Krogh & Roos, 1995). Maturana and Varela (1987) note that this theory largely depends on the "observer". The observer is always a man as an agent of organizational system and all cognitive processes and learning processes rely on its objectivity or subjectivity.

Individual knowledge through social communication creates the phenomenon of organization and organizational knowledge (Maula, 2006). The organization is formed through the interaction of people and their merger. One of the phenomena of „autopoiesis“ theory is structural coupling. This is actually the assumption of co-evolution, but essentially means two individual entities or entity and its environment where their mutual interactions over many repetitions create compatibility of these two systems or entities and create a unique trajectory (Maturana & Varela, 1987).

Furthermore, knowledge is, as already stated, closely related to the observation (perception) and systems that can perceive are autopoietic systems. Individuals create knowledge in an autonomous way. It is based on previous knowledge and created in co-evolution with the environment. Their knowledge depends on the interaction within the organization, while the organization operates as a specific space for “structured association” that allows individual agents to reproduce cognitive processes (Von Krogh & Roos, 1995).

From the above we can observe that organizational learning is not just an ISO 9001:2015 requirement, but also a specific mechanism through which learning and knowledge management occurre and are adapted over time, while organizational systems form patterns of behavior by just using the gained knowledge.

5. CONCLUSION

Organizations are chaotic systems, as they possess certain opposing forces that are used to move the organization from a state of balance and push it into the chaos. Some forces are pushing the system to stability and order and they usually involve activities such as planning, structuring, inspection and control – all of this being very important subprocesess of the quality management, while other forces are pushing the system in the opposite direction, i.e. to instability and they include activities such as innovation, initiatives, experiments, etc. (Thietart & Forgues, 1995).

In the context of organizations and their quality management systems complexity provides a useful framework that explains how organizations behave, and how individuals and organizations interact, how to connect and survive within a larger system, i.e. environment. Furthermore, the complexity also explains why a particular influence on the processes gives unpredictable consequences and unexpected results. There is a number of intertwined links among elements within a complex system that lead to the creation of greater interdependence, which means that the changes affect the elements at all levels of the system. The changes usually occur between the elements at lower levels in parallel and then move on to the whole system (Maldonado & Gómez-Cruz, 2012).

It is important to ask the question whether it is a linear control mode suitable for the current situation and the dynamic of the environment in which organizational systems exist. Quality management system may remain without a necessary flexibility, despite the fact that it is implemented by all the details related and arising from ISO standards, national legislation, working procedures etc. These procedures are usually very complicated, sensitive to change, it takes some time to create them, but are also quite inefficient and can cause unforeseen side effects and costs. If system would work as previously discussed, minutely management would require great amount of energy and resources. Complex natural systems use self-organization that contains certain principles and thus the system operates in the desired direction (Helbing, 2009).

All of this indicates that informal systems can be more efficient and more capable of solving some problems then formal systems. The nonlinearity is very strong and emerging patterns and mechanisms lead to different dynamic of the system. In the informal system the existence of a system of simple rules or principles is very important, in order to maintain the system’s organization. Otherwise, there would be chaos and the system would be very likely to collapse.

From the perspectives of the theories elaborated in this paper, it may be concluded that quality management system acquires additonal dimensions enabling it to solve main organizational issues more efficient and effective than ever beofre.

The goal of future researches should be to find the generic concepts that can help organizations to achieve a certain degree of agility, flexibility and efficient mechanism for the collection of knowledge on the level of organization, all of these being requirements of the new ISO 9000 series.

Abstract: *The Institute for Standardization of Serbia (ISS), as the main national body for standardization (defined by the national Standardization Act), adopts, publishes, reviews, and withdraws Serbian standards. Promptly after the ISO 9000:2015 was published, the Institute offered its identical Serbian version entitled SPRS ISO 9000:2015 Quality Management Systems – Fundamentals and Vocabulary (SRPS ISO 9000: 2015 Sistemi menadžmenta kvalitetom – Osnove i rečnik). This paper presents some observations on terminological solutions offered both by the abovementioned standard, and the ISO 9000 Standard Series as a whole. The paper identifies challenging terminological units, analyzes them and offers possible solutions, thus indicating the need for more adequate terminology management.*

Keywords*: terminology, quality management system, ISO 9000:2015, translation, standardization*

1. INTRODUCTION

The Institute for Standardization of Serbia (ISS) as an independent, non-profit entity is the legal successor of the Federal Commission for Standardization (1946-1962), the Yugoslav Institute for Standardization (1962-1978), the Federal Institute for Standardization (1978-2003), and the Institute for Standardization (2003-2006). According to the Standardization Act ("Official Gazette of the Republic of Serbia", No. 36/2009 and 46/2015) and the Decision on Amending of the Founding Act of the Institute for Standardization of Serbia ("Official Gazette of the Republic of Serbia", No. 88/2009), this Institute is the only official national standardization body in the Republic of Serbia, and a legal entity that operates in accordance with the regulations governing the legal status of the public services.

Operating as the national organization for standardization, the Institute represents and protects interests of the Republic of Serbia in the following international and European organizations for standardization (http://www.iss.rs/):

- International Organization for Standardization (ISO); a full member since 1950,
- International Electrotechnical Commission (IEC); a full member since 1953,
- Worldwide System for Conformity Testing and Certification of Electro technical Equipment and Components (IECEE); a full member since 1965,
- European Committee for Standardization (CEN); an affiliate member since 2008,
- European Committee for Electro technical Standardization (CENELEC); an affiliate member since 2005,
- European Telecommunications Standards Institute (ETSI); a member since 2011.

International Organization for Standardization (ISO) as an independent, non-governmental international organization including 161 national standards bodies *brings together experts to share knowledge and develop voluntary, consensus-based, market relevant International Standards that support innovation and provide solutions to global challenges (*http://www.iso.org/iso/home.html). The ISO Technical Committees (TCs) are in charge of preparation of international standards, while rules for the structure and drafting of International Standards are contained in ISO/IEC Directives Part 2. At least 75% of ISO members have to support an International Standard draft for it to be published.

In this paper we are specifically interested in the ISO 9000 Standard Series that can be applied to organizations of any size. This series includes some of the ISO's best known standards that address various aspects of quality management and quality assurance providing guidance and tools for companies and organizations in order to improve quality consistently and ensure that their products and services consistently meet customers' requirements.

The ISO 9000 family comprises the following standards:
- ISO 9001:2015 - sets out the requirements of a quality management system;
- ISO 9000:2015 - covers the basic concepts and language;
- ISO 9004:2009 - focuses on how to make a quality management system more efficient and effective;
- ISO 19011:2011 - sets out guidance on internal and external audits of quality management systems.

Standard ISO 9000:2015 was originally published in 1987, but has later undergone several revisions: a major one in 2000, another one in 2008, and the final one published in September 2015, immediately followed by its Serbian version. Standard SRPS ISO 9000:2015 *Quality Management Systems – Fundamentals and Vocabulary* (*Sistemi kvaliteta menadžmentom – Osnove i rečnik*) is a product of the CASCO Technical Committee of the ISS. The ISS also embodies a technical committee named Terminology (A037), but it mainly dedicates its activities to ISO TC 37 standards.

The purpose of this paper is to draw attention to a number of terminological issues observed in this standards series, and to particularly focus on the quality, adequacy and consistency of term use in the Serbian version of ISO 9000:2015 indicating the third chapter of this standard *Terms and Definitions* as the limelight.

2. TERM FORMATION AND EXAMPLES OF TERMINOLOGICAL INCONSISTENCY IN THE FIELD OF MANAGEMENT

Management is a specialized subject field undergoing rapid development, thus in constant flow of newly emerging terminological units, very often representing the same concept by more than one term and consequently, often causing terminological confusion. New terms in Serbian are generated from (1) adopting terms from other languages, (2) accepting internationalisms or (3) transferring words from the language for general purposes (LGP) into terms (the process known as *terminologization*). It is not infrequent that a single concept and a single foreign term in Serbian have several alternatives, originating from different linguistic processes. Despite the obvious need for an organized and unambiguous system of terms for adequate professional communication in this subject field, the reality is undoubtedly chaotic. It seems necessary to establish methods for selection of the most appropriate term alternatives, and carry out systematic process of terminology standardization in professional communication. Jakić (2014) claims that the following terminological principles are applied in the process of management terminology standardization (pp. 94-103):
- Precedence of Serbian terms over loan terms,
- Precedence of Latin and Greek terms over English, French, German, etc.,
- Adaptation of terms on all linguistic levels (phonological, morphological, syntactic),
- Precedence of shorter loan terms over longer Serbian terms.

2.1. Precedence of Serbian terms over loan terms

Loan words have an obvious dominance in the Serbian language management terminology. Having that the development of every language domain is important for the general language development we suggest the use of Serbian words whenever and wherever possible. There is no reason for avoiding a Serbian term even when it is used in parallel with an internationalism (generally Latin or Greek word): e.g. *obim* instead of *volumen*, *nespojivost* instead of *nekompatibilnost*. Even in such cases, only the basic term is to be taken, but further derivations should follow the linguistic rules of Serbian. It is necessary to work on Serbian term formation systematically and continuously in order to create useable, useful, practical and linguistically correct terminology. Table 1 provides some Serbian management terms as examples of precedence over loan terms.

Table 1: Serbian management terms and their loan equivalents

Loan term or term with a loan element	Term in Serbian
Bridžing	*Premošćavanje*
Incidenca	*Pojava*
Prevencija	*Sprečavanje*
Kompetencija	*Konkurencija*
Border line	*Poremećaj, granični poremećaj*
Flow chart	*Dijagram toka*

2.2. Precedence of Latin and Greek terms over English, French, German, etc.

Jakić (2014) indicates that unlike other loan words, Latin and Greek easily find their place in the Serbian language system (p. 96). The experience of borrowing lexical items from these two languages is centuries-long and Serbian (as many other languages all over the world) has developed certain mechanisms for adoption and adaptation of Latin and Greek lexical materials. These internationalisms have secured themselves a special position within other language systems (including Serbian), so it is not always necessary to insist on finding a proper translation of a Latin or Greek term (or a term including their elements).

Table 2: Examples of diachronic development of words with Latin or Greek root

Term	Serbian	Latin or Greek root
Company	*Kompanija*	Latin words *fed up* and *panis*, *bread* combined give the root of a word *company*. At a later stage it started being used in a business context.
Cash	*Gotovina*	Derived from a Latin word for "box" *cassa*. At the beginning it was used by French and denoted "moneybox".
Consumer	*Potrošač*	Latin expression *consume* means "*eat it all*". This has led to the use of the term *consumer*.
Economist	*Economist*	Comes from a Greek word *oikonomia*, which means *house management*.

2.3. Adaptation of terms on all linguistic levels (phonological, morpho-syntactic)

Adaption of terms on the phonological level is obvious in translations. Phonological form of a translation should be defined by the pronunciation in a source language, its orthography and influence of the language mediator.

2.3.1. Phonological level

Several levels of phonological adaption (transmorphemyzation) of translated management terms could be noted (Jakić, 2014):

Table 3: Adaptation of terms on phonological level

Complete transformation	Phonemes of a source language are replaced with compatible phonemes of a target language with completely the same phonological description: - *AQAP (a ku a pe)* (Allied Quality Assurance Publications) - AQAP (ej kju ei pi); - *PDCA (pe de ce a)* (Plan-Do-Check-Act) - PDCA (pi di si ei);
Partial transformation	Phonemes of a source language are replaced with semi-compatible phonemes of a target language: - brainstorming - *brejnstorming*; - benchmarking - *benčmarking*; - reengineering – *reinženjering;*
Free transformation	Phonemes of a source language find neither complete nor partial compatibility in phonemes in a target language; as a result, they are replaced in a free form. - E- business - *E- biznis* - Brand management - *Brand menadžment*

2.3.2. Morpho-syntactic level

The level of morpho-syntactic adaption of translated terms is measured by the difference - similarity criterion in parts of speech that the term elements in both source and target language belong to.

Table 4: Adaptation of terms on morpho-syntactic morphological level

Brain + storming	*Moždana + oluja*
Bench + marking	*Tezga za rad + reperi*
Re + engineering	*Ponovo + inženjering*
Reverse engineering	*Unatrag + inženjering* ili *inženjering unatrag*

Lexical and semantic adaptation of borrowed and translated terms is related to lexical synonymy, translation pairs and definition or all those translations that show interlingual semantic changes between source and target equivalents. Here are some examples of management terms and their translation equivalent forms:

Table 5: Translation equivalents

ROA (return of assets)	*PS (povraćaj sredstava)*
VAE (value added per employee)	*DVPZ (dodata vrednost po zaposlenom)*
MS (market share)	*UNT (udeo na tržištu)*

2.3.3. Precedence of shorter loan terms over longer Serbian terms

Although we think that Serbian words and expressions should get the status of a term whenever and wherever possible, for the purpose of language economy many shorter loan terms should be accepted.

Examples:
- The term *mobing* (mobbing) is used instead of a longer expression in Serbian *zlostavljanje na radnom mestu*;
- The term *percipirani kvalitet* (perceived quality) instead of a *korisnikovo poimanje kvaliteta*.

Filipović and Đurić (2009) tried to find a terminological solution to the translation of the expression *5W2H* (*what, why, where, when, who, how, how much*) and they proposed seven standard questions asked in the quality planning. The reasons for the possible precedence of the first (English) terminological alternative over the suggested Serbian one may be the length and language economy. Almost all scientists, both linguists and subject field experts, Bugarski, (2007), Cabré (1999), Filipović and Filipović (1997, 1998), Milić (2013), Silaški (2009, 2012), Wright and Budin (1007) and Šipka (1998), are unanimous when it comes to some basic characteristics of scientific and professional terms. With certain differences, they all agree that a term should be (1) monosemous (have only one meaning), (2) non-synonymous, and (3) as short as possible.

3. ISO 9000:2015: SPECIFIC TERMINOLOGICAL ISSUES

We observed the following three terminological issues in the ISO 9000:2015 standard, namely:
- Terminological inconsistency;
- Terminological ambiguity;
- Terminological acronyms.

3.1. Terminological inconsistency: Use of *management + noun in the instrumental case vs. management + noun in genitive case*

By analyzing Serbian terms as used in this standard, we noticed the frequent use of the instrumental case in terminological expressions after the noun management. Table 7 presents examples of the terminological construction *management + noun in the instrumental case* as identified in SPRS ISO 9000:2015, together with their English equivalents. The numbers preceding the terms are their referent numbers from the standard.

Table 6: Terminological construction *management + noun in instrumental case*

Term in Serbian (SRPS ISO 9000:2015)	Term in English (ISO 9000:2015)
3.3.4 Menadžment kvalitetom	3.3.4 Quality management
3.5.4 Sistem menadžmenta kvalitetom	3.5.4 Quality management system
3.1.2 Konsultant za sistem menadžmenta kvalitetom	3.1.2 Quality management system consultant
3.4.3 Realizacija sistema menadžmenta kvalitetom	3.4.3 Quality management system realization
3.3.9 Menadžment konfiguracijom	3.3.9 Configuration management
3.3.12 Menadžment projektom	3.3.12 Project management
3.5.7 Sistem menadžmenta merenjem	3.5.7 Measurement management system
3.8.11 Plan menadžmenta projektom	3.8.11 Project management plan

The examples above point out that ISS apparently opts for the use of instrumental case following the term *management*. Namely, Technical Committees of the ISS are *Sistemi menadžmenta zaštitom životne sredine (Environmental management), Ocenjivanje usaglašenosti i menadžmenta kvalitetom (Conformity assessment and quality management), Sistemi menadžmenta bezbednošću hrane (Food safety management systems)* and all of these contain the same construction: *management + noun in instrumental case.*

Unlike the translation of the original ISO standard terms done by the members of the working committee within the Institute for Standardization of Serbia, management experts that belong to Serbian academic community unmistakably insist on the use of genitive case (*management + noun in genitive case*). This is obvious in the names of courses and study departments at universities. For example, the Faculty of Organizational Sciences in Belgrade, as the institution of the supreme authority in management studies has a department named *Menadžment kvaliteta i standardizacija* (Quality management and standardization) and among numerous courses offered by the Faculty, we can find *Menadžment ljudskih resursa* (Human Resource Management), *Menadžment tehnologije i razvoja* (Technology and Development Management), *Menadžment inovacija* (Innovation management), *Sistem menadžmenta kvaliteta* (Management quality system) (Jaško and Petrović, 2009). Following the given examples noticed in the Serbian academia, we can conclude that the forms of the previously listed terms from the standard should be like those given in the Table 7.

Table 7: Terminological construction *management + noun in genitive case*

Term in Serbian (SRPS ISO 9000:2015)	Term in English (ISO 9000:2015)
3.3.4 Menadžment kvaliteta	3.3.4 Quality management
3.5.4 Sistem menadžmenta kvaliteta	3.5.4 Quality management system
3.1.2 Konsultant za sistem menadžmenta kvaliteta	3.1.2 Quality management system consultant
3.4.3 Realizacija sistema menadžmenta kvaliteta	3.4.3 Quality management system realization
3.3.9 Menadžment konfiguracije	3.3.9 Configuration management
3.3.12 Menadžment projekta	3.3.12 Project management
3.8.11 Plan menadžmenta projekta	3.8.11 Project management plan
3.5.7 Sistem menadžmenta merenja	3.5.7 Measurement management system

There is an obvious lack of communication and cooperation between the Institute for Standardization of Serbia and the academic community, resulting in a discrepancy between the term variants adopted by the national standards and the national educational system. The first ones are primarily used by current management experts working in different fields. The second ones, however, are preferred by the educational system which prepares future experts and provides them with terminological knowledge. It is clear that both sides share responsibility for the state of terminology of the subject field.

3.2. Terminological Ambiguity

Jakić (2014) draws attention to the frequently occurring incorrect translation of the English terms (p.102):

- Control vs. Inspection;
- Interested parties vs. Stakeholders

3.2.1. Control vs. Inspection

The term *control* is repeatedly translated into Serbian as *kontrola* or *kontrolisanje* while the meaning of the concept that it denotes in Serbian is *upravljanje*. Even in scholarly articles on management, *quality control* is often transferred into Serbian as *kontrola kvaliteta*, but its correct translation is *upravljanje kvalitetom*. SPRS ISO 9000:2015 clearly confirms this fact, so it offers the following terms: *3.3.7 upravljanje kvalitetom* (*quality control*) and *3.3.10 upravljanje izmenama* (change control). The mentioned errors are the consequence of the negative transfer from English. Both, *kontrola* and *kontrolisanje* are two expressions for the same concept and its English equivalent is *inspection*. It is interesting that SRPS ISO 9000:2015 chooses only *3.11.7 kontrolisanje*, even though *kontrola* is used more often in the professional communication. Since these terms are synonyms and the one out of the standard is more frequently used, perhaps its introduction into the standard should be considered.

3.2.2. Interested party and stakeholder

The terms are seen as synonyms and defined as *"a person or organization that can affect, be affected by, or perceives to be affected by a decision or activity*" (ISO 9000:2015). SRPS ISO 9000:2015 also equates terms *zainteresovana strana* (*interested party*) and *interesna strana* (*stakeholder*). Jakić (2014) underlines that their synonymous relationship should be reconsidered and underlines the need for correct understanding of their definitions (p.102).

3.2.3. Terminological Acronyms: QMS or SMK

Throughout the Serbian version of the standard ISO 9000:2015, the English acronym *QMS* (S*istem menadžmenta kvaliteta)* is used. The English acronym *QMS*, though not adapted to the Serbian phonological system (i.e. it contains an element – letter Q – which is not a part of the Serbian alphabet), does accept our flective suffixes (e.g. *QMS-om, QMS-u*, etc.). Having that one of the main terminological principles is that a source language (English) term should be fully adapted to the linguistic system of a target (Serbian) language (explained in more detail in 2.3. above), our main concerns regarding this issue are whether:

(a) the acronym should be phonologically adapted (through the process of transphonemyzation)
(b) the acronym should be adapted on lexico-semantic level, i.e. whether it should be replaced by a Serbian alternative: *SMK* (*Sistem menadžmenta kvaliteta) instead of QMS .*

The same process of adaptation could be applied to the acronym *DRP* (for *Dispute Resolution Process*) used in ISO 9000:2015. This acronym is used in unadapted form in the Serbian standard to mark *Proces rešavanja spora* instead of the possible alternative (PRS).

A very common deviation from the Serbian language norm is the disregard of the Serbian word order in noun phrases. Namely, the replication of English word order in Serbian noun phrases, especially when the first element of the noun phrase is a/an (foreign) acronym: *QMS model, QMS standard, DRP isporučilac*, etc. The Serbian alternatives to these terminological phrases would be (*model QMS*-a) or (*model SMK-a)*, see 3.4. above), (*standard QMS-a) or* (*standard SMK*-a), (*isporučilac DRP*-a) or (*isporučilac PRS-a*).
By following the English word order, Serbian terminological noun phrases also avoid using the flective suffixes, which does contribute to language economy, on the one hand, but also breaks the Serbian language norm, on the other hand.

4. CONCLUSION

The terminological issues addressed above raise several questions:

Namely, the first one is whether the translation of the ISO 9000 standards is adequate enough, i.e. whether the terms present in the standards can actually be regarded as the most representative ones and acceptable both from the perspective of Serbian language standard and the perspective of the subject field experts.

Secondly, there are some inconsistencies between term variants preferred by the Institute for Standardization of Serbia and the ones present and transferred into our educational system. This obviously stipulates close cooperation between the standardization institutions and relevant expert institutions (primarily educational). Before the adoption, all Serbian standards are accessible to the public and can be a

subject of public hearing. As long as a national institution specialized in terminological activities is not established, the existing relevant bodies should actively participate in this field.

In conclusion, one of the preconditions for monosemous and harmonized terminology should be good terminology management (Galinski, 1999), i.e. a systematic approach to all terminological activities, and especially to its standardization, as well as and a close cooperation between linguists, terminologists, and subject field experts.

QUALITY COSTS IN THE MANAGEMENT SYSTEM IN THE FIELD OF HIGHER EDUCATION

Nedeljka Zivkovic[1]
[1]Belgrade Business School, HigherEducation Institution for Applied Studies
*Corresponding author, e-mail: nedeljka.zivkovic@yahoo.com

Abstract:*The topic of this paper belongs to the research field of the significance of quality costs, that is, non-economic costs, applied to institutions of higher education, and its specificity lies in differentiatingand considering actual costs and lost opportunities costs, which, as a rule, are significantly higher. Measuring and identification of quality costs is a complex process because these costs are, as a rule, hidden and not represented as actual costs, rather aslost opportunities costs. The aim of this paper is to consider and interpret quality costs applied to a higher education institution, to show the need to invest resources in support costs of introducing and implementing quality systems, considering and assessing the possibilities of lowering quality costs as opportunity costs,correlated with considering lost opportunities costs, quality and total benefit, should these costs not be incurred. The identification and consideration of total quality costs and their division into categories are presented as costs actually incurred by missing to invest an asset as real costs of current operations.*

Keywords*:costs, quality, higher education, students, investments*

1. INTRODUCTION

The starting point for the quality costs is determined and generally accepted amount of costs for the implementation and application of the quality system which serves as the basis point, and is necessary for higher education institutions to be able to decide about the acceptability of the amount of initially actually incurred quality costs with consideration of the consequences presented through the measurement of the scope of potentially incurred of costs due to the failure to implement the quality system.*Filipović and Đurić (2010, p. 384) point out thatquality costs are defined as "costs incurred in an organization in order to secure the quality of the product".*The optimization of quality costs in higher education institutions is based on the increase of quality costs manifested through investments into prevention, consequently leading to a decrease of costs which can occur due to failure to implement quality and the total implementation costs and application of the quality system. *Summers (2009, p.270) points outthat "using quality costs, a manager can determine the usefulness of investing in a process, changing a standard operating procedure, or revising a product or service design".*The optimization of quality costs is a process of balancing the quantity of resources used to insure the level of quality, which means to fulfill the user's request. Unlikethe actually incurred costs resulting from the functioning of a higher education institution, and unavoidable in all organizations, therefore also in higher education institutions, the actual quality costs are difficult to identify and locate. The actually incurred costs resultingfrom the business operations activities represent the actualization of business policies set by the management of the higher education institution in the planned annual budget in terms of types of costs and their scope, adhering to the following goals:

- Preserving the financial strength through the scope of assets engaged and sources available for financing, while defining the business policy of preserving permanent payment ability, permanent financing ability, that is, investing in the development and modernization of equipment and assets for the realization of the teaching process;
- Preserving assets and increasing assets;
- Maximizing the financial result, as the highest long-term goal, and
- Permanent ability to pay salaries and encourage employees, the ability to settle liabilities to creditors on time, as well to state bodies and organizations.

Quality costs in all organizations, as well as in higher education institutions, are defined as hidden costs which wouldn't be incurred if everything were done correctly the first time, that is, if the product/services were always without errors. Objectively, this is impossible. So, quality costs or bad quality costs are actually costs of lost opportunities. All quality costs incurred occur due to incorrect process performance and are measured as costs incurred or which shall incur above the initial investment costs in the quality system being applied. Organizations measuring their costs discovered that the situation in certain institutions is such that total quality process costs can make up to 30% of total sales, which is an extremely high scope of costs. *Pyzdek and Keller (2013, p. 22) point out that "the lower cost of quality than competitors, translates to lower overall*

*cost".*There are situations when the costs caused by not applying the quality system are two to three times higher thanthe potential gain, so that the decrease of costs which are in correlation with the quality systems can influence the operational profitability and increase the profitability rate as the measure of operational yield. Hence, quality costs are costs incurred if each activity in the organization is performed correctly each and every time. Initial quality costs in higher education institutions consist of all that was invested in the implementation and application of the quality system and they are part of the primary costs, but all that was lost or can be lost due to bad quality makes for the secondary part of costs caused by failing to apply or the untimely application or implementation of quality in business processes. In higher education institutions these costs can be qualified as loss of accreditation costs, transfer of students to other faculties, inadequate choice and calibration of the teaching program, incomplete teaching performance and such. Seemingly these costs do not exist. However, the analysis of the gain lost, as a rule,in the long-term quantifies the amount of lost opportunities costs – quality costs.

2. QUALITY COSTS STRUCTURE

In the structure of total costs there is a certain amount we call primary quality costs. Those are the costs an organization incurs in order to achieve the aimed quality. Quality costs can be defined as costs incurred by activities (primary costs), costs referring to the prevention of errors (accompanying costs) and lastly, secondary costs incurred by failing to apply the quality system entirely or partially, or as a consequence of making errors arising from the non-compliance to the determined procedures and processes. The most significant characteristics of quality costs are:

- Initial or primary–accompanying quality costs;
- Secondary costs or costs arising by failing to apply or applying inadequately the quality systems; these costs are hidden as a rule;
- They are contained in the financial statements, not as separately presented items of current costs in the income statement, rather as opportunity costs of decreased utility (revenue);
- As a rule, their structure is not obviously known, but they can be identified;
- They are missed, potentially unexploited chances of possible, lost profit;
- The degree of knowledge about these costs is a measurement of the degree of awareness about the quality;
- As a rule, these costs are significant in scope. Although hidden, they must be identified by the management in order to take steps to decrease them or eliminate them through intensive monitoring of the quality application (hotspots of cost – loss incurrence);
- Due to their specific nature manifested in a hidden – opportunity effect, these costs can be latently very high and significant for survival and development.

Evans and Lindsay (2002, p. 408-412) mention that the termquality costs first appeared in the 1950s.
Quality cost structure can be presented as follows:

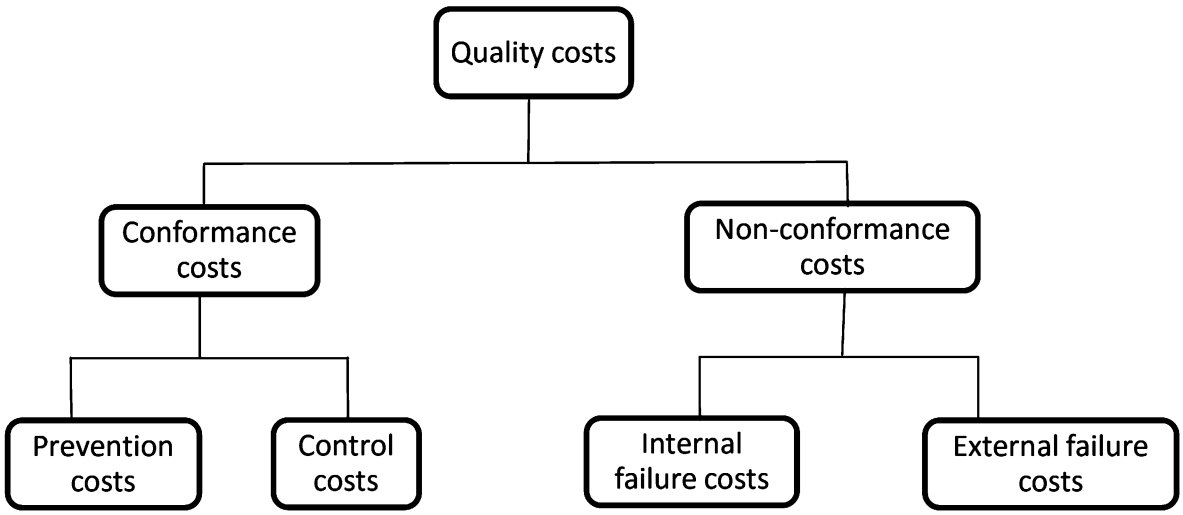

Figure 1: Outline of the quality costs

Charantimath (2011, p. 14)states that "cost of quality has two main components – cost of conformance and cost of non-conformance".When the term cost is mentionedin this case, it refers to the failure to satisfy the user's requests. Costs of not applying quality are, as a rule, very high and should they be incurred they are manifested and significantly influence the direct decrease of profit though revenue lost and performance lost. For this reason, top management takes all measures and activities to identify bottlenecks and reasons for hold-ups in the application of the quality systems and measures which will in the shortest period possible effectively remove the problems identified.

2.1. Prevention costs

Prevention costs are costs of all activities undertaken in order to stop the occurrence of non-conformities. In higher education institutions prevention costs would be identified as:

- Educational services and employee education;
- Participation fees for educational seminars;
- Participation fees for professional training;
- Participation at fairs and symposiums;
- Literature and professional examination expenses;
- Other professional education expenses.

Douglas (2013, p. 33) discusses that the application of prevention costs could be unclear. These costs are desirable but they must be directed where they are most effective and can decrease other undesirable quality costs. Prevention begins with market research, that is, the understanding and complying with the users' needs, as well as expectations. These costs are also called conformance costs in the literature. They include all techniques and measures preformed in order to prevent errors. Error prevention costs are proportionate to the cost of removing errors in accordance with the rule "1:10:100". The rule "1:10:100" basically means that the removal of errors during the planning process costs 10 times more, and the removal of errors during the realization process costs 100 times more than the prevention of errors. Applied to higher education institutions in the process of gaining accreditation it would mean that if the prevention of an error costs one monetary unit, the correction of the error during the review of accreditation documentation costs 10, and the correction after the documentation was returned by the accreditation committee costs 100 monetary units. Prevention costs are several times lower than correction costs incurred due to non-conformity. These costs can be regarded as an investment in quality.

2.2. Assessment costs

Assessment costs are the costs of measuring and rating quality conformance along with the costs of research and control.*Quality assessment costs in the words of Živković and Glogovac (2015, p. 158) are "initial assessments in relation to the quality which are not based on experience, rather on assumptions"*.They are the costs incurred in the adjustment of the degree of conformity to the quality requests, such as:

- Incoming control and testing;
- Control and testing of the process;
- Final control and testing;
- Monitoring service quality;
- Maintenance of research equipment and software;
- Control and testing of material and services and
- Valuation of inventory.

Filipović, Đurić and Teodorović (2008, p. 1) point out that „the education is a specific, but also a classic service activity".One of the most important differences between education and production (and other service activities) is that here we find an intensive and permanent interactive role between the user and the provider of the service. In higher education institutions these costs may be identified in the field of testing the achieved level of quality of service provided to the students.
Within them the following can be identified:

- Testing and monitoring the curriculum;
- Monitoring the work of all departments (student administration, accounting...)
- Monitoring the work and work quality of teachers;
- Testing by applying a trial classification exam;
- Surveying the students.

2.3. Costs of non-conformities

Costs caused by errors are referred to as non-conformities costsin literature. These costs include all direct and indirect costs in relation to the correction of errors of any type, wherever they occurred. The mentioned errors include all accidental and system errors occurring in organizations. The majority of costs for the correction of errors directly depend on the location and scope of their influence on the application of quality, after their identification. The later the error is detected, the higher the costs. Non-conformancecosts occurwhen the quality system is not applied and due to the unsuitability of the quality system. In higher education institutions these costsare identified when students are lost, that is, when they transfer to other faculties due to their dissatisfaction; they can also bebased on the loss of accreditation due to non-compliance with certain requirements such as the number of teachers necessary for a quality performance of classes and exercises in relation to the number of students, existence of adequate space for the delivery of classes (necessary number of classrooms, laboratories and lecture halls). Depending on where the non-conformanceis identified, that is, within the organization itself or externally, we differentiate between internally detected and externally detected non-conformities.

2.3.1 Costs of internal non-conformities

Costs of internal non-conformities or internal errors comprise those costs that have not fulfilled users' requests and have been detected within the organization itself. These costs include:

- Write-offs, badly provided services;
- Reprocessing, that is, the need to provide the service again;
- Costs of lower level quality ;
- Reexamination.

Applied to higher education institutions these non-conformitiescosts refer to cases when, for example, during the exam registration in the current examination period, the wrong exam was registered for a student by the administrative worker in the student administration, or during the change of the study program, a student was enrolled to a wrong study program due to an error of the administrative worker.*Ušćumlić andLukić (2008, p. 214) state that internal costs of failures are redundant, that is, they do not lead to the increase of the value of output, and they contain: costs of corrective actions or measures, costs of re-inspecting and re-examining, costs of repeat work and such.*

2.3.2 Costs of external non-conformities

Costs of external non-nonconformitiesoccur when a product or a service reaches the user, that is they leave the organization, and they do not conform to the user's request. These costs include:

- Costs incurred from processing appeals and objections;
- Costs incurred by processing and conducting a litigation;
- Costs of recalls and liabilities;
- Corrective actions;
- Costs of realized warranties;
- Liability costs;
- Examining objections.

During the reporting of non-conformities it is necessary to define the cause of error and to make a decision about the application of measures to remove the identified non-conformities. External costs of non-conformities decrease the profitability of the organization. External failure costs take up a considerable share of total costs. This can be presented in the following way using an example of investments in prevention in a higher education institution:

Table 1: Review of quality costs based on investments(in 000 of dinars)

Investments	I period*	II period	III period
Net monetary investments	50.000.000	80.000.000	120.000.000
Effectsof investments	90.000.000	130.000.000	150.000.000

*period of one accreditation or 5 years

As in all organizations, in higher education institutions investments are necessary in order to deliver education of "the best quality product" and the most significant resource of a higher education institution

efficiently in accordance with the set quality standards. Consequences of not caring about the application of the quality system and managing quality costs are, as a rule, unrecoverable, considering that their occurrence is measured with the opportunity loss of expected gain. They are presented as:

- Loss of accreditation;
- Transfer of students to other higher education institutions;
- Bad reputation and a decrease of the enrollment interest of prospective students ;
- Poor rating, etc.

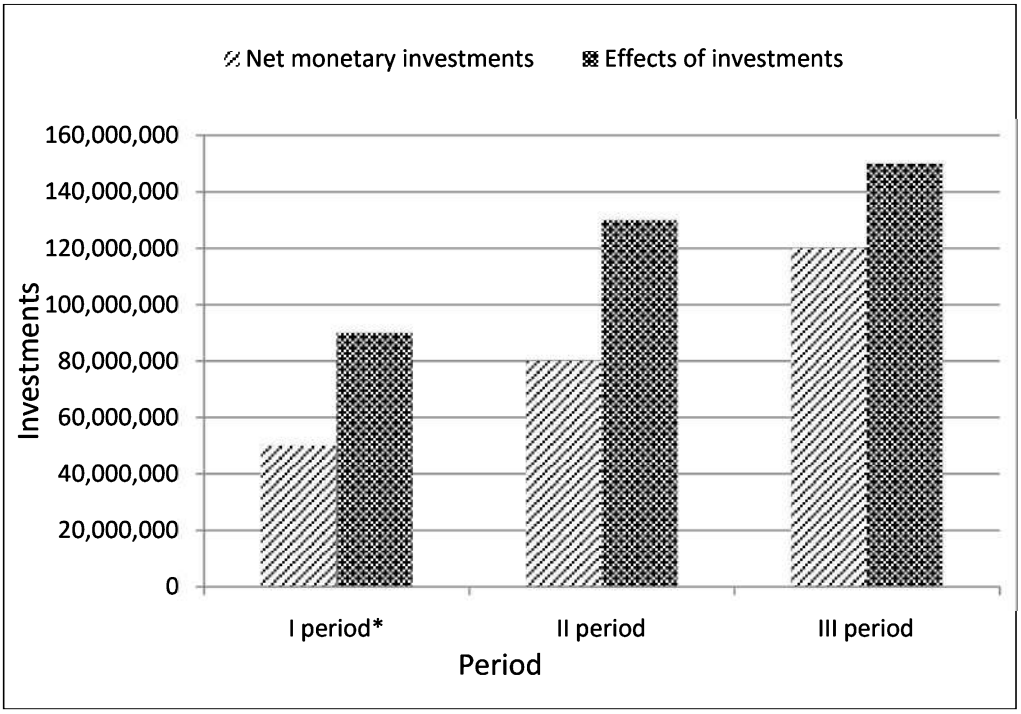

Figure 2: Graphicalview of quality costs (in 000 of dinars)

The table and graphical view clearly show that the investment in costs, that is, net monetary investments, produces the effects of those investments. The breakdown of investment costs would be as follows:

- Investments in IT support,
- Investments in software (software adjustments),
- Investments in furnishing,
- Investments in human resources (teaching and non-teaching employees).

3. AIMS OF QUALITY COST ASSESSMENTS

*Drury (2015, p. 48) points out that the present business conditions where the only thing that is constant is change, there is a general agreement in business practice that costs, quality, time and innovation are key variables to achieve user satisfaction.*Striving to developa concept of managing quality costs, as comprehensible as possible, has resulted in the creation of numerous concepts aimedat decreasing both quality costs and total costs.

Juran and Gryna (1999, p. 20) emphasizethatall organizations assess quality costs for several reasons.

- Quantifying the size of the quality problem expressed through the measurement of money – improving communication between middle and senior management. At some organizations the need to improve the communication between the levels of management is so present that it has become the main topic of the case studies about bad quality. When preparing case studies, assessment of quality costs is significant for two reasons: first, quality costs have shown to be much higher than managers and management assumed, and second, while the allocation of quality costs confirms some known problems, it reveals other problematic areas previously unknown.
- Major opportunities to decrease costs could be recognized. Bad quality costs do not exist as a homogenous mass. In reality they consist of a whole of specific segments, each of which can be identified, as well as their cause. When assessing bad quality costs the most important thing is to recognize segments directly causing bad quality.
- Opportunities can be recognized for decreasing user dissatisfaction and dangers related to the realization of products or services. Some bad quality costs are the result of management omissions.

Viewing and assessing the costs can help recognize vital areas of high costs. With total view of all business success markers of an organization there is a realization not only about the quality costs, but also about total costs in an organization. Quality costs assessment in higher education institutions is identified through managing and monitoring quality costs of all business processes, monitoring the work of all departments (student administration as an important process with a direct relation to the users - students), then the accounting department as the financial department performing indirect work with students though analytical monitoring of settling student obligations, while Departments assume a special place, and in accordance with the study programs, they professionally coordinate and monitor the delivery of classes, at the same time analyzing all quality segments and processes of monitoring the functioning of the teaching process, the basis of higher education work.

4. COMPARING QUALITY COSTS WITH BUSINESS MARKERS

Understanding the total amount of costs is made easier by comparing total quality costs with other markers presented to management. Markers with the highest influence on higher management are:

- Quality costs as realization percentage (revenue),
- Quality costs compared to net gain,
- Quality costs as a share in total realization costs,
- Influence of quality costs on the cost-effectiveness threshold (yield).

If we take the example of an organization such as a higher education institution, primary quality costs measured according to their size in relation to revenue, yields or their share in total costs aren't a true measurement of quality costs, because we have determined that quality costs represent opportunity costs of missed uses and as such can be extremely high and are not measurable and comparable with costs, revenues, gain, etc. of a certain period.

5. QUALITY COST ANALYSIS

Analyzing interrelations of quality costs leads to different understandings. Studies in many organizations about quality control show that omission costs surpass assessment costs. If management becomes aware that prevention costs are extremely low, this would alarmingly mean that non-conformance and omission costs will be high. In order to achieve a significant decrease of quality costs, one must take control of the assessment costs. An increase in prevention costs can bring gain to the later decrease of costs. *Filipović and Đurić (2010, p. 409) point out that, "if it turns out that the highest percentage of costs belongs to non-conformance,then the management is spending money on the wrong things".*This mostly refers to production organizations, but below is an attempt to apply it to a service organization. A higher education service institution functioning on a state level wants to improve the quality of services to its users – students through both teaching and non-teaching processes. Top management of the higher education institution is familiar with the work and functioning of other faculties and colleges and has come to the knowledge that it could decrease non-conformance costs. Gathering data on an annual level in the cost analysis per categories is presented in the following table:

Table 2: View of quality cost control analysis per category

Purpose of quality expenses	Annual costs (in m.u.)	Quality cost category
Errors in printing forms – for keeping students register	11	Internal non-conformance
Training costs	40	Prevention
Complaints – student's exams were not registered due to a clerk's error	8	External non-conformance
Testing regularity of classes	70	Assessment–testing

After identifying individual costs and determining to which category they belong, a sum and percentage review was made and is presented in the following table:

Table 3: Quality cost analysis per category

Quality cost category	Amount (inm. u.)	Percentage in the total
Total prevention costs	40	31%
Total assessment costs	70	54%
Total costs of internal non-conformance	11	9%
Total costs of external non-conformance	8	6%
Total	129	100%

Based on the datapresented in the table, one can draw the conclusion that it would be advisable for top management of the higher education institution to spend more money on investments in prevention in order for quality costs of the control and examination to decrease. Costs of internal and external non-conformities are low which is certainly a good result; it would be even better if the costs of prevention which amount to 31% were much higher on account of assessment costs. If we assume that an inadequately prepared teaching process and insufficient, that is, inadequate number of teaching staff necessary to deliver classes, in accordance with the Bologna convention in higher education institutions (HEI) which fails its accreditation in one out of five parts of up until now accredited teaching processes (study programs), quality costs will influence the decrease of the direct revenue of HEI in the next five years in the level of enrollment fees of self-financed students increased for the accompanying studying revenue (exam registration, semester registration, etc.) in the amount of 90.000 RSD annually for approximately 150 students. Aside from the direct loss of the period, indirect loss will be identified as the loss of the period due to the withdrawal of prospective students from studying at the higher education institution due to bad acquisition image entirely determined by the loss of one study program. That loss is assessed to about 80 students annually.

Loss without one program accredited:

I year:	150+80=230 x 90.000=	20.700.000 RSD
II year:	150+80+105 (70% transfer from first of 150 students) = 305 x 90=	30.150.000 RSD
III year:	150 +80 + 75 (50% transfer from II into third year)= 305x90=	27.450.000 RSD
IV year:	150 + 80 + 75=	27.450.000 RSD
V year:	150 + 80= 230 x 90.000 RSD = 20.700.000 + loss of the next three years until the enrollment (9.450.000+6.750.000+6.750.000) =	43.650.000 RSD
TOTAL:		**149.400.000 RSD**

Projection of HEI revenuewithout the loss of accreditation for one study program:

I year:	1.200 students (5 departments – study programs x 90.000) =	108.000.000 RSD
II year:	1.200 +840 (70% from1.200)=2.040x90.000=	183.600.000 RSD
III year:	1.200 +600 (50% from 1.200) = 1.800x90.000=	162.000.000 RSD
IV year:	1.200+600=1.800 x 90.000=	162.000.000 RSD
V year:	1.200x90.000=	108.000.000 RSD
TOTAL:		**723.600.000 RSD**

Table4: Review of revenue decrease

Year	Total revenue (without loss of the accreditation)	Revenue (without accreditation of one program)	Difference – revenue
I	108.000.000	20.700.000	87.300.000
II	183.600.000	30.150.000	153.450.000
III	162.000.000	27.450.000	134.550.000
IV	162.000.000	27.450.000	134.550.000
V	108.000.000	43.650.000	42.570.000
TOTAL:	723.600.000	149.400.000	552.420.000

Graphically it can be presented in the following way:

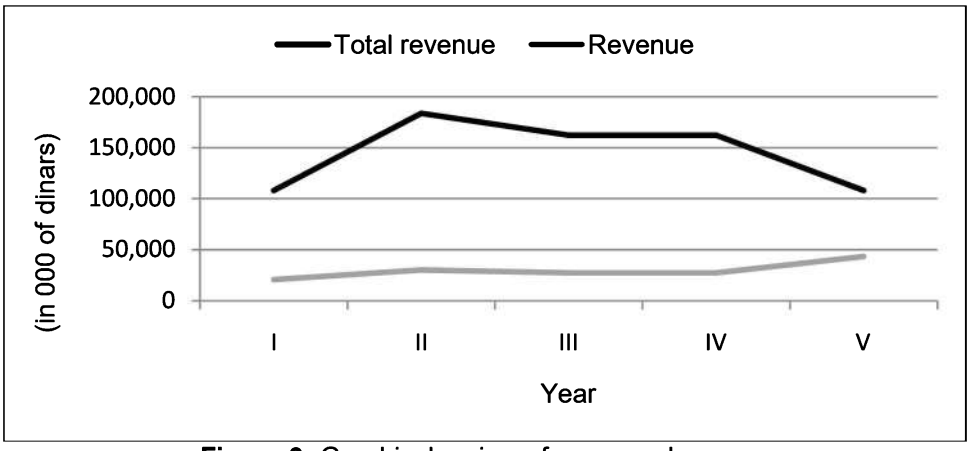

Figure 3: Graphical review of revenue decrease

The example shows that quality costs manifested as opportunity costs of revenue decrease due to insufficient application of the quality system significantly influence the decrease of revenue from HEI during the accreditation period (five years). Their average share in revenue decrease in the observed period is 21% or on an average RSD 29.880.000.

6. QUALITY COSTS DECREASE

*Total quality costs can be significantly decreased with reallocation.Uščumlić and Lukić (2016, p. 143) point out that "the higher level of quality decreases total costs".*The increase of prevention and control costs influences the decrease of costs of both internal and external non-conformities. Costs in relation to bad quality are present both because of occasional and permanent problems with quality. Constant improvement (called Kaizen by the Japanese) is necessary, as well as constant efforts in order to improve all processes within organizations. *Goetsch and Davis (2016, p. 19) indicate that"reducing the costs associated with poor quality is mandatory for companies that hope to complete in the marketplace. Reducing such costs is one of the principal drivers behind the total quality concept of continual improvement".*Financial markers and financial measurements are usually critical because they sum the economic influence of different physical activities in a manner understandable to managers, although the way of financial presentation might not correspond to the actual flow of economic events. On the other hand, financial accounting requires exclusively financial markers. Quality costs consist of financial costs during the process of introducing and monitoring quality systems. While the quality functions, those costs are correlated with other costs and revenue as measurements of success during the work of the period. However, missing the application of quality entails missing the primary cost of applying, controlling and monitoring in the current period which will be presented as a significant cost in the future periods, and not as current costs, rather as the opportunity costs of lost opportunities – unrealized gain, volume of business, references etc.; these costs are immeasurably higher and difficult to recover. When it comes to quality costs it is very difficult to find the right mix of financial and non-financial measurements to satisfy expected financial revenue and reconcile requests and effects of business decision makers. Lowest quality costs are those that maximally invest in quality.

7. CONCLUSION

Specificity of quality costs research applied to higher education institution as a service organization makes them objectively hard to divide between internal and external non-conformities because the largest part of quality costs in service organizations is related to the work of employees and the level of quality system application on that organizational level, so that internal non-conformance immediately becomes external in relations with the users – students. They are investment costs applied to the quality system. As to whether their amount is objective, the answer lies in the analysis of quality functioning. Costs of quality omission are not operational costs presented as direct costs in the income statement. This type of costs is presented as opportunity costs of missing on a chance of achieving revenue or some other type of benefit in the long-term period. Due to this, their amount is disproportionately high and significant. The paper pointed to the significance of quality costs or costs due to bad quality manifested in unrecoverable consequences such as loss of accreditation, if we take the example of a higher education institution which doesn't have space equipped to perform classes or has insufficient expert and competent teaching staff teaching and holding

classes. Then the cost of opportunities lost refers to the next five years, until the new accreditation, and the consequences are considerably higher, which is the measurement of the value of lost quality application costs. A complete overview and understanding of the bad quality costs is important and if every product (printing books and forms) or service were perfect, than these costs would be eliminated.

DOCUMENTING PROCESSES: CHALLENGES FOR FIRMS OPERATING IN SERBIA

Marina Momčilović*[1], Ivan Stefanović[2]
[1]Junior Business Process Analyst, CCBill SRB doo
[2]Business Processes and Procedures Department Head, Vojvodjanska Bank ad Novi Sad
*Corresponding author, e-mail: marinam@ccbill.com

Abstract: *In general, managers in firms operating in Serbia do not have a proper knowledge on how processes ought to be documented in order to achieve high level of process standardization and, as a result, to create opportunities for increasing process performance. With this fact in mind, the authors of this paper set out to show the importance of this problem, hoping to raise awareness about the overwhelming space for significant improvement of business results in this area. For this purpose, insights on challenges facing three firms operating within different industries in Serbia are presented. Each of them, dealing with its own problems of document management system and process management, bears some sort of resemblance with the other two when it comes to challenges of documenting processes. The paper ends with practical guidelines for managers on how to properly document the processes within their firms in order to achieve benefits of process standardization and performance improvement.*

Keywords*: document, process, standardization, performance, firm*

1. INTRODUCTION

Establishing highly efficient processes within a firm and making them run smoothly is not an easy task to master, but this has become a necessary condition for all firms trying to prosper in contemporary business environment. In order to achieve high degree of process efficiency, firms must carry out their operations in a consistent manner, which is achieved through process standardization.

Standardization may be seen as the degree to which work rules, policies and operating procedures are formalized and followed (Jang and Lee, 1998), while standard represents an approved specification of a limited set of solutions to actual or potential matching problem or a time-wise frozen end product of a standardization effort (Vries 1999). When process is standardized, variations in performing tasks within it are reduced to a minimum, i.e. each task performed by a different employee gives the same results. Standardizing a process requires process participants first to gain sufficient understanding of the process, and only then to start developing accompanying documentation that will describe the process in sufficient level of details.

Therefore, in order to achieve high level of process standardization and, as a result, to create opportunities for increasing process performance, firms must get to know and document all of their processes in a proper way (cf. Teece, 1998). It is well known that use of process documents can improve the output consistency, efficiency, and learning rate of a given process (Edelson & Bennett, 1998; Monden, 1983; Suzaki, 1993). While on the one hand standardizing business process variants across their functional and geographical structures is very attractive for organizations for a number of reasons, on the other hand, over standardizing business processes might actually decrease the aimed advantages and prevent meeting local requirements with the rolled out standardized processes (Mustermann, 1976).

Despite its great importance for contributing to firm competitiveness, there is an evident lack of papers on standardizing and documenting processes (cf. Ungan, 2006a). Therefore, this paper is a small attempt to fill this void.

The paper starts with theoretical background explaining contemporary issues in documenting processes within firms. It continues with illustrating the challenges of documenting processes at three firms in Serbia operating in different industries. Finally, recommendations for practitioners working in Serbia are provided along with some concluding notes.

2. THEORETICAL BACKGROUND

The origin of documenting processes can be traced back to Frederick Winslow Taylor and his concept of scientific management (Taylor, 1911/1998). Taylor believed that workers were incapable of designing efficient processes, hence the need of management to develop documents describing how the work is to be done. The objective of documents under Taylorism was to have industrial engineers determine 'scientifically' the 'optimal' way to perform a given process.

The way in which process documents are developed and used today has changed radically. Best practice of process document development, in contrast to Taylorism, calls for the active involvement of workers in development and refinement of these documents (Adler, 1993a, 1993b, 1996, 1999; Edelson & Bennett, 1998; Monden, 1983; Suzaki, 1993). The objective of process documents today is to ensure that all workers are performing tasks in the same way, which is a necessary condition to achieve an adequate level of coordination between workers in order to obtain consistent output from the process. On the other hand, solid process documentation may help newcomers to adjust rapidly to the manner in which they are expected to work and perform. When all workers perform their tasks consistently, it becomes possible to run controlled experiments to test the impact of changing various process parameters. When a process change is shown to improve process performance, process documents are updated and workers are trained according to new documents (De Treville, Antonakis and Edelson, 2005).

Process documents gained great popularity among contemporary firms since they represent practical tools for understanding, analyzing, improving and standardizing processes (Ungan, 2006b). In order to develop high quality process documents, it is necessary for a firm to take several steps: (1) identify all processes within a firm, (2) optimize processes, (3) establish document hierarchy and define precise criteria for different document types, and (4) documenting processes.

Having all processes identified means becoming familiar with all the processes being run within a firm by making a list of them. The result is a process register (or catalogue) usually listing main process categories, which are being decomposed to groups, then processes and finally activities. Identified processes are usually classified using one of the mostly used and accepted process classifications, such as the one developed by Michael Porter (Porter, 1985) or by Jay Galbraith (Galbraith, 1998). The aim of developing a process register is to have an overview of all processes within a firm, identifying their scope and the manner in which they interconnect in order to create value for the customer, and knowing who is responsible for each process (identifying process owners).

After the process register is developed, the next step is to develop criteria for the sequence in which processes will be optimized. Process optimization starts with process mapping (developing process maps), then moves to stating the goals of optimization (achieving the same performance as competitors, minimizing costs, minimizing errors, etc.), continues with identifying process measures, performing benchmarking, analyzing AS-IS process, developing optimized (TO-BE) process, and finally ends with implementing optimized solution. Process optimization always results in process effectiveness and/or efficiency increase.

Optimized process needs to be standardized in order to be communicated effectively to all employees within a firm, but to do so, a firm has to have a document hierarchy in place. Establishing document hierarchy is a quintessential step in any firm, not only because of the need to document processes, but because it is necessary to prescribe the norms, values and rules that will govern a firm. Document hierarchy depends on firm's needs, but usually involves documents such as: policies, procedures, work instructions and records. Figure 1 illustrates usual document hierarchy in a firm.

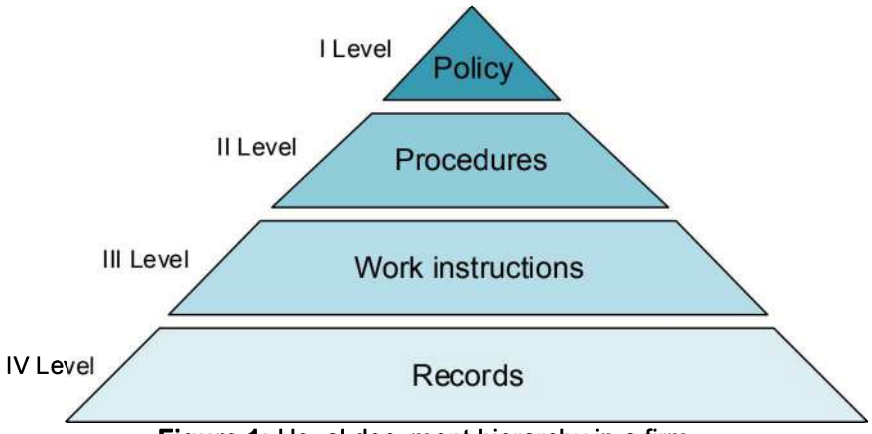

Figure 1: Usual document hierarchy in a firm

No matter what types of documents are defined within the hierarchy, each document type must have clearly defined criteria distinguishing it from the other document types. In other words, for each document type it must be defined what it is used for, what it describes, how it is connected to other document types, etc.

The final step in developing process documents is documenting the process according to the established rules (it is necessary to prescribe how the process is being documented). Very important aspect of documenting a process is to determine the level of detail in which the process will be described. Some authors indicate that process documents should not be very complicated and long, because such documents are difficult to comprehend and use (Babicz, 2000). On the contrary, Symons and Jacobs (1997) state that processes must be documented in sufficient level of detail to allow for substantial improvements. Another approach is taken by Ungan (2006b) who claims that level of detail in documentation depends on its purpose.

Next sections of this paper show how problem of documenting processes is being handled by three firms operating in Serbia. Their experience combined with theoretical background from this section will provide some insight for developing guidelines that will be helpful to other firms in Serbia struggling to gain competitive advantage through process standardization and process performance increase.

3. DOCUMENTING PROCESSES IN FIRMS OPERATING IN SERBIA

The following sections provide an illustration on the manner in which documenting processes is being done at three firms in Serbia operating in different industries: oil and gas, finance, and IT. Each of these firms is dealing with its own problems of process documenting, but the challenges they are facing bear some sort of resemblance.

3.1. Oil Company

The first firm described from the aspect of experience with documenting its processes is in oil and gas industry and will be referred to as the Oil Company. Oil Company is one of the biggest vertically integrated oil and gas firms in Southeast Europe. It was established in 1940s and since then it has gone through several periods of profound ownership and organizational restructurings, resulting in significant growth and business development. Nowadays its main activities are: (1) production of renewable energy, (2) exploration and production of oil and gas, (3) crude refining, and (4) sales and distribution of broad range of petroleum product. Oil Company operates in several countries in Southeast Europe and counts around 10,000 employees.

Due to the firm's size and complexity, one of its major challenges is to have all processes documented and standardized in a proper manner. Oil Company is coping with this difficult task by having established document hierarchy and precise criteria for different document types, continuously developing its process register, and trying to cover all the processes with sufficient amount of documents.

Oil Company has a very detailed business process register that is subjected to frequent updates. This document lists all processes being performed within the firm and its subsidiaries. It defines process hierarchy consisting of five levels:

1. Process category – the highest level in process hierarchy indicating basic business areas and grouping them into those creating value, the ones providing support and those that manage the business;
2. Process group – a set of interconnected processes within one business area;
3. Process – a set of interconnected and interacting activities that transform inputs into outputs;
4. Sub-process – a part of process composed of interrelated activities;
5. Activity – a unit of work composed of interconnected operations.

Business process register also indicates business owners on the first three levels of hierarchy: process category, process group and process.

Oil Company has developed its document hierarchy based on quality management system requirements. This hierarchy consists of three levels (depicted in Figure 2):

1. **Level I** includes the documents containing the main rules that apply to the whole firm, defined by management. These documents do not describe processes, but provide main guidelines and directions for action;
2. **Level II** refers to the documents describing process flow;
3. **Level III** comprises of documents describing parts of processes in a detailed way.

Since there are a lot of different document types in document hierarchy, each document type has a concise and clearly defined purpose, scope and criteria for its development.

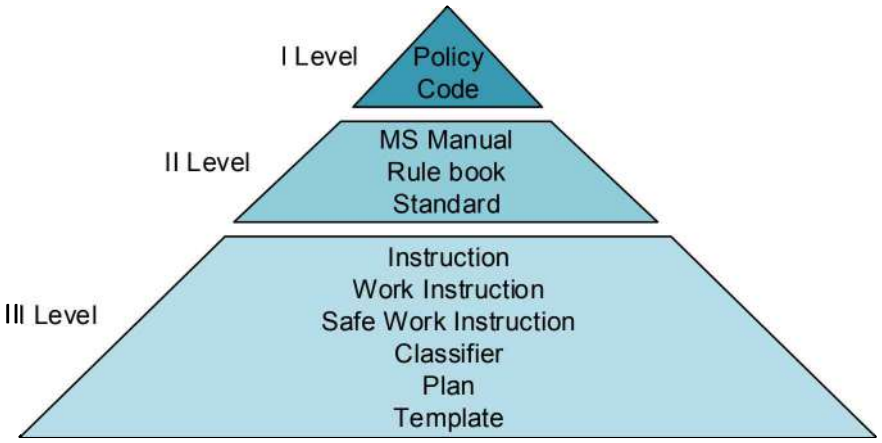

Figure 2: Document hierarchy levels in the Oil Company

When it comes to documenting processes, there are some formal rules that should govern the manner in which documents are developed, but this is not always the case in real life. For example, there is a rule that establishes relations between document hierarchy and business process register in a way that the first level of document hierarchy (policies and codes) concerns process categories, the second level (manuals, rulebooks and procedures) describes process groups and processes, while the third level (instructions, work instructions, classifiers, etc.) is connected to sub-processes and activities. Another rule proclaims that it is not allowed to have any repetition or collision within or between documents. There is also a rule concerning the number of procedures: one process must be described only with one procedure.

As already mentioned, these rules are not always being followed. As a result, some processes are not described in an adequate manner. For example, within Refinery process category, there is a process group entitled Petroleum Product Refining. One of the processes within this group is Raw Material Processing. This process is described by two procedures that have some overlapping – it is immediately clear that two aforementioned rules are broken in this case: the process is not described with one procedure and there is a repetition of text. Another example illustrates the case of insufficiently documented process: within Procurement process category, there is a process group entitled Procurement Planning that is defragmented into two processes – Procurement Plan Development and Inventory Management. Inventory Management is not documented properly – there is only one work instruction describing one activity in this process, while other activities are not described at all.

Even though Oil Company has made some significant steps on a journey toward documenting and standardizing processes, it still has a long way to go in order to develop a proper system with clear rules that will be obeyed by everyone in the firm.

3.2. Bank

The second firm experiencing significant challenges in the area of process documenting is operating in the finance industry and will be referred to as the Bank. Bank is one of the oldest banks in Serbia with a 145-year long tradition. It represents one of the most recognized local brands in the country. From 2006 the Bank is a member of one of the leading international banking groups. Today, it is among top ten largest banks in Serbia by asset size. With the fifth largest network in Serbia and almost a million clients, Bank covers the entire territory of the country.

During the last several years, Bank has developed a process register with process hierarchy consisting of three levels:

1. Process area – the highest level in process hierarchy indicating basic business areas, i.e., management processes, enabling processes, main processes and support processes;
2. Process category – a set of interconnected processes within one business area;
3. Process – a set of interconnected activities that transform inputs into outputs.

On the other hand, document hierarchy has never been established. There are a lot of different types of documents such as: policies, rulebooks, procedures, methodologies, instructions, work instructions, manuals, etc. Since the relations between these documents do not exist and rules for making them are not clear (except for procedures), it is very difficult to manage documents on a large scale. Due to this fact,

numerous problems arise when it comes to documenting a process, even though rules for documenting processes do exist. For example, Cash Management process is covered by 14 procedures and 1 rulebook with a lot of overlapping, but still one portion of this process has remained undocumented. After completing analysis of this process by the internal team consisting of process experts, it was decided to develop 2 procedures and two instructions that will cover the entire process in a satisfactory manner.

Based on everything said about the Bank, it is clear that it has just embarked at the beginning of a journey toward process documenting and that it will most certainly face numerous challenges along the way.

3.3. IT Service Provider

The third firm described in this paper operates in IT industry and will be referred to as the IT Service Provider. IT Service Provider is a recognized firm in global payment solutions established in 1998. It processes more than a billion dollars in transactions each year and is one of the largest third-party payment processors. IT Service Provider maintains a comprehensive set of proprietary backend and web-based administration systems to effectively process transactions for a wide variety of markets and help provide businesses the tools and practices necessary to successfully operate. In 2002, IT Service Provider decided to start supporting processing needs of European online merchants. It expanded its business to provide a processing solution to European-based businesses that wish to offer Visa as a payment option.

IT Service Provider has not yet finished its process register due to the fact that not all processes are identified. This is the result of focusing only on processes that have been selected as priorities for documenting. All the processes that have been identified were mapped with some of them even being automated using some cutting edge software solutions.

Regarding the process hierarchy levels, all identified processes belong to a particular category, which means there are two levels of hierarchy: categories, as basic business areas, and processes within these categories.

IT Service Provider does not have a document hierarchy established, even though it has several types of documents (procedures, work instructions, etc.), but with there are no relations between them. Criteria for different document types are not precisely defined and rules for documenting processes are not established. For example, a process is documented only if process owner realizes that process he/she is responsible for will be more efficient if documented. Process owner then chooses how he/she wants to document the process, create the document and share it with all process participants. If he/she wants to define all activities and responsibilities within the process, process maps are being developed. Alternatively, word documents and wiki pages are used to describe processes in more detailed way or to define main rules in some business area.

The problem IT Service Provider is facing at this moment is that there are still some unidentified processes, while some other processes are insufficiently covered by documents. For example, Human Resources is identified as process category. Within this category, process entitled Hiring, Transferring and Termination of Employees is documented and even automated. On the other hand, Payroll process, which is also located in this category, remains undocumented and even unidentified.

Therefore, the main challenge for the IT Service Provider is to complete identification of its processes and develop a business process register. After this is done, process mapping and documenting needs to take place for all the processes not being identified at this moment.

3.4. Comparative Analysis of Three Firms

Previous sections provide an insight into the challenges three firms operating in Serbia are facing when it comes to documenting their processes. After presenting each of these cases, it is interesting to make a comparison between them. Table 1 illustrates three firms compared on several parameters regarding documenting processes.

Analyzing all three firms at a glance in comparative fashion shows that Oil Company has gone the longest way toward process documenting, while the Bank is lagging and IT Service Provider is left behind due to the fact it does not satisfy any of the parameters provided. In reality, IT Service Provider, even though it still does not have its process register and document hierarchy developed, has gone the farthest way. All processes identified until now have gone through a very detailed mapping, optimization and automation using sophisticated software solutions.

Table 1: Comparative analysis of three firms operating in Serbia on documenting its processes

	Oil Company	Bank	IT Service Provider
Having all processes identified	X	X	
Document hierarchy established	X		
Precise criteria for different document types	X		
Rules for documenting processes established	X	X	
Rules for documenting processes obeyed		X	
Processes adequately documented			

After seeing problems all three firms are facing, it may be concluded that neither one of them is on a high level of documenting its processes, but every one of them is putting significant effort to reach that end.

3. RECOMMENDATIONS FOR PRACTITIONERS IN SERBIA

Documenting processes in a proper manner and enforcing employees to act according to the formal documents will most likely lead to standardized processes. Once this is achieved, processes are stabilized and predictable in terms of process performance. Due to the high frequency of repeating their tasks while working on some activities within a process, employees will be able to incrementally improve the manner in which they perform, resulting in increasing the overall process performance.

Several guidelines are helpful for practitioners in Serbia to reach this end. These guidelines should be understood as sequential steps that are required to be taken in order to start improving process performance on a continuous basis:

1. It is imperative for management to recognize the importance a proper process documentation plays in terms of understanding the process flow and its underlying logic, as well as why is that so important for competitive advantage of firm.
2. Management must start raising awareness among all employees throughout a firm about the need for proper process documentation and standardized processes.
3. Document hierarchy and process register should be developed and confirmed by all major stakeholders.
4. Process mapping needs to take place process by process according to the previously established priorities. This should be done with process participants who need to confirm that processes are correctly depicted with diagrams.
5. For each process mapped, process measures need to be developed and process measurement should take place.
6. AS-IS process analysis and TO-BE process development are the following steps, after which TO-BE solution needs to be implemented.
7. TO-BE process implementation should be accompanied with development of process documentation in order to effectively communicate the process flow to all stakeholders, especially to employees in charge for that process.
8. After the optimized process starts running and learning curve takes place, it is necessary to capture (document) any improvement that might come up along the way, as well as to systematically investigate and seize opportunities for further optimization.

Managing processes in this manner will most definitely yield significant results in terms of process effectiveness and/or efficiency increase. Even more, it will foster the development of a culture of continuous improvement that is more than needed to become an integral part of every firm trying to prosper in the competitive market.

4. CONCLUSION

Survival and thriving in contemporary business environment requires that firms manage their processes effectively. To do that, they need to become familiar with their end-to-end processes in sufficient level of details by documenting them in an appropriate manner.

Proper documentation requires that processes be presented in the simplest manner to make them easy to understand. Often, using a graphical flow chart can suffice to relay all the relevant information quickly and easily. The less complicated the process documentation, the easier it will be to ensure that all employees can deliver repeatable, quality outcomes for the processes.

Authors hope that this paper will contribute in filling the void that currently exists in the literature concerning the manner in which processes are being documented. On the other hand, we are also hoping that it will help raising the awareness of managers working in Serbia about the impact that proper process documentation may have on increasing process performance and making better business results. We claim that thorough understanding of the process flows within firm, as well as their underlying logic, may be of great significance for managers in times when they are making decisions that will impact the competitiveness of their firms in the evermore demanding marketplace.

Abstract: *This paper deals with the structure of the Media Center for Quality, also with the needs of all target groups and the public and analysis of them, in order to create specific offers of the center, along with the implementation of the quality management system in its work. It discuss the potential strategy to create a focal point for dissemination for information with regard of quality. The paper is also addressed to the directions of development of the Media Center for Quality that are specifically engaged with quality management approach, research and the provision of different services in the field of quality, but also deals with the existing trends and needs of the local market.*

Keywords*: quality management system, quality media center, stakeholders reporting*

1. INTRODUCTION

Firstly, it is necessary to say something about the field of interest of this work, and that is quality. If we look closer to the development of quality and quality movement in general, we can conclude that the fundamental needs for the emergence of quality on global market and society can be generated from the development of quality movement. The Movement for Quality traced its way back in medieval Europe, where the craftsmen were organized in unions, so called guilds, in the late 13th century. Quality management in the guilds took up a very important place. It created check-ups, controls and certain forms of audit, performed by craftsmen, to ensure compliance with quality specifications (Filipovic J., Djuric M., 2008)..

The quality system is defined as "a set of interrelated or interacting elements which is using a variety of resources to achieve objectives related to quality." These objectives are focused on fulfilling and overcoming user's requirements (Filipovic J., Djuric M., 2010).

Examples of international practice show that the issue of quality and business excellence can not be reduced only to the implementation of standards, but also to a comprehensive organizational reports of the business and working methods (Weissingeer R., 2014). In order to fully meet the requirements of all stakeholders and interested parties, organizations must provide a valid, up to date information of the business methods. It can no longer be only the financial statements, but information that provide insight on procurement, manufacturing, suppliers, vendors, working conditions, social responsibility and other activities of interest to stakeholders. (Idowu S. O., Louche C*., 2011)*

Worldwide, and especially in Serbia and the region, there is no existing consensus of opinion when it comes to corporate reporting and quality. The practice is tantamount to parts of PR campaigns and the work of advertising agencies.

Strategic communications will become a key factor for all organizations - whether it is a public, private sector and civil society. Communication can play an important role in removing misconceptions, resolve conflicts and bring together the common sides to improve the world in which we live. (Aras G., Crowther D, 2009)

2. GLOBAL TRENDS IN QUALITY REPORTING

The global market has been allocated to several organizations that deal with quality, quality research and quality reporting. Some of them are:

- International Organization for Standardization (ISO),

- Global Reporting Initiative (GRI),
- UN Global Compact (GC),
- Organization for Economic Cooperation and Development (OECD),
- Global voice of quality (ASQ) (the American Society for quality),
- International integrated reporting Council (IIRC) and others.

ASQ business model could be one of the key models for establishing a strategy for the development of the Media Center for Quality in Serbia. ASQ is organized primarily as a global network, which provides information on the quality, certification, training, seminars, conferences, meetings, literature, and above all it provides training, performs certification of quality managers, organizes scientific meetings and conferences for its members and provides a unique database which is formed during many years of research, and a database of professional literature and other information in the sphere of quality. (Campanella J, 1999)

2.1. IIRC solutions

International Integrated Reporting Council has developed a model of integrated reporting "IR" as a process that is based on integrated thinking which results as an integrated periodic report on the organization's created value in terms of the communication aspect of creating value. (Integrated reporting, 2011)

The integrated report reperesents a summary of ways of leading the communication strategy, management, organization's performance and its objectives in the context of its external environment, to the creation of value in the short, medium and long term.

Business and investors need IR, enterprises need a reporting environment suitable for understanding and articulation of its strategy which helps with keeping the performance internally and attracting financial capital for investment. Investors need to understand how the strategy creates value over time.
Integrated reporting is the market's response to nowadays challenges in corporate reporting. Businesses and investors from more than 25 countries are the pioneers in the work of the IIRC (International Integrated Reporting Council) and they have contributed to the development of an international integrated reporting framework.

IIRC has attracted the world's leaders and has included integrated reporting in their business network. Those are the companies such as Unilever, HSBC, Deutsche Bank, Hyundai, Microsoft, PepsiCo, National Australia Bank, Tata Steel and over a hundred more.

2.2. Global Reporting Initiative and IR

Along with the development and implementation of standards, there was the practice of reporting companies on the way of doing business, as a norm of quality. GRI (Global Reporting Initiative) introduced the practice of making recommendations and guidelines for the preparation of such statements, which are necessary to achieve business excellence, and which later are stabilized as a practice on the International level.

Companies should include in their reporting practices in the real world and real time. Very few companies have voluntarily signed up for a transparent way of doing business, although some have taken the initial steps. Transparency in corporate reporting is easy to describe, and implement it in practice is the hard part. All actors want information of high quality, delivered on time, in a form they can use them. They also want information that will give them a complete picture of the performance and to be updated as often as necessary. (Samuel A., Robert G, 2002)

Successful companies will have an integrated strategy for achieving financial results in the future, in order to create lasting value for themselves and for all stakeholders of society. The integrated report should be the result of an integrated strategy and integrated reporting process.

3. MEDIA CENTER FOR QUALITY AND GENERATING TRENDS

Media Center for Quality should represent an upgrade of its kind of organization. It will not only create a network of corporations, institutions, other stakeholders and interested parties concerning quality, databases and working method reports, but it should be able to arrange consultations and trainings by the listed world centers and create sustainable connections with them. It should also be the initiator of conferences, dialogues, seminars and other business events and provide adequate information, conclusions and reports

from such events, making them available to the wider community, and in order to business and social progress. The Center should basically gather the information about quality, standardization, implementation of standards, certification, control, and then to connect the public, institutions for standardization and consulting agencies primarily with companies and their stakeholders and all other potential users of such information and services. The information that it receives from its members and program participants should be selected and appropriately presented to the public and to other media centers. Within the Media Center for Quality, users will be able to obtain information on global trends in the field of quality, training, seminars, summits, literature, and the local market.

This center should give an important role to scientific research, as a part of its main activities. For the research process and professional consulting, as well as for organization of lectures, panel discussions, dialogues and conferences, Media Center for Quality may primarily hire professors and associates of the Faculty of Organizational Sciences, also students who can gain a practical experience by participating in the work of the Center.

The profitability of the center can be achieved by membership and by package of services that the center may provide in accordance with the status of the members.

Furthermore, one of the innovative solutions is also the establishment of the Center's video channel with uploaded lectures which may be included in the service package. The lectures would be run by experts, and would be about certain topics, conclusions of conferences, and specific meetings.

Media Center may represent their clients and large corporations which have no conditions or staff for performing tasks of corporate reporting and communication with stakeholders, society or state.

In Serbia and the region, there is no organization type similar to Media Center for Quality, so its establishment under the auspices of the Faculty of Organizational Sciences, can very quickly gain key role in the field of quality in our region, thanks to human resources, knoledge, contacts and reputation as a competitive advantage in relation to other institutions and centers.

In regard to global business trends, as well as regulations of the European Union which require the implementation of quality standards in the business, the need for real, proven information on the quality, finding new solutions through research and reporting in this area will eventually get significantly better. For any successful business it is important to be a step ahead, and the Media Center for Quality has such a starting point.

3.1. Case Study – NIS, as a guideline for Media Center for Quality

When we talk about the market of the Republic of Serbia, considering quality and business excellence, the work of one of the largest and most successful companies - Oil Industry of Serbia (Naftna Industrija Srbije), can be considered as a case study.

The company follows global trends in the sphere of quality and it can be considered to be the leader in the region when the application of standards and reporting are concerned. NIS applied global trends primarily through transparency of its operations and business.

We can see that they prepared their annual reports on the work of the company, as well as reports on sustainable development in according to the guidelines of the GRI (Global Reporting Initiative), and also that the implementation of quality standards can be observed through the organization of their business and the availability of other types of documents, such as company profile.

NIS applied the Indicators of GRI agencies for the creation of the report, and audit was conducted by KPMG. Model of the NIS company can also be applied as an indicator of market needs, but also as a guideline for the offer of Media Center for Quality.

Profile	DESCRIPTION
3.3	Reporting cycle
3.4	Contact for questions about the report and its content
3.5	Methodology of preparing the report and a procedure for determining the content
3.6	Boundary of the report
3.7	Limitations in scope and boundaries of the report
3.8	Basis for reporting on joint ventures
3.9	Techniques of data measuring and basic calculations for the estimation
3.10	Explain existing corrections of data from the previous report
3.11	Significant changes comparing to previous reporting periods
3.12	GRI indicators
3.13	Audit (revision) report

Figure 1: GRI reporting indicators of the NIS company

Therefore, this is the company that has introduced quality standards, follows the trends of global organizations when reporting and its control is concerned, continuously strives to improve performance through review and training, takes care of the community and works in a transparent manner.

It can be considered as some kind of a model for quality, so when it comes to services that Media Center for Quality provides, directions for quality to be drawn in dealing with this type of companies are:

- Monitoring and present global trends in the field of quality to customers in Serbia and the region, as well as creating a link between these organizations and companies in Serbia;
- Analysis of user requirements, coordination and consultation with a certified and professional staff of the Media Center for Quality;
- Training and advising about the implementation of standards, certification and reporting;
- Control, review and improvement;
- Connecting community groups, organizations, institutions (companies, governments, NGOs, experts, consulting companies, institutes, media centres);
- Distribution of information from the client to its stakeholders;
- Presentation of trends, research results and reports of companies, as well as their connecting to other target audiences and media centers;
- Organizing dialogues, conferences and seminars and presenting new solutions;
- Publication, reporting and transfer of trends in the field of quality at the local level.

3.2. The mission of the Media Center for Quality

The mission of the Media Center for Quality is creation of social solutions when it comes to the field of quality, through development of an organization that continually reviews its options, following global trends of quality and passing them on the local market. As already mentioned more complex systems, this organization should belong to a kind of network that will provide quality services information to certain users by linking and grouping them by their interests, providing the necessary information in the sphere of quality in an appropriate manner and by creating databases and the ability to further research.

3.3. Objective

The objective of the Media Center for Quality is a successful notification of targeted public about the quality, organization of scientific meetings and an increase of the number of reports, implemented standards and certified workers in the field of quality.

3.4. Creating a strategy of the Media Center for Quality

The key of the strategy of development of the Media Center is to identify market needs, as well as the continuous improvement of the organization itself in accordance with those needs. As in the theory of

complexity, in this case the most important thing is to set up a clearly defined line or points of support depending on which the structure itself and the offer of organization will continue to change along with market trends and social conditions. (Johnson, G.; Scholes, K., 1988)
Finally, that points of support are knowledge, networks, learning, feedback of national and transactional and cooperation.

3.5. Strategic Analysis

In order to better formulation of development strategy for Media Center for Quality, we should explain all the factors that affect it.

A careful plan or method designed to achieve the goals of the organization, is often called strategy. It means doing the right things at the right time in order to ensure success in the future. From the perspective of the leaders in the company this means focusing on the future survival and success of the company. Traditional concepts assume that adequate strategies will be generated according to the systematic analysis and assessment of the current situation. These methods can then be implemented in order to take the company on the road of successful future. Johnson and Scholes present a basic model for the development of strategy. Getting an overview of the options and choosing the right strategy is based on the strategic analysis.

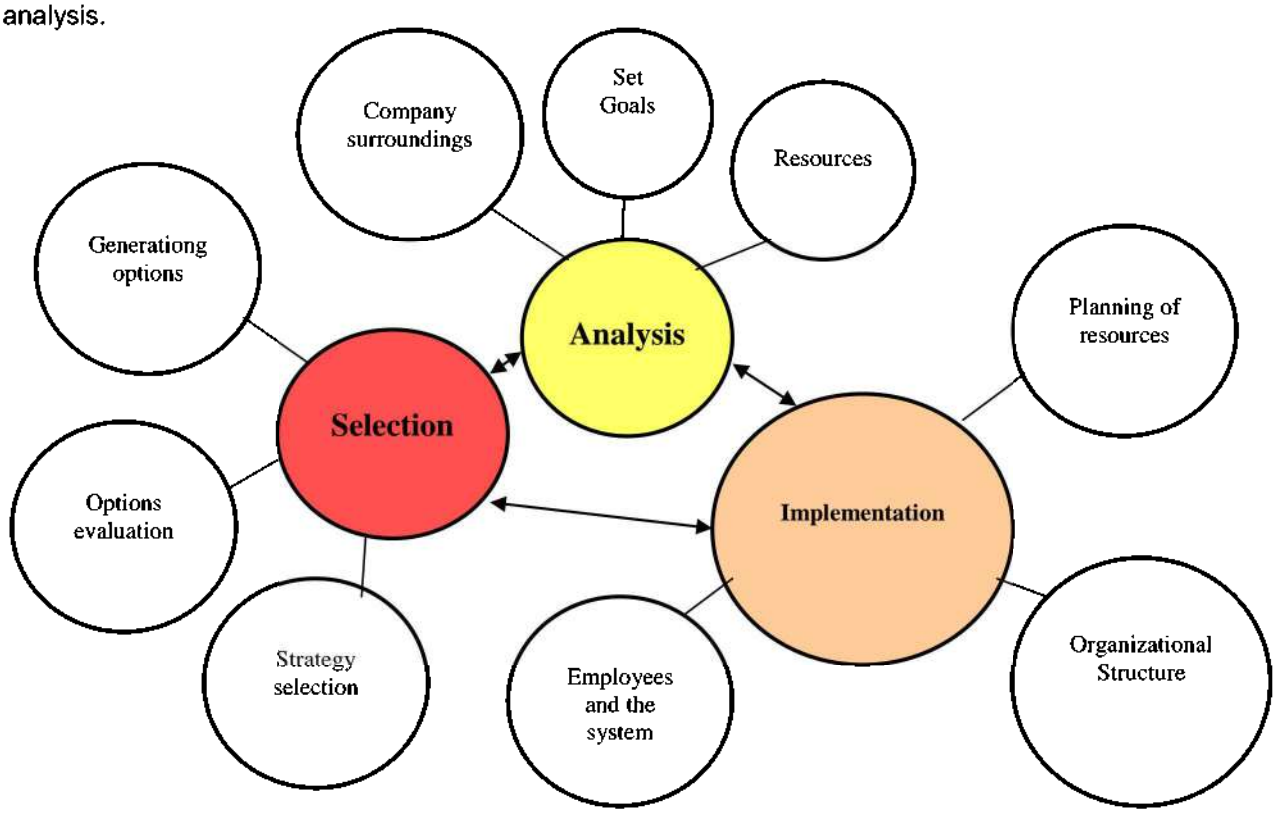

Figure 2: A copy of the Corporate Strategy: It is not this easy: Corporate Strategy (Johnson 1988.)

To formulate a strategy for the development of the Media Center for Quality, it is necessary to go through the process of analyzing the factors that affects its analysis, selection and implementation. Recognizing the indicators for analysis, selection and implementation is different on each case:

- Analysis - Indicators are recognized through the company surroundings analysis, set goals and resources;
- Selection - Indicators can be recognized by generating options and selection of strategic decisions;
- Implementation - Indicators are recognized through employees and the system, organizational structure and planning of resources.

4. CONCLUSION

On the one hand, regarding to its organizational structure, Media Center for Quality should make a network of social subjects, inform them in the right time, and also should provide them the access to the services related to quality. On the other hand, it should make available the information related to quality and enable

their further distribution and channeling to the requirements of other users by following the movement of information society and work of other media centers, and by the use of certain media.

Based on the analysis of the global trends of Quality, local case study, all the analysis needed for formulating Media Center for Quality's strategy of development according to prior check and knowledge of rational planning trough the corporate, global, business and functional strategy, it has come to the conclusion that the strategy can be created trough several key points, such as: knowledge, network, learning, national and transactional feedback, and cooperation.

According to trends that indicate complexity, synergy and cooperation, points of support are the foundation of the structure and operation of the Media Center for Quality, leaving the opportunity for development which follows new market and social trends.

Besides transferring knowledge, information and networking, the Media Center needs to needs to enable a proper analysis of requirements for each client and their further coordination to other clients and stakeholders.

Competitiveness is achieved by competence of human resources, the reputation of the founder institution, the existing infrastructural, technological and communication resources, but also by possession of databases, knowledge, contacts and experience in the field of quality, certification and standardization.
Profitability can be acquired by making an appropriate package of services and products for customers and members, also by the status of members of the Media Center for Quality publishing, and by distribution of information and knowledge through certain media. (Tapiero S. C., 1996).

Some companies apply social and environmental reporting for 15 years, but for many others it is still new. Most companies - mostly large enterprises - presents these information in the form of a report. Over time, these reports have become more extensive and more detailed with a wider range of measures of social and environmental performance included. Therefore, most organizations have reached this stage of maturity. The problem today is that there are no standards that indicate what should be reported, so the organizations still report on various matters, thereby impeding comparability. Therefore, it is probably true that this is a crucial phase of development for most organizations. (Aras G., Crowther D, 2009)

Without coordination with other companies and stakeholders, the impact of their operations may be limited. Partnerships with governments, international organizations, non-governmental organizations and other enterprises can greatly help to maximize the potentials of the company.

Formation of the Media Center precisely represents the necessary type of social solution that has to connect users, manage their requirements, analyze their needs and continue the distribution of knowledge and information gathered during the work.

*Corresponding author, e-mail: ana.trajkovic@fon.bg.ac.rs

Abstract: *Since the popularization of application of international standards, consulting plays an important role in the implementation of quality systems and other management systems. The beauty of consulting is that in its framework, it allows creativity and offers opportunities for innovation. This paper suggests three dimensions of consulting that can help in achieving success in the implementation of management systems, while presented model suggests a holistic approach. For the purpose of thorough explanation of certain claims, the examples from practice are offered that show that masterpiece actually consists of fine details. If by reading this article, consultants or those who are about to become consultants, acquire an idea how to help an organization in the implementation of the management system, then the goal of this work is fully achieved.*

Keywords*: consulting, quality, standard, management systems, holistic approach*

1. INTRODUCTION

For many years, consulting work in the field of management systems, stands as the main link between standards in the international arena and business systems that operate in free markets. Although the responsibility for the implementation of management systems lies with the organizations, it is consulting that has significant influence on whether the system will be adequate for the particular organization.

Figure 1: Consulting as a link between international standards and business entities

As almost all areas are regulated by an international standard, so the consulting has received its frameworks in the standard EN 16114: 2011 - Consulting Services in management. The International Organization for Standardization (ISO) is currently developing a standard ISO 20700 - Guidelines for the provision of consulting services in management.

However, as it is stated by Mr. Jeremy Webster from the Committee on Professional Standards (BSI) standard EN 16114: 2011 deliberately foresees only inputs and outputs in the process of consulting leaving it to consultants to apply different methods of work with clients. This has encouraged innovation and diversity that consultants must apply in their work. As the framework of providing services in consulting has already been clearly defined, skills to provide consulting services are reflected in the commitment to each organization separately.

Insight into the statistical data on the number of certified organizations and standards that have been implemented in those organizations unfortunately does not tell anything of the quality of these systems and the improvements that they bring, primarily to their business system and then to the development on the local, regional or global level. Although the standards are the framework within which we must operate in order to meet the requirements, there is always the opportunity for experts

who work on the implementation of these systems to make their unique "stamp". Within professional circles it is well known that a management system must rely on System and Process approach. However, in order for the consultant to be on his way to be proud of his work, he should apply Holistic approach.

Seldom is an organization really identical to another one, so it goes without saying that the consulting should be tailored to the differences. Any management system must be implemented so that it is perfectly suited to the organization and not to be "a tight shoe." Often, in practice, we see systems that focus on documentation and form and the proof during a certification audit can only be seen on paper by repeating platitudes composed of technical terms of each individual management system. What is the added value of such management systems on an everyday level, it is hard to assume and measure.

2. 3D MODEL – HOLISTIC APROACH TO CONSULTING

Consulting is a profession universally accepted and well entrenched throughout the business world. Whether it is providing objective analysis, supplying a specific expertise, managing a project, or simply adding extra manpower, consultants can add value (Pliner N., Thrall J., Boland G. and Palumbo D., 2004). In order to achieve the best results and meet the goal of implementation in each segment, it is necessary to approach completely, i.e. holistically. Knowing that any form is geometrically best represented in the three-dimensional coordinate system, and that this is the only way to examine its real dimensions, we will apply the same analogy to consulting services aimed at the creation of a particular organization in accordance with the requirements of the quality management system, environmental management, occupational health and safety, information security and others Figure 2.

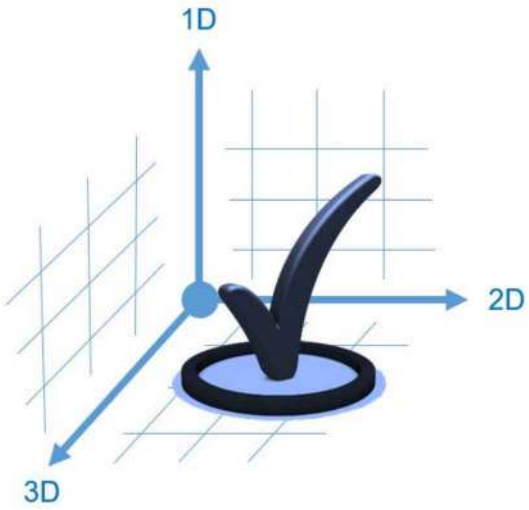

Figure 2: Dimensions of holistic approach to consulting

2.1. The first dimension – organization (1D)

- Size of the organization
- Method of organizing
- Type of business activity
- Financial and infrastructural capacities.

The volume of documentation to be expected depends largely on the **size of the organization**. However, conclusions should not be made ad hoc. Usually when we hear that the organization has a large number of workers or more locations, it can be assumed that it is a complex and demanding organization. Although in most cases, a more extensive work on the implementation of the system may be expected, sometimes this is not the case. Attention should be paid to the number of

employees in certain workplaces, processes should be identified and the mode of communication should be determined.

For example: production organization which has 400 workers and complicated process model cannot have the same volume of documentation as a distribution organization that also has 400 workers. Distributor organization has mostly employed the drivers who do the delivery and this is the most important process for them. On the other hand, in the manufacturing organization, arranging of production requires much more attention and precision, and the connection with other processes is multiple

The previous example touches **the type of the activity**, which also greatly affects how the requirements of the standard will be met. In this case there is also a link with the third dimension of the model, which, among other things, provides legislation that sometimes significantly differs for various activities. Those who provide consulting services should take into account that the process of standards implementation will run faster and easier if the consultant who personally lacks technical knowledge of the industry, hire a person who will act in the capacity of expert advisor.

The method of organizing, regardless of the management system, affects the allocation of responsibilities, powers, speed and effectiveness of internal communication. There are many forms of organizing but everybody has an obligation to describe them in detail through the organizational charts and job systematization. Consulting must begin by learning the methods of organizing.

For example: Statistically the most common is a functional method of organizing, however there are organizations that have chosen project method of organizing. If one looks at just this aspect of an organization, it is clear that the management system itself will vary. While the first organization must clearly identify all the functions because their job descriptions are separated, the second organization focuses on projects.

Very often, the measures that can realistically be implemented by the organization depend on **financial capacities**. This is especially true for the infrastructure for which it is usually necessary to engage significant financial resources. Some activities, such as food production, for example, have specific requirements when it comes to infrastructure. A consultant does not need to know exactly how much funding the organization has but it is necessary to gain insight into their capabilities and show understanding when proposing solutions that involve spending money. In this way, besides providing the best solution for the organization, consultants will also show their commitment to the organization and gain its trust.

2.2 The second dimension – human resources (2D)

It is not enough to understand a business, one should understand people as well. Although this often ends up with defining the organizational structure, division of responsibilities and determining the number of staff, consultants should pay more attention to employees. After all, they are the ones who will implement and improve the management system. In this regard, it is necessary to pay attention to:

- The educational structure
- The age structure and personal constraints
- The way of thinking
- The cultural framework.

Each consultant must be prepared to recognize the way of thinking of people working with him on implementation in order to get the right answers to the questions. It should be noted that the extent to which the consultant will motivate top management to participate fully in the implementation process also depends on this. In the case that the consultant speaks a language they do not understand, management will quickly pass their participation in the implementation process onto other employees.

If the organization has a large number of engineers or lawyers, the approach must be adapted to their way of thinking. Different professions have different views on the same issues. Sometimes the success of the implementation of the management system depends on that, so it is important to have insight into the **educational structure** of employees.

Besides educational structure, age structure is also important since sometimes solutions that are to be used depend on it too. This implies that the habits of experienced people are probably already formed and it is better to use solutions that they are used to as this will ensure efficiency and effectiveness in the implementation of quality systems. This applies particularly to information technologies the changes of which are more easily followed by younger generations who are susceptible to significant changes.

Also, the argument is that manufacturing SMEs have not considered socio-emotional and intellectual factors and ethics values within a quality culture, that is part of an integrative model of QMS to improve the aptitude and attitude of people who represent the most important value faced to any other asset in the business, and can carry an innovation process and value-added products and service to get customer and stakeholder satisfaction (Hernández, González and Aquiahuatl, 2011).

All of us in some way participate in the struggle neither to let **personal constraints** to reflect on the job nor the employee to be treated differently because of that, but in certain situations it is important to choose a solution that will fit into personal limitations. It is therefore very important to have that type of information as well. How ignorance of this aspect in employees can directly influence the implementation and sustainability of the system, can be seen from the following example:

For example: The obligation of any organization that is engaged in the production of food is to provide separate kits for the maintenance of hygiene in industrial and sanitary facilities. One of the common ways to solve this is to purchase kits of different colors. The organization has implemented this method, done risk analysis, defined work procedures, formed the records, provided kits, however it was found after two months that one of the hygienist is color-blind and very often mixes kits. The hygienist in question considered that this is the rule and did not question the decision of management and no one asked if such separation of cleaning kits suited her. Such a mistake at first glance may seem trivial, but it can unfortunately lead to disastrous consequences in case of contamination of food by bacteria of fecal origin.

The business world usually takes into account the organizational culture and works on its construction, however, when it is necessary to introduce certain changes, the general cultural context must also be taken into account. The beauty of the management systems is that they are designed to fit into any country, however consulting must have more knowledge of the cultural environment into which the management system has to be implemented. This applies to both communication with people and the solutions that are an integral part of the management system. It must be borne in mind that sometimes people are very sensitive to disrespect to their cultural values and that can be one of the main obstacles in the implementation process.

2.3. The third dimension - socio-legal framework (3D)

Through the first two dimensions the internal environment and the characteristics were considered, however the third dimension that is focused on the external environment is required for a more complete insight. Some elements of the environment are:

- Legislation
- Interested parties (social framework)
- Customary law.

It is well known that legislation is the basis for all management systems. Virtually all solutions of management system must be in accordance with the legislation. In addition to standards obliging organizations to undertake regular monitoring and implementation of legislation, it is important that consultants have precise knowledge of legislation. They are required to have the skill of interpretation of the law, on which sometimes depends whether the organization can adequately coordinate the requirements of the standards and requirements of the law.
In order for an organization to conduct business seriously, it must identify its **interested parties** and regulate its proceedings in accordance with them. Consulting should also seriously consider the interested parties because a number of activities that are part of the management system may depend on them.

For example: According to the claim of standards, a consultant has predicted that suppliers should be identified and evaluated, but has not conducted a detailed study of the structure of suppliers. Without

this information, procurement procedures were established, which projected that foreign suppliers should be contacted every Friday, with the obligation to confirm the deliveries for the beginning of next week. The idea of this solution was to organize "Just in time" supply and to reduce storage costs. However, as soon as the first week of the application of the procedure, it was found that 30% of suppliers come from the Arab region and it was not possible to apply the approach because Friday is their day off.

The importance of customary law may sound redundant when considering the approach to consulting. However, in all communities, there are traditions deeply rooted in the behavior and although not part of the legal and legislative norms, they often carry the same weight. They should be taken into account both in the part that relates to the communication between the consultant and representative of the organization and in the creation of solutions as part of the management system.

3. POTENTIAL PROBLEMS IN CONSULTING

In every profession, although it sometimes indicates problems, experience actually represents a source of valuable information which identifies room for improvement and raise the knowledge and skills to a higher level. Therefore, it is necessary to recognize the potential problems that may arise in the consulting business because it is the only way to prevent their actual occurrence.
Some of the problems could be:

- **Routine** - mapping systems from an organization of the same type of business activities. - In practice organizations that have the same business activity, sometimes have only that in common, the same activity. The process model may be different, the method of organizing also, as well as many other elements that are of great importance for the design and implementation of a management system.
- **Establishment of documentation without taking into account the level of knowledge of those who will actually use those documents**. – Grudzień Ł., Hamrol A. (2016) discuss the main function of information found in process documents is to provide knowledge regarding how to executing a process and to standardize this process by providing a specific path of execution. However, it is not easy to determine a standard level of quality of process information optimal from the viewpoint of the owner and the process executor. After the consultant leaves, documentation that remains has to be an essential tool in the everyday work of the organization. If what it says is clear only to the consultant, it is not a system that will bring the improvement to the organization.

  For example, if people with disabilities are hired for simple operational tasks, what should the instructions be like? Will the paper full of words be more useful than pictogram with simple sentences? Probably not.
- **Meeting the form and not the substance** - every document of the quality management system or any other management system must have a defined shape, however it must seriously deal with the substance. If the document does not give precise answers who needs to do what, when and where, it usually deals more with the form rather than substance. This potential problem particularly applies to procedures.
- **Developing a system for external auditors** – To cut corners – All experienced consultants and their systems were subject to certification audit and as professionals they record remarks of external auditors. Since the auditors have the freedom to interpret the extent to which a requirement is met, consultants may unconsciously think not about how to really help the organization but to go through the audit without any complaints. To a consultant the client should always come first. His task when it comes to the external check is to defend a system that he designed specifically for that client.
- **Too little time to get to know the organization and establish the initial balance** - Market needs - Although in practice sometimes to customers a motive for entering into the process of implementation of an international standard is not primarily the improvement of its operations, but only the requirements of the market, the consultant still must provide sufficient time to get to know the organization itself.
- **Lack of creativity** - Whether consultants will literally apply all the requirements of the standard, or they will have an innovative look at them always depends on their interpretations of standards, personal styles and experiences. Regrettably, completely uninteresting documents and solutions that add no value to management system may be encountered in practice. One should bear in mind that clients must recognize themselves in the

documentation. It is not good if it takes only one look on the documents to recognize the consultant who worked on the implementation of the system.

- **Inadequate volume of documentation** - generally accepted claim that **"what is not written, has never even occurred"** may be supplemented by the following statement, **"but also if something was written down does not necessarily mean it happened."** Sometimes the wish of the consultant to create the best documented system may lead into oversize records which are burden for workers who have multiple tasks. Often in practice we find that the records are filled mechanically at the end of the day, sometimes without checking the actual situation. It is desirable that the consultant steps out of the generally accepted "fill in the chart" system. It is always good to ask whether this volume of documentation will provide the realistic data.

Also, according to Mingaleva Z. (2013) “consulting is carried out in the field of activity in which the ethical code is simply necessary. The basic ethical standard for the adviser means not to abuse the trust of the client. Only trusting the adviser the director can tell him about the problems in business and will allow him to use confidential information of the enterprise and will follow the recommendations”.

4. IMPACT OF CONSULTING ON BUSINESS SYSTEM

Greiner and Metzger (1983) define management consulting services as “an advisory service contracted for and provided to organizations by specially trained and qualified persons who assist, in an objective and independent manner, the client organization to identify management problems, analyze such problems, and help, when requested, in the implementation of solutions” (p. 7).

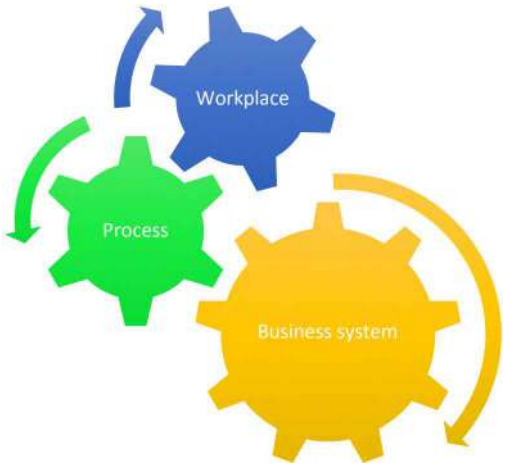

Figure 3: The mechanism of influence in one business system

When the process of implementation of a management system is entered, one of the main goals is to bring an immediate improvement to the organization and provide tools that these improvements are continuous in the future. On the effects of the application of quality systems or other management systems, there are a numerous studies and works and they all clearly testify to the positive effects on the business system.

However, in order to know how consulting influences what the effects will be like, it is important to understand the mechanism of influence within the business system (Figure 3). Unless even the slightest positive change is brought to each position, we cannot expect that the entire operating system will benefit from the management system.

4.1 The mechanism of influence in one business system:

- Workplace
- Process
- Business system

The direction of the individual workplace determines the direction of the entire business system. Mutual influence is inevitable and the only proper one in a well-implemented system.

The consultants are asked to give advice, to discover and propose solutions and to participate in their implementation in a wide range of issues related to company management. If we are to look just at the pole of the field of action of the consultants we may say that they can offer either classical solution, tested methods, properly defined instruments, in a standardized format, or new methods, solutions and instruments tailored to the specific situation of a client (Ciumara T. 2011).

Sometimes the opinion of operatives is unconsciously disregarded in the implementation of the management system. Thus is the initial and expected resistance only increases and the expected change will not be possible. It is extremely important that all employees, regardless of hierarchical levels understand that it is in the interests of them all and why it is important for the entire business system. If they their personal role in the improvement of the organization is clearly presented to them, the greater the chance that they will not only scrupulously respect the rules of the system, but also possibly make suggestions for improvements. For example, small number of employees, which means cumulative responsibilities and functions, especially in manufacturing companies, reducing the number of procedures, along with a document management using information technology, can be a solution to simplify QMS in order to increase its effectiveness (Pop L. D.,2016).

All data which are discussed in the annual management review speak of the importance of a single employee. Consulting service suppliers have the obligation to explain how the operation of one employee affects the operation of the other, how it reflects both on the process and the entire business system. Until a consultant does not ask himself who he designs the system for, the implementation and application of the management system can give unexpectedly bad results.

5. CONCLUSION

The term "holistic" is mentioned in the literature together with the description of the quality system however it is necessary that the approach in its implementation also be holistic. Thus the circle that leads us to permanent improvements is closed. From all aforesaid, it can be concluded that the consulting is more than just a job. Management consultants are often central figures in not only the promotion and diffusion of new organizational practices, but also their implementation (Wright, Sturdy and Wylie, 2012). As it were, it has a unique mission that can bring a lot of benefits not only in the level of the business world but in generally. The model presented is a good tool that helps in understanding all the basic elements that can affect both the effectiveness and the uniqueness of the implemented management system. The model also implies that the consultants should have a wider knowledge and a lot of experience in real business systems. By raising awareness of the seriousness of the consulting work, we encourage the next generation to improve methodology and maintain credibility that this profession requires.

According to Srinivasan R. (2014) the challenges facing the management consulting industry fall into three broad categories:

- Competition and differentiation
- Organizational design of the management consulting firm
- Internal organization of knowledge flows to serve client needs

Ciumara T. (2011), discuss most of the consulting services are situated somewhere between absolute standardization and absolute innovation. It is important to find a balance between innovation and standardization to maximize the results of all agents involved. As Larina L. N. (2015) discuss the system of components management should correspond to a flexible structure, adaptable to users' needs and a changing environment, which organizes and maintains the processes' functioning and creates a medium for their existence. The quality management system is an integrated instrument of management for all processes. It is necessary, however, to form not only the quality system as a priority, but also the integrated management system as a whole, and there it is important that consultants play a key role.

FMEA APPLICATION IN RISK MANAGEMENT AS RESPONSE TO THE ISO 9001:2015 REQUIREMENTS

Sanja Markovic[*1], Jelena Ruso[1], Ana Horvat[1]
[1]University of Belgrade, Faculty of Organizational Sciences
[*]Corresponding author, e-mail: sanjamarkovic035@gmail.com

Abstract: *The requirements in newest revision of the quality management standard ISO 9001 are related to risk management. For organizations in transition phase there is the challenge of meeting these requirements. Therefore explored was the identification of the critical risk points in telecommunication service using quality method Failure Mode and Effect Analysis (FMEA). The case study regarding spreading failures by causes was performed during the period of one year in Telecom Serbia Company. Findings of the case study on the application of FMEA has shown that this is a good model for performing risk assessment in telecommunication industry in accordance with quality management system requirements. Corrective actions were proposed for detected failures. Implementation of this actions leads to a greater quality of telecommunications service.*

Key words: *FMEA, ISO 9001, risk management, telecommunication service, Risk Priority Number*

1. INTRODUCTION

As an International Standard, ISO 9001 (Quality management systems - Requirements) is subject to review on a regular basis. When considering the 2015 revision, the committee responsible decided that some changes were necessary, such as Clauses related to “risk”. Risk-based thinking is something we all do automatically and often sub-consciously to get the best result. The concept of risk has always been implicit in ISO 9001 - this revision makes it more explicit and builds it into the whole management system. In previous editions of ISO 9001, a clause on preventive action was separated from the whole. Now risk is considered and included throughout the standard. For example, In Clause 6 the organization is required to take action to identify risks and opportunities, and plan how to address the identified risks and opportunities (ISO 9001:2015).

Therefore the paper will focus on widely used quality method (Failure Mode and Effect Analysis - FMEA) and its application in services. In that manner, we try to identify risk points in enterprise in order to prevent and eliminate defects in service processes. FMEA is a step-by-step approach for identifying all possible failures in a design. The model fulfils the basic requirements of ISO 9001:2015 reference in terms of identification of the main and auxiliary processes.

The aim of paper is to identify the critical risk points in telecommunication service and, in accordance with that, suggest preventive and corrective measures. The first part of paper talks about literature review and FMEA method. The second part of article is focused on research methodology and third part is dedicated to case study on the application of FMEA method in telecommunication services in Serbia, more precisely Telecom Serbia Company. In this paper we have a detailed description of how the estimates were awarded and how we get risk priority number (RPN) for definition of the necessary corrective actions and their priority such as preventive measures to management risk.

At the end we discus about what we have done through the research and about practical solutions that could find their application in the future.

2. LITERATURE REVIEW

FMEA is the best analytical method, because allow for establishing links between causes and effects of defects, as well as searching, solving and withdrawing the best decisions concerning applying

proper action" (Dudek-Burlikowska, 2011). FMEA was developed for the US Army as an official analysis methods. Military Procedure MIL-P-1629, entitled "Procedures for Performing a Failure Mode, Effects and Criticality Analysis" originally dates from 1949. (The International Marine Contractors Association, 2002).

"FMEA is a methodology for analyzing potential reliability problems early in the development cycle where it is easier to take actions to overcome these issues, thereby enhancing reliability through design. FMEA is used to identify potential failure modes, determine their effect on the operation of the product, and identify actions to mitigate the failures. A crucial step is anticipating what might go wrong with a product". While anticipating every failure mode is not possible, the development team should formulate as extensive a list of potential failure modes as possible. The early and consistent use of FMEA in the design process allows the engineer to design out failures and produce reliable, safe, and customer pleasing products . FMEA does also capture historical information for use in future product improvement" (Huber and Mraz, 2005).

All products and processes follow these ten steps of FMEA method (McDermott et al., 2009):

- Review the process or product;
- Brainstorm potential failure modes;
- List potential effects of each failure mode;
- Assign a severity ranking for each effect;
- Assign an occurrence ranking for each failure mode;
- Assign a detection ranking for each failure mode and/or effect;
- Calculate the risk priority number for each effect;
- Prioritize the failure modes for action;
- Take action to eliminate or reduce the high-risk failure modes and
- Calculate the resulting RPN (Risk Priority Number) as the failure modes are reduced or eliminated.

FMEA is very popular risk assessment method which was the subject of many articles within different topic (Fazlovic and Karahmetovic, 2012, Mentes and Ozen, 2015; Mock et al., 2002; Ookalka et al., 2009; Rhee and Ishii, 2003; Tavne et al., 2010). For instance, Fazlovic and Karahmetovic (2012) analyzed internal processes in one of the telecom operators in the market of Bosnia and Herzegovina by FMEA methodology, and gave suggestions for quality improvement. They analyzed the following package dimensions: voice services, data transmission services and terminal equipment. Also, Vriezekolk et al.(2011) are one of those who recommended FMEA as a way to analyse telecom service model in order to perform a risk assessment in crisis management where is essential knowing their service availability risks. Similar to previous authors, Pranoto and Nurcahyo (2014) used FMEA to identify the root cause of Network Performance High Speed Downlink Packet Access in telecommunication industry. They used this method „to examine the failure of a potential product or process, evaluate the risk priority, and help determine the appropriate action to avoid the problems that have been identified" in telecommunication industry with the purpose of quality improvement. Gómez Fernández et al. (2016) applied FMEA in a telecommunications company to measure the influence of failures occurrence on losing customers.

Likewise, Zeng and Chun (2010) in China used the same method for risk management analysis within Integrated Management System, that includes OHSAS 18001 (occupational health and safety management), ISO 14001 (environmental management) and ISO 9001 (quality management). The authors showed the application of this method in organizations, where FMEA helps them to identify potential risk problems. They've discovered five major potential risks, including "Roof related falls", "Elevator shaft falls", "Holes in flooring on construction site", "Hit by falling objects", and "Run over by operating equipment" that are graded to be unacceptable, and suggested minimizing them using prevention such as protection.

In addition, in paper written by Xiao et al. (2011) „the minimum cut sets theory has been successfully incorporated into the traditional FMEA for assessing the system reliability in the presence of multiple failure modes". They „expanded the definition for RPN by multiplying a weight parameter to characterize the importance of the failure causes or components. Following the weighted RPN, the utility of corrective actions is improved".

3. RESEARCH METHODOLOGY

Telecom Serbia Belgrade is a modern, fully local telecommunications company that has the leader role in the field of home and mobile telephony, Internet and multimedia, both in Serbian and in the region, for the past 18 years (Telecom Serbia, 2016). The subject of FMEA analysis refers to the executive unit Jagodina and includes spreading failures by causes during the period January-December, 2010. The total number of observed failures is 129, sorted by the causes. The data were obtained in the company Telecom Serbia, executive unit Jagodina, with the approval of the General Director, at the request of a competent person for maintenance and repair. Original data contains objects grouped by interference, with defined causes of interference for each object, numerically and by percentage displayed eliminated interference as well as other parameters on which the estimate RPN (Risk Priority Number) was configured. Following the example of McDermott (2009), we estimated the next parameters:

- Severity (S)—The consequence of the failure should it occur.
- Occurrence (O)—The probability or frequency of the failure occurring.
- Detection (D) —The probability of the failure being detected before the impact of the effect is realized.

In order to help defining these parameters, some values were calculated:

• mean time between failures (MTBF);

$$MTBF=t/r \tag{1}$$

• failure intensity (ƛ);

$$ƛ = 1 / MTBF \tag{2}$$

• the total time of inactivity (Down Time) -The average duration of the interference.

Assessment of the probability of occurrence and failure severity were obtained using Ford's scale (Ford, 1996), while the estimate of the probability of detecting failure was based on the opinion of experts (Reliability and Risk Analysis, 2016). RPN is a mathematical product of numerical score for Severity, Occurrence and Detection:

$$RPN = Severity \times Detection \times Occurrence \tag{3}$$

It is used to determine the priority items that require additional quality planning or action.

4. CASE STUDY

In order to estimate risk priority number for further risk management, failure Severity-S, likelihood of Occurrence-O, and probability of Detection-D of every failure effect was measured.

The assessment of probability of Detection-D was obtained using the opinion of experts. The question that was asked during the visit to the company and interview with experts was: "What is the probability of detecting a system failure before the service user observes it and reports the malfunction? According to the submitted scale, where the scope of score ranges from 1-10, rate the probability of

detection while having in mind that the score is inversely proportional to the possibilities of the detection capabilities, so that failures with the least possibility of detecting will have highest score, and vice versa.

Probability of Occurrence-O was based on the MTBF (Mean Time Between Failure) value, which represents the ratio of total time in which the failures are observed (in this case represents a period of one year) and the number of failures in the stated period for every interfered object.

Example: In the case of ADSL user equipment, where the fault was observed in incorrect connecting, the number of removed interference would be 23 over a period of one year, or 8760h, where the ratio of this two would give us the mean time between failures, MTBF = 8760/23 = 381. Then, using Ford's scale we can determine that the value belongs to the range corresponding the score of 7 on given scale. Part of the table that relates to the mentioned interference and the probability of occurrence are given below.

Table 1: Annual report on the interference of 2010, the executive unit Jagodina (Excerpt 1)

Interfered Object	**Cause of failure**	**Interference removed**	**MTBF**	***Occurrence***
ADSL user equipment	Incorrect connecting	23	381	7

Assessment of the severity of the effects of failure (Severity-S) was obtained based on DT (Down Time), is total interval of failure, which represents the average duration of removed interference.

Example: Assessment of the severity of failure, calculated on the same case which was taken for assessing the probability of occurrence, is calculated using total time of inactivity which represents the average duration of removed interference, which in this case is 68 min, or 1.33h. By using Ford's scale it is determined that the severity score is 6. Part of the table containing mentioned information is provided below.

Table 2: Annual report on the interference of 2010, the executive unit Jagodina (Excerpt 2)

Interfered Object	**Cause of failure**	**Average duration of interference removal**	**DT**	***Severity***
ADSL user equipment	Incorrect connecting	68	1,33	6

In cases where the scale does not precisely define boundary between grade 5 and 6; 6 and 7; 7 and 8, the value which is closest to the inactive time (DT) was chosen.

Below is part of the FMEA worksheet that contains information on ways of failure, failure descriptions, the causes of failure, as well as the assessment of failure severity, probability of occurrence and the probability of detecting any effect of failure. Based on those values the estimate RPN was configured and preventive measures that could forestall failure occurrence or soften its effects and accelerate the possibility of detection were proposed.

Table 3: FMEA worksheet

Object	**Failure Description**	**Cause of failure**	**S**	**O**	**D**	**RPN**	**Preventive measures**
ADSL user equipment	User equipment	Inadequate equipment	6	4	7	168	Mandatory application and submission of procedure which defines the types of equipment.
ADSL user equipment	User equipment	Incorrect configuration	6	6	7	252	Testing the equipment before the mounting.
ATC	Commutation equipment	Age of equipment	6	8	3	144	Recycling and disposal of obsolete equipment in accordance with the Law and regulations.

Base station	Wireless network	Loss of power	5	7	4	140	Introduce greater quality equipment control.
Box	Wireless network	Equipment quality	5	3	10	150	Introduce greater quality equipment control.
FM	Wireless network	Unknown	6	2	10	120	Periodic inspection and maintenance of equipment in accordance with the instructions for maintenance.
Main hub	Wireless network	Poor quality construction	6	4	10	240	Training employees for work on field.
External copy	Wireless network	Cable sheet damage	6	9	10	540	Protect cables by placing insulation and protective equipment.
Telephone booth	Group fault on Telecom equipment	Third party	6	2	5	60	Periodic inspection and maintenance of equipment in accordance with the instructions for maintenance.
Internal copy	Wireless network	Reconstruction of the access network	6	2	10	120	Informing users about the reconstruction period.
Main cable	Wireless network	Creeping cable	4	2	10	80	Protect cables by placing insulation and protective equipment.
Distribution cable	Wireless network	Incorrect maintenance	4	2	10	80	Application of instructions for maintenance and staff training.
Cable hub	Wireless network	Severe weather	6	3	10	180	Protect machinery and equipment from severe weather by placing the appropriate protective box.
Network Termination (NT1)	User equipment	Unprofessional handling of NT ending	4	2	7	56	Application of instructions for use and training.
PCM	Wireless network	Power fallout	6	7	10	420	Introduce more frequent control of telecommunication installations

Based on the given FMEA worksheet, in which RPN is calculated, priority of corrective actions is determined. Failures with the highest RPN value have priority in the implementation of corrective actions. Sorting of failures by RPN was done in descending order, and after completion it came with the following conclusion: from the total number of failures that have been analyzed, which in this case is 129, 32 failures have RPN greater than 400, which represents about 25% of the total number of failures, while as many as 103 failures have RPN greater than 125, indicating that nearly all failures have an extremely high risk level.

While analyzing failures with the RPN higher than 400, which represent an unacceptable risk, following corrective actions were established (sorted by the priority of actions):

- Protect cables by placing insulation and protective equipment.
- Recycling and disposal of obsolete equipment in accordance with the Law and regulations.
- Informing users about the reconstruction period.
- Protect machinery and equipment from severe weather by placing the appropriate protective box.
- Periodic inspection and maintenance of equipment in accordance with the instructions for maintenance.
- Application of instructions for maintenance and staff training.
- Introduce more frequent control of telecommunication installations.

5. CONCLUSION

The subject of research is the analysis of maintenance in telecommunication company Telecom Serbia, the executive unit Jagodina, using FMEA method, with the goal of continued administration of potential risks as part of the international standard ISO 9001: 2015.The subject of analysis were failures and interferences of the system, along with their causes, that occurred during the 2010s. All the basic data used for the actual implementation of the method were collected during the visit to the company. Based on the description of failures and data on the manner and cause of the failures estimates were made for the severity, probability of occurrence and detection of any failure effects. Using these parameters RPN was calculated, sorted in descending order, and used to determine the priority of corrective actions, which were defined by the completion of the analysis.

The limit which represents an unacceptable risk in the system was determined, and failures in which the RPN exceeded defined limits were specifically discussed, as well as the actions that affected them. Corrective actions that have been proposed to accelerate the ability of detection, prevent failures in system or soften their effect, are applicable to all parts of the observing system and can lead to strengthening the position of Telecom Serbia in the market and achieve higher customer satisfaction by increasing the reliability and quality of a major part of their services.

Certainly the most important action to implement is the protection of cables used for installing devices that clients use. Furthermore, same protection should be built on network installations, by placing protective tapes that will prevent damage to the cable sheath and other damage that can lead to cable breaks and therefore the loss of flow of signals necessary for the provision of services. Recycling and disposal of old equipment is also a measure with a high level of priority, because it can cause additional costs and lead to customer dissatisfaction, while satisfied customer is one of the most important goals of the company. It is important to constantly check the accuracy of the equipment, and if found to be worn, act in accordance with the law that applies to recycling, recycle and dispose it properly in order to prevent its unintended use.

If it is a period of reconstruction of telecommunication facilities, or any type of activities that can lead to malfunctions or even downtime, it is necessary to promptly inform customers and, if possible, provide them with an alternative to be able to access the network.

Weather conditions are very common occurrence that may cause adverse effects to the equipment which is not protected well when installed. If the devices used for receiving signals and other switching equipment are located outdoors, it is necessary to put them in appropriate protective box resistant to any influences from the environment (including natural disasters, as well as physical damage).

As already mentioned above, the equipment should be periodically reviewed and maintained in order to maintain in proper condition. Because of this, it is necessary to have instructions for maintenance, that the employee will follow and which will contain regulated ways for the reviewing and maintaining as well as recommended frequency of inspection. Likewise, the manual should be also delivered to users when their product is installed, and they are expected to follow the same. Employees must go through the proper training to be competent with appropriate knowledge, skills and experience to perform duties of providing all kinds of services. This applies to all, from those who work in the field, to operators and workers who are in direct contact with users.

And finally, quality control of devices customers use to acquire their services, as well as control of telecommunication facilities that enable them to do so is of crucial importance. The Law regulates the actual process and it is necessary for it to be performed by a professional team, at least twice a year, in order to reduce failures to the lowest possible level.

QUALITY OF SOCIAL RESPONSIBILITY ACTIVITIES AND STAKEHOLDERS NEEDS IN SERBIAN EDUCATIONAL INSTITUTIONS

Bojana Lukić*[1], Maja Glogovac[1], Nedeljko Živković[2]
[1]Faculty of organizational sciences, University of Belgrade, Serbia
*Corresponding author, e-mail: maja.glogovac@fon.bg.ac.rs

Abstract: *Although many authors point out the multiple benefits of social responsibility for not-for-profit organizations, there is no many research about attitudes of educational institutions of such activities. The survey conducted in this study aims to determine the importance as well as the level of quality of social responsibility behavior of educational institutions in Serbia. Social responsibility activities are observed through three groups: charity work (donations and providing free education), getting involved in research beyond the curricula; cooperation with the corporate/business community. When it comes to the all of the social responsibility activities, results indicate a satisfactory level of the respondents' consciousness, but the implementation degree is not seen as high. The results are compared with results of such research in educational institutions of other countries Hence, the analysis can be useful for social responsibility - related positioning of the institutions and for the revealing the level of their social responsibility consciousness.*

Keywords*: social responsibility, educational institutions, quality and importance of social responsibility*

1. INTRODUCTION

Social responsibility refers to ensuring the success of a business by the inclusion of social and environmental considerations into a company's operations (Chopra & Marriya, 2013). Social responsibility is about values and standards by which a business operates and commitment of a business to behave ethically, operate legally and contribute to socio-economic development while improving the quality of life of its employees and their families as well as local community and society at large (Mang'unyi & Chege, 2014).

Organizations around the world, and their stakeholders, are becoming increasingly aware of the need for and benefits of socially responsible behavior (ISO 26000:2010). The perception and reality of an organization's performance on social responsibility can influence, among other things, its stakeholders which can also reflect the quality management system of the organization. Especially in view of changes of ISO 9001:2015, all the stakeholders have to be taken into consideration when designing quality management system. The international standard ISO 26000 provides guidance on the underlying principles of social responsibility, recognizing social responsibility and engaging stakeholders, the core subjects and issues pertaining to social responsibility and on ways to integrate socially responsible behavior into the organization.

In the last decades social responsibility has forcefully and irreversibly become a part of the corporate actions of a growing number of companies and continues to provoke the interest of governments, international institutions, scientists and researchers (Slavoval & Bankovall, 2015). As such, the notion of social responsibility is becoming more prevalent in the curricula of universities also (Elobeid et al., 2016). However, according to Idowu (2008), researchers in the field of social responsibility have tended to concentrate more efforts on the social responsibility of profit seeking corporate entities. Unfortunately this does not appear to be the case when it comes to the social responsibility of not-for-profit (NFP) corporate entities such as educational establishments (schools, colleges and universities) and other NFP entities that play equally important roles in modern economies. After that, Ojha (2012) points out that social responsibility is becoming more central to the societal expectations from commercial organizations, with the possibility that spending a certain percentage of corporate income on societal welfare is likely to have legislative sanction. Education is the most powerful weapon which can be used to change the world and to help in lighting the darkness of the society (Singh et al., 2015). Collaboration of social responsibility with the core education will require a change in the mindset of all stakeholders in realizing the importance of rigorous evaluation of educational programs and willingness to alter policies and practices in the light of the findings. The desire to change the current state of education and of the current less-than-adequate regard for the impact of business on larger societies are, however, prerequisites (Nandi, 2013).

Certain academic institutions have recognized the activities which they consider to be important in their work. For example, Bundaleska and Dimitrova (2012) have pointed out that in Macedonia there is a lack of implementation of social responsibility activities, but have also made suggestions about which activities could be conducted in order to raise the level of social responsibility. Some of those activities are: designing the curricula in such a way that challenges students to evaluate business behavior along environmental, social, and ethical dimensions; establishing Social Responsibility Centers within schools and universities; raising awareness and understanding of social responsibility via various events, seminars, conferences, trainings, etc; valuing student effort trough awards for student projects and activities related to social responsibility and other. In Kenya, for example, a research by Mang'unyi and Chege (2014) has found that among the interviewed employees the statement social responsibility improves the school reputation had 75% of the responses being neutral. Most schools are not explicit in their social responsibility programs. However 15.625% strongly agreed and 9.375% agreed to the statement. The statement on social responsibility increasing employee motivation and retention was put and 84.375% of the responses agreed. Finally, 84% agreed and 16% strongly agreed that social responsibility protects resources on which the school depends. These resources include members of the community, the physical environment and employees. McDonald and Liebenberg (2006) have conducted a study to determine the level of understanding what social responsibility is and how it is perceived among employees in South Africa. They have found that there is no common understanding of social responsibility in South Africa amongst participants, or a common appreciation of the need for social responsibility. Participants generally confused social responsibility with human resources issues and felt that employee benefits and employee assistance programs should be primary areas of social responsibility focus within the organization. There was also a general tendency amongst participants to assume that social responsibility was more about spending money, than investing in a socially responsible manner

Besides the educational institutions that have only recognized the importance of social responsibility and are yet to implement social responsibility activities in their field, in some countries, there are educational institutions that are already implementing social responsibility activities. Some of those countries are listed below:

United Kingdom (Idowu, S.O. 2008):

- Widening participation;
- Developing and communicating performance on sustainable developments;
- Contributing both to national and international systems of university education;
- Managing the economic, social and environmental impacts of their activities;
- Take into account the interests of all stakeholders and act as good citizens;
- Joining Business in the Community (BitC) as an initial step;
- Responding to social needs in terms of education and Innovation;
- Engagement with corporate bodies through staff;
- Providing a more effective community service;
- Challenging, inspiring and supporting students to grow;
- Sustaining and adding value to country's culture, economy and the natural environment;
- To manage and govern itself with responsibility and sensitivity.

Kenya, Busia County (Mang'unyi & Chege, 2014):

- Provision of sanitary towels to 'unlucky' girls at school;
- Donation of clothing;
- Free education to needy bright children;
- Community use of school resources, e.g. playing ground, bore holes, school bus, electricity, etc;
- Subsidized training fees at resource training centers;
- Discussion groups with public schools.

Turkey, Istanbul (Dahan & Senol, 2012):

- Donation of their income for research;
- Free lessons for high school graduates;
- Free sports schools;
- Education made available to the poor;
- Courses, education centers etc.

Upon examining the data shown above it is concluded that these activities cannot be all observed as a whole so for the purpose of this paper they shall be divided in to three sub groups:

- Charity work (donations and providing free education);
- Getting involved in research beyond the curricula;
- Cooperation with the corporate/business community.

2. THE FRAMEWORK OF THE RESEARCH

2.1. The aim of the research

Although many authors emphasize the multiple benefits of social responsibility for not-for-profit organizations, very few have dealt with the survey of attitudes of educational institutions of such systems. The survey conducted for this study aims to determine the importance as well as the level of social responsibility behavior of educational institutions in Serbia. The results could be compared with results of such research in educational institutions of other countries. This analysis can be useful for social responsibility - related positioning of the institutions and for the revealing the level of their social responsibility consciousness.

2.2. Research questions

Taking into account the low level of social responsibility behavior research, there are two main research questions in this paper:

- Research question 1 – what is the level of social responsibility activities importance from the educational institutions point of view;
- Research question 2 – what is the level of social responsibility activities implementation the educational institutions.

2.3. Research instrument and sample characteristics

The research in this paper is conducted using the questionnaire. Through 20 questions, teachers expressed their attitude toward the importance and the level of implementation of social responsibility activities in their institutions. The Likert scale containing five levels was used for both the answers – the importance of social responsibility activities and the level of implementation of these activities. On the basis of the relevant literature, the elements that make social responsibility behavior involved in the questionnaire are:

- Help provided for students in welfare class;
- Institution involvement in any type of charity work;
- Students informing about the social issues trough the curricula;
- Staff engagement in some type of socially responsible activities;
- Students engagement in some type of socially responsible activities;
- Staff engagement in research that enables you to be socially responsible;
- Institution cooperation with other institutions on a wider scale (national, international) in the field of social responsibility;
- Institution cooperation with the business sector on social responsibility activities;
- Students opportunities to further their education trough the cooperation between the academic institutions and the business sector;
- The degree of social responsibility contribution to the reputation of academic institutions.

In the view of the standard ISO 9001 as well as the standard 26000, all the stakeholders should be taken into account when designing quality management system and social responsible activities. That is why several stakeholders are included into questions within this research.

The questionnaire was sent by e-mail to teachers of primary schools, high schools and faculties. From 50 questionnaires sent, we received and processed 35 questionnaires that were correctly filled out. The responding rate is 70%. The sample structure is given in Figure 1.

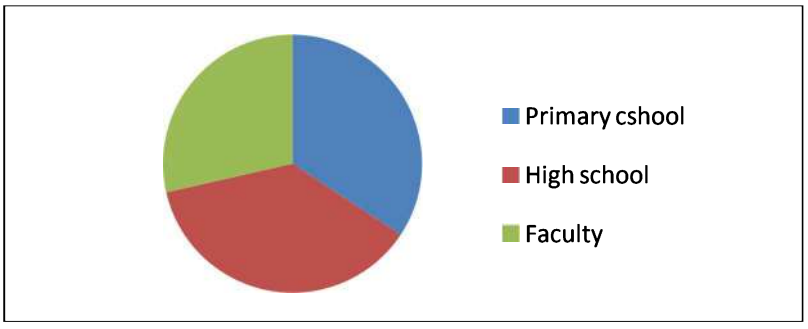

Figure 1: Sample structure

3. RESULTS

Ten key social responsibility activities are considered in this paper and results about the importance as well as the level of implementation of each activity are given and explained below.

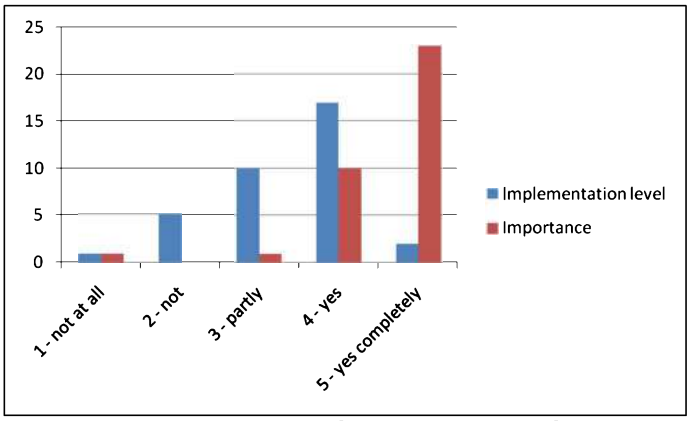

Figure 2: Help provided for students in welfare class

When it comes to the help provided for students in welfare class, it can be seen that there is a high level of recognition regarding the importance of providing help to students in welfare class. 28,5% of the teachers agree that help should be provided, and 65,7% absolutely agreed. When it comes to their opinion on if help is actually being provided, 48,5% of them consider that some form of help is provided, while 14,3% chose to answer with "no" and 1 with "not at all".

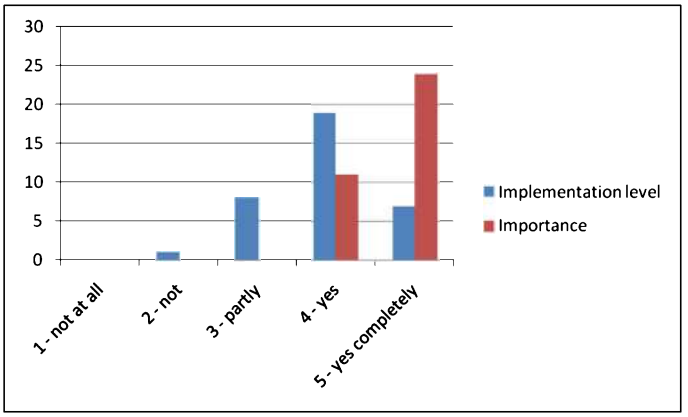

Figure 3: Institution involvement in any type of charity work

When asked about the school's involvement in any type of charity work, 19 of them consider that the school does some type of charity work, 18 answered with "partly", 7 with "yes completely", while one participant chose "not" as their answer. Similar as in the previous question, most of the participants of the survey recognized the importance of charity work, 68,6% of the participants strongly agreed with the statement that the institutions should be involved in charity work and 31,4% agreed with the statement.

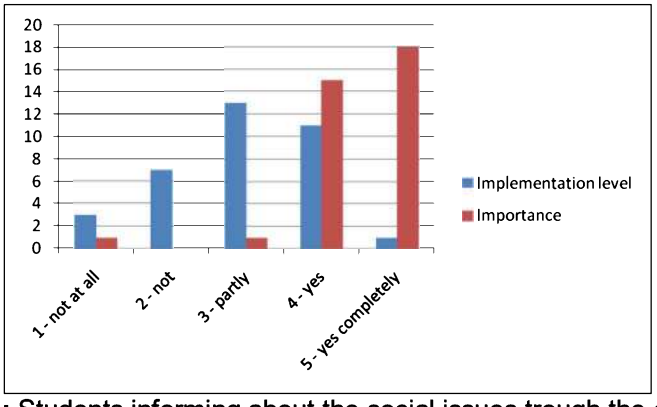

Figure 4: Students informing about the social issues trough the curricula

Regarding the informing students of social issues trough the curricula 37,1% of the participants consider the students to be partly informed, 31,4% consider the students to be informed, 20% found that the students are not informed, and 8,6% answered with "not at all". Only one of the participants answered with "yes, completely". As far as their views on the importance of the matter, 51,4% teachers completely agreed that students should be informed about the social issues trough the curricula, 42,9% agreed with the statement, and 2,9% of the participants answered with "partly" and "not at all" each.

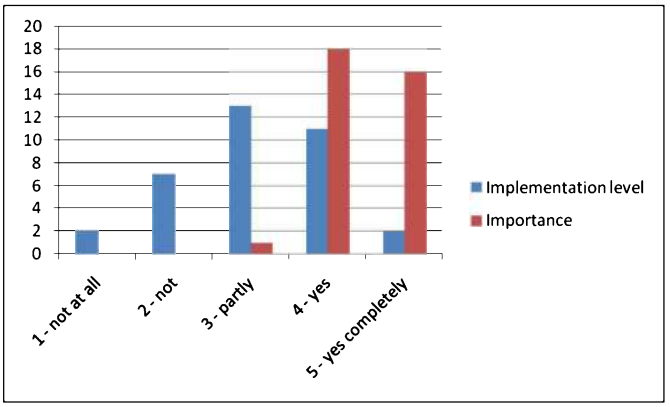

Figure 5: Staff engagement in some type of socially responsible activities

When asked about the extent to which the staff is involved in social responsibility activities 37,1% of the participants answered with "partly", 31,4% with "yes", 20% answered with "no", and options "not at all" and "yes, completely" were each chosen by 5,7% of the participants. On the other hand, when it comes to the importance of staff involvement in social responsibility activities, only 2,9% partly agreed with the statement, while 45,7% agreed completely and 51,8% answered with "yes".

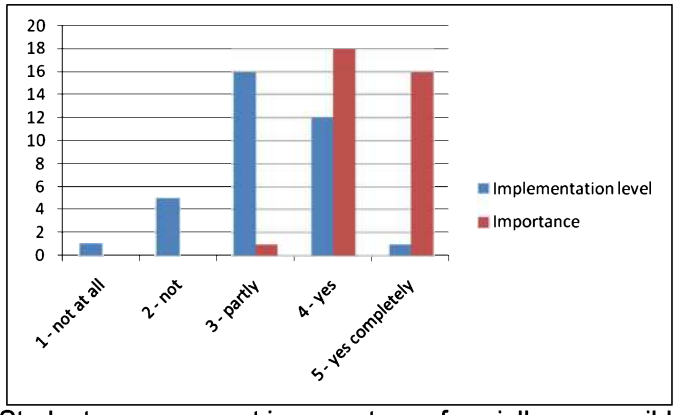

Figure 6: Students engagement in some type of socially responsible activities

Most participants consider their students engagement in social responsibility activities to be neutral, 34,3% consider them to be involved, 14.3% answered with "no" and options "not at all" and "yes, completely" were chosen by 2,/9% of the teachers. But only 2.9% consider this to be of neutral importance, while 45,7% thought this to be completely relevant issue and 51,4% answered with "yes" when asked if students should be involved in social responsibility activities.

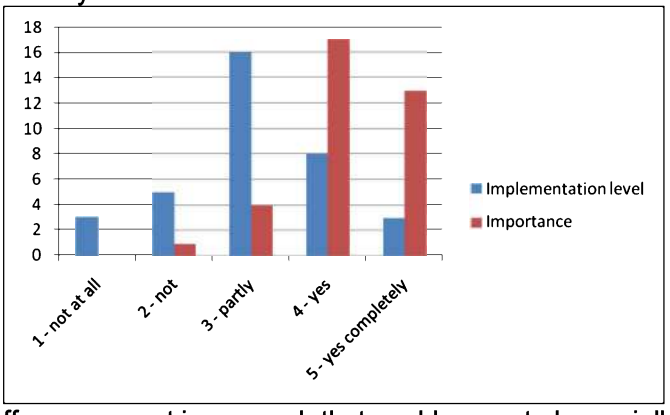

Figure 7: Staff engagement in research that enables you to be socially responsible

When asked about their involvement in research that enables them to be socially responsible, 45,7% of them were neutral on the matter, 22,9% said that they are involved in such research, 14,3% answered with “no”, while 8.6% of the participants answered with “not at all” and “yes, completely” each. 2,9% of the participants don’t consider this to be an important issue, 11,4% are neutral on the subject, 37,1% completely agreed that the issue is relevant and 48,6% answered “yes” when asked if such research is important.

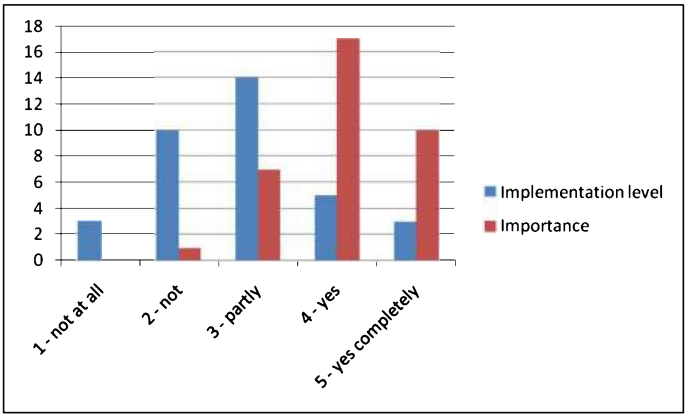

Figure 8: Institution cooperation with other institutions on a wider scale (national, international) in the field of social responsibility

40% of the teachers found that the institution they work for is neutral on the subject of cooperation with other institutions, 28,6% think that such cooperation does not exist, 8,6% thought that there is absolutely no cooperation, 14,3% think that there is some cooperation and 8,6% find that cooperation with other academic institutions is satisfactory. When asked about the importance 2,9% do not think such cooperation should be conducted, 20% are neutral when it comes to such cooperation, 28,6% find it absolutely important and 48,6% agree that it should be implemented.

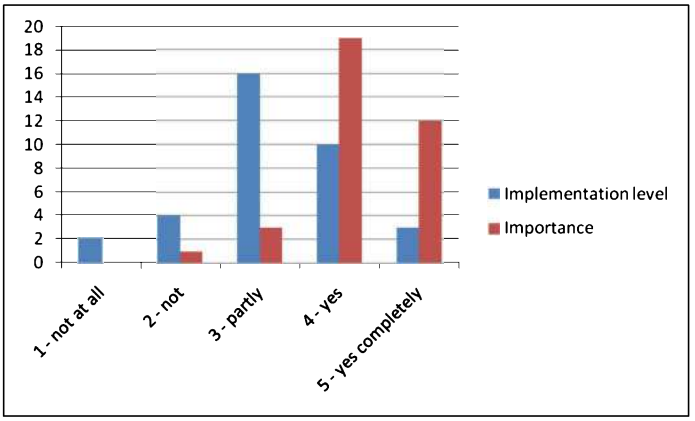

Figure 9: Institution cooperation with the business sector on social responsibility activities

Most of the teachers find their school to be neutral in cooperating with the business sector (45,7%), 28,6% thought that some form of cooperation exists, 11,4% think that there is no cooperation, 5,7% said “not at all” and only 8,6% thought that the level of cooperation is high. When it comes to the importance of such cooperation, only 2,9% don’t find such cooperation to be necessary 8,6% are neutral on the matter, 34,3% find such cooperation is absolutely important while 54,3% find it to be important.

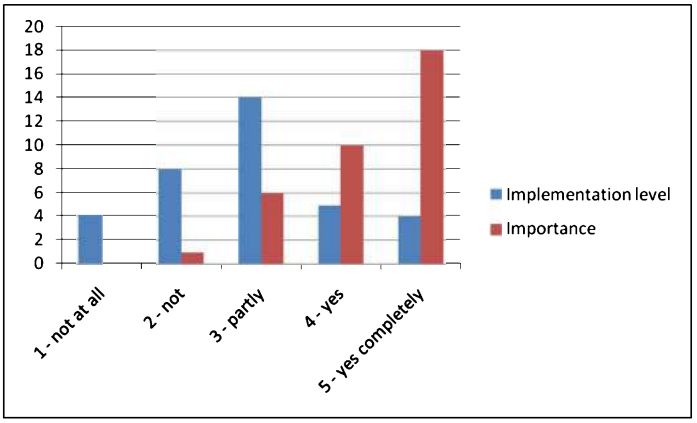

Figure 20: Students opportunities to further their education trough the cooperation between the academic institutions and the business sector

When asked if their students have opportunities to further their education trough cooperation with the business sector, 40% answered with "neutral", 22,9% answered with "no", 11,4% said "not at all", 14,3% of the teachers thought that there are opportunities for students and 11,4% answered with "yes, completely". On the importance of students furthering their education with such cooperation, 2,9% think that this is not important, 17,1% were neutral on the issue, 28,6% think that furthering students education in such way is important and 51,4% completely agree that this type of furthering students' education is important.

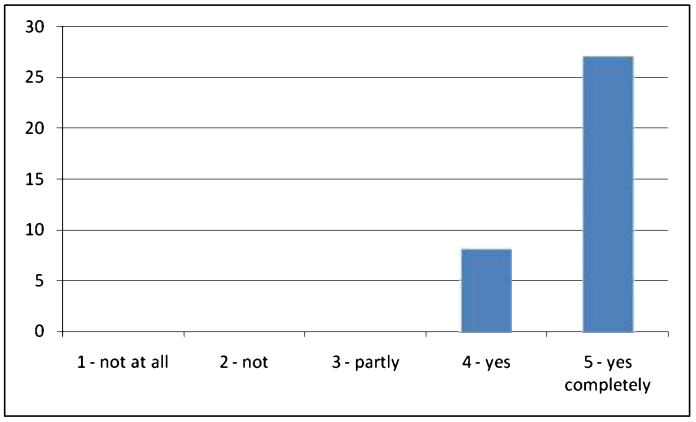

Figure 31: The degree of social responsibility contribution to the reputation of academic institutions

Finally, when asked if they consider if social responsibility activities contribute to the reputation of academic institutions, all participants agreed, with 22,9% answering with "yes" and the rest (77,1%) answering with "yes, completely".

4. CONCLUSION

The idea of this paper was to explore the quality of various social responsibility activities in Serbian education institutions and the key stakeholders' level of awareness of the importance of social responsibility in today's environment. Our biggest restriction was the small sample of teachers we had the opportunity to distribute the survey to. In order to have a more comprehensive understanding of the general state in the country a more extensive research is necessary, for which the authors of this paper did not have the appropriate conditions. Regarding the results of the research, we have concluded that on almost every issue, the level of implementation is mostly on a medium level while the teachers agree that all of these issues are of high importance.

First two questions, which fall into the first category (Charity work – donations and free education) show that most schools do have some type of social responsibility activities that are correlated to students in welfare class. The questions of the second category (getting involved in the research beyond the curricula), most of the schools are in the "neutral" category on every type of the activities that the poll suggested, but the level of importance was estimated as high by almost all teachers. From this we can conclude that while the schools perhaps do not have the means to conduct such activities, the benefits of this type of activities are recognized among the staff. The questions from the third category (cooperation with the corporate/business community) also showed that most schools have a neutral stand on the subject, but unlike the previous

category, less teachers consider this to be a valuable asset to both the schools and the students, seeing as some teachers when asked if they consider such activities have a positive effect choose the "neutral" option or simply answered "no". This might be a result of including primary school teachers in the survey, but the authors considered that the poll would not be as representative without their input on all issues.

From our research we can conclude that the academic institutions in Serbia can be placed in to the medium category when it comes to the implementation of social responsibility activities in education. We are yet to reach the level of implementation that the schools in UK have, but we have certainly surpassed the level that schools in Kenya for example are currently on. The teachers in our country already have a high level of awareness of the importance of social responsibility activities but the mechanisms of their implementation are yet to be developed. As for further academic research on this subject, inquires can be made to address the reasons of low implementation of social responsibility activities when there is a high level of awareness. Also, some suggestions about the ways of implementing social responsibility activities could be used as a guideline to show education institutions how to continue contributing society in new, innovative ways. The Guidance on social responsibility given in ISO 26000 should be incorporated into the design of organizations' activities that would direct them to include needs of all the relevant stakeholders.

WHO IS GOING TO BE MORE INTERESTED IN ISO 50001 CERTIFICATION?

Sanja Kandić
e-mail: kandic.sanja94@gmail.com

Abstract: *This paper's main purpose was to indicate whether the countries in Europe with a higher usage of renewable sources of energy are more interest in getting ISO 50001 certificates and which ones will be more interest than others in the future. Data regarding the usage of wind power and solar thermal power was gathered, together with the data about the number of ISO 50001 certificates in European Union Member countries in order to determine which have the highest renewable sources of energy usage and ISO 50001 certificates, and to see if those two are proportional. Member countries have been split in three groups based on the level of their usage of renewable resources of energy and data about the number of ISO 50001 certificates has been added in order to present those countries which might be interested in ISO 50001 certification most.*

Keywords: *ISO 50001, Europe, renewable energy, renewable sources*

1. INTRODUCTION

Standardization has been working hard to make this world a better place. Therefore, many standards have been developed in order to affect certain areas of life. In the 21st century resources have become a grave issue, threatening to bring economical fall, increase in hunger and many more other disasters. Producing and using energy is another very important issue to be dealt with. A great number of countries does not address these issues as seriously as they should, but some are doing exactly what needs to be done. Having this in mind, this paper will gather the usage of renewable energy sources in the European Union Member Countries and the number of acquired ISO 50001 certificates, in order to present which countries would be most interested in certification in the future and if there is a connection between the renewable energy recourses usage and the number of certificates. Those with a high rate of usage of renewable sources of energy and a number of ISO 50001 certificates that grows year by year, are very important for the future of Europe as a continent and the world as a whole, since they can serve as an example for others and be the leaders in this area.

2. LITERATURE REVIEW

2.1. Overview of the Standard ISO 50001

Using energy efficiently helps organizations save money as well as helping to conserve resources and tackle climate change.(ISO 50001:2011) "Organizations are supported to use energy more efficiently in all sectors by ISO 50001, through the development of an energy management system (EnMS)." The purpose of this International Standard is to enable organizations to establish the systems and processes necessary to improve energy performance, including energy efficiency, use and consumption.(ISO, Requirements with guidance for use, 2011)This standard is, like many others, based on the management system model of continual improvement which allows it to make it easier for organizations to integrate energy management into their system and raise quality to a higher level. "ISO 50001:2011 provides a framework of requirements for organizations." Those are:

- Develop a policy for more efficient use of energy
- Fix targets and objectives to meet the policy
- Use data to better understand and make decisions about energy use
- Measure the results
- Review how well the policy works, and
- Continually improve energy management , according to ISO 50001:2011.

Implementation of this International Standard is primarily intended to lead to reductions in greenhouse gas emissions and other related environmental impacts and energy cost through systematic

management of energy (ISO, Requirements with guidance for use, 2011). It is applicable to all types and sizes of organizations, no matter their geographical state or the cultural and social conditions. The Standard gives general requirements, management responsibilities, energy policy and planning and checking requirements.

Implementation of ISO 500001 is not obligatory. This allows companies to implement this standard simply because of the benefits both they and their environment can receive from it. Unfortunately, the number of companies which do not realize the vast specter of possibilities and benefits this standard offers, is great.

Many organizations think of energy consumption as a fixed overhead that can't be controlled nor reduced (ISO practical guide for SMEs, 2011). "However, energy consumption can be managed and even reduced if the right approach is used." Organizations that take action and implement this standard in the right way make significant energy savings, which lead to financial savings and all that without any additional investments in new machinery or technology.

According to ISO practical guide for SMEs (2011) some of the direct financial benefits of managing energy effectively are:

- Reduction of cost of energy consumption
- Reduction environmental impact from the use of energy and reduced CO2 emissions
- Reduction exposure to rising energy prices
- Reduction availability of utility services
- Reduction production reliability and production output/yields
- Improvement of equipment performance
-

Additional indirect benefits will occur as well, and their value often exceeds the financial value of the saved energy.

Companies can achieve all of the above, without implementing the standard, but that is a less reliable and effective approach. Implementation of ISO 50001 would save a lot of time and energy for a company, and a certificate would use as a proof to all third parties which require it to build cooperation.

The process of certification requires a company to undergo a two stage ISO 50001 audit process of its Energy Management System (EnMS). "The first stage is pre-assessment and the second is certification."
Stage one is conducted with the goal to determine if the mandatory requirements of the standard have been, and are being met. It is also meant to conclude if the management system is capable to proceed further. Stage two determines the effectiveness of the system and seeks confirmation that the management system is implemented and operational (Certification Europe, 2012) .If there have been any problems in phases one and two and if any corrective measures were supposed to be taken, the execution of needed actions is reviewed in the recommendation for certification phase. Certification review and decision follow. Organization's files are reviewed by an impartial panel and the decision whether the organization gets certified is made. Finally, if all turns out to be in sync with the requirements, the organization is issued a certificate.

For an organization to comply with ISO 50001 energy management system's requirements and achieve certification to ISO 50001 it must develop a number of policies, procedures and protocols in relation to energy management (Certification Europe, 2012). Some will be listed here:

- Management responsibility for energy management
- ISO 50001 energy policy
- Energy planning, review and baseline process
- Energy design requirements
- ISO 50001 energy performance monitoring
- ISO 50001 management review etc.

2.2. Renewable energy in the European Union

Renewable energy and its technologies offer long-term solutions regarding the saving of environment , breakthroughs in physics and engineering, as explained by Sorensen B. in *Renewable Energy-physics, engineering, environmental impacts, economics & planning* (2011).
Renewable energy policy in EU has started in 1997, and since then European states have started introducing measures to improve the development of energy from renewable sources such as wind power, solar power, etc. (Pascelia et al., 2016). Implemented policies resulted in rise of renewable sources' share in total primary production of energy from all sources to 24% by the end of 2013(Pasceila M.and all, 2016). Each state of EU contributed differently, since their climate conditions and natural endowments vary.

Eurobserver barometers have been pointing out progress of every Member State of the European Union in the field of renewable energy, since 1998(Eurobserver, 2014). The date shown by the Barometers was regarding solar thermal, solar power, solid biomass, heat pumps and photovoltaic. Comparative analyses regarding electricity production from renewable and head consumption in Member States of the European Union have been presented as well. Additionally, the Eurobserver team publishes bimonthly reports (the so-called thematic barometers) that track and analysis the development of eight renewable energy technologies (wind, solar PV, solar thermal, hydro, geothermal, heat pumps, biomass, bio fuels, biogas) in the EU Member States in the previous year. (Eurobserver, 2014).

In the form of compact and descriptive reports, the barometers help policy makers and other stakeholders understand the developments in all renewable energy sectors in the European Union (Eurobserver, 2014). The barometers describe completed projects, provide policy background information and information specific for each country. Eurobserver's report : " The state of renewable energies in Europe, edition 2014" provides a complete over - view of the twelve renewable sectors.

Only wind power and solar thermal power data will be presented and analyzed in this paper, since those two sources are most popular in building eco houses that produce energy from renewable sources.

2.3. Wind power

The terms wind energy or wind power describe the process by which the wind is used to generate mechanical power or electricity (Office of Energy Efficiency & Renewable Energy, 2015) Wind is a clean source of renewable energy and it produces no air or water pollution, as mentioned in National Geographic's web site.. Since wind is free, there are zero costs of operations after the wind turbine has been built and set. Turbines used to be very expensive, however action has been taken and costs of production are significantly lower now. Many governments offer tax incentives to spur wind-energy development, as well. Turbines can be nearly twenty stories tall with up to sixty meter long of blades. Even though the costs decreased dramatically in the past few years, there are still some issues regarding wind power. To start with, it is important to explain how the wind turbines work. "Wind turbines work opposite of a fan." Instead of using electricity to make wind, like a fan, wind turbines use wind to make electricity (Office of Energy Efficiency & Renewable Energy, 2015).This means that the strength of wind pushes the blades of the turbine, making them spin. This can be dangerous for bats and birds, even though the blades spin slowly. However, turbines kill much less birds and bats than cars, for example. The second problem that arose is the noise and it is followed by the claim that turbines ruin the esthetics of their surrounding due to their design. The biggest problem of wind power usage would be the inconsistency. Although wind is an abundant source of energy, one has to bear in mind that it is not a constant source with a constant supply (Hemami, 2012).

Despite all of these problems, many countries managed to use wind power efficiently, by building wind farms away from settlements, and building a smaller number of turbines on many different locations, so that most of the wind current can be caught.

Regarding wind power, United Kingdom and Germany were leading countries in 2013, as stated in "The state of renewable energies in Europe, edition 2014" report. Developers' resolve to exploit the best wind power purchasing terms before the new renewable energies law reform came into force in August 2014, holds most of the credit for Germany's market success (Eurobserver, 2014). In 2013

the level of UK off shore activity was high with more than 1 out of every 3 MW connected being offshore (Eurobserver, 2014). According to DECC (Department of Energy and Climate Change), the country connected 2 314 MW (1 614 MW onshore and 701 MW offshore), also mentioned in the Eurobserver report from 2014. However the market declined slightly on its 2012 level, when 2 437 MW was connected to the grid. The UK's aim, restated by the Energy Ministry in November 2013, is to install 39 000 MW of offshore capacity by 2030.

Eurobserver report states that the year 2015 was very important for the future development of wind energy and its share in the energy mix planed for 2030. The momentum surrounding the 2020 target has long been ahead of the set target, however the one in 2013 and 2014 was not large enough to reach the intermediate Europe wide target set for 2015.

2.4. Solar thermal power

Solar thermal power plants are designed in a way that allows them to use the heat of rays of sun in order to heat fluids to high temperatures. The fluid is then circulated through pipes so that it can transfer its heat to water and produce steam (U.S. Energy Information Administration, 2015). The technology behind solar thermal power generators is almost the same as the one behind generators that use fossil fuels to produce steam. There are three main types of solar thermal power systems: parabolic trough, solar dish and solar power tower (U.S. Energy Information Administration, 2015).

European Union solar thermal sector for hot water and heat production has proved to be problematic in the past several years. It has been suffering from development problems and in 2013, the market had slipped for the fifth time in a row, like Eurobserver report from 2014 shows. "The Eurobserver survey found out that in 2013 the amount of installed collector surfaces was 13.3% smaller than in 212." Installation figures for solar thermal collectors now resemble those of 2007, and are getting further away from the annual installation record set in 2008.

The key solar thermal markets in EU are France, Germany, Austria, Italy, Portugal and Greece. However, they were severely put off course by the 2013 market slide. United Kingdom had also been affected, due to a delay in implementing the Renewable Heat Incentive (RHI) for private individuals. Fortunately, the UK managed to get the RHI to kick into play in 2014, so that it has effect in more sectors than before.

3. RESEARCH METHODOLOGY

The main objective of this paper was to analyze the usage of two renewable energy sources – wind power and solar thermal power in Member States of the European Union in order to conclude which countries might be most interested in ISO 50001 certification.

The first step was to gather data from EUROSTAT, Eurobserver and to analyze the information given in a paper by Pascelia et al., 2016. on renewable energies in the European Union. The result was the separation of EU countries into three groups. Members that belong to the same group show similar tendencies and behavior in the field of using renewable sources of energy. The next step was to gather data about the number of exiting ISO 50001 certificates in those countries.

3.1. Data Collection

The paper by Pasceila Mihaela and all from 2016 on renewable energies in the European Union and data gathered from EUROSTAT suggest that EU countries can be separated in three groups:

- 1st group: Sweden, Denmark, Romania, Estonia and Czech Republic. These countries have registered energy dependence rates less than 30%.

- 2nd group: Austria, Latvia, Finland, Slovenia, France, Germany, Croatia, Bulgaria, Greece, Poland, Slovakia, Hungary, Netherlands, United Kingdom. These countries have registered energy dependence rates between 30% and 70%.

- 3rd group: Portugal, Lithuania, Italy, Spain, Ireland, Belgium, Cyprus, Malta, Luxembourg. These countries have registered energy dependence rates higher than 70% (Pascelia et al., 2016).

Sweden and Denmark , from the first group are very successful in achieving their targets. Sweden has even managed to achieve a share of 52.6% of renewable energy in gross final energy consumption, while Denmark was very close to achieving its target of 30% by having 29.2% in 2014. Swedish share of renewable energy production is 50.97%, however 28.70% is imported. On the other hand, Denmark has a lower percentage of renewable energy production 25.9%, but they managed not only to import additional energy, but they export 3.4%.

Latvia and Austria are the countries from the second group that have come very close to fulfilling their targets. Latvia had 38% out of 40% and Austria 33.1% out of 34%. Austria has the dependence of 64% and Latvia of 56%.

Lithuania is a country from the third group that has managed to surpass its target of percentage of renewable energy in gross final energy consumption in 2014, by having 23.9% while the target was 23%. However, it is an exception from the rest of the group, since others have achieved 17%-20%. Regarding their dependence, Lithuania is 80% dependant, and the rest are more than 80% dependant.

4. RESULTS

The table below (Table 1) shows the cumulative capacity regarding wind power at the end of 2013 (MW), the corresponding capacities regarding solar thermal power (MWth) in 2013 and the number of ISO 50001 certificates in member countries of the European Union.

Table 1. "Cumulative capacity regarding wind power, solar thermal power and number of ISO 50001 certificates in Member countries of European Union"

Country	Cumulative capacity regarding wind power at the end of 2013 (MW)	Corresponding capacities regarding solar thermal power in 2013 (MWth)	Number of ISO 50001 certificates in 2013	Number of ISO 50001 certificates in 2014
Germany	34660	728.0	2477	3402
Italy	8 542	207.9	258	294
Poland	3 429	191.9	22	38
Spain	22964	162.8	196	310
France	8 202	159.9	86	270
Greece	1 809	147.7	16	25
Austria	1 684	126.4	67	109
Denmark	4 810	72.8	45	51
Czech Republic	270	55.7	16	32
Netherlands	2 713.2	42.1	21	24
Belgium	1 653	41.3	28	28
Portugal	4 731	40.1	11	12
UK	11 209	31.5	330	376
Ireland	1 896	19.4	64	56
Romania	2 459	16.8	60	56
Hungary	331	12.6	13	29
Croatia	254.3	12.2	6	10
Cyprus	146.7	12.0	*	*
Slovenia	2.3	6.3	14	16
Sweden	4 194	6.3	94	87
Slovakia	3.1	4.7	12	12
Luxembourg	60.6	4.3	3	1
Bulgaria	676.7	3.9	6	12
Finland	447	2.8	9	10
Latvia	67	1.9	2	4

Lithuania	279	1.3	*	*
Estonia	248	1.3	1	3
Malta	0	1.2	*	*

5. DISCUSION

Countries from the first group who stand out by the amount of renewable sources of energy usage are Sweden and Denmark.

Sweden can do this thanks to its good natural conditions. One of its most valuable characteristics is that 53% of land is covered by forests while the global average is only 30%. This allows the amount of 85% to be provided by this sector. The district heating and cooling became free of fossil fuels, thanks to the widespread of heat pumps and biomass. They have also set a goal to use machines and transportation equipment without any fossil fuels by 2030. Due to the incentives to support renewables (quota system, tax regulation mechanisms, subsidy schemes, tax exemptions) and to the requirement to purchase green electricity, the number of companies that are invested in renewable energy is growing.This is crucial because investors are exactly what this sector generally lacks.

Denmark has a well-developed renewable energy sector, although it is almost completely devoid of hydropower resources (Pascelia et al., 2016). The usage of biomass, solar power, hydropower, tidal power and bio fuels all contribute to the amount of electricity obtained from renewable sources. A number of households, 60% of them, are provided with heat buy the power received from mostly biomass and other renewables. The heat system is a result of long planning and the awareness of need to conserve energy. The Danish government has introduces a premium tariff and net-meeting, together with other initiatives to support renewable sources of energy such as loan guarantees and subsidies. These mostly refer to the encouragement to build wind power plants and install small-scale renewable energy systems. Tax exemptions and obligations to use renewable heating and cooling systems in new constructions have been made in order to support the hearing and cooling sector.

Germany, however has biggest capacities regarding both wind and solar thermal power. It is also the leader in the number of ISO 50001 certificates in both 2013 and 2014, having had 2477 certificates in 2013 and 3402 in 2014. Denmark and Sweden had a much smaller amount of certified organizations in this period, and Sweden even had a smaller number in 2014 compared to 2013. However, ever since 2011, its numbers had been going up and it can be assumed that the same would happen in the future.

6. CONCLUSION

This paper's main goal was to analyze the data regarding the usage of renewable energy sources in European Union Member Countries together with the data about the number of ISO 50001 certificates in them and see which ones have been most interested in certification so far as well as try and predict which will be interested in the future and if there is a connection between the level of usage of renewable and the number of certificates. Data was gathered from Eurostat, ISO survey, Euroobserver, the paper my Pascelia M. and all (2016) "Analysis of renewable energies in European Union" and other sources.The analysis shows that countries which belong the European Union can be separated into three groups, based on their energy dependence. Countries with the lowest dependence are Sweden, Denmark, Romania, Estonia and Czech Republic. Sweden and Denmark are most involved in making renewable sources of energy widely used and Germany has had most certified organization regarding ISO 50001.

It can be concluded that those countries with the highest usage of renewable sources of energy have been more interested in ISO 50001 certification than those with lower usage rate. Given the fact that the number of certificates grows each year in most of the countries, it can be assumed that those leading ones in renewable energy resources usage will be most interested in certification in the future.

THE ROLE OF HIGHER EDUCATION IN BUILDING AND IMPROVING NATIONAL QUALITY INFRASTRUCTURE – THE CASE OF SERBIA

Jelena Ruso*[1], Jovan Filipović[1], Gordana Pejović[1]
[1]University of Belgrade, Faculty of organizational sciences
*Corresponding author, e-mail: jelena.ruso@fon.rs

Abstract: *The paper investigates presence of quality infrastructure elements within higher education curriculum. The target institutions are public universities in Serbia as an important part of quality infrastructure institutions. The data were collected from the official web sites of faculties in Serbia, using syllabuses of optional and compulsory subjects. The analysis is performed to classify the faculties into three categories depending on usage term related to quality infrastructure. The results show that nowadays quality and standards are widely recognized as interesting and popular topic of study but usually offered through optional subject within certain departments of faculties. Results of our study showed that only four faculties within University of Belgrade offer more than five QI subjects, and only one is from University of Novi Sad (Category I). Four faculties from Universtiy of Belgrade belong to Category II and only one from University of Kragujevac. Finally, four facultis of University of Belgrade are categorized within Category III.*

Keywords*: higher education, quality infrastructure, standards, syllabus, Serbia*

1. INTRODUCTION

The growing educational opportunities and needs for development of education are creating a changing environment for higher education systems throughout the world. Most countries have developed an entire industry of service providers that specialize in the diffusion of quality and standards through the provision of quality assessments, technical assistance, information, and training services. Higher education institutions are one of the public institutions that are important link in developing of national quality infrastructure (from now on referred to as: NQI). Nowadays, a functioning quality infrastructure (hereinafter referred to as: QI) is a prerequisite for access to regional and global education market and a key determinant of competitive advantage. In our research we will only focus on program and syllabus of public faculties in Serbia. Aim of this paper is to provide basic insight in current situation about involvement of QI elements in higher education in Serbia. For that reason, we analyzed contents of compulsory and optional subjects using official web pages of faculties. The results show that nowadays quality and standards are widely recognized as interesting and popular topic of study but usually offered through optional subject within certain departments of faculties. Only Faculty of organizational sciences, University of Belgrade – Department of quality management and standardization develops and offers the largest number of mandatory subjects focused on quality, standards, accreditation, metrology and conformity assessment as basic part of QI.

The reason for the investigation is popularization of the topic (QI and its elements) as well as accentuation of importance of educated experts (in the quality management and standardization field), who make decisions and policies at all macro, micro and meso levels. If the quality of education is not treated the right way, consequently, it will decrease the quality in the whole country.

2. NATIONAL QUALITY INFRASTRUCTURE

“Quality Infrastructure is the totality of the institutional framework (public or private) required to establish and implement standardization, metrology (scientific, industrial and legal), accreditation and conformity assessment services (inspection, testing and product, system certification) necessary to provide acceptable evidence that products and services meet defined requirements, be it demanded by regulatory authorities (technical regulation) or the market place (contractually or inferred)” (Kellermann, 2011). „These activities provide a vital link to global trade, market access and export competitiveness as they contribute to consumer confidence in product safety, quality, health and the environment” (Pejović, Filipović, Tasić, 2011).

Also, QI is important for the international recognition of product and service and its further competitiveness. Correspondingly, national quality infrastructure is significant for export. Therefore, we can say that establishing the good quality infrastructure is a step towards good governance which creates a favorable trade climate in region. “Good governance is understood as good political framework conditions, rule of law and a responsible handling of political power and public resources by the state and thus an important

precondition for poverty alleviation and ensuring sustainable development“(PTB, 2007). What is necessary is that all these QI elements are connected through QI institutions and communicate with regional and international institutions, making the invisible global network (Figure 1).

In the QI system, accreditation plays a very vital role. “It is a formal confirmation that a body is competent enough to perform certain tasks” (Shaukat, 2010). It builds confidence in the work of testing laboratories, certification and inspection bodies, and facilitates mutual recognition of certificates, in addition to promotion of trade (Ibid.). No less important QI elements are „metrology“, which guarantees accurate and reliable measurements (See Wehmer and Frota, 2012), and “standard“, as a tool in free trade and in conformity assessment. International Standard ISO/IEC 17000:2008 defines conformity assessment as a “demonstration that specified requirements relating to a product, process, system, person or body are fulfilled.” What is necessary is that all these QI elements are connected through QI institutions and communicate with regional and international institutions, making the invisible global network.

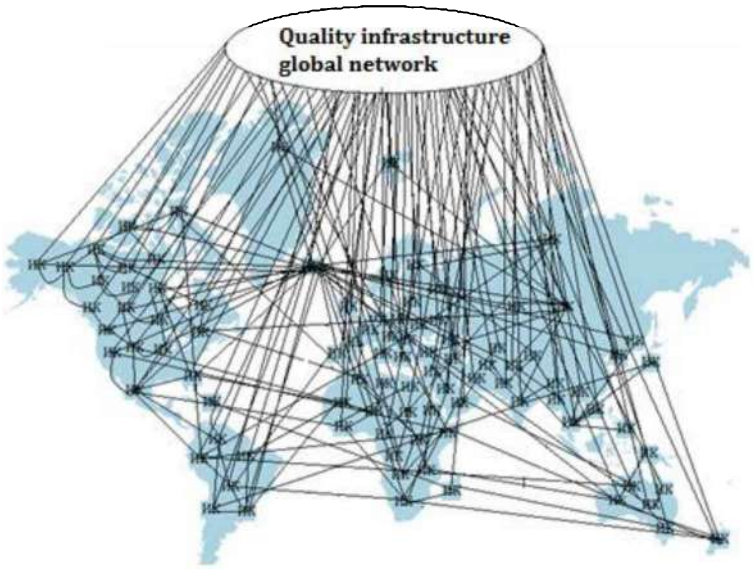

Figure1. Quality infrastructure global network (Inspired by Wheatley и Frieze, 2006)

3. KNOWLEDGE AND POLICY MAKERS

The article "*How to strengthen the Serbian politicians*", published in 2013 on the web page "Policy Online", said that "our political elites are semi-educated, regardless of formal education, without experience and morals. Only few people in politics are from practical sphere and they do not confer with science. In accordance with Hulnick (1986), “policy makers are government officials who formulate, choose, and implement policy”. In the decision making process, policy makers’ education and professional experience is likely to be important because they are more likely to distinguish good from bad advice and might be more able to resist the pressure of lobbying groups preferring the status quo. Dreher et al., (2009) had tested whether the educational and professional background of heads of governments influences the implementation of reforms and their results showed that “reforms are significantly more likely when the politician has an entrepreneurial or scientific background” and vice versa. They claimed, entrepreneurs are strong leaders and have a proven record of experience in leading a company and they have basic knowledge of the issue while trained and educated policy makers are more rational and less emotional in taking economic decisions.

The research was limited just to heads of governments in economic field. They did not consider other policy makers and other policy fields. Similarly, Jones and Olken (2004) find a positive relation between the education of leaders and the rate of growth and Besley et al. (2011) find that more educated politicians generate higher growth. Mikosch and Somogyi (2008) quoted by Dreher et al. (2009), find that political leaders with education in economics generate significantly lower budget deficits than those with education in law. Accordingly, we can say that “more educated politicians are better” (World Bank, 2005) in decision making. Therefore, if we want to develop national prosperity, we need educated and competent decision/policy makers with a lot of experience. The correlation of education background and other characteristics of decision makers could be interesting for this topic. Actually, how much “knowledge base” allows them to locate that knowledge in a broader social and political context.

All this indicate that education in the field of quality infrastructure is very important, because if there are no institutions that educate people in this area, many wrong decisions could be made. So, in the next chapter we are going to position faculties as a part of QI network.

4. HIGHER EDUCATION IN SERBIA RELATED TO QUALITY INFRASTRUCTURE

Higher education institutions are one of the public institutions that are important link in developing of national quality infrastructure (See Ruso et al., 2015). The modern University faces the challenge of adjusting to a complex world with new demands for professions and skills associated with the knowledge society. To successfully meet these important challenges, it is fundamental that universities' governing bodies have good relation with the academic community in order to respond to the social and productive needs of its environment (Espinoza and González, 2013). If the policy is embraced by institutions that have the ability to influence decisions and actions, such institutions can be called policy makers.

In Figure 2 we mapped the QI institutions and relationships among them. The basic institutions in the QI network are Directorate of measures and precious metals, Accreditation body, Institute for Standardization, Ministry of Economy (QI department) and conformity assessment bodies. Partly involved institutions in the QI network by certain departments are Ministry of trade, tourism and telecommunications, Ministry of finance, Ministry of agriculture and environmental protection, Ministry of education, sciences and technological development, the Chamber of commerce and industry and faculties. Faculties educate people in the QI field that are employed in other relevant institutions in Figure 2. Other connection between faculties and QI institutions are QI experts which are involved in teaching as visiting lecturers. Also, institutions' cooperation allows students to do internship and volunteer in quality management and standardization sector.

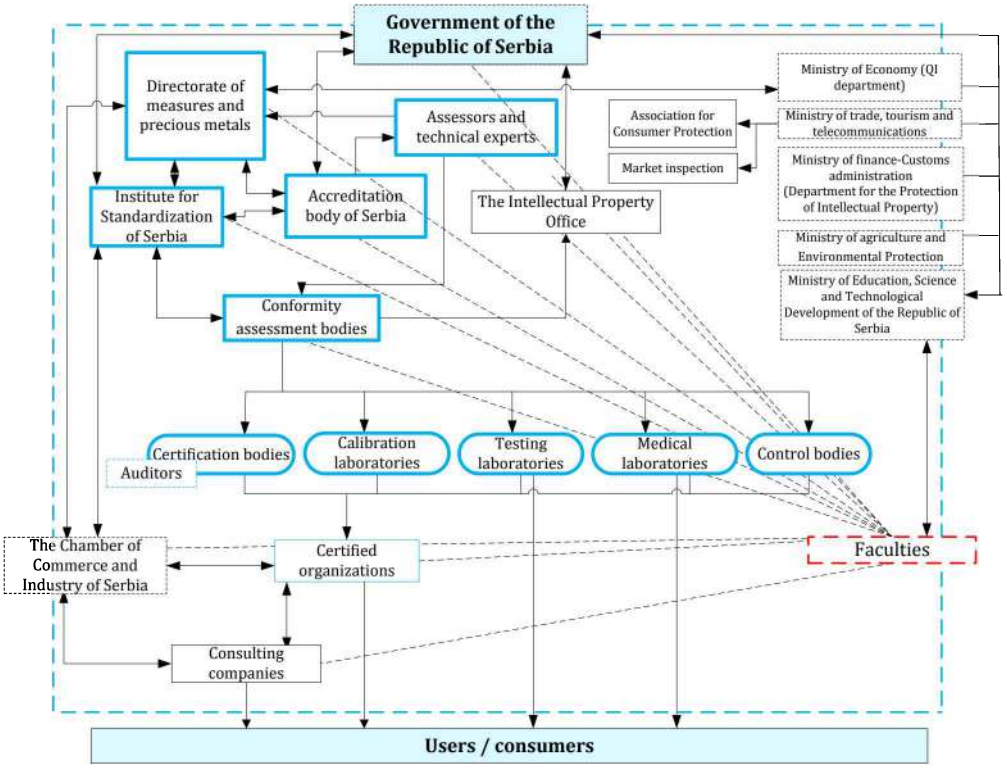

Figure 2. Quality infrastructure institutions (Source: personal)

People who have knowledge about IQ and its elements are more competent to plan, control, improve and assure quality at all levels take initiatives and make decisions related to it. Therefore, quality infrastructure and its elements should be recognized as essential topic of study in Serbia. With the aim to investigate the current state, we carried out research to display if Serbian higher education system recognizes IQ as important and essential part of quality life.

4.1 Methodology

4.1.1 Data Collection

The data were collected from the official web sites of faculties in Serbia, using syllabuses of optional and compulsory subjects. Key search words were: quality, standard/standardization, accreditation, metrology (for Category I), control, measure, production, technology, management, business, environment (for Category II) and marketing, sales, trade, market, transport, and trade laws (for Category III). The total number of faculties, used in this analysis was 19 (University of Belgrade, University of Novi Sad, University of Kragujevac and University of Niš).

4.1.2. Data Analysis

An analysis was performed to classify the faculties into three categories depending on usage term related to quality infrastructure. In Category I we grouped faculties which directly study subjects such as metrology, standardization, quality and accreditation. In Category II, we grouped faculties whose subjects are important for the issue. This kind of subjects could partly shape knowledge about QI, and people who pass it could possess enough knowledge to understand and manage problems related to QI. The last but not the least, in Category III we grouped faculties which are somewhat important as input in decision making processes. They can give some basic knowledge for understanding the problem, but not enough for making main decisions and quality control.

4.2 Results

The results show that faculties which directly target quality infrastructure elements (Category I) are Faculty of organizational sciences - FOS (Quality Management and Standardization Department) - University of Belgrade, Faculty of Technology and Metallurgy, University of Belgrade (Chemical Engineering Department - Quality Control), Faculty of Sciences, University of Novi Sad (Chemistry, Biochemistry and Environmental Protection Department - Quality control and environmental management) and Faculty of Agriculture, University of Belgrade (Food Technology Department – Safety and quality control in food production). Particularly subjects are: standardization, metrology, accredited laboratories, quality control, quality planning, quality costs, fundamentals of quality, quality system, quality control of industrial products, quality assurance system in production, quality control of environment, quality inspection and environment control, quality standards, statistical quality control, techniques for quality improving, normative regulation of quality, quality control in agribusiness etc.

Faculties which offer quality infrastructure subjects related to IQ elements, could help in better understanding of the topic and they are classified into Category II: Faculty of organizational science, Faculty of Agriculture, Faculty of mechanical engineering, Technical Faculty in Bor (University of Belgrade) and Faculty of engineering (University of Kragujevac). The list of subjects includes: production systems, management of key production performance, cost control, risk control, sales management, packaging and food packaging, the management of the food industry, business management system, production management, process management, merchandising, measurement and control processes in the metallurgical industry, protection management systems etc.

Finally, the third category of faculties includes Faculty of Transport and Traffic Engineering, Faculty of Economics, Faculty of Law and Faculty of Pharmacy. These faculties offer the subjects related to some of the QI elements at the introductory level. For example: transport of goods, fundamentals of logistics, supply chains, economic relations of Serbia with foreign countries, trade marketing and sales management, international business and management, foreign trade operations, International commercial Law, Trade Law etc.

5. CONCLUSION

Aim of this paper is to provide basic insight in higher education curriculum and investigate how the curriculum, including subjects (optional and compulsory), is connected to QI elements. In syllabuses, we analyzed the presence of usage of the term standards, quality, accreditation, certification and other (control, measurement, production, service, risk etc.) by the official faculty web sites. We categorized faculties in three groups depending on the number of subjects, directly linked to QI. Results of our study showed that only four faculties within University of Belgrade offer more than five QI subjects, and only one is from University of

Novi Sad. Specific subjects belong to Category II, where the subjects indirectly target QI elements such as FOS, Faculty of Agriculture, Technical Faculty in Bor, Faculty of mechanical engineering and Faculty of engineering, University of Kragujevac (more than 10 subjects). Ultimately, the third group includes the subjects at the introductory level refers to market, marketing, trade, trade laws, supply chains, logistics etc. The faculties which take place in the Category III are Faculty of Transport and Traffic Engineering, Faculty of Economics, Faculty of Law and Faculty of Pharmacy. In summary, our results suggest the least number of subjects belong to Category I and Category III. The subjects in Category II are most numerous. Only Faculty of Organizational Sciences develops certain department with the biggest number of mandatory subjects directly connected to quality infrastructure.

However, our results have certain limitation due to availability of syllabuses. For example, University of Novi Pazar does not have all "book of subjects" available on the web site. Also, the investigation does not include master, PhD studies and private faculties, therefore the limitations are suggested as an area for future research. We need to keep in mind that the results are not so strict, because they give just basic insight in current situation in Serbia. Likewise, there is the possibility of carrying out research among the Balkans and compare it with Serbian higher education program related to IQ elements such as quality, standardization, certification, accreditation and conformity assessment. Also, the students of quality management and standardization department could be interviewed and asked for their opinion and satisfaction about subjects in comparison with market needs for experts in the field of quality management and standardization. Also, the experts in the QI field could give their opinion about the education system (QI departments) and it could be compared with the students' opinions.

The results could help scholars, policy-makers, decision makers and the Government to understand how the quality and standards are perceived and considered in higher education in Serbia.

*Corresponding author, e-mail: milica_littly@hotmail.com

Abstract: *The problem in this research study refers to the review of the standard ISO 22000 management system's role for food and safety, applied by a company which implements the requirements of this standard through its processes, managing risks for food safety, ensures a safe product which customers would recognize as a necessary quality for their needs. The topic of this letter is tied to the explanation of terms of the standard, brief explanation of standards, Global GAP, British Retail Consortium (BRC), International Food Standard (IFS), and particularly the system of Hazard Analysis and Critical Control Points (HACCP), representing an introduction to the explanation of the standard ISO 22000 and review of its structure. The significance of the above mentioned is shown by the results of the conducted survey, its ultimate target being to increase profitability in the food supply chain industry and ensure customer protection by improving food health safety.*

Keywords*: standards, quality, HACCP, ISO 22000, food safety*

1. INTRODUCTION

A business system that aims to achieve a profit, survive and secure development in the domestic and global markets, as an imperative must have quality, as the most important condition of success and longevity of each subject, and therefore cannot have an alternative. The mentioned quality of the product, understood from a customer's subjective viewpoint, can have multiple dimensions, and when discussing about food as a product, the most important aspect is indeed its usage safety. For this reason, the aim of this paper is to demonstrate the role of ISO 22000, which ensures the customer with a safe product and a feeling of satisfaction, by applying such standard demands of food safety from the customer.

Firstly, this paper will briefly explain the term standard, after which it will mention the international standards for food safety, Global G.A.P., the British Retail Consortium (CONNIE), the International Food Standard (IFS)and the system for Analysis of Hazards and Critical Control Points HACCP displaying their connection with the standard ISO 22000 primarily through a common goal – which is to increase food security, from the consumers' point of view as well as market operators who apply them.

In terms of what was said at the beginning, about the subjective way of looking at quality, the final section of this paper will focus on user perception, where the terms quality and food safety will be explained for which we can consider to represent the two key terms of this standard. Survey seeks to answer the user's position on certain aspects related ISO 22000.

2. STANDARD

A standard is a document established by consensus and approved by a recognized body, which shall set out for the general and reusable rules, policies, characteristics of activities or their results, in order to achieve an optimal level of quality in a given context. Standards should be based on validated results of science, technology (techniques) and experience, in order to achieve optimal benefits for the society (Zakon o standardizaciji, 2005). Therefore, the standards are accepted and defined norms that define specific properties and characteristics of products, methods and ways of their production, testing and evaluation of conformity with the requirements of the product.

3. INTERNATIONAL STANDARDS FOR FOOD SAFETY

The current situation on the market implies rapid changes to the selling methods of food that will increasingly lead consumers to supermarkets. Supermarkets will demand, through certification and different standards, for all products to have clear and distinct traceability.

Global G.A.P. is a standard that includes the production of primary agricultural products and activities after the harvest. This standard is intended to provide assurance about the retail and consumers, as well as to show that all the necessary measures and controls to make the product safe for consumers' health were taken. The principles of these standards are (R. Mijatović & M. Mirčevski, 2011):

- manufacturing of high-quality products;
- environment protection;
- the optimal use of natural energy resources;
- support of economically acceptable agricultural production;
- combining the best available profitable practice;
- improvement of local communities' living conditions.

The British Retail Consortium (CONNIE) was created because of the need for certification bodies that inspect food vendors in accordance with a unique set of requirements and, thus, avoid duplication and extra work when they check it. CONNIE allows food distributors to focus on market and in doing so, doesn't have to think about food safety. The standard was developed to assist retailers in fulfilling statutory obligations andprotection of clients, or consumers, as a basis for the evaluation of companies delivering branded food products. Also, the standard gives suppliers an opportunity to meet the criteria of different retailers with a single certificate, which on the one hand reduces costs, and on the other , these same traders reduce the costs related to suppliers' control.

International Food Standard (IFS) is a standard developed to verify the competence of food producers in terms of security, but also the quality of the food with the help of a single standard, thus saving time and money. The IFS is the standard of quality and standard for food safety all in one. Those highest standards of food are based on the principle of traceability i.e. the possibility to, at any time on the way from the primary producer to the end user, escort the correctness and quality of the product at each stage of production and distribution. The standard applies to suppliers at all levels of the food processing, except for agricultural production.

3.1. HACCP (Hazard Analysis Critical Control Points)

HACCP Definitions

The HACCP system involves a series of procedures to control processes and sensitive points in the chain of food production with the ultimate goal of consumer's food items used in a state and in a way that is safe for his/her health. The World Health Organization has adopted it as the most effective means to control diseases caused by food (R. Mijatović & M. Mirčevski, 2011).
HACCP is currently defined through five preliminary steps (from 1992) and seven principles. HACCP is not testing end products in order to guarantee food safety. Instead, it incorporates food safety in the production process and relies on the process of control to prevent or reduce existence of known risks to acceptable level of in food product.
Key aspects and objectives of Codex HACCP are (R. Mijatović & M. Mirčevski, 2011) :

- measurement and control;
- critical control stage;
- risk analysis;
- preventive actions;
- corrective actions;
- planning;
- HACCP (control) system;
- the HACCP team;
- surveillance and monitoring;
- seriousness
- V&V (verification and validity).

The main goal of the HACCP plan is to identify potential hazards, evaluate what points in a manufacturing process lead to a high risk for food safety, and in which it is possible to control such danger.

Benefits of HACCP

As one of the first food safety management system that is widely accepted in food processing operations, its gains obtained from the establishment of an effective HACCP system are multiple. For operators who operate with food, these include producing safer foods and lower business risks, improving and maintaining your reputation, better organization and staff time utilization. From the consumers' point of view, they include reducing the risk of food-borne disease and greater confidence in food safety. For the country's government, the gains include rational control food safety, reducing the cost of healthcare and facilitating international trade in food.

4. FOOD SAFETY MANAGEMENT SYSTEM ISO 22000

Food comes to consumers through a supply chain, which can link different types of organization and that can be spread through multiple borders. One weak link can mean unsafe food that is hazardous to your health. When this happens, the risk for consumers can end up being very dangerous, and expenses for a chain of suppliers of food very high. How a risk to food safety can occur at any point in the chain, it is very important to have adequate control on every step of the way. Food safety is the responsibility of all participants in the production and distribution of food and requires common efforts by one goal (M.M. Markuš, 2006).
The growing demand for food safety by pressuring manufacturers and distributors to develop food safety management system based on HACCP led to the ISO to take measures for the development of appropriate standards in 2001. The first intention was to rise above the usual requirements for food safety.
The goal was harmonization of national and private standards and inclusion of the management system of ISO 9001.

4.1. The Scope of Application

The standard ISO 22000 refers to a food safety management system. A subject to the application of ISO 22000 is managing risks to food safety in order to ensure a safe product and hence enhance the satisfaction of end-users. The work is focused on controlling measures that should apply to ensure the harmonization process with the client requirements and regulations concerning health food safety.
The standard is intended for communication between business partners (B2B) and is not intended for communication with end consumers, and thus set the logo on the product is not allowed.
ISO 22000 is designed to enable for all organizational types in the movement of food to implement food safety management system, its requirements apply to all types of organization in the food chain: food producers, primary producers, food processors, transportation and storage, along with mutually related organizations such as producers of equipment, packaging material, cleaning agents, additives and food ingredients. That is, for all organizations, regardless of size, that are involved in any aspects of the food chain and that want to implement a system that would constantly produce products safe for health (Z. Abdirahman & L. Sauvee, 2012).

4.2. Structure Standards

ISO 22000:2005 is a proprietary standard, established by the International Organization for Standardization (International Organization for Standardization-ISO). It uses the methods of management of health food safety through specifying requirements that combine key elements to ensure food safety throughout the food chain to the point of final use. The before mentioned requirements encompass (N. Živković, 2012):

1. **The management system** of the ISO 9001-as 22000 standard gives requirements to management responsibility, measurable objectives and expected impact as a basis for quality management system, contributing to constant improvements through continuous monitoring, through corrective and preventive measures.
2. **Communication in the food chain** – as already mentioned in the course of this paper, the danger for the security of food can occur at any stage of the food chain so accordingly it requires an efficient control and elimination, or reduction of error possibility. The purpose of ISO 22000 is to require from all participants in the food chain to communicate and provide effective flow of information.
3. **Previously necessary programs (PRP)** are the basic conditions and activities that are necessary throughout the whole food chain for maintaining hygienical environment that is suitable for the production, handling and supplying safe final products and safe food for human consumption (J. Babić, 2014). Previously required programs are aimed at the protection of products from contamination caused by biological, chemical and physical food safety risks, the control of bacterial growth that can be a consequence of temperature disturbances and maintenance equipment. PRP is practically representing those activities that do not belong to specific HACCP plans, what would later be covered, that affect health food safety.

4. **HACCP Plan**

Training and formation of teams for HACCP-The staff operator that operates food needs first to finish training for HACCP, which is adapted to their responsibilities in the HACCP plan. For anyone who is into direct or indirect contact with food, the HACCP plan should be clearly shown and explained, and procedures that this feature must be adhered to.
The HACCP team typically makes more people because for the development of HACCP system is necessary to rule a broad spectrum of knowledge and experience. The team shall possess all the necessary specific

knowledge about the products and processes, in combination with the general knowledge in the field of systems of quality management and food hygiene (United States Department of Agriculture, 1999).

Description of the product and a description of the intended use-the HACCP team must be provided the complete insight into all of the products that the HACCP plan applies to. The description of the products is a necessity to be composed for each product separately.
Also, it is important to identify the potential users of the products and, if relevant, especially look at the use of the products by the sensitive group in the population (infants/children and youth, old, pregnant women, sick).

Manufacturing process flow diagram – the flowchart process needs to be designed by the HACCP team and to cover all steps in the production of what is it in reality. For each production operation there are steps that precede and follow the specific operation and production process present in the HACCP plan. The
HACCP team needs to verify the accuracy of the (verified) flowchart process carefully by comparing them with actual activities along the whole line of production ("on the spot"), during all stages of actual work. Then, if necessary, it needs to improve or add value to it (United States Department of Agriculture, 1999). Similarly, comparing constructed diagrams and actual activities on a production line, the competent authority shall verify later that the flowchart is true and complete.
Each step in the manufacturing process necessarily has to be described in form of standard work procedures/operations (SOP).

Principle 1 – Risk Analysis

Risk analysis involves listing all potential hazards for which there is a realistic expectation that will affect every process in the area of primary production, processing, and distribution to consumption that can threaten the health of consumers and includes two main elements:

1. Identification of danger - the HACCP team needs to identify and accurately specify all dangers for which reasonably expects that could be associated with the product as a result of direct or indirect contamination on any point of the production process. By their nature, hazards can be biological, chemical and physical.

2. Categorization and ranking the risk of specific hazards - For each risk it is necessary to perform risk assessment. The main goal is to create a clear picture of which of the identified hazards is the most important problem for the safety of the products. Depending on the results, the main efforts and resources should be focused on the successful prevention of the the most important problems, because they represent the highest risks for the safety of the product.

After that, the HACCP team needs to consider what control measures are available to eliminate or at least reduce the risk in the product, as well as whether, how and on what process step those measures can be applied.

Principle 2 – Determine the critical control points

Process step where a risk is unacceptably high risk is considered critical for the safety of the product and is called the critical point. At this point, the risk must be eliminated or significantly reduced by applying specific control measures; named critical control point (CCP). In order to identify critical control points, use the decision tree for the CCP (D.A. Corlett Jr., 1998).

Principle 3 – Establish critical limits for each CCP

A critical limit is the criterion that separates the acceptable from the unacceptable. In other words, a critical limit defines the parameters of the process which must not be exceeded (H.Hughes, 2008). When this value is exceeded, is considered that CCP is no longer controlled and corrective action must be taken (J.G. Surak & S. Wilson, 2014). These limits must be based on scientific, measurable, and validated knowledge.

Principle 4: Establishing monitoring procedures

Definition of monitoring Codex Alimentarius reads as follows: "the implementation of a planned sequence of observations and measurements to assess whether a CCP is under control and security/keeping accurate records for use in future verification." (D.A. Corlett Jr., 1998)

Principle 5: Determine corrective measures

Specific corrective measures must be developed for each CCP in HACCP system, which resolves the errors and deviations of the process if/when they arise. Corrective measures must ensure that the CCP is brought under control(H.Hughes, 2008); to prevent potentially noxious food reaches consumers and preventing it happening again.

Principle 6: Establish procedures for verification

The HACCP system must be adequately and regularly checked to ensure its effectiveness and coherence between what is meant or planned and what is really going on regarding food safety in a given subject.

The HACCP plan validation is performed before implementation of the HACCP system, and is a confirmation of sucesfuly developed all elements of the HACCP system. That is, it means that the HACCP plan, once applied, control food safety adequately.

Verification of the HACCP plan is a confirmation, after its implementation, the plan is effectively implemented and that is effective – that the danger for the security of food is under control.

Principle 7: Establish procedures for documentation and records

A successful and orderly maintenance of documentation is essential in the application of the HACCP system. All activities undertaken in the system of HACCP must be planned, documented, and they must take the records as proof that they were executed (Lj. Jovanović, M. Pavlović, D. Panković, N. Penezić, V. Radović, M. Pucarević, G. Dugalić, N. Bokan & M. Petrović, 2014).

A review of the standard structure

In the structure, similar to ISO 9001, in addition to the foreword and introduction, ISO 22000 contains eight parts: the first three are global, while the following five are related to the requirements of the management system.

Point 4 of the standard: food safety System-This point is stressing the health food safety management system requires establishing, documenting, implementing and maintaining an effective ISO 22000. This includes procedures and required records to ensure the effective development, implementation and updating of ISO 22000.

Point 5 standards: leadership Accountability-Accountability of leadership for this standard is covered through eight detailed requirements related to: dedication, the establishment of a food safety policy, for planning activities, responsablity and influences,naming the team leader for safety, ensuring effective communication processes, review of management (M. Bugdol & P. Jedynak, 2015).

Point 6 of standard: Management resources-Effectively applied FSMS requires the top level management to provide adequate resources, budget and staff to the system so it works effectively.

Point 7 of standard: Planning and delivering safe products – the ISO 22000 standard requires the Organization to plan and develop the processes needed for the realization of safe products. The organization will establish, implement and ensure the efficiency of the planned activities, as well as any changes in these activities, which are expected to include previously required programs, as well as the HACCP plan.

Point 8 of standard: Validation, verification and improvement of FSMS - to maintain and demonstrate the effectiveness of FSMS, organizations need to verify that all of the assumptions that were used in the system, scientifically based, or implemented are a validation rule. In addition, organizations need to plan, implement and document the regular verification of all system components, to assess whether, or not, modifications are necessary. Verification would also have to be a part of a continuous process of advancement, which is why organization verifies the system (I.S.Arvanitoyannis, 2009).

Organization needs to worry about constant improvement of effectiveness of product safety management system using policies, objectives, results, analysis of data, and corrective and preventive measures reviewed by management.

Advantages of application and the role of ISO 22000

The role of standard for a company is to, by applying it, achieve several advantages such as:

- better communication in food chains;
- enhanced document management;
- a better planning process;
- strengthen confidence in State agencies that control the quality of food (R. Mijatović, M. Mirčevski, 2011);
- lead continuous improvement process;
- reduction/control check by business partners;
- increase the safety of products, reduce cost and risks related to the return of products;
- greater efficiency and control food safety hazards;
- ensure the production of safe products;
- increase the confidence of users of the product.

5. USER PERCEPTIONS SURVEY

The behavior of consumers in relation to food security can be predicted if there is a systematic understanding of how consumers perceive the risks and benefits, in connection with various food safety issues, which will be attempted in a survey below.

The aim of this study is to examine the user's position on the importance of using safe products intended for human consumption, the procedure and the method of its use, its features bearing on the manufacturer of the product in case of submitting complaints, as well as their attitude about the need for the use of standards in the food industry and familiarity with standard ISO 22000.The survey covers 97 respondents, and largely consists of students of the Faculty of Technical Sciences in Cacak, while a smaller part is composed of employees of Chips Way Company.

The first two questions help in categorizing and analyzing results and relate to the gender and age of the respondents. Out of total number of respondents 70.1% are men, and 29.9% women. As for the age, 89.69% of the respondents are in the group between 19-26 years, 3.09% in a group between 27-35 years old, 4.12% in a group between 36-45 years, 2.06% in a group between 56-65 years, and 1.03% in over 65 years. The following questions in the questionnaire are designed according to the specific requirements of ISO 22000, which agrees to the stated objectives of the research. In this regard, the results and their graphical representation are presented below.

Question 3: Assess the level of security of food products that you buy?
The term refers to food safety, i.e. obligations of food companies to classify the products and the user's stance on this issue.

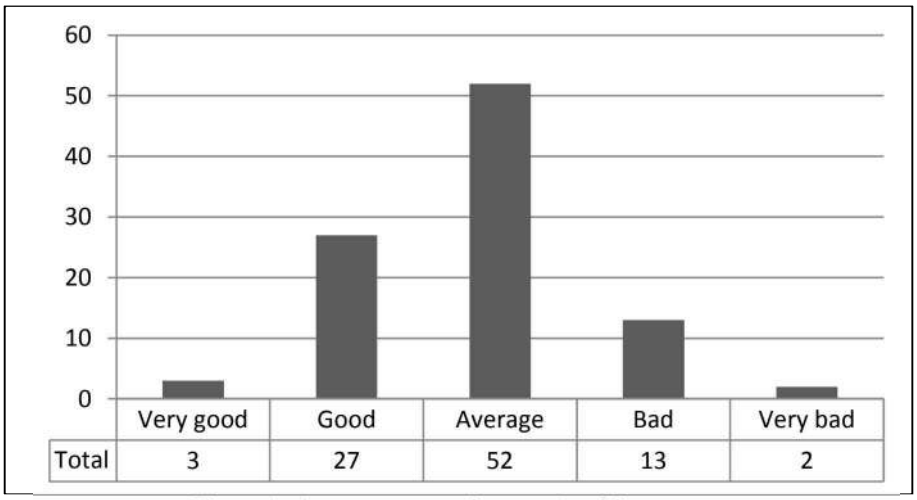

Figure 1 - Answers to question number 3 in a survey

The results show that 53.6% of the respondents considered that the food that they buy the average quality, where together with those respondents who responded with bad or very bad that percentage is even 69,07

percent. These data tell us that companies must make efforts to increase awareness by consumers and assure them that the products placed on the market are safe for consumption.

Question 4: Rate the level at which you think food companies are trying to eliminate all potential dangers in the production process of their products?
Refers to the requirements of point 4. ISO 22000-Risk Analysis.

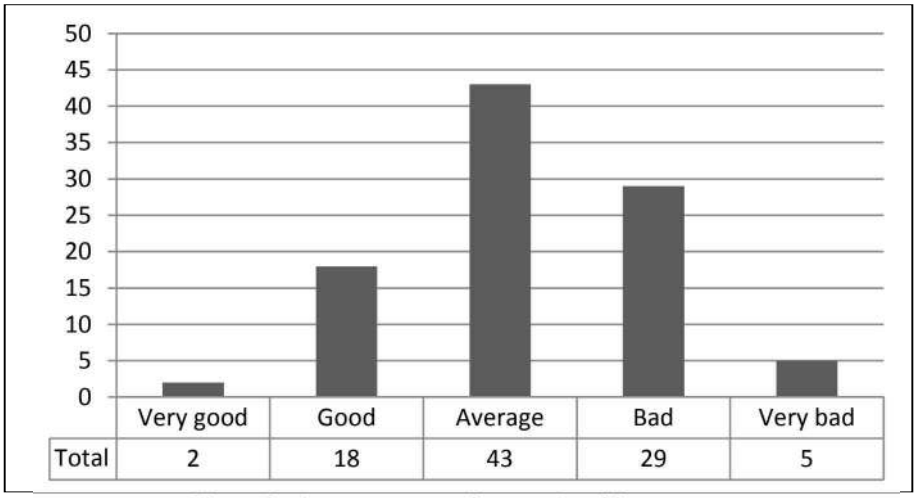

Figure 2 - Answers to question number 4 in a survey

The results show that the largest number of respondents considers the effort food companies are putting in eliminating potential dangers in the production process average and makes 44.33%. If we combine this group of subjects with those who gave as "Bad" or "Very bad" as their answer to the previous question, they make a percentage of 79,38%. Same with the previous question, companies engaged in food production, in case they want to change this attitude of respondents, should primarily change the picture of themselves and their actions in the food industry.

Question 5: Rate the importance of options of filing appeals on the safety of the purchased food products?
Refers to the requirements of point 5 of standard ISO 22000 – External communication.

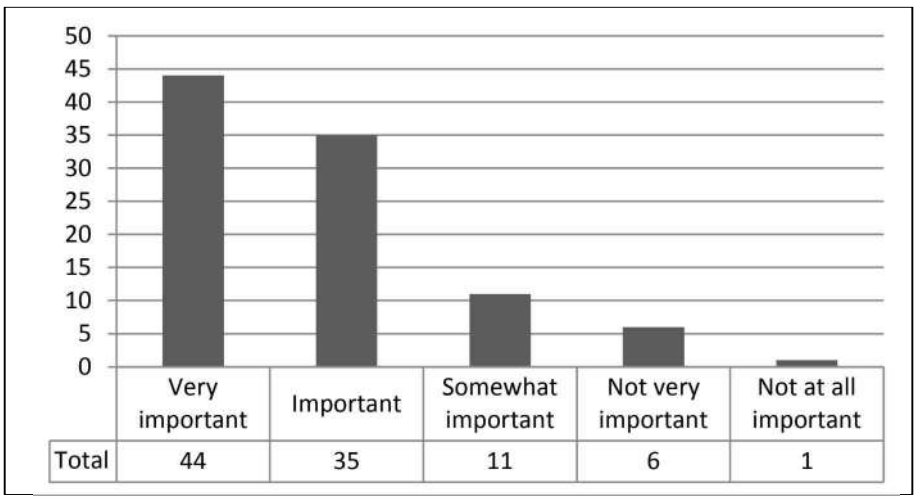

Figure 3 - Answers to question number 5 in a survey

As expected, the highest percentage of respondents makes for 45.37% and gives great importance to the possibility of submitting complaints to the observed failure of the purchased products. When we add this to the number of respondents who graded this question as "Important", that makes for 81,15%, which proves the importance of established procedures for appeal for users in every company that deals with the production of food products, and what the requirements of ISO 22000 are essentially about in the above mentioned point of standard.

Question 6: How well do you consider staff involved in the process of manufacturing food products is trained for tasks that affect food safety?
Refers to the 6. ISO 22000-Management resources, human resources.

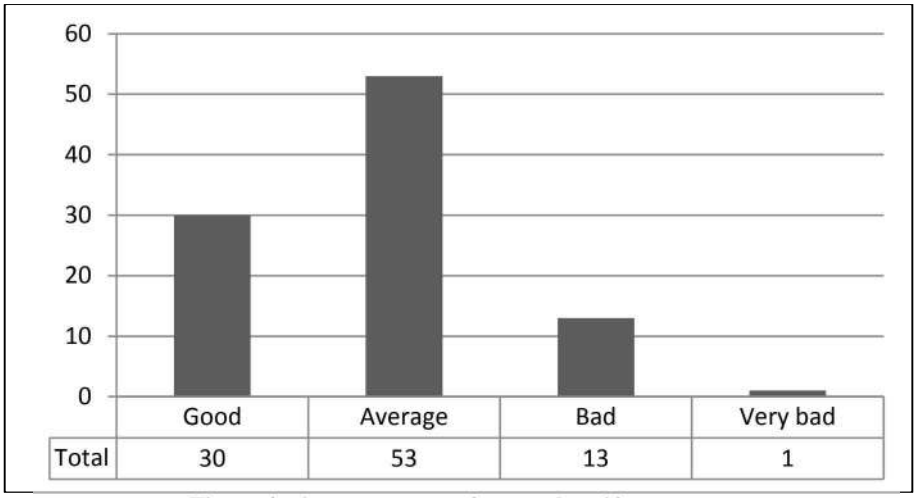

Figure 4 - Answers to question number 6 in a survey

The results of testing where none of the respondents did not answer the question as "Very good", returns us to the field of activity of companies in terms of increasing awareness of their activities and efforts to increase food security, and requiring users to recognize it. as what is shown, the answer that was given most frequently in this issue is "Average", which makes for 54.64% of the total.

Question 7: Rate the importance of hygiene in the production process/ storage process/distribution.
Refers to the previously required programs, i.e. good hygienic practice.

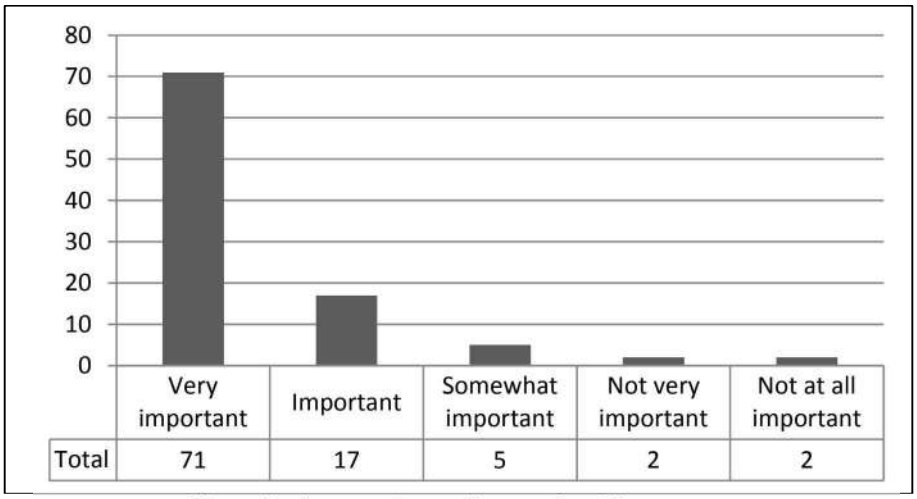

Figure 5 - Answers to question number 7 in a survey

The result of this issue is, as with the fifth one, completely expected. Primarily serves as a confirmation on user's general attitude about the importance of hygiene products in all processes of managing food. So, response to this question that is most often given is "Very important" and makes 73.20% ,and answer "Important" is given 17 times and makes 17,53%. If we add the percentages of the two responses up we get to 90.73% of respondents considers it very relevant for every company that approach the hygiene seriously in the sense that the end product is safe for consumers health.

Question 8: Are you familiar with standard ISO 22000 - food safety management system?

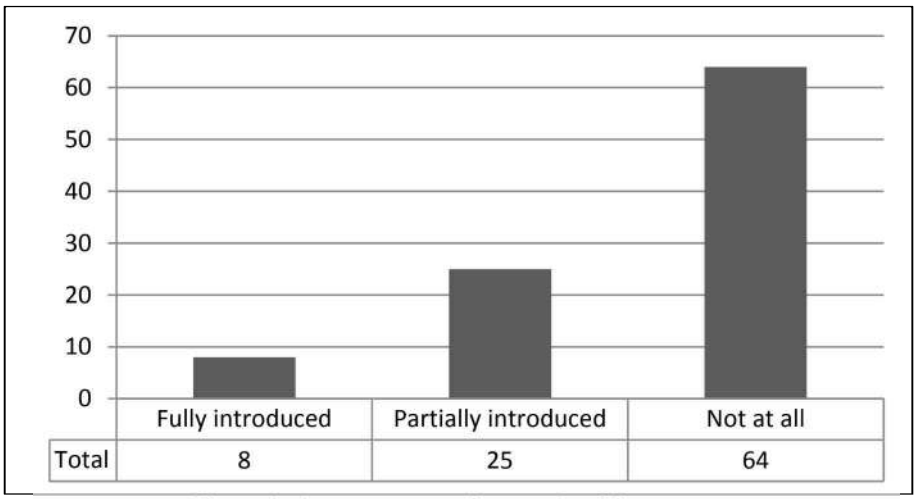

Figure 6 - Answers to question number 8 in a survey

The last question in the survey refers to the examination of those surveyed about knowledge of ISO 22000. The result of examination is such that 65.98% of respondents did not know about it, 25.78% is partially introduced, while only 8.25% is fully introduced with this standard.

6. CONCLUSION

The period of the last few years can be noted for how discussions relating to quality and food safety have become very common. The risks in ensuring food safety, as serious problems, are identified by international organizations, governments around the world, as well as our legislation and society as a whole. Parts of the public are becoming more interested and often critical in terms of raw materials, technology and hygiene of food production, both at the level of primary production and processing, and at the level of distribution/selling/serving.

ISO 22000 food safety is improving health and it provides consumer protection. In this way it strengthens the confidence of customers and increases the profitability in the food industry. It is used to accelerate and simplify the processes without compromising the other quality management systems or the health, safety and also, once implemented, this standard increases international acceptance of food products marketed on the market.
The results of implemented surveys unmistakably demonstrate the importance of requirements of ISO 22000 and the importance of the implementation of these requirements for every company that deals with the production and processing of food. Further on, these results also show that each company in addition to having efforts to meet the requirements of this standard, must make even greater efforts to that end that users become familiar with the level of the products' safety, aimed to be provided, because the end user, although considered relevant, is not familiar with the requirements of the company with an implemented standard ISO 22000 needs to meet. A solution to the problem can be found in implementing the channels of communication to the end-consumer and presenting work and effort in obtaining high-quality and safe products.
It should be emphasized that in today's business world, primarily in highly affluent markets where there is strong competition, but also the willingness of users to pay more for better quality, it is almost impossible to break in, for example in a chain supermarket, without the quality or safety of the product. Not only that consumers will not choose such a product, but it is also impossible to enter the market without them.

Abstract: *This paper is aiming to raise issue of employees' competence development for future global business environment in quality management. The quality management professionals lately point some key trends which are transforming the future of quality: talent of people, creativity and innovation or knowledge and agility. The quality management profession needs "leadership talent worldwide" and the role of the quality managers are changing. The skills critical to the success at the work places are: teamwork/collaboration, creativity and innovation, critical thinking, problem solving, professionalism/work ethic, oral and written communications, information technology application, leadership and lifetime learning. The main challenge in higher educational institutions is how to prepare students for their future jobs and what type of learning method should be applied to match business environment needs. Creative active teaching includes using case study method in classroom and preparing talent students for case competitions. This innovative learning strategy integrates curriculum objectives with learning outcomes. Based on previous researches, case competitions have been shown to have multiple benefits for the students who are participating: developing managerial skills with focus on creativity and innovation, learning benefits and employability skills.*

Keywords*: quality management, higher education, case study competition, managerial competence*

1. INTRODUCTION

According to data of Word Bank Enterprise Survey, based on sample of 10,690 enterprises from 23 Eastern European countries, one of the most important obstacles for doing their business is inadequately educated workforce. It is particularly important to note that inadequately educated workforce is stated as obstacle after others obstacles: access to finance, corruption, political instability, practices of competitors in the informal sector and tax rates. According to same data source and based on data collected in 2012 in Serbia 37.5% of enterprise representatives reported inadequately educated workforce as obstacle to current operations.

Global and dynamic business environments influence the changes in the needs for organizational knowledge and competence. Social (global village), economic (global economy, worldwide sourcing and global offerings) and technological (technological progress as a base for globalization) changes influence practically every society and company. In many organizations obsolete knowledge, competence and skills are the main obstacles to development. Everett and Pege (2013) pointed that: "*At no time in the recent past have flexibility and creativity been needed more in rethinking and retooling the models of the relationship between universities and society…society wants value for its investment…But what is this socially sanctioned values? It includes at least that the average college graduate will be a more informed and better thinking citizen, better able to live a personally satisfying life because of their higher education experience – to be a prepared citizen. This in itself does not seem so different from past aspiration, except that now 'value' the idea that practical knowledge produced by higher education experience should be measureable in the short term and of sufficient magnitude…*".Based on OECD (2008) forward looking perspectives on higher education:

- The differentiation of the HEIs leads to an increasingly visible profile of institutions. What would be desirable is that different missions and visions (i.e. world-class research vs. catering for the needs of the national/regional labor market) are accepted as equally valid and worthwhile in terms of public support.
- The intensive networking among institutions, scholars, students and with other actors such as industry - more on collaboration than on competition. International collaborative research is also strengthened by the dense networking between and among institutions, driven by the availability of free and open knowledge.

In both cases the results related to research and/or quality of students are measureable which suggest that future of higher education will be highly competitive. The average first time employee with university diploma

should have practical knowledge, competences and skills of sufficient magnitude which can be used and evaluated by his/hers employer in the short term.
This paper is aiming to raise issue of employees" competence development for future global business environment in area of quality management. The paper is organized into five sections. The next section briefly introduces some new trends which are transforming the future of quality management. The third section deals with the need for crossing the lines between the corporate and academic world and the role of higher education in providing adequate future employees in such situational frame. The fourth section is presenting results of research studies related to case study method and case study competitions as creative and innovative tool for knowledge acquiring, developing of competence and skills needed in the business. Finally, the fifth section derives conclusion remarks.

2. THE QUALITY MANAGEMENT NEEDS TALENTS AND INNOVATIVE PEOPLE

The quality professionals lately point some relatively new words: *talent of people*, *creativity and innovation* or *knowledge and agility.* Many of the more or less new concepts in the quality management might be in connection with Draker"s claim: "management is doing things right; leadership is doing the right things" and need to better connect quality with "right things" in knowledge economy. According to the research report of Gutner and Adams (2008) key trends which are transforming the future of quality are: globalization, customer sophistication, talent management and leadership issues and environmental concerns and social responsibility. The authors elaborate that future "*leadership talent worldwide will likely be in short supply and a battle for the best and the brightest will continue*" and that critical aspect will be knowledge transfer within an organization. The role of the quality professional must become that of teacher and mentor, coach and player (Nash, 2014).

Study of Power (2014) showed that quality management in the plants in industrialized economies can be expected (on average) to be more competent (better in terms of "what we can do now") than those in emerging economies, however, the plants in emerging economy group are able to leverage investment in quality management programs to both promote greater competence in quality management, and to build capability for further improvement over time – which does not proved to be case in the group of the plants from industrialized economies. The data and results provided by Power (2014) can be read from different points of view – the industry organizations from developed countries might be faced with pressure to innovate and to connect their quality management learning initiatives and activities with results in the short term, while quality management in developing countries still can use existing knowledge to achieve improvements – not for a long time.

Not by the chance, new version of ISO 9001:2015 standard introduces new concepts in quality management system standards: concepts of risk and risk based thinking and its counterparts – opportunity, as well as concept of knowledge (Bureau Veritas, 2016). In the new version of ISO 9001, concept of knowledge as a resource and knowledge management have seen as a key to successful business development – requirements related to identification necessary knowledge, anticipation changes in knowledge needs as well as risk of failing to acquire needed. This was starting point for many management systems" training providers and consultants to start with courses related to the managerial competences and knowledge management - with the main idea that every organization within its context should deal with knowledge such as every other resource (in the meaning of PDCA).So, the quality managers are again in the trouble - if they do not have at least decent business management education.

The new edition of the EFQM excellence model integrates, for the first time the fundamental concepts such as: managing with agility, developing organizational capability, harnessing creativity and innovation and succeeding through the talent of peoplewith explanation that "excellent organizations value their people and create a culture of empowerment for the achievement of both organizational and personal goals." Knowing that the fundamental concepts of excellence have been identified through a rigorous process that included benchmarking globally, this is novelty in fundamental concepts can be explained by new needs of global business.

However, the roots of those new concepts can be found in quality management theory. According to Dahlgaard-Park (2011), "as the most widespread quality management approach during the last 25 years, the term TQM seems to have lost its attractiveness in Western parts of the world and instead new terms such as Business Excellence, Organizational Excellence, Six Sigma, and Lean seem to have overtaken the position even though the contents of these new terms can be understood within the framework of TQM". The study of Dahlgaard-Park et al. (2013) show that the total number of articles under the subject of TQM has been decreasing after having reached its peak in 1995, at the same time papers focusing on concepts within the quality management framework (e.g. Lean, Just in-Time, Toyota Way and Six-Sigma Quality) have been

increasing. Many reports about ineffectiveness of TQM were based on its highly complex concepts, many different forms – some authors of the TQM approaches define TQM as philosophy, some as dominant management practice. However, many TQM models, for example TQM models provided by Oukland, Besterfield or Dahlgaard, are underlined importance of management of organizational knowledge, competencies and skills. With implementation many quality initiatives and practices, it was difficult to link these initiatives within a single business framework and transferring ownership from Quality Department to the business as a whole (O'Brie and O'Hanlon, 2000, taken from Adebanjo). Problems of many quality management initiatives are related to insufficient capabilities of quality managers to cope with deploying activities, responsibilities and commitment to the issues. That might be one of the reasons for popularity of term business excellence.

According to the European Foundation for Quality Management (EFQM) - excellence is about doing your best. The EFQM Excellence Model, based on a cause and effects, provides a holistic framework for assessing how effective you are in developing and delivering a stakeholder focused strategy. The EFQM model was largely based on the concept of total quality management TQM and European Quality Award (EQA) was based on other TQM models such as Malcolm Baldrige National Quality Awards (Adebanjo, 2001). Regarding to effectiveness of EFQM models and based on present studies, still it is difficult to have hard positive or negative opinion. The EFQM models and many other authorized business excellence models (authored by individuals or other organizations) or customized versions are generic and effects are not only results of the model but of the quality of activities or solution conducted in order to obtain specific results. Integration in the processes of the organization in various ways can highly influence effective implementation of the EFQM Excellence Model (Davis, 2008). According to Gomez (2011), based on analysis of the relationships in the 2003 version of the EFQM model, leadership has a significant effect on policy and strategy, people and partnership and resources, however policy and strategy, people, or partnership and resources have no significant effect on operative results and processes. The study of Aryanaslet al. (2016) explored whether the EFQM Excellence Model mentioned model is suitable for the businesses that are based on cleaner production and sustainable business models - it was shown that despite adoptability of the fundamental concepts of EFQM Excellence Model, there were some lacking criteria for adapting them to sustainable business model.

The quality management development of competitive excellence emphasized a new role of recruiting the right talent as imperative for providing sustainable and profitable organization for long term.

3. CROSSING THE LINES BETWEEN THE CORPORATE AND ACADEMIC WORLD

In order to adopt higher educational needs to US market, Rochester Institute of Technology conducted research of key drivers of change in higher education today, including: technology (on line learning), globalization, changing demographics, changing students" expectations and understanding the Net Generation and changing employer needs (Casares et al, 2011). The rate of technology change and growth has been exponential and on line learning is growing. Millenniums generation expect flexible work hours, expect to be mobile and work from home, office and cafes. The most important millennial work values are: meaningful work and high salary (Meeker, 2015). Globalization influences higher education in multiple ways from a need to “internationalize” the curriculum and provide support services for non-native English speakers. International dimension is crucial for preparation of students for international careers developing educational program (European business) that fit the needs of students (Teichler, 1999). Another very important phenomenon to researchers relates to the impact of demographic changes, such as a large population growth in Asia, which represents an opportunity for business schools. On the other hand, characteristics of countries in the eastern part of Europe, such as very low birth rates, out-migration and rather high death rates, influence a decrease in the number of young population. That further implies a decrease in the number of potential students, and increased competition among business schools (Lutz,2011).

In the knowledge economy, employer needs for new entrant skills as critical to success in work: teamwork/collaboration, creativity and innovation, critical and thinking/problem solving, professionalism/work ethic, oral and written communications, information technology application, leadership, lifetime learning. The University of Glasgow (2011) investigated employers" perceptions of the employability skills of new graduates, and the steps which universities take to develop them. They used interviews method with 22 key informants from representative organizations for employers HEIs and other relevant groups (e.g. Association of Graduate Recruiters, Chambers of Commerce, Council for Industry and Higher Education etc) to explore issues pertinent to the research objectives and identify examples of good practice. Employers expect graduates to demonstrate a range of skills and attributes that include team working, communication, leadership, critical thinking, problem solving and often managerial abilities. Employers are frustrated that

higher education courses do not meet their needs. There is also a lack of systematic practice to promote employability across higher education institutions and schools do not see employability as an important part of their mission.

4. CASE COMPETITIONS AS CREATIVE AND INNOVATIVE STRATEGY

In modern business arena higher education provider is facing increased pressure that competitive advantage can be built not only with research but also through excellent in creative active teaching. Creative active teaching includes using case study method in classroom and preparing talent students for case competitions as innovative strategy in a manner that integrates curriculum objectives with learning outcomes.

Erskine (1998) defines case studies as “a description of a real event, which includes a decision, challenge, opportunity, problem or attitude with which a person or people in an organization are faced”. There are two main areas for using case study method in higher education in the classroom and case competitions. The implication is that the classroom needs to include active and interactive learning as the basis for developing understanding of core disciplinary concepts, and these underpin academic success with strong implications for student retention (Crosling et al, 2009.) Active learning is often associated with experiential, problem-based and project-based learning, and other forms of collaborative learning, and less reliance on the large lecture format. Problem-based and project-based learning promote collaboration among students to solve problems, and by using realistic problems or situations for learning, a deeper understanding of the relationship between theory and practice can be developed and understood by students. Considering Jelenc"s (2011) comparison study of using case methodology in classroom in the West (USA) and East (Croatia), it is crucial to point out that the role of the student in the West is to become a partner with the professor, while in the East the student has a subordinate role. Another important difference in applying the case study method is that students in Western countries are more stimulated to prepare themselves for the classroom and are motivated to actively participate. Furthermore, in the East students are usually not familiar with the material used in class and are less interested to learn. The main constraints of students in Serbia, as an eastern representative, with regard to the case method in classroom are: focus only on knowledge covered by the exam, lack of time to learn more and demotivation for active learning (Damnjanovic, 2011). This study will focus on case competition as innovative strategy approach.

However, applying active case learning at the case competition described an opportunity for undergraduate students to apply concepts they have recently seen in their coursework to „real world" business problems (Bale et al., 2013). Competitions enable students to deal with the challenge of delivering results under pressure, given an enigmatic real-world business problem. The Auckland University has compiled a list of results from past undergraduate international case competitions with invitation only from 2011 to 2016. This list contains information on the winner of the competition, as well as universities that came second and third (or made it to the final). Statistics show that number of global case competitions that are being organized yearly has increased from 13 in 2011 to 18 in 2015(The University of Auckland, 2016).

Our best practice from the Faculty of Organizational Science University of Belgrade with great results at the global level at the prestige case competitions from 2012 to 2016 enabled organizing The Belgrade Business International Case Competition. Belgrade Business International Case Competition is a global undergraduate business case competition organized by the Faculty of Organizational Sciences of the University of Belgrade since 2013 in South Eastern Europe. This competition consists of 16 leading business schools from all around the world (USA, Canada, Europe, Australia and Oceania, Asia) and the jury members, who evaluate student solutions in Power Point format, are practitioners and business consultants. Students have two cases to solve, the first one in five hours and the second one in 30 hours. They have 20 minutes for presenting their solutions, followed by 15 minutes of question-and-answer (BBICC, 2016).

Based on previous researches, case competitions have been shown to have multiple benefits for the students who are participating: managerial skills with focus on creativity and innovation, learning benefits and employability skills.

4.1.Managerial skills

According to Umble et al (2008) using team case projects in education can encourage the development of problem-solving skills, engender deeper and more critical and creative thinking, increase confidence, provide a context for the relevance of the subject matter, encourage group interaction. Students felt that the Consulting Challenge as case competition in Minnesota helped them be effective teammates, manage heavy workloads, apply theory, solve organizational problems, present a persuasive argument to a client, manage their emotions, answer difficult questions from a client, present creative ideas to a critical audience, perform

under short deadlines, manage time, complete large amount of work in a short time (Sachau and Naas, 2010).In order to use case competition to prepare students for the future work case study method helps students develop managerial skills: problem - solving approach, critical reasoning and analytical skills. Student participation in case study competitions can enhance their communication skills, making them more suited to negotiate an increasingly competitive work environment. (Burke at el, 2013).

In reviewing materials available in case competitions in South Eastern Europe - Serbia and Croatia (Damnjanovic and Dlacic, 2015) it is evident that skills that students' developed the most are teamwork skills and learning how to perform market research. The rest of the answers are distributed among developing creative thinking, developing presentation skills, identifying target markets, collaboration with companies, learning how to make decisions and identifying trends on the market. Considering the teamwork in business student case competition in Serbia, Radisic and Nedeljkovic (2012) point out the creativity and thinking out of box in brainstorming session are crucial for development of business ideas for company representatives in order to provide different solutions for companies. Brainstorming as the initial stage in case solving analysis include: everyone write ideas on paper, all ideas being equally valued by the decision making criteria and no criticism of other people's ideas is allowed. Besides learning individually, students from Serbia and Slovenia at case competitions are additionally improving their skills through interaction with their colleagues. Cases make learning relevant and meaningful to the student through active participation in analyzing, discussing and solving real problems (Todorovic at el, 2014)

4.2. Active Learning

Active learning benefits from cases approach usually recognized alignment of theory with practice, and using managerial tools for solving life problems. Cases make learning relevant and meaningful to the student through active participation in analyzing, discussing and solving real problems. Learning is moved from memorization of numerous facts to practical application of theories, concepts and techniques to real problems. Students are in a position to accumulate the knowledge and experience of older people, lecturers and jury members (Todorevic at el. 2014). Case study competitions expose students to real world experiences, encourage them to take ownership of their learning and help to assimilate their ideas into theory and practice (Burke at el, 2013). Furthermore, case studies not only make theory and principles meaningful and useful in practice but also provide specific knowledge and the ability to act in real life. The skills and knowledge attained from well-planned application of case studies are transferred and imposed on the student. Case studies improve personal integrity and the ability to choose right action with active learning through case competition. The case study thereby contributes to the realization of the aim of educating good managers and administrators (Rendtorff, 2015).According to research from New Zealand (Corner at el., 2006) case competition reflects the four elements of a grounded learning exercise. These elements are: creating a real-world experience, optimizing learning transfer, integrating theory and practice, and shifting learning responsibility to the students.

4.3. More attractive on the job market

Referring to potential employability skills case study competitions improve teamwork, critical thinking and communication skills, which are the skills that employers want from their new employees (Burke at el, 2013). Case competitions provide an opportunity to make business education meaningful to business students, while providing students an opportunity to prepare for upcoming career challenges. Competitions enable students to deal with the challenge of delivering results under pressure, given an enigmatic real-world business problem (Bale at el., 2013).Reflections from past participants suggest that the competition is a more memorable university experience than are obligatory prerequisites for career qualifications and better prepare students for future career (Ali at el., 2011, Damnjanovic, 2012).Lastly, the benefits for managers and company side from case competition are: potential employment - selection and recruiting of the best students and networking of organization that provide case with faculty.

4. CONCLUSION

An obsolete knowledge, competence and skills are the main obstacles to development of many organizations. The global dynamic business environment needs new entrant employees ready for the immediate start and in many companies there is no time for learning at working place. All of the given changes have an impact on the fact that business schools have to be competitive on the market of higher education, and have a leading role in terms of providing the “best” students for the “best” companies in the job market (Damnjanovic et al, 2014). Role of the business schools is in providing “a prepared citizen” (see Everett and Pege, 2013) is crucial for the future of the business. What is the future of the business? “It"s not

necessarily overnight shifts – they're ongoing and perpetual – but they're going to change everything the way we know it today. If you're not competing for the future, you're by definition competing for irrelevance" (see more in Clark, 2013).

The quality professionals lately point some key trends which are transforming the future of quality: *talent of people*, *creativity and innovation* or *knowledge and agility.* The quality profession needs "*leadership talent worldwide*" (Gutner and Adams, 2008) and the role of the quality professionals must become that of teacher and mentor, coach and player (Nash, 2014). Study of Power (2014) indicated that quality management in developing countries can still use existing knowledge to achieve improvements however innovative approaches are expected in the near future. Considering difference between students from Western and Eastern countries (Jelenc, 2011, Damnjanovic, 2011) such as: collaboration with professors, motivation to actively participate, familiarity with the material used in class and factual learning - the main constraints of students from Eastern European countries might be seen in absence of needed skills for global business. In the knowledge economy, critical to success skills of new entrants are: teamwork/collaboration, creativity and innovation, critical and thinking/problem solving, professionalism/work ethic, oral and written communications, information technology application, leadership and lifetime learning.

Even though future of higher education in area of the quality management is complex issue, the general strategies for the specific skills development should be based on new and innovative higher education. Creative active teaching includes using case study method in classroom and preparing talent students for case competitions as innovative strategy in a manner that integrates curriculum objectives with learning outcomes. Based on previous researches, case competitions have been shown to have multiple benefits for the students who are participating: improved managerial skills with focus on creativity and innovation, learning benefits and employability skills of the talent. Our best practice from the Faculty of Organizational Science University of Belgrade, with great results at the global level and the prestige case competitions from The Belgrade Business International Case Competition (BBICC) are the excellent starting point for recruiting the right talent.

Abstract: *This paper analyzes the approaches of quality management in the software industry and emphasizes the application of quality concepts in software development, which includes the key elements necessary for the survival of an organization and its growth. The paper also shades some light on the ways quality management principles are applied throughout all stages of software development. It also elaborates in one of the specialized and belonging disciplines, such as: software testing. In this context, various aspects in the field of quality assurance in software development: methods and techniques of software testing and software lifecycle are described. In the paper is given compared quality management principles and principles of software development.*

Keywords*: quality assurance, software, testing, CMMI, PDCA, quality documentation, process approach*

1. INTRODUCTION

This paper is about different quality management approaches in software industry. Use of quality in software development is essential for advancement and development of a company, especially if one of the goals is long-term business success.

It is necessary to make a distinction between testing and software quality assurance, as well as what can be achieved by software testing. Each project has its beginning and end, which is also the case with software development. Which phases of development is software going through and can those phases apply not only to software development, but also to other products we want to successfully place on the market?

Why is the process approach important and how can the direct connection between this approach and Deming's well known cycle be made? What is test plan, test case and software quality assurance plan and why is the documentation in software development usually formatted like this?

Some of the most common methods and techniques in the field of testing and quality assurance will be mentioned. In order to ensure software quality, as already mentioned, it is necessary to conduct software testing. Black and white box methods are essential in order for tester to start testing process.

Software industry is engaged in development, maintenance and software delivery, as well as related services such as trainings, documentation, advising and support for software use. Software testing consists of verification and validation correctness of the software itself, but it also identifies important defects, errors caused by people or environment, lack of knowledge or mistakes in the application code.

Software development process includes:

- Definition and detailed documents for development
- Prototype as a proof – concept
- Presentation of prototypes and correction of products (if necessary)
- Software encryption and code verification
- Individual product testing

2. PHASES IN SOFTWARE DEVELOPMENT

Each phase of software development should be tested in order to ensure quality of end product. So

in each of those phases quality can be ensured by testing. Testing without preparation, which is mostly for informational purposes, is called walkthrough.

Inspection is more formal than casual testing and it usually includes three to eight experts. The subjects of supervision are phases of development that are documented and specified and the goal is to find the lack but not to be removed. Participants should prepare for this type of check by reading the documentation and procedures where all of the development steps are being defined. The result of inspection is also written report.

There is a huge similarity with internal check from ISO 9001:2008 where it says - „The organization shall: plan, establish, implement and maintain an audit programme(s) including the frequency, methods, responsibilities, planning requirements and reporting, which shall take into consideration the importance of the processes concerned, changes affecting the organization, and the results of previous audits."
Planning, analysis, design, implementation and testing are the phases through which the software evolves. From a conceptual phase to delivery, software must be monitored and tested in order to prevent problems to happen. The earlier you recognize the potential defect or defect itself, debugging will be more efficient and with lower costs.

Three famous models of software development are:

- Waterfall model
- V-model
- Spiral model

Waterfall model is the oldest and most commonly used model. It follows software development through all phases, characterized by clearly identified user requirements, procedures with clearly defined development processes where any deviation can cause an error or bag. In more traditional models, such as the waterfall model, the testing phase is done after defining the requirements and when the encoding process is completed. However, this practice is obsolete, and even though the testing phase is the last phase, it is used at all phases of development so that each phase can be well tested and ready to make it to the next phase.

3. TESTING AND QUALITY ASSURANCE IN SOFTWARE DEVELOPMENT

It is necessary to make a difference between testing and software quality assurance. *Jonassen Hass (2008) says that testing is an activity that can be applied in all phases of software development in order to secure software quality as the main goal and that testing involves system or application operations under defined conditions and evaluation of system's testing results.* What makes testing interesting is creating such conditions where things will go wrong, in order to determine when and why software doesn't work and its correctness or malfunction if the software doesn't respond to changed conditions. (ie. will Facebook homepage start if username and password are not entered; if it starts under those conditions, that can cause huge privacy concerns.)

Software testing is process of validations and verification in order to prove that:

1) Software meets business and technical requirements
2) Software works as planned.

Muyers, Badgett and Sandler (2012), describe software testing as identifying defects and mistakes that must be corrected, therefore, from the perspective of the end user, mistakes and defects must be removed so the functionality of software isn't changed or damaged.

As Desikan and Ramesh (2008) describe, software testing can give an answer to some of these questions:

- *Does software really work as expected?*
- *Are the user requirements met?*
- *Are users satisfied?*
- *How does it work and is it "user friendly"?*

- *How does it react when it's being used by many people at the same time?*
- *Which parts of software have to be improved?*
- *Is it ready for delivery to the end user?*

Software quality assurance includes whole process of software development, tracking and process improvement, making sure da each process, standard and procedure are being followed. Quality assurance ensures that the process is noticed in the early stage of development and the team of experts was involved in removing the potential or existing problem. Quality assurance is focusing on "preventive action". Software quality assurance can provide complex approach to maintenance, not only in the context of eliminating mistakes, but also:

- Work on re-engineering solutions that meet new requirements of the market
- Solutions improvement
- Contribution to the overall evolution of the solution through the implementation of proactive analysis of key causes for all critical questions,
- Quality improvements of original solution through refactoring the original code, etc.

Definition proposed by ISO standards for software quality (ISO/IEC 2001, 2003a, b, 2004) says that *"QA is a measurable physical or abstract property of software product that bears on its ability to satisfy stated and implied needs"*. According to *Balasubramaniam et al. (2009), "achieving QAs in SBS is critical due to the following reasons:*
• *Application developers need to be confident that the services (and compositions of them) will meet end user quality requirements.*
• *"Application developers need to understand the cost and risk of achieving quality requirements, given that system QAs often must be traded off or built in" (O'Brien et al. 2007).*
• Application developers require information for selecting between alternate services with similar functional capability.
• Application developers require information about Quality of Service (QoS) to monitor and enforce service level agreements (SLAs).

4. QUALITY IN SOFTWARE DEVELOPMENT

Software quality implies the absence of bugs in the software, delivering at the right time and to the right place with minimal costs, the software that meets the requirements and expectations of users and that is suitable for maintenance. But quality is a subjective term. It depends on who is the software's end user and what is its impact on the development phase. The end user may be a foreign buyer, internal tester that gives a confirmation for the further development, the employer of organization itself, shareholders, etc. The perception of quality depends of priorities and requirements of the end user.

4.1. The use of CMMI maturity model

Falessi, Shaw and Mullen (2014) point out that five levels of "maturity" process model helps in providing the efficiency in quality software delivery. CMMI models are collections of best practices that help organizations to identify and improve their processes. That model is focused on larger organizations. However, many of the quality processes are generic and applicable to all organizations, regardless of the size and complexity. Organizations can obtain an estimation of CMMI maturity levels by authorized valuators, or it can be conducted by organization itself.

Maturity levels:

- ✓ At the *initial level*, processes are disorganized, even chaotic. Success is likely to depend on individual efforts, and is not considered to be repeatable, because processes would not be sufficiently defined and documented to allow them to be replicated.

- ✓ At the *repeatable level*, basic project management techniques are established, and successes could be repeated, because the requisite processes would have been made established, defined, and documented.
- ✓ At the *defined level*, an organization has developed its own standard software process through greater attention to documentation, standardization, and integration.
- ✓ At the *managed level*, an organization monitors and controls its own processes through data collection and analysis.
- ✓ At the *optimizing level*, processes are constantly being improved through monitoring feedback from current processes and introducing innovative processes to better serve the organization's particular needs.

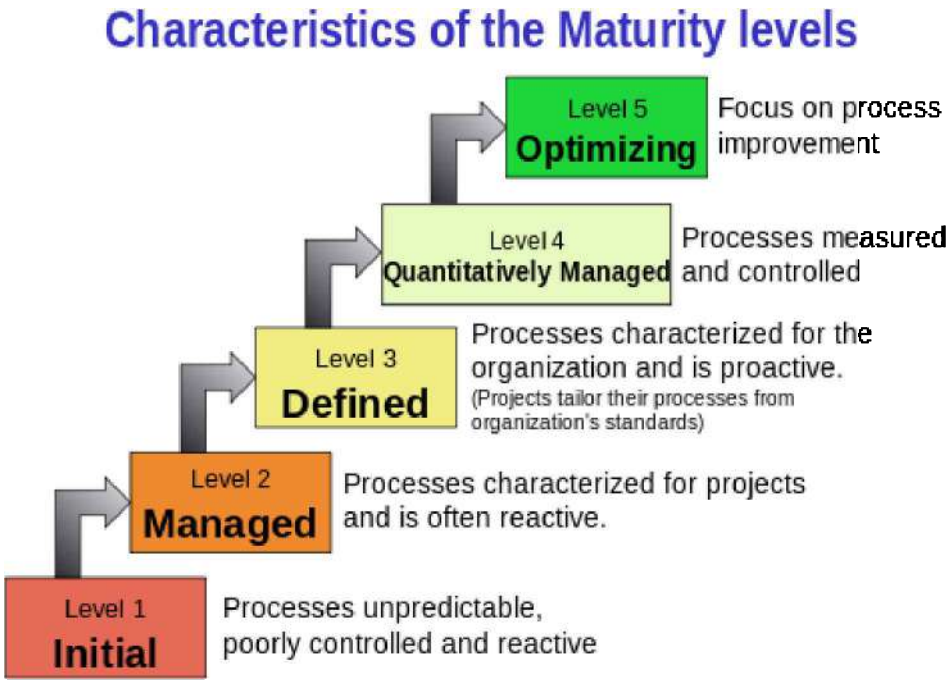

Figure 1. CMMI Maturity Model Levels - Falessi, Shaw and Mullen (2014)

4.2. Introduction of quality assurance process in organization

The introduction of quality assurance processes in the organization depends on the size of the organization and possible risks. For larger organizations with high-risk projects, formal processes of quality assurance and great commitment of the management is necessary. Not only the leadership but all employees must be aware of the importance of introducing quality processes and they have to be involved in the introduction of these processes. Communication between users, testers, programmers and managers must be adequately permeated throughout the organization, because of the cooperation and regular communication is the basis for coordination and improvement of business processes.

Other possibilities for the introduction of process quality can be seen in the implementation of different approaches, such as Kaizen - a method of continuous process improvement, Deming's method Plan-Do-Check-Act and many others.

Example model of Deming's PDCA (Plan-Do-Check-Act) in software development

Company "Mera" is in charge of software production. One of the clients ordered a software as a desktop application for the computer. The application is called Team Tracker, which is used as an internal application, where employees can enter their work tasks, time spent on working on activities, time spent outside the company (having a break), vacation planning, problems and plans for the next day.

Application of PDCA cycle is given below as an example.

Plan

Company "Mera" has found his client's claims:

- Making daily reports
- Launching applications quickly and easily
- Transparency commands
- Relation with other operating system
- Expansion possibilities, introduction of new options
- Easy maintenance

Do

Processes are being realized and mistakes are being processed simultaneously.

Check

Process performances are being monitored and measured. Mistakes and bugs are identified. It is checked if application is working in the required environment and whether it can operate in alternative environment.

Act

Continuous improvement of process performances. It is possible to give certain remarks and comments, it is important that both employees and end users are being involved. New solutions or edit of the existing ones are being proposed. Every employee has the right to propose improvements. Degrees of influence are being determined - how much influence do certain software features have on individual customer requirements. Standardization of process or the introduction of a model of maturity is being conducted.

4.3. The role of documentation in providing software quality

Processes of quality assurance should be documented to ensure the repeatability of success. Specifications, standards, schemes, business rules, configurations, test plans, test cases, reports, manuals etc. should be documented in some form (electronic, paper…).
Based on the good documentation, the system can be set up where certain information can be easily found. Documentation often becomes more important when it comes to long term projects.

What is test plan, test case and software quality assurance plan?

"Test plan is a document which consists of basic information about testing and it is describing objectives, scope, approach and focus which help in software testing approach", Filipovic and Djuric (2009) point out. The process of preparing the test plan is useful way of thinking which phases software should go through, which methods are used and what are the expected test results.

Test plan includes:

- Name
- Version of the software that is being tested,
- Document audit that includes test plan makers, date, who approved it,
- Content
- The purpose of the document and to whom it is intended,
- Testing objective
- Description of the software that is being tested
- Relevant documents that is connected with test plan, such as standards, procedures, project documentation and other test plans,
- Traceability requirements
- Test team,
- Scope and limitations of testing,
- Risk analysis,

- Results
- Additions, vocabulary, abbreviations, etc.

Filipovic and Djuric (2009) explaine that "test case is a collection of different environmental conditions under which the software is being tested and it's being determined whether software system or its part works as planned." They also point that it must describe the desired result. Test case won't be evaluated if there is no defined statement about the expected output.
It describes the entrance, action or event and the expected result in order to determine whether the characteristics of software application work correctly.

Test case can consist of information such as:
- Test number
- Test name
- Creation date
- Test description
- Objective
- Test conditions
- Requirements necessary to perform the test
- Steps of implementation
- Expected results

The level of detail can vary depending on the organization and project. Organizations often use less detailed test cases that allow documentation that is simple and more flexible, that refers to test implementation.

Test developing processes can help find problems in requirements or application design because it requires thinking about how exactly the application will work. Because of that, it is useful to prepare tests at early stage of software development, if possible.

5. TESTING METHODS OF SOFTWARE QUALITY ASSURANCE

Burnstein (2003) said there are many ways and testing methods of software quality assurance, such as:

Black box testing - does not require knowledge of the inner code design or how the application is being programmed. Basic functionality and compliance with the requirements are being tested.

White box testing - based on knowledge of the internal logic and application code. The internal code, algorithms, environmental conditions, etc. are being tested.

Alpha testing - application testing before the end of development process; minor design changes can also be the reason of such testing. Usually the alpha testing is done by end users, not programmers or testers.

Beta testing – it's done when the development and all necessary testing are completed; bugs and problems need to be found before the final delivery to the user. It is usually done by end users, not programmers or testers.

Mutation testing - a method for determining whether existing tests are useful even when some changes (errors) are deliberately made. Changed (muted) parts of application are being tested again using the original tests, to determine detected errors, which are expected because they are deliberately made changes ie. mutations.

Sanity / smoke testing - the simplest initial testing of basic functionality of the application components. If such testing proves to be reasonable, or if the results are acceptable, it is sent to the next phase of testing.

Load testing - testing of the application under load when it's being used by multiple users or when it opens simultaneously with other applications, to determine at what point an application stops working

due to the overload.

Recovery testing - How and for how long the system is recovering from a crash, hardware failures, or other catastrophic problems.

6. THE PRINCIPLES OF QUALITY MANAGEMENT AND SOFTWARE DEVELOPMENT

Filipovic and Djuric (2010) say that "The eight quality management principles represent a comprehensive, fundamental rules followed by the organization, with the goal of continual improvement of performance relevant for customers and other stakeholders."
Those are:
1. Customer focus
2. Leadership
3. Involvement of people
4. Process approach
5. System approach to management
6. Continual improvement
7. Factual approach to decision making
8. Mutually beneficial supplier relationships

Jung, Seung-Gweon and Chang-Shin (2004) point out that, as is known to software engineering experts, the ISO/IEC 9126 was a long run software evaluation standard which dealt with a quality of software products, "by presenting an appropriate framework for modeling the processes by segregating quality dimensions into six categories (functionality, reliability, usability, efficiency, maintainability, portability), consequently divided into 27 smaller groups."

Polillo (2012) claims that "these processes should lead to better customer satisfaction with the software quality, while within the organization they serve as enablers for understanding of software quality dimensions and open space for new improvements." Recently, this standard has been replaced by the newer version entitled ISO/IEC 25010:2011.

6.1. Focusing on the customer

By ISO 9000:2015 customer satisfaction is the "customer's opinion of the level to which the customer's requirements are being met." "Organizations depend on their customers and therefore should understand their current and future needs, the need to meet their requirements and strive to overcome their expectations."
Customer satisfaction is achieved when goods and services match or overcome the demands and needs of the user. Therefore, all processes and all employees in the organization must be focused to users. In software development, quality is defined by group (users, clients or customers) which software is dedicated to and organization should identify their stated and possibly unexpressed needs and approaches to software development in a way to satisfy customers.
Essential aspects of focusing on users are:
• Understanding clients' needs and overcoming their expectations,
• Taking responsibility for customer satisfaction, so the quality of service the highest priority,
• Confidentiality of information, intellectual property protection and business reputation: own and reputation of users.

Measuring customer satisfaction can be achieved in various ways, by using direct (surveys) and indirect (Monitoring Body) methods. For example, the software company "Mera" uses methods of colors - next to the each software features is green, yellow or red color, representing satisfied, medium satisfied or dissatisfied users.

"Recently, the User Experience concept (UX) has become more used than usability in the Human Computer Interaction (HCI) discipline and SQUARE (Systems and Software Quality Requirements and Evaluation) [1] is the standard that defines the system quality or the software quality. Nevertheless, HCI practitioners still have not come to an agreement about defining UX. Also, the standard attributes which researchers use for analyzing the UX in a specific interactive system do not exist. For these reasons, the main aim of this research is the specification of UX based on the facets

that the ISO/IEC 2010:2011 considers according to its attributes." (Masip, Oliva and Granollers, 2011)

6.2. Staff involvement

ISO 9000:2015 says that "the staff at all levels makes an essential part of an organization and their full involvement enables to take advantage of all capabilities for the organization's benefit."
It is good idea to listen to ideas, suggestions and comments of employees, because everyone has some additional features, knowledge and skills. Opinions of programmers and testers should be considered, because together they can come up with the right solution. It is well known that if a thing is being impartial observed, better conclusions and solution proposals can be made. A new idea can easily be accepted, does not only applies to projects, but also to the policy of the company, interpersonal relationships etc. Employees should be treated with respect and their rights have to be protected. It is necessary to create equal conditions for employees with the same qualifications.

6.3. Process and system approach to management

In ISO 9000:2015 is said that "the desired results can be achieved more efficiently, if the management of certain activities and resources is done through processes."

The use of this principle leads to lower costs and shorter software development time and respect deadlines for testing and delivery, more efficient use of resources, improved and predictable results, prevention of the possible occurrence of errors or bugs, creating more capable workforce, establishing clear responsibilities and competencies for managing key activities.
Process approach in software development means that processes are defined, managed and measured.

"Identifying and understanding of a system of interconnected processes, and management of that system, contribute to the effectiveness and efficiency of the organization in achieving its goals" as defined in ISO 9000:2015.
The purpose of the quality management system is to achieve customer satisfaction.

Key advantages of this principle are: the creation of comprehensive plans that include test plans, integration process through the stages of software development, the ability to focus all efforts on the key processes that need to be tested in particular, a better understanding of the errors causes and taking timely actions to prevent or remove the deficiency.

7. CONCLUSION

From all mentioned in this paper it can be concluded that use of quality has a major impact on business processes, which are of prime importance for the success of an organization.

Through this paper is explained the application of quality in software development.

The basic difference between the software testing and software quality assurance and that testing is an activity that can be applied at all stages of software development, in order to ensure software quality. Quality assurance can influence on costs reduction, process efficiency improvement, because the software that was delivered to the user's perception of quality, will definitely be adequately valued in the market.

Successful software has successfully passed through all stages of development, and by testing each stage quality of parts and then the final product or software can be provided. The application of Deming PDCA cycle in direct application production that is delivered to user after the last phase of development and testing is shown.

Some of the most common methods and techniques in the field of testing and quality assurance are explained. It is necessary to implement software testing to ensure its quality.

Abstract: *This paper presents the ways and types of interpretation of the concept of the platform independency, as well as the tools and mechanisms of its realization in real world environment. The paper introduces General Concept of the Independency (GCoI) model. The model is derived from most important platform independence mechanisms. The paper identifies four key mechanisms for achieving platform independence, and all of them are described using GCoI model. The GCoI model represents the fundamental concept that lies behind the platform independence.*

Keywords*: platform independency, General Concept of the Independency (GCoI) model, mechanisms for achieving platform independence, software engineering, platform independent software architecture*

1. INTRODUCTION

Appearance of new software architectures (Liu et al. 2011; Bass, Clements and Kazman, 2003; Gorton, 2011) and software platforms, especially in context of cloud computing approach, impose the need and challenge for identification and understanding of concepts and mechanisms which enables integration and adjustments in heterogeneous environments.

The main goal of this paper is to identify the mechanisms for achieving independency between software architectures and software platforms. While developing new platform or software architecture, engineers should be aware of all necessary elements that need to exist in order to achieve platform independence. In that sense, we will first try to define platform independent architectures and to identify main characteristics software architecture needs to poses in order to be considered as platform independent. In addition, we will try to classify the types of platform independence, and to identify mechanisms that are used for achieving each type of platform independence. By analyzing identified mechanisms, we will establish a general model for achieving platform independence. We will use platform independent architectures such as SOA (Vitvar et al. 2007; Erl, 2005), COA (Gorton, 2011), and MDA (Meghan; Object Management Group, 2003), and most important software platforms Java and .NET as examples for practical explanation of the general model for platform independence.

In this paper, we defined and explained the platform and platform independent software architectures and referred to the main problems in platform independent software development in the section2. Section 3 introduces the platform independent classification. This classification is based on noted relationships between software architecture and software platform from which we derivate different type of platform independency. The next section, describes four key mechanisms used for platform independency. Each of these mechanisms is explained by the General Concept of the Independency (GCoI) model. The GCoI model represents the fundamental concept that lies behind the platform independence and in the last section (section 5) authors point out importance of this model and emphasize future directions of research.

2. THE PLATFORM INDEPENDENCE

This section defines and explains the platform and the platform independence concepts as well as platform independent software architectures. It also discusses key concepts related to platform independence and objectives that lead to its realization. The part of this section refers to the main cause of platform independence implementation problems.

2.1. Definition of platform

The platform independence and platform as a concept appear in a various segments of the software engineering science. Consideration of the platform independence concept begins with considering the concept of platforms and their basic classification.

According to Object Management Group, a platform is defined as:
"Set of subsystems/technologies that provide a coherent set of functionality through interfaces and specified usage patterns that any subsystem that depends on the platform can use without concern for the details of how the functionality provided by the platform is implemented (Object Management Group, 2003)

A typical definition of a platform is: *A platform is a combination of hardware and software used to run software applications. A platform can be described simply as an operating system or computer architecture, or it could be the combination of both.*

There are two basic types of platform:

- A hardware platform can refer to a computer architecture or processor architecture. For example, the x86 and x86-64 CPUs make up one of the most common computer architectures for general-purpose computers.
- Software platforms can either be an operating system (Microsoft Windows, Linux, Mac) or implementation technologies, though more commonly it is a combination of both. Java and .NET are software platforms; they represent a set of technologies and programming languages, which together with specialized development environments enable the development of complex software systems. Java and .NET represent platforms that enable applications (implemented using these technologies), to work on multiple operating systems and hardware platforms.

A platform represents a subsystem or a set of subsystems that provide certain functionality. Platforms represent foundation for execution of other software systems and applications. The Figure 1. illustrates the basic platforms classification.

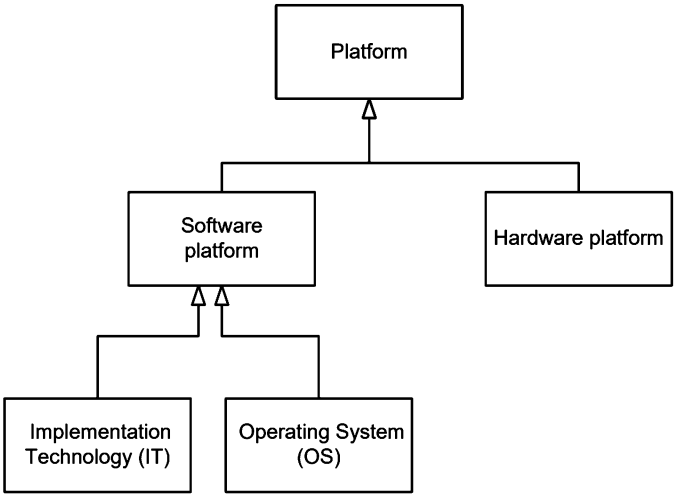

Figure 1: Basic platform classification

2.2. Platform independent software architectures: definition and characteristics

In its strict sense, a software architecture is "a description of the subsystems and components of a software system and the relationships between them." (Buschmann et al. 1996) Software architectures that will be further discussed are Model Driven Architecture – MDA (Meghan), Component Oriented Architecture – COA (Gorton, 2011) and Service-Oriented Architecture - SOA (Erl, 2005).

The platform independent software architecture does not include any specifics of implementation technologies, nor the details of target hardware platforms or operating systems on which software applications executes.

The platform independent software architecture should meet the following requirements:

- Platform independent software architecture does not contain details relating to the hardware platform on which software executes.
- Platform independent software architecture does not contain details relating to the operating system on which the software executes.
- Platform independent software architecture does not contain details relating to the implementation technology.
- Platform independent software architectures are specified with universally accepted languages for software systems specification.
- Platform independent software architectures can have large number of implementations.
- Platform independent software architectures are based on platform abstraction.

Because implementation and target platform details are excluded, the participants in the development process may focus on the key and essential aspects of software architecture and software systems. Also, it is much easier to explain the architecture to non technical people, who have interest or influence on the software systems financing and implementation.

Universally accepted notation and method makes platform independent software architectures important in understanding the software system and making the communication more comfortable.

2.3. Platform independence concept: goals and importance

The concept of platform independence is related to the concepts of portability, reusability, universality and financial viability. Portability, multiple usage and financial viability can be considered as primary objectives for realization of platform independent software architecture.

Universal and widely accepted rules have not been changed as quickly as the hardware platforms, operating systems or technologies. Universally accepted principles often go beyond the boundaries of time and space in which they have appeared. Platform independent software architectures tend not to obsolete rapidly, because they keep the knowledge and experience accumulated over years and generations, knowledge that can be reused in a number of situations. Such architectures are strong foundation for future development of software systems.

Based on the above mentioned we can conclude: The ultimate goal of platform independence realization is software applications that can run on many operating systems and hardware platforms, without modification or adaptation. Such solutions have maximum portability level.

The ultimate objectives of the software architecture platform independence realization in respect to the software platform are:

- Provide that the same software architecture can be used for various implementations using different technologies.
- Protect the results of software design process from the danger of rapid obsolescence, caused by the changes in technology, operating systems and hardware platforms area or platforms of any kind.

3. THE PLATFORM INDEPENDENCE CLASSIFICATION

While considering platform independence, it is necessary to specify the type of platform independence to which the review relates. Therefore, in this paper, we often use terms ”**which/what”** is independent **"in respect to" "what"** with the term and concept of platform independence**.**

Independence can be achieved in respect to:

- Software platform or
- Hardware platform
- Within the software platform, we distinguish:
- Operating systems
- Implementation technologies

Platform can be observed as software or hardware platform. We make distinction between implementation technologies as a platform (like Java and .Net) and operating system as a platform. The implementation technology is executed on an operating system while the operating system is executed on some hardware platform. Software system is based on software architecture, and is implemented using concrete implementation technology and it executes on some operation system.

Based on the above-mentioned relationships between software architecture and software platform, the following basic classification of platform independence is derived:

- PI1 – Independence of software architecture in respect to the implementation technology
- In this category, we have particularly considered:
  - PI11 – Independence of MDA in respect to the implementation technology
  - PI12 – Independence of COA in respect to the implementation technology
  - PI13 – Independence of SOA in respect to the implementation technology
- PI2 – Independence of implementation technology in respect to operating system
- PI3 - Independence of operating system in respect to hardware platform

4. THE PLATFORM INDEPENDENCE REALIZATION MECHANISMS

In this section, we have described four key mechanisms used for platform independency:

1. Services-based mechanism
2. Component-based mechanism
3. Model-based mechanism
4. Virtual machine-based mechanism

These mechanisms are presented below on the Figure 2.

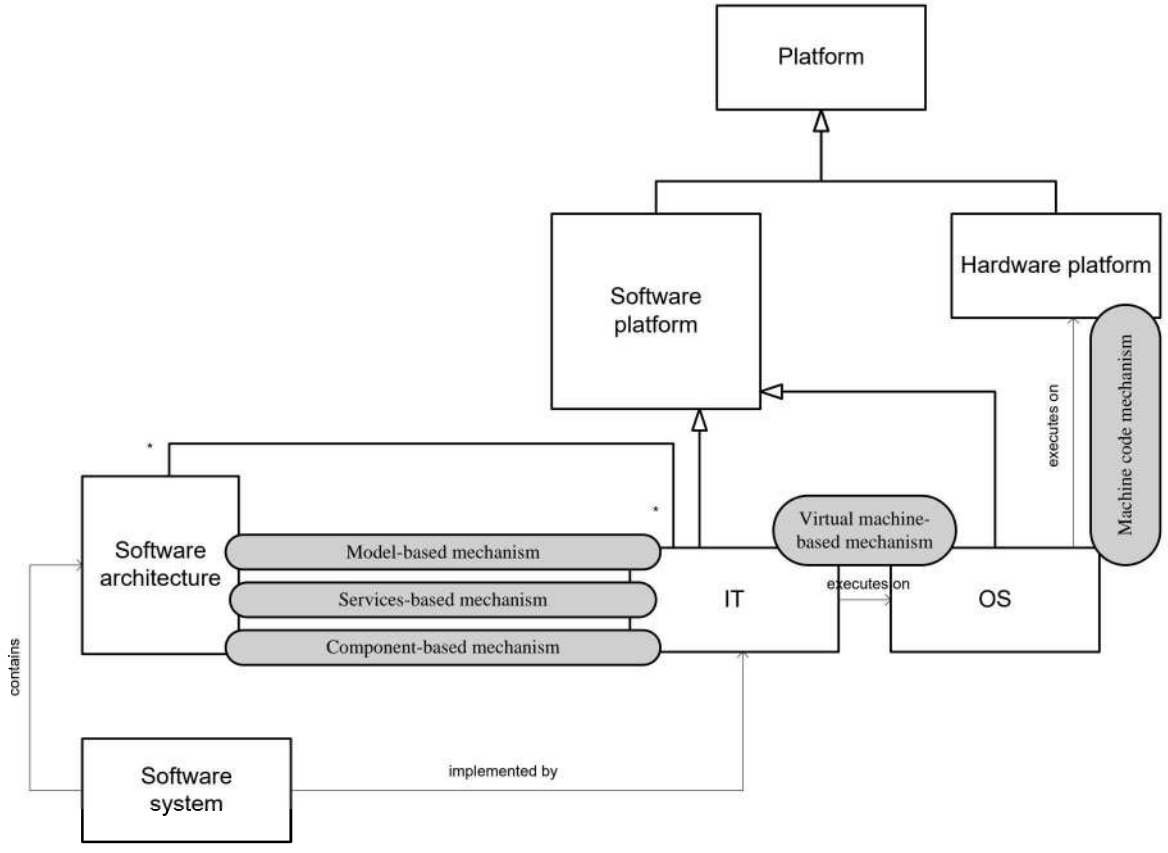

Figure 2: The relationships among software application, software architecture and platform

Model-based mechanism, services-based mechanism as well as **component-based mechanism** is used in achieving the independence of software architecture in respect to software platform.

Virtual machine-based mechanism is used in achieving the independence of the implementation technology in respect to the operating system on which the software system executes. The independence between software architecture and operating system is achieved indirectly (transitive relation) using this mechanism.

In addition to these four mechanisms that are covered in detail in the paper we have also identified the **mechanism of machine language** that enables operating system independence in respect to the hardware platform. In this paper, we have not specifically discussed about this mechanism. The independence between software architecture and hardware platform is achieved indirectly (transitive relation) using this mechanism.

Each of these mechanisms will be explained by the General Concept of the Independency (GCoI) model, which is presented on the Figure 3.

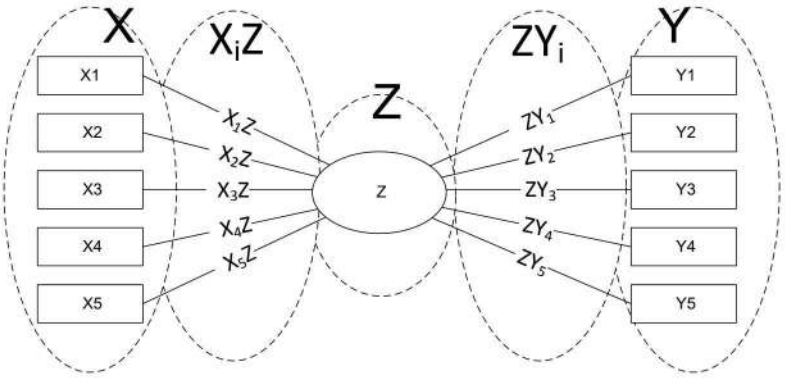

Figure 3. General Concept of the Independency (GCoI) model

The GCoI model represents the fundamental concept that lies behind the platform independence. The model consists of five elements (X, XZ, Z, ZY,Y). For each type of platform independence (PI1, PI2 and PI3), we have identified X and Y as elements between which we want to establish independence. X and Y can be observed as pair of software architecture (SOA, COA, MDA) and implementation technology (Java, .Net) in PI1, or as a pair of implementation technology (Java, .Net) and operating system (Windows2000,WindowsXP, Linux) in PI2 as well as pair of operating system (Windows2000, Linux) and hardware platform (x86 PC, AS/400) in PI3. In order to achieve independency between X and Y we have introduced independent component Z. Each element from sets X and Y should have different transformation to Z (XiZ or ZYj, i=1..n, j=1..m). If XiZ and ZYj exists, we can say that set X is independent to set Y.

Therefore, contrary to dependencies between every element from X (X1..Xn) to every element from Y (Y1 …Ym), these elements are only dependent on Z element. The GCoI model can be observed from two different aspects: as structure when we consider all the elements involved in achieving independency or as process of transformation between elements of set X and elements of set Y.

GCoI model can be applied to different mechanisms for achieving platform independence. If we consider Christopher Alexander's definition of patterns (Christopher et al. 1997), we can conclude that GCoI model obey this definition, and can be observed as a pattern. In software engineering, patterns are largely used for solving the problem of dependencies (coupling) between classes and objects. For creating maintainable software systems, it is important to reduce coupling as much as possible. The following part of this section describes mechanisms for achieving platform independence through GCoI model.

Services-based mechanism is used in achieving the independence of software components usually implemented as services (e.g. Web Services) using an implementation technology in respect to components implemented by another implementation technology.

Service-Orientated Computing (SOC) has become a main trend in software engineering that promotes the construction of applications based on the notion of services (Erl, 2005; Jonathan et al. 2008).

Web services provide a standard means of interoperating between different software applications, running on a variety of platforms and/or frameworks. A Web service is a software system designed to support interoperable machine-to-machine interaction over a network. It has an interface described in a machine-process format (specifically WSDL). Other systems interact with the Web service in a manner prescribed by its description using SOAP messages, typically conveyed using HTTP with an XML serialization in conjunction with other Web-related standards.

We have observed characteristics of web services, and ways of achieving platform independence in two different times:

1. Development time and
2. Runtime.

It is important to analyze both situations because in each of those we can notice different technologies, transformations, protocols, languages, but the same principle. This principle conform to the GCoI model.

According to General Concept of the Independency (GCoI) model, we have identified key elements of services-based mechanism, which are shown on the table below.

When we observe web service in development time, we can notice that both sides – provider agent and requestor agent can be developed using different technologies. Table 1 presents these elements.

Table 1. Services-based mechanism applied WS in development time

X - provider agent	**XZ**	**Z**	**ZY**	**Y-** requestor agent
Java	wsgen	WSDL	wsimport	Java
.Net	wsdl		wsdl	.Net
C++	wsdl2h		soapcpp2	C++
Delphi	delphi IDE		Delphi IDE wsdl importer	Delphi

Both sides need to have access to the WSDL document (Table 1, column Z). With access to the WSDL document both sides can generate programming code for components that will be used in runtime to establish communication (Table 1, column XZ – tools for generating components for provider agent, column ZY – tools for generating components for requestor agent). In this way, the XML based WSDL document stays the only component that gathers different technologies together and allows platform independent development of provider and requestor agents.

When we observe web services in runtime, platform independence is achieved using SOAP (Table 2).

Table 2. Services-based mechanism applied WS in runtime time

X - provider agent	**XZ**	**Z**	**ZY**	**Y-** requestor agent
Java	SOAP	SOAP Message	SOAP	Java
.Net				.Net
C++				C++
Delphi				Delphi

When the requestor agent calls some functionality of web service, the request is transformed into SOAP message (Table 2, column Z), and delivered to provider agent most commonly using HTTP protocol. The SOAP message is then transformed into platform specific call to provider component that will execute requested functionality, and optionally create the response and send it to requestor agent in the same manner.

Component-based mechanism is used in achieving the independence of software components usually implemented as services (e.g. CORBA) using an implementation technology in respect to components implemented by another implementation technology.

Development of software that is reliable, efficient and highly flexible, component-based software development can be employed for the complex software systems. (Jonathan et al. 2008) The Common Object Request Broker Architecture (CORBA) is a standard defined by the Object Management Group (OMG) that enables software components written in multiple computer languages and running on multiple computers to work together (i.e., it supports multiple platforms). It provides a platform-independent, language-independent architecture for writing distributed, object-oriented applications.

There are two perspectives (times) that, we have considered under the CORBA to explain component-based mechanism of the platform independency:

1. Development time and
2. Runtime.

From the development perspective, Interface Definition Language (IDL) is key concept that is used in component-based mechanism in order to achieve independence of a software system that was implemented through an implementation technology in respect to another implementation technology. According to General Concept of the Independency (GCoI) model, we have identified key elements:

- Different implementation technologies that conform to the X element on the GCoI model
- Different specification that enables transformation from IT to IDL interface (XZ elements on the GCoI model)
- IDL interface (Z elements on the GCoI model)
- Different compiler that generate code for different implementation technologies from IDL (ZY element on the GCoI model)
- Different implementation technologies that conform to the Y element on the GCoI model
- These elements are shown below on the Figure 4. and on the Table 3.

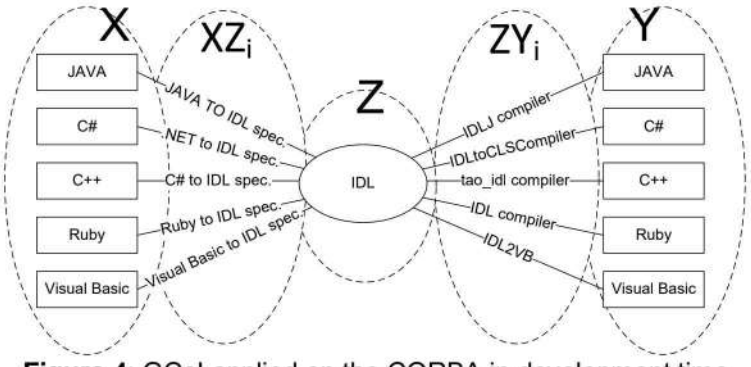

Figure 4: GCoI applied on the CORBA in development time

Table 3. GCoI applied on the CORBA in development time

X	XZ	Z	ZY	Y
Java	JAVA to IDL specification	IDL interface	IDLJ compiler	Java
C#	.NET to IDL specification	IDL interface	IDLtoCLS compiler	C#
C++	C++ to IDL specification	IDL interface	Tao_idl compiler	C++
Ruby	Ruby to IDL specification	IDL interface	IDL compiler	Ruby
Visual Basic	Ruby to IDL specification	IDL interface	IDL2VB	Visual Basic

From runtime perspective, client and server classes, generated by specific ORB programming language compiler, communicates among themselves using ORB vendor classes. ORBs communicate using IIOP protocol that enables software platform independence on both sides (client and server).Therefore the IIOP protocol is the key concept used in order to enable different software components to communicate among each other. According to General Concept of the Independency (GCoI) we have identified key elements:

- Different implementation technologies (Java, C#...) that conform to the X element on the GCoI model
- Different implementation of the CORBA standard (XZ elements on the GCoI model)
- IIOP CORBA that conform to the Z element on the GCoI model
- Different implementation of the CORBA standard (ZY elements on the GCoI model)
- Different implementation technologies (Java, C#...) that conform to the Y element on the GCoI model

These elements are shown on the Figure 5. and Table 4.

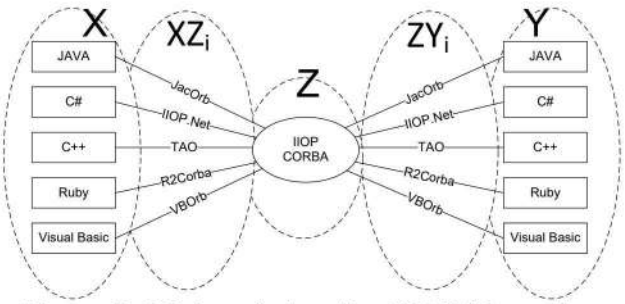

Figure 5. GCoI applied on the CORBA in runtime

Table 4. GCoI applied on the CORBA in runtime

X	XZ	Z	ZY	Y
Java	JacOrb	IIOP CORBA	JacOrb	Java
C#	IIOP.Net		IIOP.Net	C#
C++	TAO		TAO	C++
Ruby	R2Corba		R2Corba	Ruby
Visual Basic	VBOrb		VBOrb	Visual Basic

Model-based mechanism is used in achieving the independence of software architecture in respect to software platform. This mechanism is implemented under Model-Driven Architecture approach.

The concept of Model Driven Architecture (MDA) is published by OMG. It is based on creation of models and transformations between them. OMG describes different type of models and their relations but it does not specify how to create these models and which exact models and notations to use for their representation and how to transform them with one another. The top three models are created as graphical models while the last one as implementation code model.

Computation Independent Model (CIM) - CIM is a model that does not display details of IS construction but it specifies activities that are being processed in the IS. It represents business processes of the organization for which the IS will be developed. (Kardos, 2010)

Platform Independent Model (PIM) – PIM is a model, which describes IS, but hides details in usage of concrete technology. The PIM describes the behavior and the structure of the system. It does not specify operating system, programming language and hardware. PIM models are used to model the functionality and structure of the information system independently of the technological details of the platform, upon which it will be implemented.

Platform Specific Model (PSM) – PSM connects specification from PIM with details that specify what type of platform IS. will use. The PSM is responsible to specify the technical details to implement the PIM, e.g. the operating system, the programming language.

Implementation model (IM) – IM presents platform specific code. This model is usually generated from PSM but also it can be generated from PIM. It represents the deployable code that could be directly compiled and deployed without human interaction.

According to GCoI model, we have identified key elements the can be found in MDA. These elements are presented in Table 5.

Table 5 GCoI applied on the MDA

X - CIM	XZ - CIM-PIM	Z - PIM	ZY - PIM-PSM	Y - PSM
UML activity diagram	Query/View/ Transformation DSL	UML use case	UML Profile Query/View/Transformation DSL GPL	JavaEE
Business Process Model		UML activity diagram		
Data Flow Diagram		UML activity diagram		.Net
		UML use case diagram		
		UML sequence diagram		ORM
		UML class diagram		

PIM in MDA presents element used to achieve independence software architecture in respect to software platform. Different transformation from CIM to PIM can be written in DSL as well as transformation from PIM to CIM.

Virtual machine-based mechanism is used in achieving the independence of the software system, which was implemented through implementation technology in respect to the operating system on which the software system executes. The Fig.13 presents this mechanism.
This type of mechanism is slightly different from other types of mechanisms for achieving platform independence, because it is not directly related to a software system or software architecture, but indirectly through the implementation technology that is used for implementation of the software system. As mentioned earlier in this paper, implementation technologies and operating systems are different types of software platforms. Virtual machine-based mechanism enables independence of implementation technologies in respect to operating system. This mechanism is crucial mechanism because, in combination with other types of mechanisms, that enables independence for different software architectures, it enables independence related to different operating systems, and by that to different hardware platforms.

Virtual machines are used in a number of sub disciplines ranging from operating systems to programming languages and processor architectures. By freeing developers and users from traditional interface and resource constraints, VMs enhance software interoperability, system impregnability, and platform versatility. Despite their incredible complexity, computer systems exist and continue to evolve because they are designed as hierarchies with well-defined interfaces that separate levels of abstraction. The simplifying abstractions hide lower-level implementation details, thereby reducing the complexity of the design process.
Java and .NET are technologies and software platforms that both have the mechanism that realizes platform independence of software systems/applications in respect to a hardware platform and operating system. Java and .NET have a very similar approach to the implementation of the platform independence.
Java virtual machine is a virtual processor "a virtual CPU" that allows the same software to run on the multiple platforms, because software itself does not work directly on the operating system, but works through the Java virtual machine. Java applications can work on all platforms for which Java Virtual machine (JVM) exists.
Furthermore, the goal of Microsoft in the .NET development is to provide independence of .NET applications from the hardware platforms and operating systems. During compilation of .NET source code, compilers, instead of machine code produce common intermediate language (Common Intermediate Language) instructions. These instructions are translated into machine instructions or processor instructions on the machine where the application executes.
According to GCoI model, we have identified key elements:

- Different implementation technologies that conform to the X element on the GCoI model
- Different compilers that compile source code to bytecode or CLI (XZ elements on the GCoI model)
- Bytecode or CLI (Z elements on the GCoI model)
- Different interpreter which interpret compiled source code to concrete operating system (ZY element on the GCoI model)
- Different operating systems that conform to the Y element on the GCoI model

Table 6. presents the key elements of the GCoI model for Java and .Net technologies.

Table 6. Virtual machine-based mechanism applied on the Java and C#

X	XZ	Z	ZY	Y
Java	javac	Bytecode	JVM	Windows, Solaris, Linux
C#	csc	CLI	CLR	Windows 2000,Windows XP, Windows 7

The similar mechanism is identified for programming languages such as Jython, Scala, Boo and IronPython. Table 7. presents the key elements of the GCoI model applied to these programming languages.

Table 7. Virtual machine-based mechanism applied on the other programming languages

X	XZ	Z	ZY	Y
Jython	jythonc	Bytecode	JVM	Windows, Linux
Scala	scalac	Bytecode		Windows, Linux
IronPython	pyc	CLI	CLR	Windows, Linux
Boo	booc	CLI		Windows XP, Windows 7.

Table 8 shows the relationship between types of platform independence and mechanisms of its realization. Columns PI11 to PI3 indicate which type of platform independence is achieved, and rows R1 to R4 refer to a type of mechanisms used in realization.

Table 8. Relation between platform independence types and realization mechanisms

▼ *REALIZATION MECHANISMS* ▼	*PLATFORM INDEPENDENCE TYPES*				
	PI11	*PI12*	*PI13*	*PI2*	*PI3*
R1 (Services-based mechanism)			•

R3 (Model-based mechanism)			•		
R4(Virtual machines- based mechanism)	•				
R5(Machine language mechanism)					•

5. SUMMARY AND CONCLUSION

There are books and papers in literature related to Java's architectural support for platform independence (McGovern et al. 2003; Gong et al. 2003) as well as Web service platform-independent model (Szyperski, 1999; Alonso, 2004) and Corba platform independent model (Merle et al. 1997; Merle et al. 1996; Wang et

al. 2000). Although these papers describe platform-independent model, we could not found papers that analyze all these models of platform independence integrally.

There is no research in literature that analyzes the various mechanisms for achieving platform independence in this way, so we can say that this is the first study of this kind with the goal to not only analyze and compare the ways of achieving platform independence, but to define the general rule that enables it.

The key contribution of this paper is the introduction of the GCoI model, and identification and explanation of different mechanisms for the platform independency realization. The GCoI model represents the fundamental concept that lies behind the platform independence.

This model has multiple significances. While developing new platform or software architecture, engineers should be aware of all necessary elements that need to exist in order to achieve platform independency. In the era of cloud computing, and smart devices, the need for this kind of solutions and "adapter" mechanisms arises, and GCoI model represents the general principle for creating them.

Our practical experience, as university teachers, proved the value of this model when teaching relationships between any new software architecture and platform. When students know the elements of GCoI model, and the concept of platform independency, they can understand it much easier and faster.

Abstract: *Period when mobile phones were just devices used for voice and text communication are far behind us. Thus we must to consider option to use them with different approach where they will be accepted as main source to find, discover and learn. We find basis of this idea in mobile applications which - versatile and acceptable, can bring focus to new way of studies which will then transform user's habits and give them alternative for learning. Respecting the results of previous research in the field of using mobile phones for the purpose of education, as well as habits of modern generation of students, we created the educational student application whose content complements the lectures and, if necessary, consultations. This application represents a solution for students of naturally humanities faculties which was, for the first time, in contact with software for databases. The application is based on the respective subjects which are responsible for the further understanding of study programs.*

Keywords*: Android, application, education, studies*

1. INTRODUCTION

While generation X use internet as product which slowly show in their lives creating enough space to learn and get new experience, in the next generation Y it become part of their life making them more informational educated. The period of the latest generation Z is in the progress, but we can predict that diversity in making new knowledge and experience will be bolder and cause can be internet itself – for those generations internet is product that just "exists" (Bogdanović, 2012.). From that point of view, from any new student's generation we can expect to be more and more in connection with internet and new technology, which basically lead to high end devices such as mobile phones. With that information on mind, academic society must find better respond in seek for knowledge for new generations – mobile phones can be used as tube (or channel) which will provide accurate information's to anyone on any place at any time (Milutinović, 2014.). So, if we percept application as tool for learning, we accept future of high education (as well as undergraduate or mid school learning). Of course, any educational app can't be accepting as one and only knowledge source. Instead of be self-enough, those digital learning tools must coexist with formal sources and that compound will provide unique, modern, faster, quality and more dynamic presentation of information's that represents subject of study (Bogdanovic, 2014.). Besides that, we have two additional benefits: first, classes wouldn't be crated only with instructor knowledge and creativity, and second – it will represent domestic educational system with high range of availability to modify content to meet new standards (Pasek K.H, 2015).

2. VERBAL MODEL

Logic that lay in root of the application represent practical product which will connect technical solutions with conventional information's sources. Thus, application must be simple and logically oriented for use, with main concept that will represent standards of Android operating system which users of the platform already known with integrated organization well known in books and educational literature which students use on every day basis: get correct answer fast and in clear way at the same time. Additional functionality will be created with option to take personal notes. Last but not least, application need to use less battery power (Chen, 2015, Flinn, 1999, Morley, 2015.). With all this in mind, we create map of the application where main content is away from user with maximum two clicks. Possibility to create notes is structure which is separated from others and user need just one click to use it (Figure 1). Please keep in mind that diagram shows few activities with the same name, but that is not mistake: content of fields is different.

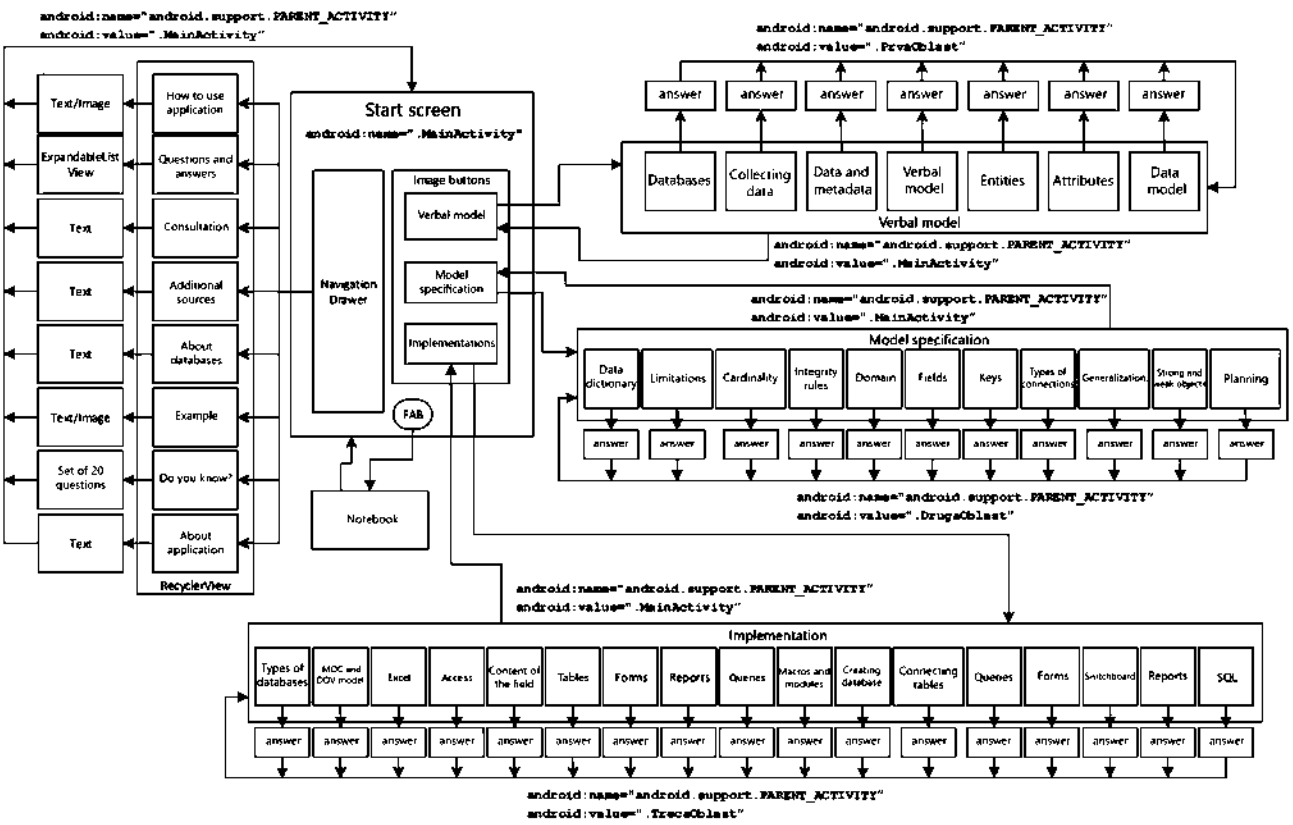

Figure 1: Diagram of the application based on verbal model

Start screen consolidate three application segments: main content which is split into three areas and which represent central part of the display, note taking part which open with click on the button at the lower right corner and additional menu position at the left top corner represented with "hamburger" icon (Figure 2).

Figure 2: example of the main application screen

At the top of any page lay unification App bar.

Main content has three areas:
1) verbal model – contains question and answers about actions which applied prior to planning and implementation, and explains what are entities, attributes, how and why the data are collected and more.

2) model specification – allows users to find explanations of all basic factors that are necessary to create a database such as aggregation, constraints, data dictionary...

3) implementation – the third area define the practical application of the previous steps, explaining database creating software as well as connections, query's, report generation, etc. Also, students have practically described processes step by step.

Content doesn't need to be used by any fixed order. User can open, read and use part of application that is important for him in the moment. Keeping that in mind, simplicity and usability of the application is created in less than three clicks: from main category, user choose question which lead them to the answer and vice versa. So, first choose is category and the second one is the question. All answer contain text and (if there is appropriate) picture (Figure 3).

Figure 3: navigation through application. Main content is only two quests away

Part of the application which provide possibility to take notes lay behind circle Floating Button in bottom right corner of the main screen. Blank field provide user a space to create important information's which later he could copy or modify. Once entered, content stay available as note even after application is close or the phone is rebooted.

Finally, slide menu on the left side of the main application screen contain additional information's such as: how to use application, frequently asked questions, further resources, about databases, example, test and about application.

2.1 CHOOSE RIGHT ARCHITECTURE, TECHNOLOGY AND TOOLS

First step was to define right architecture, technology and tools which will be used during creating application with main purpose to satisfy concept standards. Keeping that in mind, core architecture was Linux kernel with Dalvik virtual machine (or Android runtime – ART) and program languages Extensible Markup Language (xml) and java (Ward, 2014.). Objective API's (Application program interface) in java language determine specific class which ask to implement accompaniment library for objects of that class type can be held by adequate methods. Lower API limit is 15, which means that any device with operating system 4.0.3 or newer can run the application. One of the special requests was Material design which natively run on systems version 5.0 and newer which set up the task to modify xml and java files to cover older Android versions (Annuzzi, 2014.). At the end, the tool which used was Android Studio with support and additional API 23 library's (Jackson, 2014.).

3. MODEL SPECIFICATION

First contact of students from humanity and social sciences with software used to create databases such as Excel, Access or MS SQL Server can be very complex and represent issue for normal learning and afterward using at work. Reason lay in specific logic of work and using programming languages and operations which are usually strange to those students that they didn't use earlier. Therefore, it is necessary for the purposes of understanding the basic definitions and architecture procedure, technology and applied tools, to prepare a unified solution in the form of applications that can provide answers in these areas represent them verbally and graphically.

3.1 OBJECTS-CONNECTION DIAGRAM AND THE DATA DICTIONARY

The application basically has a very simple structure, which is one characteristic that is set as a condition in its drafting – function before form. From the above we see that the home screen aggregation main categories, notebook and side menu (Figure 4).

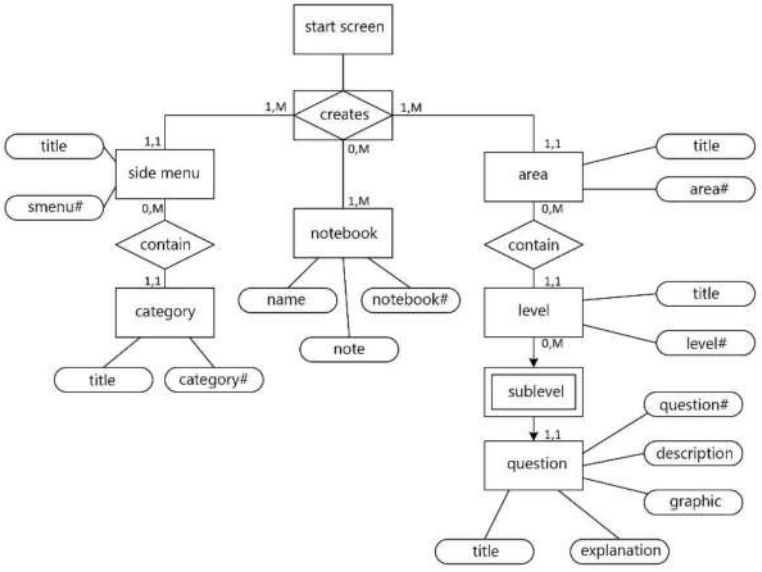

Figure 4: Diagram chart objects - connections for Android app

Start screen can contain one or more side menus, while a side menu can be found in only one home screen. Time this menu can be expanded if necessary by adding new content. Side menu does not have to but it can contain a number of different categories. On the other side, a category may belong to only one side menu. One initial screen doesn't need to contain but can have multiple notebooks and one notebook can be on one or more screens. Since the notebook represent additional functionality that is not a high priority in this case it's cardinality indicates that the same notebook can be accessed from other screens (such as the level of some areas) which isn't obligation. Finally, the area doesn't not need to have a single level, which practically makes possible to adapt the application to a new study program at any moment. Last one, each level (list of issues) should have area to which it belongs.

When we talk about the list of questions (layers), they must have at least one query (defined by entity "question"), and one question must belong to one level. Open condition of the connection between the entities "area" and "level" is defined with cardinality 0, M which giving us freedom of adapting content to other study programs and departments.

Diagram also characterized a simple data dictionary with a mere value-limits (Table 1). Answer, which represent the core of application can't be empty, so we're talking about a very elemental restriction imposed by the requirement that said the field can't be empty.

Table 1: data dictionary for Android application

			simple value limit

4. IMPLEMENTATION

Application does not become popular by chance – it is the result of the right decisions made at the right time. It is important to understand the role of performance, quality and robustness that must be respected in the broad market of different devices, considering that the same application can behave completely differently in the two models even if they are both on the same version of the operating system and with the same hardware specification. This is the result of platform fragmentation, as well as free modification of Android OS which is often used by device manufacturer that created them in all shapes and forms rarely updating the core version of the operating system. Also, other software corrections which can be applied on devices (such as manufacturers and operator's modes) may affect the stability and performance of other applications. Finally, it should be understood that the operating system is also the software such as the application that we want to create.

Creating an application create resources that need to be connect with the data sources. System construction (script) takes all sources (XML and java files) apply appropriate tools (for example, converts java classes in dex format) and then grouping them into a single compressed file, with APK extension. Gradle scripts are used in order for this process to be automated (Lee, 2012.). The most important part for developers is build.gradle (Module:app), which sets the lowest value of Android system on which the application can be installed, and to determinate and import the dependent libraries such as RecyclerView or FloatingActionButton.

4.1 THE LOGIC OF CREATED ENVIRONMENTS AND FORMING ELEMENTS

It has already been stated that the minimum requirement to install application is API version 15 or higher. This means that it is necessary to adjust the Material Design environment (which is native at KitKat, Lollipop and Marshmallow systems) to systems where they are not provided by default. Of course, functionality of the application isn't put behind design at any point during creation process. Rather, appearance and specific elements (such as the App bar, Floating Action Button, Recycler View) are used in a way to provide the content on the most functional way closer to user.

The first step in creating and customizing functionality of the new application environment was the adaptation of the Toolbar into an App bar (formerly the Action bar) in the way to hold additional functionality (Phillips, 2013.). In order to achieve a new look and functionality desired, it was necessary to couple the steps of:

1) it is necessary to prevent the system to display a predefined bar with selecting specific theme: basic theme of the application (which is located in styles.xml) need to be changed in the parent value which will invoke the theme without the Action bar:

<style name="AppTheme" parent="Theme.AppCompat.NoActionBar">

At the moment, the activity will show a window without Action bar.

2) define the xml file containing Toolbar: under resources> layout it is necessary to create a new XML file that we will call app_bar while Toolbar define as RootElement. After Android Studio (AS) creates the desired xml file, it will be marked as a Toolbar widget which we don't want. That is the reason why we will instead enter predefined: android.support.v7.widget.Toolbar. Another important step is the change of the content presentation, so instead of "match_parent," the android: layout_height should call "wrap_content".

3) in the layout xml file you need to add <include>: in xml file activity in which we want to show a new Toolbar you need to enter the following code:
<include
android: id = "@ + id / app_bar"
layout = "@ layout / app_bar "/>
This step must be repeated within each newly created activity because the AS will apply the theme that we selected in Step 1.

4) Toolbar initialization using findViewById within the Activity class and use setSupportActionBar () in the Toolbar: in the context of java class activity in which is projected a new Toolbar, first we define a variable private Toolbar toolbar (while respecting that it is android.support.v7.widget.Toolbar) and then in the method onCreate we bring the following:
toolbar=(Toolbar) findViewById(R.id.app_bar);
setSupportActionBar(toolbar); (This command requires that the system does not use the system defined toolbar)

When creating a variable, AS automatically creates a menu item under onOptionsItemSelected that appears in the right corner of the Toolbar in the form of three vertical points (menu). While we don't want this to show up in our application, we completely remove this method from the code.

5) adjustment of various properties of the Toolbar using the Toolbar object or through getSupportActionBar (): opening another activity that also initiated a new Toolbar, the title of the chapter will appear in the header (defined by string and AndroidManifest files) but the button which allows back to previous, parent (parent), activity will miss. Therefore, in the new java class activities under the onCreate method we need to add the following (just below setSupportActionBar (toolbar)):
getSupportActionBar().setDisplayShowHomeEnabled(true);
getSupportActionBar().setHomeButtonEnabled(true);
getSupportActionBar().setDisplayHomeAsUpEnabled(true);
Last method – setDisplayHomeAsUpEnabled (true) must have a boolean value of "true" to return the user to one level instead of at the beginning (start screen) of the application.

AppBar usually contains navigation icon ("hamburger" menu) in the top left corner, the name of the application and a filter option (if there is multiple hierarchical levels), action icons (for access to certain features of the application) and the menu icon in the upper right corner. We decide to look for more simple, cleaner look (Figure 5).

Figure 5: appearance of the native AppBar menu (left) and AppBar menu in our application (right)

4.2 LAYERS AND FUNCTIONS

Most part of user interface was created using ListView containers in RelativeLayout plan, while TableLayout was implemented in several activities. Specific solutions include Navigation Drawer fragment, Recycler View, List View Expandable and Floating Action Button.

For side navigation we chose Navigation Drawer Fragment (NDF) located on the left edge of the screen that will appear only on user request over the home screen (activities), and will represent additional informations. For NDF to be implemented, it is necessary to modify the XML and java file activity in which will be located. The first step represents use of DrawerLayout which contains two items (child) with the corresponding IDs: FrameLayout which hold the main content and NavigationDrawer, while the root XML file activity instead of LinearLayout became android.support.v4.widget.DrawerLayout. Xmlns attributes are transferred to DrawerLayout which then became holder of the LinearLayout who's actually FrameLayout with main content. Adding NavigationDrawer's is done by creating a new fragment (Java and XML files) which is initiates in the XML file of the main activity within DrawerLayout and below LinearLayout. The width of the fragment is 280dp while using android: layout_gravity = "start" we defined a fragment to be on the left side of the main screen until user action. We want to system recognize that fragment so in the last line we entered location of the created xml file. To use NDF, it is necessary to call methods within main activities Java class in order to bypass Toolbar, which is created under the Java class Navigation Drawer Fragment. It is necessary to apply the constructor ActionBarDrawerToggle that implements class DrawerLayout.DrawerListener. In other words, in this way the NDF, Toolbar and layout activities will be linked into one which, in practice, mean that when user select an icon in the toolbar it will open NDF (Lee, 2013.).

If we run the application at this point, we will have transparent fragment covering the main activity while in the Toolbar will be "hamburger" menu. Therefore, it is necessary to adjust the value of the background color in xml file fragment, while the java class NavigationDrawerFragement must have method: mDrawerToggle.syncState ().

With this step we have created the NDF, which is empty and respond to the user's reference. In the next step we need to input content.

4.3 RECYCLER VIEW (RV)

Recycler View is not a substitute for the List View. It is far more advanced solution which use Layout Manager and allows us to view content at a much more dynamic way than the List View can provide (Jackson, 2014.). The architecture shown in Figure 6 explains the work of RV. Data Model is a menu item. Adapter draws each menu item and trying to display them with a View holder who is the xml layout for each menu item, which is incorporated into the java code. View holder decides whether the item will be

permanently displayed or not. Recycler View will use View holder to display each menu item. On the other hand, the Layout Manager determines how the content will be displayed (as a list of fixed width, in parallel columns or as a group of cards in different sizes). Item Animator is responsible, as its name suggests, to animate Recycler View such as removing items from a list, move them in the order, etc. Item Decorator allows items to be grouped into different sections according to their content. RV represents a flexible solution for viewing large amounts of data on a limited area of the screen. Since the creation of content composed of images and text represent complex and demanding task for application (each line requires the creation of an independent xml file that must be inserted in the code via the Layout inflator as well as finding items by using the TextView, ImageView and the related controls findViewById) calling (inflate) the item only when recycled and which is already found represents a significant beneficial solution. The point is to avoid use of the View Holder object or method findViewById every time you want to display a longer list of items on display but

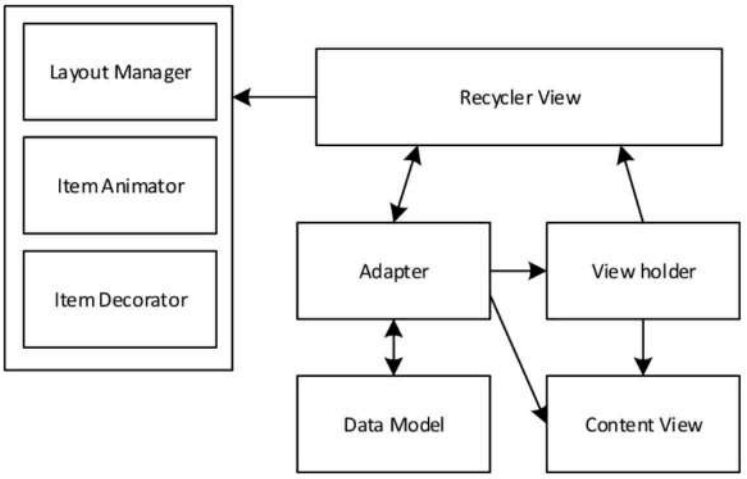

Figure 6: construction of the Recycler View

rather to allow the first item from the list to be cashed and appears only when it is needed. In fact, the limited area of the screen that is able to show, for example 5 items, when we move through the menu to display the paragraph 6, paragraph 1 shall be removed from the list. It will then move to recycler status and wait to be invited again.

The first step of the implementation is compiling a support library in Gradle script for recyclerview v7 widget while next represents its implementation in NDF xml file. It is important to enter the code below Linear (or Relative) Layout in which is placed an image that is part of the NDF. When rendering in Android Studio, review will not show any content. The reason for this is that unlike the List View, content must be initialized in Java code in the Layout Manager since it is not fixed. Before that, it is necessary in NDF java class to define Recycler View which is achieved by the following code:

recyclerView= (RecyclerView) layout.findViewById(R.id.drawer_list);

In this code, R.id.drawer_list represent id which we assigned to RV in xml file.

To populate the menu list, it is necessary to create a new java class (which we'll call Information) in which will be defined integer for the icon, and string value for the name. This data will provide adapter that represents a new java class that extends RecyclerView.Adapter which owns argument <VH> or ViewHolder which means that the latter is expected to have another class that extends a ViewHolder to represent argument. View Holder is there to describe the appearance of the item and its place in the RV and that the source, once found, automatically draws and displays in the required order. Therefore, in the construction we use parent class ViewGroup and viewType. In order for content to be developed, it is necessary to create a new xml file which will represent the appearance of a row, whose content will define the ImageView and TextView. Data from the newly created file are referenced in the java class adapters to allow the ViewHolder data calls and shows itself without the need for constant creation. Contents will be displayed by entering a few lines of code and linking with the previously created files. First you must enter the following classes in the java file adapter:

List<Information> data = Collections.emptyList();

and then in onBindViewHolder:

Information current = data.get(position);

```
holder.title.setText(current.title);
holder.icon.setImageResource(current.iconId);
```

Displaying the contents is calls by the NDF java file, creating methods:

```
public static List<Information> getData(){
List<Information> data=new ArrayList<>();
int[]icons={R.drawable.ic_lightbulb_grey600_24dp};
String[]titles={"Kako koristiti aplikaciju"};
for (int i=0; i<titles.length && i<icons.length;i++)
{
Information current=new Information();
current.iconId=icons[i];
current.title=titles[i];
data.add(current);
}
return data;}
```

Adapter initialization that displays content is created under onCreateView.

We want to connect content of RV with new activities which referred to, thus in the adapter Java class we need to create OnClickListener and in the NDF Java class method itemClicked. Because the Java class adapter has very little code, it makes it very flexible and opens up the possibility that the same adapter be used for other RV if they call the same information.

By implementing Recycler View in Navigation Drawer Fragment and creating connections with external activities that carry content, we finally fill the side menu and make it available to the user.

4.4 FLOATING ACTION BUTTON (FAB)

Floating key of activities represent the specific solution that characterizes Material environment (Jackson, 2014.). As NDF, this element is not recommended for use if there is no meaningful purpose that is usually reflected in the functionality that need to be quickly available - shortcuts to applications segments, arranging and writing messages, custom content (for copying and pasting content) etc. Therefore, we created FAB at the bottom right corner that leads directly to a notebook activity which characterized up to 100 lines of text input with up to 20 lines to display at the time (as defined in the value of its XML files). All the entered text is stored in the notebook until delete, which means that leaving the application or restart the device does not affect the stored text, which is achieved by entering the created content in SharedPreferences of corresponding java file. Entered text can be marked, copied, cropped and pasted, but because we didn't set any specific requirement when installing, it can't be send directly from the application.

Creating of the FAB can be do manually or using existing library. In our case, we have created a library using existing sources which is why we are in the Gradle script called and compile a dependent library CircularFloatingActionMenu: 1.0.2. Within the java class activity in which the FAB will occur, it must be initializing under the method onCreate and determine the icon that will appear (located in the drawable folder). Button background also is also called from drawable folder and represent an XML file that defines the layout when the key is pressed and in standby mode (lighter and darker background). Since FAB is removed from the screen when the notebook activity is open, this step is not necessary since there is no visual effect. Newly formed FAB must be connected with corresponding XML files, which is why necessary to implement OnClickListener after which it calls creation of tag icon.setTag("fab"); icon.setOnClickListener (this); after which in the onClick method needed to initialize event that will trigger the activity:

```
public void onClick(View v) {
if (v.getTag().equals("fab")){
startActivity(new Intent(this, Beleznica.class));}}
```

When a user clicks on FB on the home screen it will open activity notebooks. User will be return to the home page, which is the parent of this activity, after he done editing.

5. CONCLUSION

This paper presents a simple application for education of students and others who want to learn more about the possibilities of creating a database on their smartphones. Respecting the results of previous research of using mobile phones for the purpose of education and habits of modern generation of students, created the

content that complements the lectures and, where appropriate, consultations. The application is based on the respective subjects who are responsible for the further understanding of the matter that students learn. To avoid any compromise between content and form, the application is designed, created and implemented by respecting and implementing of the Google standardization of Material environment that will make users of newer mobile devices to use it in friendly, easy environment. Most of the time was spent on special modification of code and application structure. The development of application core took about four weeks, gathering materials and implementation additional fifteen days while the extra week spent for removing bugs and code optimization.

COMPARATIVE ANALYSIS OF UML MODELING TOOLS WITH FOCUS ON BUSINESS LOGIC SPECIFICATION

Vojislav S. Stanojević*[1], Saša D. Lazarević[1], Milić Ž.Miloš[1]
Faculty of Organizational Sciences,
*Corresponding author, e-mail: vojkans@fon.bg.ac.rs

Abstract: *Growing need for software products and reduced time for software development are crucial for success of a software project. Therefore, there are lot of approaches for software development in order to reduce time to market. One of the most popular is Model Driven Development. Main goals are to narrow the gap between all stakeholders in software development process and to decrease time from requirements specification to final version of software. There are lot of tools that supports UML modelling and MDD approach in order to shorten software development process. Using case study we will analyse three selected tools (Enterprise Architect, Visual Paradigm and Papyrus) in order to determine which one is best suited for MDD. For that purpose we will determine criteria for comparison and give a summary.*

Keywords*: MDD, business logic, UML, models, code generation, UML tools*

1. INTRODUCTION

If we look at economic development in recent years, even decades, the obvious conclusion is that the information systems and technologies are one of the most dynamic industries, where a lot of resources are invested. In such an environment, continuous development and progress are necessary.

In step with the progress of technologies, market requirements have become more sophisticated. The critical factor is response time needed to meet those requirements. High-quality of system architecture assures achieving this. The software architecture must support the complex requirements, frequent changes and quick response to those changes.

The aim of this research is reducing development time, and more importantly reduce response time to the frequent changes required by the client. In addition, it is preferable to avoid repetitive tasks and processes, and make them to be executed automatically. Model driven development is approach that reduces response time, complexity of requriements, business processes modellling and implementation at the end. Approach that will be used in this research is to use model as basic component and set of business rules defined for that model.This reserach should give an answer regarding possibilites of automatic code generation for elements of business logic using specific tools. For this purpose we will conduct case study survey analysing tools supporting UML models and code generation. For this purpose we selected Enterpise Architect, Visual Paradigm and Papyrus (plug-in for Eclipse) .
We will first give a short introduction to MDD, UML and OCL. Afterwards we will determine place and role of business logic in a software system and then present results from tool analysis and then give final conclusion.

2. MODEL DRIVEN DEVELOPMENT - MDD

Start of a software project can be very difficult. The path from requirements elicitation to software product is long and there is a problem with requirements validation. Often mistakes made in requirements gathering and specification are identified in late stages of software development which can have great impact on software success. One of approaches that tried to narrow the gap is Model Driven Development (MDD). Main idea in MDD is that there is no model which will be thrown away. One of key features is model transformation. This is very important because there are lot of interested parties which has different levels of technical knowledge. For instance on one side there are persons like sponsors and domain experts, with poor technical knowledge, and on the other side there are software engineers (architects, software, testers...). All of them are interested in software development from their point of view. Therefore there is a need for different type of models, but essential thing is to keep those models in tune with each other. This is not always easy but there are lot of software tools which offer help in model synchronization and their use throughout software development. Language which is widely used for purpose of software modelling is UML. Very important concept in MDD is model to model transformation. Final model is usually programme code and that is most important concept for software development.

3. UML LANGUAGE

Unified Modelling Language (UML) is language and a standard for software modelling and design. Besides structural and behaviour models UML defines models for business process modelling [5]. It is widely used in object-oriented software development methods. There different models that are used in different development phases. The main idea behind all models is to keep them simple as possible in order to make them understandable for large variety of stakeholders.

UML advantages:

- Is a standard for software development
- There is a lot of tools that supports UML models
- Shortens software development
- UML models overcame software engineers problems (Schmidt, 2006)

From our point of view most interesting models for the paper are:

- Structural models: Class diagram
- Behavioural models: Use case diagrams, State diagrams, Sequence diagrams

UML supporting tools enable model integration and model transformation, which is of big interest for this paper. For purpose of this paper it is very important to mention Object Constraint Language (OCL) and it use and integration with UML models.

4. OBJECT CONSTRAINT LANGUAGE - OCL

Object Constraint Language, widely known as OCL, is semi-formal language for describing constraints of object-oriented models (F. Barbier et al., 2001). It is very important addition to UML language and it can be considered as integral part of UML. Formal languages require big knowledge of math, which business analyst and modellers usually do not have. OCL is less formal and it is easier to write and read. It is not directly executable.

```
context Person::getCurrentSpouse():
   Person
pre:   isMarried = true
body:  mariages->select
       ( m | m.ended = false ).spouse
```

5. BUSINESS LOGIC AS PART OF SOFTWARE SYSTEM

The focus of our work is business database applications. Most of software systems of this kind have multi-tier architecture and most common one is three-tier software architecture. Larman identifies these tiers as **User interface**, **application logic** and **data storage** (Larman, 2004).

Figure 1: Three tier software system architecture

Furthermore, application logic has three logical parts: **Application logic controller**, **Business logic** (Domain objects, Services) and **persistence framework**.

In his book Vliet describes that from users point of view user interface represents whole system (H.V.Vliet, 2008). Research showed (B. Myers and M. Rosson, 1992) that 48-51% of time needed for software development goes to user interface. We have already written about models and tools, which we proposed for user interface generation in (Antovic et al. 2012). Business logic development takes around 15% and we think that this is not in accordance with significance that this tier has in software system. This was a sort of alarm because we think that business logic development does not get as much attention as it should.

We will define UML models of great interest for business logic modeling. In order to do that will will look for models used in different stages of software development.

5.1 Business logic in requirements phase

This phase of software development is marked as crucial for success of software project. This paper focuses on use case technique. There are lot of use case definitions and all of them point out interaction between actor and the system (Cockburn, 2000; Vlajic, 2011; R. Schach, 2010; Adolph, 2001; Jacobson et al.1992).

From a business logic perspective, it is very important to consider an action (transaction) types. *Ivar Jacobson* mark off four types of transactions (Jacobson et al.1992). Only one relates to a main actor and Jacobson defines it as User request action. Three remaining actions are relates to the system: System validates request and the data, system changes its internal state and the last one refers to response showed to the actor.

Vlajic gives a little different list of actions (Vlajic, 2011) :

Actor actions:

- Actor prepares input for system operation. (**APISO**)
- Actor calls system to execute system operation. (**ACSO**)
- Actor executes non-system operation. (**ANSO**)

System actions:

- System executes system operation. **(SO)**
- System shows result of system operation execution. **(OutA)**

5.2 Business logic in analysis phase

During the analysis phase, one should describe **logical structure** and **behaviour** of a software system. System sequence diagram and system operation contracts describe behaviour. Conceptual and relational model defines structure of a software system.

The use case specification is a starting point for analysis phase. System sequence diagram is made according to use case, and only two types of actions are shown ACSO and OutA. In order to create

these diagrams one must identify system operations signature. While APISO action describes name and parameters of a system operation, the IA action refers to return value and messages that has to be show to the actor.

Preconditions are conditions that have to be met in order to execute SO. They are highly related to constraints of a domain and relational model. On the other hand **post conditions** are related to conditions expressed through state of a domain object after successful SO execution

5.3 Business logic in design phase

In this stage of software development detailed architecture of software system is given. In the introduction of this paper, we wrote that the area of our research is software systems divided in three logical parts. In this phase of a software development one must take implementation technologies in to the account.

This phase of software development must give answers to questions about system operation execution. For this purpose detailed sequence diagrams for every system operation is made in this phase. In contrast, we believe that it is important to make some kind of technology independent specification. This will provide an open space of possible implementations.

6. UML MODELING TOOLS ANALYSIS USING CASE STUDY

In this section we will give an overview of tools which are marked as important. Chosen tolls are Enterprise Architect, Visual Paradigm and Papyrus plug-in for Eclipse IDE.

We will conduct a survey that will give an answer how well the tools support business logic specification and it transformation to programme code. We marked models that are important for a business logic modelling. In addition to that we should add a decision table which is related to business rule specification. Will examine how decision tables are integrated in code generation process.

During the research we have marked criteria important for analysed tools. The criteria are as follows:

- Visual view and drawing diagram utility
- Complex business rule definition support
- OCL support
- Model - code synchronization

Next we will give an overview of tools analysis. We will compare their features related to the criteria.

We analysed the tools using several use cases. Next use case model diagram created in Visual Paradigm shows all use cases used in tool analysis (figure 2).

Firstly, authors will like to point out glossary option in Visual Paradigm. One has option to define terms and even synonym for it, which can be very useful to end users. Next figure (figure 3) shows terms which are often used in case study.

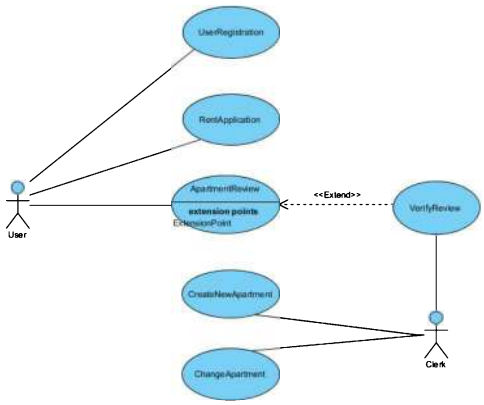

Figure 2: Use case modl diagram - Visual Paradigm

Figure 3: Term definition in Visual Paradigm glossary

The terms from the Glossary are automatically recognized in all UML diagrams. Figure 3 shows Use case definition where are terms recognized. One can see it as underlined word. This is very useful feature. Enterprise architect also enables Use case specification.

Figure 4: Use Case in Visual Paradigm

Diagram that is most often used is class diagram. All of the tools enable visual class diagram modelling. There is slight difference between the tools. It is mostly related to model constraints definition. Figure 5 presents class diagram designed in the tools. It important to address that Papyrus tool enable profiles, so one can choose its own profile instead of default one (for instance JAVA). This will enable JAVA type support for attribute definition and method signature as well.

As one can see models are almost the same and difference is present in OCL constraint support.

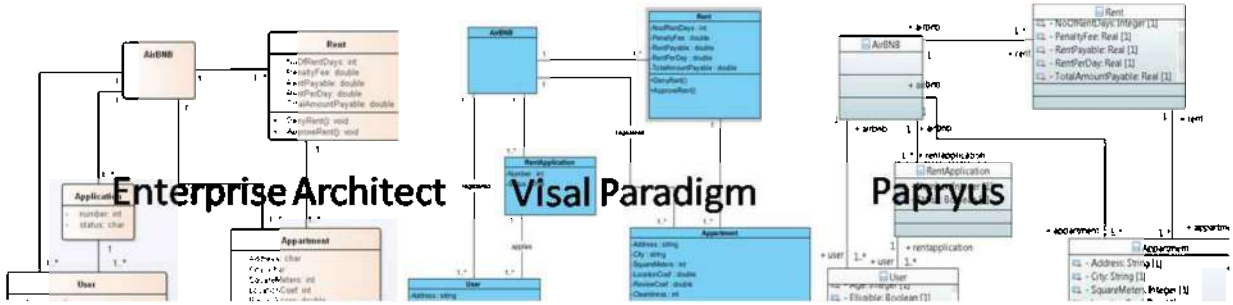

Figure 5. Class diagram in all tools

Papyrus tool has the best OCL integration. It is present in Enterprise Architect as well but with poor integration. Visual Paradigm does not have support for OCL.

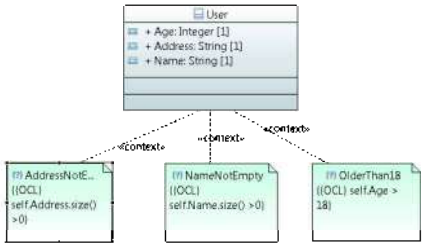

Figure 6: OCL constraints - Papyrus

When it comes to business rule specification it is best supported by Enterprise Architect. It is based on decision tables and in addition it enables code generation. At the first stage user define textual specification for business rules and afterwards one should define rules in specially designed decision table. On the other side Visual Paradigm offers same decision table functionality but authors did not find any code generation feature for it.

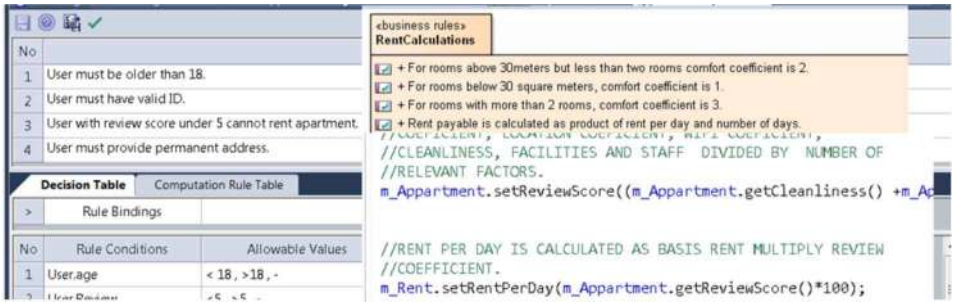

Figure 7. EA decission tables support with generated code

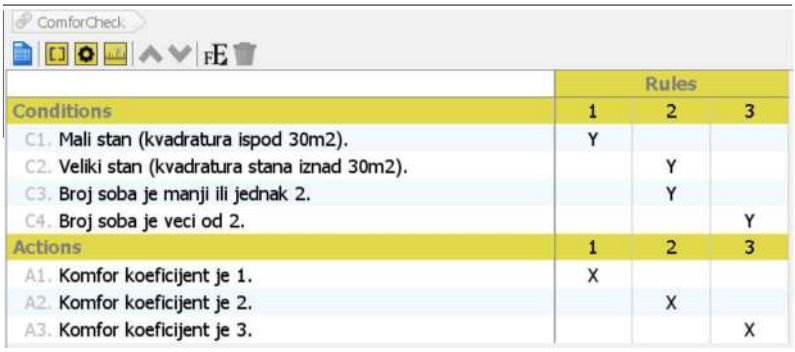

Figure 8: Visual Paradigm decision table

All tools have support for sequence diagram. Visual Paradigm enables transformation from Use Case specification to system sequence and activity diagram. It is very strange that Visual Paradigm does not support transformation from sequence diagram to programme code. It offers only reverse engineering option from code. Other tools supports code generation from sequence diagrams.

Very important feature is model-code synchronization. All tools in certain degree have model-code transformation but it is hard to expect that all features are covered, especially business rule and decision table support. For instance changes detected in Domain class code is reflected in Class diagram in all tools. All the tools support synchronization from programme code to sequence diagram.

We will give short summary for every chosen criterion.

Visual view and drawing diagram utility:

Enterprise Architect *enables modelling of every aspect of software development. It has good performance even when loading big models. Its environment is user friendly models are simply and easy to maintain.* ***Visual Paradigm*** *has very large community which is pushing forward tool development. It has good support for UML diagrams.* ***Papyrus*** *has well designed environment but it is not very easy to use. It does not have automatic align functionality so models can be difficult to read.*

Complex business rules definition:

Enterprise architect is absolute winner by this criterion. It has very well business rule definition system and good code generation utility. **Visual Paradigm** has very poor support for business rule specification. **Papyrus** does not have decision table support as two already mentioned tools but it has best OCL support.

Code generation options:

Enterprise Architect has several models to code transformations. It enables transformation to target programming platform from Class diagram, decision tables and sequence diagram. Visual paradigm

has very poor support for code generation. Only this tool does not support code generation from sequence diagram. Papyrus has most sophisticated support for code generation. It very easy to generate programme code skeleton for chosen target platform. It is also possible to add OCL constraints to UML models and include it in transformation process.

Final results are presented in table 1.

Table 1. Summary results

Criteria	Enterprise Architect	Visual Paradigm	Papyrus
Visual view and drawing diagram utility	4	**5**	3
Complex business rules definition	**5**	3	3
Code generation options	4	3	5
OCL support	2	1	**5**
Model - code synchronization	**5**	**5**	4

7. CONCLUSION

Growing need for software products and reduced time for software development are crucial for success of a software project. Therefore, there are lot of approaches for software development in order to reduce time to market. One of the most popular is Model Driven Development.

From one side MDD narrows the gap between all stakeholders in software development process and from the other side it decrease time from requirements specification to final version of software. Market offers lot of tools that supports UML modelling and MDD approach. For the authors most interesting tools that supports UML modelling are Enterprise Architect, Visual Paradigm and Papyrus.

Firstly we gave introduction to Model Driven Development approach, followed by UML and OCL. Afterwards we have presented place and role of business logic in a software system and then present results from tool analysis and then give final conclusion.

This research gives an answer regarding possibilities of automatic code generation for elements of business logic using specific tools. Using case study survey we have analysed tools supporting UML models and code generation (Enterprise Architect, Visual Paradigm and Papyrus).
We made a conclusion that all tools supports visual UML modelling but the extent of business rule specification and related code generation varies. All in all we made conclusion that all tools have some advantages and disadvantages. Visual efects are best in Visual Paradigm and Enterprise Architect are almost at the same level. When it comes to code generation papyrus is best solution.
Authors will give a slight advantage to **Enterprise Architect** tool.

A POSSIBLE APPROACHTOAUTOMATING THE DESIGN OF NoSQL DOCUMENT-ORIENTED DATABASES

Dejan Stojimirović*[1], Siniša Nešković[1], Nina Turajlić[1]
[1] Faculty of organizational sciences, University of Belgrade
*Corresponding author, e-mail: dejan.stojimirovic@fon.bg.ac.rs

Abstract:*Even though NoSQL databases are being used more and more for the development of web applications, there is no systematical approach or methodology for their development. A methodological approachtodocument-oriented NoSQL databases design is laid out. In the presented approach semantically richExtended Entity-Relationship modelsare used as conceptual data models,which are then transformed into concrete document-oriented NoSQL data models through the application of a set of rules. The paper suggests a possible approach to automating this transformation which is in accordance leading approach to software development today – Model-Driven Development (MDD).*

Keywords*:Extended Entity-Relationship model, document-oriented NoSQL databases, database design, transformation rules,automated transformation, model driven development*

1. INTRODUCTION

Nowadays so-called NoSQL (*Not only SQL*) databases are being used more and more for the development of web applications. The popularity of these databases can be attributed to the fact that, on the one hand, they are geared towards rapid and easy manipulation of large volumes of data, while, on the other hand, most existing NoSQL database management systems are open-source, thus the costs of developing web applications when using such systems are much lower. An additional advantage of NoSQL databases, over traditional relational (SQL) databases, is that the data is stored in a far more flexible manner given that they do not presume the existence of a database schema, or more precisely put, they do not require a rigidpre-defined data structure.

Even though a schema structure is not required, there is still a need for knowing how the data is structured in order to be able to manipulate it in the application.In other words, it is necessary to map the data thatis to be stored in the database onto the concepts which are available in the chosen NoSQL database type (e.g. collections, tables, documents, key-value pairs, etc.). The design phase, as is the case with traditional relational databases, should result in a database which enables easy and efficient manipulation of the stored data. Even though NoSQL databases have been in use for a number of years, no precise methodological approach to designing such databases has, thus far, been put forth. Thus, the design of these databases is usually based on the general recommendations of individual NoSQL database vendors.

Apossible methodological approach to designing NoSQLdocument-oriented databasesis presented (*Stojimirović & al, 2015*). It follows the traditional phases of database design (*Simsion& Witt, 2004*): conceptual design (i.e. defining a technology-independent specification of the data that is to be stored), logical design (i.e. translating the conceptual model into a model defined in terms of the structures of a DBMS) and physical design (i.e. the specification of the physical storage, access mechanisms, performance optimization, etc.). Extended Entity-Relationship (EER) models are used as conceptual data models, which are then transformed into concrete document-oriented data models through the application of a set of rules.

However, the manual coding of CRUD (Create, Read, Update and Delete) operations for complex data structures can be very time-consuming and is often prone to errors (even more so in view of the absence of a rigid data structure schema). This paper, expounds on the work presented in (*Stojimirović& al, 2015*)and suggests a possible approach to NoSQL document-oriented database design that is in accordance with the leading approach to software development today – Model-Driven Development (MDD). The main goal of MDD is to enable the automation of software development. In MDD models are primary software artifacts and development is automated through appropriate model transformations. Hence, model transformations are a key component of MDD as they represent a means for the automatic generation of target models from source models, with the ultimate goal of producing a concrete implementation (i.e. executable code) starting

from a conceptual model (i.e. a platform independent model – PIM). Thus, the main goal of the suggested approach to automating the design of NoSQL document-oriented databases is to eliminate the need for manually coding CRUD functionality by automatically generating the data structures and corresponding CRUD operations for a document-oriented NoSQL database, from an EER model.
The paper is organized as follows: Section 2 gives a brief overview of the current state of the art pertaining to this issue. The main concepts of Extended Entity-Relationship models and document-oriented NoSQL databases are presented in Section 3. The proposed methodological approach is outlined in Section 4. Finally, Section 5 concludes the paper and discusses future work.

2. CURRENT STATE OF THE ART

An assessment of the current state of affairs in the field of databases reveals that relational databases are prevalent (*Sadalage& Fowler,2013;Vaish, 2013; Lazarević& al, 2016*).Given that they have been in use for more than 30 years, a good deal of research effort has been dedicated to the issue of their design, resulting in a number of methodologies and approaches with clearly set rules regarding the manner in which a database schema should be designed.

While NoSQL databases do not presume the existence of a database schema, it is still necessary to structure and organize the data in a manner that facilitates its manipulation. Consequently, a number of decisions must be made when designing NoSQL databases, which are influenced, on the one hand, by user requirements, and on the other, by demands related to their scalability, performances and especially their consistency. These issues also aroseformerlywhen it came to the logical design of relational databases or mapping XML (eXtensibleMarkup Language) documents to relational databases (*Sadalage& Fowler,2013*).

The introduction of an abstract NoSQL database model, as an intermediate model between logical concepts and NoSQL database concepts, has been proposed in (*Bugiotti& al, 2013*) with the aim of simplifying the management of data in such databases. This paper presumes the existence of a semantically rich model (i.e. the extended Entity-Relationship model) as a conceptual model.

To the best of our knowledge, as of yet, there is no systematical approach or methodology for developing NoSQL databases. Even though a number of researchers have indicated the need for such an approach (e.g. *Vaish, 2013; Sadalage&Fowler ,2013*) NoSQL database development is currently based on the best practices in this field (*Lazarević& al, 2016; Katsov, 2012; Baker & al, 2011*).

3. OVERVIEW OF THE FUNDAMENTAL CONCEPTS

3.1. Extended Entity-Relationship (EER) model

Entity-Relationship (ER) models (*Chen, 1976*) are semantically rich data models which can be graphically expressed and, as such, are extensively used for database design. The original ER model was later extended in order to incorporate additional (semantically rich) concepts for more accurately modeling complex systems.Ametamodel of the Extended Entity-Relationship model is depicted in Figure 1.

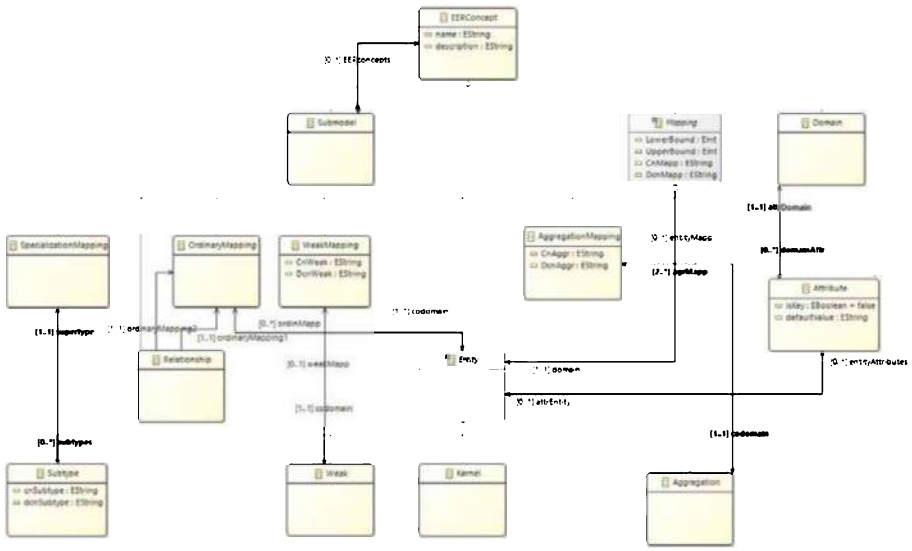

Figure 1: Metamodel of the Extended Entity-Relationship model

The *EERConcept* concept represents the core concept from which all of the other concepts are derived. The *Submodel* concept represents a concrete EER model and is the root element which encloses all of the other concrete model elements. An *Entity* is an abstract concept, representing classes of objects, which is specialized into the *Strong Entity (Kernel)*, *Weak Entity*, *Subtype* and *Aggregation* concepts. An *Aggregation*is a type composed from other entities. A *Weak Entity* is an entity whose existence depends on the existence of another entity, while a *Subtype* represents a specialization of an *Entity*.Entities are described by their *Attributes* which take their values from *Domains*. A *Mapping* represents an abstract mapping(wherein a relationship is specified by two mappings)and is characterized by two attributes: *upper*(maximum) and *lower*(minimum) bounds of the mapping cardinality. The *Mapping* concept is specialized into the *Aggregated Mapping*, *Weak Mapping*, *Specialization* and *Ordinary Mapping*.Each specialized entity is associated with a specialized type of mapping, i.e. an *Aggregation* is associated with an *Aggregated Mapping*, a *Weak Entity* with a *Weak Mapping*, and a *Subtype* with a *Specialization*.

3.2. Document-oriented NoSQL databases

As stated in (*Katsov, 2012; Vaish, 2013*) several types of NoSQL databases exist: *key-value* databases, *column-oriented* databases, *graph-oriented* databases, *document-oriented* databases and *hybrid* databases (asacombination of the other types).Given the scope of this paper, only the fundamental concepts of document-oriented NoSQL databases, adapted from (*Katsov, 2012; Chodorow, 2013*), will be elaborated.

Collection

In NoSQL databases *collections*are used for storing (i.e. physically grouping) *documents* which are to be accessed collectively (i.e. as a group). This concept corresponds to the *table* concept in relational databases but with the key distinction that the elements of a *collection* (*documents*) may have different structures (sets of fields) whereas all elements of *table* (*rows*) always have the same structure.

Document

A *document*is the main unit of data (stored in some standard format or encoding like JSON) in document-oriented NoSQL databases. The creation of a separate document for each concrete entity (i.e. a normalized structure) is recommended in the following cases (*Hamrah, 2011; MongoDB, 2016*):

- If the embedding of documents would result in a data redundancy which is not outweighed by sufficient read performance advantages;
- When representing complex M:M relationships;
- When the data set that is to be modeled is large and has a hierarchical data structure.

The elements of a document (i.e. its fields) can be either simple fields (holding a value), arrays of elements or sub-documents.

Identifier

The *_id* field is used for representing a unique attribute (i.e. an identifier) in document-oriented NoSQL databases. The value ofan *_id* field must be unique in a collection. If the user does not specify a value for this field, the value will be automatically generated. The value of the *_id* field can be of any data type, save for arrays, and it is immutable. The *_id* field must appear as the first field in a document. If it is not specified as the first field in a document, it will be relocated to the beginning of the document.

As stated in (*MongoDB, 2016*)the key issue when designing data models revolves around the structure of the documents and how the relationships between the documents will be represented.Contrary to relational databases, most NoSQL databases do not support the joining of documents in queries. Thus, when it is necessary to relate documents, one option is to store a *reference* to a document within another document (which results in a normalized database structure) while the other option is to store an entire document within another document (which results in a denormalized database structure).

Reference

Referencing is accomplished by storing the value of the *_id* field of one document (i.e. a reference to the document) in another document thereby relating the two documents. Given that NoSQL databases do not provide support for resolving references, it is necessary to execute a separate query in order to retrieve the referenced object. Thus, while references provide greater flexibility, in comparison with embedded structures, their main drawback is that they inherently necessitate the “generation” of multiple queries when retrieving a complex data structure, whereas with embedded structures the entire data structure can be obtained by a single query.

Sub-document

A sub-document is a document which is stored within another document. In contrast to references, where only the identifier of the document is stored in another document, in this case the entire structure of the document is stored (i.e. embedded) within the other document. This approach is recommended in the following cases (*Hamrah, 2011; Chodorow, 2013; MongoDB, 2016*):

- When representing weak objects;
- When representing 1:M or 1:1 relationships, and the embedded documents should always be displayed within the context of the main document.

The creation of sub-documents yields better read operation performances, in comparison with references, as all of the related data can be retrieved in a single queryand, in addition, the sub-documents can also be updated using a single write operation. However, the creation of sub-documents can lead to an increase in the size of the main document after its initial creation (for example, if an invoice, initially containing three items, is created and stored in the database, and subsequently five additional items are added) and the additional memory may entailthe relocation or fragmentation of data on the disc which is an expensive operation(*MongoDB, 2016*).

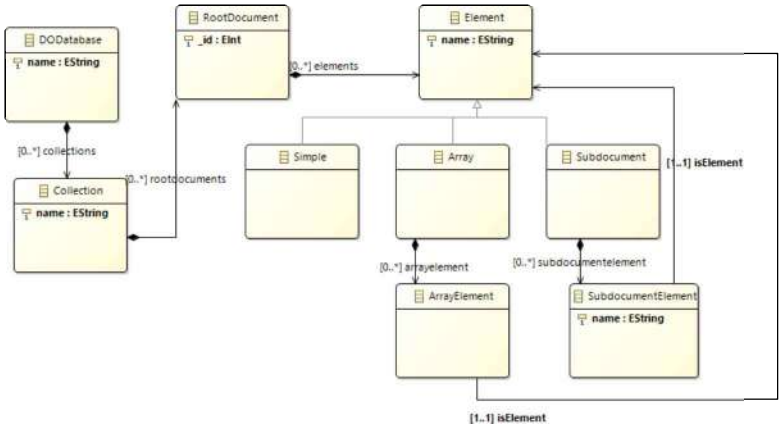

Figure 2: Document-oriented NoSQL database metamodel

4. PROPOSED APPROACH

In general, to design a database is to decide how to organize data into specific forms and how to access them (*Chen, 1976*). Database design is usually conducted in three phases (*Simsion& Witt, 2004*): conceptual, logical and physical design. The proposed approach also follows these three phases:

- Conceptual design – during which the real-world concepts, and their relationships are defined using an EER model.
- Logical design – during which the real-world concept are mapped onto NoSQL database concepts.
- Physical design – .during which additional physical characteristics of the NoSQL database are defined (e.g. indexes, etc).

Due to space constraints, and given the focus of this paper, only the conceptual and logical design phases will be further elaborated and illustrated.

4.1. Conceptual design

The conceptual design phase of the proposed approach would not significantly differ from the conceptual design of relational databases. In this phase the relevant real-world concepts are identified and their attributes and relationships are defined. The utilization of the EER model, as a semantically rich data model, is proposed for the conceptual design of NoSQL document-oriented databases.

The EER model which will be used for illustrating the proposed approach is presented in Figure 3. The *Person*, *Department*, *Course*and *Student Organization* represent strong entities. A *Person* is further specialized into either a *Professor* or a *Student*. A *Student* can be a member of multiple *Student*

Organizations. A *Professor* can belong to one and only one *Department*. The *Pay Slips* for each professor are recorded as weak entities. An *Exam* is an aggregation of the *Student*, *Course* and *Professor* entities.

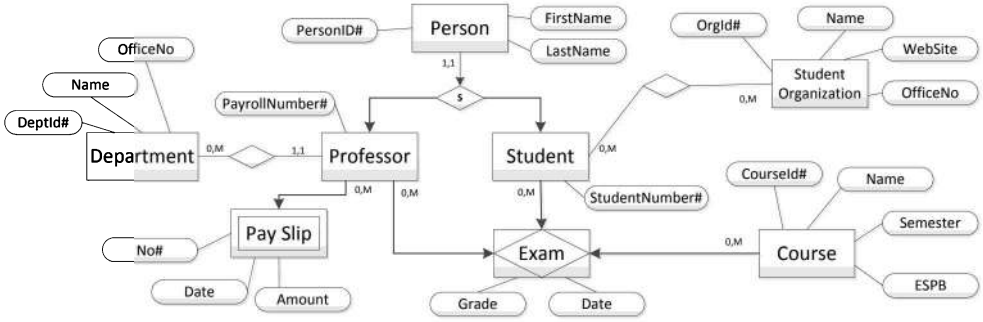

Figure 3: An example of an EER model, adapted from (*Lazarević et al, 2016*)

4.2. Logical design

In the course of the logical design phase, the concepts, which have been identified in the conceptual modelling phase, are transformed into NoSQL database concepts using a set of rules for mapping (transforming) EER concepts onto NoSQL document-oriented concepts. The proposed rules(*Stojimirović& al, 2015*), Figure 4,have been formulated in accordance with the existing recommendations and best practices in this field (*Katsov, 2012; Lazarević& al, 2016; Vaish, 2013; Baker & al, 2011*).

Rule R1: *A strong entity is transformed into either a document or a sub-document. If a strong entity is transformed into a document, then the identifier of the strong entity becomes the identifier of the corresponding database document. If the strong entity is transformed into a sub-document then the identifier of the strong entity becomes a field in the corresponding sub-document.*

Rule R2: *A subtype is transformed into a document. The identifier of the supertype becomes the identifier of the corresponding database document.*

Rule R3: *A weak entity is transformed into an array of sub-documents. The identifier of the weak entity becomes a field in the corresponding sub-document.*

Rule R4: *An aggregation is transformed into either a document or a sub-document. If the aggregation is transformed into a document, then the identifier of the document will either be the identifier of the entity which participates in the mapping with maximal cardinality of "one", or a composite identifier consisting of the identifiers of the entities participating in the mapping with a maximal cardinality "many". If the aggregation is transformed into a sub-document document, then the identifiers of the participating entities (except for the entity corresponding to the document in which the sub-document is embedded) will become fields in the sub-document.*

*Relationships with M:M cardinality are regarded as aggregated entities, thus Rule **R4** will also be applied to such aggregated entities.*

Rule R5: All entities which are transformed, by applying rules ***R1*** through ***R4***, into documents, also become collections.

Rule R6: *The attributes of an entity become the fields of the document, or sub-document, corresponding to the entity.*

Rule R7: *The identifiers of all entities onto which a given entity is mapped with a maximal cardinality of "one", become fields in the document (or sub-document) corresponding to the given entity.*

Rule R8: The *fields, obtained by applying rule **R7**, represent references.*

Figure 4: The rules for transforming EER concepts into document-oriented NoSQL concepts

The outcome of this phase is a logical model of the database structure. It should be emphasized that, as is the case with any other design, several different logical models can be derived from the same conceptual model.One approach would be to model a completely normalized structure. Given that a NoSQL *collection* can be regarded as being similar to the *table* concept in relational databases, all EER entities (i.e. strong and subtype), save for weak entities, can be transformed into separate collections. On the other hand, since the collection concept, unlike the table concept, does not prescribe the structure of documents that will be stored within the collection, it is also possible for all entity types to be stored in a single collection. Consequently, the first step is to determine which collections will exist in the database. The next step would then be to establish which entity will be stored in which collection, unless the creation of separate collections for each type of document was decided on. Finally the established transformation rules will be applied.

Rule ***R1***states that a strong entity can be transformed into either a document or a sub-document. The application of this ruleto the EER model in Figure 3, resultsin four types of documents: *Department*, *Student organization*, *Course*and *Person*. Given that these entities also have attributes, rule ***R6***is also applied, so the attributes of each entity become fields in their corresponding documents.Figure 5depicts a representation of instances of these entities, stored as concrete NoSQL documents. It should be noted that a strong entity can

also be transformed into a sub-document. This type of transformation is performed when, for optimization purposes, an entity on the "many" side of a 1:M relationship is regarded as a weak entity.

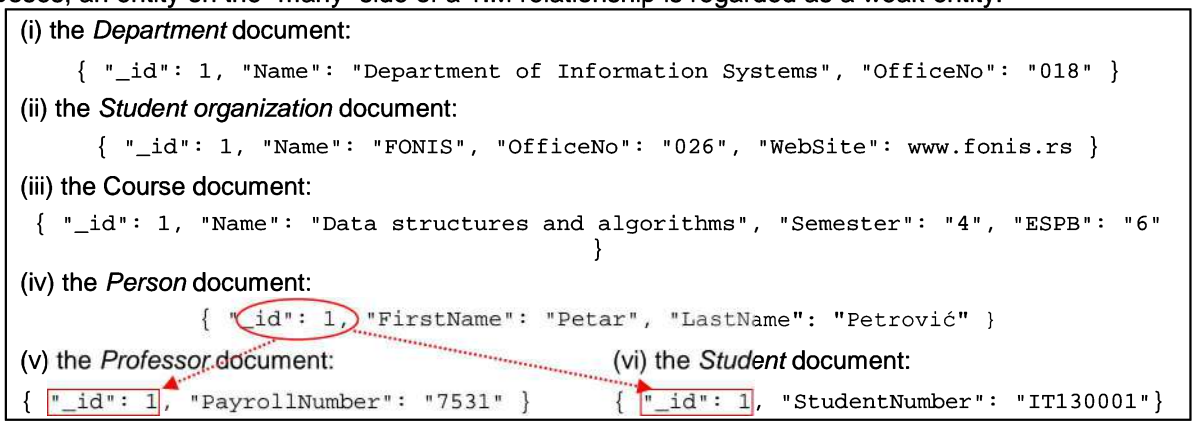

Figure 5: Examples of concrete NoSQL documents

Rule ***R2***is related to the mapping of subtypes which are transformed into documents. By applying rules ***R2***and ***R6*** to the *Professor* and *Student*subtypestwo additional documents are obtained, Figure 5 (v)and (vi).

Since a weak entityis both existence dependent and identifier dependent on itsstrong entity, it will be transformed into an array of sub-documents within the document corresponding to the strong entity.Aweak entity in an EER model cannot exist without the existence of its parent entity. The same principle applies to sub-documents in document-oriented NoSQL databases.Consequently, the deletion of the parent document from the database also entails the deletion of its sub-documents, as they are contained within the parent. In the EER model (Figure 3) the *Pay Slip* entity is a weak entity of the *Professor* entity. By applying rule ***R3***it is transformed into an array of sub-documentsof the document corresponding to the *Professor* entityFigure 6.

the *Professor* document:

```
{
    "_id": 1,
    "PayrollNumber": "7531",
    "PaySlip": [
      { "No": 1, "Date": "15.03.2016.", "Amount": 35743.41 },
      { "No": 2, "Date": "31.03.2016.", "Amount": 31454.22 }
    ]
}
```

Figure 6: Aconcrete NoSQL document with a sub-document

The *Exam* aggregation of three entities: *Course*, *Student* and *Professor*in Figure 3,is transformed by applying rule ***R4***. In this case there are two options, either the *Exam* entity will be transformed into a document, or it will be transformed into a sub-document of one of the documents corresponding to the participating entities. The choice will depend on the intended usage of the stored data.

If the first option is chosen then a concrete *Exam* documentwill be stored in the database. Its *_id* field will be a subdocument containing the identifiers of the documents corresponding to the entities participating in the aggregation (since an *_id* field of a document cannot be an array). In the depicted example (Figure 7), the identifier of an *Exam* document is composedfrom the *Course_id*, *Student_id*, and *Professor_id* fields.

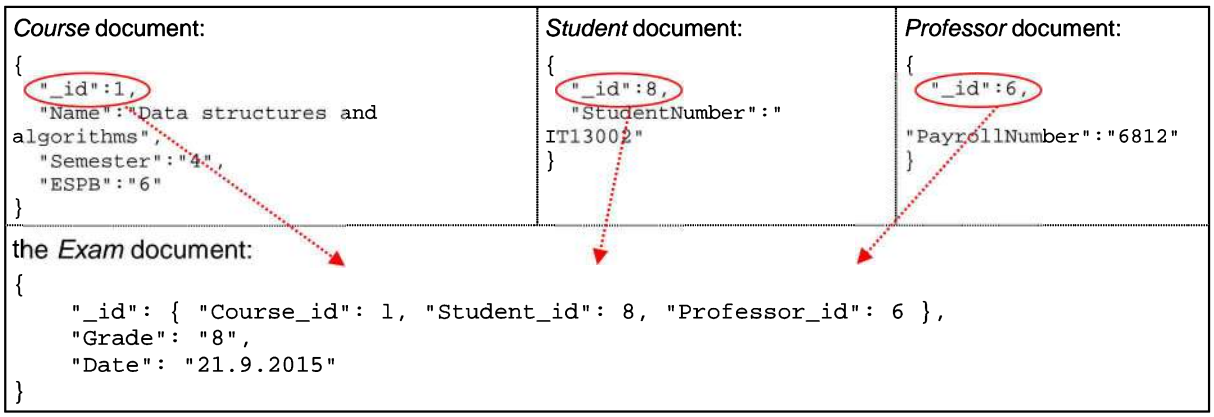

Figure 7: An example of a concrete NoSQL document generated by transforming an *Aggregation*instance

However, if the application requires that the exam results are customarily to be viewed alongside the student data, and are only occasionally to be displayed summarized per professor or course, a better approach would be to choose the second option and transform the *Exam* entity into an array of sub-documents of the *Student* entity. The identifiers of the documents corresponding to other entities participating in this aggregation (i.e. *Course* and *Professor*) will then become fields of a sub-document. A concrete example of one such document is shown in Figure 8. It should be emphasized that the *Exam* entity could be transformed into a sub-document of any of the documents (or sub-documents) corresponding to the entities participating in the aggregation. The choice is left to the designer, and will depend on the application requirements.

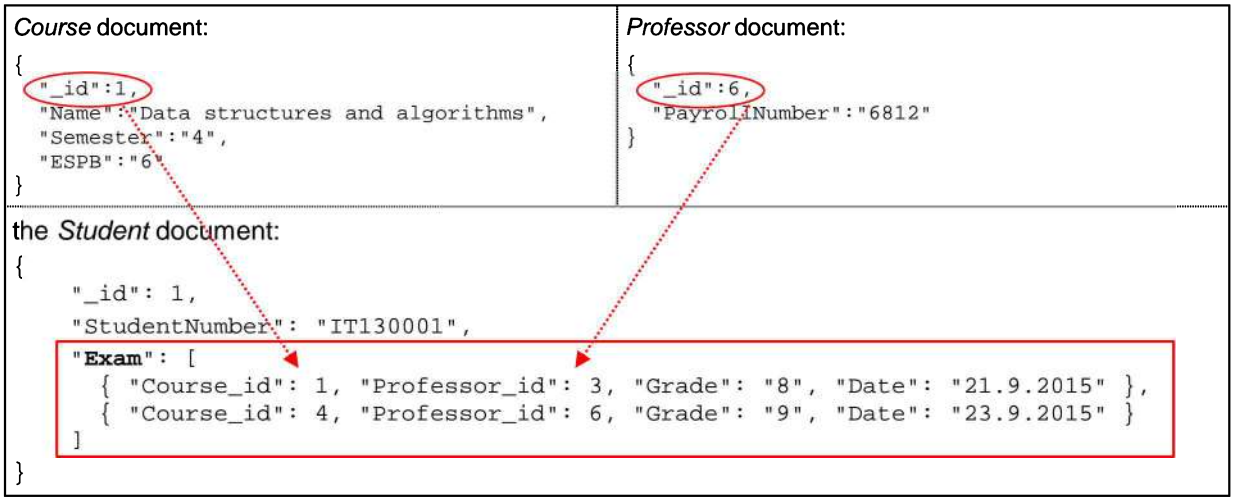

Figure 8: An example an *Aggregation* instance transformed into a concrete NoSQL sub-document

The main advantage of the first approach (i.e. a normalized structure with aggregations transformed into documents) is that such a structure offers greater flexibilityand is more easily maintained in comparison with the second approach (when aggregations are transformed into sub-documents). On the downside thefirst approach entails the execution of multiple queries in order to retrieve the relevant data.

4.3. Automating the execution of the transformation rules

The manual application of the transformation rules and coding of the necessary CRUD operations (responsible for manipulating the stored data) can, as mentioned in Section 1, be a very complex and error-prone task. The absence of a database schema makes this task even more challenging, given that it is impossible to check whether the data is actually stored in the correct format. Thus this paper suggests a means for automatically generating the code (necessary to create the data structures and corresponding CRUD operations for a document-oriented NoSQL database) from a conceptual EER model.

As defined in (*OMG, 2014*): “transformation specifications [in the context of MDD] provide the mechanisms to transform between representations and levels of abstraction or architectural layers”. In general, the transformation specification is based on a set of rules which define how the concepts of a source model (in this case an EER metamodel) are to be automatically transformed into the concepts of a target model (in this case a document-oriented NoSQL database metamodel). The transformation specification is then executed by a transformation engine which has an EER model (conforming to the EER metamodel) as its input and

generates the necessary artifacts as its output. Since document-oriented NoSQL databases, contrary to relational databases, do not possess a schema, the suggested approach would not follow the traditional EER -to-relational model transformation. It is proposed that the specified transformation could be a model-to-text transformation (M2T), wherein the source would be an EER model while the generated target would be a textual artefactrepresenting code (e.g. Java). The proposed approach suggests that three artifacts should be generated: the domain classes (for representing the in-memory object model in which the data will be stored at runtime), a generator (responsible for knowing how to transform an object into a JSON document using generated text templates storing the structure of a concrete document type) and brokers (responsible for executing the CRUD operations by invoking the generator to obtain concrete JSON documents).

Thus the first step would be to map the EER metamodel elements onto the document-oriented NoSQL database metamodel concepts. However, in order to obtain the flexibility, which the presented rules offer, the designer would need to specify, for those rules which provide alternatives, how certain concrete concepts should be interpreted e.g. how to transform aggregations, or if strong entities should be transformed into sub-documents. In general this can be accomplished in two ways: either by annotating the concrete EER model elements or by initially configuring the engine throughstatic rules providing the desired settings as XMI.
The transformation engine would read a concrete EER model and use a visitor pattern, such as topological sortor a similar algorithm, to traverse the EER model (and for each element its related elements would be visited)whereupon the necessary domain classes, brokers and JSON generator (based on text templates representing the structure of the corresponding document types) would be generated, on the basis of the specified metamodel mappings and, if prescribed, the EER model annotations. At runtime, upon the invocation of a concrete CRUD operation, the broker, responsible for the execution of the operation, would invoke the generator which would extract the information from the domain objects and populate the previously generated document template with the concrete values, thereby generating a concrete JSON document that can be stored in the document-oriented NoSQL database. The metamodels, EER model instances and transformation rules could be stored, for example, as XML (eXtensible Markup Language) documents conforming to the XMI (XML Metadata Interchange) standard, while the transformation engine could be built using e.g. Java code or, preferably an existing one could be used.

5. CONCLUSION

Contrary to relational databases, NoSQL databases do not enforce a database schema and, in addition, in relational models the data structure is decoupled from the actual data, which is not the case with the JSON documents stored in a document-oriented NoSQL database. Yet it is still necessary to design the data structures that will be stored in a NoSQL database in order to be able to correctly manipulate the stored data in an application. A possible approach to automating the design of NoSQL document-oriented databases, in accordance with the leading approach to software development today – MDD, is outlined in this paper. The aim is to automatically generate the data structures and corresponding CRUD operations for a document-oriented NoSQL database, from a conceptual model. Consequently, there would be no need for the error-prone manually coding of CRUD functionality.In the presented approach semantically rich Extended Entity-Relationship models are used as conceptual data models. The rules for transforming EER concepts into NoSQL document-oriented database concepts are presented, and a possible approach to automating these rules is outlined.

If the transformation is automated there would be no need for manually coding the CRUD functionality (which is usually very time-consuming and prone to errors). Thus the proposed approach reduces the risks of incorrect mappings, thereby ensuring consistency and reliability, while at the same time increasing productivity and lowering the costs of web application development. Moreover, the runtime performances of a web application would be accelerated, as it will not be necessary to store the object mappings separately and then check theses mappings, to determine the how to handle an object (document), each time a CRUD operation is to be executed, rather the entire manipulation logic will already be embedded in the code.

Future work would be aimed at providing a concrete implementation of the proposed approachand testing it in different real-life scenarios.

Abstract: *This paper takes a strategic perspective on performance management and discusses the integration challenges that most organizational continuously face. This is done by relating an integrated performance management framework to Swedish university organizations way of managing overall performance.*

Keywords*: integrated performance management, university governance, strategic relevance, evaluation*

1. INTRODUCTION

In the higher education discourse and literature, especially in the last decade, one might find terms like globalization, competitiveness, market forces and strategic management (Foskett and Lumby, 2003, Hoffman, 2000, Shattock, 2006). Internationalization and globalization of higher education are topics that have occupied the discourse for many years now and have been a driving force for change, adaptation and improved management of performance and outcomes. The ever-growing need to be competitive, in both the economic and academic sense of the word, affects every aspect of management and leadership as well as the staff and their performance within an education institution. This poses very tough challenges at every management level of the institutions but also affects the teaching and learning processes (Macfarlane, 2004). The shift of the late 20th century towards operational and strategic planning and coordination as well as the accountability movement brought about changes in perspectives on management in general and performance management and measurement more specifically (Foskett and Lumby, 2003, Hoffman, 2000 Skoog&Johansson, 2015).

Different types of stakeholder focuses, given that universities are in most cases and to a large extent state funded, sustainability movements of the last decades, all have influenced governance issues in higher education as well. Being an important part of the society, higher education is now facing challenges of disseminating research results for the sake of performance for its own existence (Skoog&Johansson, 2015).

Higher education institutions (HEIs) have broadened their role from teaching and research to becoming complex, many-sided organizations greatly involved in achieving social inclusion and building the knowledge economy (Shattock 2003). The challenges which HEIs have to face come in various forms and are quite multipart: the new competition created by market forces, financial/funding issues, changing demographics in both student and professional bodies and ever growing concerns and demands from the business sector regarding skills necessary for the work life (Hoffman, 2000).

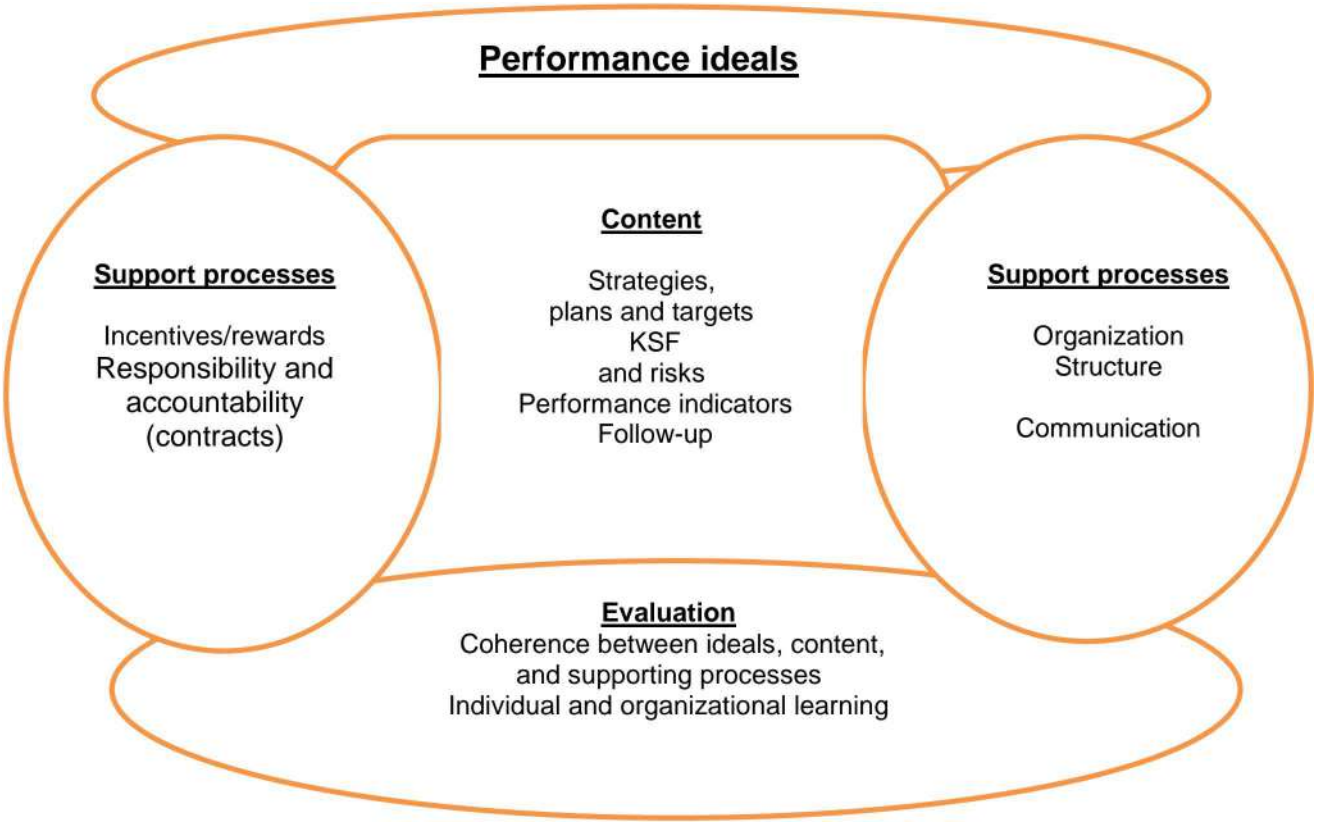
The terms *human resources* and *human resource management* have surfaced in the 1990s as interchangeable alternatives for *personnel* and *personnel management* respectively, with the idea of presenting the human component as much more complex and demanding than before in terms of satisfaction, continuity, stability and performance at work (Orlic, 2005, Armstrong, 2006, Salaman, Storey and Billsberry 2005).

An educational institution is generally no different to a business organization, when it comes to the leadership issues. Furthermore, it is said that it is even more complex and difficult to manage since there are complications in leading academics who, given their professional status, have certain discretionary authorities in their respective areas of work which are in some cases even guaranteed by the legislations in terms of freedom to form one's own research and teaching (Skoog&Johansson, 2015). Today's university lecturers and professors still have the unchanged basic responsibilities and tasks such as teaching, mentoring, evaluating, assessing and counseling students throughout their learning life at the university level and participating and leading research and projects, however, the context has changed significantly in the past decade or so (Macfarlane, 2004). In addition to these tasks there are also responsibilities of evaluation and assessment of internal management and administration, as well as self-evaluation and reporting to higher instances, various committee duties, consultancy and interaction with the society and media, i.e. the performance landscape for academics has been at least partly transformed.

When it comes to management of HEIs there used to be a tendency to look for the step-by-step model, a linear (bureaucratic) model of management and decision making which has in the past decade or so been regarded as "slow-to-react" and inflexible, even too simplistic in relation to contemporary educational issues (Hoffman, 2000). In the last part of the 1990s there was a shift towards more coherent and strategic performance approach which includes more planning than reflection, meaning more prediction of influencing factors rather than just analyzing decisions after they are already made (Hoffman, 2000, Skoog&Johansson, 2015). New models of governance, originating from business organizations, have made their way in the public sector arena. New Public Management, managerial accounting focusing on decision makers, budget steering and control, balanced scorecard, integrated reporting, are merely examples of theoretical models converted to praxis in the business world that have found their way in the public sector. Being a part of the public sector, higher education is not immune to these new influences. It is safe to say that, in the beginning, strategic planning of physical, financial and human resources became the embraced model in management of HEIs with the center notion of accounting for all the possible variables which could influence the achievement of a more successful overall strategic plan for educational performance and outcomes.

2. APPROACHES AND MODELS

Different approaches are constantly being investigated, analyzed and implemented in order to find the winning combination of administrative and academic management which will, consequently, be capable of achieving good results when it comes to educational outcomes, performance and the overall image of the institution. Furthermore, the desired model of management would have to be able to motivate the academic staff to keep the quality levels high, on one hand, and on the other keep the administrative staff active and stimulated for higher performance and effectiveness. All having in mind the stakeholders and accountability towards the tax payers. Management has become more businesslike with management processes such as strategic planning, resource allocation and performance management that includes physical resources (buildings and teaching spaces), learning support resources (for example, IT support) and human resources (teaching staff, managerial other support staff) and how these interact in producing decent teaching and research performance (Foskett and Lumby, 2003, p. 129). There is probably no *best practice* when it comes to organize management of an academic organization, especially in today's unforgiving conditions of market forces and competition for students and research funding. Educational management systems have been undertaking changes in structure, introducing some business views and models, such as human resource management, strategic planning, New Public Management, etc. But, there is however improvement possibilities for most institutions when it comes to integrating different aspects of performance into the actual management and measurement processes. (Johanson & Skoog, 2015). These improvement possibilities can be identified by using the framework presented below:



In university organizations, as well as in many other organizations, there is a constant challenge to integrate long term ambitions (visions) with more short term targets and operational needs. In order to gain relevance and acceptance in for example the performance evaluation processes organizations needs to not only take a number of supporting processes into account, but also identify and discuss different performance ideas that exists within the organization. Meaning that, performance can be interpreted in various ways, especially within university organizations that needs to perform pedagogically, research oriented and financially to a certain degree at the same time. In order to reach long term acceptance and understanding in relation to different performance processes and targets the supporting processes also seem to play an important role. (Johanson et al, 2001, Johanson & Skoog, 2007, Johanson and Skoog, 2015, and Skoog, 2015 in Lövstedt edt).

3. THE CASE OF INTEGRATED PERFORMANCE MANAGEMENT AT SWEDISH UNIVERSITIES

New models of governance and management of public institutions have, as stated, reached the universities. Being organizations of strongly individualistic character in terms of performance and results, universities' organizational model and structure are difficult to identify in terms of theoretical models. Universities in Sweden are strongly influenced by the bureaucratic and functional models given that they belong to the public service sector, alongside National Tax Office, hospitals and Social Services. The duality of such a system as well as the parallel processes in terms of research and education on one hand, and administration on the other, that occur and steer the universities in different aspects, are a significant challenge to address by the university administration. Many universities have, on top of this, decided to decentralize the decision making process, turning the university central administration into a control unit following up on the operations of the departments. Such a complex organization and context needs a complex, yet implementable and context-oriented governance model which takes into consideration the *soft values* of the organization, such as collegiality in decision making, health and satisfaction at work, stakeholder satisfaction, etc. A model where parts are mutually interactive, processes are formed to support the vision in order to achieve results and evaluation of operations is conducted in each part of the organization for the sake of improvement and learning (Skoog&Johansson, 2015) would be of great support for such an organization. The developed analytical framework for evaluation of governance models, mentioned above, is depicting the importance of integrating visions, content, processes and evaluation. By analyzing different organization from different sectors shown in Skoog&Johansson, 2015, one might conclude that the higher level of integration between these parts of an organization, the higher results it will achieve, both in the terms of financial numbers and the more "soft", non-financial ones. Decentralized organization of Swedish universities poses a challenge for such a governance model. This is not to say that more centralized systems should be in place; it is rather a reminder that the organizational models applied to universities should be contextualized, both in terms of actual implementation, but even more importantly in the terminology used. The, so called, autonomy reform conducted several years ago in the Swedish higher education system reiterated the academic freedom of universities and dropped the micro management approach the government had for many years.

Integrating different governance processes on a departmental level in such conditions, having in mind the constant rise of administrative tasks that educators in general, including higher education faculty are expected to conduct, imply a need of high coordination and high efficiency of internal processes without raising expenditures – do more with what you have.

In analyzing how integrated the different governance processes actually are in a university, we will discuss the aspects crucial to implement in order to achieve higher levels of integration between vision and governance in practice. Discussion is based on experiences in the higher education sector. In the analysis we will be using a model of integrated governance processes as described in Johansson & Skoog (2015) where elements such as governance vision, strategies, goals, critical factors, etc. are described.

An excerpt from Stockholm University Strategies 2015-2018 shows the *vision* for the University:

> *All research at the University should strive to be nationally leading and internationally prominent. Stockholm University should focus on education with close ties to research. The operations should be based on collegial work in strong, independent departments that develop in close collaboration with the University's management functions. The courses and programmes will be reviewed continuously in a strategic effort to achieve the highest possible quality and meet societal needs. The University should actively carry out pedagogical development work and provide an attractive study environment to all students.*

Structurally, the operative part of implementing the strategies lies with the departments, which by decentralized structure consequently have relatively wide independence. *Goals* and *critical factors* are also identified and are, based on experience, applicable across the University regardless of the area of study and research. Issues such as funding of research, internal and external, lack of research and education infrastructure, global competition, drop-out rates and new educational challenges in the classroom are raised among others as challenges the University is facing. Importance of follow up is stressed, however without a clear indication as to the ways this process is to be carried out. This might be a consequence (or a challenge) coming from the decentralized organization, given that the operations are conducted at the department level.

The different nature of the departments has led to different ways of resource distribution. Despite the different nature of the departments, the process of *reward* for achievements is more or less the same for all departments and it is based on the outreach and number of publications for the research part of the resources and the throughput of students, for the teaching part of the resources. In terms of correspondence between reward system and vision, one could say that it is rather high. On the departmental level, the governance models look different depending on the size, area of study and/or other factors, which leads also to differences in implementing the reward system both in terms of teaching and research. Given the collegial model of governance in terms of choosing the administrative and academic leader of a department, the legitimacy that a leader of a department has offers the opportunity of deciding the direction of the departmental research and teaching. These decisions are often conducted in a collegial process; however, there are also cases of one-sided decisions which are inevitably leading to resource distribution that might not always be in line with the University or even department strategies. How does a reward systems' next of kin, the penalty system, works in these cases is unclear; it is even unspoken of, since it unequivocally goes against the core of the Universities – the academic freedom where all researchers are free to choose and conduct their own research. If there are no consequences linked to the research activities that differ dramatically from the ambition (vison), the risk is that the vision becomes an "empty formulation" even if it is formulated based on collegial agreement and has an interdisciplinary orientation. On the other hand, the teaching part suffers often direct penalties which are implemented in the same way across the University – by reclaiming the funding that has not been used in terms of educating the number of students the resources were for or by not transferring extra funding in case the number of students exceeded the budget prognosis. At the same time, reward system is not exactly clear, some would say even existing, when it comes to teaching. Here we have an example of lack of integration of governance processes. Scarce stimulation of the departments' teaching improvement processes, together with complete transfer of responsibility and accountability to the department level in terms of teaching leads inevitably to disparate pedagogy across the University. This is, of course, not to say that diversity in teaching is wrong, rather pointing out an important aspect of integration of leading and management processes.

Another important aspect of integrated governance processes is *responsibility* for the content and follow-up of the results (performance). In the university world, the division of responsibility is clear, at first glance. However, this does not imply that the heads of departments share the vision of the university governing bodies or rectors, simply because they have been given the responsibility of a head of department. Although, it is easy to share the vision of *nationally leading and internationally prominent* research and education, the implementation of different processes if quite different in praxis. The departments are entirely responsible for and are leading the operations in teaching and research, while the University central administration takes on a controller roll. It is only in recent years that the importance of in service training of both academic and administrative heads gained more attention, aimed at supporting the vision spreading, supporting decision making, communication and bearing of decentralized responsibility by the heads of departments.

One very important aspect in achieving synergy between vision and results in any organization, public or private, is attaining and sustaining an overall view of the operations. Having an integrative approach to University governance processes in terms of collegial knowledge and value sharing, and collective leadership processes on one side and administrative procedures, the bureaucratic nature of public organizations on the other, is critical for making sure that the governance and support processes are in line with the responsibility sharing, decision making and follow up of results. Integrating governance processes should include even the *soft, non-material, values* of the organization such as health of all the employees, competence level of the faculty as well as stakeholder satisfaction. How these processes of integration of vision, support processes and evaluation of results can be implemented in a widely decentralized organization is a key challenge. It is significantly more difficult to integrate operations between units of an organization that are individualistic both in terms of how faculty views themselves, but also in the way units are run. Control mechanisms from central administration are viewed as an outside attempt of interfering with the operations, rather than evaluation of results.

4. CONCLUSION

In an organization such as a decentralized university, strategic processes should be initiated from the top with a wide department-based acceptability and accountability in order to achieve the goals set up in the vision. At the same time, the operations at the department level should, in the strategic sense (both short and long term), be in line with the vision, while respecting the academic freedom of the faculty. Transferring the governance and leadership models from other sectors into higher education, without the contextual translation of such models and adaptation to the specific nature of academia, would only create more obstacles in the governance processes. Stakeholders are asking for more practical use of the produced knowledge and research results, as well as higher levels of practical, work related benefits of the education provided to students. Demands from the stakeholders and the society as a whole, on one hand, and balancing state resources between administration, teaching and research on the other, are putting forward the importance of integrating governance, management and measurement processes at the university level.

*Corresponding author, e-mail: natasamaric91@gmail.com

Abstract: *Performance management become crucial for all media companies which do business in highly competitive market and whose goal is not just to survive, but also to progress in these conditions. Today, media companies in Serbia are aware of the fact that performance management is important part of doing business properly, but still, most of them has performance management implemented partially, not integrated in a whole company. Additional specificity of the media is that performance must be considered from two different, but related perspectives. The first is the perspective of the viewer/reader/listener and the other is perspective of the client/advertiser. The purpose of this paper is to provide guidelines that include useful instructions for setting strategic direction of a company, using specific techniques, creating action, operational and annual plans, properly implementing tracking, reporting and awarding systems all in order to ensure better business results.*

Keywords*: performance, management, media, strategy, plan, technique*

1. INTRODUCTION

Performance management represents a highly used concept which has a major influence on company development and prosperity, all in order to achieve company goals. Performance management can be defined as a result of work of individual employee as well as a work of organizational unit or company in general (Hale, 2003). According to the same author, set of values and principles for performance management includes: focus on a results, systematical approach, having in mind wider picture including process of identifying ways to work efficiently in order to achieve competitive goals, providing added value for the customers, employees and organization, always having in mind that their prosperity is crucial for achieving company goals, cooperation with target groups and individuals that has a major influence on company prosperity, work discipline, fact analysis, participation of future challenges, testing ideas and alternatives as well. Performance as an indicator should have several main characteristics (Woolum, 2011), it should be relevant, time limited, understandable, comparable, measurable, and reliable.

Due to increased competition in business environment, performance management become crucial for all companies whose basic goal is not just to survive, but also to grow. Today, media companies which do business in Serbia are aware of the fact that performance management is important part of doing business properly, but still, most of them has performance management implemented only on highest hierarchy levels, and not integrated in whole company. Additional specificity in the media is that performance must be considered from two different, but still related perspectives. The first is the perspective of a viewer/reader/listener and the other is the perspective of a client/advertiser. The purpose of this paper is to provide guidelines for implementing performance management in media companies. It could be useful not only for top managers of media companies in Serbia, but also for marketing and advertising managers, editors, writers, other company employees and all individuals interested in implementing strategic performance management.

Strategic performance management is an approach that has been elaborated in theory and accepted in the practice. However, to the best of authors' knowledge, its implementation in the media industry, especially in Serbia, has not been examined enough. As one of the author works in a media company in Serbia, the framework presented in this paper is based not only on theoretical background, but also on practical experience. The paper provides several examples that are developed for the purpose of better understanding.

After the introduction, second section presents the framework for performance management. As we focused on the very process, as a part of performance management system, in particular, this section covers setting the strategic direction of a company, plans that have to be prepared, techniques that should be used and evaluation systems that should be implemented. The final section presents concluding remarks.

2. FRAMEWORK FOR IMPLEMENTING PERFORMANCE MANAGEMENT PROCESS IN MEDIA COMPANY

In this paper, authors focused on the process of performance management, as process that helps organization in creating, implementing and changing strategy in order to fulfill stakeholders needs (Verweire & Van den Berghe, 2004). This section follows steps of the process, by presenting the strategic direction of company at the beginning and techniques usually used for transforming strategies into plans. Furthermore, basic plans are presented, as well as systems for evaluation and measurement that should be implemented. Every step is elaborated and supported by examples of media company.

2.1. Setting the strategic direction of a company

At the beginning of the process of performance management, company sets its strategic direction, through defining of mission, vision, values, corporate and business strategies and goals.

According to Obradović V. Petrović D., Mihić M., and Mitrovic Z., (2015) mission statement defines what an organization is, why it exists, and its reason for being. Although there are differences among companies from the media industry, general mission of the media company should be to provide truthful and timely information which can have entertaining, educational and/or informative character. Furthermore, according to Murray and Richardson (2002) vision statement provides a key stakeholders with a picture of what the company corporation ultimately intends to become in the period of five, ten or fifteen years in the future. For media company, vision could be to become absolute leader on local market in next five years.

According to Lencioni (2002) core values are the deeply ingrained principles that guide all of a company's actions and serve as its cultural cornerstones, such as teamwork, trust, professionalism, timely and truthful information and others.

One of the commonly used strategies in media is growth strategy, and company can opt for one of the following: Vertical integration which occurs when a firm takes on activities that were formally done by others on its behalf. In a way, vertical integration is just a special case of diversification, a firm is diversifying into either its suppliers' or its buyers' industries. When a company starts making components for its products or starts distributing products directly to customers, it is a sort of a vertical integration. One example could be when publisher buy its own printing machines or cooperates with distributors and, in that way, has influence on whole process from creating content to the process of selling the final product. Horizontal integration can be defined as a strategy when company cooperate or buy competitor's company. Some examples of horizontal integration in our market can be fined. The first occurred in December 2012 when Kurir bought Adria Media Group and in that way made its portfolio wider. The other example is cooperation between two major televisions with national frequency – Prva TV and B92.

When choosing strategy, company should also consider diversification strategy. Diversification can be either related or unrelated. The key issue here is if the operations of the firm in the new industry share some link with the firm's existing value chain. For example, is there some value-adding activity that can be shared, such as a distribution network, or a marketing competence that both can use. Historically it was thought that related diversification would be better than unrelated diversification. However, the coordination costs of related diversification appear to consume a lot of the expected benefits. Therefore, while most firms seem to engage in related diversification its benefits are only slightly, if at all, better than unrelated (Palich et al., 2000).

After determining the strategy, corporate goals, for a period longer than five years, should be set. Some examples of media company corporate goals should be: 20% revenue increase until 2023 (for printed media and Cable TV such as HBO); placing all TV channels/newspapers/magazines and websites as the best in its market segment until 2023; making portfolio which will be wide enough to satisfy needs of its readers/listeners/spectators in next 7 years; or 25% revenue increase until the end of 2020.

Further step in setting the strategic direction of a company is defining a business strategy. It comprises a set of guiding principles that, when communicated and adopted in the organization, generates a desired pattern of decision making, and according to (Miller, D., 1988)it was shown that strategies must be matched with complementary environments and structures to promote success. In that way company ensures realization of global strategy and achieving company goals.

One of the common used approaches in defining business strategy is by using Ansoff's matrix (Watts, G., Cope, J., & Hulme, M., 1998), that defines possible choices on the basis of two dimensions, products and customers. Combining the existing of new products with existing or new customers, Ansoff proposes market penetration, or product development, and market development or diversification. Another approach in defining business strategy is provided by Porter (1980), who identified three generic strategies. Cost leadership strategy represents a strategy when company lowers its cost in order to place product on a market with lower cost than competitors. In the time of the crisis, media tried to implement this strategy by cutting printing cost and start making low budget shows and series. In the beginning that had major effect on profitability and cash flow, but on a long distance it could negatively affect customers' (viewers/readers/listeners) loyalty, rating and income as well. Second strategy tha can be implement is a differentiation strategy that is mainly used when focusing on customers that are not price sensitive. This strategy should be implemented when company has premium product and when a projected difference between profit before and after differentiation is greater than amount of money spend on a process of differentiating. The third option is focus strategy that can be implemented by both, major and small companies when niche segment is spotted. When they find a niche segment, they must decide, according to the customer needs, to focus on lowering cost or to differentiate. The main idea is to fulfill needs of niche customers by focusing on one or two small segments. The main goal of this strategy is to create that kind of products that practically have no competition.

After defining business strategies, media company should define goals. Business goals are usually set for a less than a five years, and have to be in line with corporate goals. For example, the media company can set following business goals: 10% sale increase of print media in next 3 years (goal for print media industry), 10% increase number of viewers (television with national frequency), or strengthen the position on the market in next 3 years (online and premium cable televisions).

Financial goal for all media is to increase the revenue from the clients' campaigns, and by achieving these goals media company will fulfill strategic goal.

2.2. Techniques

In this paragraph three crucial techniques for implementing strategic performance management and translating strategic direction of a company into plans will be explained. These techniques include Balanced Scorecard, creating strategic and map of processes. The balanced scorecard, BSC, (Kaplan & Norton, 2005) allows managers to look at the business from four important perspectives. It provides answers to four basic questions: How do customers see us? (customer perspective), What must we excel at? (internal business perspective),Can we continue to improve and create value? (innovation and learning perspective) and How do we look to shareholders? (financial perspective)

Media companies usually consider customers perspective as the most important one, but the complexity here comes from the fact that media has two different categories of customers. The first one includes readers/viewers/listeners, while the second includes the clients/advertisers who place their campaigns in media. Because of this complexity, considering customers perspective may be crucial for companies' survival and prosperity.

Usually, media companies in Serbia have more than one "product". For example, one publishing house can have newspaper, weekly and monthly magazines, as well as web sites. Each of these products has its own market share and internal value for the company. Having in mind the whole portfolio of product, media company should manage it. For example, a company should identify the product which has highest future potential and then build business and corporate strategy according to that. In the media industry, one of innovative products with high potential in our market might be YouTube shows, and companies should consider the idea of introducing it in their product portfolio. If media company respects both categories of customers, rise market share with its most profitable product, and at the same time invest in new product which has highest potential, that would lead to better business results.

Strategic map is technique considered as an upgrade of BSC. Main characteristics of strategic map are (Kaplan & Norton, 1992): through integration of crucial processes companies plan the activities in that manner that every employee understands its contribution, it is a pattern that can be used for describing main strategies and it enables organizations to describe its tasks and initiatives that are the foundation of a general strategy. One example of strategic map in the media industry isl be presented in the next table.

Table 1: Example of strategic map of media company

Goals (business strategies)	**10% average sale increase in next 3 years**	**10% rating increase in next 3 years**	**Strengthen the position on the market in next 3 years**
Financial perspective (tasks)	Positive cash flow (advertising revenue)	Positive cash flow (advertising revenue)	Positive cash flow (advertising revenue)
Customers perspective (tasks)	1. High quality of information for customers 2. Reach of a client's campaign 3. Satisfied price/quality ratio		1. High-quality program for which clients are prepared to pay more than average 2. Clients satisfaction of the placed campaign
Internal processes perspective (task)	1. Tracking rating and customers opinion 2. Adequate positioning of a client's campaign 3. Events which have purpose to acquaint clients with brand		
Learning and development perspective (tasks)	1. Employees development 2. Creating knowledge base for the organized events 3. Create knowledge base for all clients		

After creating strategic map, next step is creating processes map. For each of the crucial processes in the company should be created process list.

Every process consists of materials, information and resources entering the process and the output. Next step is defining all process parameters such as target values, place, authorities and all resources needed. For performance management, it is crucial to determine place where activity should be processed and the person who will be responsible for it (Obradović V. Petrović D., Mihić M., and Mitrovic Z., 2015).

2.3. Strategy implementation plan

Stakeholders are essential for a business development. For that reason, it is crucial to observe their impact on business and to permanently plan interactions with them.

When we define our stakeholders, there are a few crucial questions for company management to answer on:

- Where are they now – answering this question we can see how stakeholders see the company, and what is their opinion about it;
- Where we want them to be – one of the goals of project management is to change the state of mind of the stakeholders, from the one it was on the beginning to the one it suits the company best;
- Communication – how do the company communicate with stakeholders?
- Goals – what is the main company goal?

- Activities – What the company should do to reach the target?
- Communication frequency – It is crucial to determine the right frequency. For example, contacting shareholders too often can make them irritated, but on the other hand if we do not communicate with them it can be interpreted as company's indifference;
- Responsibility – As we mentioned in paragraph concerning performance management, it is crucial to have a responsible person in the company for communication with groups of shareholder

In the next table the example of communication plan with customers as a stakeholder is presented. The example shows how we can position customers in print media (magazines).

Table 2: The example of communication plan with customers

Stakeholder	Where are they now	Where we want them to be	Communication	Goals	Activities	Communication frequency	Responsibility
Customers	Stable readership	To maintain loyal readers but also to attract new ones	Placing campaign in other magazines and newspapers	Increase of the number of readers	Better quality Promotional campaigns	5 times a month	Publisher

2.4. Action, operational and annual plan of performance

The most complex phase in implementing strategic performance management is the process of transforming strategy to initiatives and actions. The process of transforming has its own path according to Obradović et al. (2015) and it includes defining program, project and program activities, and defining annual performance plans. Programs/projects must be defined in that way that every task/action has the person responsible for executing it, suitable resources and person responsible for a whole program/project. According to same authors, process of planning has two main phases, identification and planning phase. During identification phase, top management decides whether the project will be realized or not, according to the ratio between needed resources and predicted results. In this phase it is essential to enclose the budget calculation. Planning phase starts after positive decision in identification phase and include next steps, identification and mapping all program/project benefits, choosing the right tasks that will lead to the fulfillment of individual goals and the goal of the company, business changes that will bring the company desired benefits, and profiling the benefits - description and the type of the benefits, link with the program/project mission, a list of outputs and identified risks.

Table 3 presents the example of an action plan of the project which goal is to increase the revenue from selling media space.

Table 3: Example of an action plan

Action plan
Specific goal: Increase revenue (from selling media space)
Project : Organizing events and product presentations for a clients
Description: Organizing an event/presentation during which every brand manager will have an opportunity to present issue/television show/online possibilities, focus groups and all other important information for a clients.
Date: yearly
Project results:
10% revenue increase, 90% right positioned ads, 30% increase results for a clients, all because after listening about the media brands advertiser can better choose the right communication channel to promote

their product or service

Responsible: Brand and advertising managers

Financing: Company invest money

Budget: 10.000€ per presentation

R.B.	Activities	Responsibilities	Duration	Resources	Cost	Result
1	Creating presentation	Brand manager	3 days	Human resources – brand manager, research manager and designer	Uses resources in the company, no additional costs	Final presentation

An operational plan can be defined as a plan prepared by a component of an organization that clearly defines actions it will take to support the strategic objectives and plans of upper management, according to operational plans further develop from strategic initiatives and determine which activities are required. Also, operational plans indicate costs, performance measures and expected results. To ensure that company activities will be carried out properly, it is crucial to assign responsibility to the one person for all activities (Obradović et al., 2015) For easier understanding, next table presents an operational plan for one initiative that is further developed through several activities.

Table 4: Example of an operational plan

Initiative	Activities	Costs	Expected results after 3 years	What will be measured	target	Responsibility
			10% revenue increase	% revenue increase	+3%	
Events for clients	Creating presentation	Depends on various factors, but approximately it is 10.000€	90% right positioned ads	% right positioned ads	+50%	Brand and advertising managers
			30% increase results for a clients	% increase results for a clients	+25%	

Annual plan consists of yearly performance targets and person responsible for achieving them (Obradović et al., 2015). As the most common elements of annual plan, these authors define: strategic targets and tasks, strategies, measures (depending on the level at which we want to show) and the person responsible for the

tasks, Key Performance Indicators – KPI, performance measures, targets and baseline values, and responsible persons.

Next table describes example of one of the target goals in annual plan.

Table 5: Example of an annual plan

Strategic goal				
10% Sale increase in next 3 years, 10% viewers increase in the next 3 years, Better brand position on the market achieved in the next 3 years				
Strategic task				
Positive financial result				
Responsible	Manager of the distribution			
Performance measures	Baseline	N	n+1	n+2
% of sale increase	0%	3%	5%	10%

2.5. Responsibilities and awarding system

After developing plans of activates according to the strategic direction of a company, the rest of the performance management process includes defining the responsibility and awarding system, as well as tracking and reporting system (Obradović V. Petrović D., Mihić M., and Mitrovic Z., 2015).

The employees, depending on their position in a company, have the tasks and obligations they are responsible for. In the media company, responsibilities of employees vary from entire business (CEO and top management), over operations at the level of division (Division Manager), operations at the level of the organizational unit (functional or project managers) to the individual level. For each of these levels it is necessary to define expectations, responsibilities, as well as benefits that employees will receive if they exceed set of the expectations and consequences for the performance below expectations. Some of the performance indicators in the media industry includes readership/viewership/number of visits, or a level of income and the number of campaigns that client's customers book. At the individual level, the most optimal is to do precisely defined job description with the expectations and requirements.

One example of job description is in the next table:

Table 6: Example of the job description with responsibilities

Responsibility – personal responsibility				
No.	Employee	Manager	Duties	Responsibilities
1	Journalist	Editor	Creating content that will be interesting enough to the viewers / readers / listeners, in accordance with the issue policy, agreement with the editor and in accordance with the annual plan.	Personal integrity , ethics , morality , trustworthiness and honesty

The system of responsibilities and reward system in the company are two almost inseparable systems. Reward system should be determined and introduced for each part of the business process. Large media companies' goal is to place adequate content to viewers/readers/listeners in order to be competitive in the market and achieve best possible ratings, because ratings are directly connected with client investment.

Generally, in media company structure one can roughly identify two parts, one that includes, editorial and creative staff, and business part. The editorial and creative part of the company consists of editors, journalist, designers and photo and video crew. They are responsible for creating the content that will be interesting to

viewers/readers/listeners, and their performance parameters are viewership/readership/listenership and general ratings of the company. Goals are set on annual basis but monitored daily, weekly or monthly. Thus, for example, viewing TV programs can be monitored on a daily basis, but the average pulls in a week, and once a month. If there is deviations from the plan, manager needs to take corrective actions that include changing the content and implementation of marketing campaigns in order to further promote the show/program. Creative people generally have their own system of performance measurement and reward.

On the other side, the business team is responsible for the coordination of all segments of the company and communication with clients. Media companies are funded by sales of media space. The objectives for the advertising are to cover all operational costs and achieve positive financial balance. The rewards should be determined and introduced in this part as well..

2.6. Tracking and reporting system

Operational monitoring and reporting systems are set to monitor key performance indicators, strength and weaknesses, target area of potential development and check whether the performance is achieved and set out the measures to be taken in the case that there has been a plan deviation (Ammonos, 2007.). As a part of the operating reporting system there should be some resources planned for getting plan on a track. The following table shows one example of reporting system.

Table 7: Example of tracking and reporting system

Tracking and reporting system						
KPI	**Performance measure**	**Target**	**Current status**	**Deviation**	**Measures when deviations occur**	**Using resources**
Readership increase	5%	5%	6%	1%	Bonus for editorial team	% of money advertising team earned more because od the deviation

Generally, in media two systems must be followed, sales and advertising. All viewership/readership data are permanently monitored in R&D sector in the form of daily and weekly reports. Regarding print media, it is also important to monitor sales in different locations, and react on time if any deviation occurs. For example, monitoring can show that in some cities all distributed magazines are sold out, just in a few days, while in some other cities, stores sell only small percent of distributed magazines. In that case, distribution manager can redistribute printed magazines and increase sales with the same costs. Regarding advertising system, when campaign is to be realized in media, the client must send campaign order, which is processed in finances. Tracking financial report on daily basis, which includes reserved media space and comparison with a target is crucial for fulfilling the company's goal.

3. CONCLUSION

Having in mind the very business of media company, we can identify two key stakeholder groups. The first one includes viewers/readers/listeners, to whom companies from the media industry placed the contents in order to attract their attention. Attracting greater attention will have an effect on the overall rating. The second includes clients who place their campaigns and invest money in media.

This paper presents guidelines for introducing a system for managing performance in the media industry with a purpose to show how through all the steps, form setting strategic direction of a company, creating strategic maps, operational plans, systems of responsibility, and monitoring and reporting as well, company always must have in mind its stakeholders. In the case of media company, by implementing performance management it always will have in mind the customers who are the ones who decide where the clients' campaign will be positioned and how much money client will invest in it. This guidelines might be useful not only for top managers of media companies in Serbia, but also for marketing and advertising managers,

editors, writers, other company employees and all individuals interested in implementing strategic performance management.

We can conclude that in contemporary environment, which is characterized by strong competition, the media themselves cannot afford to stagnate, but must constantly develop their business and improve overall business performance. These guidelines for proper performance management can lead media company to meet the needs of the viewer/reader/listener and consequently attract clients to invest their money, through placing their campaigns.

DEVELOPMENT AND TRENDS IN THE MANAGEMENT CONSULTING INDUSTRY

Jovan Krivokapić*[1], Milica Savić[1], Mladen Čudanov[1]
[1]Faculty of Organizational Sciences, Belgrade, Serbia
*Corresponding author, e-mail: krivokapicj@fon.bg.ac.rs

Abstract: *This paper will introduce the importance of management consulting, its development, as well as the current trends in this industry. A review of the literature and official statistical reports indicates that organizations, due to the lack of necessary expertise, increasingly use consulting services in order to improve their performances, so consulting, both globally and locally is becoming very important concept in the modern business world. Following trends, this industry has changed its face throughout history, and it has especially experienced some turbulent changes in the last hundred years. Today, consulting is most widely used in the field of improving operational performances and financial counselling, but its constant growth in other business areas should also be emphasized.*

Keywords*: management consulting, history, development, current trends*

1. INTRODUCTION

Management consulting has found application in various business activities. It can be said that there is no area without experts who have specialized in providing assistance to those who fail to cope with everyday pressures and difficulties (Florzak, 1999). Even many strong companies no longer consider the option of performing businesses without a help of consultants (O'Mahoney & Markham, 2013), regardless the fact that the price of their involvement is often extremely high. Considering all the benefits that could be gained, the price of such agreements is acceptable.

Having that in mind, the term "*consulting*" can be observed in many ways, from different aspects. There are views that the consultants are all those who are trying to change or improve business processes or situations, although they have no control during the implementation, so it might be noted that there is large number of them in organizations, though not explicitly under that name (Kubr, 2002). A help that is expected of them is most often in the form of providing important information or advices and recommendations concerning the activities that should be performed in order to achieve those objectives, while the client can be both an individual and another organization. Accordingly, it can be said that consulting is "*a process by which an individual or organization assists the client to achieve a stated outcome"* (Biech, 2011). In practice, however, this term is usually narrowly observed, and it can be defined as "*knowledge-intensive service which independent business professionals provide to managers of client organizations, and consists of objective advice on management's decisions regarding the solutions to the client organization's problems and opportunities"* (Baaij, 2013). Just like the other services, consulting does not have tangible outputs (Haksever & Render, 2013), but the effects of this kind of cooperation can be both observed and measured (Phillips, Trotter, & Phillips, 2015). However, it is not an easy task. Specific problem arises when there is a number of factors that influence the results gained by the client after the implementation of the proposed solutions (Baaij, 2013), so sometimes it cannot be said with certainty that the consultants' solutions led to the observed changes

Despite the fact that the current trends point to increased usage of consulting services, it can be said that the proper significance of consulting was not fully recognized until the last decades of the twentieth century. A review of the relevant literature indicates that up to a few decades ago a small number of researchers have pointed out the potentials of consulting industry (Armbrüster, 2006). Since then, the situation has changed significantly, and this statement might be supported through the analysis of the growth of this industry, which indicates that the total revenues in this field has increased more than one hundred times in the last thirty years (O'Mahoney & Markham, 2013).

2. A BRIEF HISTORY OF MANAGEMENT CONSULTING

Consulting is a very old industry, but through the history its role was significantly different from the concept as we know it in the twenty-first century. Initially, the role of consultants was mainly in the provision of specific advices and recommendations to the rulers and members of the higher social classes. However,

with the growing complexity of relationships in the markets, this role has changed and evolved significantly, so that in the last few centuries, following the significant improvement of the economy, consulting gets real contours of what it represents now.

Radical changes in consulting activities have occurred after the industrial revolution, especially at the end of the nineteenth century, with the advent of scientific management. Many organizations have decided to hire experts whose task was to improve the existing methods of work, and therefore provide a more rational use of resources. Frederick Taylor, his associates and other followers who modified and improved his ideas had special importance in the development of consulting services in this period. They have written a large number of professional articles and have performed many practical experiments with the idea to improve operational processes, which laid the foundations of modern consulting. These principles of management and organization have found extensive application in industrial companies throughout the United States and Europe, so the workers had the opportunity to increase their earnings, if they were able to produce much more than they did before (Jaško, Čudanov, Jevtić, & Krivokapić, 2013).

Due to a certain degree of exploitation of the employees, following decades have brought many analysis on their needs and behaviors in the workplace, in order to discover main factors that influence their commitment and motivation. Studies from this period pointed to the importance of the human factor, thus creating conditions for the development of the behavioral management. Numerous studies have shown that various intangible incentives have a significant impact on productivity (Cropf, 2008), thus causing the change of previous attitudes about the nature of business management. Organizations were increasingly focused on the analysis of the factors that affect the motivation of employees, their commitment, job satisfaction, and the results they achieve (Jaško, Čudanov, Jevtić, & Krivokapić, 2013), which led to the review of the management but also of the consultancy focus. Consequently, it resulted in large differences in the characteristics of consulting based on these two concepts, with more attention devoted to the strategic consulting. Comparative review of these perspectives is shown in the following table.

Table 1: Historical Management Perspectives (Stryker, 2011)

Period	**Perspective**	
	Scientific Management	**Behavioral Management**
Early (1890 – 1920)	▪ Few consulting firms ▪ Use of scientific method ▪ Emphasize on efficiency ▪ Principles of management articulated ▪ Time-motion studies ▪ Accent on material incentives	▪ No consulting firms ▪ Based on scientific method ▪ Emphasize on effectiveness ▪ Accent on employee education
Middle (1920 – 1940)	▪ Private sector consulting ▪ Extended scientific method ▪ Emphasize on efficiency ▪ Principles of management extended ▪ Work simplification ▪ Accent on material and individual incentives	▪ Consulting institutes ▪ Based on behavior studies ▪ Emphasize on effectiveness ▪ Employee-centered management ▪ Accent on personnel department
Modern (1940 - ?)	▪ Public-private sector consulting ▪ Based on Operations Research methods and techniques ▪ Emphasize on efficiency ▪ Generalized management principles ▪ Methods analysis ▪ Accent on material and individual incentives ▪ International consulting	▪ Public-private sector consulting ▪ Based on Organization Development methods and techniques ▪ Emphasize on effectiveness ▪ Participative management ▪ Accent on personnel training and counselling

In the mid-twentieth century, and especially in the years following the World War II, consulting services have begun to appear in almost all developed countries. It was believed that many organizations were unable to recover after years of war and crisis, so it was necessary to seek the assistance of external experts (Biggs,

2010). This is the period marked with the geographic expansion of consulting, and this growth was followed by significant changes that were reflected in (Kubr, 2002):

- Wider and more diversified service offerings,
- Growing competition in consulting,
- Internationalization of these services,
- Progress in the methodology of consulting,
- Progress in the technology that was used,
- Increased client competence in using consultants' services,
- Emergence of large consulting organizations,
- Internal consulting.

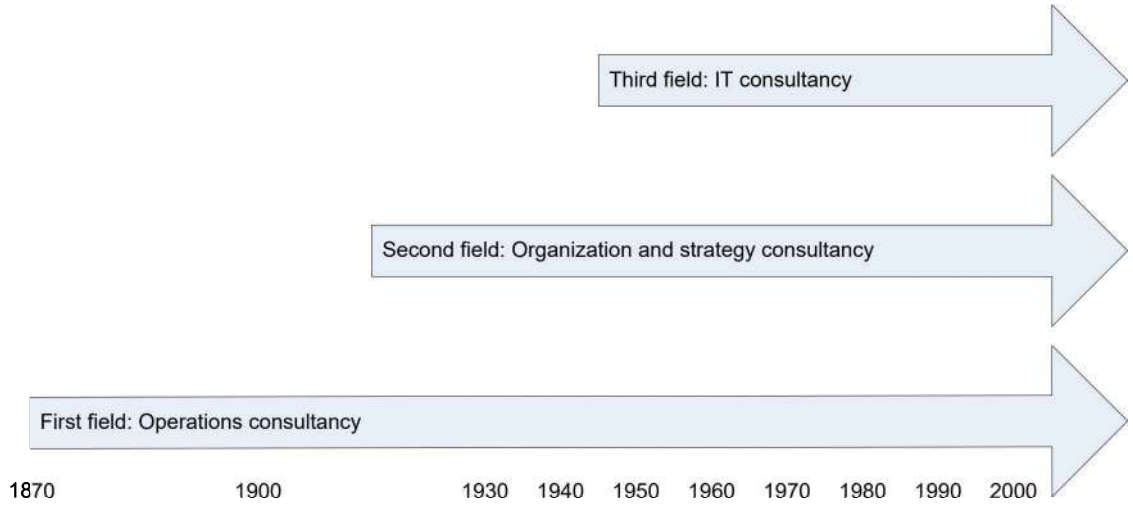

Figure 1: The emergence of management consulting fields (Baaij, 2013)

At the end of the twentieth century, the IT revolution predominantly shaped the nature of consulting (McKenna, 2006). This period is considered to be the golden era of consulting, since the annual growth of the industry ranged from 15 to 20% (Poulfelt, Greiner, & Bhambri, 2010). This growth has stagnated during the first years of twenty-first century, but it achieved stability again at a bit lower rate during the current decade (O'Mahoney & Markham, 2013).

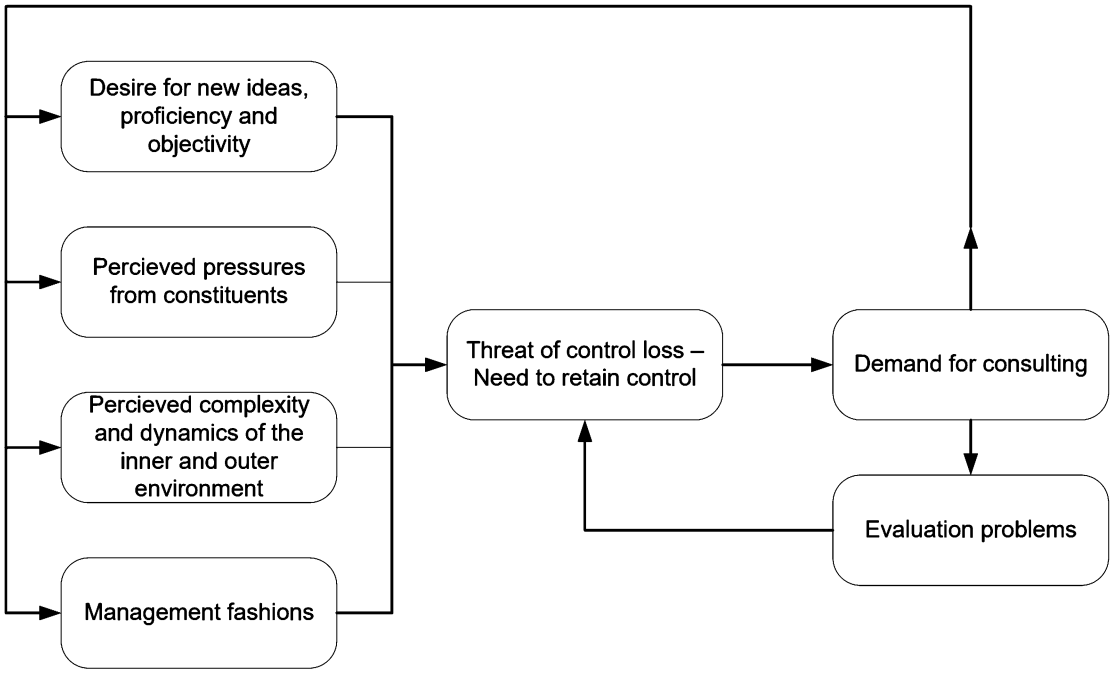

Figure 2: Factors leading to the growth in demand for consultants (Orr & Orr, 2013)

It should be noted that in recent decades the consulting industry was developing faster than the economies of many western countries (Kipping & Clark, 2012). Many large consulting companies decided to expand their offer, following some new problems that have emerged, but it is also interesting that many organizations which previously have not been engaged in consulting started to provide specialized services in a search of new business opportunities (Kubr, 2002). The previous illustration shows a set of factors that influence the demand for consulting services.

3. CURRENT TRENDS IN MANAGEMENT CONSULTING

Many authors point out that the consulting industry is now more focused on providing expertise in terms of organizational and strategic planning rather than making recommendations in order to increase efficiency at the lower level (Wright & Kipping, 2012). Through the analyses of the statistical data on consulting, it can be concluded that there are different views on its wideness, which sets the stage for discussion on the actual size of the consulting industry. Widely observed, the value of this market is over $330 billion (O'Mahoney & Markham, 2013). However, according to the reports of Kennedy Information LLC, leading information source on management consulting, the total value of this market is a little less than $250 billion (Consultancy.uk, 2016). In any case, estimations of this market value it higher than five-fold GDP of Republic of Serbia in the year of 2014th. These reports also confirm that there is a constant growth of this value during the second decade of the twenty-first century, while dominant consulting fields are related to operational improvement and financial consulting

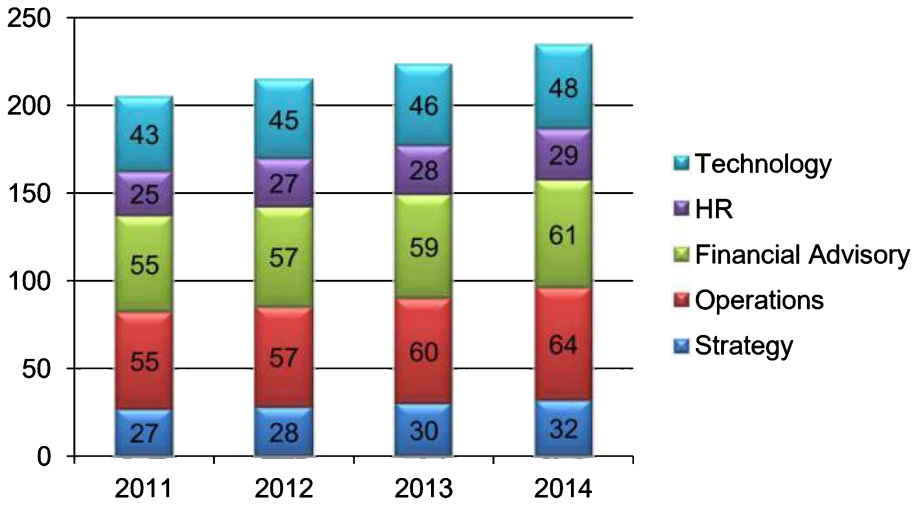

Figure 3: Size of the global consulting industry in $ billion (Consultancy.uk, 2016)

When it comes to the distribution of these values by regions, it can be concluded that this industry is especially developed in Europe, Middle East and Africa (EMEA) as well as in the countries that belong to the North America.

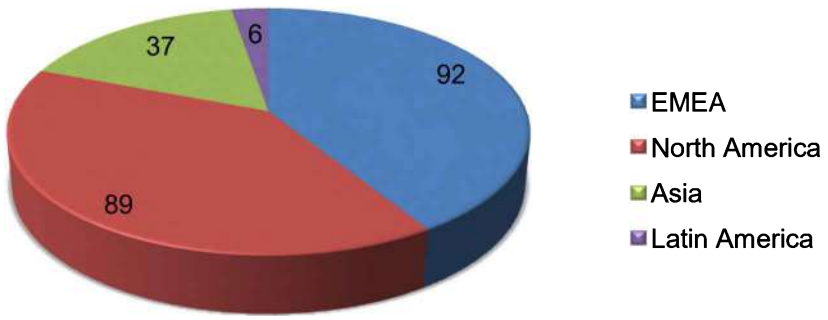

Figure 4: Global consulting market by regions in $ billion (Consultancy.uk, 2016)

The analysis of the European consulting market shows that the most of transactions in this region is conducted in Germany, Austria and Switzerland, but also that consulting services are quite popular in the United Kingdom and the Republic of Ireland. Countries in the Balkans, on the other hand, do not have a large share on this market. It should also be noted that in Europe, as well as at the global level, the highest percentage of the value of provided services is related to the operational, financial and IT consulting, while the strategic and HR consulting appear to be less represented. Concrete values vary among regions, which is not unexpected when it's known that there are differences in the level of economic development among them.

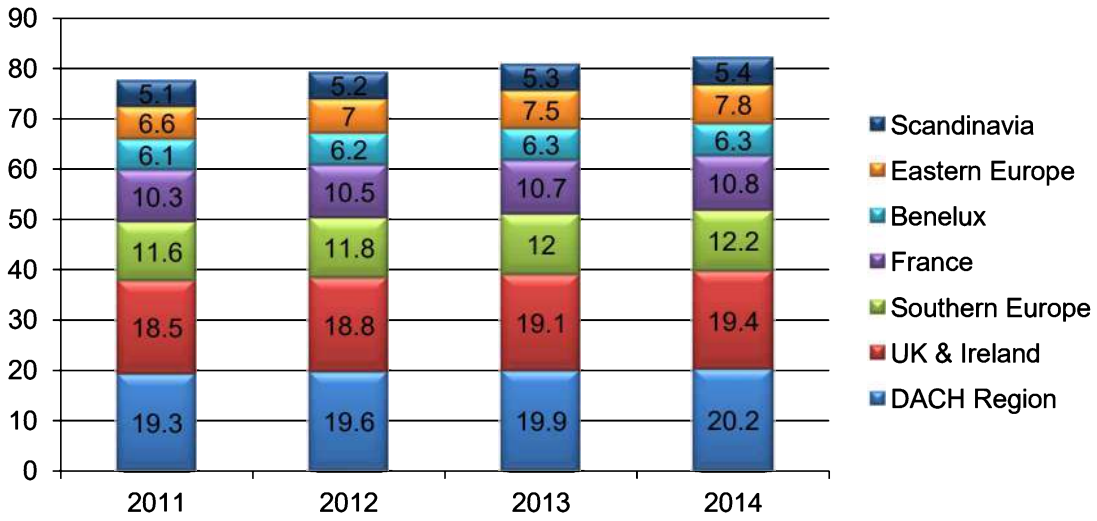

Figure 5: European consulting market in $ billion (Consultancy.uk, 2016)

Nowadays there is a large number of consulting firms that perform their businesses in several countries. The most famous consulting companies are so-called "*The Big Four*" consisting of "*KPMG*", "*PricewaterhouseCoopers*", "*Ernst & Young*" and "*Deloitte*" (WetFeet, 2008). It is interesting that these companies have started businesses by providing consulting services in the field of accounting and auditing, but during the years they have spread spectrum on the management consulting.

Observing modern trends it can be said that consulting organizations could be classified in several categories, such as (Kubr, 2002):

- Large multifunctional consulting firms,
- Strategy and general management consultancies,
- Information technology and e-business consultancies,
- Employee benefits consultancies,
- Medium-sized generalist and specialist firms,
- Sole practitioners and small partnerships,
- The consulting professors,
- Consulting services of management schools and productivity centres,
- Non-traditional suppliers of consulting services,
- Consulting networks.

Having that in mind, the client organizations have options of hiring (Armbrüster, 2006):

1. *External consultants* who can provide services (Werr & Linnarsson, 2002):
   1.1. Temporarily, in order to solve some specific problems for client;
   1.2. On the long term, to help directing the organization constantly towards its goals; and
2. *Internal consultants* who can:
   2.1. Coordinate the efforts of external consultants during the implementation of their projects;
   2.2. Be employed permanently in providing advices and assistance with the critical issues to the management of the organization.

It is interesting that the practice, especially in developed countries, shows a growing trend of engagement of internal consultants (O'Mahoney & Markham, 2013). Their responsibilities are different but mostly related to the issues with the organizational structure and its development, management processes within the organization, new technology and its application, development and training of employees, and so on.

Advantages of hiring internal consultants are numerous (Scott, 2003), as they are very familiar with the organization and therefore they can get better insight into the problems that occur. Also, when the organization has internal consultants, the fear that there will be a spread of confidential information is reduced, and it is very likely that it would be easier to implement changes appropriately, having in mind that employees know these people and trust them more than they trust experts who come from outside.

However, in addition to unquestionable benefits that internal consultants can bring, the fact is that, unlike external consultants, they generally do not have much experience in different situations, and their knowledge and competences are mainly limited to a certain number of problems, which can be a big disadvantage. In addition, the question of their objectivity arises, given the fact that they know other employees and they have established relationships with them, so sometimes it is more difficult for them to decide to make some unpopular moves, although they are aware that that should be the best solution. External consultants do not have this kind of dilemma, and their recommendations are objective and more realistic (Anderson, 2012), but also accompanied by higher resistance in the organization.

4. CONCLUSION

Although consulting practically exists as much as the society does, its role gains in special importance in last hundred years. This industry has been changing its face through the history in order to adapt to the current, mainly economic standings. The analysis of current trends in this field shows that this industry has rapid growth in the last couple of decades and that at this moment its value reaches about $330 billion. It is indicative that the consulting is in general mostly popular in the developed countries, especially in Europe and North America, but there is much space for the improvement in countries in the Balkans.

Regardless of the type of the consulting, it should be noted that nowadays the clients expect not only a recommendation, but more and more some concrete results and improvements. Consultants are no longer seen as advisers but as professionals who need to ensure achievement of the targets, so they have more autonomy and more resources in order to succeed in that. The width of their work is also changing, so the business consulting takes the position of management consulting, which can lead the organization to the complete transformation and change of portfolio activity.

Further research on consulting can develop in several directions. Different practices between “The Big Four”, aimed mostly at consultancy, and strategic, creative consulting practices such as exercised by other large consulting companies, e.g. Bain, McKinsey and BCG can be elaborated by formalizing description of the consulting process and goals. Also, network nature of all observed large organizations can be researched as a specific form of organizational structure, with specific attention to correlations between network parameters (centrality, degree, neighbors, average paths) and performance of the company. Performance of the consulting companies can also be benchmarked, and further research has one large challenge – common benchmark for consultant’s performance, in order to regulate and formalize this industry.

Related to performance measurement in consulting, a huge field of transaction costs, which yielded research of three Nobel-prize winners is also interesting direction. Large fraction of costs services which are hard to specify are transaction costs (Jaško, Jovanović, & Čudanov, 2015) and that fraction does not directly create any value. Two different threads of research can be joined, because regulation and diminishing of opportunism by common formal benchmark standards would diminish transaction costs by theory. It can be concluded that the consulting industry is still evolving, in line with the trends and developments in the global market. Organizations clearly recognize the importance of the assistance they can get from the experts, and in accordance with their ability they decide to use this help in order to improve their business and keep pace with the growing competition.

APPLYING A GENERAL MORPHOLOGICAL ANALYSIS IN LONG-TERM DEFENCE PLANNING PROCESS

Milan Kankaraš*[1], Dejan Stojković[1], Ranko Lojić[2]
[1]Ministry of defence of the Republic of Serbia, Defence Policy Sector, Strategic Planning Department
[2] Ministry of defence of the Republic of Serbia, Human Resources Sector, Military Academy
*Corresponding author, e-mail: kankaras.milan@outlook.com

Abstract: *Long-term defence planning process is of huge importance for defence system development. In the process there are many uncertainties and non-quantifiable issues. Defence planners should assess environment as well as describe possible solutions and scenarios for military force engagement. There is no unique approach to a scenario building as a main tool of long-term defence planning. One of the possible models to identify and describe conditions and solutions is applying a general morphological analysis. This paper presents possible ways of applying a general morphological analysis to solving the problems and solutions as an authors' vision for continuous long-term defence planning process improvement. This paper could be useful for the development of military science, as well as practical solutions for management in public sector organizations and other organizations.*

Keywords*: defence, planning, scenario, general morphological analysis, development*

1. INTRODUCTION

Contemporary organizations operate and achieve their activity in different political, economic, security, social, demographic, technological and other conditions. Dynamic changes in these conditions raise new and complex demands to organization management. Results achieved in a short period of time become obsolete and unusable. The management is faced with the problem of constantly increasing demands of stakeholders, as well as maintaining the quality of general interest activities.

For defence system, as a specific public sector organization, an activity of general interest is the protection of the defence interests. In this regard, the defence system develops capabilities necessary to fulfill that mission..Long-term defence planning process enables determination of necessary capabilities in accordance with political requests, conditions of complex environment and resources constraints.

Defence planners are faced with many different problems in the long-term defence planning process. These problems more often are multi-dimensional and they are not quantifiable. One of the possible modes to solving such problems is applying a general morphological analysis (hereinafter: GMA).

General morphological analysis enables consideration of problems link to parameters and structuring, as well as of multi-dimensional and non-quantifiable issues analysis. Also, GMA enables determination of relationship between their issue parameters and selection of issue parameters based on internal consistency. In long-term defence planning process GMA enables consideration of environment condition parameters and specific parameters of possible force engagement scenarios.

2. LONG-TERM DEFENCE PLANNING

In relation to the time planning period there are three main time horizons: long-term, middle-term and short-term planning (Stojković & Dahl, 2007). In management theory there is no accepted time span for long-term planning period, but usually one considers a time horizon of fife years or more.

Also, in management theory there is no accepted long-term defence planning definition. Long-term defence planning could be defined as „a process that investigates possible future operating environments and develops a force structure development plan to best adapt the defence organization to these environments given a host of constraints – including financial ones" (RTO/NATO, 2003). In other hand, (Stojković & Dahl, 2007) was defined long-term defence planning as „a process of defining long-term defence objectives and a strategy for their fulfillment".

Long-term defence planning relies on many different approaches usually used in complementary not singly way. In his discussion Faber (Faber, 2016) claims there are at least six types of approaches: top-down planning, resources-constrained planning, incremental planning, capability-based planning, scenario-based planning and threat-based planning.

Process of long-term defence planning shown on Figure 1 includes the following phases: political guidance analysis, environment assessment, mission analysis, scenarios development, capability requirements, capability assessment, options development and solution choice (Stojković & Dahl, 2007).

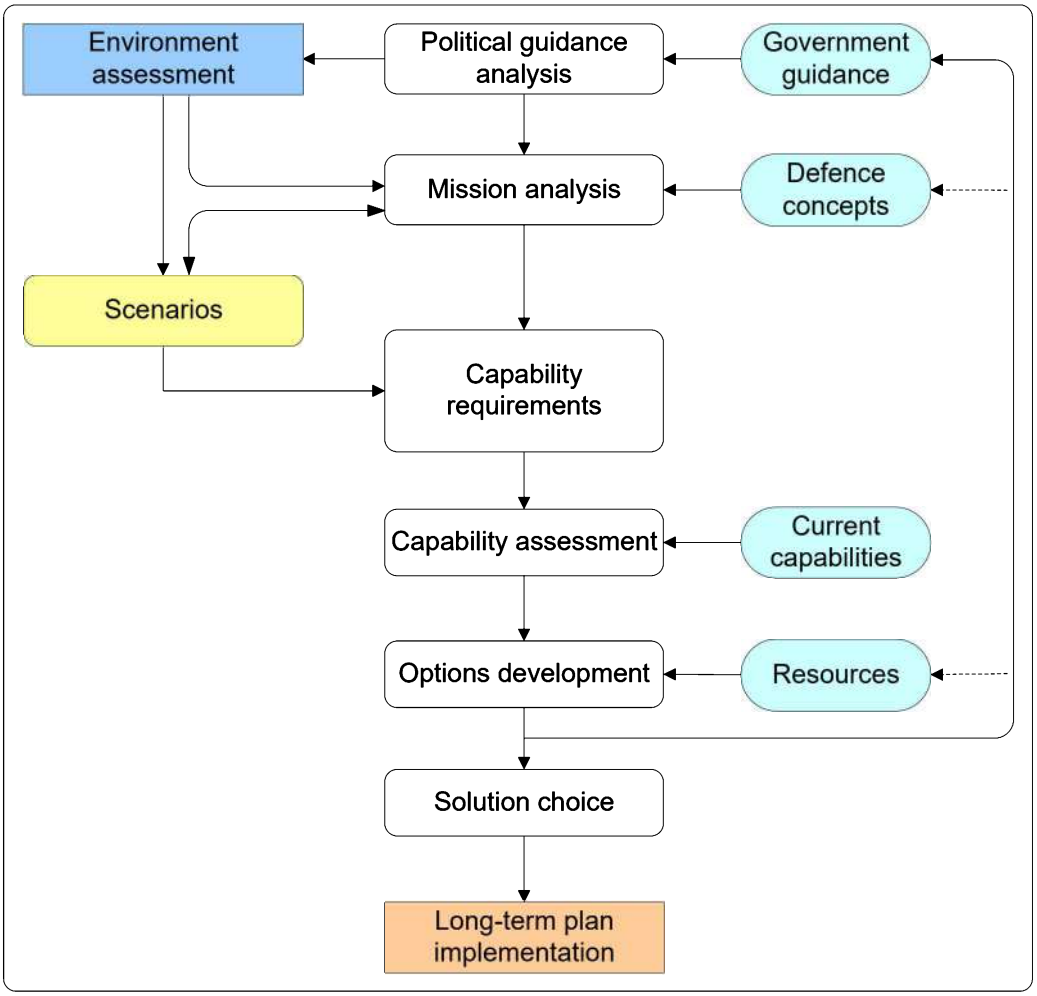

Figure 1: Process of long-term defence planning (Stojković & Dahl, 2007)

The process starts by asking question *what defence system should do.* Answer to this question is given by political guidance analysis. The second stage of this process is environment assessment. In this stage planners need to realize future security, political, economical, social and technological issues.

Mission analysis is the third phase of the long-term defence planning process, and its purpose is to identify what should be done in order to achieve determined political requests. In this stage defence planners identify main missions, their objectives, mission tasks and tasks decomposition. In accordance with the political requests, and based on defence concepts, result of this stage is a task structure.

Scenario development is the next stage in this process, and main end of this stage is a creation of future situation or conditions for military force engagement. Based on possible scenarios defence planners can determine future capabilities as a capability requirements. In accordance with the current capabilities and capability requirements, capability assessment is conducted. Result of capability assessment stage is the capability gaps.

Different modes can be used to solve capability gaps. Defence planners develop different approaches to solve capability gaps, assess feasibility of each approach and define some possible and realistic options. The last stage of long-term defence planning process is a solution choice. Purpose of this stage is to analyse the options and select optimal one. Result of this stage and long-term defence planning process as whole is long-term defence plan.

3. MORPHOLOGICAL ANALYSIS

In the process of long-term defence planning there are many political, social, economical and other factors affects the process, and it is necessary to solve many multi-dimensional problems. One of the available methods is general morphological analysis.

Ritchey (2011) points out that GMA „is a method for systematically structuring and analyzing the total set of relationships contained in multi-dimensional, non-quantifiable problem complexes". The method enables investigation of problem complex by developing a discrete parameter space, and determination of the relationship between the parameters on basis of internal consistency. Such an internally banded parameter space is called a morphological field.

The purpose of GMA is identifying and investigating the total set of possible relationship contained in a problem complex. These possible relationships are called configurations. Determining the configurations is accomplished through two phases of GMA: analysis and synthesis. Bearing in mind the foregoing it is possible to conclude that morphological analysis is a specific process of analysis-sinthesis.

General morphological analysis starts by identifying the most important parameters of the problem complex. In the next step is determination of values or conditions for every determined parameter. In that manner is constructed morphological field (Ritchey, General Morphological Analysis (GMA), 2011). Morphological field represents a set of parameters against each other in order to create an n-dimensional configuration space (Table 1).

Table 1: Morphological field

Parameter 1	Parameter 2	Parameter 3	Parameter 4	Parameter 5	Parameter 6
Value or condition 1-1	Value or condition 2-1	Value or condition 3-1	Value or condition 4-1	**Value or condition 5-1**	Value or condition 6-1
Value or condition 1-2	**Value or condition 2-2**	**Value or condition 3-2**	Value or condition 4-2	Value or condition 5-2	**Value or condition 6-2**
Value or condition 1-3	Value or condition 2-3	Value or condition 3-3	Value or condition 4-3	Value or condition 5-3	Value or condition 6-3
Value or condition 1-4	Value or condition 2-4		Value or condition 4-4	Value or condition 5-4	Value or condition 6-4
	Value or condition 2-5		**Value or condition 4-5**	Value or condition 5-5	

Every morphological field can contain many possible configurations, and it depends on number parameters and their values or conditions. Number of possible configuration is calculated as product of the number of values or conditions for every parameter. Morphological field in Table 1 contains 6000 possible configurations (4x5x3x5x5x4).

As it is shown, there are many possible configurations. However, there are some inconsistent configurations. Inconsistent configurations are determined in the GMA's next step – cross-consistency assessment (Ritchey, Modeling Alternative Futures with General Morphological Analysis, 2011).In this step all of the parameter values or conditions are compared whit one another. The comparison is realized in a cross-impact matrix (Table 2).

Table 2: Cross-impact matrix (Ritchey, General Morphological Analysis (GMA), 2011)

Parameter	Value or conditions	Parameter 1				Parameter 2				Parameter 3			
		1-1	1-2	1-3	1-4	2-1	2-2	2-3	2-4	2-5	3-1	3-1	3-3
Parameter 1	1-1												
	1-2												
	1-3												
	1-4												

Parameter	Value or conditions	Parameter 1				Parameter 2				Parameter 3			
		1-1	1-2	1-3	1-4	2-1	2-2	2-3	2-4	2-5	3-1	3-1	3-3
Parameter 2	2-1												
	2-2												
	2-3												
	2-4												
	2-5												
Parameter 3	3-1												
	3-2												
	3-3												

In the cross-impact matrix every pair of parameter values or conditions is examined..The purpose of this step is to determine consistent relationship, i.e. the pair can coexist. This purpose is achieved by comparing every parameter value or condition parameter value or condition with another in the morphological field. The judgment is mainly based on morphologists' individual expertise, knowledge and experience. It is necessary to find logical contradictoriness, and take to account empirical and legislative limitation which could relay on some ethical or even political issues.

After pair-wise consistency assessment inconsistent configurations are discarded, and in the morphological field remain only consistent configurations. Using this technique a morphological field can be reduced by more than 90% depending on problem structure. One of the consistent configurations is shown in the Table 1 (the darkened cells).

General morphological analysis is used to solve different multi-dimensional and non-quantifiable problem complexes in contemporary organizations. Also, GMA can be used to solve problems in the process of long-term defence planning especially in scenario development stage.

3. APPLAYING MORPHOLOGICAL ANALYSIS

General morphological analysis can be used for analysis of all kind of complex issues and finding alternative options for the future (Ritchey, Modeling Alternative Futures with General Morphological Analysis, 2011) like:

- developing scenarios and scenario modelling laboratories;
- developing strategy alternatives;
- analyzing risk;
- relating means and ends in complex policy spaces;
- developing models for positional or stakeholder analysis;
- evaluating organizational structures for different tasks;
- presenting highly complex relationships in the form of comprehensible, visual models.

In the process of long-term defence planning there are many uncertainty, multi-dimensional and non-quantifiable problems. They have an effect on all stages in the process, especially on outcome of the process – the long-term plan. As we mentioned before, GMA is one of the solutions for such a problems, especially in two phases of long-term defence planning: environment assessment and scenario development.

During the environment assessment stage defence planners identify future conditions in security, political, economic, social, technological, and other areas of interest. Also, it is necessary to define some possible values or indicators for every area. That requires knowledge and experience, as well as engagement of experts for certain areas.

In this phase GMA can be applied in different ways. One of possible ways enables an equalizing areas and parameters. In this case environment assessment makes a morphological field, and each area becomes a parameter for itself. An example of environment assessment as morphological field is shown in Table 3.

Table 3: Possible environment assessment morphological field

Security area	Political area	Social area	Environment area	Technological area
S-1	P-1	So-1	E-1	T-1
S-2	P-2	So-2	E-2	T-2
S-3	P-3	So-3	E-3	T-3
S-4	P-4	So-4	E-4	T-4
S-5			E-5	T-5

Because of complexity of environment it is necessary to conduct thorough assessment. Other mode of applying GMA enables an equalizing parameters values or conditions and parameters. The area of assessment makes a morphological field. Each value or condition becomes one parameter, and defence planners define value or conditions for every parameter. In this case it would be made five different morphological fields (Table 4).

Table 4: Possible security area morphological field

S-1	S-2	S-3	S-4	S-5
S-1-1	S-2-1	S-3-1	S-4-1	S-5-1
S-1-2	S-2-2	S-3-2	S-4-2	S-5-2
S-1-3	S-2-3	S-3-3	S-4-3	S-5-3
S-1-4	S-2-4	S-3-4	S-4-4	S-5-4
	S-2-5			S-5-5

Possible configurations total set reduction enabled selection of possible environment assessment configurations and description of each area conditions.

More often GMA is used in scenario development phase. This phase enables future consideration of state. Scenario can be defined as a future situations or conditions..It is not prediction or prognostic set of issues rather what could possibly happen. Also, scenario is hypothetical set of situations for military force engagement (Kovač & Stojković, 2009).

Scenario development stage begins with identification of scenario parameters. That parameters should be the best description in details of a possible situations. Later on, every parameter must be fragmented in a number of values or conditions. Joining parameters and values we establish a certain number of configurations. Defence planners should reduce the total set of possible configurations to set of internal consistent configurations in the next step. And last but not least, planners should select possible situations and create some possible scenarios.

Practically, a creation of possible scenarios is similar to GMA procedure. Each scenario represents a possible situation for military forces engagement, and a certain morphological field. Morphological field contains scenario parameters and their values or conditions, and after reduction of total set of possible configurations defence planners can select possible scenarios. An example of scenario as morphological field is shown in
Table 5.

Table 5: Possible scenario morphological field

Scenario parameter 1	Scenario parameter 2	Scenario parameter 3	Scenario parameter 4
1-1	2-1	3-1	4-1
1-2	2-2	3-2	4-2
1-3	2-3	3-3	4-3
1-4		3-4	4-4
1-5		3-5	

As it is shown, GMA can be applied in different ways depending on needs and projected outcomes. General morphological analysis enables solving multi-dimensional and non-quantifiable problems and generates phases of long-term defence planning process. Ministry of Defence of the Republic of Serbia has created software for conduction GMA. Applying the software enables significantly shorter time for GMA conduction and completely reliable products of process.

4. CONCLUSION

Long-term defence planning is very important for defence development and enables determination of future capabilities and risks. In the process defence planners are faced with many uncertainty and non-quantifiable issues. One of the possible modes to solving such problems is applying general morphological analysis.

General morphological analysis enables consideration of problem parameters, structuring and analyzing multi-dimensional and non-quantifiable issues. In long-term defence planning process GMA enables consideration of environment condition parameters and specific parameters of possible force engagement scenarios.

Based on the previous general morphological analysis can be useful for long-term defence planning process and enables achieving different effects:

- consideration of different problems;
- structuring and analyzing multi-dimensional and non-quantifiable problems;
- determination of relationship between problem parameters (possible configurations);
- selection of problem parameters ob basis internal consistency;
- selection of consistent configurations and
- solving problem.

The presented mode of applying GMA may be applied in defence sector, as well as in public sector organizations and other organizations. Application of GMA in other organizations does not require an adjustment, just determination of issues, their parameters and parameter values or conditions. In further, researchers should address the improvement of this method, and its wider application.

Abstract: *As the defense and security are some of the most important functions of the political system, jobs in defense planning should be approached cautiously and responsibly. The rapid development processes important segments of human society are calling for the important political action based on the results of strategic planning. This means the necessity of a well-planned in advance of decisions based on the results of modern science. Given that scientific forecast is one of the possible important scientific objectives and the highest level of scientific knowledge, prognostic research deserve an important place and role in creating a defense system based on strategic planning. In the present study, the prognostic role of research in the complex process of strategic defense planning.*

Keywords*: scientific prognosis, prognostic research, defence system development, strategic planning*

1. INTRODUCTION

Strategic defence planning requires the need for the necessary application of prognostic research. Prognostic studies are carried out in various stages of the process with the goal of more efficient planning for defence purposes. They are primarily aimed at anticipating of possible threatening conditions and methods, and ways of circumvention, prevention and reduction of the effects of the attack, which represents a social action to overthrow the state.

Possible sources, forms and processes of compromising modern states are very numerous and varied. Just an estimation is not only enough for their determination, due to the fact that any evaluation represents the most intuitive form of measurement. Therefore, the development of the defence system should not be based on the intuition of individuals and groups of people who are currently in positions of making major political decisions, but exclusively on the strategic defence planning based on prognostic studies.

As such, a reasearch may be exploratory or formulative, descriptive, diagnostic or hypothesis testing, etc. In Saho (2003) opinion „research can be oriented to explore new things or new solutions and new insights in a particular phenomenon. This type of research can lead to the formulation of new things.“ Scientific prognostic represents one of the possible important scientific objectives and the highest level of scientific knowledge. A research think she prognostic studies that aim to predict future events based on known parameters. (P.3). Well known forecasters in the field of social sciences are Huntington Fukuyama and Brzezinski. Prognostic research are different from other types of research, in two important characteristics. The first one concerns on their case studies that can represent not only likely but also possible, and preferred future events. Another characteristic is reflected in the need to present a complete holistically view of the current reality and its impact on future events.

In our deliberations, we will not deal with the problems of research projecting. Our presentation will refer to the importance of these research in the complex process of strategic defence planning and emphasizing the necessity of application of their results in the development of defence plans.

2. THE CONCEPT AND IMPORTANCE OF STRATEGIC DEFENSE PLANNING

In order to adequately explain the concept and importance of strategic defence planning, it is necessary at the beginning, to dedicate a little attention to the importance of planning in general. Shortly, planning is the process of making decisions about the organization's goals and strategies for their implementation. It is connected with all the other functions of managing the organization, and performance of all other functions is conditioned by the planning. Danilovic N, Gordic M. and S. Blagojevic (2015) considered that "the strategic defence concept is determined with basic human and material resources in society and developed to a comprehensive and complex system of defence" (p 145).

Defence is an organized counter action in terms of thwarting, preventing and reducing effects of the attack which is the social action to overthrow the state. The final result of planning should be a defence system that is tailored to the needs and capabilities of the state, and which is able to contribute to the protection of vital national interests.

Based on the mentioned, we can conclude that the defence planning represents continuous control activity and specific planning discipline, which is implemented by the state administration and the armed forces in the area of defence. As part of this activity, targets are determined, subjects - holders of certain activities are established, as well as ways how to achieve these goals. Therefore, defence planning includes the development of a number of concepts, strategies, plans and subplans which are necessary for the implementation of the process of harmonization of policies and the system of defence, and for the coordination and integration of activities and actions that are in the responsibility of the defence system.

According to Davis (1993), defence planning in a broader sense include: strategic planning, operational planning and planning of deployment. (P.3.). Such clasification is conditional, and it is made according to the nature of the problem which is solved through the process of planning and the decisions made meanwhile.

Strategic planning is a part of defence planning in which the competent national authorities through the highest level documents, determine the strategic objectives in the field of defence and establish ways of their realization. Strategic planning aims to ensure compliance of state of the defence system with its environment, and to allow the defence system to rationally and timely react to the changes in the environment. The outcomes of strategic planning are: national security strategy, defense strategy, military strategy, Strategic Defence Review, the long-term plan for the development of the defence system and the like.

Operational planning is a part of defence planning where strategic orientations are translated into concrete activities to achieve certain results, and strategic goals are implemented and the tasks of the defence system are carried out. Within operational planning, strategic goals of the defence system are associated with the resources necessary for their realization. The outcomes of operational planning are: medium-term plans and programs of development of the defence system, the instructions for making medium-term plans and programs, ministerial guidance, financial and other plans, etc.

As with business planning, strategic and operational planning of defence are closely linked and interdependent. The operational planning comes from the strategic planning of defence, in the sense that the strategic destinations of the defense system are concretized and operationalized through it. On the other hand, strategic defence planning precedes, or knowingly includes operational planning activities that will demonstrate the validity of the strategic ideas.

Planning the use of force is a specific part of defence planning which determines the mode of operation of the armed forces and other defence forces, in order to achieve the stated objectives in war and emergency. Within planning the use of forces, the obligations and duties of all subjects of defence in terms of organization and preparation of forces, resources and procedures in war and emergency, or crisis, are defined. The outcomes of the planning process of deployment are: plan of use of the armed forces, mobilization plan, a plan of engagement of the state organs and the like.

3. LONG-TERM DEFENSE PLANNING

In our work we accept thinking of Tagar (2015), who is considering a long-term defense planning a time horizon of 10-30 years (p.9). Do the fact that long-term plans in many countries, both NATO members and partners, as well as in other countries is considered a time period longer than 10 years, has led us to this commitment.

Long-term planning of development of the defence system is one of the important factors of strategic defence planning, which has a significant impact on the future efficiency and effectiveness of the defence system. It aims to ensure that the defence system possesses the necessary power and resources, or the ability to execute future missions and tasks. It is oriented toward the relatively distant future. Therefore, in the process of long-term planning, we are facing with the numerous difficulties which are the result of uncertainty and ambiguity in the future. In the opinion of Kovac and Stojkovic (2009) "The uncertainty and ambiguity pose a major challenge for planners in the defence system, as well as for policy makers." (P.425).

Long-term planning of development of the defence system is an interdisciplinary process that includes a number of interdependent but different actions and activities. In their implementation, a lot of adjustments and reconciliation between political and military elite, planners, military commanders and other subjects of the defence system are required.

In the NATO publication "Handbook for long-term defense planning" (2003), long-term planning of development is defined as "a process that considers the future operating environment, and create a plan for the development of force structure for optimal adjustment of the organization of the defence system to that environment, considering the constraints, including financial ". (P.3.). Thus defined, the term indicates that the purpose of long-term development planning is a model of the defence system, that will be developed based on identified needs and available resources, on the basis of precision tailored plans of development.

Long-term planning of development of the defence system is a complex process that first predicts the possible future environment and then create a plan of development so that the defence system could in the best way adapt to that environment, regardless of the existing and possible limitations (normative constraints, resource constraints, financial and other constraints) . Based on the above facts, the long-term development planning of the defence system can be briefly defined as the process of determining the long-term development goals of the defence system and strategies to achieve them.

Stojkovic and Dahl (2007) considered that "Long term defense planning is never just a technical procedure. It is also a highly political process that needs to be discussed in political terms (i.e., good and continual dialogue must exist between long-term planners and policy makers). At the same time, if care is not taken to Ensure objectivity and LTDP, it risks being dismissed as a politically biased process. (P.31.)". It is important to emphasize the importance of the dialogue approach to research because it is a matter of effective communication of all relevant stakeholders who are interested in the process of defense planning. It includes external stakeholders, ie the entire public that is sensitive regarding questions of security and defense. In the opinion of Flyvbjerg (2012) "Highly specialized media such as scientific journals and monographs are suitable for addressing academic audiences. But they are utterly inadequate when we need to reach out to groups that are relevant in the practical world of politics, administration and planning. Public dialogue that includes communication through daily media is necessary (p.214)".

4. THE PLACE AND ROLE OF PROGNOSTIC RESEARCH IN CERTAIN PHASES OF THE PROCESS OF LONG-TERM PLANNING OF THE DEFENCE SYSTEM

The process of long-term planning of development of the defence system essentially consists of the following essential phases, namely:

1. Harmonization and coordination of political and defence objectives,
2. Adoption and consideration of policy guidelines,
3. Analysis of the security environment,
4. Analysis of the missions,
5. Anticipating changes in the security environment,
6. Development of possible scenarios,
7. Determination of the necessary abilities,
8. Determining the difference between the required and actual abilities,
9. Developing options and
10. The choice of solutions.

In each of these mentioned phases, subjects of alignment of the politics and the defence system fulfil their important role. In our case, political and military leaders can be considered as subjects. With due respect to the above facts, we can conclude that the long-term planning of the defence system according to this model, represents a dynamic social and political process in which the degree of compliance depends not only on the general social and political circumstances, but also on the capacity and personal prestige and influence of the military and political leaders. Attitudes based on experience, professional knowledge, but also on valuable scientific prognosis can raise the credibility of military elites, which are not in an equal position in this process.

In any political process, and therefore in the long-term defense planning, political behavior occupies an important role. In this regard, Blakvel (2003) argues that "political behavior can and must be scientifically studied, especially by quantitative method", in order to plan future actions based on empirical data (p.44.).That is why, a great attention is given to researching global strategic trends for a longer period, by modern armies of the world. A typical example is the research conducted by the British Ministry of Defence. The results of a recent survey which aimed to provide a strategic context to identify long-term threats and opportunities by 2045, was published the fifth edition of the publication Global strategic trend GST (2014). It was pointed out that the aim of their research was not to predict the future. Instead, it describes those phenomena that can have a significant impact on the future and combines different perspectives to create multiple image possible outcomes. "Global Strategic Trends (GST) describe a broader strategic context aimed at those in the Ministry of Defence (MoD), the Government and beyond, who are involved in the development of long-term plans, policies and capabilities. Without this strategic context, there is a risk that planners, policy makers and creators of the development capabilities assume the future based on already preconceived thoughts and assumptions. "(P.3.). Of course, an important role in this process is communication with the public and the timely and adequate information, and information operations doctrine in which Great Britain has a hundred years of experience. Principles and concrete examples of British news operations described in his work Richard L. (2015) with special end view on the current experiment Rainbow in the dark (41-66).

In the view of Termiz (2014) "security activities are specific activities, so their research also necessarily occur as research into specific conditions, and the methodology of their research as a special methodology applied" (p.96.). Results of the prognostic research should be considered in each of the preceding phase of long-term planning, but their significance is particularly highlighted in certain phases. In our further work, we will make special reference to only those phases where scientific prognosis has highlighted character.

5. PREDICTION OF CHANGES IN THE SECURITY ENVIRONMENT

Consideration of policy approaches to their own and other countries, the analysis of the current security environment, as well as historical trends and events must precede the quality prediction of possible changes in the security environment. Basic entering at this phase are the analysis of national interests and objectives, strategy of national security, the defence strategy of potential opponents and allies, their future role, the role of international organizations and alliances and more.

The first step involves a detailed study of the basic documents relating to national security, defence and foreign affairs to determine the political intentions of other countries, as well as the political implications on the defence system. Thus, the results of this phase are forecasts of the political ambitions of neighboring countries and the important countries on the world political scene, as well as their political priorities in the field of defence. We are often faced with the fact that in the available documents of many countries all the security and defense objectives and interests are not explicitly formulated, and the key role of prognostic research at this stage is that they are timely detected.

By this, we can identify national interests, which can be influenced by future events, developments and trends in the security environment.

In order to reach a good prognosis, it is necessary to carry out the four important steps:

- collect the necessary data,
- analysis, sorting and processing of data,
- identification of opportunities, risks and threats and
- prognosis of the required number of strategic situations.

In the first step, the data needed for further work on the prognosis of the future environment is collected. Of particular importance are the data relating to future security, political, economic and social issues, as well as the technological development and the environment. Data sources can be different, from the intelligence services to scientific institutions.

The second step requires a good understanding of scientific methodology, analytical knowledge and experience. To obtain reliable results. Subjects of the development of the defence system can use the services of methodologists and other scientists trained in the application of scientific methods in the fields of politics, economy, technology, defence, security, etc.

In the third step, the results of the analysis are used for the consideration of the future impact of environment on the national interests and objectives. At this stage, the aim is to identify future opportunities, but also risks and threats to national interests and objectives.

The final step in forecasting future security environment is the development of an adequate number of possible strategic situations which represent future developments of events in various fields.

6. THE ROLE OF PROGNOSTIC RESEARCH IN DEVELOPING OPTIONS AND SELECTING SOLUTIONS

The development of options and choice of solutions represent some of the last phases of a long-term development planning of the defence system in which prognostic researchs can achieve an extremely important role. At this phase, we determine the possible approaches for overcoming or reducing the difference between the required and existing abilities that have been identified in the previous phase of the planning process. Therefore, it is extremely important that in previous phases, scientific prognosis has produced good results. If the prognosis were incorrect, it is likely that they will develop a wrong option, e some of the bad solutions can be chosen, which can have unforeseeable consequences for the system of defence of the country.

Basic enters in this phase of the planning process are the differences in capabilities and available resources, while the basic result of the realization of this phase is a list of potential options based on resources. The results of prognostic research at this phase should answer the question of whether changes in capacity factors (doctrine, organization, training, leadership, human resources, etc.) and / or operating concepts can overcome the established difference in the ability of the existing defence system that needs to be achieved in order to provide defence system ability respond to future threats.

The development of more realistic options is an essential step in overcoming the differences between existing and required abilities. One of the most complex issues in the course of scientific prognosis is obtaining the realistic costs, particularly for options that include a long-term period of time or involving development of new abilities. Prognosis of costs should be precise and comprehensive in order to enable comparison of different options and a selection of the most suitable.

The result of the previous phase of long-term development of the defence system is a list of options for resolving differences between existing and required abilities. The purpose of the last phase of the process of long-term development planning is the selection of an appropriate solution. The first step in this phase involves consideration of options for every difference in abilities. If the options do not allow overcoming the differences, defence planners will describe the potential risk. Options that allow overcoming the differences will be tested in order to choose the one that is optimal. The test will be a combination of cost-benefit analysis and risk analysis. Finally, the selected option for overcoming the differences in capabilities and the risks will be included in long-term planning documents relating to the development of the defence system.

7. CONCLUSION

In practice, it happens very often that short-term views dominate, when considering issues related to defence, They are based on a superficial analysis of the challenges and threats to security, the costs of the defence system, and the superficial assessments of subjects currently in the role of decision makers. In such situations, the argument that if there is no risk, there is no need to invest in defense, dominates. However, experience shows that the strategic situation could change relatively quickly while much more time and resources are needed to build defense capabilities. In order to avoid this, it is essential that the development of the defence system is based on long-term planning and long-term planning should be based on quality planned and implemented prognostic research.

Given that the activities of the security system, and thus the defence system as its important subsystem, are preventing and disabling systematic and permanent threat to individuals and society, we agree with the opinion of Professor Termiz that defence activity essentially consists of two major components: research and taking measures of intervention.

We particularly emphasize the importance of scientific research because the facts speak in favour of that many long-term development plans were not realized, respectively they were not of much use for defence systems in a changing and uncertain environment, just because that during the planning process the

scientific method was not applied and the results of the planning were not based on the principles of the methodology of scientific research.

Long-term planning of development of the defence system, based on scientific prediction of future risks, increase the likelihood of achieving political and defense objectives. Also, long-term planning based on prognostic research improves understanding of the strengths and weaknesses of the defence system to operate in a changing environment. By using valid scientific prognosis, we create conditions for careful consideration of the abilities of the defence system and the allocation of resources, which is based on the priorities. Also, long-term planning establishes a connection with the long-term financial and political challenges.

Such an approach provides the State an opportunity of dealing with all security needs and problems in a coherent, comprehensive and reliable way. The development of the defense system based on prognostic research represents a pledge for the future in an ever changing world, because it is the long-term investment that we need to keep alive our freedom of action, to defend our values and to preserve our liberties

All these reasons indicate the need of each country to develop its long-term development planning model defense system that is tailored to its needs. Important subject of this model are certainly people in the vocation and science, who are specialized for solving technical and scientific problems. It is therefore important that in this complex process, in addition to participation of the political and military leaders, there is also participation of the experts in certain fields, and the group of experts. Also there is need for participation of the entire institutes that are dedicated to the realization of the defence studies but also other institutes that perform all other scientific studies that can and are used for defense and security. This prevents the political elite to make important political decisions alone and without access to the findings of science and vocation, which may be fatal, both for the security of states and regions, and for the security of all humanity. Only valid prognostic based on the application of the scientific method ensures the proper development of the system of defense and security and the achievement of its important social role.

ON METHODOLOGICAL APPROACHES TO DEFENCE SECTOR REFORM

Nebojsa Nikolic
Strategic Research Institute, Ministry of Defence
e-mail: nebojsa2008_g@yahoo.com

Abstract: *Public sector reform became a permanent challenge in many countries and subject of studies for many researchers. At the same time it attracts attention of business companies who have interest in doing business with the public sector. Specific part of the public sector is the defence branch -that is Ministry of Defence and Armed Forces. Reforming organizations that are large, specific, complex and hierarchically organized as the military, is a big challenge. Besides defence reform is clearly a unique process –specific for each country and each epoch, it could be very useful to know experiences of different countries. This paper presents few examples of defence reform efforts. From the research point of view, one of the most interesting findings are similarities in problems identified in different armed forces, as well as a general methodological approach applied in the reform process..*

Keywords*: defence, military, organization, reform, transformation, management*

1. INTRODUCTION

Reforms in public sector administration are an actual issue in many countries today. In spite of the opinion that the problem of public sector reforms exists mainly in transitional societies, it is present in developed and stable countries, as well. Due to the size, structure and associated functions to the public sector organization, reform plans and actions are characterized by complexity, uncertainty and continuance. Reforms in public sector produce and induce many direct and indirect consequences (financial, economic, social, political, psychological, technical, organizational, etc), and that is additional reason for comprehensive designing, balanced planning, sensitive corrections and agile remaining on the main course of the reform.

This paper deals with approaches to the reform process in the defence branch (ministry of defence and armed forces) as a part of the public sector. Lessons learned and experience gained from the reforms of the defence sector and military transformations process in foreign countries (like those presented by Catignani (2004), Leslie (2011), Peever (2014), and domestic as well) could be helpful for future reform's endeavors as well as for other public sector branches. In the military context, transparency and the exchange of knowledge and experiences at the international level have become usual activity and applied even by the biggest ones and considered as the most advanced military organizations. It is particularly the case regarding some specific reform questions that modern militaries face today, like issues on the following topics: reserve forces, Keene (2015), Sedivy (2013); wartime army structure and composition, Petrovic (2007); funding questions, Alock (2014); motivation for military service, Taylor et all (2015), Wiggins et all (2014), Nikolic (2015); suspension of conscription system Szvircsev (2014), and so on.

Due to characteristics of security sector and defence branch particularly, special care is added to the comprehensive defence reforms. The term "Defence reform" is related to all reform process and activities undertaken towards changing the two essential components: (1) structure, functions and processes inside the ministry of defence administration including all its underling organizations and units; and (2) all changes of the military units and commands in the armed forces, including changes of missions, doctrines. From the aspect of the Management Science, there are many possibilities and challenging opportunities for inventive application and use of different methods and tools from the organizational sciences. Problem structuring methods is useful for setting clear perception of actual situation as well as for creating reasonable vision of the desired end state. Strategic decision making contributes to producing sound and realistic strategic documents with clear and sustainable relations among fundamental ends (goals), available means (resources) and possible ways (methods). Application of multi-criteria decision making methods and other sub-disciplines of the Operational Research are almost regular in considering organizational challenges in the military branch and defence business. Problem of creating appropriate organizational design, Anand and Daft (2007), continues to occupy researchers and managers in the field of defence and military issues besides other branches in the ongoing epoch, Miles et all (2010).

2. APPROACHES TO DEFENCE REFORM

It could be identified more different methodological approaches to the defence reform process. Reforms itself could be caused by different sources: political decisions, changes in strategic environment, changes in orientation in external politics, alliances, social changes, canceling conscription, economical-financial pressure, technological change-modernization, downsizing, reduction, etc.). Organizational entity that could be tasked to prepare and conduct transformational change in defence organization (perpetrator) could be composed in various ways: interdepartmental working groups, transformation teams or commands, external agent-consultation companies, external top-managers, etc. Fields of change can be different: security perceptions and reevaluations; budgeting system reform; transformation of organizational structure; advancement for military capabilities; improvements of acquisitions processes, etc. Here, it will be presented three examples of methodological approach related to the very beginning of the reform that is, determining the entity those who will create the reform agenda:

- Reform entity is an interdepartmental working group composed from representatives of internal organizational units from the Ministry of Defence (MoD) and armed forces, but possibly open to external experts.
- Main reform entity is an internal organization of the Ministry of Defence or of the armed forces which already deals with a long term organizational development (known also as Transformation command, in some armed forces).
- Reform entity is some external organization or a team of external experts (external means not MoD and not armed forces members).

2.1. Interdepartmental Teams in Defence Reform

Methodological approach marked here as “Interdepartmental Teams in Defence Reform” means that some interdepartmental groups are formed and tasked to analyze situations and make proposals for changes. Members of the teams come from different departments of the ministry of defence (MoD) as well as form different military units including the highest commands.

In the Serbian case there has been created “Defence Reform Group Serbia-NATO” (DRG) in 2006, with a general mission to provide advice and assistance to the state’s authorities towards implementation of modern reforms in a defence sector. Use of “DRG” mechanism was additionally supported after December 2006 when Serbia has joined the Partnership for Peace programme (PfP). DRG was established with intention to contribute to the following goals: to support and accelerate then ongoing reform of the military forces; to advance and promote cooperation and communication among departments; to stimulate project-oriented approach in reform; to effectively use foreign experiences; and to prepare participation in the “Partnership for Peace” program. DRG’s teams were complex and layered, with international and political leaders at the top of the group structure. At the lower level there were numerous specialized interdepartmental working groups entitled as “Working Tables” (WT) which were dedicated to some narrow problems already identified.

The Defence Reform Group in 2006 was consisted of 16 different working teams formed on temporary bases with participants from different departments and organizations from MoD and military units and commands. Those teams were called “Working Tables” (ISAC Fund, 2006) and each of them had gotten titles and numerical codes, as it is presented in Table 1, column two. In order to have better insight in the general orientation of each of those 16 working teams, column one in Table 1 presents general subjects to whom some specific working team is dedicated.

Table 1: Working Tables in DRG Serbia-NATO 2006

Topic	Working Table
Defence policy	WT-6 -“Drafting a Presentation document for PFP”
	WT-7 -“Development of system for effective and efficient defence planning”
	WT-1 -“Development of procedures for defence cost and analysis”
Intelligence and security	WT-13 -“Democratic control and reform of intelligence and security system”
Human resources management	WT-2 -“Development of system for human resources management”
	WT-8 -“Making a project of military professionalization”
Military education and training	WT-3 -“Reform of military education system”
	WT-14 -“Reform of the military training system”
Capability	WT-12 -“Development of mid-term and long-term equipping plans”

development	WT-15 -"Development of command and communication systems"
	WT-16 -"Development of system for emergency management"
Civil-military issues and public relations	WT-4 -"Development of public relation strategy"
	WT-9 -"Development of civil-military cooperation"
Defence infrastructure	WT-5 -"Military bases conversion"
	WT-10 -"Development a model for housing issues"
	WT-11 -"Conversion of military material"

Main topics of all "Working Tables" were very different and covered very broad scope of issues and problems: from public relation strategy, across military training and education, towards human resources management and military infrastructure conversion. Output results and achievements of all groups had been different and specific according to the difference of the main subjects. Similarities among working groups were mainly of methodological nature: teams were composed in a similar way, with similar tasks and mandates, with almost the same main deadlines and with similar general structure of the report which had to be offered to higher authorities. This kind of approach to the reform process contributed without a doubt that decision making at the strategic level became more informed. Also, DRG contribute to the exchange of ideas, information, customs and other, among different departments with accompanying relaxation spirit, which is immanent to the horizontal level of hierarchies.

Besides DRG type of working teams, there are other kinds of working groups as well. Those are formed on a temporary base and dedicated to some specific issues, like: managing emergency situation, drafting proposals for new normative and strategic documents, issues connected to the international military and defence cooperation in some specific fields (European integration, professional military education, emergency management, gender issues, organizational development, terminology unification, standardization, language training, interoperability issues, etc). As military reforms and transformations are almost a constant in many countries, so the research efforts are always actual (Clarke, 2013) and similar modes of engagement are possible in the future. Due to the specificity of the defence and the military issues compared to other public services, there are a lot of opportunities for exchange of experience at an international level. Particularly in regard of transformational process flow, empowered organizational authorities that lead the change, chose among approaches towards organizational transformation, issues of resourcing, measuring of the change progress, etc.

2.2. Internal Transformation Team Approach

Internal transformation team approach is the case when leading members of the team come from an internal organizational entity that is dedicated to transformational and organizational developments of the MoD and armed forces. In favor of this approach is a logical expectation that professionals that already have worked for MoD and armed forces for a respective number of years and having respectable experience gained from different appointments will have enough knowledge about missions, visions, organizational structures, problems, limitations, possibilities and opportunities for MoD and armed forces. Also, it is expected that those "insiders" will have a wide perspective of possible options for organizational change.

On the other side, weakness of this approach (Internal transformation team) in general, could be: unbalanced approach to reform changes (preference towards one organizational unit against other ones); induced resistance to change efforts offered by other organizations; lack of authoritative power, questionable transparency; possibility to be impacted by superior command; lack of the sense of the role and place of the organization in a wider context of the state and society; etc. This approach has huge potential for both general cases: positive and negative. On one hand, referential knowledge about the system under study may offer excellent proposals for relevant changes. On the other hand, fear of consequences and unfair over-control from superiors might produce only false picture of the current state (which has to be, of course, almost ideal) and illusive proposals for "transformation".

This approach could be ilustrated by the recent efforts in Canadian defence structures towards undertaking reform of the military and defence system. In the Canadian case there were more transformation and reform cycles in the longer period. Here it will be presented, in short, only the last one known as the „Report on Transfromation 2011". Transformation team for Canadian Forces (CF) and the Department of National Defence (DND) was established in 2010 and was consisted of military and civilian professionals and was lead by highly ranked general Andrew Leslie (a respected and experienced soldier with impresive professional biography). The team worked hard and in the summer of 2011 they released a comprehensive, evidence based detailed analysis of the current state and main problems as well as detailed proposal for transformation of the CF and DND. Their proposal actally consisted of 43 detailed suggestions and measures that sholud be taken in order to conduct a real transformation. However, it seems that this report

on transformation was too radical for the taste of some stakeholders, and somehow, by the end of the year (2011) the leader of the transformation team has been retired.

Findings of the Transformation Report showed that defence budget has a growth of 51% over the period from 2006 to 2010. Having in mind that was a period of intensive military deployment abroad (Afganistan, Iraq, etc), defence budget enlragement is a logical consequence. However, growth rate was not the same for the whole defence structure institutions. For example, inside a total defence personnel growth of 18%, distribution of personnel growth for different categories was variabile (and surprising):

- Regular force grow was 11%, reserve force growth was 23%, while growth of civilians in defence organization was even 33%.
- Operational units growth was 10%, senior executive growth was 25%, while Headquartiers and Static jobs growth was even 40%.

Those numbers ilustrate a surprising direction of organizational growth for a defence organization that is put in a state of a high level of military engagement at a distant area and hostile environment. Main conclusion of the report was that „teets" (meaning units and resources for engagement at the operational level –at the area of engagement) have to be strenghten instead of strenghting the „tail" (backward organizations and supporting elements of the defence organization).

Sharp, but clear and effective approach that was profiled by the Report on Transformation 2011, made an influence on many stkeholders and wider community. Notwithstanding that the leader of the transformation team was retired, it is recognized that serious changes are needed. As a result, in 2013 it was issued a new document related to the transformation issues but under the new name: Defence Renewal Charter. It was a joint institutional product of the Department of National Defence (the same as MoD) and the Canadian Armed Forces, DoD&CAF (2013). In spite of some contraversials and discusions initiated after the issuing this transformational document, later events confirm that many findings of the Report on Transformation 2011 were valid and found its way towards implementation. According to De Kerckhove (2015), in the following years after famous Report (2011), 35% of the Reports' recommendations have been implemented while another 35% are still considered for future implementations and remaining 30% were rejected.

2.3. External Experts Team in Defence Reform

In some cases of the reforms of the national defence system external expertize was used. Under term "external expertize" it is considered engagement of some external (out of the ministries of defence and out of armed forces) resources that have credible and appropriate level and capacity to enable proposals for reforms of defence system. Entity that will provide external expertize may appear in different forms:

- Expert teams formed on temporary base and consisting of outstanding professionals in their fields (managers, businessmen, university professors, consultants, prominent public servants, statesmen, etc.). They may be domestic, international or mixed. Usually, teams are interdisciplinary.
- External expert support could be provided as well, as a contractual service. In this case, Ministry of defence does hire by contract a consultation agency in order to make a professional and an unbiased plan for performing defence reform.

Each of these approaches to obtaining external expertize for defence reform have pro and con aspects. Which way is better often depends on many factors. Above all, main problems that external team may be faced with are the following: a referential knowledge about system under study (Ministry of defence and the armed forces), its purpose, mandate, organizational structure, operational and functional procedures, as well as strengths and weakness, bottlenecks, etc. However, external experts' team has to be clearly informed about organizational strategical vision and what is a desired state in a prospective future, as well as what are available resources, limitations and time to achieve desired end state.

The main contemporary document for the defence sector reform in Australia was released by the Department of Defence (DoD) on April 2015. This document was commissioned in August 2014, when Minister of Defence has engaged a team of external experts (called the Review Team). Those experts were already well-known and proved in their fields of expertise and willing to make their contribution to the public service. Their task was to scan the situation in defence sector, to identify problems and make proposals for solutions in order to answer the main question: is the Defence ready to fit its mission defined by its strategy in an efficient way. The Review Team has done its task and offered a document entitled "The First Principle Review: Creating One Defence".

The members of the Review Team were all recognized experts and managers with very respective experience and achievements in different organizations and branches. Chairman of the team was David

Peever, former managing director of famous multinational mining company Rio Tinto and has a number of other high appointments in business, industry, academia and society. The team members were also respective experts: Peter Leahy is former Army general with 37-year military career, and Director of the University of Canberra's National Security Institute; Jim McDowell has been Deputy Chair of Australian Nuclear Science & Technology Organization, and Chief Executive in a defence industry company (famous BAE Systems); Robert Hill was a minister in a few mandates in different branches including DoD, and barrister and solicitor before entering politics; Lindsay Tanner is a professor at Victoria University, special adviser in a financial consultancy company, former minister of finance and member of parliament.

This team made extensive work including wide circle of consultation with relevant subjects (parliament, government agencies and departments, military, academia, society, foreign experts, industry and union, and a number of public hearing) for defence issues, and they precisely reported about those consultation in their final document. General findings of the team are expressed through a short list of dominant principles that should be followed by the DoD and ADF in the upcoming reform and future work (Peever, 2014):

- Clear authorities and accountabilities aligned with resources
- Outcome orientation (making results that are required and relevant to the Defence)
- Simplicity (eliminating complicated and unnecessary structures, processes, systems and tools)
- Focus on core business (doing only for itself what no one else can do more effectively and efficiently)
- Professionalism (committed people with right skills in appropriate jobs)
- Timely, constable advice (professional support to decision makers)
- Transparency (honest and open behavior enables insight in what the Defence is doing and why).

Besides above general principles and other findings, the team has offered a list of a seventy detailed and more concrete proposals for making the reform. Also, this transformation document offered a data about growth of senior leadership, similarly as in the Canadian case, but for a different time frame (it was compared following years: 1998 and 2014). The document states that the growth of a senior military leadership including generals was 75-80%, while all other (lower) ranks growth was only 3%. Level of growth of a senior civilians in defence sector was 86-108%, while all other lower positioned civilian growth was 18%. In spite of evident domination of the growth in senior positions, the document does not prefere quatification in advance for „Teeth-to-Tail" ratio, but suggests carefull analysis. It will be interesting to follow future reports about the level of realization of a given transformational proposal as well as about associated implementation problems and obstacles.

3. CONCLUSION

Defence sector reforms are a specific but an important part of the public sector reforms in general. Experiences from reforms of military organization as a highly organized and very complex entity may be useful in considering reform efforts in other branches of public sector. Also, reform experiences and lessons learned from different countries could be very useful in profiling our own reform process. According to up-to-date findings from defence reforms efforts in presented countries, it could be concluded that the sharp cuts and huge changes in a short time are not probable to be completely successful. But, success in defence reform could be expected in a longer period with detailed, comprehensive and resilient planning and engagement of an dedicated reform team with associated mandate for doing reform.

Future research will be related on analyzing reports about ongoing defence reforms in presented countries, as well as in some other states. Besides the issues on reform content and reform team composition, of particular research importance will be methodological questions and issues related to gathering, analyzing and using of data of different kind and types but related to defence and military organization.

STRATEGIC PERFORMANCE MANAGEMENT SYSTEM IN PUBLIC SECTOR: THE ROLE OF KNOWLEDGE MANAGEMENT

Zorica Mitrović*1, Dragan Bjelica[1] Danijela Toljaga Nikolić[1]
[1]Faculty of organizational sciences
*Corresponding author, e-mail: zorica.mitrovic@fon.bg.ac.rs

Abstract: *The aim of this paper is to argue the introduction of knowledge management as a building pillar for strategic performance management in Serbian public administration. First, the practice of developed countries already confirmed that strategic performance management system is a key for increasing efficiency and effectiveness of public sector organizations. This paper provides the theoretical background for considering the importance of establishing a strategic performance management system to enable public sector bodies to move forward with the reform process. Second, the knowledge management is confirmed to be a crucial element of organizations capability to achieve high organizational performances. The success of the concept in the private sector led to its introduction in public sector organizations. This paper provides a rationale for considering the knowledge management as an integral part of the strategic performance management system. Finally, the paper recommends the further research in this field and promotion of such idea among both scholars and practitioners.*

Key words: *knowledge management, performance management, strategic management, management system, public sector*

1. INTRODUCTION

Strategic performance management system is a key for increasing efficiency and effectiveness of public sector organizations (Mitrović, Todorović, & Bjelica, 2013). Even though there is no widely accepted definition, the most authors define it as an umbrella concept that provides integrated application of different methodologies including Strategic Management, Performance Management, Knowledge Management, Total Quality Management, Six Sigma, etc.

The first driver for the introduction of performance-based management was the wave of reforms in a public administration known as New Public Management (NPM). The performance-based management was introduced in the 1990s as an NPM initiative. It represented result-based management practice and one of the basic doctrines of NPM. As a concept, the NPM represented a wide range of reform programs and the step forward from narrow debates that were normal in the area of public policy administration and management most of the 20th century (Hood, 1991). It emerged in the 1980s in Great Britain during the mandate of Prime Minister Margaret Thatcher. Even though the idea already existed, Margaret Thatcher was the first to successfully made culture, size and cost of the British public service as a political issue. After that, the changes were made in the policy of public sector in the field of organization and methods, public services and employment, expenditure planning and financial management, audit and evaluation, and supply (Brazelay, 2001) (Mitrović, Todorović, & Bjelica, 2013). Further, the issue of public sector management was high on the agenda of the Conservative government too. Agenda included initiatives such as the *"Next Step Initiative", "Citizen Charter Initiative"*, *„Competing for Quality"*, *„Resource Accounting and Budgeting"* and *„Private Finance Initiative"* (Brazelay, 2001). Similar initiatives emerged in the United States. One of the most significance were *"National Performance Review"* and its transformation in the Law *"Government Performance and Results Act"* (Brazelay, 2001). During this period, the issue of public sector management has become a very popular area of policy in many other countries, such as New Zealand, Australia, Sweden, Canada, etc. As a result of these changes in developed countries all around the world, the Organization for Economic Cooperation and Development (OECD) established Public Management Committee and Secretariat (PUMA) to help its members to address the challenges. Following the path, the developing countries started with an application of the wide-ranging public administration reforms. The NPM provided standardized, Western approach to public administration reform with the principles such as citizen-centric governments, decentralization, the split between policy making and policy implementation, etc.

The second driver for the introduction of performance-based management as a part of the public administration reform process in developing countries were Structural adjustment reforms mainly initiated by International Financial Institutions. Structural adjustment programs were targeting cost reduction of the government. Finally, the third driver was the transition from central planning to market economy what initiated the change in orientation of the system of public administration.

All three drivers influenced the public administration reform in Serbia. The following chapter provides the background for public administration reform and the roots of establishing strategic performance system in Serbian public sector. Also, it provides the rationale for considering the knowledge management as a next step for improving the performance of Serbian public sector.

2. PUBLIC ADMINISTRATION REFORM AND THE STRATEGIC PERFORMANCE MANAGEMENT SYSTEM IN SERBIA

The reform process of Serbian public administration started in 2004. The main objectives that Government of Serbia (GOS) planned to achieve through the reform was the creation of democratic state and citizen-centric public administration. The reform process started with the adoption of two main documents The Public Administration Reform Strategy (PAR Strategy) and an Action Plan (AP) for implementation of the PAR Strategy. With these documents, GOS set a goal to build efficient, responsive, transparent and accountable public administration. On the other hand, PAR was developed as a very comprehensive framework, that included regulatory reform, public finance reform, but also targeted reforms in specific areas. With the aim to harmonize Serbian public administration with the principles of the European public administration space the five principles of decentralization, de-politicization, professionalization, rationalization and modernization were adopted.

Since 2004, a wide range of actions has been undertaken in different public sector institutions, including ministries, public agencies, special organizations, local self-governments and public companies. The aim of the whole range of actions was to provide efficient management and efficient state functioning at all management levels. For example, in the field of planning, budgeting, monitoring and reporting, the process started in 2005 when the Government of Serbia launched the project *Joint Project - Towards the More Effective Implementation of Reforms: Improving Planning, Budgeting, Monitoring, and Reporting.* The aim was to improve the efficiency and the effectiveness of the central public administration.

The implementation of extension projects followed from 2007-2012 under different names and financed by different donors, but with the same objectives. As a result, the policy-making and co-ordination system was improved. The legal framework was revised including a revised Rules of Procedure, Regulation on the General Secretariat of the Government, and Regulation on the Cabinet of the Prime Minister. Further, there were legally established committees of ministers to discuss items before their reaching the government session, all supported by the General Secretariat of the Government.

The new Rules of Procedure enabled the introduction of the government's collective responsibility, requiring that in all public communications members of the government should support its decisions regardless of their views or of how they voted in the government sessions (Obradović, Mihić, & Mitrović, 2011). Also, it provided with basic requirements for policy preparation in ministries, including appropriate procedures for inter-ministerial consultations, public debate, certification of harmonization with the *acquis*, assessment of alternative approaches, assessment of financial consequences, and a full regulatory impact assessment (RIA) (Obradović, Mihić, & Mitrović, 2011). A new Budget System Law introduced a more policy-driven budget process and the middle term planning methodology as a key element of policy and budget planning. From 2013-2015, major efforts were put in the implementation of budget programming at central government level, but also on local self-government level.

To summarize from 2005-2015 in the field of planning, budgeting, monitoring and reporting, reform process included building and developing capacities firstly for annual planning, upgrading to middle-term planning and program budgeting. This included building capacities for result based management by the introduction of elements of strategic performance management such as setting strategic direction within budget plans and the introduction of performance measures. Also, the reform process included building the accountability system and monitoring and reporting system. But to close the management loop the reform process need to build capacities to use performance information and knowledge to drive the improvement. This paper advocates that knowledge management is the missing piece of the strategic performance management in public sector organizations.

The rationale is that all high-performance organizations are in need for effective strategic performance management systems since it is the only way that enables them to remain high-performance organizations. The building pillars of such system are strategic planning, performance measurement, accountability system and knowledge management system (Mitrovic, Todorovic, & Bjelica, 2015). Further, the knowledge management system has a significant impact on improving the performance of the organization (Ahn & Chang, 2004; Al Mashari, Zairi, & AlAthari 2002; Choi Poon, & Davis, 2008; Fugate, Stank, & Mentzer, 2009; Syed-Ikhsan & Rowland, 2004). Since the Serbian public sector is under pressure to improve performance

the knowledge management system could be the solution to the problem. Establishing a knowledge management system requires the definition of the process of knowledge management, the necessary data, tools, and organization. This knowledge management system should integrate monitoring and reporting system to include data collection and the process of analyzing, reviewing and reporting, but also to use the information to create the knowledge and use it to improve performance. In the context of Serbia, the big challenge is to understand what the knowledge management is and experiences of developed countries to define the possible role in the strategic performance management system in Serbian public sector. The following chapters provide the theoretical considerations of the concept of knowledge management and the application of knowledge management in public sector mostly in developed countries.

3. THE CONCEPT OF KNOWLEDGE MANAGEMENT

The contemporary theory of management promotes Knowledge management (KM) as prominent and an important management topic in organizations all around the world. Companies that recognize the importance of knowledge management shape their business strategy and appoint chief knowledge officers for knowledge creation, diffusion, and utilization and establish knowledge management systems (Noh, Kim, & Jang, 2014).

In the context of the knowledge-based economy, the concept of knowledge management is a building block of the new integrated value chain where knowledge is both product and resource that enables organizations to achieve success in the struggle with complexity in a highly competitive environment. Further, the competitive advantage is not guaranteed with the process of generating knowledge, but rather with knowledge value as a factor that represents the potential of an organization to create additional value (Tisen, Andriesen, & Depre, 2006).

The importance of knowledge is recognized by the various scholars who perceive the need for managing the knowledge as an ultimatum of contemporary business (Riege & Lindsay, 2006). For example, the theory of resource-based view highlights the knowledge as the most important strategic resource, and a means to achieve competitive advantage (Pee & Kankanhalli, 2015). Peter Drucker states that knowledge is a basic resource in the post-capitalist society, where capital, natural resources and labor take a second place (Drucker, 1993). However, the knowledge as a resource gets its practical value only with the implementation of knowledge management system, which transforms knowledge into an added value and as a result enables improving organizational performance (Drucker, 1993) (Nonaka & Takeuchi, 1995).

The idea of knowledge as the value of the organization is articulated in the early 1980s when organizations started to use expert systems. However, the first discussions about the role of knowledge in shaping the organizations future as well as the term «knowledge worker» is defined back in the 1950s in Peter Drucker's work *"The Landmarks of Tomorrow"* (Drucker, 1954). The very own term «knowledge managment» originated in the 1980s, characterizing the way that value is created for customers with the unique offer of products and services (Porter, 1985). Besides authors like Drucker, Porter, Nonaka and Takeuchi-a, the outstanding contribution to the development of the doctrine of knowledge management had Peter Senge by developing the theory of "learning organization" (Senge, 1990).

However, the momentum of development of the knowledge management theory was in the early 1990s. Firstly in the corporate world, and the decade later the interest was gradually transferred to public sector organizations. The complexity of the environment of public sector organizations and the role they have indicated the need for the implementation of interdisciplinary business model based on knowledge, which will enable them to stand at the forefront of changes that shape society, not chasing for the changes that the corporate world imposes.

Knowledge management is a complex concept. There were various attempts of researchers to define the knowledge management and still there are many different definitions, and each of them is widely accepted. Fore example, Nicolas (2004) describes KM as a systematic process of creating, acquiring, disseminating, leveraging and using knowledge to achieve competitive advantage. Similarly, the knowledge could be defined in various ways. One of the widely accepted definitions is by Davenport and Prusak (2000): *"Knowledge is a combination of experiences, values, contextual information and expert insights that enable organizations to evaluate and absorb new experiences and information."* Further, there are two types of knowledge, explicit and tacit. Tacit knowledge is difficult to articulate or communicate, and typically resides in a human mind, it is deeply rooted in action, commitment, and involvement in a particular context (Nonaka, 1994). Explicit knowledge refers to knowledge that has been captured in some tangible forms, and the knowledge that is transmittable in formal, systematic language (Nonaka, 1994). The knowledge is created via conversion between tacit and explicit knowledge, through processes of combination, internalization, socialization, and externalization.

To utilize created knowledge, organizations need to build knowledge capabilities that will enable them to achieve superior performances and competitive advantage. The knowledge capabilities are based on the level of development of knowledge infrastructure that some authors refer as infrastructure capabilities (Wu and Hu, 2012) or knowledge enablers (Noh, Kim, and Jang, 2014). Regardless the term, this infrastructure refers to technology, structure, and culture (Gold, Malhotra, and Segars, 2001) and people. The other element of knowledge capabilities of organizations is knowledge process. The four primary organizational knowledge management processes: knowledge creation, knowledge storage and retrieval, knowledge distribution, and knowledge application (Alavi & Leidner, 2001).

Various researchers investigated the relationship between knowledge infrastructure, knowledge management process and performances of organizations (Adeoti, 2002) (Noh, Kim, and Jang, 2014) (Pee and Kankanhalli, 2015). The authors agreed that knowledge management capabilities are determinant of organizations performance (Murray, 2002) (Marques and Simon, 2006) (Choi, Poon, and Davis, 2008) (Akdere, 2009) (Ho, 2009) (Gholami, Asli, NazariShirkouhi, and Noruzy, 2013) (Todorovic, Petrovic, Mihic et. al, 2015). On the other hand, the organizations need a systematic approach to knowledge management to enable full use of created knowledge. The knowledge management system has to be integrated as a building pillar of the management system.

Successful application of knowledge management concept in private sector organizations led to increasing interest in public sector organizations. The interests came with pursuing greater efficiency and effectiveness in public sector institutions at all levels including the central level (ministries, public agencies, and special organizations), local self-government institutions and public companies.

4. KNOWLEDGE MANAGEMENT IN PUBLIC SECTOR

Knowledge management in public sector organizations is not a new idea. However, many factors have influenced to become an important topic of discussion and the topic of numerous discussions. Globalization, the impacts of the information society, demographic changes and a constant high level of unemployment have created unprecedented pressure to improve the competitiveness of the public sector organizations (Sotirakou & Zeppou, 2004). The pressure is even higher with the role that public sector organizations have in the creation of the necessary conditions and infrastructure for achieving competitiveness and efficiency of the private sector at national, regional and local level (Hartley & Skelcher, 2008). With the increasing importance of knowledge as a source of competitive advantage and the critical resource used to create value, public sector organizations are beginning to pay more attention to the implementation of strategies, policies, and programs for the knowledge management (King & Zeithaml, 2003).

The wave of reforms that started in the 1980s made significant changes in the way public sector organizations were functioning before. The pressure was even higher when the new stream of analysis what public administration do and how does it, started back in the 1990s. In the context of modernization running the government as an enterprise become imperative (Sotirakou & Zeppou, 2004). And public sector organizations adopted the new principles of management such as efficiency, effectiveness, economy, transparency, and accountability (Flynn, 2005). At the same time, the public administration institutions recognized the benefits of knowledge management practice in improving efficiency and effectiveness (Yao, Kam, & Chan, 2007) (Riege & Lindsay, 2006) (McAdams & Reid, 2001). For example, connecting the silos of information across different level of the state administration ensured the improvement of the efficiency and effectiveness of the process of public services provision (Riege & Lindsay, 2006). Similarly, improving accountability through the faster decision-making process and solving the problems enabled access to integrated, transparent information beyond organizational boundaries (Riege & Lindsay, 2006).

Further, the reform initiated the promotion of service design and the citizen-customer orientation (Flynn, 2005). That created the need for organizations to improve the quality of service (McAdams & Reid, 2001), what was done through constantly learning and innovating to satisfy the requirements of end-users, but also the other levels of government, various stakeholders and complex inter-organizational structures (Rashman, Withers, & Hartley, 2009). Furthermore, the NPM has promoted collaboration, arguing that it is needed in the service area as well as in the area of policy-making (Flynn, 2005). With public sector organizations increasingly use information technology for collaboration, there was an increasing need to develop the capacity of organizations to support these processes (Pee & Kankanhalli, 2015). One of the creations for the improvement of collaboration were so-called "public sector knowledge networks".

These networks emerged with the implementation of advanced networking technologies and the development of e-government, representing socio-technological systems in which the human, organizational and institutional factors exist in interdependent connection with processes, software and other information

technology (Dawes, Cresswell, & Prado, 2009). Depending on the function that should be carried out, the focus of the network is to provide a solution to the problem or to provide the support to the certain processes by creating system capacities to share knowledge and information within the organization. Examples of such networks are the national information system for the distribution of geodetic information and expertise, or the network that supports the distribution of data on public health, environmental data, etc.

The concept of knowledge management has been and still is instrumental in modernizing the public sector. Over the past two decades, it was present in the different parts of the public sector and influenced the changes that have taken place over this period. In these circumstances, the strategic knowledge management becomes the key to the success of the transformation process of public sector organizations (Sotirakou & Zeppou, 2004) (Edge, 2005). At the same time, the knowledge management was defined as an eclectic body of knowledge that includes knowledge management in a systematic manner, including all kinds of knowledge within all levels and types of organizations (McAdams & Reid, 2001).

Not only that the knowledge is necessary for transformation, but it is also central to policy making and public service delivery (Blackman, Kennedy, Burford, & Ferguson, 2013) (Kim & Lee, 2006). Both politicians and civil servants use knowledge to shape the environment in an attempt to create additional value (Bridgman & Davis, 2004). In the case of public sector organizations, additional value is not profit, but the public value that is in many cases perceived as the way the citizens' needs are satisfied (Moore, 1995). Regarding, the public administration has an important role in public policy that will affect the successful creation of value for the whole community (Riege & Lindsay, 2006). This responsibility for the delivery of public policies that bring public good increases the importance and role of effective knowledge management in the public administration (Wiig, 2002).

On the other hand, it seems that good public policy occurs when the knowledge owned by the society is effectively transform into public administration knowledge and when the different policy options are in return tested by appropriate transfer of knowledge between the government and the stakeholders, through the publication of policy monitoring and review (Bridgman & Davis, 2004). Knowledge management in the public sector includes the different roles of stakeholders in policy development, through the process of creating knowledge, design skills, knowledge dissemination and application of knowledge (Riege & Lindsay, 2006).

Knowledge management enables organizations to deliver the right information to the right person at the right time, helping organizations to make right decisions. In this process creation and transfer of knowledge becomes a critical factor in competitiveness and organizational success (Chawla & Joshi, 2010). The way the knowledge is managed determines the decisions that will be made and actions to be taken. Therefore, it is clear that improving the quality of the knowledge management process, determines the quality of the decision-making process and resulting activities of the organization (Chawla & Joshi, 2010).

Wiig (2002) proposes following areas of knowledge management application: improving the decision-making process within the public sector organizations, the help to the public to effectively participate in decision-making in the public sector, the construction of a competitive society intellectual capital and competitive development of the workforce, whose competitiveness is based on knowledge.

Further, Pee & Kankanhalli (2015) identifies two trends: the human capital crisis due to downsizing, resignation, or retirement calls for more effective capturing of knowledge to minimize knowledge loss; and increasingly use of information technology in public sector organizations to collaborate with one another. For instance, McAdams & Reid (2001) noticed that knowledge management is especially important in the public sector if we take into account that civil servants have long been identified as key knowledge depository. And the organization itself as a knowledge-based organization (Khan, 2009). The problem is caused by the perception of knowledge as the private property of employees in the public sector (Kim & Lee, 2004). Therefore, one of the critical issues and big challenges, since 2000 was how to retain critical skills in organizations and how to make the transfer of knowledge - especially tacit knowledge – to the younger generation to ensure institutional memory (Aija, 2001).

This increasing interest in the use of knowledge management in the public sector was related improved efficiency, cost reduction and improved quality (McAdams and Reid, 2000). On the other hand, (Wiig, 2002) studied the role of knowledge management in building society's intellectual capital to improve the effectiveness of public decision-making and situation handling. More recently, (Pee and Kankanhalli, 2015) literature review showed that knowledge management found to be instrumental in policy development, law enforcement, crisis and disaster management, health and human services, and electronic government. There are, however, some challenges associated with successful implementation of knowledge management practice in the public sector. Lastly, public administration tasks and services are being perceived as knowledge-intensive in nature and excelling in KM can potentially enhance public organizations'

effectiveness. Further, examples of knowledge management practices include the application in different sectors such as education (Edge, 2005), police (Seba and Rowley, 2010), health sector (Van Beveren, 2003), etc. Efforts also included the research on specific aspects of knowledge management framework such as collaboration and networking (Dawes, Cresswell, and Prado, 2009), organizational learning and knowledge sharing (Rashman, Withers, and Hartley, 2009) (Yao, Kam, and Chan, 2007) (Amayah, 2013), and relation between KM and organizational performance (Pee and Kankanhalli, 2015).

The importance of the topic gains the attention of the OECD, which in 2002 launched an international survey regarding the practice of knowledge management in the ministries, agencies, central governments of OECD countries. The key findings of the survey were following:

- KM ranks high on the management agenda of a good majority of central government organizations across OECD member countries.
- Central government organizations are making concrete efforts to improve their KM practices increasingly using.
- Cultural change is taking place.
- Increased openness, transparency policies, as well as investments in ICTs, have resulted in a perceived increased efficiency, transparency and outward focus.
- The improved competitiveness of the public employer, a more horizontal and less silo type of hierarchical structure, a better make up for the loss of knowledge and the promotion of life-long learning.
- The improvement of KM practices requires time and long-term efforts to change behavior, and to impact on the culture of the organization. Good KM practices are best enhanced by long-term behavior reflecting trust among civil servants, team spirit, and selflessness and best supported by a relatively stable organizational and cultural environment.
- Finally, improved KM practices come with an added cost regarding information overload and wasted time in consultation for a majority of organizations and a dilution of responsibilities for a large minority of organizations.

European Union also initiated the actions regarding knowledge management practice in public sector organizations, recognizing that organizational innovation and the creation of knowledge-empowered e-government will lead to better and more efficient services and empower civil servants in his / her task, supporting the complexity of decision-making and collaboration (Butler, Feller, Pope, Emerson, & Murphy, 2008).

This literature review showed the various roles that knowledge management has in improving the performances of public administration at all levels.

6. CONCLUSION

The paper argued that knowledge management should be integrated as a building pillar for strategic performance management in Serbian public administration. The argumentation is based on experiences of developed countries that strongly suggested that strategic performance management system is a key for increasing efficiency and effectiveness of public sector organizations. This paper provides the theoretical background for considering the importance of establishing a strategic performance management system to enable public sector bodies in Serbia to move forward with the reform process. The rationale is based on three drivers. The first driver for the introduction of performance-based management was the wave of reforms in a public administration known as New Public Management (NPM). The second driver for the introduction of performance-based management as a part of the public administration reform process in developing countries were Structural adjustment reforms mainly initiated by International Financial Institutions. Finally, the third driver was the transition from central planning to market economy what initiated the change in orientation of the system of public administration. As a result from 2005-2015 in the field of planning, budgeting, monitoring and reporting, reform process included building and developing capacities firstly for annual planning, upgrading to middle-term planning and program budgeting. This included building capacities for result based management by the introduction of elements of strategic performance management such as setting strategic direction within budget plans and the introduction of performance measures. Also, the reform process included building the accountability system and monitoring and reporting system. But to close the management loop the reform process need to build capacities to use performance information and knowledge to drive the improvement. To further support the discussion the knowledge management concept, as well as its application in public sector organizations is discussed. The argumentation presented in this paper strongly recommends the further research in this field and asks for full cooperation politicians and scholars.

THE SIGNIFICANCE OF THE PARADIGM OF GRADUAL EVOLUTION FOR THE DEVELOPMENT OF THE DEFENCE SYSTEM

Vladimir Ristić*1, Srđan Blagojević [1],
[1]University of Defence in Belgrade
*Corresponding author, e-mail: vladimir.ristic@mod.gov.rs

Abstract: *The development of the defence system, in a certain way, represents the creation of the system's future that is appropriate to the environmental conditions, and the current and future needs. It is a process or procedure of selection and implementation of optimal goals whose achievement is the best way of dealing with a particular situation. If the state and politics do not develop strong defence, then they have a very limited ability to conduct certain policies. The development of the defense system necessarily is characterized by paradigmatic foundation. Although in the Systems Theory many paradigms are known, regarding the specificity of the defense system and its permanent character, the paradigm of gradual evolution is the most important. The paper gives a description of the importance of paradigm of the gradual evolution for the development of the defence system.*

Keywords*: defence system, development, paradigm, evolution*

1. INTRODUCTION

Modern defence system must be dynamic due to the dynamism of external and internal factors that determine it and must have a permanent feature of the system with regard to the sustainability of the reasons for his constitution.

However, to provide accuracy of the defence system of a certain country at any moment and time, it is necessary for the state to plan and implement its ongoing development. Development, as a term, is nothing more than adding certain positive features to the system, and corresponding changes in the existing situation of a certain system.

Developing power of the system is its ability to survive and develop in a modern society. Survival of the defence system is not treated as a mere possibility of its maintenance, but its ability to respond to current challenges and trends and to achieve the intended function.

Contemporary approaches to the development of the defence system are based on the theory of the system, which enables a comprehensive science-based knowledge of military organizations, as well as specific social entities. As a general systems theory represents scientific discipline that studies the different phenomena in the system, ignoring the specific nature of particular system, there is a need to consider the defence system constantly bearing in mind its specificity. Systems theory explores the formal interconnections between different factors over which manifests appear, and the nature of changes of these interconnections under the influence of external factors and the influence of the environment in general. The focus of the study of the systems are mutual influences of their factors.

As the consequences of bad decisions regarding the development of the defence system could have unforeseeable consequences for the state and society, there can not be place for approaches based on trials and errors and hope that the resultant of this process will be positive. Considering all known paradigms which treat organizational change in general, the paradigm of gradual evolution has the greatest significance for the development of military organizational system.

2. SPECIFICS OF THE DEFENCE SYSTEM AS AN ORGANIZATIONAL SYSTEM

The defence system is a complex organizational system. A precondition of its effective and efficient functioning and the development also, is an appropriate management. In theory, there are numerous attempts to define the concept of managing organizational system in general. This is done in different ways, depending on the point of observation of the problem which needs to be analyzed and depending on the characteristics that want to be highlighted.

From our point, definition offered by Stoner (2000) looks quite acceptable. According to which the management of organizational system is defined as: "the process of planning, organizing, leading and controlling the efforts of all members of the organization and the use of all organizational resources to achieve the objectives of the organization (P. 66). By using this definition, it is possible to identify the key characteristics of this complex process.

We consider planning, organizing, leading and controlling as essential functions of the process of managing the organizational system. Management of the organizational system is aimed at achieving predetermined goals. Managers, as a key drivers of process of managing of the organizational system, decide on the allocation and use of the organizational resources.

However, when it comes to the defence system management, there are certain differences between the defence system management and management of other organizational systems. Objectives and tasks of the defence system are determined by the competent national authorities (Assembly, President, Government, etc.). Managers in the defence system can participate in nomination of its objectives and tasks, but they are solely responsible for their implementation. The purpose of the existence of the defence system is not to make profit but to meet certain state and social needs.

The competent state authorities provide the necessary resources for the realization of the objectives and tasks of the defence system. The jurisdiction of the defence system is purely in efficient use of resources used to achieve the identified goals and objectives. These facts show us that the direction and course of development of the defence system largely depends on the decisions of state authorities. Although all management functions play an important role in ensuring the appropriate functioning of the defence system, the most important one is the function of planning, because it creates the preconditions for the successful implementation of all other functions.

There are certain boundaries between defence system and other social systems. They have a role to prevent many types of interaction between people in the organization and beyond. They are selectively permeable and human, material and information flows that are essential for the normal functioning of organizational systems, freely pass through them.

Hierarchical structure is important trait of the military organizational system. A hierarchical division is not unique to organizations only, but this is the general and common feature of all complex systems. In addition to the hierarchical arrangement that is characteristic for other forms of social organization, subordination constitutes itself as one of the essential specifics of military organizational system.

The defence system is a system of dynamic balance which is very important from the aspect of military organizational system and environment that is not static. For military organizational system's existence under conditions of dynamic environment, it also must be very dynamic and to be able to establish a balance while walking forward, namely to balance in the progressive movement. Feedback mechanism enables defence system to notice the consequences of its activities and activities of the environment and to use these information for appropriate regulation, coordination and adjustments. This mechanism is important for internal-internal relations but also for internal- external relations.

Mechanisms for adaptation and maintenance are very significant and very often they might be in conflict. The mechanism for adaptation's task is to make internal changes on the basis of changes in the environment, in order to adapt the defence system with the external environment, and thus to ensure a dynamic balance. This adjustments cause internal changes that are aimed for a higher level of organization. The mechanism for maintenance's task is to establish an internal balance between organizational subsystems and elements of the defence system. As adaptation mechanism operates continuously and causes changes in order to maintain dynamic balance, then mechanism for internal maintenance is constantly active, too. Given all the specifics of the defence system reported in the previous paragraphs, it is important to state that the changes are necessary in the defence system, but the defence system itself is slow and cumbersome and that is why the dynamics of change must be systematically designed and planned according to social needs.

3. POSSIBLE EFFECTS OF THE DEVELOPMENT OF THE DEFENCE SYSTEM

The effects of the development of the defence system are multiple and can be graded from highest to lowest proportion, according to the goal achieved. The maximum effect is confirmed by the creation of current and future defence system that are appropriate to environmental conditions, current and future needs, which provide permanent deterrence of actual and potential holders of threats and their intents. In order to provide

that the defence system of a state is up-to-date at any moment and time, it is necessary for the state to plan and implement its ongoing development.

The effects of the development of the defence system are multiple, since they mean the highest level of contribution to the vital social interests and goals. In order to give as many as a possible contribution to achieving the vital social interests and objectives, it is necessary to know the exact content and the objective actuality of security. Above all, it is necessary to know the origins of contemporary threats to security and the ability to build a defence system that allow preventive action.

If we observe that the most positive effect of the development of the defence system is compliance with current and future requirements, then our general provision would be defined as follows: The highest level of development of the defence system is reached when it is achieved:

- compliance of defence system with the external policy objectives;
- compliance of defence system with the constitutional provisions;
- harmonization of defence concepts with the strategy of foreign policy.

Accordingly, we can examine the differences among countries relating to these important questions, from which arise different directions of development of the defence systems. In fact, some countries tend to develop as an independent state with full international independence, without entering into alliances and international organizations. To achieve that they need to develop a defence system based on the development of independent forces that are capable of ensuring the country's self-defence against potential risks and threats to its security.

Spheres and the necessity of harmonization, as well as the performance of this complex process are changing the character of the alliances and international organizations. A number of countries decided to enter into an international organization, on condition of maintaining their full sovereignty and the satisfaction of certain conditions which they set themselves before entering a particular organization. There are a large number of countries entering into certain organizations and alliances, and consequently lose their full and receive some limited sovereignty, which is in practice being imposed by the alliance, an organization to which it belongs. Depending on the status of the state and its development aspirations, desired effects depend too.

The effects of the development of the defence system can be considered through achieved agreement that reflects the strength of the defence system, through the directions of its development focused on building the capabilities needed to support certain political decisions relating to the defence of the country. Also one important effect of the development is defined character of the armed forces.

The effect of the development of the defence system is the prominent role of the armed forces in the conduction of foreign policy. Armed forces can be a prominent factor of peace also. Here is a characteristic of omission of aspirations for superiority over the armed forces of other states and the existence of desire to maintain balance and develop trust. In such cases, the effects are achieved by appointing or omission naming enemies and balanced development of cooperation between the two countries with the aim of preserving peace. Full focus of the state on achieving these effects of harmonizing policy and state defence system, will protect state against excessive consumption of state energy in the state financing costly armed forces. However, total reliance on a common accepted peace, and lack or insufficient developmentin the spirit of modern military, may produce tragic consequences for the state.

The effect of development can promote a defence system as a major factor in the offensive policy, too. Strong armed forces and defence system as a whole, provide to the country ability to conduct offensive foreign policy based on the factor of power. As an argument for this is the fact that countries that have a strong military force and nuclear potential, have not been attacked by other countries in recent history. On territories of such states, there were not any international military missions conducted. The pursuit of nuclear powers to suspend the creation of new nuclear powers is only one of the forms of political action to limit the sovereignty of individual states. Conflict of impacts in this area never stops. The effects of the development of the defence system, therefore, can always be shown through military force, the economy and the de facto international relations.

4. PARADIGMATIC AND THE THEORETICAL FOUNDATION OF DEVELOPMENT

A comprehensive planning process of development of the defence system, in addition to reliance on significant diagnostic research requires the need for the necessary application of prognostic research. Prognostic research are carried out in various stages of the process, with the goal of more efficient planning

for defensive purposes. They are primarily aimed at anticipating possible threatening conditions and methods, and ways of circumvention, the prevention and reduction of the effects of the attack which is a social action to overthrow the state. Termiz (2014) believes that "Research methodology of safety occurrences and safety activities is not possible without fundamental understanding of those phenomena and that there are two major difficulties in determining the role and functions of security activities. The first concerns its connection with the state government and the other is conditioned by the characteristics of social power and force, whose main characteristic is versatility". (P.25)

In order to develop a defence system, and to fully present findings that have been reached on some phenomena, it is necessary to know paradigms, theories, concepts, and practical programs developed by the theory and practice. According to Milosavljevic, Radosavljevic (2014) the first action after the observance of the problem which is the reason and a possible general object of the research, is to gain insight into the existing research fund. "Theories and knowledge contained in scientific fund, as a rule belong to certain scientific directions, and are associated with certain paradigms that are in the paradigmatic system." (P. 414). Perhaps this is the key reason why the historian of the development of science Thomas Kuhn, puts scientific paradigm in the center of his theory of the science development, in his book The structure of scientific revolutions (1970). In his view, normal or mature sciences differ from the others in fact that they have a paradigm. The paradigm is not determined by the theory. It is a framework that determines the way of thinking about a phenomenon. The paradigm does this by defining three kinds of assumptions: ontological (about the nature of the phenomenon being studied), epistemological (knowledge about the nature of this phenomenon) and methodological (methods of acquiring this knowledge). It is a framework in which are theories developed, while in the theory are framework of concepts and programs developed, for the practical exploration of the phenomenon. An important feature of the paradigm is that they are not checked. They are composed of axioms, that are impossible to be verified, but only to accept them or not. Therefore, one could say that the paradigm is a kind of religion or ideology for scientists.

But the paradigms tend to developmental changes. So Lida (2004), looking at possible changes in the paradigm that can be a base for the the development of an organizational system, states: "Even if this is minor change within a major paradigm, because it affects corporate and consumer behavior to significant extent, it causes a great concern to policy makers. (P.42.)."

According to their degree of development, sciences can be found in a paradigmatic or preparadigmatic stage. The sciences that are in paradigmatic stage are mature, because in one time they have only one paradigm, to which all valid theories of that time belong. Unlike them, the sciences of the preparadigmatic stage are characterized by the existence of multiple paradigms, and the existence of multiple mutually exclusive picture of reality that is being investigated.

Research of the organizations and organizational change is in the preparadigmati stage. Masic (2001) has considered that in the area of organizational change, three paradigms can be identified (p. 303), as follows:

- The paradigm of gradual evolution;
- Paradigm of interrupted balance;
- The paradigm of revolutionary changes.

5. THE PARADIGM OF GRADUAL EVOLUTION IN THE DEVELOPMENT OF THE DEFENCE SYSTEM

Due to the above specifics of the defence system, its enormous size, the strict hierarchical structure and subordination, the stiffness of the system, changes directed to achieving the development goals are necessarily slow and gradual. It is impossible to develop abilities of the defence system in a short period of time, because it is a complex process that takes some time, and also is determined by need to maintain balance of the system. The defence system cannot be developed when there is a certain crisis that Boin (2010) considered as unexpected and undesirable situation (p 12). That's why we decided to subject to our review would be only paradigm of gradual evolution, while the other two paradigms will not be discussed.

According to the paradigm of gradual evolution, an environment of the organization is relatively stable, and changes are slow, predictable and occur gradually, step by step. By the Kovac and others opinion (2006), the entire organization development takes place through a process of constant change, which gradually changes its appearance and character. (Page 71) According to the paradigm of gradual evolution, the organization adapts to the demands of the environment. These changes have partial character, and they are being implemented gradually and with low intensity. They are also called first order changes or alpha changes.

This setting may impose a number of questions regarding the development of the security environment changes which we have witnessed in recent years. Perhaps many will disagree with our conclusion that the paradigm of gradual evolution has primary application in the development of the defence system and to express argument of rapid and radical changes in the security environment, starting with the Arab Spring, the war in Ukraine, a new cold war cry in Syria and the refugee crisis. However, if you carefully analyze the important factors that led to these changes, it can be concluded that the number of a occurrences have developed much earlier than the events themselves. This confirms the fact that many events could properly and timely predict using the prognostic research based on the paradigm of gradual evolution and which would allow the identification of the necessary directions of development of the defence system.

Given that according to the paradigm of gradual evolution, the changes of environment are slow and predictable (based on trends from the past), the management is able to design appropriate changes in the organization, with minimal time lag. Through implementation of organizational changes, management successfully and continuously maintain the organization in a dynamic equilibrium with its environment.

The development of the defence system is constant, evolutionary process which is determined by the strategic orientations, stimulated by technological advances and a limited economic and political factors. The aim is to maintain the necessary defence capabilities in the era of cuts in public expenditure and increasing demands for efficiency and effectiveness. The paradigm of gradual evolution presupposes the development. According to her, the gradual change of the defence system always lead to a development, or progress to a higher level of organization. The state of defence system after the change will be in some ways and always better than it was I previous situation. The development includes qualitative changes, and they happen according to this paradigm as accumulation of incremental changes, or changes that may be fixed or variable, but they are always positive and developmental.

It is especially important to plan long-term development of the defence system. Long-term planning of the defence system development is an interdisciplinary process that includes a number of different actions and activities which are interdependent and a lot of adjustments and reconciliation between political and military elite, planners, military commanders and other subjects of the defense system are required in their implementation. In connection with long-term defence planning, Kovač and Stojković (2009) argue that "uncertainty and ambiguity pose a major challenge for planners in the defence system, as well as for policy makers." (P.425).

That is why, the great attention is given to researching global strategic trends for a longer period, by the modern armies of the world. A typical example is the research conducted by the British Ministry of Defence. The results of a recent survey which aimed to provide a strategic context and to identify long-term threats and opportunities by 2045, they have published in the fifth edition of the publication Global strategic trend GST (2014). "Global Strategic Trends (GST) describe a broader strategic context which is aimed at those in the Ministry of Defence (MoD), the Government and beyond, who are involved in long-term development plans, policies and capabilities. Without this strategic context, there is a risk that planners and creators of policy and development capabilities assume the future based on already preconceived thoughts and assumptions."(P.3.). Of course, an important role in this process is communication with the public and the timely and adequate informing, and information operations doctrines in which Britain has a hundred years of experience. Principles and concrete examples of British information operations were described in Richard L. (2015) work, with special turn to the current experiment Rainbow in the dark (41-66).

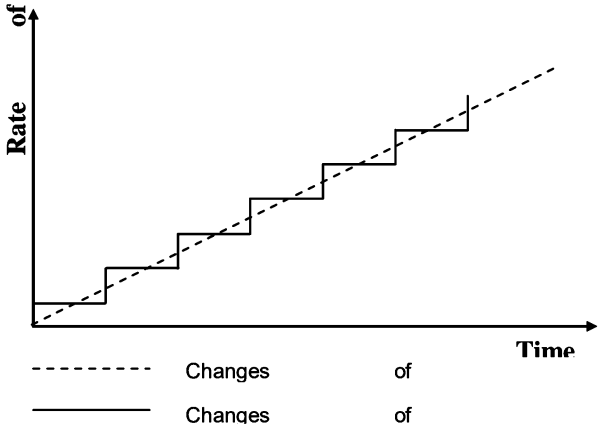

Figure 1: Incremental changes, Kovač and others (2006: 71)

In addition to assuming progress, the paradigm of gradual evolution also includes the assumption on which all subjects experience changes in the same way and they all have the same development path. Such an assumption has led to the creation of the concept of the life cycle of the organization as an instrument for evaluating the performance of management and development of the organization. In the context of the defense system, these development cycles can pose certain planning cycle, from long-term, over the medium and short term.

Therefore, process of changes based on the paradigm of gradual evolution has planned and rational character.

Consideration of policy approaches of own and other countries, analysis of the current security environment, as well as historical trends and events must precede the quality prediction of possible changes in the security environment. Basic entering at this stage are the analysis of national interests and objectives, strategy of national security, the defence strategy for potential opponents and allies, their future role, the role of international organizations and alliances and more.

The first step involves a detailed study of the basic documents relating to national security, defence and foreign affairs to determine the political intentions of other countries, as well as the political implications on the defence system. Thus, the results of this phase are prognosis of political ambitions of neighboring countries and the countries that are the important factors on the world political scene, as well as their political priorities in the field of defence. We are often facing here with the fact that in the available documents of many countries, security and defence objectives and interests are not explicitly formulated, so the key role of prognostic research at this stage should be that they are timely detected.

By this, we can identify national interests that could be impacted by future events, developments and trends in the security environment.

In order to reach a good prognosis, it is necessary to carry out the four essential steps:
- collect the necessary data,
- analysis, sorting and processing of data
- identification of opportunities, risks and threats and
- prognosis of the required number of strategic situations.

In the first step, we will collect the data needed for further work on the prognosis of the future environment. Of particular importance are the data relating to future security, political, economic and social issues, as well as the technological development and the environment. Data sources can be different from the intelligence services to scientific institutions.

The second step requires a good understanding of scientific methodology and analytical knowledge and experience. To obtain reliable results the development of the defence system, operators can use the services of other methodologists and scientists trained in the application of scientific methods in the fields of politics, economy, technology, defence, security, etc.

In the third step, the analysis results are used for the consideration of the impact of future environment on national interests and objectives. At this stage the aim is to identify future opportunities, but also risks and threats to national interests and objectives.

The final step in forecasting future security environment is the development of an adequate number of possible strategic situations which represent future developments in various fields.

It is important to emphasize the importance of the dialogue approach to research and development because it is a matter of effective communication of all relevant stakeholders who are interested in the process of developing the defence system. It includes external stakeholders, respectively the entire public that is sensitive to the issues of development of security and defence. According to the opinion of Flyvbjerg (2012) "Highly specialized media such as scientific journals and monographs are suitable for addressing academic audiences. But they are utterly inadequate when we need to reach out to groups that are relevant in the practical world of politics, administration and planning. Public dialogue that includes communication through daily media is necessary (p.214)". This provides support from the wider public in order to take concrete development steps.

The paradigm of gradual evolution also includes adaptive learning about the possible forms, dynamics and intensity of the security environment changes. However, in addition to the adaptive learning, generative learning is also important for the organization. Adaptive learning or learning in one round (single loop

learning), is based on the knowledge and understanding of changes in the security environment and adaptation to these changes, while generative learning or learning in a double round (double loop learning) is creating and exploring new areas for development of the system. Generative learning does not improve the existing knowledge, but create entirely new competences. Unlike adaptive, generative learning involves another round of referring to the review of the basic premises on which the existing knowledge is based and creating new knowledge, competencies and strategies. However, the strategy itself has no value if it is not implemented properly. Dess, Lumpkin and Isner (2007) nice noted the importance of implementing strategies to achieve the final effect, considering that "the organization must have adequate control and strategic organizational design, but still leadership has a central role in this business." (17)

7. CONCLUSION

By choosing to handle these issues, we were aware of the fact that due to the complexity of the defence system, and the complexity and importance of the process of its development, we cannot expose all aspects of the position and role of the paradigm of gradual evolution in defence research. Therefore, we limited ourselves to only those essential aspects.

Important components of power that are able to directly determine the system of defence can be considered: technical and technological, intelligence and communication, the appropriate number and qualifications. The development of these components will be conditioned by the functioning of various factors whose development, the scope and intensity of the operation cannot always be reliably predicted. Factors that determine the development of the defence system are certainly political, economic, material and energy, social, technological and others. The development of the defence system can be affected by many other factors, but the impact of these specified, primary and fully determines the direction and dynamics of its development.

To perceive these factors in proper perspective and to take advantage of their potential benefits and opportunities created for the defence system, it is necessary to pay special attention to scientific research. As any research is necessary based on a particular paradigm, that requires special emphasis on the types of paradigms which are known in the theory of the systems.

If we consider that the development of abilities and capacities of the defence system is a process that requires some time, because they cannot be built in a short period of time, it is necessary to conclude that the paradigm of gradual evolution is the most important paradigm of development of the defence system. Establishing development without relying on this paradigm, could lead to the situation in practice that some developing countries are caught / surprised by socio-political situation in the country or region. It happens that the defence systems of some countries in certain situations sometimes do not have the ability to meet the requirements that policy puts in front of them, and stay unprepared to respond to a specific attack or other forms of threats that can be applied by compromising entities. This is a manifestation of non-compliance, which can cost a state lack of realization of their vital interests and the objectives, and weakening its overall power, and in worst cases can sometimes lead to state's disappearance.

ANALYSIS OF POSTAL MARKET AS A PRECONDITION DEFINING THE MODEL ACCESS TO POSTAL NETWORK IN REPUBLIC OF SERBIA[1]

Marija Unterberger*[1], Dragana Šarac[1], Spasenija Ožegović[2]

*Corresponding author, e-mail: marijaunterberger@gmail.com

Abstract: *The Strategy for accessing the public postal operator (PPO) network is one of the planned Strategies for achieving the objectives of the development of postal services in the Republic of Serbia for the period from 2013 to 2016. The implementation of the Strategy is done through several activities. Some of these activities have already been implemented since the end of 2014. National regulatory authority (NRA) has adopted an „Ordinance on the methods and conditions of access to the postal network of the public postal operator“, and in March 2016 the Post of Serbia has adopted the "Ordinance on special conditions for access to the postal network". Certain planned activities are yet to be realized. Full liberalization of the postal services has not been achieved. There is still a reserved area on the PE Post of Serbia market that hinders the further course of liberalization itself. The final result is to define a model approach with strictly defined conditions of access (access points, the price of access, quantity of items with which to access the postal network). One of the steps in the implementation of these activities is the analysis of the postal services market, which will provide a review of the current state of market liberalization and basic directions for further research in defining the model approach*

Keywords*:* universal service obligation*, postal market, access, the postal network, the public postal operator*

1. INTRODUCTION

The Universal Service Obligation (USO) is one of the main achievements of civilization, which is why each country shall take appropriate steps that should ensure its general availability. In the last twenty years many factors have caused the postal sector in Europe and beyond to review its role on the communication market. The impact of competition, privatization, liberalization, the demand of users for a better and more reliable services, and new technologies have had a major impact on the postal sector and particularlyon designated postal operators. Each state has assigned the obligation to provide universal postal services to designated postal operators, giving them the right and obligation, and on the other hand the ability to secure further existence.

The postal services market in the European Union is still in the process of gradual liberalization. The Directives of European Parliament and Council on the liberalization of the postal market limit the postal monopoly and harmonize the obligations of its members towards the common universal service. The adoption of Directive 2008 (Directive 2008/6/EC) the European Commission has stipulated the need to create a legal framework in the Member States to the full opening of the postal market. On the other hand, the basic objective is the sustainability of the universal service so that all citizens have the possibility of using these services, and the possible appointment of one or more providers USO.

One of the recommendations of Directive 2008, in order to achieve sustainability of the USO, was that *“Member states of the European Union have to adopt measures to ensure access to postal network under transparent, proportionate and non-discriminatory terms, whenever this is necessary in order to protect the interests of users and/or promote effective competition“,* in order to protect the interests of users and ensure continuous, quality and sustainable provision of a universal postal service “ (Directive 2008/6/EC, article 11a).

Access to the postal network implies that the access user shall receive postal items from postal services users, then give them in at an agreed point of access to the postal network for further routing, transport and delivery to the addresses of the recipients, or to act in the same way with their own items, or to use postal network in which the access user delivers mail to the addressee.

The analysis of past experiences in a number of countries that have already defined access to the postal network has showed that the model access differ and are specific for each country, so there is no

[1]*The work is the result of research on the Project TR36040 funded by the Ministry of Education, Science and Technological Development*

transparent methodology for defining the value of certain criteria that define the very model access. Each country defines its own model of access depending on the characteristics of the postal network of the public postal operator as well as of the many characteristics of the postal services market. There is no typical model of approach which could be applied to a particular country or group of countries. For these reasons, each country, based on their characteristics (demographic, social, political, etc.), primarily on the basis of an analysis of the market, creates such a model approach that will protect the interests of all access users, and at the same time ensure the sustainability of USO.

2. RESEARCH METHODOLOGY

For the purposes of work, in order to develop a doctoral dissertation on the topic "Development of a model of access to the postal network," an analysis of the state of the postal market and overall postal infrastructure in the Republic of Serbia was done. The survey was conducted over a period of six months (from November 2014 to April 2015), and the participants were the National regulatory authority - RATEL and 39 postal operators on the territory of the Republic of Serbia. The results obtained in this paper are useful for defining the mode of access and access points on the network public postal operator (PE Post of Serbia).

The main objective of the research was to use the analysis of the postal services market to determine:

- Communication way between postal operators and users of postal services;
- Methods of cooperation and partnership existing among postal operators;
- The level of infrastructure development and means of the network used by postal operators to perform postal activities;
- Future directions of development of infrastructure and the need to increase the availability of services and networks;
- The current situation and plans regarding an expansion of the range of services;
- Problems that exist in the provision of postal services and quality of services.

3. NETWORK ACCESS IN EUROPEAN COUNTRIES

Postal network of the public postal operator has a significant role in a liberalized postal market. The public postal operator has high network maintenance costs and does not use its postal network enough. In the paper (Miletić, 2013) it is specifically stated that the increasing competition is very important to encourage current operators to become more efficient in order to maintain a high level of quality of services from the scope of universal services. The paper also states that increasing competition may directly endanger the existence of the public poslal operator. Therefore, regulators must take into account the different views and create such a model access that will be functional for both the public postal operator and other access users i.e. postal operators, consolidators and users who only submit their shipments (Ordinance, 2014; 2016).

According to relevant papers (Miletić, 2013; Dieke et al., 2013; Jaag, 2014; ERGP, 2012; ERGP, 2013) it can be concluded that on a fully liberalized postal market postal operators can use two basic models of access: upstream and downstream access. Downstream activities imply local network for delivery of postal items, while everything else is considered as upstream activities. Upstream activities are often referred to as “worksharing” and include activities of acceptance, grouping, sorting and stamping, before accessing the public postal network. Accessing the public postal operator network, access users are given an opportunity to fully or partially use the public postal operator network (Jaag, 2014).

Crew and Kleindorfer (2002; 2003), Panzar (2002), Moriarty and Smith (2005) discussed the advantages and disadvantages of downstream access. All the authors agree that regulation of downstream access may facilitate the entry of postal operators on the market, but also most agree that such a policy could have additional costs.

According (HR Strategy, 2014), upstream activities include working operations of collection, sorting and transport of items, while downstream activities include working operation of delivery of items (Figure 1).

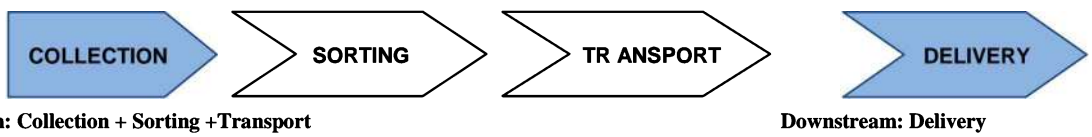

Figure 1: Upstream and downstream activities in the chain of transmission of postal items

In addition to these authors who have described and discussed models of approach, in Republic of Serbia there were a number of analyses and discussions regarding the access to the postal network. Thus, for example, in the paper (Kujačić et al., 2013) it is pointed out that access should be a balance in terms of

providing the universal postal service, since the public postal operator has an obligation to provide it, unlike its competitors. It also states that operators entering the market need to have a network access (especially in rural areas). According to (Gezović Trubint, 2011) regulation of access is one of the important steps in the process of market liberalization which should protect users' interests an densure the provision of universal postal services throughout the territory of the Republic of Serbia, under the same conditions and affordable prices and required standards of quality. The paper (Unterberger et al., 2015) describes various models of access in the Danube region, with the analysis of the efficiency of the public postal operators that provide access to the postal network.

As can be seen in Table 1, which shows the extent of access in European countries after the date of liberalization, Germany, United Kingdom and Slovenia are the only countries that have more than 5% of access to the postal network. The speed of liberalization of the postal market has varied: since January 1st 2011, 13 Member States (Austria, Belgium, Bulgaria, Denmark, Estonia, Finland, France, Germany, Ireland, Slovenia, Spain, Sweden and the UK) have fully liberalized their postal markets. Switzerland has maintained a reserved area up to 50 g, while the Republic of Serbia has maintained a reserved area up to 100g (ERGP, 2012).

Table 1: Dates of liberalization and scope of access in European countries.
(ERGP, 2013; Postal Regulatory Database, 2013)

Liberalized their market before EU deadline	**Liberalized their market by the deadline, in 2011.**	**Liberalized their market between 2011 to 2013.**	**Did not fully liberalized their markets to 2015.**
More than 5% competition access			
Germany (10 %) **United Kingdom (44 %)**	**Slovenia (7,6 %)**		Cyprus Norway **Serbia** Świtzerland Italy
Less than5% competition access			
Estonia Finland The Netherlands Šweden	Austria Belgium Bulgaria Denmark France Ireland	Czech Republic Greece Hungary Latvia Lithuania Malta Poland Portugal Romania Slovakia Croatia	

Italy is a member of the EU, but until 2015 the access was not regulated. In Switzerland, the Access to post office boxes in the destination post office and to database with addresses was provided. **In Serbia**, at the end of 2014 the *„Ordinance on the methods and conditions of access to the postal network of the public postal operator" was adopted, and* the *„Ordinance on special conditions for access to postal network " was adopted* in March 2016. **Cyprus** provides the access to the public postal operator through: units for providing customer service (post offices), post office-boxes and letter-boxes, although the market is not yet fully liberalized (ERGP, 2013). **In Norway**, the Law regulates the access (ERGP, 2013), although there is no information whether and to what extent is the access to the postal network implemented (Postal Regulatory Database, 2013).

In Slovenia, full liberalization happened in 2011 and it has led to the emergence of competition on this market with the entry of four access users. Currently, the main job of these oparators is printing and preparation of accounts. On the Access market, about 7.6% of the total number of letters addressed is handled byAccess users, while the remaining 92.4% is handled bythe public postal operator. **In Germany**, there are numerous active companies on the market, which mainly operate as consolidators and postal operators, which conclude agreementson access to postal centers for sorting items. There are five postal operators (Access users), which handle 10% of the total volume of letters on the postal market.

More than half of the countries included have a legal requirement for access to the postal network (in postal centers), but most countries have a legal requirement for access to the postal infrastructure (eg. The system of postal address code, database for shipments routing,data on change of address, letter-boxes) (Miletić, 2013). All the three countries in which there is more than 5% of competition havea legal obligation of access to the postal network, while Slovenia and the United Kingdom have a legal obligation to provide conditions for access to the postal infrastructure to varying degrees.

Only the three countries that have opened their markets within or before the deadline of the EU, have a greater scope of access than the countries that have opened up their markets after 2011.

3. ANALYSIS OF THE CURRENT SITUATION ON THE POSTAL SERVICES MARKET

Postal services have a key role in the economic and social development of each country, being a priority due to their multiple benefits for businesses and citizens. According to the data, in 2014, the postal sector had 17,630 employees, which is approximately 1% of the total number of all employees in the Republic of Serbia (RATEL, 2015b). Since the National regulatory authority (NRA) was formed in 2010, until 2014 there is a constant growth the number of postal operators in the market of the Republic of Serbia, as well as the growth the number of employees in this sector. This growth is as high as 50%, as shown in Table 2.

Table 2: Number of staff in the postal sector in the Republic of Serbia (RATEL, 2015b)

	2010.	2011.	2012.	2013.	2014.
Public postal operator	14981	14939	15068	15155	15015
Postal operators	1747	2048	2618	2464	2615
TOTAL	16728	16987	17686	17579	17630

Analyzing the public postal operator in Serbia, based on available data of the Universal Postal Union (http://www.upu.int/en/resources/postal-statistics/query-the-database.html), brings forward the following conclusions:

- If we look at **the resources** available to the PE Post of Serbia, there is a decline in the number of staff and number of post offices, with a higher decline in staff than the number of post ofices, which is a characteristic of the postal market in other European countries. There is also a large decrease in the number of mail-boxes (by 49.45%) and a small increase in the number of post office-boxes (2.68%);
- Looking at the number of different **postal services**, the analysis showed that in Serbia there is a 6% drop in the number of letters. It is important to note that the number of items of direct mail (addressed and unaddressed) is three times bigger, the number of express items five times and the number of ordinary money orders is two times bigger than it was;
- **Financial indicators** recorded a decrease in net revenue and revenue from letters and financial services;
- **Quality parameters**, expressed for example: „*Average area covered by a permanent office* (km²)", „*The percentage of the population having mail delivered at home", „Percentage of items delivered through post office boxes"* and „*Average number of letter-post items posted per inhabitant*", on an annual basis. *Percentage of items delivered through post office boxes*drops every year. In 2014 it was 16.2%, which represents a 22.85% less coverage than in 2005. *The percentage of the population having mail deliverred at home*in the last few years is without significant changes, as a quality parameter has a satisfactory value of 98.5% (according to the quality parameters shown in RATEL, 2015a).

Analysis of the postal services market was carried out in cooperation with the NRA - RATEL. Postal operators have submitted a survey / questionnaire containing three groups of questions, with a total of 21 questions:

- The first group of questions was related to general information about the postal operators, customers and business partnerships of postal operators and consisted of 7 questions;
- The second group of questions was related to infrastructure and access to services and networks, and consisted of 6 questions;
- The third group of questions was related to the range and quality of services (8 questions).

The questionnaire distributed to postal operators electronically is shown in Table 3.

Table 3: The structure of the questionnaire for postal operators

Parts of the questionnaire	Asked Questions
I **General data, users and business partnerships**	1. Postal services as a main activity 2. Total annual turnover - "VAT system" 3. Cooperation with other operators 4. Percentage of the provision of services of another operator 5. The most common way to communicate with customers 6. Availability of "Special Conditions for the provision of postal services" 7. Method of communication with customers
II **Infrastructure and access to services and networks**	1. The number and type of vehicle 2. Equipped means for receiving items 3. Territory operation ie. provision of services of postal operators 4. Places that may not be covered for that there was a need 5. The number of items that operators cannot collect from the user, as well as reasons for failing to collect them (if any) 6. Planned investments for the future
III **Range and quality of services**	1. Expanding the range of services 2. Planning of new services 3. The territory that operators can not cover the need to have 4. Reasons for not collecting items from the sender 5. The percentage of delivered items within the guaranteed delivery date 6. Number of complaints 7. The average time for solving complaints 8. Average compensation paid in dinars

4. RESEARCH RESULTS

Out of the 39 postal operators who participated in the survey, only 13 operators submitted the answers, which is 33.33% of the total number of registered postal operators in Republic of Serbia. Based on their analysis, the following conclusions were made:

- Main business activity of majority of postal operators is postal services (61.53%);
- Majority of postal operators is located within VAT system (the VAT system in Republic of Serbia are those operators that have an annual turnover in excess of 8 million dinars);
- Communication with users is established in many ways. The most common way to communicate with customers is by using Mobile or landline (34%), followed by the use of electronic e-mail messages (26%), call center (24%) and direct contact (16%) (Figure 2);
- Majority of operators cooperate with the public postal operator (PE Post of Serbia);
- Only 3 postal operators achieve more than 30% of their business by using other postal operators, mostly the public postal operator;
- With 92.30% of postal operators “Special conditions for the provision of postal services" are available to all users;

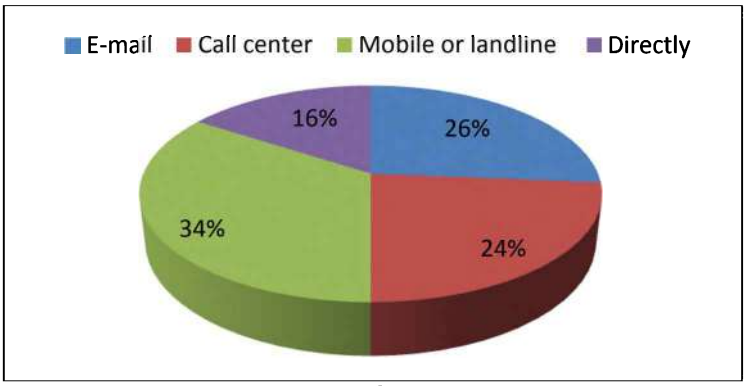

Figure 2: Way communication of postal operators with the users

- Trucks over 3.5t, cars and mopeds are mostly used for transport of items, while trucks over 12t and buses are less used (Figure 3).

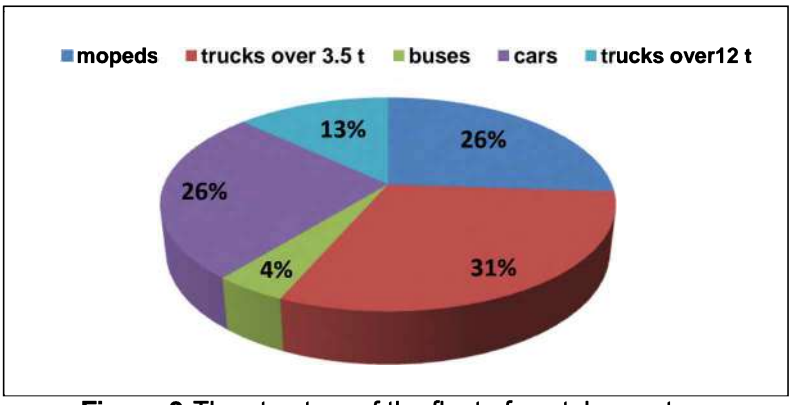

Figure 3: The structure of the fleet of postal operators

- Other means of postal network include scanners and scales, and rarely means of internal transport (forklifts, conveyors, belt conveyors);
- 5 postal operators conduct their business in the whole territory of Serbia, 5 conduct their business in the the territory of Vojvodina (22%), while the others operate on the territory of Belgrade (48%) and Europe (8%) (Figure 4);

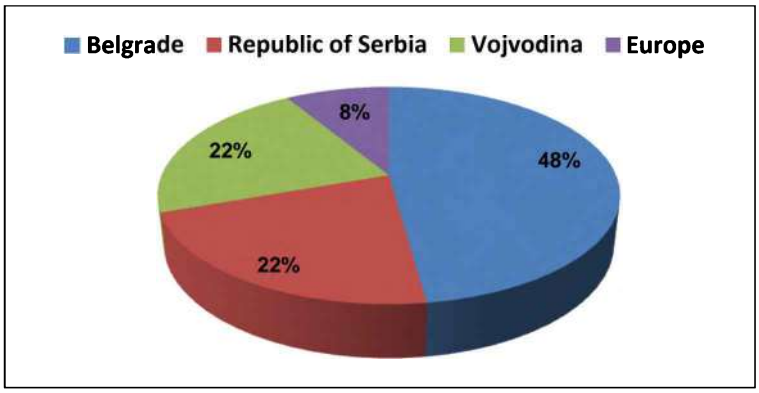

Figure 4: The territory of operation of postal operators

- 92.30% postal operators responded that there is no need to increase the availability of their services and networks;
- Majority of investments by postal operators is spent on the equipment and less is designated for employee training;
- Majority of postal operators do not plan to increase the range of services, and none of the operators plans to provide universal postal services;
- The level of service quality is satisfactory, which is shown by the percentage of delivered items in a guaranteed period of time, and the number of complaints.
  If we observe the delivery of the consignment to a guaranteed period of time, as one of the main indicators of the quality of postal services (Figure 5), the largest number of operators realized delivery of 100% - 37% of postal operators, and the lowest percentage of delivery (90%) occurred in 26% of operators.

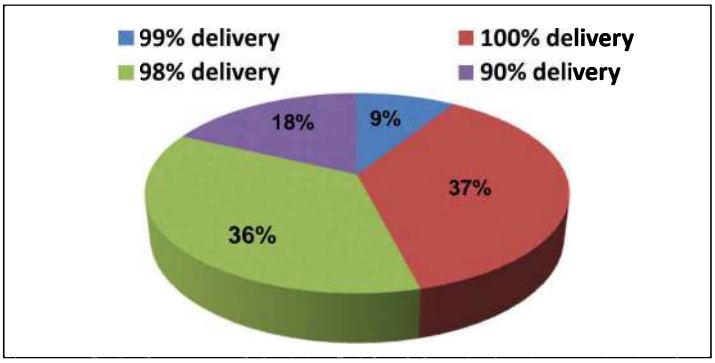

Figure 5: Percentage of delivery of items within the guaranteed period

- The average time for solving complaints is 2.33 days, while the average paid compensation is 4,923.00 dinars.

Operators who did not give answers were contacted by telephone.They mentioned several important reasons why they had failed to submit their responses. The most common reasons why operators did not submit their answers are shown in Figure 6. It is noted:

- that 21% of postal operators are dissatisfied with their position on the existing public operators monopoly market;
- 8% of the operators state that the main reason why they did not provide answers is that the market is not yet fully regulated, and it is precisely these operators who have focused their operations on the transfer of consignments in international traffic;
- 18% of operators believe that they have insufficient cooperation with the regulator, and as many as 20% are of the opinion that "access to the postal network will not significantly impact on their business" (the reason for such an opinion could be attributed to lack of information by the Regulator).

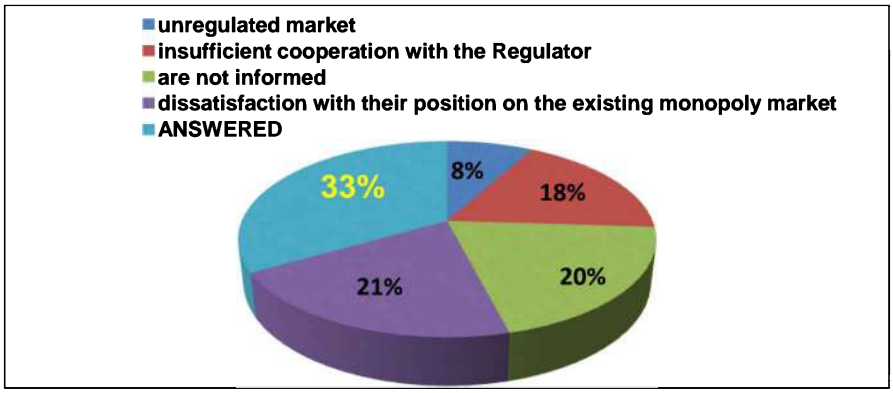

Figure 6: The most common reasons for not receiving appropriate by the postal operators

5. CONCLUSION

In Republic of Serbia, the access to the postal network, based on two key documents, namely*„Ordinance on the methods and conditions of access to the postal network of the public postal operator", and "Ordinance on special conditions for access to postal network".* Analysis of the research results points to the fact that few postal operators plan to increase their services and network availability. Consequently, there are operators interested in providing a set of postal services in the domain of universal postal services. Studies have shown that in 61.53% of operators main business activity of majority of postal operators is postal services

A small number of postal operators have cooperation with other operators. Only few operators have collaboration with PE Post of Serbia, in the field of commercial services. Postal operators are able to transfer items, as confirmed by the structure of their vehicle fleet, which indicates that most operators have trucksup to 3.5 t and cars. This creates a possibility for downstream access to the postal network in units to provide customer service (post offices) and in units for sorting items (postal centers). When it comes to quality of execution services, it is pointed out that 82% of the analyzed postal operators have more than 97% of the guaranteed delivery of items within the delivery date.

The analysis of the postal services market haspointed out the following factors which directly influence the market of postal services.:

- **The existence of a reserved area** for letter-post items up to 100 grams, which provokes the question: Does the existence of the reserved areas affect market development in the Republic of Serbia?
- **Uncertain regulation**, as well as a partial regulation of the market. In connection to this, it is necessary to reduce the impact of uncertainty through coordinating the dates for full liberalization of the market, and the adoption of other important documents, in addition to the already passed Ordinancesin 2014 and 2016.
- **Insufficiently informed postal operators**, insufficient cooperation with NRA - RATEL, as well as operators'**dissatisfaction** with their position on the existing monopoly market.

Identified factors are just the basic factors that can be of great influence on the access to the postal network, and whose impact needs to be further explored in order to be able to define an adequate model of access to the postal network in the Republic of Serbia.

MEASURING SECURITY MANAGEMENT PERFORMANCE

Dragan Bojanić
University of defence
*Corresponding author, e-mail:dragan.bojanic@mod.gov.rs

Abstract: *Performance management is at the heart of most modern organizations, whatever their purpose and irrespective of whether they are privately or publically owned. It is only through the measurement of performance that an organization can demonstrate to itself and its stakeholders that it is achieving its goals, which most commonly include financial, operational, safety security and environmental performance. The crucial role within management and control of security systems should be played by top management, i.e. the key element in this process is the responsibility of security and safety management system.*

Keywords: *security, management system, performance, measurement, efficacy*

1. INTRODUCTION

Preventing and mitigating the effects of external and internal threats are always current problems in almost every organizational system. Therefore, if not all, but most of organizational systems must be designed to include safety in their plans. In fact, people who are working to develop a security management must take into account other objectives of the system, or to choose dual alternatives that offer additional benefits for business owners. It is therefore of great importance that security is viewed in the context of the broader system.

Many organizations in developed countries apply a systematic approach in solving security problems. In most of such companies, a security management system has been introduced and it protects the organization from their own mistakes. However, methods for determining the performance of the security management system, or to measure its effectiveness and efficiency, are not sufficiently developed. The main problem, lies in the fact that in many countries, safety standards which organizations must adhere to, are still not equally and clearly defined, and they should represent a landmark for identifying the safety targets. Therefore, different methods are used for determining the deviation from the norm. In addition, there is a problem that relates to the "profitability" of security management. If security is not set as a strategic, general and basic goals of the organization, its importance cannot be explicitly expressed. The goal of security management actually is that "nothing happens". Although it is difficult to measure the safety and sometimes even seems impossible, yet it is the only reliable way to answer the question of whether an organization is able to solve security problems, and to successfully cope with security risks.

2. THE TERM AND SYSTEM OF SECURITY MANAGEMENT

The term "security management" is relatively recent, so we can say that there is still no definitive definition. The very concept of security management in a broader sense means Dragišić (2007) "determination of the safety objectives of the organizational system, on ways and means to avoid the adverse impacts that come from the environment or the organizational system, or to mitigate their adverse impact" (p. 14), while the Italian and Slavković (2011) defined it as "guiding activity of the industry leaders in the field of security, which leads security forces in the process and towards achieving security goals and tasks" (p.298). A more detailed definition is given by Borodzicz (2005) 'security management includes management of safety and health in the workplace, audits, crisis management and planning for emergency situations, video surveillance, harassment in the workplace and mobbing, track employees, equipment and people for physical security in fact everything that can affect the functioning of the organization, its profitability and vitality. "(p.50).

Various challenges, risks and threats that organizations exposed to, and organization's responsibility towards the environment in terms of safety, have a crucial impact on security management, and the way in which decisions regarding security will be made. In addition, Fowler and Pierce (2012) say that "security in itself is not an attribute, but it is a trait of systems that depend on other attributes and the context in which the system is used" (p.115).

According to Trivan (2012) security management system in the company, in addition to the physical and technical protection of persons, property and operations, must involve in itself: data collection and risk assessment, protection from fire, explosions and accidents, protection and safety in the workplace, but also it

forms the basis for management decision-making, providing access to confidential information to top management and establish processes and procedures for the protection and security of data (p. 227-236.). Thus, this system has to integrate all aspects of security and protection.

System security management can be understood as a set of policies, strategies, processes, procedures, roles and functions related to safety. This is a mechanism that is integrated into the organization and aims to control hazards that may affect the health and safety of employees, products and services, but also on the environment and the survival of the company. At the same time, this system allows the organization to adapt more easily to the legislation. In order for the security management system to be efficient and effective, it must be accepted and fully applied by employees. Therefore, the system must promote the positive security climate, or culture. Therefore it is necessary that all levels of management, and in particular top management, support and promote a system of security management

3. PERFORMANCE OF SECURITY MANAGEMENT SYSTEM

Working in a complex environment requires substantial resources and may affect the profitability of the organization. Protection of the financial condition and stability of the organization is one of the main issues tackled by management. All this leads to great challenges for many activities within the organization, especially for security management. Costs directly affect the organization's operations, and therefore they receive great attention. Given the dynamic changes in the modern environment, it is clear that every organization that wants to survive, must think in along term about way of investing the funds. To be able to monitor the efficiency of investments, according to Christophers, Carino, and Ferson, (2009), the organization introduced performance management processes and control operations, and for this there must be clearly defined indicators (p. 5). According Dochy, Segers and Wijen (1990) indicators are empirical data of qualitative and quantitative nature. These data become indicators of performance if the participants express the intended targets in a process (p. 135). This gives them the contextual and temporal character..

Performance are mainly monitored over the following six basic criteria: effectiveness, efficiency, quality, timeliness, productivity and security. However, every organization shapes these measures according to their own needs. Therefore, in the performance measurement of the system security management, we have decided on the efficiency and effectiveness as such basic indicators of successful operation of the system. The biggest problem in this regard is the lack of an accepted and measurable indicators which would indicate a return on investment. It's little of what the organization can do in this area. Measurements are often made in the context of avoiding incidents or influence of perceived risk (for example, the impact would be less than the cost of controls and therefore provides a positive rate of return.

Performance of organization indicate the effectiveness of its operations, and for this reason, measurement of its performance is performed. Thus, the performance of the process can be translated as the effect or success of the process, but it must express some size. Measuring performance literally means the process of quantifying past activities, or a set of criteria that are used to quantify the efficiency and effectiveness of activities. From the point of this work, I decided to show performance measurements by quantifying the effectiveness of the action.

4. MODEL FOR ASSESSING THE EFFICIENCY OF SECURITY MANAGEMENT

The purpose of an organization is reflected in her mission, through which one could recognize the core business, and it contained all the requirements of all stakeholders. The mission is translated into goals and then processes and activities are defined that are necessary to achieve them. The degree to which the objectives are met, and thus the mission itself, shall be determined by measuring and comparing with the set target. Comparison of actual and established performance values of a process or the organization itself with the desired value can lead to a change in the mission of the organization.

There are four basic steps to establish a performance measurement system (figure 1):
- Security objectives of the organization are converted to the desired standards,
- Development of the criteria that allow the comparison of the desired safety standards with the achievement of the security situation,
- Determination of the deviations,
- Taking corrective action.

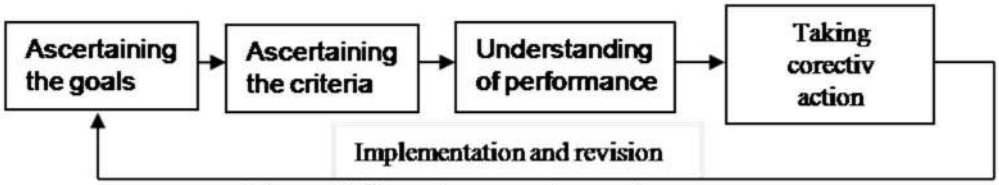

Figure 1. Steps in measuring performance

Measurement is a set of actions with a view to determining the value of a size. Definition of measurement given by Milosavljević, Radosavljević (2013) suggest that the measurement is procedure of systematic determination of the quantitative properties of a phenomenon by defined and appropriate measures and standards (p.571). Performance measurement process, therefore, may relate to determining the value or performance of the process. If the process is defined as a set of interrelated activities that transform inputs into output, then the output of the key elements of process are safety reports and assessments, and the input are plans, objectives, funds invested. The measure of performance is always in relation to the objective, which is the desired state, and the desired value performance. The value of performance can be expressed through a one dimensional measurement unit (time, the dollar, the number of reports, the number of errors and the like.), which typically represent the basic criteria of a process. The measurement process of the safety performances can't be conceived as a simple collection of data, but must be viewed solely as the overall management system that is focused on meeting the demands of all stakeholders and continuous improvement.

Model should provide to any manager, especially to security managers, the kind of information necessary to make high quality and timely decisions. In addition, this model should be a system that should enable the organization to accumulate knowledge about their customers, processes and resources and implement continuous improvements in security, ensuring the survival, growth and development of the organization.

4.1The algorithm for measuring the effectiveness of protection in systems security management

Based on the models which are set by prof. Petrović L. and Z. Petrović, we present an algorithm that looks at the effectiveness of protective measures in security management systems. According to the model that Petrović and Petrović gave (2002) "state of the organizational system can be represented by a matrix sheet [S_{rs}], the situation at the entrance to the system can be represented by a matrix of input [X_{ij}], and at the exit, matrix output states [Y_{pq}]. On the organizational system is operating activities endangering that can present matrix compromising [U_{mn}]. The elements of this matrix represent the demonstrated effects compromising ***m*** acting on n elements of the organizational system. After compromising effects manifested in the system apply certain safeguards, which are represented by a matrix of protection [Zk_n]. The elements of this matrix represent the number of protection measures (k) applied to the n elements of the organizational system" (p.2-6).

In the proposed model, the state of the system is best represented as follows:

1. The set of elements of the organizational system consists of a number of organizational units, jobs and the final number of participants end (1),

$$[S]=[S_{od}, S_{rm}, S_{ku}] \quad (1)$$

wherein:
S- set of elements of the organizational system
S_{od} - the total number of organizational units,
S_{rm} - the total number of working places,
S_{ku} - final number of final participants

2. Environment operates with **m** different forms of threat on organizational system. A set of expressed compromising effects presents a matrix of endangering [U_{ij}]. The set of expressed endangering effects are:

$$[U] = [FU, U_{žs}, P, UI] \quad (2)$$

wherein:
U - a collection of expressed compromising effects,
FU - physical endangerment of the organizational system,
$U_{žs}$ - endangering the environment,

P - fires
UI - endangering information system in the organizational system. Matrix effects manifested compromising $[U_{mn}]$ can be written as:

$$[U_{mn}] = \begin{pmatrix} u_{11} & u_{12} & - & - & - & u_{1n} \\ u_{21} & u_{22} & \cdot & \cdot & \cdot & u_{2n} \\ & & & & & \\ u_{m1} & u_{m2} & \cdot & \cdot & \cdot & u_{mn} \end{pmatrix} \quad (3)$$

Elements of matrices u_{ij} be zero if the j -th element system u_{ij} manifested i-th effect compromising, otherwise it is equal to one.

3. In the organizational system, safeguards were applied that can be presented matrix applied measures of protection $[Z_{kn}]$, which can be written as:

$$[Z_{kn}] = \begin{pmatrix} z_{11} & z_{12} & - & - & - & z_{1n} \\ z_{21} & z_{22} & \cdot & \cdot & \cdot & z_{2n} \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ z_{k1} & z_{k2} & \cdot & \cdot & \cdot & z_{kn} \end{pmatrix} \quad (4)$$

Element matrix applied measures of protection z_{ij} is equal to zero if the j-th element of the system has not been implemented i-protection measures, otherwise it is equal to one.

4.The state of the system at the exit of the system [Y] is determined by the parameters of forming the [X] and the current state of the system [S]. Current status depends on the threat to [U] and the measures of protection that are defined matrix of protection [Z].

5. Matrix System status [S] can be determined as the product of a matrix of endangerment and protection of dies (4):

$$[S_{mk}]=[U_{mn}]x\ [U_{kn}] \quad (5)$$

Respectively

$$[S_{mk}] = \begin{pmatrix} s_{11} & s_{12} & \cdot & \cdot & \cdot & s_{1k} \\ s_{21} & s_{22} & \cdot & \cdot & \cdot & s_{2n} \\ & & & & & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ s_{m1} & s_{m2} & \cdot & \cdot & \cdot & s_{mk} \end{pmatrix} \quad (6)$$

It is the glow of <S, and if they did not neutralized the effect of compromising the j-th measure of protection and $s_{ij}>S_u$ otherwise S is the mean value obtained by the matrix elements of the system status.

If the amount of the matrix sheet is less than the mean value obtained by the matrix elements of the system status, it means that the effect of compromising, which is manifested in any element of the organizational system, it is not neutralized by the application of protective measures in a given element of the organizational system. If the amount of the matrix sheet is greater than the mean value obtained by the matrix elements of the system status, it means that the effect is manifested compromising on any of the elements of the organizational system neutralized by applying protective measures in a given element of the organizational system.

In a real situation, the manager can form a matrix compromising on the basis of data obtained from security assessments, as well as the matrix of protection based on the knowledge of the security system, and

implementation measures. Using this algorithm, it is possible to quickly reach the information that applied protection measures can counteract the effect of the manifest danger or not.

5. CONCLUSION

Models for assessing the effectiveness of security activities in organizations in Serbia have not been developed, and the only indicator that executives use the service cost is the price of safety. That is, the top management in most organizations decide on how to organize the security system on the basis of costs involved in its organization and functioning. Very rarely take into account the costs that would be incurred in the event of an incident. Therefore, it is necessary to determine the method for determining the effectiveness of the security management in order to point in the clear way to the essence of its existence, but it is actually its main goal, and that is, survival, smooth functioning, growth and development of the organization itself.

MILLENNIALS AS A FUTURE DOMINANT WORKFORCE - STRATEGIC FRAMEWORK FOR UNDERSTANDING AND CREATING CHALLENGING ENVIRONMENT

Tanja Ilić*[1], Milica Pavićević[1]
[1]Faculty of Organizational Sciences
*Corresponding author, e-mail: tanja.ilic.94@gmail.com

Abstract: *The purpose of this research was to explore and define key characteristics that distinguish the generation of Millennials, workforce that will represent 50% of the global workforce by 2020 and to define strategic framework for creating an organization which is desirable employer. The paper presents evaluating results on key elements that constitute challenging and enriching workplace environment, according to Millennials, which encourages them to thrive and give their best. This paper presents theoretical and practical overview and comparison of Millennials' expectations, both in Serbia and worldwide. The research showed that in order to attract and retain Millennials at workplace, employers should create a flexible work culture, build a sense of a community through teamwork and provide a constant feedback. In addition, organizations should embrace new technologies and social networks, encourage learning and allow faster advancement. Foundationally, it is essential to understand the Millennials' mindset and reshape the world of work in accordance with the expectations of this new workforce entering the employment.*

Keywords*: strategic management, Millennials, Millennials' traits, shaping organization, workplace, workplace engagement, research*

1. INTRODUCTION: MILLENNIALS. WHO ARE THEY?

The Millennial generation, also known as Generation Y, Net Generation or Generation Next, is generation that follows Generation X. Millennials are, according to the PwC survey (Millennials at work – Reshaping the workplace, 2011), those born between 1980 and 2000. They are now entering the workplace and reshaping it toward their needs. Their career objectives, ambitions, attitudes about work and, in general, their mindsets will have a huge influence on the working world in the future years.

Millennials were identified as "digital natives" in the Pew Research Center's survey *Millennials in Adulthood* (2014). As Bannon, Ford and Meltzer (2011) point out Millennials are more technologically savvy and better educated than the previous generations. The PwC survey (2011) suggest that "they have grown up with broadband, smartphones, laptops and social media being the norm and expect instant access to information", which implies that "one of the defining characteristics of the Millennial generation is their affinity with the digital world".

Besides being tech-savvy, there are other characteristics that are defining the Millennial generation. As DeVaney (2015) puts it "traits attributed to the Millennials include: entitled, optimistic, civic minded, close parental involvement, values work-life balance, impatient, multitasking, and team oriented. As found in many surveys, Millennials are also described as sociable, talented, well-educated, collaborative, open-minded, influential, and achievement-oriented (Raines, 2002). What also distinguishes Millennials from the previous generations is their desire "to feel like they are a part of something and that they can make a difference in the world and workplace" (Spano, 2015).

Millennials are also described as "selfish generation" by some; and as we can see from the PwC survey (2011), they have "ambition and desire to keep learning and move quickly upwards through an organization", "they want to feel their work is worthwhile and that their efforts are being recognized", but are willing to "move on quickly if their expectations are not being met". Wasley (2015) agrees by saying that Millennials have "unrealistic expectations about the workplace and a propensity to job-hop rather than settle for a career they find unfulfilling", and adding that they "value creativity and a flexible work environment over stability".

Influenced by the global Economic crisis, Millennials tend to value their personal needs more than those of the organization, as the PwC survey (2011) suggests. The PwC survey also shows that Millennials expect rapid progression, an interesting career, constant feedback, encouragement, but in the same time, they also want flexible approach to work.

We have conducted a survey among Serbian students, which will be presented hereafter, in order to see what they are looking for in an employer. The results we got are similar to those shown above. Namely, among most important criteria, when choosing an employer, are opportunities for advancement and learning, good working conditions (working hours, work-life balance etc.) and work environment (atmosphere at the workplace, collaboration, recreation opportunities etc.).

As found in Pew Research Center's article by Bruce Stokes (2015), Millennials represented 24% of the adult population in the European Union in 2013, and, on the other hand, they formed about 27% of the adult population in the United States in 2014. According to the PwC survey (2011), Millennials will represent half of the global workforce, by 2020.

It is clear that Millennials will have a huge impact on the organizations and on the way they operate. They will certainly influence many changes in the workplace, thus becoming one of the major challenges that employers need to deal with. That is why it is really important for companies to understand Millennials and to attract the best among them. The key is not to specifically target Millennials, but rather create work environment appealing to this generation.

2. THE MAIN TRAITS OF THE MILLENNIAL GENERATION

Combining the key findings from different surveys, we have identified a few distinct characteristics of the Millennial generation. These traits include their advanced technological skills, as well as their attitudes toward work and life balance, loyalty, social responsibility, development, collaboration, and diversity.

2.1. Tech-savvy

Millennials, the first generation to experience globalizing world, are often referred to as "digital natives". Being tech-savvy is one of the main characteristics of today's youth and that can be seen in many aspects of their lives. As Bannon, Ford and Meltzer (2011) point out "they grew up untethered - with wireless devices, workplace mobility, and texting—and remain connected with friends via social networks". According to the Pew survey (2010), about 75% of Millennials are members of an online social network.

Palmer (2015) states that "employees expect companies to use the latest technology and be committed to improving technology on a frequent basis", because "technology allows employees to work remotely; employees can work smarter, not harder by using technology, and technology allows managers to focus on the results through better data tracking versus the number of hours an employee is sitting in the office".

Employers usually criticize their employees when they are texting or connecting to some of the social networks. But Millenials are actually turning online social networks into business opportunities, observed Lancaster and Stillman (The M-Factor: How the Millennial Generation Is Rocking the Workplace, 2010).

According to the Pew survey (2010), a majority (56%) of Millennials think technology helps people use their time more efficiently. As found in the PwC survey (2011), more than 50% of the respondents use their own technology at work daily and 78% said that access to the technology they like to use makes them more effective at work. This survey (PwC: Millennials at work - Reshaping the workplace, 2011) also suggests that "Millennials will expect a workplace technology ecosystem that includes social networking, instant messaging, video-on-demand, blogs and wikis", because "these social tools will enable this generation to instantly connect, engage, and collaborate with cohorts and managers in ways that are natural to them, leading to better productivity across the enterprise".

2.2. Work-life balance

According to the Pew survey (2010), to Millennials, as well as to all the other groups, family matters the most, while fame and fortune are much less important. Both, the Generation Y and the Generation X place a higher value on family relationships than career goals.

Spano (2015) points out that "Millennials have become accustomed to flexible work styles and want to have a "life" outside of their careers". Moreover, Krupienski (2016) says that work-life balance is generally regarded as more important criteria than the compensation.

In Global Millennial survey (INSEAD, 2014), 58% of respondents said they would spend time with family if given the opportunity to prioritize. Bannon, Ford and Meltzer (2011) noticed that importance of Millennials' life goals such as spending time with family, having a healthy marriage, and being a good parent may cause transformation of the conventional (nine-to-five) working hours into a more elastic time frame; and that is

because they are "willing to trade security and stability for the ability to better integrate their professional and personal lives".

PwC's NextGen Study (2013) shows that "Millennials want more flexibility, the opportunity to shift hours—to start their work days later, for example, or put in time at night, if necessary", and not only Millennials want that, but other employees as well. Furthermore, Ludden emphasizes that retention rates have dramatically increased at companies that offer flextime or part-time telecommuting (Jennifer Ludden, *When Employers Make Room for Work-Life Balance*, NPR, 2010). That is why companies must focus on providing more flexible working schedules.

2.3. Loyalty-lite

The PwC survey (2011) shows that over 25% of the Millennial generation expects to have six employers or more, compared to only 10% in 2008. Why is that so? This survey explains: "Millennials have seen that corporate loyalty does not necessarily bring rewards or even long term security in today's economic environment". That is the reason why many Millennials are checking out new opportunities, even if they are not actively looking for a new job, which leads to these results: "38% of the Millennials questioned, who are currently working, said they were on the lookout for new opportunities, and a further 43% said they were not actively looking, but would be open to offers".

Millennials want to work in a workplace that meets their needs, and if it doesn't, they will not hesitate to leave the current organization. Krupienski (2016) also points out that Millennials are "more apt to move to the next job than older generations would have been", "if they feel that they are in a place where their personal values are not being satisfied".

Moreover, Millennials are not only willing to switch employers, i.e. to go to work for competitors, but also many of them have ambitions to create their own businesses, which makes it even harder for organizations to keep them engaged. Therefore, employers certainly need to make an effort to understand Millennials' needs and desires, in order to attract them, on the one side, and to decrease the turnover rate, on the other side.

2.4. Social responsibility

Although Millennials are often described as selfish generation, that is not completely true. On the contrary, they are eager to help their communities and to feel useful. Pew survey (2010) reveals that many Millennials have a strong desire to contribute to their communities. Data shows that 88% of Millennials seek employers with social responsibility values that reflect their own. Many among the Millennial generation would accept to work for lower wage if their work contributed to the community, i.e. if they feel like they are doing something important and meaningful for the environment they are living in.

2.5. Development

The PwC survey (2011) indicates that „Millennials' desire to learn and progress is apparent in their view of the benefits offered by employers". They actually would like to get, as an award, training and development and flexible working opportunities more than financial benefits. This survey also suggests that „Millennials expect to keep on learning as they enter the workplace", and that opportunities for learning are very important criteria when choosing an employer, but also among the benefits they value the most.

Palmer (2015) says that Millennials are in constant need of getting a feedback on their performance. As found in the PwC survey (2011): "One of the strongest Millennials' traits is that they welcome and expect detailed, regular feedback and praise for a job well done – 51% of those questioned said feedback should be given very frequently or continually on the job and only 1% said feedback was not important to them".

Esoda (2013) emphasize that Millennials require immediate recognition for their accomplishments, especially because of the emerging usage of social media. Palmer (2015) points out that Millennials "want to constantly grow in positions, learn more, take on more responsibility, and know they are trusted to make profitable changes". Lancaster and Stillman (2010) have also mentioned that „whether they expect perks before others think they have earned them or they want to move up the career ladder in record time, Millennials have been labeled as entitled". The PwC survey (2011) reveals, likewise, that „career progression is the top priority for Millennials who expect to rise rapidly through the organization; 52% said this was the main attraction in an employer, coming ahead of competitive salaries in second place (44%)".

2.5. Collaboration

Lancaster and Stillman (2010) describe Millennials as generation raised in a time of team projects and group scores. Therefore, they are in need of a pleasant working atmosphere and good professional networks, which will enable them to keep up the team spirit. Krupienski (2016) suggests that Millennials want to have fun. That means that the work environment needs to be lively and positive.

Employers should make an effort in meeting the needs of this generation by creating a positive workplace. But employers also need to listen, meet with the Millennial workforce, seek and give feedback, mentor them, and take what they have to say seriously.

2.7. Diversity

Bannon, Ford and Meltzer (2011) explain that today's workforce is among the most complex, with many generations and cultures working together, and, therefore, business activities have become more globally connected than ever before. That brings a need for having intercultural communication skills. They also label Millennials as a diverse and inclusive generation. Thus, it is easier for the Millennial generation to imagine a world without boundaries: they want global experience and they are connected through social media with different people all over the world. Therefore, they are ideal candidates for international assignments. According to the PwC survey (2008), 80% of Millennials expect to work in other countries and 70% expect to learn and use a foreign language in their careers.

3. RESEARCH METHODOLOGY

Research was conducted in the February 2016, and with the sample of 192 students from the University of Belgrade, in Serbia. Data is collected using online questionnaire, which can be found on https://docs.google.com/forms/d/1By7ddgwL5XyScOETOHrAMOsGfC6zZC14SF_V50MSXxI/viewform, in Serbian language.

The main objective of this survey is to provide practical research about Millennials' view on how business should be performed and what are the main characteristics of employers that they seek and appreciate at work. Considering the fact that the Millennial generation has increasing share of the workforce, employers need to understand what Millennials overwhelmingly believe in - and that is business reset in terms of paying more attention to people and their needs.

Sample consisted of 192 respondents; most of them (59 (30.7%) out of 192) were students from third and (44 (22.9%) out of 192) students from second year of study. Further, 16 (8.3%) respondents were students of Masters and PhD studies, 32 (16.17%) students from first year, 36 (18.8%) students of fourth year of study, and the rest - 5 respondents, were students from fifth and sixth year.

Table 1: Sample characteristics	N (%)
Characteristics	
Year of study	
First	32 (16.7%)
Second	44 (22.9%)
Third	59 (30.7%)
Fourth	36 (18.8%)
Fifth	3 (1.6%)
Sixth	2 (1%)
Post-graduate (Masters and PHD studies)	16 (8.3%)
Sex	
Male	66 (34.4%)
Female	126 (65.6%)

Respondents in the target population of Millennials completed a total of 192 surveys, where male comprised 34.4% of the respondents, and female 65.6%.

The research results and discussion are presented in following section.

4. RESULTS AND COMMENTS

A survey and data analysis revealed important elements and criteria that contribute in creating a challenging, productive and motivating work environment for the next future leaders - students belonging the generation of Millennials. Following are the research findings.

Table 2: The most important criteria when choosing an employer	(%)
Opportunities for learning	(87.4%)
Opportunities for advancement	(92.1%)
Challenging assignments	(61.2%)
Working environment (atmosphere at the workplace, collaboration, recreation opportunities etc.)	(81.2%)
Good working conditions (working hours, work-life balance etc.)	(83.3%)
Team spirit	(52.4%)
Compensation	(83.2%)
Social responsibility	(50.8%)
International company/Prestige	(36.6%)
Organization's mission	(45.1%)
Springboard	(82.7%)

An analysis of the data collected from online survey, that was conducted among Millennials in Serbia, showed that the most important and respected factor mentioned by majority of respondents is opportunity for advancement with 92.1%.

Millennials in Serbia, as a future dominant workforce, recognize the full worth of opportunities for learning with 87.4%, as one of the leading criteria when choosing future employer or when evaluating existing.

Also, a quite large percentage, even 83.3% representatives of "Me generation", stressed that good working conditions relating to working hours and work- life balance, are key motivators for them. Following are criteria such as compensation with 83.2%, springboard with 82.7% and work environment with high level of collaboration, various opportunities for recreation and good working atmosphere with 81.2%.
Setting aside the previous chosen criteria, one of the key findings of this survey, that employers in Serbia can use in order to create inspiring work environment for Millennials, is the fact that 61.2% of respondents identified challenging assignments as one of the key drivers at work. This is not surprising since most young workers appreciate working on vitally important projects that allow them to expand their knowledge and use new skills (The Ken Blanchard Companies: Creating A Motivating Work Environment, 2009).
On the other hand, research has shown that young people in Serbia, who belong to this generation, in most cases, ignores international presence and prestige when choosing an employer, where 50.8% of them consider social responsibility more important factor.

5. COMPARATIVE ANALYSIS

To broaden our understanding of Millennials' expectations from work and how organizations should shape their work environment, we have compared the obtained results with those from Collegefeed Survey,

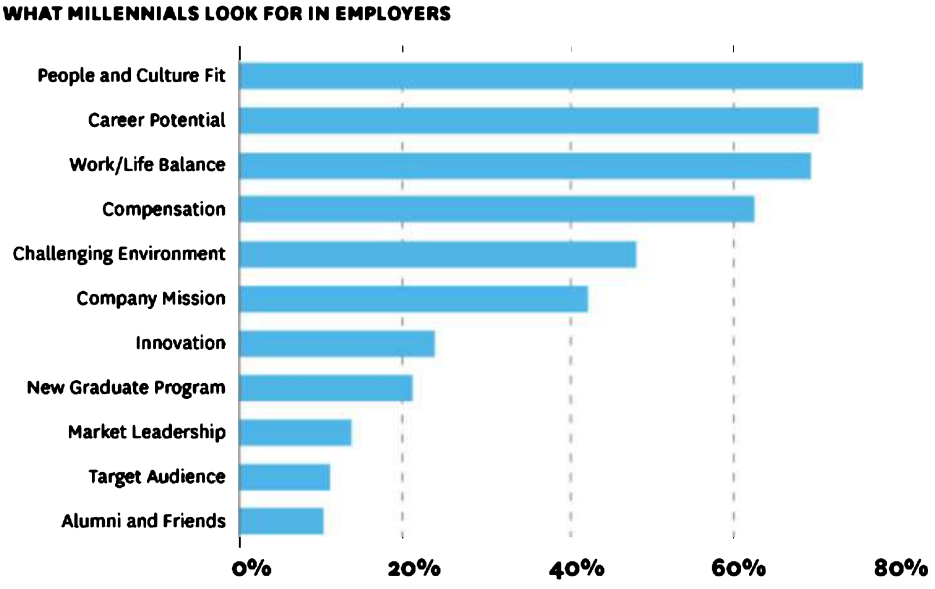

Figure 1: What Millennials look for in employers, HBR

published by Harvard Business Review, which contains answers of 15,000 polled Millennials worldwide. We have found that some assumptions and results are common for Millennials in Serbia, while other are not.

Even if criteria like company mission and market leadership are expected to be on the top of the priorities, people and culture fit and career potential are leading with more than 70%, which is similar to the responses of Serbian Millennials. Both groups of Millennials, in Serbia and worldwide, highly appreciate work-life balance, more than any other generation before.

Respondents in Serbia, 83.2% of them, evaluate compensation, as key criteria, on higher level, than respondents worldwide (about 60%).

Globally, teamwork is ranked fairly high, while among Millennials in Serbia this percentage is much lower. The cause of this probably lies in the education system and the methods used during the years of education, which vary.

6. CONCLUSION

The Millennial generation will represent 50% of the global workforce, by 2020. This generation has many specific characteristic that differentiate it from all the previous generations. This is why organizations find it challenging to create a workplace which is appealing to the Millennial generation. Obradović (2009) also points out that creating a motivating work environment is a great challenge for managers because different types of employees expect different working conditions, depending on the generation belonging.

According to Bannon, Ford and Meltzer (2011) "the challenge for businesses will be to motivate Millennials by playing to their technological strengths, embracing social networking relationships, celebrating their diversity, and helping them balance work and family".

The PwC's NextGen study (2013) suggests that emotional connection drive retention, and emotional connection can be created through providing a work-life balance, engaging work, development, different opportunities, but also through people and teams, and last, but not the least, through competitive pay.

According to this study, employers should create a flexible work culture, build a sense of a community through teamwork and constant feedback, connect with people, embrace the new technologies and social networks, encourage learning and allow faster advancement - in order to attract and retain Millennials.

SUSTAINABLE BUSINESS DEVELOPMENT

SUSTAINABLE DEVELOPMENT AS AN ALTERNATIVE SOCIETY OF THE FUTURE

Davorin Žnidarič
FOV- Kranj, Slovenia
e-mail: davorinznidaric@gmail.com

Abstract: *A quick glance at the past and recent periods of time with accumulated environmental problems in time and space, certainly can't give us any pleasure, that we have developed in the right direction as a society. Many years of materialistic exploitation of the environment and it's natural resources, forces us into a completely different concept of development of the future soceity, with it's practical and negative consequences because of the degradation in space. Rivarly, selfishness, egoism, have to be replaced with cooperation, empathy, harmony and solidarity, in between all segments of time and space. Thus between society and nature, be it living or nonliving or between individuals or society as a whole. Involving the wider society in decision-making and accountability, but the basic prerequisites for a change in attitude towards the environment and nature.*

Keywords: *environmental problems, society,natural resources, cooperation, time and space*

1. INTRODUCTION

The time we live in, has been marked by a period of neo-liberal policits, which was based on materialistic exploitation of the environmanet and it's natural resources, social and societal changes that led to the social stratification of the broadest masses and establishment of the elites and capital. At a time when the idea of Milton Friedman (author of the liberal concept and the leader of the so-called Chicago school) in the countries of South and Central America and transition countries (especially Eastern Europe), and Slovenia, was developing in all its "power" is marked by the loss of the middle class, inequality, wild transition in terms of appropriation of firms by individuals and elites, as well as the exploitation of natural resources beyond all reasonable limits. With the increase of the number of inhabitants, the development of industry and transport, have increased demands for goods which have resulted in enormous exploitation of natural resources. Consequently causing pressures on the environment and loss of natural habitats and biodiversity by reducing the animal and plant species. If we have lost 0,2 to 0,5 species in a natural way in a period of a million years (Rockstroem & others in Plut, 2010), we have lost 30% of biological wealth of the planet from 1970 to 2008 (WWF& Living Planet Report, 2008), which can not be replaced by any kind of material assets. The consequences of such practices in and on the environment have led to changes that may be in the area combined with a common denominator as:

- changes in provincial land use and vegetation
- changes in the composition of the atmosphere
- changes in the composition of natural communities and biodiversity loss

Among the anthropogenic (manmade) effects on biodiversity by Jones (2004 in Plut 2010) we can include the following key factors:

- deforestation, primarily due to agriculture
- the use of mineral fertilizers and protective agents for the control of agricultural ecosystems
- increasing urban and industrial land use, thereby burdening the environment
- increasing pressures on flora and fauna due to the growth in population and habitat loss
- climate change due to fossil fuel use

Environmental and social degradation, increasing social disparities and pressures on nature, force us to seek alternative routes for the existence of the planet. Many of domestic (Plut, Kirn, Luksic, Vintar - Mally) and

foreign experts (Bookchin) are of the opinion that radical social changes are necessary if we want to change, or at least maintain the state in which we currently live in and future generations will live in and at the same time enable more or less a decent life. Currently the only option is given by sustainable development, based on the balance of society, the environment-nature and economy-industry. It is a way, which should replace the neo liberal, materialistic concept, because that in the long run leads to shortage (some parts of the world already) and conflict among civilizations, such as the nature.

2. SUSTAINABLE DEVELOPMENT - BASIC CONCEPTS

The concept of sustainable development today can be traced on different levels and different topics. Munro (1995) suggests that it is reasonable to separate sustainability or sustainability as a concept and a key assessment criterion for development and sustainable development as an achievable goal. And states (Munro, 1995), that sustainable development is "a set of activities that would permanently improve the situation for humanity" or "improving the quality of human life within the supply capacity of ecosystems." Thus conceived definition, (Plut in Plan B, 2007) excludes any "sustained economic growth and sooner or later exceedes the universal ecosystem, biophysical capabilities and limitations." The concept of sustainability (Plut, 2004) is seen as a three-dimensional concept, which integrates environmental, social and economic note, but it is necessary to add another two fields, namely a democratic political decision-making process and society's value system. Mansfield (2009) states that the concept of sustainability must include not only technical, but also ethical and political field power centers, which have a strong influence on the creation and on the other hand, solving environmental problems (Mansfield in Plut, 2004). Plut (2014), sustainable development is seen as the environmental, economic and social responsibility, based on a comprehensive, multi-faceted inter-generational responsibility, which is based on the well-being of humanity in the context of local and global capabilities. Most cited but rather vague, is the definition given by the World Commission for the Environment and Development, or the so-called Brundtland Commission, which by one of the definitions, defines sustainable development as; "development that meets the needs of the present without compromising the capacity of future generations to meet their needs "According to WCED (2015) Sustainable development is a delicate balance between the human need for improved lifestyle and a feeling of well-being on one hand, and preserving natural resources and ecosystems on which we and future generations depend. Sustainable growth and development, therefore, are based not only on economic growth but are designed to lead to social and environmental benefit, based on stability, therefore, in the context of environmental, social and economic constraints. That modern civilization has reached the point where we have already reached the limits of the biosphere, and in some cases we have also already exceeded, which has to be dealt with and the need to consciously abandon the paradigm of sustainable economic growth and the associated burden on the planet, is also pointed out by Kirn (2012). Kos (2016) is of the opinion that economic growth has to be in balance with social and environmental performance. Plut (2004) in the article Planet and Slovenia faces the challenges of globalization and sustainable development and states, that "the economy is environmentally acceptable only if it satisfies the principles, the principles of environmental sustainability (sustainability), based on the ecology."

Environmental and social interpenetration instead of discernment of nature and human activity is also pointed out by Mansfield (2009), who discusses the current development model of modern civilization and the proposed adjustment of the economic sub-system capabilities of a wider planetary ecosystem. Sustainable development, such as integration, interdependence, coexistence of three separate fields of the economy, environment and society are determined by Bell & Morse (2003).According to Omladič (2011), a sustainable model can be defined as the pursuit of the four core objectives of mankind, enabling the satisfying of basic human needs and well-being of humans and all other creatures, achieve a more equal and more comparable level of life of all people within the (local, regional) and outside the regional Community. In the development we must consider biodiversity in terms of maintaining it and minimizing pressures on the environment. The last goal, Omladič (2011) states is that development should not undermine the ability of future generations and to simultaneously provide a similar or better standard of living than it is now. Importance of the sustainability, individual organizations such as the Sustainable Seattle, define as "long-term, cultural, economic and environmental health and vitality", with an emphasis on long-term, "along with the integration of social, financial and environmental prosperity " or "improving the quality of

life, taking into account the capacity of the planet" (World Wide Fund 2016). According to Pearce, Makandi & Barbier (1989) Sustainable development involves the creation of a social and economic system that with growth in real income, will help improve the standard of education, quality health care, thereby improving the quality of life. That the definitions of the concept of sustainable development are almost as many as individuals and professions from which they arise, and thus varying in definitions is pointed out by Seljak (2000).

2.1 Models of sustainable developments

For the optimal choice of a sustainable development, it is necessary to take into account several factors, which include, the geographical characteristics of individual areas, such as location, natural and human potential, which includes investment in society and the individual, the social situation and the development potentials of the area, environmental - ecological conditions or state of the environment in time and space. Among the most important (factors), we can include the degree of awareness of companies and individuals through participation and taking responsibility for the situation and their relationship in the area.
Lukšič (2005) mentions two approaches to the process of achieving the goals of sustainable development:
•top-down approach: in the implementation of the principles of sustainable development, the state plays a major role; (which has been in the current practice proved to be an extremely flawed option, at least in setting policies and their implementation in practice).
•bottom-up approach: there is a decentralization of power at a lower level. Local authorities have an important role in the management of local ecosystems, land use planning, are responsible for the disposal of waste, arranging local transportation, etc. (Their effectiveness and adaptability to existing problems depends on the orientation of a local policy, but in most cases do not follow the social requirements and are often better placed to defend the capital - such as Zasavje). In this case, most of the problems lie on the shoulders of local communities, not however on the shoulders of environmental burdeners, but the price is paid by all, irrespective of the fact that inhabitants and the civil society on important environmental social issues generally have no effect, or the possibility of decision-making. We believe that it is necessary that both concepts are adjusted to the reality in time and space, and connect them with eachother (national and local), so we can ensure coordinated operation and their accordance with the norms and concepts of sustainable development, and in advance, depending on the situation in the area identify certain goals and then on the basis of the given analysis find the optimal options for balancing the developments and solutions in practice.

2.1.1 Designs available to us (by Baker, Lukšič & Bahor) can be divided into four phases/periods:

- **Ideal (ecocentric) model - strong sustainability,**

Is the model, which as a desired stage of development of Slovenia and the regions belongs to the years between 2030 to 2050. The time of the near future and the continuation of the previous phases of development (a very strong sustainability) and related activities. This type of development is both a sequel and upgrade of all models of developmental stages and represents the final stage, which is completely different, with a not-materialistic concept of development of society and thought. Development rests on the foundations of a priority as environmental well-being, a moderate material prosperity for all, within the limits of the environment, it provides social security, and the predominant use of renewable energy sources. At the spatial level, upgrade continues in the direction of bio-regionalism, the dominance of eco-villages and buildings, as well as the actualization of regional and local self-sufficiency.

- **Strong sustainability**

Type of development goes in the direction of balancing economic, social and environmental areas of prosperity based on the principles of environmental ethics. At the same time the model includes market valuation of ecosystem services, which need to be incorporated into the prices of goods and services. Invest profits into new technologies that allow reducing consumption of regional resources to strengthen local and regional economies as well as the reduction of regional disparities. Looking at the policy of realization, this is based on the active participation of the public, as well as the integration of environmental considerations and environmental technologies in sectoral policies through sustainable education and training at all levels.

- **Weak sustainability**

Proponents of this model are of the opinion that economic growth and environmental protection are not mutually exclusive and, therefore, are not completely at odds. They defend the principle that future generations should not reduce the total capital, but the decrease of the natural can be compensated by increasing the created. They advocate for the global market, at the expense of modest initiatives to the local economy. Advanced concept (weak sustainability) has been committed to solving the pollution at the source. Overall, the strategic development documents of Slovenia among this model (weak sustainability), which integrates economic growth with environmental concerns, does not seek to reduce the consumption of natural resources. Therefore, Slovenia is still relying on a policy to improve substantial energy flows with the aim of (quantitative) growth. But from the perspective of a sustainable future society is by no means an acceptable way, especially given the fact that the market only partially takes into account the environmental policy (Lukšič & Bahor, 2006). Weak sustainability (sustainability) after based on the assumption that with a sufficient degree of accumulation of capital and technical developments can compensate for the depletion of natural capital. Implementation of such a policy, or a model (weak sustainability) can be "seen" in the environment as the adoption of urgent environmental measures by polluters, and even then only in case of extreme coercion, as was the case with Zasavja when the maximum polluters (Larafge cement and TET) built the desulphurisation plant only after we entered the EU and thus require policy from the outside. As a positive factor for weak sustainability we could only accept a more environmentally adapted but sustained economic growth to eliminate poverty in the world (Plut, 2014).

- **Pollution control**

Is the lowest level of realization of the greening of development, based on the exploitation of natural resources, exponentially, market guided growth, and the thesis that nature has practical value. At the spatial level tends to globalization and the exploitation of the less developed areas of the world that have looser laws in terms of environmental and social standards. Solutions of this approach are in the construction of treatment plants, thus resolving the consequences, not in terms of eliminating the causes. While maintaining or realizing policies that support capital-intensive technology. Each of the above models has its own characteristics, which makes the top-down (ecocentric model - the control of pollution) follow in the direction of greater emphasis on nature and the environment, the exploitation of natural resources, and the different spatial levels and policy realization (Baker, 2006, Lukšič & Bahor, 2006). What model and to what extent, should be selected according to environmental, social and socio - economic characteristics, which are based on the development and the level of the observed region.If the individual models are time defined according to the desired sustainable development and the current situation, the stages follow: the stage of very weak sustainability, and pollution would have long since surpassed, at least with regard to the time period (the period between 1985 to 2004), weak sustainability should have ended in the previous year (2005-2015), the most pronounced stage is still in store for us in the following years. Strong Sustainability (2016-2030) as well as a very strong one (2030 and 2050) from this year until the middle of this millenniu. Featured models may only offer support and guidance, so we can in practice choose a way of implementation of individual activities in the three supporting pillars of sustainable development, which without the active involvement of the wider community, and especially their participation will not be able to successfully perform in a way, that will satisfy all three basic segments, society, environment and economy. Especially given the fact, as the sustainable development of society and its engagement in the decision-making gives a special role and importance.

In short term the company is treated in a completely different way than a before generally valid concept, based on more vertical-hierarchical decision-making process, and is inclined to the horizontal, which includes the increasing role of the civil society. In social decision making, is therefore an increase of active roles of individuals and communities, thereby gaining an important role in decision-making on important issues, not only on the environment but also in the political field. This increases participation on the one hand and responsibility on the other hand, of the decision-making system. As stated by Lukšič (2005) active society that are "understood as those members of society who are able and willing to let their actions be guided by the rules of collective-racional and responsible self commitment", thus taking over the work and roles that were previously the exclusive domain of state institutions. The same author states, (Lukšič) that only in this way (Participation of) "individuals related to social connections and associations and movements, and environmentally aware public, thus shaping what is common best."

3. THE PILLARS OF SUSTAINABLE DEVELOPMENT

Despite the different definitions of sustainable development, the supporting pillars of the above mentioned developments are combined in the following denominators:

- stabilization of the world population,
- URE and use of OVE,
- reuse - recycling of materials,
- materially moderation installed consumerism,
- reduction of material and energy flows,
- the balance between economics, social affairs and the environment, and
- orientation to development, social, environmental, solidarity and ethics (Plan B, 2010).

If we want to survive on a planet that is spatially and materially limited, it is necessary to radically change some consumer habits. First, on a personal hereinafter even at the social level. Energy consumption, consumption goods, especially a change in thinking and attitude towards the environment must present a hierarchical way of relating to nature and the environment, which was based on the dominance of -the power of the individual- EGO, change the way of the general equality and empathy, or ECO-but among all stakeholders live and inanimate nature.

4. CONCLUSION

After Mintz (1992) we will achieve sustainable development when we can introduce participatory democracy, which will not be dominated by the interests acquired. So in the time when intergenerational solidarity and equality irrespective of skin color status dominate, based on respect for diversity, raising global awareness of environmental and social standards, which will be the same for all living beings on the planet. Planet, which according to Elliot (2003) survives only if the economy and technological activities remain sustainable within the carrying capacity of the environment and its natural resources. The society of the future will have to be based on a totally different basis, than the society of the past, we are witnessing today. The values of solidarity, cooperation, coexistence, understanding will have to be predominant in relation to society, the environment and especially nature. Conservation of fauna and flora, healthy and clean environment, not only desire, but a basic right that should not be just an empty word written on a piece of paper.

Sustainable development paradigm of the future of the society, which is based on the balance of social, environmental and economic indicators and areas, does not have an alternative if we are to survive on this planet.

SUSTAINABLE TECHNOLOGY AND BUSINESS INNOVATION PRINCIPLES – A COMPREHENSIVE APPROACH

Maja Levi Jakšić[1], Jovana Rakićević*[1], Milica Jovanović[1]
[1]Faculty of organizational sciences, University of Belgrade
*Corresponding author, e-mail: jovana.rakicevic@fon.bg.ac.rs

Abstract: *Society is looking for solutions leading to sustainable development (SD). The paper focuses on sustainable innovation in technology and business as cornerstone for developing sustainable economy and society. In this context, the paper aims to identify the key relationships and develop the key principles of sustainable technology and business innovation by integrating the general SD dimensions, sustainable business goals and technology and business innovation principles. This paper uses a systematic literature and practice review approach to formalize a categorization of technology and business innovations to deliver sustainability. The research results in the form of a comprehensive framework and contributes to the theoretical background for creating more sustainable business and technology solutions in practice.*

Keywords*: Sustainable development (SD), SD principles, sustainable technology, sustainable business model, sustainable innovation, sustainable economy*

1. INTRODUCTION

Sustainable technology and business development is viewed as the central pillar of sustainable development (SD). Relevance of the subject is based on the necessity for firms to reconcile sustainability aspects, simultaneously fulfilling all the stakeholders' needs while reaching profitability and respecting the diversified demands of social goals fulfillment (Adams, 2014; Epstein & Roy, 2001, Levi Jaksic, 2015). Traditional technology and business innovation models need rethinking (Ricart, 2014; Chesbrough, 2003, 2014; Levi Jaksic, 2006, 2015).

SD is most commonly defined as "the development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (Brundtland Report, 1987) and since then it has been developing and countries, organizations, institutions worldwide have committed towards the goals incorporating shared principles, objectives, instruments. In the past decades there is evidence of a rising interest of researchers and practitioners in sustainable technology and business innovations, especially dealing with technology innovation embedded in a business environment that contribute to developing sustainable economies and societies. (Boons & Ludeke-Freund, 2013; Bocken et al., 2014; Raney, 2006). The challenge for SD is in transforming goals, objectives and principles into concrete actions, behaviors and attitudes at all levels of the economy and society.

Radical technological breakthroughs and innovation in the light of social, economic and ecological impacts and goals, call urgently for new business and technology models and solutions. In this paper the key dimensions of sustainable development (SD) are transformed into sustainable business goals, and further extended to technology and business innovation principles related to these goals.

Sustainable business development rests upon sustainable technology and innovation, and managing technological change directly influences sustainable competitiveness of business operations (Popa, 2014; Rainey, 2006; Levi Jaksic, 2012; Porter, 1985; Chesbrough, 2006; Levi Jakšić, 2006, 2007, 2012, 2015; McIntyre et al., 2013) and more specifically "it is indeed at the strategic level that sustainable development can fully uncover its value creation potential for a company" (Sempels & Hoffman, 2013, p. 3). The relevant literature and practice review shows that in some cases, sustainable solutions in industrial practice appear to be ahead of academia in exploring and developing novel business models (Bocken et al., 2014; Chesbourough, 2014; Moore, 2014).

The remainder of the paper is organized in the following manner: Section 2 presents literature review and basic concepts elaborating the main objectives and hypothesis of a comprehensive approach towards sustainable technology and business innovation. Section 3 elaborates on the relations between SD dimensions, sustainable business goals and sustainable technology and business innovation by developing a set of related matrices. Section 4 deals with concluding remarks, indicates limitations as well as elements of future research. At the end the References are presented.

2. THEORETICAL BACKGROUND – BASIC CONCEPTS OF TECHNOLOGY AND BUSINESS INNOVATION MODELS

The aim of this paper is: 1. to investigate the relationships between the SD dimensions, sustainable business goals and Sustainable Technology and Business Innovation principles and models, and 2. to develop a comprehensive framework for a systematic approach towards business sustainability leading to more direct firm strategies for capturing the sustainability synergetic effects. The problem is approached through developing a model of related matrices establishing relationships between SD goals focusing sustainable economy routes and dimensions, sustainable business goals and technology and business model innovations. More precisely, the paper deals with the overall strategic perspectives of business, technology and innovation management for sustainable development. The research is based on perspectives of conceptual reflection in literature and is based on methods of analysis and synthesis, of interpretation and relevant comparisons.

Technology and business innovation drive the economy towards achieving the sustainable development goals. The technology we use in performing business operations affects the environment, society and economy, and in this way technology and business enterprises are generators of potential damage and unwanted effects to global environment, while simultaneously, they are the key solutions to these problems by developing sustainable technology for sustainable businesses. Hence, the emphasis is on technology and business innovation, where sustainable technology and business strategy is approached through sustainable business, technology and innovation principles and models (Adams, 2014; Mendelson, 2014; Hall et al., 2010). "If the business model cannot align economic, environmental and social issues, the only credible solution is to change it....the business model should be innovated by integrating sustainability in order to build or keep a competitive advantage in an ever changing economy" (Sempels & Hoffman, 2013).
In the Society and Environment Pull Business Model (Levi Jaksic, 2015), the external and internal factors of the firm environment are interrelated in a virtuous cycle model with social and environmental objectives affecting sustainable business strategy, leading to business and technology innovation, further affecting the processes of creating and delivering value in the form of goods and services which are by market reaching customers and are affecting consumption, further influencing the fulfillment of the initial social and environmental objectives.

Review of relevant literature on the definitions of business model, it is evident that the concepts of technology and business innovation are closely linked. A business model is a conceptual tool to help understand how a firm does business and can be used for analysis, comparison and performance assessment, management, communication and innovation (Osterwalder & Pigneur, 2005). Also, a business model is used as a plan which specifies how a new venture can become profitable (Boons & Ludeke-Freund, 2013) and it describes "how companies create and deliver value to their customers and how they get rewarded for doing that" (Mendelson, 2014; Callon et al., 2007).

The relevance of business model innovation in delivering greater social and environmental sustainability is increasingly recognized and all the relevant components of the Business Model are to be included (Bocken et al., 2014). It means changing the ways you do business and shifting the focus from developing individual technology towards creating new systems, with a broader perspective of stakeholders necessitating a value network perspective for innovating and transforming the business model (Bocken et al., 2014). In the relevant literature, business model consists of different blocks: value proposition, value architecture and economic equation (Sempels & Hoffman, 2013), or value proposition, supply chain, customer interface, financial model (Boons & Ludeke-Freund, 2013). In this paper a business model is defined by three elements: value proposition, value creation, and delivery and value capture.

In this paper, technology innovation is approached by adopting the OECD definition (1995): "Technological product and process (TPP) innovations comprise implemented technologically new products and processes and significant technological improvements in products and processes. A TPP innovation has been implemented if it has been introduced on the market (product innovation) or used within a production process (process innovation)". In this definition 'product' comprises not only manufacturing output, but also services (Cetindamar et al., 2009).

An answer to the dilemmas concerning the relations between business model and technology innovation, especially the dilemma of which is more significant "the hen or the egg", could be found in the brief statement by Chesbrough (2014) "Innovate the business model, not just the technology" further explicated as "a better business model often beats a better technology". In this article it is argued that sustainable technology innovation is inseparable from sustainable business, as represented in the Sustainable Technology and Business Innovation Push - Pull Model (Levi Jaksic, 2015).

3. RESEARCH FINDINGS

Business models have received attention in literature and industry and it is increasingly suggested that business model innovation is the key to business success (Chesbrough, 2006, Boons & Ludeke-Freund, 2013, Bocken et al., 2014). The main question and concern is how to encourage corporate innovation that significantly changes the way companies operate to ensure greater sustainability. "Sustainable business models with a focus on technological innovation are market devices that overcome internal and external barriers of marketing clean technologies: of significance is the business models ability to create a fit between technology characteristics and (new) commercialization approaches that both can succeed on given markets" (Boons & Ludeke-Freund, 2013).

3.1. Sustainability goals in innovative company practices

Innovative firm performance measures (Epstein, 2001; BRW, 2015; FastCompany, 2015; FastCompany, 2016; FORBES Innovative Companies, 2016), the main indicators used for innovativeness and the results of the analysis identify sustainability goals as the main driving force for innovation.

The results of a detailed analysis of innovative performance of companies from the *FastCompany* list presented in Table 1. The table indicates the rising relevance of sustainable goals embedded in technology and business innovation. The list taken into consideration includes analysis of 100 companies, 50 most innovative companies in 2015, and 50 in 2016. As it is shown in Table 1, 73.20% of companies have at least one component sustainable (technology and/or business model).

Table 1: Share of each SB&T model combination on the selected sample

		Business model		
		Existing	New	Sustainable
Technology	Existing	0%	7.22%	**17.53%**
	New	5.15%	14.43%	**17.53%**
	Sustainable	**13.40%**	**4.12%**	**20.62%**

These companies are considered further in order to examine which component of sustainability they focus on the most (environmental, economic, or social). Table 2 refers to the analysis of sustainability aspects of technology, examining existing, new or sustainable business model. It is evident that in all these cases, the main focus is on economic and social aspect of sustainable technology, but is important to emphasize that all the three aspects of sustainable technology are present.

Table 2: Analysis of presence of sustainability aspects in technology

	Sustainable technology		
	Environment	Economic	Social
Existing business model	38.46%	92.31%	69.23%
New business model	25.00%	100.00%	100.00%
Sustainable business model	45%	80%	85%

Table 3 refers to the analysis of sustainability aspects of the business model, testing three technology cases (existing, new or sustainable). Again, the results indicate that although companies focus mostly on economic and social aspects of the business model, in all the cases ecological aspect is detected.

Table 3: Analysis of presence of sustainability aspects in business model

	Sustainable business model		
	Environment	Economic	Social
Existing technology	41.18%	88.24%	88.24%
New technology	35.29%	88.24%	100.00%
Sustainable technology	30%	88.24%	100.00%

3.2. The related matrices of SD dimensions, sustainable business goals and sustainable technology and business innovation

The complex goals of sustainable development (SD) are based on a set of social, economic and environmental equations, noted as the Triple Integrated Equation (TIE). Within this framework the principles of sustainable business and technology innovation are developed involving 'a holistic view of the business environment taking into account social, economic and environmental considerations as well as the more conventional concerns of customers, markets, and competition" (Rainey, 2006). The crucial goals of SD are in relevant literature examined as specific "routes" or "principles" leading to sustainable economy and society.

The "route to sustainable economy" (Jackson, 2009) postulates the characteristics of a sustainable economic system. "Hannover" principles were developed for the purpose to articulate the basis for integrating business management with the realities of humanity and nature (Raney, 2006) comprising the following: insist on the rights of humanity and nature to coexist; recognize interdependence; respect relationships between spirit and matter; accept responsibility for the consequences of design; create safe objects of long term value; eliminate the concept of waste; rely on natural energy flows; understand the limitations of design; seek constant improvements by sharing of knowledge.

Based on relevant literature and practice review we have identified the following dimensions of sustainable economy:

- Circular economy, defined by the rule of transforming 'waste' into a productive resource and transformation from linear to circular flows in the economy, cited as the "new industrial system that replaces 'end/of life' concept by restoration and regeneration by intention and design" (Sempels & Hoffman, 2013). In this manner each product at the end of its life time or each waste is likely to become a resource for a new cycle of production.
- Substituting with renewables, alternatives and natural processes in order to preserve the natural environment and reduce the exploitation of scarce natural resources. It is defined as reducing environmental impacts and increasing business resilience by addressing resource constraints associated with non-renewable resources.
- Minimizing consumption is related to the overall change of attitudes and behaviour of all the actors in the economy and society, based on a new philosophy of economic and social relations. It is also defined as solutions actively seeking to encourage sufficiency based business models reframing the value proposition to better address the broader range of stakeholders (Bocken et al., 2014).
- Establishing S-E benefit/cost relationship, related to maximizing S-E benefits and minimizing S-E costs based on rethinking and reconsideration at a global scale the principles and models that have been developed in the traditional approaches and applied in practice. Field and Field (2006) argue that the social cost components include the external costs. It is a cost that appears for society and the environment caused by the activity of an enterprise. "Social entrepreneurship provides a social value from its business activities which has an impact on society or the environment" (Bagus & Manzilati, 2014). The rethinking of the business models includes efforts to appraise the costs and revenues in a broad social and environmental perspective, and some solutions introduce Costs and Benefits for Society and the Environment in the sustainable business models (Sempels & Hoffmann, 2013).
- Positive and motivating work experiences enhancing human creativity and skills is emphasizing the satisfaction of working population as the driving force of creativity and innovation.
- Collaboration and sharing rather than aggressive competition is a quest for more integration and cooperative solutions in the activities of the agents in the economic system. It means strategic orientation towards Blue Ocean strategy (Sempels & Hoffmann, 2013).
- Factor 4 is defined as a strategy of halving resource use and doubling wealth indicating integration of the triple equation goals (Bardy & Massaro, 2013).

In Table 4 the dimensions of sustainable economy are related to Sustainable Business Goals (SBG) and presented in a matrix relationship model. It is noted that the elements of the matrix do not represent an exhaustive list; it is open for new considerations.

The SBG are listed as follows:

- Maximize material and energy efficiency, based on material productivity resource efficiency and waste reduction. It means doing more with fewer resources and generating less waste, emissions and pollution. It is in line with the traditional cost reduction goals of the manufacturing sector designated as 'lean manufacturing' seeking to minimise waste in production processes;
- Create value from waste is the concept by which waste is eliminated by turning waste streams into useful and valuable input to other production and making better use of underutilized capacity;

- Zero waste & emissions goal sets high business operations quality management standards and procedures;
- Delivery of functionality rather than product ownership is a strategic goal to provide services that satisfy users' needs without having to own physical products (Bocken et al., 2014);
- Stakeholder satisfaction is a goal that identifies the interests of firm's various stakeholders and articulates the specific goals and strategy to satisfying these goals. The company responds to all stakeholders' needs: those of consumers, employees, suppliers, local community and other stakeholders (Adams, 2014, Epstein, 2011);
- Reduce costs as the general goal reducing all costs is specified also in relation to identifying all the costs in the long-term perspective of business operations affecting the society and the environment, including all the costs: direct, indirect, hidden, external and publicly imposed (Rainey, 2006).

Table 4: Matrix relationship between Sustainable Economy Dimensions (SED) and Sustainable Business Goals (SBG)

SBG → / SED ↓	Max. material and energy efficiency	Create value from waste	Zero waste & emissions	Deliver functionality rather than product ownership	Stakeholder satisfaction	Reduce costs
Circular economy		x			x	x
Substitute with renewables	x		x		x	x
Minimize consumption				x	x	
Maximize social and env. benefit	x	x	x		x	
Positive work experiences enhancing creativity & innovation					x	
Collaboration and sharing			x	x	x	
Factor 4	x	x	x			x

In Table 5 the matrix relations between Sustainable Business Goals (SBG) and Sustainable Technology and Business Innovation (ST&BI) principles are established and an open list of the ST&BI principles is listed as follows:

- Open, agile T&B innovation platforms, open models of technology and business in literature often cited as frugal, lean, sustainable, eco innovation and business models. Open innovation models (Chesbrough, 2003, 2006, 2014) integrate a significant number of players across multiple roles in the innovation process expanding beyond the limits of a single organization. Open innovation is a process that makes more effective use of internal and external knowledge in every organization (Chesbrough, 2014). The platform model is an open business and innovation model and considered as the most valuable kind of business model as it can inspire and motivate customers and developers and others to join the platform (Mendelson, 2014). Open innovation is an approach that seeks the systematic adoption of partnerships in the innovation process rather than resorting to internal R&D structures as in the classic model of innovation (Caetano & Amaral, 2011; Chesbrough & Appleyard, 2007).
- Use-oriented Product-Service Systems are based on the transition from products to use- oriented services which are aimed to redefine the relation with 'tangible' goods, by making them available without transfer of ownership with numerous examples and possibilities: hiring, leasing, pooling, shared consumption. It is the transition from ownership to usership (Sempels and Hoffman, 2013), often cited as “servicification, service transition, product-service systems (PSS), Integrated product service engineering” (Reim et al., 2015).
- Reuse, and recycle, also referred to as re-manufacture, up-cycle or down-cycle means reuse of non-renewable materials including fossil fuels, which means that waste and emissions are either avoided or up-cycled. Up-cycling (Bardy & Massaro, 2013) denotes up-cycling as a kind of recycling that produces materials of at least equal quality while down-cycling converting materials and products into new raw materials of lesser quality
- Eco-efficiency and eco-design in a broad manner, for companies means applying the principle of “doing more with fewer resources” and it applies to both products and services. It comprises “reconsideration

of the design of a product, a service or a process in order to decrease its environmental impact" (Sempels & Hoffman, 2013). Eco-design principles are based on the whole life-cycle approach and comprise considerations on the functionality of the product to improve usability and use efficiency, reduce the material and energy intensity and minimise the use of non-renewable resources, minimize toxic components, introduce durability, easy maintenance (Sempels & Hoffman, 2013).

- Value constellation platforms are related to reframing the company activity considering the stakeholders in the value constellation instead of the value chain alone (Sempels & Hoffman, 2013).
- Decouple product from revenue, i.e. decouple revenue generation from raw materials and energy consumption based on the approach 'guarantee of result' instead of the sale of the means to reach that result, which entails the transition from product to result based integrated solutions (Sempels & Hoffman, 2013).

Table 5: Matrix relations between SBG and ST&BI principles

ST&BI principles → / **SBG ↓**	Open, agile T&B innovation (platforms)	Cradle-to-cradle	Use-oriented Product-Service Systems	Reuse, Recycle	Eco-efficiency Eco-design	Value constellation platforms	Decouple product from revenue
Max. material and energy efficiency	x			x	x	x	x
Create value from waste		x		x	x	x	x
Zero waste and emissions				x	x		
Delivery of functionality rather than product ownership	x		x			x	x
Stakeholder satisfaction	x	x	x			x	x
Reduce costs	x			x	x		

In Table 6 the matrix relations between ST&BI principles and Technology and Business Innovation Models are presented. Technology Innovation Model is defined by the innovation of products and innovation of process, while the business innovation model is represented by the innovation of the basic business model components: value proposition, value creation and delivery, and value capturing. The assertion is that with careful business model redesign and sustainable technology innovation it is possible for mainstream businesses to readily integrate sustainability into their business and for new start-ups to design and pursue sustainable business from the outset (Bocken et al., 2014).

Table 6: Matrix relations between ST&BI principles and Technology and Business (T & B) Models

T & B Model →	Technology innovation		Business Model Innovation		
ST&BI principles ↓	Product	Process	Value Propos	Value creation and delivery	Value Capture
Open T&B innovation (platforms)	x	x	x	x	x
Cradle-to-cradle	x	x			
Use-oriented Product-Service Systems			x	x	x
Reuse, Recycle	x	x			
Eco-efficiency Eco-design	x	x			
Value constellation platforms			x	x	x
Decouple Product from Revenue			x	x	x

4. CONCLUSION

As result of the review of the literature and analysis of main concepts introduced in this paper, we come to the conclusion that the concepts of sustainable innovation and sustainable business are converging. It is difficult to draw a line as innovation is understood as commercialization of invention (idea), referring to its market introduction and transfer. Focus on technology and innovation for economic growth and socio-economic development puts stress on technology innovation for achieving sustainable socio-economic development. "Research and experimental development (R&D), when appropriately valorised, lead to technological innovation in the form of new products and processes, which contribute to growth, competitiveness and job creation, and which produce other societal benefits" (Delanghe & Muldur, 2014). Relevant practice review shows that sustainability benefits are achieved often only through combining several approaches, e.g. car sharing without an efficiency focus (e.g. fuel efficiency as a new technology) is unlikely to enhance sustainability since the vast majority of its environmental impacts are in the use phase, not in the manufacturing of the machine (Bocken et al., 2014). Synergy effects are present by combining sustainability efforts at both technology and business innovation.

It is also ascertained that not all the technological solutions are in line with SD goals. The necessity to develop sustainable technological innovation and sustainable business models based on the Triple Integrated Equation involves a change and rethinking of our traditional technology and innovation models. The "idea to idea", "cradle-to-cradle" and complete "life cycle assessment- LCA" concepts and approaches (Sempels & Hoffmann, 2013) introduced in the early phases of research and development and innovation processes, lead to sustainable business solutions in the complete life cycle perspective - idea, innovation, market, exploitation, end of life, new ideas for the next innovation cycle. The solutions emerging from practice indicate new principles with an integrated aim of sustainability and embedded in both business and technological domains.

CORPORATE SOCIAL RESPONSIBILITY: PHILANTHROPY, OBLIGATION OR UTILITARIANISM?

Vesna Stojanović-Aleksić[1], Aleksandra Bošković*[2],

Abstract: *This paper examines the basic motives for the implementation of CSR, with a special emphasis on the relationship between motives and the level of engagement in this area. The aim is to explore the interdependence between the various motives and the level of development of specific CSR aspects in the context of its internal and external dimensions. Our findings indicate that CSR in general, and especially internal CSR are more developed when management is primarily motivated by ethical factors, while certain aspects of external CSR are on a higher level in companies whose management highlights strengthening brand and image as the most important motivators. Also, CSR is lower when adopted standards are the main motivators. The contribution of the paper is reflected in the different perspective of problem area, and in the discovery of new insights, which are the basis for future research, but also useful information for management.*

Keywords*: corporate social responsibility, motives, sustainable business, philanthropy, obligation, utilitarianism*

1. INTRODUCTION

Are the motives for corporate social responsibility (CSR) truly philanthropic, or is it just a cover for the achievement of some other, primarily financial or market objectives? Devinney (2009) believes that an enterprise cannot be truly socially responsible, even in the narrowest sense and that the concept of CSR is an oxymoron, just because corporations must balance between the different interests, which are, by their nature, conflicting, and it is naive to believe that their activities are designed according to the requirements of society. Companies actually manipulates social, in order to achieve their own goals. The author presents a rather extreme position, believing that paradigm *do-well-by-doing-good* reflects an unrealistic goal, a noble idea, which is unfeasible in practice.

Contradictory situations, in which the motives of CSR come into question, often occur in practice. The behavior of some well-known multinational corporations, in countries where the law does not sufficiently protect employees, consumers and the environment, is the subject of a negative public criticism. On the one hand, companies state that social responsibility is a key set of values, which they aspire to. On the other hand, they implement activities that are legal in underdeveloped parts of the world, but significantly deviate from the generally accepted code of ethics, as for example: difficult working conditions, inadequate reward system, non-implementation of environmental standards and so on. Likewise, many companies hire graduates as volunteers, thus emphasizing providing opportunities for learning and gaining experience to young people. However, the question remains whether this is the right motive, or the motive is the reduction of labor costs. It is very difficult to give a precise answer on these questions of ethical nature.

There have been made significant research efforts in the area of corporate social responsibility (European Commision, 2011; Devinney, 2009; Aguilera et al., 2007; Porter & Krammer, 2006; Kotter & Lee, 2005; Garriga & Mele, 2004; Carroll, 1999; Committee for Economic Development, 1971; Freeman, 1984; Davis, 1967; Bowen, 1953), but there are still doubts regarding the real motives and goals of these activities (Dare, 2016; Petrenko, 2016; Aguilera et al., 2006; Munilla & Miles, 2005;), as well as their effects on business performance (Surroca et al., 2010; Margolis et al., 2007; McWilliams & Siegel, 2000), but also on the environment and society. Therefore, it is necessary to further investigate the field of CSR of business organization. Particularly relevant issue relates to the underlying factors that motivate management to take initiatives in this area, since it affects the course of action and the level of CSR. Bearing in mind the lack of evidence of this interdependence in the previous research, the work is driven by the desire to overcome the

perceived gap, as well as to emphasize a different perspective on CSR, taking into account the motives that drive this activity, which is the main research subject.

According to determined subject, the basic aim of the research is to determine the extent to which differences in the level of CSR development occur as a result of differences in terms of the key CSR motives. Derivative goal is to explore the underlying factors that motivate management to undertake CSR activities, and to determine how they affect the level of internal and external social responsibility.

2. LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Attempts to define corporate social responsibility began in the mid-twentieth century, but even today there is no universally accepted definition. One of the first definitions is given by Howard R. Bowen (1953): "*Social responsibility refers to the obligations of businessmen to pursue those policies, to make those decisions, or to follow those lines of action which are desirable in terms of the objectives and values of our society*". However, the conceptualization of social responsibility as the obligation is subject to denial in contemporary approaches. One of the latest interpretation of the concept of CSR is one by the European Commission (2011, p.3.) that explains social responsibility as a concept in which companies voluntarily integrate social and environmental issues in their business operations and in their interaction with stakeholders. So, it is about activities that cross the border of obligations prescribed by law, and are based on altruism and philanthropy. The company should be responsible in relation to its internal and external environment, and to all stakeholders, such as employees, business partners, suppliers, customers, governments, non-governmental organizations, who represent the interests of local communities and the environment, and society in general. But above all, they must be able to make a profit that allows a sustainable competitive position. In order to achieve this, CSR must be effectively managed and supported by adequate organizational structures (Vlastelica Bakić, et al., 2015).

Although the socially responsible behavior is often seen in the context of external responsibility towards the environment, we should not neglect the inner dimension which mainly relates to employees. *Internal dimension of social responsibility* involves taking care of employees' health and safety at work, beyond the limits imposed by law. It includes respect for individual differences and problems that members of the collective are facing, promoting humanity and concern for people, which is not limited to the working hours but also includes an attempt to achieve a balance between work, family and leisure time. Extremely important dimension of internal responsibility relates to equal opportunities for training and learning. *External dimension of social responsibility* applies to all external stakeholders, ranging from clients to business partners, local communities, and national levels, and often the wider regional and even global environment (Stojanović-Aleksić & Bošković, 2015).

In answering the question of why companies implement social responsibility, we should start from the results of previous studies, which point to the various factors of motivation. First, it is useful to consider the main benefits of this way of doing business for the company, since they can represent important motivators. In the market economy and extreme competition in the global market, economic motives play an important, and perhaps even the most significant role in making decisions on the implementation of socially responsible activities, which is totally understandable. After all, companies are profit organizations, and it is illogical to expect from them to take actions that are inconsistent with the goal of achieving positive financial results. No matter what, the economic dimension is still the first one within the pyramid of social responsibility (Carroll, 1991). However, the link between CSR activities and financial performance is very difficult to measure, and previous research has lead to conflicting results. A group of authors conducted a meta-analysis that included 192 studies on the above relationship, and a survey showed the existence of a positive, statistically significant but small effect ($r = 0.132$) of the CSR on financial performance (Margolis et al., 2007). Present difficulties in quantifying this interdependence are primarily reflected in the fact that the financial effects of social responsibility are difficult to measure in the short term, and that this area of business, by creation of intangible resources, has many positive implications in the long term. An organization directly or indirectly generate a series of benefits through CSR, including: strengthening the brand, improving the image, strengthening the ability to attract, motivate and retain employees and consumers (Kotter & Lee, 2005, p.12), which in the long run leads to a reduction in operating costs and improvement of the competitive position (Porter & Krammer, 2006). Besides the enhancement of the share in the domestic market, CSR can be seen as a determinant of international success (Mitic, 2007). In terms of globalization, public pressure is growing and forcing international companies to coordinate their activities with the requirements of the community. In fact, CSR is not an innovation any more, since vast majority of international and multinational companies apply this concept. Moreover, it is one of the key prerequisites for success in the global marketplace. In addition, irresponsible behavior, if it finds the condemnation of the public and consumers, mainly causes high

losses, which are difficult to compensate. Accordingly, the potential positive effects, even in a very long period, are far more profitable than any possible harm to the company. In addition, studies have shown that the involvement of companies in socially desirable activities, leads to greater employee satisfaction (Koh & Boo, 2004) and their positive emotions (Onkila, 2015). Therefore, social responsibility can play an important role in retaining existing workforce, but also in attracting new high-quality workers, affecting the perception of people on the organizational culture as friendly and humane.

However, social responsibility should not be seen only as a means to improve business results. Aguilera et al. (2006) distinguish between instrumental, relational and moral CSR motives. The *instrumental motives* are related to the previously explained efforts to reach certain financial benefits by engagement in CSR. *Relational motives* are related to conformation with emerging industry norms, while *moral motives* explain the tendency to be operating in accordance with the beneficiaries' best interests. Managers, encouraged by moral motives, engage in CSR due to a higher purpose to help humanity. Particular attention should be paid to the interdependence of CSR motives and the level of CSR development. Starting from this presented model, Dare (2016) analyzed the impact of these three groups of motives on CSR commitment and proved that firms with a dominant moral motive tend to hold a higher commitment to CSR than firms with a dominant instrumental motive.

On the other hand, Munilla & Miles (2005) started from the theoretical framework developed by Van Marrewijk (2003), which is shown in Table 1. However, they classified motives into three groups: *strategic motives*, referring to the observation of social responsibility as an investment in improving operations and competence; *compliance driven motives*, referring to the observation of CSR as an obligation to society and *force driven motives*, ie. CSR expenditures perceived as a "tax" being mandated by NGOs or other external stakeholders that will diminish the firm's ability to create value for other relevant stakeholders. The same authors argue that strategic orientation can positively affect employees' contribution to creating added value for customers and the local community, while observing CSR as forced may adversely affect the motivation of employees, which leads to the alienation of certain groups of customers and a negative reputation among stakeholders, who represent the local community. Compliance driven motives showed no particular impact on any aspect of social responsibility.

Table 1: CSR motives according to Van Marrewijk (2003)

CSR motives	
Compliance	CSR as a social obligation - perception of CSR expenditures as simply a cost.
Profit	CSR as a strategic initiative - using CSR to create competitive advantage and superior financial performance. CSR expenditure perceived as an investment.
Caring	Using CSR to balance the triple bottom line of profits, people, and planet. Social and/or environmental responsibility trumps economic responsibility.
Synergistic	Use of CSR to attempt to create a "sustainable corporation". Social and/or environmental responsibility is strategically used to create competitive advantage and meet the corporation's economic responsibilities.
Holistic	CSR as a corporate culture. Social and/or environmental responsibility is strategically used to create competitive advantage and meet the corporation's economic responsibilities.

Source: Munilla, L.S., Miles, M.P. (2005). The Corporate Social Responsibility Continuum as a Component of Stakeholder Theory, *Business and Society Review*, 10 (4), p. 377.

Starting from the presented theoretical conceptualization and the results of previous research, we occupy a relatively different perspective on the problem. In this paper, we analyze several major groups of motives for CSR. Primarily, these are *instrumental motives*, which include strengthening the brand and corporate image, improving competitive advantage and increase of profits. Instrumental motives are viewed as utilitarian, because they are based on the principle of utility. Observation of CSR as a mean for achieving these goals can result in a greater involvement of the company in all aspects of external CSR, since activities, such as humanitarian actions, actions with the aim of contributing to culture, sports, environmental protection and publication of information about CSR, are often widely promoted and can directly affect financial results. The second group refers to *philanthropic motives*, which in this study encompass the tendency to increase employee satisfaction, and the different motives of moral or ethical character. Companies, whose management is encouraged by these reasons for investing in CSR, should have a higher level of internal CSR, i.e. concern for the welfare of employees. Besides, it can be expected that these motives have a positive effect on all aspects of CSR. The third category refers to an *obligation* to meet the requirements of adopted international quality standards. The paper starts from the assumption that these reasons, in the

absence of other motives, indicate an underdeveloped awareness of the importance of CSR and can have a negative impact, both on internal, and on external social responsibility.

Starting from the theoretical foundations and the results of previous empirical results, we developed a set of hypotheses which are practically tested. The hypotheses are:

H0: The level of CSR will be different among companies, if there are different CSR motives.

H1: The level of internal social responsibility will be higher, if the motives are philanthropic.

H2: The level of external social responsibility will be higher, if the motives are instrumental.

H3: The level of CSR will be lower if CSR is viewed solely as an obligation to respect the adopted international quality standards.

3. DATA AND METHODOLOGY

3.1. Methods for data collection and processing

Besides an overview of the current domestic and foreign literature, in order to develop an adequate theoretical basis as the starting point, we realized an empirical research by distributing the questionnaire in the period from March to June 2015. The sample consisted of 24 corporations, including 80 respondents, managers of various hierarchical levels in corporate sector in the territory of the Republic of Serbia. Their answers are the primary data, based on which we derived conclusions on various aspects of CSR, as well as the most important CSR motives.

Data analysis was performed using relevant methods and techniques of software Statistical Package for Social Sciences (SPSS) 20.0. We analyzed the structure and characteristics of the sample, using descriptive statistics. Reliability of a scale was analyzed using Cronbach's Alpha coefficient, with the calculated reliability of measurement scales, which amounts to 0,890, indicating a high degree of reliability, since the questionnaire consists of 30 items. One-way ANOVA was applied in order to test the hypothesis, i.e. to determine statistically significant differences in terms of social responsibility in corporation with different dominant CSR motives.

As an instrument for data collection, we used an adapted questionnaire that consists of 30 questions. The starting point for creating questionnaire are empirical studies conducted by the Dam & Scholtens (2012), Oh et al (2011), Sánchez et al (2011) and a questionnaire of Serbian Chamber of Commerce, developed for comprehensive research in order to select the most prominent organizations in this field. Renovated structure of the questionnaire is the result of authors' original scientific approach, according to a defined subject and objectives of the research. *The first part* of the questionnaire includes questions on key CSR dimensions. The respondents answered the questions, on the basis of the degree of agreement with the statements, using a five-point Likert scale. *Second part* consists of closed questions about CSR motives. General information about respondents were collected from the five questions that make up *the third part* of the original questionnaire, and relate to gender, age, position in the organization, years of service and level of education.

3.2. Sample

On the basis of random selection, we contacted more than 60 companies and distributed 233 questionnaires. However, 80 respondents from 24 companies responded the call. Genders are equally represented in the sample. The most numerous are the respondents in the age category 36-45 years (48.8%) and the sample mainly consists of respondents with 16-25 years of service (38.8%). As for formal position, operational managers (51.3%) are dominant in the sample, immediately followed by middle management (42.5%), while the top management ranks 6.3 % of the sample. The low percentage of members of the highest level is caused by difficulties in contacting these subjects, as well as their poor motivation for participation in scientific research.

4. RESULTS AND DISCUSSION

According to Central limit theorem, variables are approximately normally distributed, because sample contains a large number of observations (n=80). Hence, we applied One-way ANOVA to compare statistically significant differences between multiple subsamples, i.e. to determine differences in terms of CSR in corporation with different dominant CSR motives. Levin's Test (Table 2) confirms the assumption of the homogeneity of variance (p>0,05 for each CSR aspect and CSR-total).

Table 2: Test of Homogeneity of Variances

	Levene Statistic	p
Internal CSR	1,284	,280
Customers	1,915	,102
Environment	,598	,701
Community	2,359	,051
CSR disclosure	1,237	,301
CSR - total	,453	,810

Source: Authors

The most important results of ANOVA and appropriate descriptive indicators are presented in the Table 3 and analyzed below. Also, we derived conclusions about the relationship between the CSR motives for and the level of CSR development, in accordance with the objectives of the research.

Table 3: Differences between CSR dimensions depending on CSR motives

	Motives	Brand and image		Competitive advantage		Profit		Employee satisfaction		Moral and ethics		International standards				
CSR dimensions		M	SD	M	SD	M	SD	M	SD	M	SD	M	SD	F	p	ε^2
	Internal CSR	3,28	0,64	3,10	0,53	2,95	0,69	2,71	0,90	**3,67**	0,52	2,50	0,30	***4,74***	***0,00***	***0,24***
External CSR	Customers	4,22	0,63	4,10	0,60	3,90	0,62	3,90	0,26	4,26	0,64	4,00	0,16	0,96	0,45	
External CSR	Environment	3,75	0,72	3,55	0,83	3,80	0,84	3,30	0,76	3,78	0,71	3,00	0,59	1,12	0,36	
External CSR	Community	**4,55**	0,68	3,55	0,98	4,04	0,94	4,10	1,05	4,10	1,19	2,95	1,45	***2,73***	***0,03***	***0,16***
External CSR	CSR disclosure	**3,52**	0,84	2,31	0,76	2,88	1,22	2,63	0,88	2,95	1,04	2,44	0,72	***2,69***	***0,03***	***0,15***
	CSR - total	**3,86**	0,51	3,36	0,53	3,52	0,59	3,33	0,61	3,78	0,62	**2,98**	0,41	***2,93***	***0,02***	***0,17***

Source: Authors

Statistically significant differences were identified in three out of five observed aspects of CSR, namely internal CSR (p = 0.00<0.05), responsibility to the community (p = 0.03<0.05), and CSR disclosure (p = 0.03 <0.05), as well as at full scale CSR (p = 0.02<0.05). Also, we calculated Eta square for each aspect and results indicate high influence in Internal CSR (ε^2 = 0.24), Community (ε^2 = 0.16), CSR disclosure (ε^2 = 0.15), as well as in CSR total (ε^2 = 0.17).[1] Therefore, the basic hypothesis ***Ho is confirmed***. In addition, the level of internal CSR is the highest in companies whose management stated morals as the most important reason for CSR (Mean = 3.67). However, internal CSR is not that high if employee satisfaction is the most important motive. Thus, this result ***partially confirms the hypothesis H1***. Responsibility to the community, as well as disclosure of CSR are the most developed in enterprises, in which CSR is seen as a means of improving the brand name and image (Mean = 4,55; Mean = 3,52), as one of instrumental motives. Based on these results, the ***hypothesis H2 is partially confirmed***, since no significant differences were identified in all aspects of external social responsibility. Also, other instrumental motives are not proved to be that important for the level of these two CSR aspects. All three statistically significant aspects, as well as the overall CSR are the least developed in companies where management pointed out fulfilling the requirements of international standards as the main CSR motive. Hence, ***H3 is confirmed***. These results are in accordance with previous research which suggest that investment in CSR is generally connected to those areas and aspects of the business that can generate economic value through social engagement (Dare, 2016, p.95).

Particularly interesting result refers to the fact that the overall corporate social responsibility is on a higher level in companies where the strengthening of the brand and image is stated to be the main motive (Mean = 3.86). This result speaks of profit-orientation of domestic companies, thus indicating utilitarianism as the

[1] According to Cohen (1988, p.284-287.) 0,01 is low, 0,06 is medium and 0,14 is high influence.

most significant set of motives for CSR. However, the high level of overall CSR is also present if the philanthropic reasons are viewed as the primary motivating factors for engaging in this field (Mean = 3.78). This means that the management is highly aware of multiple importance of CSR for the success of the company, but also values socially responsible initiatives as a kind of contribution to society, encouraged not only by adopted standards, but also by the ethical reasons. However, it should be noted that philanthropic motives should not be seen as the most important factor that leads to the implementation of socially responsible business, since companies still represent profit-oriented organizations, whose survival and development depend on the achieved results.

5. SCIENTIFIC AND PRACTICAL CONTRIBUTION

The *scientific contribution* of this paper is reflected in shedding more light on the corporate social responsibility from a theoretical point of view. The study provides relevant insights into the interdependence of CSR motives and the level of CSR, thus expanding the knowledge base in this field. These findings provide the basis for identifying strengths and weaknesses in terms of CSR in Serbia. Results also indicate the level of investment in certain aspects of social responsibility, depending on the underlying CSR motives. The results have multiple *practical implications*, as well. They indicate the need for management to expand the awareness about the importance of this approach to business. Also, the contribution is reflected in providing the basis for defining measures to improve socially responsible practices in both CSR dimensions.

6. LIMITATIONS AND FUTURE RESEARCH

The inevitable limitations of the research are identified. First disadvantage stems from the limitations of the survey, as a technique for data collection, primarily from the subjectivity of respondents. This is particularly expressed in this kind of research connected to ethical issues. Also, reluctance of representatives of companies to participate in scientific research speaks of underdeveloped cooperation between academic and professional public, which significantly complicates each research in field of business and management. As new knowledge always leads to new relevant questions, the results of this study also encourage new ideas. In future research, it would be interesting to analyze these issues in more detail, considering the interdependence between motives. Due to the fact that the sample was drawn from one specific area, this research could be extended to other countries in order to make comparative analysis and to improve the generalizability of the conclusions.

7. CONCLUSION

The results of this study are consistent with initial proposal that the level of CSR is influenced by firm's motive to engage in CSR. Specifically, we partially confirm the hypothesis that the level of internal CSR is higher in companies where philanthropic motives are dominant. Likewise, second hypothesis is partially supported because significant differences are identified only in two out of four CSR aspects, pointing to strengthening of brand and image as the most important motive in companies where external CSR highly developed. Still, external CSR is not that high in companies where increase in profit and competitive advantage are the most significant CSR motives. Findings indicate that high level of CSR in general is achieved in companies where dominant motives are those connected with the acquisition of various types of benefits for the enterprise, such as the promotion of the brand and corporate image, increase in profits and competitive advantage, which we defined as utilitarian motives, as well as in those where philanthropic motives are the most highly rated, while CSR is low in the companies where these activities are viewed as a necessity of fulfilling the obligations imposed by adopted international standards.

We can conclude that utilitarian motives play the most significant role in CSR. In this regard, it is important to emphasize that utilitarianism is different from egoism. Namely, it is not only about the aspirations to achieve good for one side (owners). It is true that management in this way, by investing in CSR, strives to contribute to the goal of maximizing profits, but also creates value for other stakeholders, i.e. for society as a whole. Social responsibility as such, in business organizations, must comply with economic interests, but it is necessary for the management to be aware of importance of CSR for the entire society. Likewise, CSR should not be taken as an obligation, since it represents an investment in the creation of sustainable competitive position. Initiatives in this area, in the long term, contribute to a number of benefits for the company and they make it easier for management to balance the interests of different stakeholders.

THE IMPORTANCE OF ETHICS OF THE BUSINESS ORGANIZATIONS FOR SUSTAINABLE BUSINESS DEVELOPMENT

Ivana Erić
Belgrade Business School – Higher Education Institution for Applied Studies
e-mail: ivana.eric@bbs.edu.rs

Abstract: *The purpose of the paper is to show the importance of ethics of business organizations for sustainable business development. Aside from presenting theoretical background, this work offers the results of the empirical research. This paper shows the results of Kranet project which was conducted in 3845 companies. It also presents research about perceptions on business ethics in Serbia which were gained by interviewing 194 respondents in 5 economic organizations. The results of Kranet project are showing that our country is below the average of EU countries in the number of report on corporate social responsibility and codes on ethics. Similarly, the Business Ethics Index is under the value of 100 which suggests that our respondents feel that business ethics of organizations is relatively bad. Many areas of business ethics are precondition for sustainable business development. Only simultaneous work on economic, environmental and social initiatives can ensure the sustainable business development.*

Keywords*: sustainable business development, business ethics, business responsibility, loyalty, perceptions of business ethics*

1. INTRODUCTION

During the last decades the issue of corporate business sustainability has been increasingly receiving importance in the academic, but also in the business circles. Today, more than ever, business organizations are having an important role in encouraging sustainable development. The essence is that in modern conditions of the ruthless competitive struggle, business organizations have to ensure satisfying the needs of individuals, creating jobs and the continuous development of their own business opportunities.

In that sense, corporate business sustainability searches for ways of how business can contribute to the goals of sustainable development and how provocative opportunities can be integrated into corporate sustainability activities. Responsibility toward environment, consumers, employees, shareholders, government, lobby groups, social responsibility and others belongs to the area of business ethics in all modern organizations. Many questions of the ethics of business organizations are directly related to the issues of sustainable business development. Modern organizations report every year through the Global Reporting Initiative about their activities in sustainable business development. Similarly, many organizations inform the public about its activities in the area of corporate social responsibility and other ethical questions. In both cases, the intention of organizations is to obtain the loyalty of all interested stakeholder, as well as key assumptions for the success and long-term capacity for the sustainable business development.

In continuation of the work it will be shown the basic concept of the sustainable business development and the model of business ethics, how should be pointed out the importance of ethical image of the organization for sustainable business development. In addition, it will be shown the results of the research project Kranet about the existence of written reports on corporate social responsibility and business ethics. Finally, in this paper will be presented the perceptions of business ethics in Serbia which were gained through research conducted on 194 respondents in five economic organizations in Serbia.

2. THEORETHICAL BACKGROUND ABOUT SUSTAINABLE BUSINESS DEVELOPMENT AND BUSINESS ETHICS

Generally speaking, sustainable development can include an organizations economic, environmental and social initiatives in ensuring the future, and if it is possibly better future. *James (2001) think that "purpose of the economic development is to generate wealth, especially for poorer people, in ways that are compatible with the systematic eliminating pollution of the environment and nature and contribute as much as we can to the meeting of human needs in our society" (p. 77).* In that sense, corporate business sustainability seeks ways how business can contribute to the goals of sustainable development and how to integrate provocative opportunities into corporate sustainability activities.

The essence is that organizations can achieve business objectives with respect for their economic, social and environmental duties. According to *Rainay (2010) "sustainable business development involves formulating and implementing business strategies, innovations and initiatives to help create a more*

sustainable world. It is philosophical perspective that permanents every aspects of what corporation is, the job of management is not supervision, but leadership" (p. 29). Another interesting view is presented by *Linton and others (Linton, Klassen and Jayaraman, 2007) who see sustainable business development as "using resources to meet the needs of the present without compromising the ability of future generations to meet their own needs" (p. 1076).* In fact, all definitions have in common existence of ethical leadership, which will seek to create a better world for all members of the human community with respect to the economic purpose of business organizations.

On the other side, ethics of business organizations basically includes economic, environmental and social responsibility. According to its essence, it is not oriented only towards better economic results, but also to satisfy the interests of all concerned stakeholders. In some cases, business organizations can consciously accept the loss of profit for the sake of positive ethical image. *Holmes (2008) pointed out that „business ethics can be defined as a set of moral principles for decision-making within the organization's values, which should explain the principles of conduct in accordance with standards of right and wrong" (p. 249). According to Thoms (2008) business ethics is "the systematic study of business ethics perspective, referring to the need, and should not, and suggests the existence of standards above and beyond regulation" (p. 419). "Business ethics is the study of conflict, the conflict between the economy and values between competition, trade and capitalism, between morality, integrity, and accountability" (Wheeler, Fabig and Boele, 2002, p. 298).*

It is obvious, that none of presented definitions are not able to explain all the complexity of this phenomenon, partly due to the influence of different perspectives on ethics. Instead, *Svenson and Wood (2008) are proposed the model of business ethics which seeks to explain the phenomenon of business ethics and the ways in which we, as a society, interact with the concept (p. 303).* It is transformational, simultaneous, continuous, iterative process of creating three main components: the expectations, perceptions and evaluations, which are connected with five subcomponents (expectations, organizational values, norms and beliefs; outcomes, assessment of society and reconnection). So there does not exist real final end of this model, but instead it represents the permanent reconnection and evaluation of all parts of this continuous process (Figure 1).

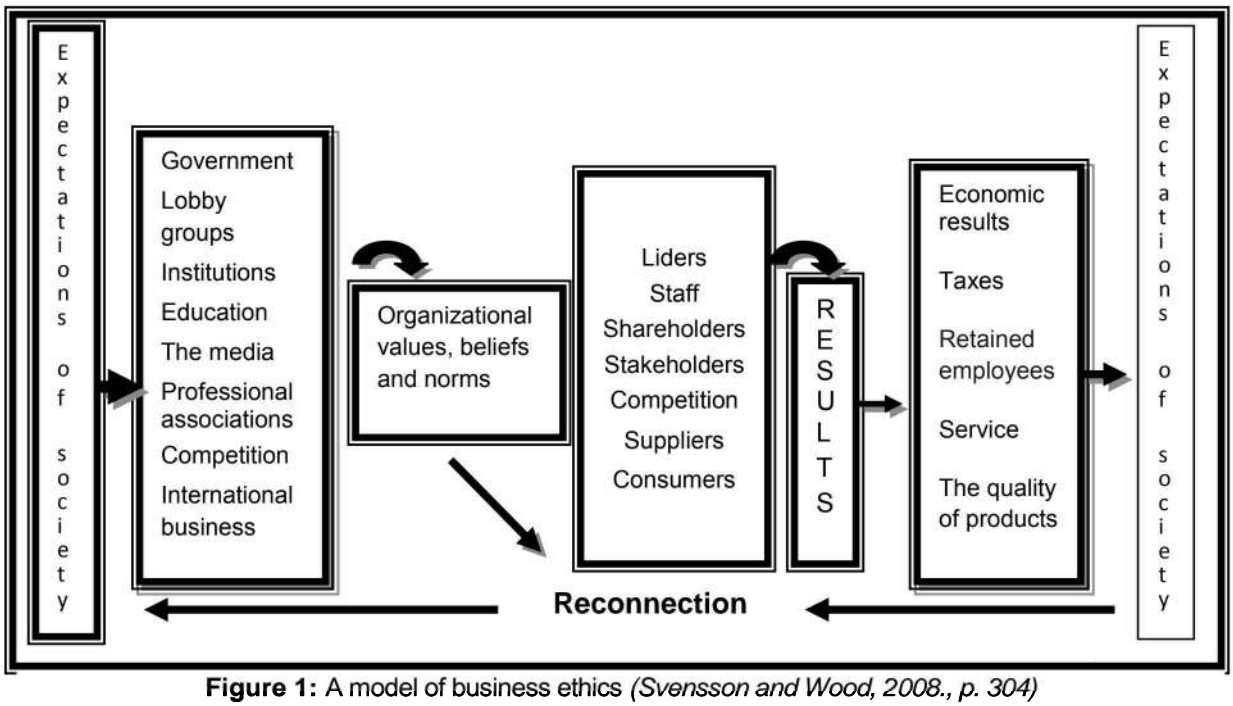

Figure 1: A model of business ethics *(Svensson and Wood, 2008., p. 304)*

The first component of a model are expectations of society about the expression of organizational behavior that allows further progress of the community in the realization of a higher level of well-being. The second component of the model consists of expectations: legislation, lobby groups, institutional responsibility, higher levels of education, media, socially responsible managers, professional associations, competition and international business with integrity. The legislation includes a whole set of laws for the creation of acceptable business behavior in the community. Lobby groups have the power to spread information, gathering disgruntled individuals and the destruction of individual business enterprise. The institutional responsibility of organization implies their participation in creating better society, through the concept of social responsibility and the creation of new laws, not just as an economic responsible entity. Enlarged level of education is predominantly a tool for change expectations, therefore it is necessary to discuss and

rationalize a number of questions. Socially responsible managers are required for contemporary organizations, and the managers who will do the right thing, make the right decisions and engage in actions that society expects, not because of fear of punishment, but because of its personal feeling. Professional associations have rules that are binding and protect all members, for the sake of achieving the highest standards of conduct in all organizations they work for. At the end, competition expects fair, just and clean fight. However, it often happens that organizations use cunning tactics, for the sake of increasing market share and survival in general.

The third component of the model - the organizational values, norms and beliefs, were created partly through affirmation of the characteristics of its members, and partly were based on expectations of stakeholders. The fourth components of model are perceptions, i.e. the way in which society perceives the behavior of organizations as ethically vs. unethically. Perceptions are considered through relationships of organizations with leadership, employees, shareholders, suppliers, customers, competitors and other stakeholders. The outcomes or results are the fifth component of the model, which measure not only a level of profit, but primarily the influence of the organization on society, through its activities or inactivity. Finally, the sixth component includes the evaluation and assessment of the organizational performances by members of society. The criteria used in the evaluation are the following: economic performance, respect for the law, retention of employees and consumers, acceptability of products and evaluation of society.

After evaluation of results of the organization it will be formed a new level of expectations (usually higher), in terms of organizational functioning, which becomes a basis for judging about ethics in the next cycle. Very often the assessment of one cycle will lead towards the creation of new laws, which will set more obstacles for illegally and immorally behavior.

The importance of business ethics for sustainable business development is undoubtedly great in the opinion of many scientists and companies. *Researchers cite the following essential reasons or motives for ethical behavior of modern organizations in terms of sustainable business development: organizational reputation, motive of managers, employees motive and the motive of investors (Trevino and Nelson, 1999; Weiss, 1998). The influence of the media on the ethical image of the organization is significant with respect that it publicly expresses positive and negative examples of ethical action, and thus it tries to create public opinion. (American Management Association, 2006).* Managers care about ethics because they can face with serious problems in the prevention and management of unethical behavior of employees. *Employees, who perceive to work for something "more" than the mere profit, demonstrate a higher degree of loyalty, satisfaction, better communication and commitment to the organization (Ethics Resource Center and Hay Group, 2012*). Finally, investors and owners have motives to think about the ethics of the organization. They invested their capital, so it is realistic to expect that they can ask questions such as: "Does the organization achieve higher profit?, and/or “Does the organization achieve profit in an ethical way?". Any kind of unethical activities can jeopardize the reputation of the organization and thus it can decrease the rate of return on investments. All this reasons imply that are very important to behave on the ethical way if the organizations want to have sustainable business development.

3. RESEARCH

The only comprehensive study, which attempted to investigate the current situation in the field of business ethics in our country, is the research conducted at the Faculty of Economics in Subotica in cooperation with Cranfield School of Management from the UK. *The survey was conducted in the period 2008-2010., on a sample of 20 countries of the European Union and Serbia and a total of 3845 companies (Economic Faculty of Subotica, 2011).* The research was aimed at obtaining answers to the question about the existence of written statements of corporate social responsibility and the written code of ethics. Respondents answered the question: "Does your company have a statement on corporate social responsibility?”. The possible responses were: Yes, written; Yes, unwritten; and No. The research results are shown in Figure 2.

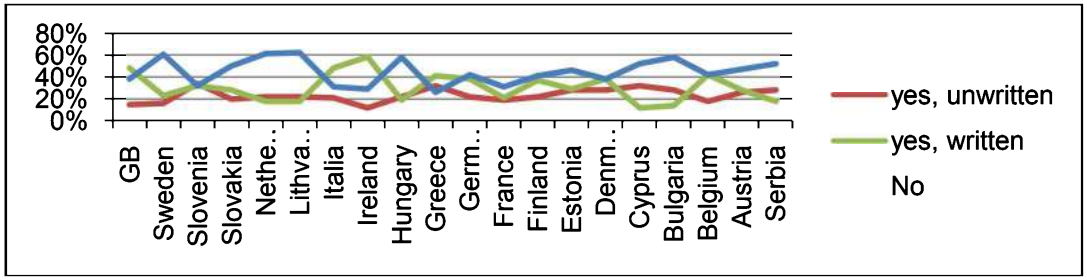

Figure 2: The existence of a written report on corporate social responsibility *(Economic Faculty of Subotica, 2011)*

The average of the European Union countries, concerning the existence of statement on corporate social responsibility is 55.2%, of which 32% is written and 23.2% is unwritten. Our country is a little under the average with only 46.1% of organizations which have statement on corporate social responsibility, i.e. 17.9% is written and 28.2% is unwritten. It is very devastating fact that even 53.8% of the surveyed organizations do not have a statement of corporate social responsibility. The best countries are the United Kingdom (47.5%), Ireland (58.3%), Italy (47.4%) and Belgium (41.9%), in terms of the written statement on corporate social responsibility. The former socialist countries like Slovakia, Hungary, Bulgaria and Serbia have shown significantly lower incidence of the declaration on CSR (between 14% and 28%) or moderate level of oral statements about CSR (between 22.7% and 34%).

On the other hand, the same study asked the question: "Does your organization possess a code of ethics?". Respondents were answered with: Yes written; Yes, unwritten; No. The results are shown in Figure 3.

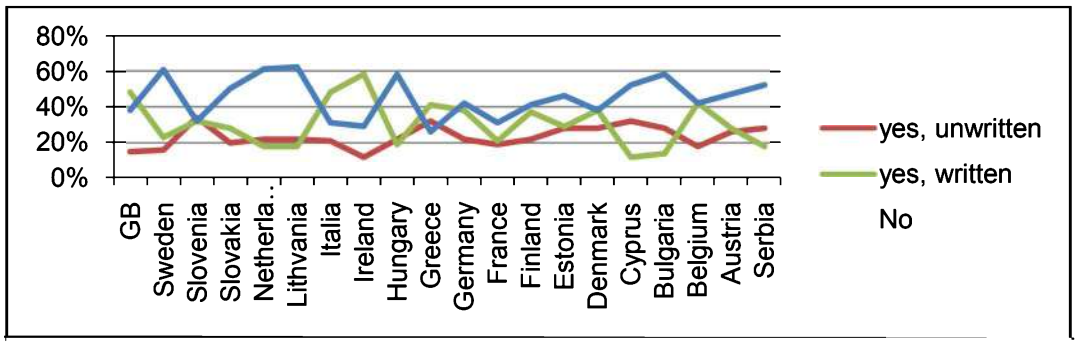

Figure 3: The existence of written codes of ethics *(Economic Faculty of Subotica, 2011)*

Situation is much better when we compare existence of written codes of ethics with written report on corporate social responsibility. The average of the European Union is 60%, of which 45.1% of the organizations possess written, and 24.9% of the organizations have unwritten codes of ethics. Significant negative deviation from the average of the EU demonstrate Netherlands (9.5% of written codes of ethics), Germany (37.7% of written codes of ethics), and Austria (25.5%). The only logical explanation would be that the above mentioned countries have highly developed ethical values as a part of the organizational culture, because their business practice are regulated systematically. Perhaps because of this, organizations do not feeling the need for formal prescribing of ethical values. However, the question arises to what extent was the code of ethics real implemented, or whether only represents a formal document. The future will give us the answer to such a complex issue.

The second research was conducted by the author of this paper and within there were analyzed past and future perceptions about business ethics in Serbia. *The research lasted for about 7 months, in period from March to November 2012 (Eric, I., 2014).* The technique of direct structured interviews was applied, due to lack of adequate secondary information's, and for all respondents were guaranteed anonymity.

Table 1: Socio demographic structure of the respondents

Organizations	**Eco**	**Piraeus**	**Marfin**	**Deles**	**Simpo**	**Sum**
Frequency (percentage)						
Number of respondents	13(6,7%)	35(18,04%)	41(21,13%)	72(37,11%)	33(17,01%)	194(100%)
Gender

***(Source**: Calculation of author)*

Perceptions of individuals about the level of business ethics in companies were examined through a special construct called Business Ethics Index (BEI - Business Ethics Index). The index measures the sensation (perception), current and future attitudes of consumers or clients on the overall situation of ethical business practices. It is consists of four components: BEI personal/past, BEI vicarious/future, BEI personal/future and BEI vicarious/past. *The formula to calculate BEI personal/past and BEI vicarious/past is (Tsalics and Seaton, 2006, p. 320):*

$$\frac{(\%\ very\ ethical - \%\ very\ unethical) + (\%\ somewhat\ ethical - \%\ somewhat\ unethical)}{2} + 100 \quad (1)$$

Calculation of vicarious / future and personal / future will do according to the following formula:

$$(\%\ more\ ethical - \%\ more\ unethical) + 100 \quad ...(2)$$

The final BEI (Business Ethics Index) is obtained by adding relative value components of the index and dividing by four. All final value of BEI, which are more than 100 demonstrate positive perceptions about the level of business ethics in organizations, and below 100 bad images about the ethical practices of organizations. The remainder of this paper will present the results of research.

Table 2: Perception of business ethics on the basis of perception in past

	Based on past experience, the business is generally observed	%	Based on what you heard in the past business is observing	%
Very unethical	51	26	51	26
Somewhat unethical	90	46	46	23
Neither ethical nor unethical	6	3	17	9
Somewhat ethical	37	19	138	70
Very ethical	12	6	24	12

(***Source***: *Calculation of author)*

Table 2 presents the data for the value of the components BEI, which are related to the experience of individuals with regard to the practice of business ethics in the past. On this basis, we can say that is the past BEI = 69, which means that our respondents think that business ethics in the past was very bad observed by all parameters.

Table 3: Perception about business ethics in the future

	Based on your previous experience what do you expect	%	Based on what you've heard, business will act in the future	%
More unethical	42	21	43	22
Same	96	49	61	31
More ethical	58	30	92	47
Sum	196	100	196	100

(Source: *Calculation of author)*

Table 3 shows the values for the components of BEI, which refer to the attitudes of individuals for the practice of business ethics in the future. Based on the results, we can say that is the future BEI = 117, and that the respondents believe that organizations in our country will become more ethical.

Calculating the value of BEI past and BEI future by previously presented formula we find that the value of the BEI index for our country is 91. This value suggests how our respondents feel that business ethics of organizations on our territory is relatively bad. However, the main reason for such a very small value of BEI - less than 100, is a result of bad BEI past. Expectations on ethics of business organizations in our country are very positive, as can be clearly observed through the current practices of organizations.

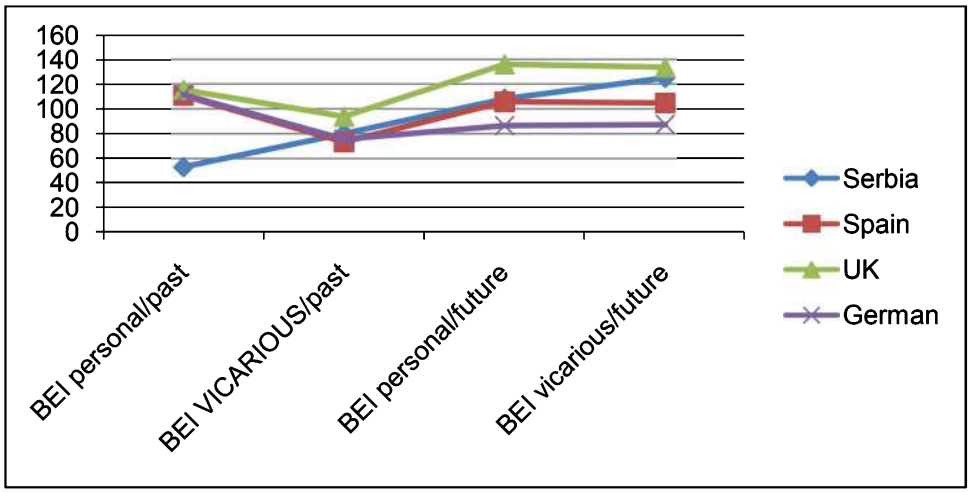

Figure 3: The value of BEI components for four countries (***Source***: *Calculation of auth*or)

Figure 3. shows the components of the index of business ethics for the four countries (Calculation of author on the own research; Tsalics and Seaton, 2006). By comparing data we can say that Serbia has the lowest value of the components of BEI personal/past, which shows that personal experience of business ethics in the past is very bad. It is interesting to note that all other values are more than the value of countries such as Spain and Germany, which should be seen as a "highly ethical". Therefore, according to the opinion of the author of this paper, our country is not "much worse" than other countries with developed market economy, as well as many individual claims. Moreover, we can expect a bright future in terms of ethics of business organizations, which operate in our country.

4. CONCLUSION

In this paper is shown all the importance of ethics of business organization for sustainable business development. Organizational reputation, satisfaction of managers, employees loyalty and the interest of investors for investing depend on the ethical image of the organization. Positive perceptions about ethics of the business organizations will be precondition for sustainable business development. It means that any kind of moving forward (in business sense) is not possible without trust of all interested stakeholders and, also it is indispensable that organization behaves in ethically acceptable way. The paper offers the results of the two empirical researches. The first researches are showing that our country is below the average of EU countries in the number of report on corporate social responsibility and codes on ethics, which is not so bad result. The second research about the business ethics suggests that our respondents feel that business ethics of organization in our county is relatively bad. These results are not surprising. Very high level of unemployment, economic crisis, problems with payment debts, problems with creating new business opportunities and others, have placed requirements in front of many organizations with a view to create mere economic survival. In those conditions, just brave organizations can integrate economic, environmental and social initiatives in ensuring the better future.

Abstract: *This paper provides an overview of the merger cases in the airline industry that the European Commission has dealt with during the past decade with respect to the conclusions and the remedies applied. Airline mergers play a key role in the EU airline industry and represent regular way for airlines to restructure, become more efficient, productive and, in the long-run, to survive in the market. However, antitrust law underpinning mergers in EU market sometimes may seem like a limiting factor of the fair and free market development. The analysis of the merger cases in EU presented in this paper raises a number of interesting legal and economic questionsrelated to the consistency in application of the criteria for assessing the mergers.*

Keywords*: airline mergers, EU Commission, EU common market, competition, remedies*

1. INTRODUCTION

For many years air transport was a tightly regulated industry, where investment and operating decisions were highly constrained. Under regulation period, the airlines did not have the freedom to set prices, frequencies and routes, while the market entry and exit was strictly controlled. In Europe, the airlines were state-owned and all international routes were arranged by bilateral agreements between the respective governments. The deregulation and liberalization of the European Union (EU) market has significantly changed the competitive environment and the nature of the airline competition. In the years following the deregulation, the number of competing airlines entered the market, fares significantly dropped and passengers' choices multiplied. However, over the last 20 years, many of the national airlines did not survive, some have withdrawn or been acquired by other airlines. Others, however, were restructured and developed into a full-service carriers (FSCs), became much stronger and continued to compete. Even if the first effect of deregulation was the emergence of new competitors, very soon many airlines began to merge resulting in much higher concentration of the contemporary airline industry in comparison to the pre-deregulation era.

The air transport sector is inherently oligopolistic. There is very high base cost in this type of services, while the consolidation of a carrier's operations at a large hub airport has various operational and cost advantages, such as reduced expenses due to fewer technical facilities for aircraft maintenance, scheduling advantages, etc. (Kociubinski, 2013). Economy of scale is in the nature of air transport.

Mergers and acquisitions intensified after the air transport deregulation and represent an important structural adjustment for the sake of an airline's competitiveness. Merger is often seen as a possible means for improving airline's efficiency and productivity. It provides an opportunity for restructuring, a more efficient allocation of resources, for achieving economy of scale and scope by extending marketable networks, enhancing access to markets, etc. (Iatrou & Oretti, 2007). There are also the benefits for consumers that arise from the larger networks with more frequent and convenient flights. Very often, mergers were one means of solving the financial difficulties of the airlines, that if there would be no merger led to its bankruptcy and withdrawn from the market. With that withdrawing from the market it would be lost of one competitor anyway, resulting in less competition than it would be if the merger is approved.

However, mergers may also have negative effects on competition in the market, by reducing the number of competitors, that can lead to weakening the competition (caused by the increased market power of emerged airline) and creating more barriers to entry. Although, merger can lead to impairment of competition in the short term, if this happens and there are no significant barriers to entry, the market forces will ensure the recovery of competition in the long term (Begović, 2010).

All this can result in the more concentrated market than it was before the merger occurred, but the prohibition of the merger can nullify all the potential benefits considering airline's efficiency. This is why antitrust authorities must balance these conflicting interests when deciding whether to approve a merger or not. The

aim of this paper is to assess the European Commission's approach with respect to consolidation (mergers and acquisitions) in the European airline sector and the application of the EU competition law in the cases of proposed mergers. Special consideration will be given to the proposed and applied remedies in cases when Commission was reluctant to sanction the merger.

2. MERGERS IN AIRLINE SECTOR IN EU

The competition law of the EU is primarily based on the Articles 101 and 102 of the Treaty on the Functioning of the European Union (TFEU) from 2007. According to the Article 102, "Any abuse by one or more undertakings of a dominant position within the internal market or in a substantial part of it shall be prohibited as incompatible with the internal market in so far as it may affect trade between Member States". Furthermore, it provides, *exampli causa,* types of abuses that are particularly problematic: a) directly or indirectly imposing unfair purchase or selling prices or other unfair trading conditions; b) limiting production, markets or technical development to the prejudice of consumers; c) applying dissimilar conditions to equivalent transactions with other trading parties, thereby placing them at a competitive disadvantage; d) making the conclusion of contracts subject to acceptance by the other parties of supplementary obligations which, by their nature or according to commercial usage, have no connection with the subject of such contracts.

The evolution of the EU competition law related to the mergers and acquisitions effectively started with the adoption of the Council Regulation(EEC) No 4064/89 of 21 December 1989 on the control of concentrations between undertakings, also known as the Merger Regulation.The objective of the Regulation was to establish a system that would ensure the competition in the internal market is not distorted. This is the core of the principle of open market economy with free competition, embedded in the Article 4(1) of the EC Treaty. The Regulation should apply only to significant structural changes, with an impact on the market that goes beyond the national borders of any one Member State. Such concentrations should be reviewed exclusively at the EU level. The Merger Regulation represented the new Community competence, while the chief beneficiary of the new development was the European Commission. Before the passage of this piece of legislation, Commission had extensive authority in other areas of the competition policy, but no formal authority in merger control.

The current Council Merger Regulation (EC) No 139/2004 of 20 January 2004 builds on the achievements of its predecessor, the enlargement of the EU, aiming at further development of the internal market and prevention of those concentrations which may significantly impede effective competition in the common market. AS to the scope of application of the Regulation, it should be defined according to the geographical area of activity of the undertakings and be limited by quantitative thresholds – targeting those concentrations that have a Community dimension. The Commission is authorized to set and implement relevant criteria, but those criteria should be developed in a way that protect competition interests of the Member States and take due account of legal certainty. While the Commission has exclusive competence to apply the Regulation, its decisions are subject to review of the ECJ.

One of the main preliminary questions we face in our analysis relates to the definition and understanding of the *relevant market* in the EU competition law.The main aim of the Regulation was to prevent "significant impediment to effective competition" within the Common market. Such distortions happen when a subject establishes and abuses a dominant position that effectively restricts the competition in provisions of certain goods or services.What constitutes the dominant market position was defined in case *United Brands v. Commission* (Case 27/76, 1976), when ECJ found that dominant position "relates to a position of economic strength enjoyed by an undertaking which enables it to prevent effective competition being maintained on the relevant market by giving it the power to behave to an appreciable extent independently of its competitors, customers and ultimately of its consumers." (para. 65).According to the Commission notice on the definition of relevant market for the purposes of Community competition law (97/C 372/03), there are two dimensions of relevant market in EU competition law – geographic market and product market.A relevant geographic market comprises the area in which the firms concerned are involved in the supply of products or services and in which the conditions of competition are sufficiently homogeneous.

A relevant product market comprises of all those products and/or services which are regarded as interchangeable or substitutable by the consumer by reason of the products' characteristics, their prices and their intended use. The key distinction is between time-sensitive passengers and non-time-sensitive passengers.

In its judgement in "Hoffman-La Roche v. Commission" case (CJEU, Case 85/76 (1979), the Court of Justice held that "the concept of relevant market in fact implies that there can be effective competition between the products which form part of it and this presupposes that there is a sufficient degree of interchangeability

between all the products forming part of the same market in so far as a specific use of such products is concerned." (para. 28).

Over the period 2004-2015, the EC has examined 21 merger proposals that took place in the airline sector in the EU. According to the EC reports, each merger or acquisition was examined on its own merits and on a case-by-case basis. However, there is some general approach that can be in common for all investigated proposals that includes definition of the relevant market, analysis of the effects that the proposed merger would have on competition in the relevant market and final decision making. The EC may approved (with or without conditions and obligations) or prohibit the proposed merger.

Analyzing merger proposals it can be noted that 8 of them (38%) are allowed without any conditions. Clearances subject to conditions and obligations happen in 10 cases (48%), while the prohibition happened only 3 times (14%).Figure 1 shows the evolution of the mergers in the airline industry that was under the EC investigation over the 12 years concerned. The number of mergers and acquisitions that occurred in Europe is not significant in comparison to the US market. Nowadays, the top five airlines in US – United, Delta, American Airlines and Southwest Airlines – are holding over the 80% of domestic seating capacity as a result of mergers, while over 53 percent of the European market is shared between the top six airlines. One of the reasons for that is certainly the fact that is much easier to do mergers in a single country in comparison to the situation in the EU where many governments are involved in protecting their national airlines.

Conditions and obligations are actually remedies determined in order to eliminate the competition concerns identified by the EC. Of course, they have to be designed not to hinder the potential efficiency gains from the merger. In order to determine the adequate remedies the EC must predict with reasonable certainty which elements will recover competition after completion of a merger. The effectiveness of a remedy depends on whether or not they return the market to the same competition level as existed before the merger. The most common remedies applied by EC in the merger cases can be distinguished between the slotsrelated, facilities related (access to Frequent Flyer Programmes and other agreements – interlining, block-space, etc.) and other commitments.

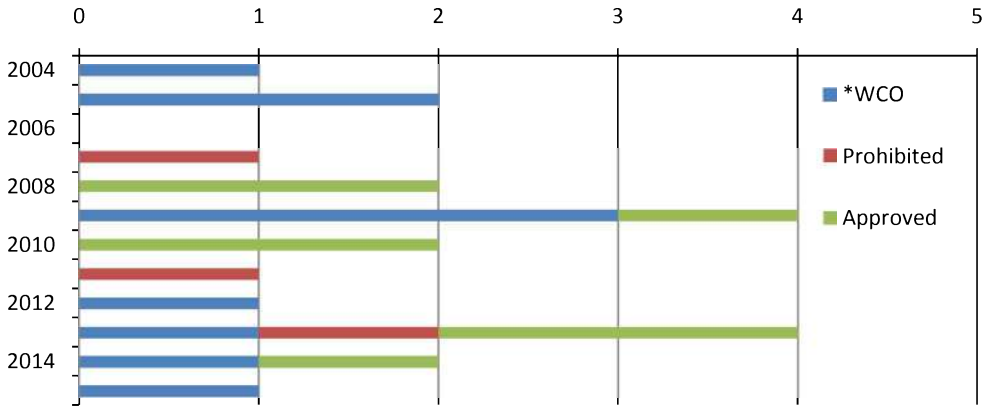

Figure 1: Mergers in EU (2004-2015)
*WCO –with conditions and obligations

2.1. Approved mergers with conditions and obligations

The list of all mergers that are proposed and considered by the EC is shown in Table 1. For each proposed merger it is indicated the year when the decision is made by the EC and in the case of the approval with conditions and obligations the applied remedies are listed.

The first airline cross-border merger in the EU was the one between two major airlines Air France and KLM. These two airlines announced their decision to create a new airline on 30 September 2003, and EC gave the clearance to merge subject to conditions on 11 February 2004. According to EC report, the airlines have complementary networks and only 14 routes are identified that will suffer from the significant reduction or elimination of competition. In order to maintain competition on the routes affected by the merger, EC approved remedies which include that both parties had to give up 47 pair of slots per day at the airports Paris Charles de Gaulle and Amsterdam Schiphol, (Case No COMP/M.3280, 2004).

In May 2005 German national carrier Lufthansa and Swiss International Air Lines announced that Lufthansa will acquire the majority of the shares in, and sole control of, Swiss. The EC's merger investigation raised

concerns about a number of intra-European routes where it may come to significant reduction or elimination of competition. In particular, the routes Zurich- Frankfurt and Zurich- Munich, and on some long-haul routes to the US, South Africa, Thailand and Egypt are most jeopardized by these potential mergers. They also took into account the impact of Lufthansa's close co-operation with members of the Star Alliance. Two months later the EC approved this merger subject to conditions and both parties committed themselves to give up slots at the airports of Zurich, Frankfurt, Munich, Düsseldorf, Berlin, Vienna, Stockholm and Copenhagen, (Case No COMP/M.3770, 2005).

Table 1: Airline mergers in EU since 2004

Merger	Year	Decision	Remedies
Air France/KLM	2004	Approved WCO	• 47 pair of slots at the airports Paris and Amsterdam (31 roundtrips per day) for the routes: • 1 roundtrip for each route from Paris to Detroit and Lagos and from Amsterdam to New York, Atlanta and Lagos • 26 roundtrips from Amsterdam to Paris, Lyon, Marseille, Toulouse, Bordeaux, Milan, Rome, Venice and Bologna • Access to Merged Entity's FFP for use by new entrants on the identified routes.
Lufthansa/Swiss	2005	Approved WCO	• Airport slots for long-haul city pairs at Zurich airport for 7 roundtrips to Boston, Chicago, Los Angeles, Johannesburg, Bangkok and Cairo. • Slots at Zurich airport for 35 roundtrips to Frankfurt, Munich, Dusseldorf, Berlin (Tegel), Hamburg, Hanover, Vienna, Stockholm, Copenhagen, Warsaw and Bucharest. • Access to Merged Entity's FFP for use by new entrants on the identified routes.
Lufthansa/ Eurowings	2005	Approved WCO	• Slots at Vienna and Stuttgart airports for 7 roundtrips for particular routes Vienna-Stuttgart, Vienna-Cologne, Stuttgart-Dresden.
Ryanair/Aer Lingus	2007	Prohibited	
KLM/Martinair	2008	Approved	
Delta Airlines /Northwerst Airlines	2008	Approved	
Iberia/Vueling /Clickair	2009	Approved WCO	• 46 roundtrips in the identified European routes: • from Barcelona to Venice, Roma, Nice and Athens • from Madrid to Venice and Naples • from Ibiza to Paris • 104 roundtrips in the identified Spanish routes: • from Barcelona to Malaga, Santiago de Compostela, Seville, Granada and Oviedo • from Bilbao to Malaga, Ibiza and Seville • from Ibiza to Seville and Valencia • from Alicante to Ibiza • from Seville to Valencia • Access to iberia's FFP for use by prospective new entrants on the identified routes
Lufthansa/Brussels Airlines	2009	Approved WCO	• Slots at Brussels airport for 10 roundtrips for the routes to Frankfurt, Zurich, Hamburg and Munich. • Access to Merged Entity's frequent flyer program for use by prospective new entrants on the identified routes.
Lufthansa/BMI	2009	Approved	
Lufthansa/Austrian Airlines	2009	Approved WCO	• Slots at Vienna airport for 19 roundtrips to Frankfurt, Munich, Stuttgart, Cologne and Brussels.
Iberia/ British Airways	2010	Approved	
United Air Lines/Continental	2010	Approved	

Airlines			
Olympic/ Aegean Airlines	2011	Prohibited	
IAG/BMI	2012	Approved WCO	• Slots at the airport in London (Heathrow) for 12 roundtrips on: • the UK city-pair routes (from London to Edinburgh and Aberdeen), in total 7 roundtrips and • the other city-pair routes (from London to Cairo, Riyadh, Moscow and Nice), in total 5 roundtrips.
US Airways/ American Airlines	2013	Approved WCO	• One daily slot pair at London Heathrow and Philadelphia airports.
Ryanair/Aer Lingus	2013	Prohibited	
Olympic/ Aegean Airlines	2013	Approved	
Delta Air Lines/ Virgin Group/Virgin Atlantic Limited	2013	Approved	
Cesky Aeroholding/Travel Service/ Ceske Aerolonie	2014	Approved	
Alitalia/Etihad	2014	Approved WCO	• 2 daily slot pairs at Rome-Fiumicino and Belgrade airports to one or more interested new entrants.
IAG/Aer Lingus	2015	Approved WCO	• 5 daily slot pairs at Gatwick airport on routes from London to Dublin and Belfast. • Aer Lingus will continue to carry connecting passengers for competing airlines out of London-Heathrow, London-Gatwick, Manchester, Amsterdam, Shannon and Dublin.

The same year EC approved another acquisition by German airline Lufthansa over the German airline Eurowings and its subsidiary, the low cost airline Germanwings. However, this clearance was conditional upon the parties to give up 7 pair of slots at Vienna and Stuttgart airports. In addition, EC conditioned the parties to allow competitors to participate with their flights on the affected routes in Lufthansa's Frequent Flyer Programme (FFP) with the aim of making entry more attractive, (Case No COMP/M.3940, 2005).

In January 2009, the EC approved under the EU Merger Regulation the proposed acquisition of the two Spanish low-cost airlines Vueling and Clickair by the Spanish national airline Iberia subject to conditions. The parties committed to release slots at Spanish airports (104 roundtrips) and other European airports (46 roundtrips) in order to address competition problems identified by the EC. The slots are linked to the particular routes in Spain and inside the Europe, where the proposed concentration would have led to a restriction of competition, (Case No COMP/M.5364, 2009).

In June 2009, EC gave clearance to acquisition by Lufthansa over the SN Brussels Airlines subject to conditions and obligations. In this case, the remedies that EC determined referred to the routes from Brussels to: Frankfurt, Zurich, Hamburg and Munich. Lufthansa agreed to offer the slots that would reduce the barriers to entry and allow new entrants to operate flights on each of the four routes where the EC identified concerns, (Case No COMP/M.5335, 2009).

In August 2009, Lufthansa officially took over the Austrian Airlines Group after the EC approved the proposed acquisition. The EC clearance is conditional upon the implementation of a set of remedies in respect to EC competition concerns on certain routes. The routes on which the EC was concerned that the transaction would result in consumers being faced with reduced choice and likely higher prices are from Vienna to Frankfurt, Munich, Stuttgart, Cologne and Brussels. In order to remove these competition concerns on all these routes, the parties commit to make slots available at the airports concerned that will account up to 19 roundtrips for new entrants, (Case No COMP/M.5440, 2009).

In 2012, the proposed acquisition of British Midlands (bmi) by IAG was approved by the EC, subject to conditions. The investigation showed that the proposed acquisition would have led to high market shares and even monopolies on a number of domestic, European and international routes out of London Heathrow airport. In order to modify the concentration so as to resolve the doubts identified by the Commission with a

view to having the merger cleared, the parties agreed to release 12 daily slot pairs at London Heathrow which could be used on the specific routes of concern, (Case No COMP/M.6447, 2012).

The only EC approval of the proposed merger between the non-EU airlines that was subject to condition was the one between US Airways and American Airlines. This clearance was released in August 2013, and the EC revealed the conditions that will adequately address the competition concerns identified by the EC. Namely, the EC's investigation found that the transaction would lead in particular to a monopoly on the London-Philadelphia route, where US Airways and American Airlines through its membership in a metal neutral joint venture with British Airways and Iberia. Both parties agreed to the release of one daily slot pair at London Heathrow and Philadelphia airports, and of other commitments in order to induce entry on the London-Philadelphia route, (Case No COMP/M.6607, 2013).
In November 2014, the EC approved Etihad's acquisition of joint control over Alitalia, subject to conditions. The decision is conditional upon both airlines' commitment to release slots to a new entrant at the airports of Rome -"Fiumicino" and Belgrade-"Nikola Tesla". The reason for this outcome is in the fact that Etihad also controls Air Serbia, which together with Alitalia, were the only carriers offering direct flights on the Rome–Belgrade route. The EC was concerned that this acquisition could lead to a monopoly on this route that will result in higher prices and a loss of service quality for passengers, (Case No COMP/M. 7333, 2014).

The most recent decision and also the clearance subject to condition released by the EC was about the proposed acquisition of Aer Lingus by International Consolidated Airlines Group (IAG). The EC concerns were raised about an insufficient competition on several routes that would be the result of this concentration. The EC's investigation also found that the merged entity would have prevented Aer Lingus from continuing to provide traffic to the long-haul flights of competing airlines on several routes. In order to adequately address all competition concerns identified, the parties committed to release the slots at Gatwick airport, while Aer Lingus will continue to carry connecting passengers to use the long-haul flights of competing airlines, (Case No COMP/M.7541, 2015).

2.2. Prohibited mergers

Since the EU Merger Regulation came into effect in 2004, three merger proposals were prohibited by the EC, under the explanation that each of them raises concerns on a number of overlapping routes and this would impede effective competition in the common market. It is interesting to examine what were the main EC findingsthat prevailed and led the EC to take a decision on the refusal of these particular merger proposals.

The first time when the EC decided to prohibit the airline merger was the one between the Irish low cost airlines Ryanair and Aer Lingus. On 30 October 2006, the EC was notified about a proposed concentration betweenRyanair and Aer Lingus. The EC biggest concern about a proposed merger was that both airlines have a strong position in Ireland and on almost all routes they were the only two or the two main carriers active. In particular, the EC found that there would be 35 routes with very high market shares, from which for 22 routes the merger would create a monopoly. In addition, the EC found that there were a number of important entry barriers to operating flights from or to Dublin in competition with Ryanair/Aer Lingus, resulted from the well-established position at their home base. On the basis of the EC findings, Ryanair proposed the set of commitments in order to remedy the identified significant impediment to effective competition. The most interesting part is the slot related commitments where Ryanair offered to make available slots for the London-Heathrow route, in total 24-40 Dublin–Heathrow slots per day. Those slots would be exclusively reserved for British Airways and Air France (equally divided between them). Ryanair also committed to make available 4-8 slots for other overlap routes from and to Dublin, as well as a number of slots from/to Shannon and Cork airports. There were additional commitments related to operational concerns of the merged airline, such as the commitment not to increase the frequencies of any of the claimed overlap routes, to reduce Aer Lingus' short-haul fares by at least 10% immediately, to eliminate the fuel surcharges Aer Lingus applies on its long-haul flights immediately, to retain Aer Lingus' brand and to continue to operate Ryanair and Aer Lingus separately. Nevertheless, the EC concluded that: "*those commitments are not sufficient to remedy the identified significant impediment to effective competition and, thus, cannot render the proposed concentration compatible with the common market",* (Case No COMP/M.4439, 2007).

In 2011, the EC received another merger proposition from two Greek airlines, Olympic and Aegean Airlines. Again, both airlines served from the same home base airport in Athens that resulted in a high number of overlapped routes. In its report, the EC noted that together the two carriers control more than 90% of the Greek domestic air transport market, which would discourage any new airline to enter the Greek market after the merger. In spite of the openhanded proposal by the merger parties in which they committed to make available a number of slots at Greek airports, the EC prohibited this concentration with the explanation that Greek airports do not suffer from the congestion, (Case No COMP/M.5830, 2011).

However, in 2013 the EC reconsidered the Greek merger case and after the investigation into the proposed acquisition of Olympic by Aegean Airlines, approved it. In spite of the EC concerns that the proposed transaction raised serious competition concerns on a number of Greek domestic routes, the EC explained that Olympic Air would be forced to exit the market in the near future due to financial difficulties if not acquired by Aegean. Either way Aegean would become the dominant airline on all the affected routes, (Case No COMP/M.6796, 2013).

Another takeover attempt by Ryanair on Aer Lingus occurred in 2009 but they withdrew the proposal. In 2012 they had their last attempt, but a year later the EC refused again their proposition with the justification that it would significantly impede effective competition on the market by creating a monopoly or a dominant position on 46 routes where, currently, Aer Lingus and Ryanair compete against each other.As a part of the proposal, Ryanair offered set of commitments in order to overcome the EC concerns, such as the transfer to Flybe of a number of assets such as cash of EUR 100 million, a lease for at least 9 Airbus A320 aircraft, airport slots (at origin and destination), a royalty-free, non-sub-licensable, non-exclusive and non-transferable license to the Aer Lingus trademark for 3 years, personnel, contracts, real estate etc. In addition, Ryanair offered to the cession of slots to IAG/British Airways at London airports, so that IAG/British Airways would operate on 3 routes (Dublin-London, Shannon-London, and Cork-London). However, the EC decided that these remedies do not address the competition concerns and were insufficient to ensure that customers would not be harmed on the relevant routes, (Case No COMP/M.6663, 2013).

3. DISCUSION

The examination of the mergers under the EC jurisdiction raises some interesting questions, for example, what were the remedies applied in the cases when a merger is conditionally accepted by the EC and what were the proposed remedies in the cases when the mergeris prohibited. In other words, was the EC consistent in assessing the remedies in both cases?What is in common for all prohibited proposals is the fact that those consolidations were initiated by airlines (two airlines in each case) that are well established, both coming from the same countries and using the same home base airport. This fact, per se, can lead to a result in a high market power and a high number of the overlapping routes. This is not in question. What could be in question is how the EC defined the relevant market in the cases when the parties do not have the same home base airport, but their home base airports are relatively close (e.g. Air France-KLM, Lufthansa-Swiss, Lufthansa-Brussels Airlines, etc.). Precisely, the EC conclusion in the Air France-KLM case was that the airlines' networks are largely complementary and that the new entity will not jeopardize the competition in the market. This is certainly the truth when the short-haul flight are considered, but the problem may arise on the mid and long-haul flights, where passengers are less sensitive to the travel time, and direct and indirect flight can be considered as substitutes. It is worth noting that in a time when the merger between these two airlines happens, they were Europe's second and fourth largest airlines with two major international hubs. The problem here was not whether to allow the two airlines to enter into a merger, but was the remedies agreed in this case adequately, due to the increased market power of the new airline. This question could be put in another way, if these remedies were enough in the case when two major European airlines merged, why the set of commitments offered by Ryanair were insufficient, having in mind that the commitments, inter alia, included a number of high-valued Heathrow slots.

Another interesting observation from the analysis is that in British Airways-Iberia case, when the merger is approved without any conditions. Again, both were the leading airlines in their countries with strong route networks inside and outside the EU market. In addition, British Airways and Iberia have been already members of the Oneworld alliance whereby they work together and linked up a substantial part of their networks and this was taken as a base for the EC investigation. According to the EC report no competition concernsare identified from theinvestigation of the overlaps of their networks for the post-merger structure. However, if one analyzes the situation on the routes between the UK and Spain, in particular between London and Madrid airports in the summer season 2009 the result may raise some doubts about the EC judgment. Namely, the parties operated the route from London airports to Madrid with altogether 15 daily frequencies, while all competitors (Easyjet, Air Europa and Ryanair) operated with 7 daily frequencies, (Case No COMP/M.5747, 2010). Based on daily frequency, the parties' market share is more than 60% and this result may indicate the market dominance on the route London-Madrid. In the EC report, the parties argued that the merger will not change the competitive structure on the route London-Madrid, which is true, having in mind that the effects of a merger are normally assessed on the basis of the pre-merger situation when they were already allowed to operate as an alliance with the dominant position. This raises another important question:is the competition concerns addressed by the EC only related to a problem caused by the merger and how to deal with the markets where the pre-merger structure was not competitive in the first place?

Finally, the case that has attracted much public attention, Aegean Airlines' acquisition of Olympic, raises some doubts about the EC decisions of approved or rejected mergers that are not based only on legal attributes, but also succumbed to the political and economic influence. In this particular case the problem is in the EC explanation of the approval, that otherwise Olympic would be forced to exit the market in the near future due to financial difficulties if it were not acquired by the Aegean. With this attitude the EC rejected the possibility that a new competitor might entry on the routes once the Olympic withdrew. Another important issue in this case is in the fact that on the domestic market Aegean and Olympic jointly control 90% of seats, which inevitably leads to monopoly (Economist, 2014).

4. CONCLUSION

While it is still not easy to establish what has been the impact of air transport liberalization policies on economic growth and traffic in general, it is clear that mergers play important role in restructuring the transport market in line with demand for higher efficiency and effectiveness of the service providers. EU has a legitimate interest to secure the environment that offers customers goods and services at most favorable terms. The EC has extensive competences in this respect, so it is very important that criteria for allowing (conditionally or unconditionally) mergers are transparent and consistently applied. The EC's assessment of the relevant geographic and product market has to be persuasively justified, based on solid evidence and deep market impact analysis, while the proposed remedies must be in the service of the promotion of competition, and not unfair treatment for one of the sides involved.

It is evident that there are some restrictions which slow down the unavoidable process of consolidation. Although the deregulation and liberalization processes have advanced, the EU market is still characterized by a large number of national airlines and strong influence of the governments, which makes mergers more complicated, and the role of the EC still very sensitive.

THE UPRISE OF THE MIDDLE EAST CARRIERS – EMIRATES' PATH TOWARDS SUCCESS

Jovana Kuljanin*[1], Milica Kalić[1]
[1]University of Belgrade – Faculty of Transport and Traffic Engineering
* Corresponding author, e-mail: j.kuljanin@sf.bg.ac.rs

Abstract: *Aviation sector plays a prominent role in the era of rising economy of the Middle East. In the last two decades, major oil-producing countries have established their own national carriers that brought significant changes and posed a burden of challenge to their competitors, especially those that operate long-haul traffic. The paper provides a brief overview of "state-of-the-art" literature on three "emerging airlines" such as Emirates, Qatar Airways and Etihad Airways which see tremendous expansion and permanently alter traffic flows across the globe. It also underlines the Emirates' competitive advantage gained throughout implementation of hourglass network and efficient cost structure supported by the economic and social development of the Dubai Emirate.*

Keywords*: emerging carriers, Emirates, the Middle East, hourglass hub, cost structure*

1. INTRODUCTION

The region of Middle East has historically been attractive as an inevitable point on trade routes between Europe and the Far East. The archaeological documentation reports that established trade routes connecting Europe to the Far East passed through the Arabian Peninsula even 3500 years ago. Despite political and ethical unrest combined with persistent tension between different nations over decades, this region remains the important "connector" that stands on the shortest path between the East and the West in modern times.

According to AEA (2006) the 'Middle East' includes 13 countries[1], located in an area which stretches east of the Mediterranean, south to the Arabian Peninsula and north to the Caspian Sea covering a total land area of 5 million square kilometers. Within this region, the Gulf Cooperation Council (GCC) stands out as a separate sub-regional group encompassing major oil producing countries (Bahrain, Kuwait, Oman, Qatar, Saudi Arabia and the United Arab Emirates) which intend to create free cross-border investments and trade in services. The economic emergence of the region dated back to the period from 1965 to 1985 facilitated by dramatic rise in oil prices. Oil producing countries (especially large producers such as Saudi Arabia, Iran, Iraq, Kuwait) benefited directly in the form of high export earnings (Global Perspectives, 2000). In order to reduce their reliance upon oil production in the future, many countries diversify their economies and make significant effort to further develop sectors such as financing, tourism, light manufacturing and agriculture. Aviation is certainly seen as a contributor that can boost a bunch of services within tertiary sector such as tourism, hosting of international conferences and trade shows, opening luxurious corporate headquarters, etc. Therefore, the regional governments are strongly promoting the aviation sector, carrying out destination-marketing campaigns and ensuring the presence of the country at major international Travel and Transportation fairs (Vespermann et al., 2008).

In the last two decades, the role of the region has experienced tremendous transformation from the technical intermediate point for aircraft with limited range to the leading region in terms of trade and travel flows. Hooper et al. (2011) argue that this transformation represents a "principal axis shift" towards a fundamentally changed global aviation network built upon the economic and social development within the region. Arabian Gulf-based airlines, viz. Emirates, Etihad Airways and Qatar Airways, are among the fastest growing full service airlines in the world with their hubs located in Dubai, Abu Dhabi and Doha. These carriers are often called "emerging carriers", the term used in the late 2000s to describe the group of carriers based in the Middle East that were growing rapidly (Al-Sayeh, 2014). Although this term has not been precisely defined, it often refers to carriers which have remarkable growth in annual number of passengers, capacity and fleet and operate long-haul flights from their respective hubs.Therefore, Emirates, Etihad Airways and Qatar Airways represent this group adequately.

[1]Bahrain, Iran, Iraq, Israel, Jordan, Kuwait, Lebanon, Oman, Qatar, Saudi Arabia, Syria, the United Arab Emirates and Yemen

Emirates is certainly the largest carrier having aggressive expansion at phenomenal average annual pace of 12.4% in the number of passengers in the last five years (from 27.5 mil. in 2010 to 49.3 mil. in 2015). Unlike the other two carriers which cooperate closely with other carries through their membership in alliances, Emirates is still not that receptive to partnership. This carrier is considered as a "game changer" in airline industry as it brings conceptual changes and innovations in business model supported by Dubai's rapid expansion. The purpose of this paper is to reveal the key competitive advantage of Emirates over its rivals, especially those of the similar size in Europe. Thus, this paper outlines the most important findings from the current "state-of-the-art" literature (the papers in relevant journals and publications) that investigate the rising activities of several "emerging" airlines in the Middle East. Section 2 provides the most important information about the three emerging carriers. Section 3 focuses on the business model of Emirates with its distinctive characteristics which assure competitive advantage and pose a challenge to other carriers on the market. This section analyses in details the cost structure as the most important advantage which contribute to Emirates' favourable position on the market, by relying on the data provided in its annual reports. Finally, Section 4 concludes the paper.

2. OVERVIEW OF EMERGING CARRIERS' DEVELOPMENT

Gulf Air is the ancestor of today's most prosperous airlines in the Middle East: Emirates, Etihad Airways, Qatar Airways and Oman Air. The airline was founded in 1974 by the governments of Bahrain, Qatar, the UAE and Oman who purchased the company from the British Overseas Airways Corporation and later transformed it into Gulf Air. The newly formed carrier was the mutual national carrier of the four mentioned countries and had its base at Bahrain International Airport, mainly servicing flights to Europe and the Far East. In the early 1980s, Gulf Air rapidly enlarged its network,requiring new airplanes to be acquired. At that time, Gulf Air focused its operation primarily out of its hub in Bahrain, while the number of weekly flights to Dubai was reduced from 108 to 41 in mid-1983 (Hooper et al., 2011). Ambitious plan of Sheikh Mohammed bin Rashid Al Maktoum, the current ruler of Dubai and the Prime Minister of the UAE, was to "breathe new and modern life" into Dubai by developing an air transportation system as a backbone of economic activities. Thus, the state invested a modest sum of 10 million USD and leased two aircraft in order to launch its own airline – and Emirates was born in October 1985. At the beginning of its operation, the company had only a single route to Karachi. The growth of Emirates tremendously affected the growth of Dubai Airport that had merely 3 million passengers prior to and at the beginning of Emirates' emergence. CAPA (2015a) reported that passenger numbers at Dubai had grown to 12.3 million by 2000, with over 1.2 million transit passengers shuttling via the rapidly growing hub. In 2014, Dubai airport counted over 70 million passengers, two thirds flying Emirates.

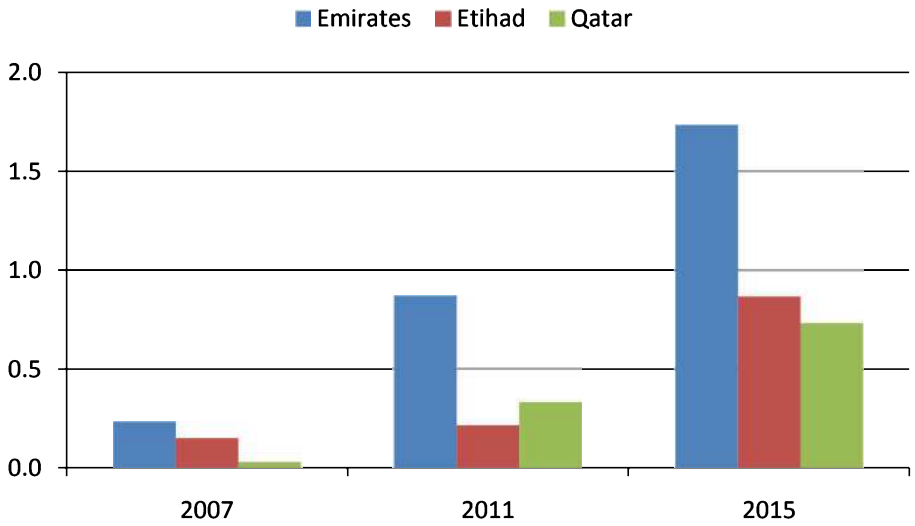

Figure 1: Emirates, Etihad and Qatar Airways seats into the US: 2007, 2011 and 2015 (in millions)

Shortly after foundation of Emirates, the neighbouring countries came up with ambitious plans to establish their own national carriers that reflected the status symbol of power and sovereignty. Oman and Qatar formed their own national carriers which allowed them to be less dependent upon Gulf Air services, although they continued to fund Gulf Air. In order to concentrate their effort solely on its own national carrier, Qatar decided to withdraw from Gulf Air in 2002, followed by Oman in 2007. Finally, in 2003 the UAE founded its own national career, Etihad Airways, and subsequently withdraw from Gulf Air. In such newly circumstances,

Bahrain remained the only country stakeholder in Gulf Air, which severely exacerbated its position on the highly competitive market. The expansion of these three airlines can be evidently observed by the increasing number of seats offered in 2007, 2011 and 2015, as depicted in Fig.1. On the other hand, Gulf Air currently offers flights within the Middle East and still provides flights to major European hubs as well as Bangkok. The short overview of the emerging carriers will be given in next sub-sections in reverse chronological order beginning with most recently founded airline, Etihad Airways and ending with the most successful one among them – Emirates.

2.1. Etihad Airways

Etihad Airways is the national carrier of the Emirate of Abu Dhabi with its base at Abu Dhabi International Airport. This carrier has both narrow and wide-body Airbus and Boeing aircraft in the fleet servicing a rapidly expanding network within the Middle East and to Europe, Asia, North America, Canada and Australia (CAPA, 2016a). Beirut was the company's first destination to offer from its base in Abu Dhabi in November 2003, adding the new destinations almost every month. The order of 29 Boeing and Airbus aircraft shortly after its set-up represents the largest ever commercial airline start-up order. Passengers carried accounted for 4.6 million in 2007, continually recording rapid growth by an average rate of 18% in the following 8 years (2008 - 2015).

Etihad highly relies on codeshare agreement as a common tool that could significantly bolster passenger demand. Since its first codeshare with American Airlines in 2009, Etihad signed over 40 codeshare agreements with some of the worlds' largest airlines such as Air France, Air Canada and Turkish Airlines, placing itselfin the first place by the number of ratified agreement. Moreover, after being rejected from global alliances, Etihad started establishing its own partnership platform by acquiring equity stake in other airlines. Until now, Etihad owns equity stakes in seven airlines that range from 3% in Air Berlin to 49% in former Jat Airways (now rebranded into Air Serbia). According to CAPA (2016a), Etihad Partners will have only about 2.6% of global ASKs compared to 18% to 24% each for the three big alliances, but it will serve half as many countries as the main alliances (almost 250 destinations in 80 countries). Unlike major alliances which mainly focus on revenue synergies, Etihad equity alliance tackles both revenue and cost structure side, describing "partnership" not as an alliance, but a "brand" (CAPA, 2014a). Thus, Etihad's goal is to achieve the quality of a membership which relies on standardizing the products across the various airlines.

The growth in passenger demand continued to surpass the airline's capacity increase which boosted the need for further fleet expansion (Arabian Business, 2016). In 2015, Etihad Airways' fleet was boosted by the deployment of the Boeing 787-9 Dreamliner, which entered commercial service on routes to Washington DC, Zurich, Singapore and Brisbane.

2.2. Qatar Airways

Qatar Airways was established in 1993 offering its flights to destinations within the GCC and the Middle East. The aim of Qatari Royal family was to transform the airline with only three wide-body and one narrow body aircraft into a strong long-haul international airline. Therefore, the aggressive expansion plan was adopted which assumed acquisition of new aircraft types in order to expand the network. At the 2005 Paris Air Show, Qatar Airways placed an order for 60 Airbus and 20 Boeing 777s, with options for 20 more. Subsequent orders were placed in 2006 and again in 2007 for additional Boeing B777s and for eighty A350 aircraft valued at over 16 billion USD (Hooper, 2011). Main network carriers around the globe carefully observed such intensive fleet enlargements which could potentially jeopardize their position on specific markets. Meanwhile, Qatar Airways showed its willingness to join Oneworld alliance as Emirates kept on putting competitive pressure on many routes due to significantly greater seat capacity and network size. In October 2013, Qatar became a member of Oneworld hereby allowing its passengers greater number of destinations. After accession into the Oneworld, Doha Airport grew into the first alliance hub in the Arabian Gulf. The new airport in Doha was opened on April 2014 and was designed specifically to accommodate A380, since Qatar Airways may order additional units in the future (by 2020, the fleet will contain 10 aircraft type A380).

2.3. Emirates

When Emirates was founded in 1985 by Sheikh Mohammed and his uncle Sheikh Ahmed, it had only two Boeing 727-200s and a start-up capital of 10 million USD as a gift from its founders. In the early period of its business, the company endeavored to build its network in the Middle East and the Indian Subcontinent. The first purchased aircraft was received in 1987 when Emirates started offering its flights to London Gatwick and Frankfurt. In the period from 1990s to 2000s, the airline was relatively unknown in the aviation world until

making the stunning 15 million USD wide-body aircraft order. Since then, the company gradually expanded its fleet by introducing only wide-body aircraft and recently became the largest customer and operator of the Airbus A380 and Boeing 777, with 44 and 121 aircraft respectively. For example, Emirates' fleet is larger than Singapore Airlines and Virgin Atlantic' fleets combined, and these airlines employ onlywide-body fleet (Al-Sayeh, 2014). Concerning the configuration of its wide-body aircraft, Emirates placed into service its latest A380 two-class version seating with 615 seats, which means 18% more seats than its densest A380 configuration (519 seats) (CAPA, 2015b).

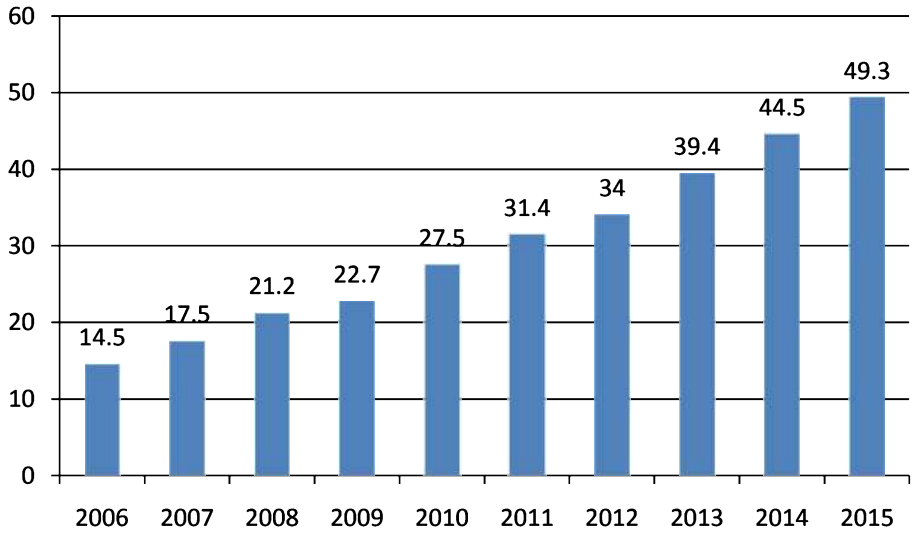

Figure 2: Emirates' number of passengers (2006-2015) (in millions)

Nowadays, Emirates is one of the leading airlines in the world and is expected to surpass even the biggest players such as Delta, United and American, in terms fleet and passenger's growth by the end of 2020. Fig. 2 shows the evident growth in the number of passengers from 2006 to 2015 which almost quadrupled during this period. Emirates' partnership was relatively limited in scope and quantity (CAPA, 2016b) which was not characteristic of other large carriers as they extensively used the benefits of codeshare agreements to gain more passengers and decrease their costs. Emirates and Qantas ratified the agreement announced in 2012 which enabled Qantas to operate through Dubai hub as a connecting airport for Qantas' passengers on their way to Europe. Such cooperation would contribute to considerable advantages, such as revenue sharing and extensive codesharing from both parties on overlapping markets, as well as behind and beyond gateways. Since recently, Emirates is becoming more receptive to those partners with whom reasonable value could be additionally extracted. Thus, the partnership with TAAG in Angola is certainly the smallest, while that with Malaysia Airlines is the larger one.

3. AN OVERVIEW OF EMIRATES' KEY COMPETITIVE ADVANTAGE

As mentioned above, Emirates as well as other airlines from the Middle East, has been absolutely marginal in terms of competition for the large carriers from Europe, America and Asia for a long time. With its aggressive expansion in fleet supported by economic rise of the region in the last decade, especially the Emirate of Dubai, Emirates became a serious threat to long-haul carriers diverting a large portion of passengers to its flights via Dubai Airport. Dubai Airport, as well as other "emerging" carriers' hubs in the Middle East, has a very favorable position since 4.5 billion people reside within an 8-hour flight of the Middle East, providing the potential for a large part of the world's population to connect through a single stop (O'Connell, 2011). The proximity of Asia which is home to more than half of the planet's population emphasizes the potentials of the emerging carriers.

Unlike large European legacy carriers, which implies a hub-and-spoke network in which short/medium-haul flights and long-haul intercontinental flights feed each other through a hinterland hub, Emirates derives substantial cost savings by forming an hourglass hub in which long-haul intercontinental flights and long-haul intercontinental flight feed each other. For example, Air France-KLM report EUR 100 million losses due to Air France regional network in 2012 (CAPA, 2013a), while Lufthansa losses in short/medium haul non-hub network may account to EUR 200 million (CAPA, 2013b). Emirates focuses its business on "secondary-hub-secondary" strategy of connecting Europe's secondary airports with cities in Asia and Australia with only one transfer enabling them to enjoy a competitive advantage in travel time on a number of city pairs because

legacy carriers offer itineraries with two transfers; "secondary-hub-hub-secondary" (Grimme, 2011). Such a network structure provides benefits for passengers' convenience by reducing the number of required connections – Glasgow-Dubai-Sydney with Emirates has one leg less than Glasgow-London-Singapore-Sydney with British Airways). Thus, Emirates offers its flights from secondary airports in Europe (Birmingham, Manchester, Newcastle, Nice, Venice, Düsseldorf and Hamburg) to Asia-Pacific region. From a theoretical point of view, Emirates designed the new concept of expanding its network by adding new "alternative" routes ("edges") rather than byintegrating additional airports ("nodes") into the network. However, choosing hourglass network does not necessarily ensure shorter travel time between certain regions. Vispermann (2008) argues that Emirates, as well as other emerging carriers, have geographic advantage (and consequently, shorter travel time) in regard to South Asia and Oceania, while European carriers offer flights with shorter travel time to destination in North Asia. Emirates is also ideally positioned for India, the second most populous country, for its travel to North America, Europe and Africa (de Wit, 2014) which is not surprising having in mind that India is in the first place by the seat capacity offered in 2016 (Fig. 3).

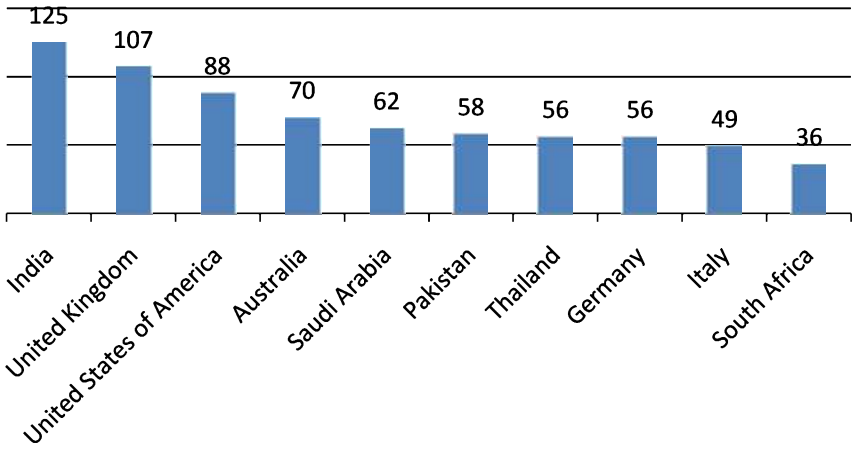

Figure 3: Emirates' seat capacity by country (28-Dec-2015 to 3-Jan-2016) (in thousands)

Likewise in any other industry, keeping unit cost as lower as possible is essential in gaining competitive advantage since it allows airlines to be profitable at low fares. However, when comparing unit costs one must have in mind that they vary according to the average trip length. In general, the cost of producing a seat-kilometre (CASK) falls as average sector length increases since fixed costs are amortized over more seat-kms, while variable costs, such as fuel, are more efficiently consumed in longer flights (CAPA, 2014b).

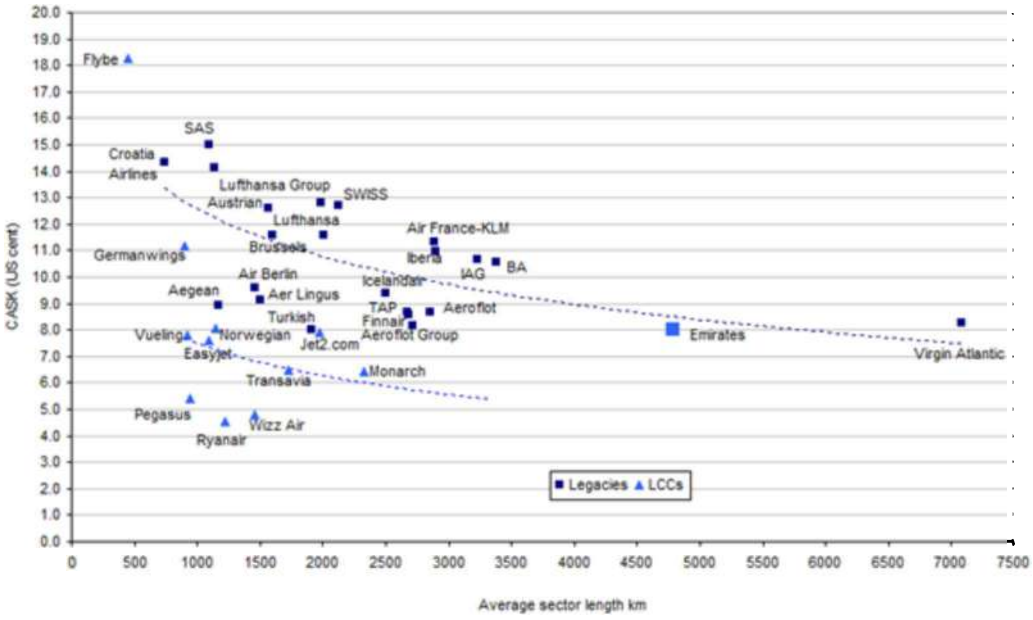

Figure 4: Cost per ASK, CASK, (UScent) and average trip length for selected European legacy and low-cost carriers and Emirates in 2012

Operating hourglass network enables reduction of costs per seat-kilometer as aircraft size increases and reduction of operational costs per kilometer as stage length increases. In other words, only the differences in network structure and design (hourglass hub *vs* hinterland hub) can lead to significant cost differences and competitive advantage to a carrier which operates hourglass network. As it can be observed from Fig. 4, Emirates' CASK is below major European carriers' trend line, as well as below Virgin Atlantic that also relies its operation on ultra long-haul traffic.

A great number of legacy carriers in Europe, supported by their governments, have complained against Emirates' expansion at respective airports. Therefore, many protectionist measures have been stipulated such as those by the German Federal Office for Goods Transport that forced Emirates to increase the price of its business-class fares by about 20% in 2009.

In order to understand Emirates' competitive advantage over its rivals, especially those in Europe and North America, it is crucial to look into airlines' cost structure (Fig. 5).

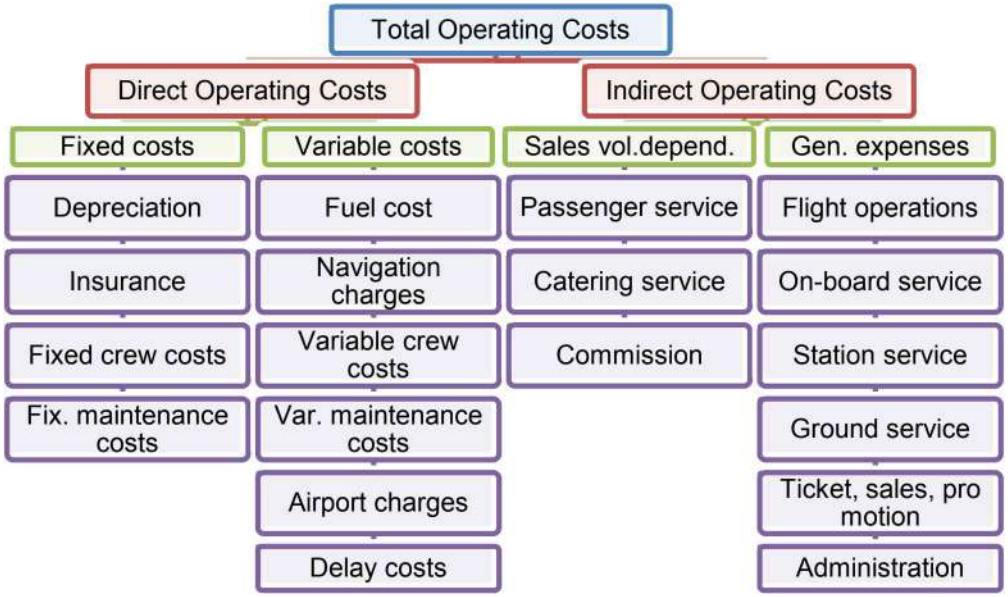

Figure 5: Airline operating costs

Direct operating costs are all those expenses associated with and dependent on the type of aircraft being operated, including all flight expenses (flight crew salaries, fuel, airport and navigation charges), all maintenance and overhaul costs, and all aircraft depreciation expenses. Indirect operating costs are all those costs that will remain unaffected by a change of aircraft type because they are not directly dependent on aircraft operations, including expenses that are passenger-related rather than aircraft-related (such as passenger service costs, costs of ticketing and sales, and station and ground costs), and general and administrative costs. (Wensveen, 2007).

In order to be consistent in unit cost comparison, the airlines' average trip length should be of the similar size. For this reason, in its analyses, CAPA (2014b) compares Emirates' unit costs by cost category with the average unit cost of IAG[2] and Virgin Atlantic, since the average trip length of the latter two approximates to the average trip length of the former.

The results presented in Fig. 6 show that Emirates has an advantage in almost every cost category (labor, fuel, maintenance, landing, parking, overflying, handling, catering, corporate overheads) except selling costs and aircraft ownership costs (depreciation, amortization and operating leases). It is evident that Emirates' gains the most significant savings in three cost categories – labor, fuel and maintenance.

Lower unit labor costs come from the practice of hiring workers from South and South East Asia entwined with Emirates' ban on unionization. Emirates' advantage in fuel cost per ATK comes from the greater fuel efficiency of its young fleet, which has more seats and fuel-efficient engines. The young fleet comprising modern aircraft further contributes to lower maintenance costs. Finally, the "landing, parking and overflying" charges are much lower in Dubai Airport from which a large portion of Emirates' flights have been operated.

[2]IAG – the holding company of Aer Lingus, British Airways, Iberia and Vueling

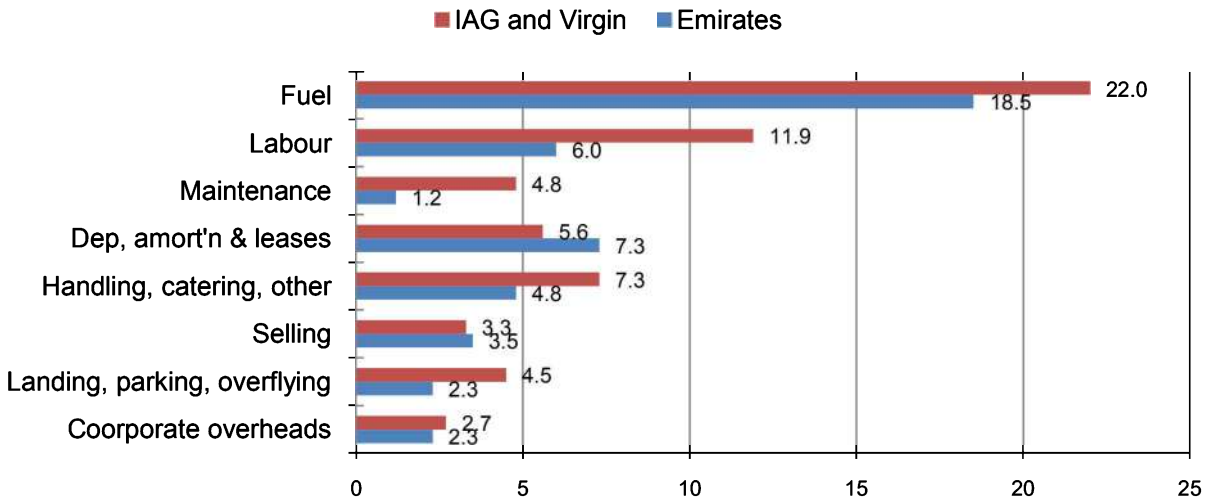

Figure 6: Cost per available tonnekilometre (USc) by cost category for Emirates versus the average of IAG and Virgin Atlantic in 2012

Higher costs per ATK (available tonnekilometres comprises both cargo and passengers) in aircraft ownership category result from huge investments in purchasing new aircraft and significant use of operating leases. In comparison to Lufthansa which has 622 aircraft, out of which a hefty share of 90% is owned (only 4% are on an operating lease and another 6% are on finance leases), Emirates has 205 aircraft, 7% of what are owned, 57% are on are on operating leases and another 36% are finance leased. However, these higher costs are further compensated by lower maintenance cost. The higher unit cost per ATK in "Commercial and selling costs" comes from extensive promotional expenditure such as sponsorship of big sport events as well as from the use of indirect distributional channels in catchment areas such as India and Africa.

4. CONCLUSION

Located at the crossroads between Asia, Africa, and Europe, the region of the Middle East has traditionally been an inevitable point on the routes connecting these regions. The most prosperous countries of the Middle East (i.e. oil-producing) invested substantially in the aviation sector in the last two decades as a part of their intensions to diversify their respective economies in post-oil era. Shortly after their establishment, the "emerging" carriers (Emirates, Qatar Airways and Etihad Airlines) started to benefit from both geographical positions, cost structure which allows tremendous savings in many cost categories and additionally generated demand for air travel. Their favorable geographical position enables approximately 80% of the world population to travel within an eight-hour flight of the region. The "emerging" carriers have broadly exploited this advantage by aggregating traffic at their hubs and offering the shortest one-stop service between many distant city pairs in the East and the West. The long-haul hourglass network developed in this way completely derives the benefits which stem from technological economies of scale of a modern long-haul wide-body fleet.

The largest and most profitable among them, Emirates, is completely owned by the government of Dubai which enables it to operate in a tax free environment with no legacy cost. The successful growth that the airline recorded over the last two decades lies in several important facts such as: flat management model adopted (organizational structure with few or no levels of middle management between staff and executives), avoiding direct subsidies and embracing the competition forced onto it by Dubai's liberal aviation policies. The paper emphasizes the importance of Emirates' hourglass network via its Dubai hub which brings significant savings as the cost of producing a seat-kilometre (CASK) falls as average sector length increases. The results of unit cost across operating costs indicate that the airline gains significant savings in the cost categories such as labor, fuel and maintenance. On the other hand, selling costs and aircraft ownership costs are the only two categories where Emirates has higher unit costs compared to its competitors with similar characteristics. In this way, it can be concluded that the "emerging carriers" has permanently altered the current outlook of aviation industry and caused legacy carriers, especially those from Europe and the United States, to revise their business in order to sustain profitable growth in the future.

*e-mail: dijana.strbac@pupin.rs

Abstract: *Manufacturing industry is regarded as a main engine of economic growth. This paper aims to reveal characteristics of manufacturing industry in Serbia in terms of its technology structure, competitiveness and relative position in a group of countries. Technology structure is presented on the basis of OECD classification of industry based on R&D intensity and competitiveness is introduced using Competitive Industrial Performance (CIP) index as an indicator of relative competitive ability. Conducted analysis has shown that Serbian manufacturing industry is lagging behind selected EU countries which has negative impact on economic growth and development.*

Keywords*: industry, manufacturing industry, technology structure, competitiveness, Competitive Industrial Performance (CIP) index.*

1. INTRODUCTION

Since the first industrial revolution, over the second and third, until the emerging fourth industrial revolution, industry is the main driving force of economic growth and development. This driving force is an integral part of the process of diversification and development of human creativity and its needs, and it depended on technological progress and the dynamics of the development of knowledge, science and technology. The development features and characteristics are based on the development and structural changes of the industry, which includes relative participation of new and technology intensive industries. There are theoretical and empirical arguments proving that the industry, especially the manufacturing sector, is the initiator and driving force of economic development and structural changes of the national economy. Compared to other sectors, manufacturing industry provides special opportunities for capital accumulation, economies of scale and technological progress (Szirmai, 2009).

The main drivers of intensive industry development and its structural changes are: knowledge, skills, innovation, technology, demand, resource efficiency, investments, company size, activities of the value chain, agglomeration and industrial policy (Mićić, 2015). In other words, technology is a factor that largely determines the characteristics of structural changes in the economy and industry.

The process in which the economic structure evolves under technological development can be explained in the following way: investment in R&D drives the development of new technologies, installation of capital stock brings new technical processes into sector production, new and old technical processes within a sector exchange their relative weights in production as they are phased in or out, and sectors evolve or transform over time (Pan, 2006).

Authors exploring economic and industrial development of Serbia consider that the most important problems of Serbian economy are structural discrepancies, obsolete technology, a low level of investments, high production costs, the social function still dependent on companies, inefficiency, ecological requirements, but also low exports, incompatibility with the EU standards, and a lack of comprehension of industrial processes in the EU (Jakopin & Bajec, 2009).

The main feature of structural changes in the economy of Serbia in the last two decades is deindustrialization accompanied by inadequate implementation of transition and privatization. Hence, there is the necessity of formulating new industrial policy that will be based on: export-oriented reindustrialization (Mićić & Zeremski, 2011), identifying and supporting propulsive sectors and industries (Aranđelović, Petrović-Ranđelović, & Marjanović, 2013), and creating incentives for specific companies and sectors by public authorities (Kočović & Radovanovic, 2013).

Analysis of Serbian industry is enriched including topics such as R&D, technology, innovation. New industrial policy in Serbia should be based on research and development (R&D), new technologies, education, effective investments and integrative networking of all key partners in all phases of reproduction (Leković & Mićić, 2013). It also recognized the necessity of introducing innovations in order to increase the technological level of the industry and improve competitiveness in the international market (Savić, Bošković & Mićić, 2012). Starting from the view that the development of science and technology essentially defines the intensity and speed of economic growth, domestic authors are also researching the capabilities of the Serbian economy to create and commercialize knowledge and technology. One of the approaches is the concept of national innovation system, which is based on the assumption that the research system is part of a larger system that includes economy, institutions, academic community and environment (Kutlača & Semenčenko, 2005).

The main objective of this paper is to point out the importance of manufacturing industry structure, technology profile and competitiveness as general conditions of sustainable economic development. In order to reveal relative position of Serbian manufacturing industry, its characteristics are compared to selected industrialized and industrializing EU countries.

2. METHODOLOGY

In empirical studies and literature there are various indicators of industry structure, technology profile and competitiveness. In this paper, base index of industrial production was used with a goal to determine general trend and dynamics of the development of the Serbian economy in the last two decades. As the base period was used 1990 in order to perceive the relative decline in the level of industrial production in the period 1991-2013. Structural changes in the manufacturing industry of Serbia were analyzed on the basis of gross value added (GVA).

Comparative research method was applied for evaluation of growth rate of manufacturing industry. Growth in industrial production in Serbia was compared to the growth rates of manufacturing industry of selected industrialized and industrializing economies. Countries were classified in two groups according to the classification presented by United Nations Industrial Development Organization (UNIDO, 2013). Selected countries from group of industrialized economies are: Czech Republic, Hungary, Slovenia, Slovakia and from industrializing - Bulgaria, Croatia, Poland, Romania, Serbia.

Technology structure of Serbian industry was analysed using OECD classification of industries by technological intensity. Starting from the premise that technological advances are a key determinant of productivity growth and international competitiveness, OECD has made a classification of industries based on technological intensity. An analysis of investments in research and development and the results of this activity, the OECD has ranked all manufacturing industries in 4 categories: high technology, medium-high technology, medium-low technology and low technology (OECD, 2005).

Competitiveness of manufacturing industry was analyzed using data on CIP index which is based on understanding industrial competitiveness as the capacity of countries to increase their presence in international and domestic markets whilst developing industrial sectors and activities with higher value added and technological content. The CIP index consists of eight sub-indicators grouped along three dimensions of industrial competitiveness: 1) countries' capacity to produce and export manufactures, 2) technological deepening and upgrading, 3) world impact (UNIDO, 2013).

3. INDUSTRY STRUCTURE AND INDUSTRIAL GROWTH IN SERBIA

After the Second World War, Serbian economy was characterized by rapid industrialization that affected the overall socio-economic revival of the country. After 1990, breakup of the federal state, civil war and economic sanctions led to the disintegration of industrial system of Yugoslavia. Transition process after 2000 brought intense structural transformation and creation of a market economy. Although in this period was planned an industry recovery, the process of deindustrialization is continued. Hence, many authors point out that it is necessary to carry out the process of re-industrialization in Serbia. Performance of Serbian industry after 1990 can be perceived using base index of industrial production (Figure 1). Base indexes of industrial production show that the period after 1990 was characterized by a drastic decline in industry production, and even after 2000 industrialization has not been stopped. In 2013 industrial production amounted only 47.43% of the industrial production in 1990.

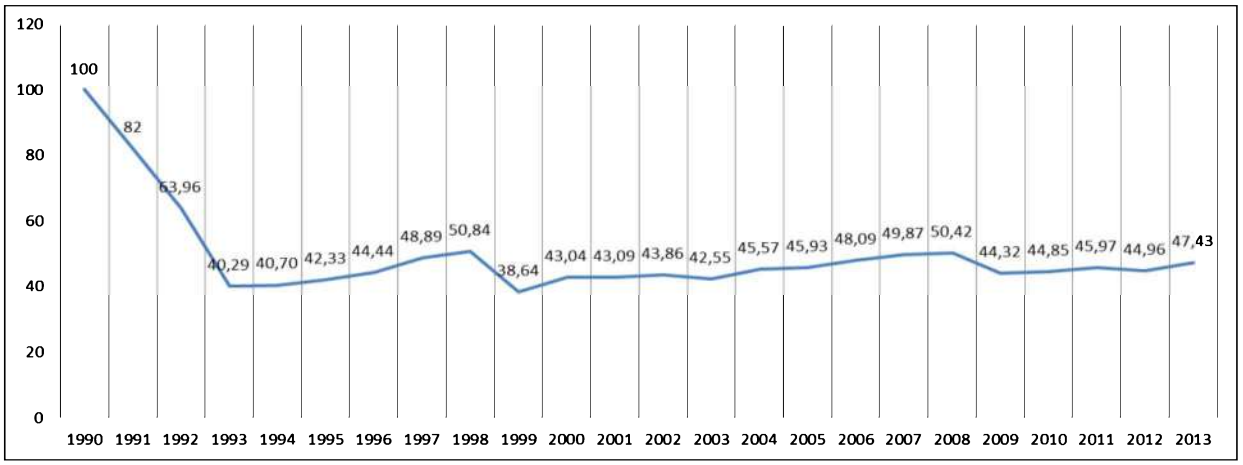

Figure 1: Indexes of industrial production in Serbia from 1990-2013.
Source: Statistical Office of the Republic of Serbia.

The decline in industrial production in Serbia after 2000 is followed with structural transformations visible in the structure of production and employment. In addition to a global trend that is reflected in the growth of the service sector and a reduction in the share of industry and agriculture, it is important to analyze the changes in the structure of industry gross value added (Table 1). The structure of industrial production in Serbia shows that the manufacturing industry had the largest share in the structure of gross value added. However, in the period 2000 to 2014 there was a reduction in the share of manufacturing industry and increase in the share of the other three industry sectors (mining and quarrying; electricity gas, steam and air conditioning supply; water supply, sewerage, waste management and remediation activities). According to the presented data, decline of manufacturing industry share in the reporting period was 7.9%.

Table 1: Gross value added by activities (current prices, structure, %)

	2000	**2001**	**2002**	**2003**	**2004**	**2005**	**2006**	**2007**	**2008**	**2009**	**2010**	**2011**	**2012**	**2013**	**2014**
Mining and quarrying	1,1	0,9	1,3	1,4	1,3	1,3	1,4	1,2	1,2	1,1	1,3	1,5	1,6	1,5	1,1
Manufacturing	**23,6**	**22,6**	**18,4**	**16,9**	**15,0**	**14,4**	**13,8**	**13,9**	**14,0**	**14,0**	**13,6**	**14,1**	**15,1**	**16,1**	**15,7**
Electricity, gas, steam and air conditioning supply	0,6	0,7	2,4	2,6	2,8	2,8	2,8	2,7	2,6	3,0	2,8	2,9	2,9	3,6	2,9
Water supply, sewerage, waste management and remediation activities	0,8	0,9	1,0	1,2	1,2	1,2	1,2	1,1	1,0	1,0	1,1	1,2	1,2	1,2	1,2

Source: Statistical Office of the Republic of Serbia.

Average growth rate of Serbian manufacturing industry in the last 15 years was 0.75% which is considerably lower than in selected countries in both country groups (Table 2). For example, average growth rates in Slovakia, Poland and Czech Republic were 8.58%, 6.05% and 4.54% respectively. Since growth rates of manufacturing industry represent and indicator of total economic results in certain period, general conclusion is that manufacturing industry of Serbia has insufficient impact on GDP and productivity growth.

It is interesting to note that almost all observed countries have high volatility of growth rates of manufacturing industry (which shows their standard deviation) and very low minimal values. This is mainly due to the impact of Global economic crisis which resulted in extremely negative growth rates of manufacturing industry in 2009.

Table 2: Growth rates of manufacturing sectors from 2001-2015, in %.

Country group/ country		Average	Min	Max	Standard deviation
Industrialized economies	Czech Republic	4,54	-14,70	12,40	6,92
	Hungary	4,43	-18,20	11,70	7,41
	Slovenia	1,83	-19,10	8,50	6,55
	Slovakia	8,58	-18,70	21,60	10,24
Industrializing economies	Bulgaria	4,40	-22,40	17,60	9,12
	Croatia	1,23	-10,40	6,20	4,79
	Poland	6,05	-3,50	14,50	5,45
	Romania	4,06	-6,60	13,30	5,44
	Serbia	0,75	-15,90	7,70	5,63

Source: Eurostat

The reason for very modest results of Serbia in terms of growth rates of industrial production lies in the development model applied in the observed period. It was a development strategy based on the significant role of the service sector, import and foreign direct investment. This model of development has not contributed to the increase in production and employment in those industries that could realize high productivity and rapid economic growth. Bearing in mind the developments in the last two decades it can be concluded that economic and industrial policy should be based on increase of production and productivity in the sectors of tradable goods an a reduction in costs in the non-tradable goods sectors, which will in turn affect the growth of competitiveness and creating an attractive investment environment.

4.TECHNOLOGY STRUCTURE AND COMPETITIVENESS OF SERBIAN MANUFACTURING INDUSTRY

In addition to the low growth rates, Serbian industry is characterized by unfavourable technological structure. As presented in Figure 1, in the structure of Serbian manufacturing industry dominate industries of low and medium-low technology intensity, while the lowest share have high and medium-high technological intensity industries. Average share of low-technology manufacturing in the period 2000-2013 is 46.51% and average share of high-technology manufacturing is 6.57%. In the observed period, only medium-low technology industries tend to increase, while other technology groups tend to decrease.

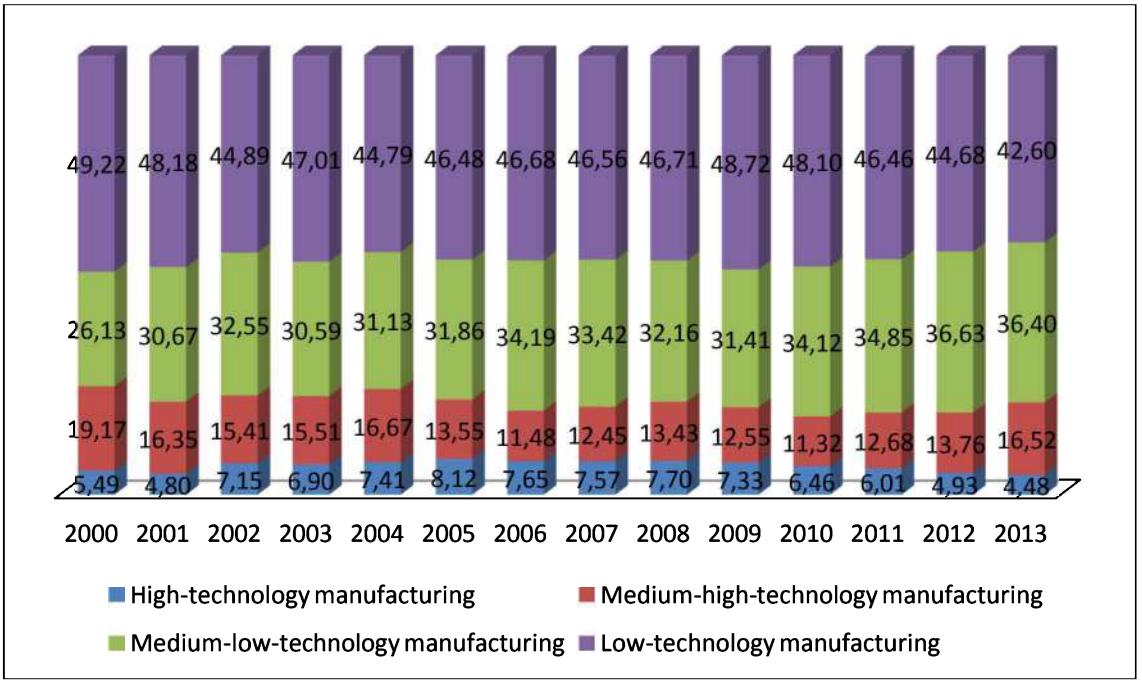

Figure 2: Technology structure of Serbian manufacturing industry.
Source: Calculated by the author on the basis of data from Statistical Office of the Republic of Serbia.

Unfavourable technology structure of Serbian industry proves that its production has low level of technology intensity, low level of finalization and a low added value. Such products are generally intensive with labour and natural resources, which has low impact on economic growth and development. Also, these results imply extremely small investments in improving the technical level of the industry, but also a lack of implementation of the results of scientific research in industrial production.

Presented data on the structure of GVA, growth rates and technological intensity of manufacturing industry of Serbia show inefficient structural reforms implemented after 2000. Structural changes have not been based on increasing the technological intensity of production which resulted in the inability of Serbian manufacturing industry to achieve a satisfactory rate of growth and competitiveness in the world market.

Manufacturing industry is not just an ingredient of development - it is the essential ingredient. Namely, manufacturing industry is: applying technological progress to production, driving innovation, diffusing innovation, developing new skills and attitudes, leading institutional development, producing beneficial externalities, stimulating modern services, generating dynamic comparative advantage, internationalizing economies, modernizing enterprises (UNIDO, 2002).

The competitiveness of a country arises from the manufacturing industry performances. Therefore, it is important to see relative positions of countries in terms of manufacturing industry competitiveness. In order to understand relative competitive position of Serbian manufacturing industry it is used Competitive Industrial Performance (CIP) index.

Competitiveness of the manufacturing industry in Serbia is at a very low level, which reveals 74th place in 2012 out of 140 analyzed countries (Table 3). All selected countries in both country groups have higher ranks which are result of more successful performances of their manufacturing industries. If the competitiveness of Serbian industry is observed in the last two decades, it can be seen that after the sharp decline during the 1990s, there was no significant improvement after 2000. Unlike Serbia, Poland, Hungary and Slovakia have significantly improved their relative competitiveness in the last twenty years.

Table 3: Ranks of competitiveness of manufacturing industries for selected countries

Country group/ country		CIP index rankings			
		1990	2000	2010	2012
Industrialized economies	Czech Republic	25	24	19	18
	Hungary	36	27	26	27
	Slovakia	37	41	27	25
	Slovenia	28	31	32	33
Industrializing economies	Bulgaria	43	63	59	59
	Croatia	33	50	54	57
	Poland	51	33	24	23
	Romania	34	44	35	34
	Serbia	54	79	75	74

Source: UNIDO, 2015.

If the CIP index value in 2012 is observed (Figure 3), industry of Serbia has the CIP index of 0.03 which is several times lower than in other countries surveyed. These data show extremely low performances of manufacturing industry in Serbia.

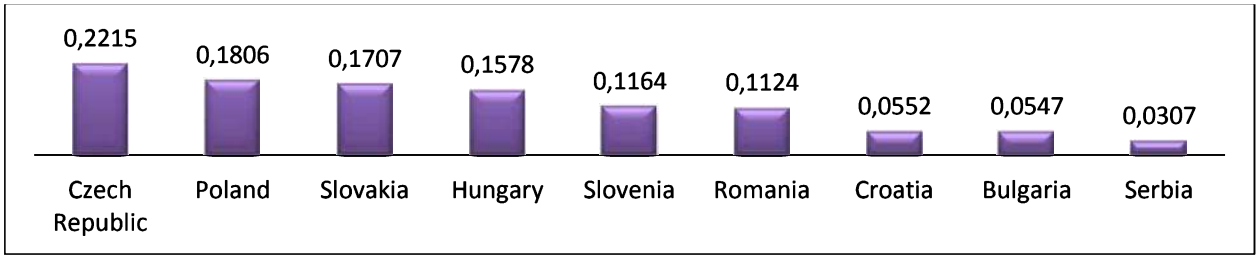

Figure 3: CIP index values in 2012
Source: UNIDO, 2015.

Although CIP index has important functions in monitoring and benchmarking industrial competitive performances, it is necessary to take it into account as a preliminary indicator of countries' industrial competitiveness. This means that using CIP index for creating industry should be complemented with other analyses on different levels (sector, industry, production task, institution, company, etc.) and topics (infrastructure, technology, labor and capital costs, innovation types).

5. CONCLUSION

Empirical analyses and economic reality have shown that successful industry and especially manufacturing industry is one of the basic determinants of long run sustainable growth. Manufacturing industry is the prime creator of value added and jobs in the economy; it is a field for application of technological development in production generates positive externalities for the rest of the economy and therefore it is a source of a country competitive ability. Manufacturing industries with higher technological intensity will create greater value added in the economy and higher growth rates.

Structural transformations in Serbian economy after 2000 were visible in the decrease of manufacturing industry share in the structure of gross value added. This was followed with variable growth rates and low average growth rate of manufacturing industry (0.75% in the period 2001-2015). The reason for this is a development strategy in this period which was based on significant role of import, foreign direct investment and service sector. Manufacturing industry was also characterized with unfavourable technology structure which means that those industries that require most R&D investments had the lowest share in Serbian GVA. According to relative industrial competitiveness indicator, CIP index, Serbian manufacturing industry competitiveness is one of the lowest in the group of industrializing countries.

Low performances of Serbian manufacturing industry indicate that there is a need to change industrial and development policy in order to re-industrialize the economy and increase production in industries that can create high productivity. To achieve this, it is critical to address constraints on technology development as important part of strategy for improving competitiveness of manufacturing industry.

GLOBAL ELECTRONIC MARKET IN THE FUNCTION OF RETAILERS INTERNATIONALIZATION

Jelena Končar[1], Zita Petrović Katai[1], Sonja Leković[1]
[1]University of Novi Sad, Faculty of Economics in Subotica
*Corresponding author, e-mail: koncarj@ef.uns.ac.rs

Abstract: *New incentives to strengthen the domination of international retailers are the development of products with the trademark and management of product categories. The globalization of markets and a steady increase in the internationalization of retailers, thanks to scientific and technological progress through interactive resources, leads to the development of electronic marketing channels. The internationalization of the business of large retailers contributes to the growth of concentration of the European and world market retail. Large retailers using modern technological innovation and business internationalization become agents of development in the electronic market.*

Keywords*: private label, globalization, internationalization of retailers, concentration, electronic market.*

1. INTRODUCTION

The structure of retailing is transformed in the European Union and other developed economies markets from a large number of small and independent retailers to the emergence of strong national and multinational retailers. Retailers develop new strength by applying technological innovation and internationalization of business. Large retailers are taking a leading role in relations with consumers and dominant position in the marketing channels. Strengthening retail power in marketing channels in the global electronic market opens numerous intensive theoretical and practical issues:

- What are the essential components of differentiation and market positioning of large retail companies in regard to competition?
- What is the achieved level of the electronic retailers' market concentration?
- What is the strengthening of the position of global electronic retailers in marketing channels like?
- Is the concentration of retailers in favour of consumers?

Based on the issues mentioned above there is a need to analyze the concentration of retailers in the global electronic market. In this sense, it is necessary to consider the largest electronic retailers regarding consumers in marketing channel system of consumer goods. Strengthening the power of retailers in relation to other participants in the global market intensifies the process of horizontal and vertical integration in the electronic marketing channels.

2. PRIVATE LABEL AND MANAGEMENT OF PRODUCT CATEGORIES AS NEW INCENTIVES FOR INTERNATIONALIZATION

Successful market positioning in relation to competition provides retailers with differentiation and strengthening of their own private label. By the development of private label large retailers achieve higher profitability and create loyal customers. Private labels allow concentrated, powerful and large retailers to strengthen their market position in marketing channels. The following figure indicates the market share of products with private label by individual countries in Europe.

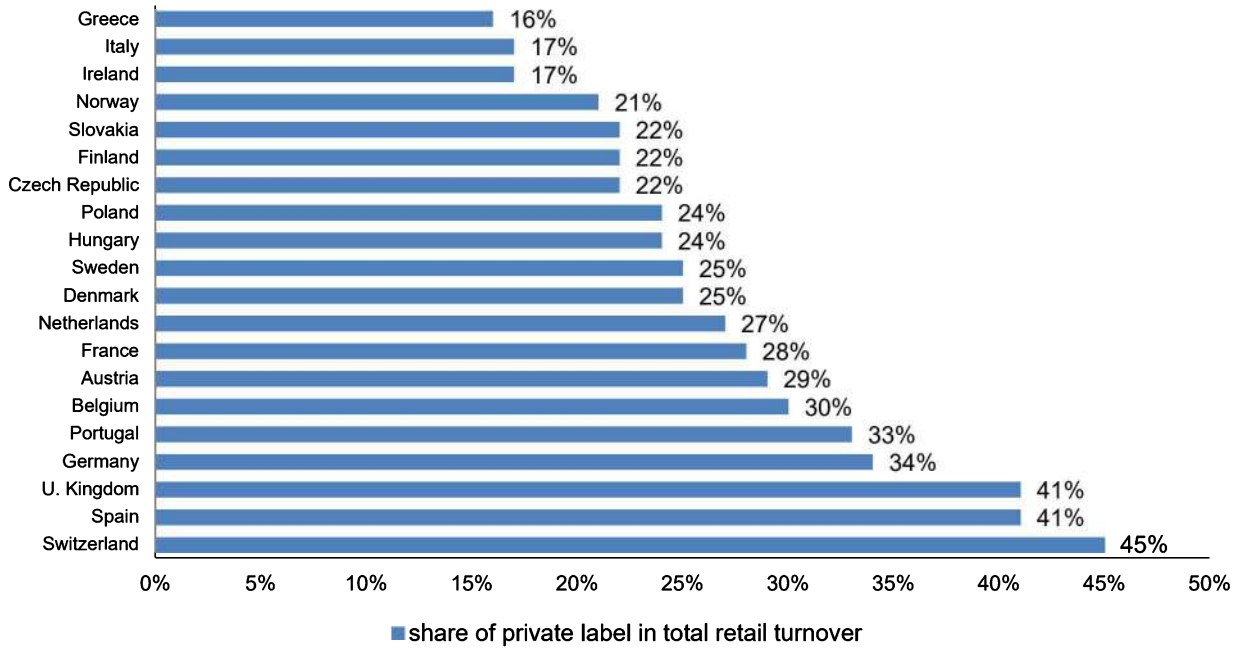

Figure 1: Market share of products with private label by individual countries in Europe in 2014 (Nielsen, 2014, p. 6)

The largest market share of products with the private label was recorded in Switzerland 45% Spain 41% and the UK 41% in 2014, but also with significant participation in other European countries. The average value of the global market share of products with the private label amounted to 16.5%in 2014. The long-term trend of development in all markets in Europe indicates continuous increase in share percentage of products with private label.

Highly noticeable processes of retail market concentration have marked the end of the last and the beginning of this century (Lovreta, Končar and Stanković, 2015, p. 213). High level of competition in Europe confirms that its intensity is an essential factor in the development of private labels. Higher concentration of retail market of food and other products of everyday consumption leads to greater share of private labels in retail. Retailers with internationalization of their business create international corporate brands.

With the development of products with the private label, retailers are creating new market-oriented brands based on a comprehensive behavior of consumer needs. Along with the development of private label there is also a parallel process of building management product categories in the internationalization of retailers. Product categories managers have the task of creating the structure of assortment, selection of producers, the arrangement of space in the retail store, all in order to achieve the set targets and product profitability. Strong suppliers who dominate in one or more categories of products, which bears greatest responsibility for achieved retailers' business results, certainly have the preference. Suppliers undoubtedly need to meet the standards in order to enter the discussion with product category managers of large retailers. Product categories managers are focused on consumer demand for producer brands, and reliability of quantity and availability of the product, in order to meet the demand of the whole chain of retail stores.

Product category managers are increasingly counting on products with private label in achieving profits nowadays. Consumers are increasingly looking for a distinctive offer from modern international retailers which is provided through a range of products with the private label. All retailers in Europe have developed a range of products with private label. The achieved level of concentration of the retail market and the participation of the trade mark in the retail market is highly positively correlated. It must be emphasized that strengthening the power of retailers would not be happening without modern technological advances that are increasingly focused on meeting the needs of consumers in the global electronic market of consumer goods. The unique technology of electronic retailing opens up new opportunities for marketing and sales on the global electronic market. The unique characteristics of e-commerce technologies are: ubiquity (Internet/Web technology is available at any location), global reach (technology across national boundaries throughout the world), the universal standard (Internet standards, as well as a collection of new technological standards), social technology (content generation technology users and social networks), personalization and customization (this technology allows the transfer of personalized messages, both individuals and groups), information density (information technology reduces costs and raises their quality), interactivity (technology

that works through the interaction with the user) and wealth (technology allows different types of messages, such as video, audio and text messages) (Končar, 2015, p. 281). Information technology has changed the structure of marketing channels where international retailers dominate in contemporary conditions with specific strategies of global performance and development.

3. ACTUAL LEVEL OF CONCENTRATION OF ELECTRONIC RETAILER MARKET

The globalization of markets and supranational regional integration contribute to the internationalization of the retail trade, which develops specific marketing and management strategies (Končar, 2015, p. 276.). The effects of the internationalization of retailing are visible on the example of the European Union single market. Intensified internationalization processes strengthen the position of retailer in relation to producers. It is difficult to imagine success in modern business environment on the international market without creating networked and long-term relationship between a larger numbers of participants in the chain of creating value for consumers (Lovreta, Končar and Petković, 2013, p. 572). Internationalization opens up new areas of growth and development in the modernization processes of markets and retailers. Higher level of market concentration of electronic retailers certainly is an important factor in the development of modern global markets and trade. Electronic retailers are getting bigger at the national and supranational level, with a growing market share that belongs to a smaller number of retailers. An important role is played by electronic retailers who take up internationalization activities and expand operations to foreign markets contributing to significantly lower level of concentration.

Internationalization and globalization lead to a higher degree of concentration and expansion of multichannel approach in trade (Končar and Lekovic, 2015, p. 361). The growth of level of concentration and strengthening the power of big electronic retailers such as Amazon.com, Apple Inc.com, J.D.com, and others, lead to changes in balance of power in marketing channels affecting the management and operation of electronic markets. Strengthening the power of retailers is conditioned by increasing the achieved level of concentration of retailing, technological development of the retail sector as well as modern management and marketing strategies. One of the most significant trends occurring in retailing is that of technological innovation (Dunne, Lusch and Carver, 2014, p. 165.). The formation and development of electronic retailing and more intense globalization of the retail activity leads to new positions in contemporary market conditions. Large retail chains are increasingly developed and become dominant in the global electronic market. Strengthening the market position of retailers intensifies changes in the development of electronic retail formats.

Table 1: Status of electronic retailing at major retailers by revenue in 2014 (Deloitte, 2015, G12, G36)

No.	Rank among largest electronic retailers	Company	Country of origin	Share of electronic retailing in total retail revenue	Growth of electronic retail revenue in 2014	Growth of electronic retail revenue from 2011-2014	Growth of retail revenue from 2009-2014
1	4	Wal-Mart Stores Inc	USA	2.5%	22.0%	24.0%	3.5%
2	6	Tesco PLC	United Kingdom	6.5%	20.0%	14.6%	1.8%
3	9	Casino Guichard-Perrachon S.A.	France	7.1%	20.1%	15.8%	13.1%
4	11	The Home Depot Inc.	USA	4.5%	36.9%	42.9%	4.7%
5	16	Costco Wholesale Corporation	USA	2.7%	18.0%	15.9%	9.5%
6	31	Metro Ag	Germany	2.4%	20.2%	56.9%	-0.8%
7	33	Target Corp.	USA	2.5%	30.0%	19.3%	2.7%
8	36	Carrefour S.A.	France	1.8%	-	-	-2.8%
9	41	GroupeAuchan SA	France	2.2%	1.7%	11.3%	6.2%
			Average	3.5%	21.11%	25.1%	4.21%
			Average of 250 largest retailers	13.2%	19.7%	22.0%	4.9%

The largest "click and brick" retailers by revenue, with the specified rank in the group of largest electronic retailers are listed in Table 1.The share of electronic retailing in the total retail turnover is from 1.8% to 7.1%.It can be concluded that retailers successfully implement electronic retailing, as indicated by the high rate of revenue growth in case of these electronic retail retailers. If we compare the growth rate of sales in

the retail and electronic retail revenue growth in general, at the level of each individual retailer, rate is several times higher. The same indicator is for all major retailers.

Growth of the global "pure play" electronic retailers has a positive influence on the growth of levels of productivity and profitability in retail phase of electronic marketing channels. Strengthening the power of electronic retailers and raising the level of concentration contributes to creating new value for customers. All this generally leads to a higher level of concentration of retail and changes relations between competitors on the global electronic market.

4. STRENGTHENING THE POSITION OF GLOBAL ELECTRONIC RETAILERS IN MARKETING CHANNELS

Strong market concentration and the dominance of a small number of major retailers change the structure of marketing channels. Modern retailers create superiority in horizontal and vertical relationships of competition in the global market. The increase in the concentration of power and strengthening the global "pure play" electronic retailers in marketing channels contributes to the internationalization and expansion of electronic markets. A higher level of concentration in the sector of electronic retailing focuses on the issues of horizontal and vertical competition within the marketing channels in the global electronic market.

Table 2: The largest global "pure play" electronic retailers by sales revenue in 2014 (Deloitte, 2015, G36-37)

No.	Rank among largest electronic retailers	Company	Country of origin	Electronic retail revenue u mil USA $	Growth of electronic retail revenue in 2014	Growth of electronic retail revenue from 2011-2014
1	1	Amazon.com	USA	70.080	15.1%	18.6%
2	2	JD.com	China	17.672	62.0%	73.2%
3	12	Vipshop Holdings Limited	China	3.701	120.2%	153.8%
4	17	Zalango AG	Germany	2.943	25.7%	63.1%
5	20	Newegg Inc.	USA	2.800	3.7%	1.6%
6	28	Vente.privee.com	France	2.311	8.0%	17.5%
7	39	ASOS Plc	United Kingdom	1.579	26.7%	25.6%
8	40	Ocado Group plc	United Kingdom	1.570	19.8%	16.6%
9	42	Overstock.com Inc.	USA	1.497	14.8%	12.4%
10	45	Ulmart, CJSC	Russia	1.300	50.0%	63.2%
				Average	34.6%	44.56%
				Average of largest electronic retailers	19.7%	22.0%

The largest global "pure play" electronic retailers according to their origin are from the countries with developed market that have developed an electronic market. Indicators of revenue growth of electronic retailers indicate higher growth rates for "pure play" electronic retailers. Revenue growth of these electronic retailers is also higher than the growth of the "click and brick" electronic retailers. Customers are becoming more and more able to make contact in physical and digital way with retailers thanks to multichannel approach. Developing strategies in-store and online technology enables the creation of links with customers through all marketing channels. Consumers are increasingly comfortable with buying through multiple channels and types of outlets, such that their purchase behavior varies not just by segment but also by purchase occasion (Palmatier, Stern and El-Ansary, 2015, p. 215). Multichannel access combines the physical and digital modes sales. By recognizing the needs of consumers, competition and market trends allow modern retailers to create long-term sustainable competitive advantage. This particular range of product categories and services provide global retailers improvement in business performance. The level of retail globalization by product category in 2014 can be seen in Table 3.

Table 3: Level of globalization by retail product categories in 2014 (Deloitte, 2015, G28)

	% Retail revenue from operations outside of the country of origin	Average number of countries in which retailers operate	% of retailers that operate in only one country
Clothing and footwear	31.6%	25.9	14.6%
The products of daily consumption	22.2%	5.3	41.3%
Technique	24.5%	8.1	33.3%
Different product categories	22.2%	11.4	36.4%
Average of largest retailers	23.4%	10.4	34.0%

Strengthening the position of large retailers by product category is the result of the development of product line selection. Retailers carry out a careful different selection of products in case of business outside the country of origin and, or if they are operating in only one country, as can be seen in Figure 2. The growth of market concentration by product category, clothing and footwear, products of daily consumption, techniques and different product categories, based the growth and strengthening of major retail chains, contributes to a growing level of efficiency in the global electronic market.

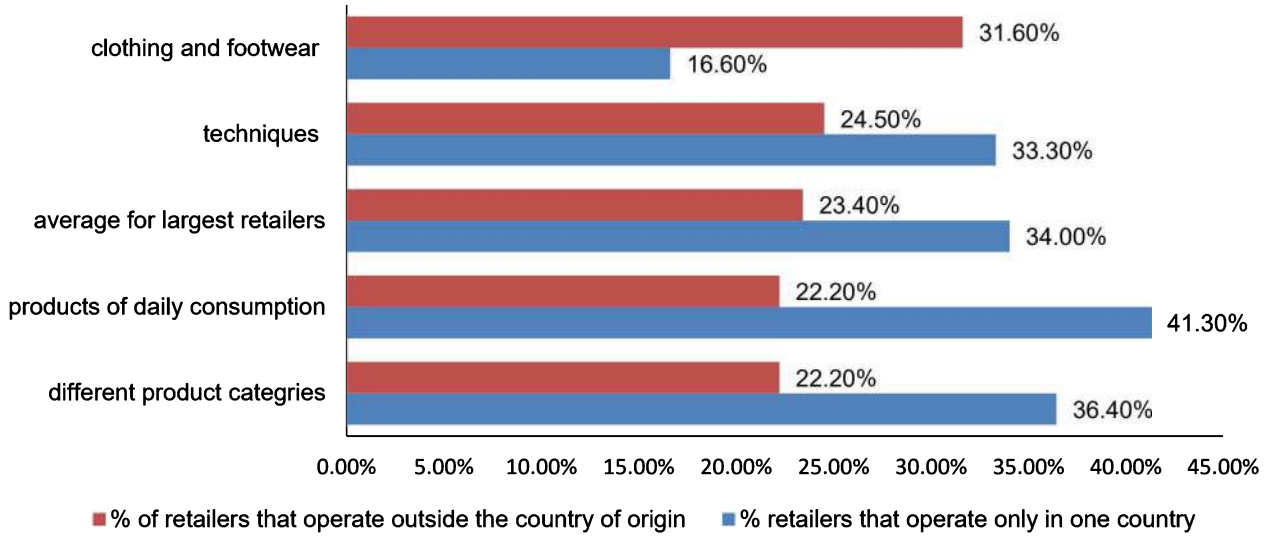

Figure 2: Retail sales by product category outside the country of origin and retailers operating in only one country (Deloitte, 2015, G28)

Online commerce is much more flexible, and what offers customers is saving time and the possibility of buying products that are not available on the local market. With the globalization of retailing customers can order online products of different brands outside the country of origin. It is anticipated that world will have 4 billion Internet users in 2019 and by 2020. Further growth of electronic retailing is linked to the growth of Internet use and the availability of infrastructure, which will facilitate the use for the consumers. Number of Internet users in the past has grown exponentially, with slower growth in recent years, but the adoption of this technology by younger users is noticeable. Its mass use and innovative potential of the Internet will certainly have an impact on the further globalization of markets, and special offers have developing countries in integration into global flows. Balanced growth of the total population in the world is expected in the preceding period, while growth in the number of Internet users has a decreasing pace of growth and stagnation in the previous period, reaching 40% of the total world population.

Effective marketing channel strategies of international retailers create a new structure of the multichannel strategy. Online catalogs are becoming leaders in the structure of the multi-channel mix. In the United States, about 74% of Internet users, age 14 and older, are “buyers”. Another 16% research products on-line (“browsers”), but purchase them off-line (Laudon and Traver, 2015, p. 378). Good multichannel strategy becomes the primary mean of achieving sustainable competitive advantages (Končar, 2015, p. 302).

5. CONCLUSION

The growing internationalization of retail activity causes changes in competitive structure of global electronic market. Product development strategy with the private label and management of product categories become the new incentives in the internationalization and the dominance of retailers. Electronic retailers internationalize their activities and contribute to the growth of the degree of concentration and change the balance of power in marketing channels. The market position of major retail chains intensifies changes in the global electronic market. Thanks to multi-channeling, retailers achieve long-term competitive advantage. Levels of retail globalization at individual product categories contribute to increasing the efficiency of electronic markets. International retailers through a multichannel strategy contribute to long-term sustainable competitive advantages in the global market.

THE CONCEPT OF HYBRID METHOD FOR RISK ASSESSMENT IN NEW PRODUCT DEVELOPMENT

Radul Milutinović*[1], Biljana Stošić[1],

[1]Faculty of Organizational Sciences, University of Belgrade
*Corresponding author, e-mail: radul.milutinovic@fon.bg.ac.rs

Abstract: *Contemporary companies are forced to assume significant risk if they want to quickly and successfully launch a new product to the market. Therefore, the ability of effective risk management is considered as very important factor in the implementation of high-risk projects of product innovation. This paper presents a new hybrid method for risk assessment suitable for new product development (NPD) projects, created by connecting two well-known methods, Risk Breakdown Structure - RBS and Failure Mode and Effects Analysis - FMEA. The RBS is employed as a foundation for this hybrid method. The method includes formulating of the RBM matrix, which is based upon two dimensions (1) Work Breakdown Structure (WBS) - presented through phases of Stage-Gate model and (2) Risk Breakdown Structure (RBS) - presented through categories of risk that can significantly impact the innovation project. FMEA method is used due to its way of overall importance of risk calculation i.e. the way risk priority number is calculated.*

Keywords*: hybrid model, risk assessment, risk categories, NPD, RBS, FMEA, Stage-Gate*

1. INTRODUCTION

In today's unpredictable business surrounding companies have to be prepared to adapt and develop if they want to survive. Therefore, most of nowadays companies with great concern refer to improvement of their innovation performance in order to achieve sustainable growth and significant competitive differentiation (Milutinovic & Stosic, 2013). Considerable number of authors and leaders from different branches identified innovation as a key driver in long-term success and profitability (Stosic, Milutinovic, Zakic & Zivkovic, 2016).

Innovation has been regarded as risky and hazardous which can be confirmed by the fact that only one of sixty product ideas brought into the innovation process reached commercial success, and about 80% of man-hours are used on unsuccessful products in innovation ventures (Epstein, 2002). Also, it is estimated that about 46% of the funds, invested by company in the development and launch of new products/services is related to unsuccessful projects (http://www.prod-dev.com/stage-gate.php).

Having in mind that innovation ventures carry considerable risk that cause more than one half of the individual innovation undertakings to fail, companies have to find the way to succeed in commercial success. In order to minimize the risk in innovation projects companies use the risk management as one of the most influential factors for innovation project success. By itself, risk can appear in any aspect of innovation project and consequently can result in cost overruns, schedule delays and even poor quality (Murray, Grantham, & Damle, 2011). Therefore, risk management in innovation projects is an important topic for practitioners and academic scholars and therefore today it is being increasingly incorporated into business models. Implementation of effective risk management strategy leads to increased performance in NPD (new product development) firm (Mua, Peng, & MacLachlan, 2009). According to survey conducted by Murray, Grantham, & Damle, (2011) the majority of participants - managers with extensive project management experience, confirmed that have used some kind of risk management techniques.

This paper presents new hybrid method for risk assessment, as a part of the overall risk management process in the NPD projects. The main goal is to provide a structured process that identifies how objectives, in this case phases of model Stage-Gate, may be affected. Additionally to analyze the risk in term of consequences and their probabilities before deciding on whether further treatment is required. Risk assessment indicates risk identification, description of the risks, and estimating their respective probabilities and impacts (IEC/FDIS, 2009). While the tools and techniques used for risk identification are designed to assist a project manager in gathering information which influence a project's objectives, scope, and budget; risk assessment provides an insight concerning how likely something is to go wrong and what the associated impact will be (Murray, Grantham, & Damle, 2011).

Starting from this point, the paper is organized in two main sections, first related to theory on risk management, especially in NPD projects, as well as explanation of concepts of RBS and FMEA method. The second one is related to description of the new hybrid method, its structure and the way the overall risk relevance is calculated combining aforementioned methods.

2. PROJECT RISK MANAGEMENT BASIC CONCEPTS

The essential purpose of risk management is to improve project performance via systematic identification, appraisal and management of project related risk (Chapman, & Ward, 1996). The risk management process can be considered as a very useful aid to decision making regarding uncertainty and the possibility of future events and their impact on established objectives. It includes the application of logical and systematic methods for (IEC/FDIS, 2009):

- communicating and consulting throughout this process;
- establishing the context for identifying, analyzing, evaluating, treating risk associated with any activity, process, function or product;
- monitoring and reviewing risks;
- reporting and recording the results appropriately.

Different approaches to the process of risk management are used in the literature and practice, according to the number of stages, location, nature and manner of the risk events occurrence (Table 1).

Table 1: Risk Management Process – selected approaches

References	Risk Management Process

Risk management is one of the functional areas of project management. Speaking of innovation projects, a high degree of risk intensifies the importance of this functional area. Innovation and innovation projects, as a rule, assume the impact of various risk factors, which importance rises with the increase of investments, but also of other factors that affect the expected innovation project success (Stosic, 2013).

Risk management in innovation projects implies analysis of all factors that could affect the innovation process. Therefore, it is desirable that the project managers – managers for risk management, as well as some of operational managers, are involved in the process of risk assessment (Stosic, 2013). Due to a large number of risk events that can be identified in an innovation project, it is often very difficult to perform their proper systematization.

Accordingly, the paper proposes a new hybrid model for risk assessment, which is constructed by combining two well-known methods, RBS and FMEA methods, and that can offer better structure of risk sources and their impact.

Based on extent literature review, this paper presents different risk categories that can affect project objectives and that can be observed for various projects (Table 2).

Table 2: Project risk categories – selected authors

Author	Risk Categories
Godfrey, 1996	Political, Environmental, Planning, Market, Economic, Financial, Natural, Project, Technical, Human, Criminal, Safety,
Akintoye & MacLeod, 1997	Environmental, Political, Social and Economic, Contractual arrangement, Financial, Construction, Market/industry, Company, Development in IT, Project

Doering & Parayre, 2000	Technological risks, marketing risks and organizational risks
Miller & Lessard, 2001	Market-related risk, Completion risk and Institutional risk
Keizer, Halman & Song, 2002; Keizer, & Halman, 2007	Technological risk, Organizational risks and Business risks
Hall, Hulett & Graves, 2002	Management Risk, External Risk, Technology Risk
Ghosh & Jintanapakanont, 2004	Financial and Economic Risk, Contractual and Legal Risk, Subcontractors related Risk, Operational Risk, Safety and Social Risk, Design Risk, Force Majeure Risk, Physical Risk, Delay Risk
Nielsen, 2006	Delivery/Operational Risk, Technology Risk, Financial Risk, Procurement Risk, Political Risk, Environmental Risk, Social Risk, Economic Risk
Murray, Grantham, & Damle, 2011	Technological and Operational Risk, Financial and Economic Risk, Procurement and Contractual Risk, Political Risk, Environmental Risk, Social Risk, Regulatory and Legal Risk, Safety Risk, Delay Risk

For the purpose of this paper, i.e. generation of RBM matrix for NPD projects, categorization proposed by Keizer, Halman & Song (2002) will be used. These categories of risk are applied since they are recognized as critical success factors in product innovation projects. Three main risk categories Technology risks, Organizational risks and Business, and twelve subcategories are identified (Table 3). These categories are chosen considering their application for risk identification and assessment for new product development projects, representing one of innovation project category. *Technology risks* refer to product design, manufacturing technology and intellectual property. *Organizational risks* refer to internal project management and external organizational influences. *Business risks* refer to issues such as the impact of a new product on the company's brand positioning, consumer and trade acceptance, commercial viability, and the potential actions of competitors (Keizer, Halman, & Song, 2002).

Table 3: NPD risk categories (adapted from Keizer, Halman, & Song, 2002; Keizer, & Halman, 2007)

	Level 1	Level 2
NEW PRODUCT DEVELOPMENT PROJECT RISKS CATEGORIES	Technology risks	Product technology risks
		Manufacturing Technology Risks
		Intellectual property Risks
	Organizational risks	Supply chain & Sourcing risks
		Screening & Appraisal
		Organizational & Project Management Risks
	Business risks	Product Family & Brand Positioning risks
		Consumer Acceptance Risks
		Trade Customer Risks
		Competitor Risks
		Commercial Viability Risks
		Public Acceptance Risks

This categorization of new product development risk can be found further decomposed on 142 more project issues which are, also, recognized as critical factors for successful NPD (Keizer, Halman, & Song, 2002).

2.1. Basic concept of the RBS method

According to Hillson, Grimaldi & Rafele (2006) RBS is a tool that groups the sources of risk that may affect the project and organize them in a way that allows a detailed analysis of the overall risk exposure of the project. RBS method is based on two dimensions: work breakdown structure – WBS and risk breakdown structure - RBS. This dimensions of WBS and RBS enable generation of a matrix structure known as *Risk Breakdown Matrix* (RBM) (Figure 1), which allows members of the project team to manage risk at all levels of the specific project (Rafele, Hillson, & Grimaldi, 2005). First step is related to definition of WBS structure of project, in this case NPD project, with all major and minor tasks. Second step is related to risk identification and classification through RBS. Third step can be defined as a process of fulfilling the RBM matrix (Figure 1)

with probability of occurrence risk ($P_{i,j}$) and impact of risk ($I_{i,j}$) for every activity and phase i.e. work package (WP).

The value of each cell in the RBM is calculated considering two components: the probability of risk event occurrence (P) and the degree of potential impact (I) that risk event can have. Probability is related to the presence of a risk in the RBS, and impact refers to the consequence of that risk in the WBS. This can be expressed by the formula:

$$R_{WP,i} = \sum_{j=1}^{n} P_{i,j} * I_{i,j} \quad (1)$$

$P_{i,j}$ is the probability of occurrence of risk- j in WP- i;
$I_{i,j}$ is the impact of risk- j in WP- i;
$R_{WP,i}$ is the global incidence of risks in WP- i.

			RBS						
			Risk sources						
WBS Work Packages			$P_{i,1}$	$P_{i,2}$	$P_{i,3}$	...	$P_{i,n}$	ΣR	WPs order
	WP_1	$I_{1,j}$						**$\Sigma R_{1,j}$**	
	WP_2	$I_{2,j}$							
	WP_3	$I_{3,j}$		**$P_{2,3}*I_{3,2}$**					
	WP_4	$I_{4,j}$							
	...	...							
	WP_m	$I_{m,j}$							
	ΣR		**$\Sigma R_{i,1}$**						
	Risk sources order								

Figure 1: RBM matrix (adapted from Rafele, Hillson, & Grimaldi, 2005)

In this paper, identification of risk events in innovation project i.e. new product development, realization was done using the two dimensional framework emphasizing that organization can identify, analyze, respond to and monitor the major risks over the process by using RBS. Risk events are structured in three major categories on the first level, and twelve subcategories on the second level of hierarchical system (Table 3).

2.2. Basic concept of the FMEA method

Failure Mode and Effect Analysis – FMEA, is a systematic method for identifying and preventing product and process problems before they occur. The main application of this method is to prevent defect occurrence, enhance safety, and increase customer satisfaction. Therefore, FMEA identifies and prioritize possible imperfections in products design or process development stages (McDermott, Mikulak & Beauregard, 2009).

One of the most cited definitions for FMEA method was given by US MILITARY STANDARD 1629A (1980) describing method as "the set of procedures by which each potential failure mode in a system is analyzed to determine the results or effects thereof on the system and to classify each potential failure mode according to its severity".

A several types of FMEA's have been used whenever failures would mean potential harm or injury to the user of the end item being designed (Table 4).

Table 4: FMEA types (http://www.npd-solutions.com/fmea.html; IEC/FDIS, 2009)

Types	Usage
System	focuses on global system functions
Design or Construction	focuses on components and subsystems
Process	focuses on manufacturing and assembly processes
Service	focuses on service functions
Software	focuses on software functions

The main idea of FMEA is to generate a risk priority number (RPN) for each failure mode. Risk priority number is determined by following three factors:

- *Severity* - the consequence of the failure should it occur (McDermott, Mikulak & Beauregard, 2009)
- *Occurrence* - the probability or frequency of the failure occurring (McDermott, Mikulak & Beauregard, 2009)
- *Detection* - the ability of detection technique or method(s) to detect the risk event with enough time to plan for a contingency and act upon the risk (Carbone & Tippett, 2004).

RPN can be described as a weighted assessment number used for prioritizing the highest risk items. The Risk Priority Number is a mathematical product of the numerical Occurrence (O), Detection (D) and Severity (S) ratings (Equation 2). All of these factors are rated on a scale ranging from 1 to 10 (Table 5, 6, 7). Ratings that affect the RPN value are taken based on the universal scale or they may be formulated for a particular system that is analyzed (Ericson, 2015).

$$RPN = O * S * D \tag{2}$$

Table 5: Occurrence Rating Criteria

Occurrence	Rating	Description
Minor	1-2	An unlikely probability of occurrence during the observed period.
Low	3-4	A remote probability of occurrence during the observed period.
Moderate	5-6	A moderate probability of occurrence during the observed period.
High	7-8	A high probability of occurrence during the observed period.
Extreme	9-10	Risk is almost inevitable during the observed period.

Table 6: Severity Rating Evaluation Criteria

Severity	Rating	Description
Minor	1-2	Risk is of such minor nature that the strategic partner will probably not detect the risk.
Low	3-4	Risk will result in slight strategic partner annoyance and/or slight consideration of negative decision.
Moderate	5–6	Risk will result in strategic partner dissatisfaction and annoyance and/or consideration of negative decision.
High	7–8	Risk will result in high degree of strategic partner dissatisfaction and cause serious consideration of a negative decision.
Extreme	9–10	Risk will result in major strategic partner dissatisfaction and cause negative decision.

Table 7: Detection Rating Criteria

Detection	Rating	Description
Very High	1–2	Detection method is highly effective and it is almost certain that the risk will be detected with adequate time.
High	3–4	Detection method has moderately high effectiveness.
Moderate	5–6	Detection method has medium effectiveness.
Low	7–8	Detection method is unproven or unreliable; or effectiveness of detection method is unknown to detect in time.
Very Low	9-10	There is no detection method available or known that will provide an alert with enough time to plan for a contingency.

Identification and prioritization of critical components are followed by an effort on reducing the criticality of the components in the system that have the highest priority. Those efforts should first be addressed to the highest ranking critical items. The main idea is to reduce the RPN by eliminating or controlling the cause of the failure; or reducing the ratings of severity, occurrence and detection (Puente, Pino, Priore & Fuente, 2002).

3. GENERATION OF THE HYBRID METHOD

The aim of this paper is said to be construction of a new tool for risk assessment in projects of product innovation. This new method is developed based on two previously defined methods - RBS and FMEA. The main reason for using RBS method is its structure, which is suitable for risk identification, primarily in the sense of possible connection of risk sources with phases of the innovation project. As it was pointed out, this is reflected through RBM matrix and its two dimensions - WBS and RBS.

Regarding WBS structure, stages of the well-known Cooper's Stage-Gate model for managing innovation projects have been used. Those are: *preliminary investigation*, *build a business case*, *development*, *testing and validation* and *full production and launching to the market* (Cooper, 2011). On the other hand, the main reason for using FMEA method is detection rating which does not exist in RBS method, and that can have a major impact on the overall relevance of the risk.

The basic idea of a hybrid method is a new way for calculations of overall risk relevance, which is adapted to identify and assess the risk of innovation projects. Therefore, the calculation is based on the following assumptions:

- P→O => the probability rating (P) - occurrence of risk events from the RBS method, is mapping into occurrence rating (O) - frequency with which a given risk occurs from the FMEA method;
- I→S => the impact rating (I) – the impact of risk events from the RBS method, is mapped into severity rating (S) - seriousness of the effect if a given failure occur from the FMEA method.

Considering these assumptions and individual formulas for both methods (RBS and FMEA), new way for calculating RPN has been proposed:

$$\begin{aligned} R &= P * I(RBS) = O * S(FMEA) \\ RPN &= O * S * D(FMEA) \\ RPN &= R * D \end{aligned} \tag{3}$$

This formula has been adapted for use in the field of innovation projects since it involves risk categories (risk sources) that are related to new product development (Table 3) and to impact that these categories have on the phases of the Stage-Gate model.

First step in the analysis is to define dimensions of WBS and RBS. Second step is to determine the probability of the occurrence of risk categories that are related to innovation project. This is followed by the determination of impact that this categories can have on certain phases of innovation project. Then the probability that a certain category of risk will be detected in time is determined, that is, before realization of its negative impact and eventually, calculation of RPN is performed.

Table 8: Hybrid RBM matrix

			Work Breakdown Structure						
			Preliminary Investigation	Build the business case	Development	Test and validation	Production and full launch	∑R	Risk sources order
Risk Breakdown Structure	Technology risks	Product technology risks							
		Manufacturing Technology Risks							
		Intellectual property Risks			$R_{3,3}$*$D_{3,3}$				
	Organizational risks	Supply chain & Sourcing risks							
		Screening & Appraisal							
		Organizational & Project Management Risks							
	Business risks	Product Family & Brand Positioning risks							
		Consumer Acceptance Risks							
		Trade Customer Risks							
		Competitor Risks							
		Commercial Viability Risks							
		Public Acceptance Risks							
		∑R						The overall risk of the project	
		Risk sources order							

As can be seen in Table 8, the overall risk relevance for risk category *Intellectual property* that can influence the *Development* phase is calculated by multiplying the risk relevance $R_{3,3}$ ($P_{2,2}$*$I_{2,2}$ or $O_{2,2}$*$S_{2,2}$), and detection rating for this risk category ($D_{3,3}$).

4. CONCLUSION

Bearing in mind that one of the most important characteristics of innovation projects is high risk taking, it is essential that companies incorporate risk management into their processes of innovation if they want to avoid exceeded costs, disposal of planned activities and poor quality of new products. Furthermore, of great importance for the companies is to use different tools for risk assessment, or to be able to adjust them to different types of projects, regarding that the various projects are being affected by different risk categories.

For this reason, the paper presents an outline of hybrid method for risk assessment that is suitable for NPD projects. Featured hybrid method can be very important in terms of identifying the impact of risk categories on the stages of model for new product development. Moreover, this method is very useful and has a lot of benefits. Some of these benefits facilitate the risk management process on a particular project, while others are relevant across set of projects. Once the RBS of NPD project is defined, it can be used in a variety of ways. Categorization of risk using RBS and consequently proposed hybrid method, provides a numerous additional insights of risk exposure on the project: understanding the type of risk exposure on the project, exposing the most significant sources of risk to the project, revealing the roots causes of risk, allowing risk responses to be developed for root causes or depended groups of risks, etc. (Hillson, 2003). Also, this tool is helpful when it comes to risk identification, assessment, comparison of projects, risk reporting, lessons learned for future projects.

Having in mind that project phases consist of various activities it should be recommended to apply this method also on the level of each specific phase. In that way the principle of decomposition can be consistently engaged on every level of the project, which enables better identification of risk parameters. This is also in line with the agile approach, thus representing one of the key features and advantages of the proposed method.

INDEX OF POTENTIAL FOR TECHNOLOGY ENTREPRENEURSHIP DEVELOPMENT: PRACTICE FROM SERBIA

Jovana Rakićević*[1], Maja Levi Jakšić[1], Milica Jovanović[1]
[1]University of Belgrade, Faculty of organizational sciences
*Corresponding author, e-mail: jovana.rakicevic@fon.bg.ac.rs

Abstract: *This paper explores the potential for technology entrepreneurship development, considered as the main force for the prosperity of countries. An index of Technology Entrepreneurship Development Potential (TED-pot) is created, in order to enable the cross-countries comparison. The index includes four indicators grouped into two pillars – ICT potential and Entrepreneurial potential. The index is applied on six ex-Yugoslav countries and the EU for the period 2009-2014. The study is aimed at determining whether the potential of Serbia lies in the entrepreneurial IT sector, which is proven to be the case.*

Keywords*: technology, entrepreneurship, development, potential, index, Serbia*

1. INTRODUCTION

In the modern turbulent and fast-changing business environment, technological progress, innovation, and sustainability are recognized as the most important forces influencing business success. Entrepreneurs are change agents seen as those who could change the overall living standards and work conditions. Apart from creating wealth from their entrepreneurial ventures, they also create jobs and represent the main 'force' acting against unemployment. Simply put, they create conditions for a prosperous society. Combining these views on the modern business world, sustainable technology entrepreneurship stands out as the modern concept contributing to actual practice and development.

As elaborated in the publication *"Entrepreneurship in Serbia – A Necessity or an Opportunity?"* (CEVES, 2014), Serbia is a country where foreign direct investments cannot replace the creativity and energy of thousands of people driven by entrepreneurial ventures and ideas. In Serbia, entrepreneurship should not be 'second-rate' because our country is an economy of small and medium-sized enterprises (SMEs), which actually are entrepreneurial ventures. We need to be aware that most of the big companies have the roots in entrepreneurial ventures, and started as small companies. If we pay attention to small businesses, with a little patience, we will have the opportunity to create a great economy.

Additionally, if we assume that technology is the basis for development, and ICT is the backbone of technology today, the potential for countries' development lies in the ICT sector. SIEPA (2015) published a brochure on Serbian ICT sector, pointing out that computer software is one of Serbia's main export products. Serbia is globally acclaimed for being the biggest exporter of raspberries, but the value of exported software and services is almost twice as big as the export of raspberries. In 2013, Serbian ICT industry was ranked 40th globally when it comes to value of exported software. This made ICT one of the most successful and export-oriented industries in Serbia. Sector's export is on the constant rise especially when it comes to export of computer and information services i.e. software development. In 2008 the value of exported services was €96 million and by 2013 it reached as much as €265 million, which is amazing 165% increase. Serbian IT market was worth around €410 million in 2013, which is still far less than before the global financial crisis outbreak in 2008, when it was worth €550 million. The potential for reaching and exceeding that result is evident (SIEPA, 2015).

Starting from such an entrepreneurial, technology-oriented way of thinking, and in order to test the potential for the development of technology entrepreneurship in Serbia, we created an index of potential for technology entrepreneurship development (TED-pot), and afterwards performed a comparative analysis which encompasses six ex-Yugoslav countries and the EU. The main idea is to compare Serbia with the average for the EU, and with the other regional countries hypothesizing that fostering technology entrepreneurship is the strategic development orientation for Serbia. The aim of the paper is to determine whether the Serbian development potential lies in the entrepreneurial IT sector, i.e. to prove that Serbian development potential lies in technology entrepreneurship. The analysis covers the period 2009-2014.

The rest of the paper is organized as follows. In Section 2 we briefly define the technology entrepreneurship concept and highlight the importance of technology start-ups in modern business. In Section 3 we present the created index of Technology Entrepreneurship Development Potential (TED-pot). Section 4 presents the comparative analysis, results and discussion. Section 5 shows the limitations of this study, future work directions, and concludes the paper.

2. TECHNOLOGY ENTREPRENEURSHIP AND IMPORTANCE OF TECHNOLOGY START-UPS

The importance of entrepreneurship, especially technology (technological, hi-tech or techno-) entrepreneurship is evident in today's business. As Harms and Walsh (2015) highlight, most of today's entrepreneurial heroes such as Bill Gates, Steve Jobs, Mark Zuckerberg and Craig Venter have one thing in common – they are technology entrepreneurs "who base their success on the recognition, creation and exploitation of an opportunity for value creation that a technology has offered". Therefore, we could notice that technology entrepreneurship drives the prosperity in individuals, firms, regions, and nations. It lies in the heart of many important debates that bring together all the participants of the famous Triple Helix model – academia, industry and government. However, according to Bailetti (2012), unless a generally accepted definition of technology entrepreneurship is established, these debates lose their focus.

In his work, Bailetti (2012) defines technology entrepreneurship as "an investment in a project that assembles and deploys specialized individuals and heterogeneous assets that are intricately related to advances in scientific and technological knowledge for the purpose of creating and capturing value for a firm". Technology entrepreneurs have a task to bring together the technical world and the business world in a profitable way (Byers et al., 2011). Therefore, we could observe technology entrepreneurship as the link between science and technology and the practical new value created for the customers, upgrading their living conditions and standards, contributing to the overall welfare of the economy and society (Etlie, 2000). Levi Jaksic et al. (2010) suggest a technology entrepreneurship cycle model focusing on new technology as an opportunity. They emphasize that it differs from the technology push model which is based on new technological innovation being "pushed" through the business operations with a "hope" that sustainable business strategies will be found and enable the success of the venture. The technology entrepreneurship model they present is initialized by opportunity – recognized or created as technology innovation; it has organization-wide context and entrepreneurial perspective.

Fostering technology entrepreneurship is understood as a means to release currently unexploited opportunities hidden in individuals, shelved technologies and resource combinations (Gilsing et al., 2010). Innovation is a precondition for success, but being innovative does not automatically mean new value for the customer and competitiveness. This is where technology entrepreneurship has a vital role, pushing the innovations to the market. In the future, technology entrepreneurs are asked to contribute to solutions to world problems (Groen & Walsh, 2013).

3. INDEX OF TECHNOLOGY ENTREPRENEURSHIP DEVELOPMENT POTENTIAL (TED-pot)

Understanding the importance of technology entrepreneurship today, we decided to create a measure of potential for technology entrepreneurship development. OECD & EC-JRC (2008) published the *Handbook on Constructing Composite Indicators – Methodology and User Guide*, which provides help in creating indices. The Handbook aims to contribute to a better understanding of the complexity of composite indicators and to an improvement in the techniques currently used to build them.

The following general steps were followed in creating TED-pot:

1. Selecting the indicators that will be included in the final index,
2. Finding the right sources for collecting the data,
3. Normalizing the data, and
4. Finding the method for weighting and aggregating the selected indicators.

Steps 1 and 2: Selection of indicators and finding the right source for data collection

When deciding which indicators TED-pot should include, it was obvious that two variables must be included: one which indicates the level of ICT potential of countries, and the other which refers to the entrepreneurial potential. Analyzing the indicators measured by the *WorldBank*, we found seven potential indicators to include: ICT service exports (% of service exports, BoP), ICT goods exports (% of total goods exports, BoP), High-technology exports (% of manufactured exports), Time required to start a business (days), Start-up procedures to register a business (number), Number of new businesses registered (number), and Ease of doing business (1=most business-friendly regulations).

After collecting the data from the *WorldBank* database, indicator on high-technology exports was excluded because of a large amount of the missing values. Number of new businesses registered turned out to show

the result and not the entrepreneurial potential, so was excluded and observed as a control indicator. Ease of doing business is measured only for the two-year period (2014 and 2015), so we stayed with four indicators grouped into two pillars (variables):

1. ICT potential (ICT-pot), and
2. Entrepreneurial potential (E-pot).

In the Figure 1 we present the structure of TED-pot index, which consists of two pillars, and four indicators – two for each pillar. The links for collecting the data on these four indicators is given in the Appendix 1.

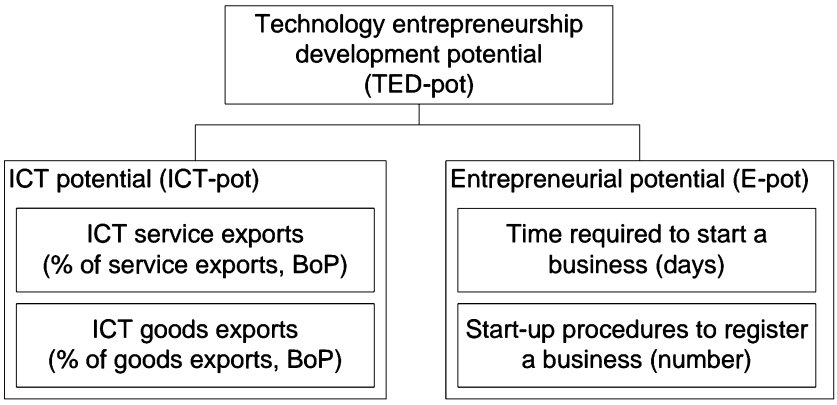

Figure 1: Structure of the TED-pot index (source: authors)

Step 3: Normalization (rescaling) of data

After deciding which indicators to include, and collecting the data, we need to re-scale the values of indicators to be suitable for aggregation. In the case of TED-pot, we observe the variables (pillars) with different natures. This means that the higher value for ICT service/goods exports, the better, but not in the case of the variables of Entrepreneurial potential where lower values show better results (it is better to have less procedures and less time needed for starting a business). This is why we needed to perform different re-scaling procedures for the two observed indicators, to make the values of indicators and the final index value positively correlated (when the values of indicators grow, also does the final index value). In the Table 1 we present the method for preparing the data for aggregation.

Table 1: Transformation of original data (normalization and preparation of data)

Pillar	Indicator	Correlation with the final index value	Normalization and preparation of the data	Correlation with the final index value after transformation
ICT potential	ICT service exports	positive	$\frac{x}{\max(x)}$	positive
	ICT goods exports	positive		positive
Entrepreneurial potential	Time to register a property	negative	$1-\frac{x}{\max(x)}$	positive
	Start-up procedures	negative		positive

As we can see from the Table, for normalization we used the max-normalization, which means that we divided the values of an indicator with the highest value for the observed year. Additionally, for the indicators of E-pot, we needed to perform one more action – subtracting the obtained value from 1 in order to make the positive correlation with the final index value. To clarify, all indicators values are now scaled from 0 to 1, where 1 is the highest value.

Step 4: Weighting and aggregation

For obtaining the final index value we used the simple weighted function with equal weights. The overall TED-pot has been built upon the equal weighting of the two mentioned pillars (ICT-pot, and E-pot), by using the following formula:

$$TEDpot = \sum_{i=1}^{2} \alpha_i P_i \quad (1)$$

where P_i represents the two pillars for each country and α_i is the constant of ½.

The value for each pillar is calculated by the same procedure used for the overall index, that is, through the simple mean of certain indicators. In total, we considered four basic indicators: two for the first pillar, and two for the second. The final TED-pot values, as well as the values for each pillar are bounded from 0 to 1.

4. STUDY ON THE POTENTIAL FOR THE DEVELOPMENT OF TECHNOLOGY ENTREPRENEURSHIP: RESULTS AND DISCUSSION

With the aim to determine whether Serbian development potential lies in the entrepreneurial IT sector, a comparative analysis was performed, which encompasses six ex-Yugoslav countries and the EU. TED-pot index, as well as ICT-pot and E-pot partially, are calculated for each country for the period 2009-2014. In the Figures 2 and 3 the results for the two pillars – ICT-pot and E-pot, are presented, respectively. The blue line shows the Serbian best value in the observed period.

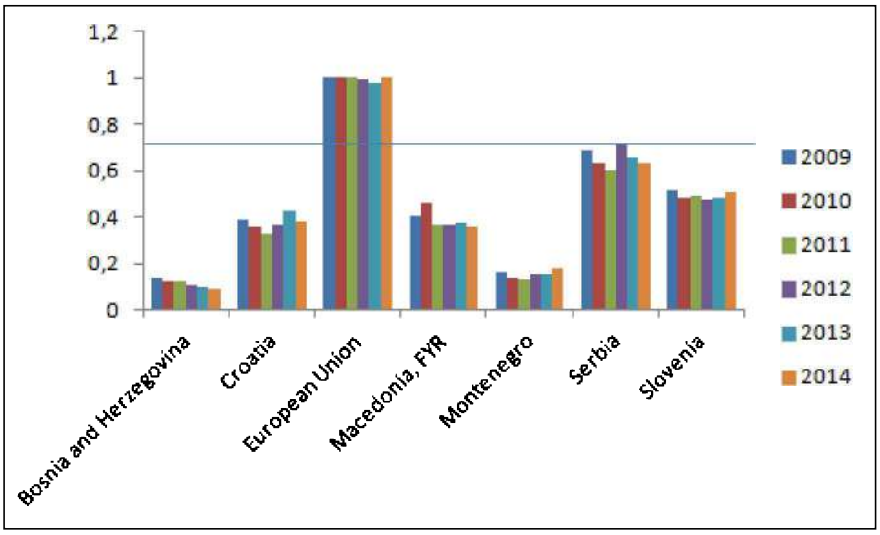

Figure 2: ICT potential (ICT-pot) - comparisons among ex-Yu countries and the EU, period 2009-2014

From the Figure 2 we can clearly see that Serbian ICT sector takes the second place with the values around 0.7 (scale 0 to 1), just behind the EU average. The EU value equals almost 1 throughout the whole time period, except for 2012 and 2013 when Serbia was above the EU average regarding ICT service exports (EU average was 35.5 and 34.59, while Serbia exported 35.87 and 35.94% of total service export). It is very interesting that regarding ICT service exports, Serbia was near the EU or above for the whole period 2009-2014. All other ex-Yugoslav countries are far behind, among which the best is Macedonia with the values around 20%. Bosnia and Herzegovina is the worst, with the values around 6%. Regarding ICT goods exports, the situation is different. The best is the EU (values around 5-6%), followed by Croatia, Slovenia and Serbia, which are intertwined throughout the observed time period (all around 1.5-2.5%). However, aggregating these values into one – the ICT-pot pillar, we can see that the EU is the best, but closely followed by Serbia, and far from the other countries which values do not exceed 0.5 (scale 0 to 1).

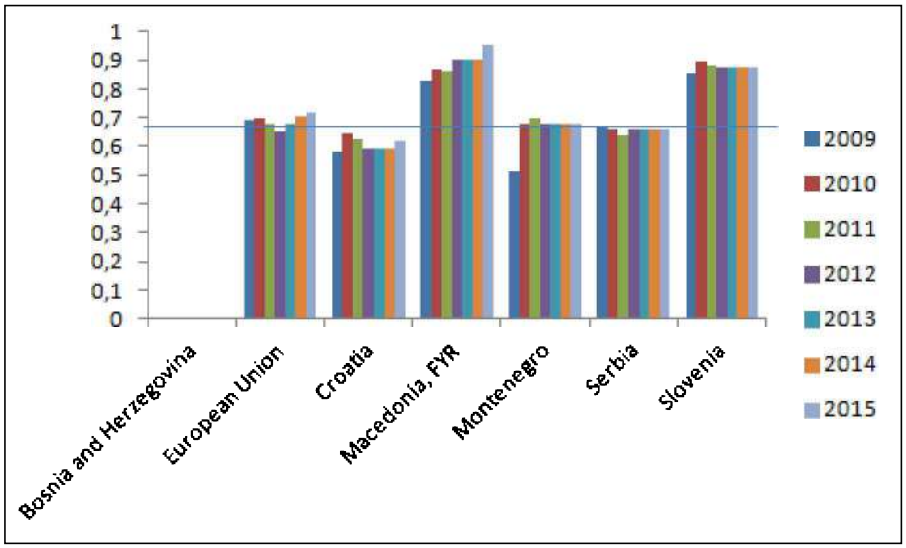

Figure 3: Entrepreneurial potential (E-pot) - comparisons among ex-Yu countries and the EU,

period 2009-2014

Figure 3 shows different results for the E-pot pillar. The EU does not have the best results. Macedonia and Slovenia, with the best (fastest) procedures for starting a business, are ranked at the top. Both the number of procedures and the time required to start a business are the lowest in Slovenia and Macedonia. Bosnia and Herzegovina are placed very low, with the values 0 for the whole time period, e.g. throughout the observed time, Bosnia and Herzegovina had the following values: 99 to 67 days for starting a business, and around 13 start-up procedures. Comparing to Macedonia, where time required to start a business is around 2-3 days, with 2-3 procedures, it is clear why Bosnia and Herzegovina has scored 0 for this pillar. Serbia, Montenegro, and Croatia have scored similar results regarding the E-pot.

Finally, the aggregated TED-pot values which indicate the potential for technology entrepreneurship development of the observed countries are presented in Figure 4. The values which are closer to 1 are better. Figure 4 clearly shows that Serbia is very near the EU average, with the highest potential for technology entrepreneurship development, far ahead of other ex-Yugoslav countries. Serbia is followed by Macedonia, Montenegro, Slovenia and Croatia which have close final values. Bosnia and Herzegovina are at the back of the list, with the final value of around 0.35 (value for Serbia in 2012 is around 0.8 on the scale 0 to 1). The values for the EU are slightly above 0.8 for the whole period (except 2009).

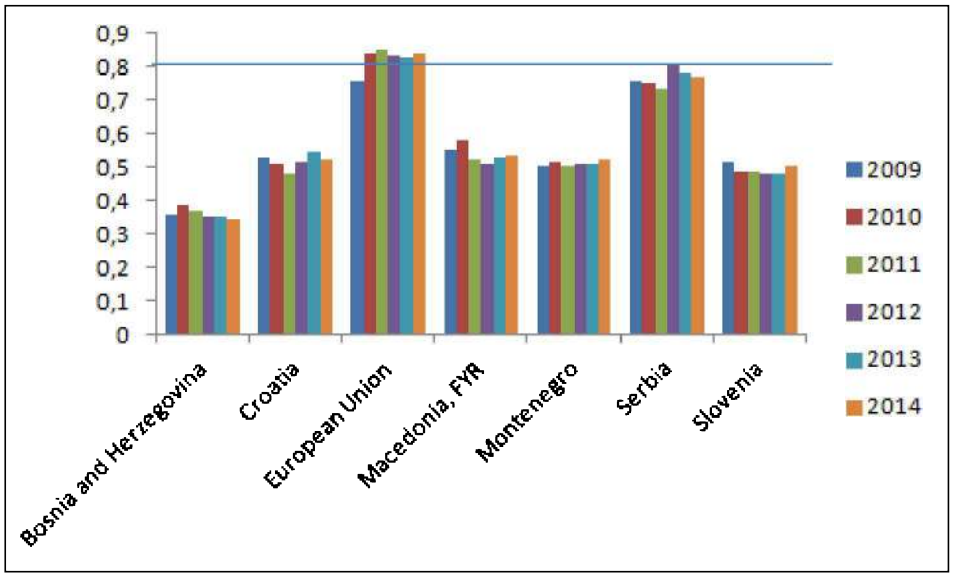

Figure 4: Technology Entrepreneurship Development Potential (TED-pot) - comparisons between ex-Yu countries and the EU, period 2009-2014

These results indicate that the potential of Serbian development lies in its entrepreneurial ICT sector. In order to really further step up this result, the state has to increase investment into research and development and science which nowadays stand at 0.3% of GDP (the EU average is around 2%). Serbia, which shows remarkable results in ICT exports, is currently investing only €60 per capita into the development of the ICT industry, far less than e.g. Croatia (€200). The EU average is €800 (SIEPA, 2015). Since ICT is considered as priority sector for the Government (MESTD, 2016), they should increase the support for this sector over the years, especially since the sector gives strong results in attracting investors and employment. One thing that proves that Serbia is on the right track is opening of the ICT hub for technology entrepreneurship in the science park Zvezdara (in 2014), as well as the Startit centres in Belgrade (in 2015) and Indjija (in 2016).These are incubators which are intended for fostering technology start-ups. Besides these, the well-known Business Technology Incubator of Technical Sciences (BITF) already fosters 53 start-ups, which developed 45 innovations, among which 10 are patented (data available on the official web-site of BITF).

5. CONCLUSION

The objective of this paper was to examine whether the Serbian development potential lies in technology entrepreneurship. In other words, we wanted to confirm the hypothesis that technology entrepreneurship is the focal development strategy for Serbia. For that purpose, we developed an index of Technology Entrepreneurship Development Potential (TED-pot) which has two pillars: ICT-potential (ICT-pot) and Entrepreneurial potential (E-pot). These pillars include two indicators each: ICT goods and ICT service exports (for the first pillar), and Time required to start a business and Start-up procedures (for the second). All the data is collected from the *WorldBank* database. The methodology for construction of TED-pot is explained in Section 3. The index was applied on a set of six ex-Yugoslav countries and the EU, for the period 2009-2014. The detailed results and discussion are presented in Section 4. To summarize, the

calculated values show that Serbia has the best potential for technology entrepreneurship development in the region, being closely behind the EU (e.g. value of TED-pot for Serbia in 2012 is 0.808, while for the EU this value equals 0.835; scale 0 to 1). Although Serbia does not have the best E-pot value in the region, based on the fact that the procedures and time required to start a business are not the lowest, it still has a fertile ICT sector which compensates the slightly lower E-pot value. It should be noted that it is in the best tradition of the history of technology in Serbia since the first digital computer in Central Europe was manufactured in Serbia back in 1960. At the time, Serbia was also one of the six countries in the world with the capability and know-how needed to do that (SIEPA, 2015). Summing up the results of TED-pot index, it could be concluded that Serbian potential is in the development of technology start-ups which could further grow and become the back-bone of Serbian economy.

Since, to the best of our knowledge, this is the first attempt of measuring potential for the development of technology entrepreneurship at country level, there are at least three obvious limitations of this paper which could be discussed. The first is the selection of indicators which are included in the TED-pot index. The second is the methodology used for constructing TED-pot (normalization of data, weighting and aggregation scheme). The third limitation is the narrow analysis, since it included only six ex-Yugoslav countries and the EU average, and should be broadened to a larger set of countries in order to validate the index results, which could be performed by comparing and connecting TED-pot values with the established values such as Ease of doing business, ICT development index, Technology readiness etc. The results could be validated only on a larger sample of countries. The future research directions are found to be: 1. revising of included indicators (considering including a larger set of indicators), 2. revising of the methodology used for obtaining the final value (considering different normalization techniques, as well as weighting and aggregation schemes), 3. broadening the analysis worldwide and enabling the global cross-country comparison, and 4. adding the third pillar - sustainability, with the aim to create a measure of the potential for sustainable technology entrepreneurship development.

USE OF MODERN TECHNOLOGY IN HOTEL ORGANISATION: THE INFLUENCE OF INFORMATION TECHNOLOGY ON HUMAN FACTOR

Olga Jovanović*[1], Gheorghe Savoiu[2],
[1]*Euro Fineks Broker,
[2]University Of Pitesti
*Corresponding author, e-mail: olgacobasjovanovic@gmail.com

Abstract: *Technological innovation is one of the most important factors in business in today's market. The most important factor in hotel business is human factor, since it is service-oriented industry but it must include use of technology to survive and have success at today's competitive market.*
The subject of this research is literature review and analysis of the concept of technology use in hotel business, and its effect on human factor.
The aim of this research is to analyze use of modern technology in hotel business, guests' and employees' satisfaction with them, their motivation and willingness to use them.
It is assumed, that the use of technology has positive influence on hotel service, but only as a way of making better service provided by employees (assuming that they are trained and motivated to use it) and that technology cannot and should not replace human factor in hotel industry.

Keywords*: hotel industry, modern technology, human factor, guest satisfaction and employee motivation*

1. INTRODUCTION

Hotel industry, like other business-oriented organizations exists on market that represents a place of demand and offer, where sellers and buyers meet and where an object of exchange must exist (a product or service) (Popesku, 2013). Hotel industry is service-oriented and operates on the market of services; therefore, the most important factor is to provide the best service. The value of services or products depends on many factors such are social, economic, hedonistic, etc. (Popesku, 2013).
Services are valued by specific characteristics that differ from products. Intangibility, creation and use of services in the same time - simultaneously, are two characteristics where human factor is very important, because human is providing services and using it. There must be an understanding between provider and user of service, because the buyer or user of services is at the same time responsible for the creation of services (Popesku, 2013).
Another important factor is specifics of touristic need that represents added value and not the basic need. The way in which the service is provided to consumer is important, in order to be satisfied. Human factor is important for the creation of service because one of the service characteristics is that consumers must meet people who provide them service in order to consume the service. Human resources and potential are the most important factor of the organization because using their knowledge, skills, abilities and competencies can contribute to the success of the organization (Dessler, 2013). However, technological changes have brought innovations in the way of providing services in all sectors, and are an important competitive factor.
Organization of hotel business is very specific. Since the consumer segment is constantly changing as trends change, hotel managers need to change and upgrade services they offer to potential guests in order to survive on the market, since without profitable customers it is not possible (Jaško et al., 2013). Hotel managers are also trying to design a business model that will adapt to new needs of consumers of service. It includes use of modern technology. According to research conducted in the USA in 2015, based on a random sample of 3.103 respondents, 60% of potential clients would prefer to stay in a hotel that has technology that allows hotel check in and entering the room by using a smart phone (Softveradvice, 2015).

2. HOTEL BUSINESS ORGANISATION

Very important factor in the hotel industry is the relationship with the customer and guest experience. Since the decision-making process in the tourism industry is led by hedonistic and emotional factors, most users choose travel destination and hotels based on emotions, fantasy and personal preferences (Štiklica, 2015). Modern hotels are organized, and divided by functions and departments. According to the European hotel standards, they can be classified into five categories. Based on Štiklicas research (2015), guests are

impressed mostly, by the hotel design and decoration, and that is the first thing that attracts them when they enter the hotel. Technical possibilities of the hotel are at the lowest level. According to research by Rauch, Collins, Nale and Barr (2015), environment where services are provided is more important in the medium category hotels (3 *), than a way service is provided or if there technological capabilities exist that would improve service. However, if the technology is used to increase the diversity of products, and basic hotel services (for example, self-service kiosks for check-in), guests think that it improves the quality of overall service.

Since the last economic crisis that affected hotel industry, as well, managers are constantly trying new ways to attract new guests and retain old ones. Use of technology in hotels may represent a successful strategy for creating a competitive advantage. Increased use of social networks and the Internet made more information available for hotel managers' research, especially in the design of strategies for the hotel business (Koutroumanis, 2011). Online booking systems such are Booking.com, Venere.com, Airbnb and many others are unavoidable strategic methods of modern hotels. Most hotels have variety of programs that allow them access to databases of the guests. Employees, though, must be taught and interested in using such technology and understand it, so they can use it to improve services. Since there are new trends and changes in hotel organization and use of technology, a strategy for organization change of human factor must be created also, since human factor is the most important in hotel industry (Ko, Pei, and Tsai, 2016). Hotel managers' focus is on guest satisfaction with use of technology innovations. Since employees are the ones using technology in every day work, it should become the focus as well, because if the employees are not motivated, educated and interested to use it there will be no successful implementation (Ko, Pei, and Tsai, 2016).

3. TECHNOLOGICAL INNOVATIONS IN HOTELS

Since the 80s, information technology is included and used in changing tourism and hotel business and as part of its strategy (Buhalis and Law, 2008), as it influence strategic management orientations (Čudanov and Jaško, 2012). Nowadays, tourist and guests are mostly well technologically educated, work in multicultural environments, have wider choice of services, and thus a wider range of demands. Technology progress has brought the chance for tourists to choose by themselves set of services and destinations through internet, and to choose package tours, less. Tourists are less tolerable for waiting, queues, and cancellations. They demand from service providers to be quick in recognizing, and satisfying their needs (Buhalis and Law, 2008).

According to Softver advice (2015), on average 13% of smart phone owners would prefer to make a reservation in a hotel through some application, 37% would prefer to choose a hotel with lobby that offers some kind of modern technology, like touch screen, or self-service kiosk to check in, 41% would prefer face recognition hotel that recognizes guest and personalizes the service. It is shown that use of modern technology in that way would cut costs for 50%. This research should be taken with caution because it is done on small sample of American population and it is biased because it is conducted by Softver Company. Touch screen, face recognition, and smart phones used to check in and entering the room instead of key, are some of technological innovations that are used mostly in USA, so far, but are planned to apply in hotel chains around the world. Making a reservation through mobile application is new channel of sale in hotel business. In some hotels, there is even option to use smart watches for check in and room entering instead of key card. Use of interactive mobile technology have made providing of some services in hotels easier. For the guests it is easier to order food, find needed information about destination they are at, and in that way they make it easier also for the employees, they do not have to ask lot of questions receptionist for example.

Guests as well as employees, who are more open, curious, and interested in games, are more likely to use mobile technology in hotel (Zhu and Morosan, 2014). Off course, in order to use these applications in hotel, employees are first who must be completely familiar with the concept and how to use it. If employees are interested and use technology often, their smart phones, and applications, they will be more motivated to use it as a tool for work and they would be satisfied because it makes their work easier (Zhu and Morosan, 2014). Big hotel chains have their human resource departments research motivation and satisfaction of employees with using technology in work, and create strategies accordingly.

However, the question is whether technology can replace human factor and to what extent it would be necessary to achieve success in hotel business."Savioke" company that specializes in robotics, invented a butler robot in 2014. that is designed to take small object (toothpaste and razor) to guests. According to their research, 56% of guests were interested in this service before the use, and after using it higher percent of guests were indifferent. According to research of Softver advice (2015), "millennia's" generation is a consumer segment that should be in focus of hotel managers, when introducing new technologies, while if they want to attract the older generation, it is not necessary to introduce many technological innovations.

Improtant factor when planning the use of modern technology, and to what extent as a tool for work, is setting goals that hotel wants to achieve. Indentifying the position of hotel in the moment of planning, setting clear objectives, and appropriate strategy, as well as the mission and vision of the hotel, will increase success (Dessler, 2013). Use of modern technology depends on guests that hotel wants to attract, but on

the structure of employees as well. It is more likely that guests, who share same values on the terms of culture, tradition, and use of technology as employees, will be attracted to come to the hotel.
Information technology in hotel business that is used appropriately has contributed to improving service quality, communication and cost reduction. In some hotels where employees and guests are not ready to use it, it may represent a problem or even cause dissatisfaction (Lam, Cho and Qu, 2007).

3.1. Information systems in hotel industry

There are three phases of the implementation of information systems in hotel, such as: accounting phase (accounting, marketing and billing), administrative phase (reservations, reception, reports) and tactical phase (technology, security, security systems) (Radaš, 2015).
Technology development created database that can be a base for carrying out a lot of research and analysis, with the aim of improving and enhancing services and relationship with guests (Kuzmanovic, 2013). Databases are important because of the data organization, consistency, and longer period of storage, multidimensionality and web-design. They are used to collect data about guests, and enable measuring the results achieved, more accurately. Big data, as modern concept, represent enormous database that is important for hotel managers to analyze and use data easier and satisfy guests. It can be used through on line reservation system, but it should be carefully used to get correct and precise data.
There are information systems for operational support (systems for transaction processing - Transaction Processing Systems) intellectual work support (systems for professional support - Professional Supporting Systems, Office System - Office Information Systems and Knowledge Management Systems) and for management support (score cards, balance card) (Kuzmanovic, 2013). In hotel industry usually CRS (Computer Reservation Systems), PMS (Property Management System) and CRM (Customer Relationship Management) systems are used, and every hotel uses some customized software for work. All hotel information systems (HIS) are designed to facilitate the work of employees and reduce their time of collecting, processing and analyzing data, provided that employees know to use them (He, Kyung, Kim and Moon, 2015). The work is made easier for all employees in the marketing, reservations and reception department. Their work is made easier because they can store all the information in computer and can find information easier by typing certain parameter in the search program. There are programs and applications that can help receptionist remember some reservations and remarks, helping to avoid possible errors (Hotelier - reservation softver, for example).

3.2. Intelligent room

Modern technology in hotels is also used through system of intelligent rooms. Significant services are: improving surveillance and warning - SOS alarm, control the temperature in the room, monitoring the status of the guest, which serves to provide the information that guest is in the room, whether he wants or does not want to be disturbed, access control and payment - payment by credit card, the card to unlock the room instead of a key, which also serve to turn the electricity in the room – electricity savings (Kuzmanovic, 2013).
Some systems are designed to facilitate services to guests while some are designed to facilitate the work of employees. Time and space solutions for time and attendance evidence, and access control systems are simple systems for employees, enabling hotel manager to control work easier (Spica, 2016). The systems do not require special training and are easy to use. Managers can easily review the working hours of employees, and receptionists use it to know the position of everyone. For example, if an error occurred while marking the availability of rooms for cleaning, to prevent entry into the room if a guest is in the room and thus avoid unpleasant situations and error employees. The system provides a pleasant environment, a better insight into the business organization, better coordination of activities and faster adjustment to modern requirements (Spica, 2016). Electronic locks provide more security and control, and maintenance and thus facilitate the work of employees (house cleaners, technical maintenance, reception, managers) and requires no special training other than in the implementation of these solutions.

3.3. Self-service technology

At first people were skeptical and reluctant to use self-service technology but eventually got used to this type of service. If a guest or an employee had a satisfying experience when using self-service technology, or heard of one's experience, he is more likely to use it again (Meutera, Ostromb, Bitnerb and Roundtreec, 2003). When guests plan a trip and want to spend less money, they are more likely to use Internet and technology, but when they want reliable and safe service, they opt for the human factor (Cheyne, Downes and Legg, 2006). Customers should have a choice to use the service in a way that will best meet their needs. Self-service technology is used increasingly in hotels and is subject of various research. It is mainly used as a substitute of human factor or as an addition to existing services. The opinions of managers on the introduction of this type of technology diverge - on the one hand, fear that by replacing human they will lose guests who prefer interaction, on the other hand is an opportunity for cost reduction and improvement of

services (Haemoon, Miyoung and Seyhmus, 2013). The advantage of self-service technology use is time saving. How the habits of people are changing, in some areas they do not have the need for personal contact, so the human factor can be replaced by technology and thus reduce the cost of the hotel. Waiting lines in the lobby or restaurant makes negative overall impression of hotel, especially when it is first encounter in the hotel. The use of self-service technology brings guests a choice how they want to use the service. They can get service the traditional way where the human factor is involved or with the help of technology (Kokkinou and Cranage, 2013). According to Kokkinou and Cranage (2013) if there is no crowd or queue for check-in at the reception with employees and at the same time self-service kiosk is available, 25.08% of guests would choose kiosk. 90% of guests consider the expected waiting time of 120 seconds, after which the queue provokes discontent. Employees can help to encourage travelers and guests to use the machines to save time.

3.4. Shortcomings and problems using information systems

The advantage of information systems and modern technology are great, but there are also disadvantages and threats that affect the quality of services. About 55% of attacks on credit card took place in the hotel business. There are threats in terms of data theft, security breaches of data and information. The hotel industry is the most interesting to hackers because of the low level of system security. In order to protect information systems, ISO standards for safety are introduced, and many programs for risk assessment (Njeguš, Grubor and Vejnović, 2013).

As an important factor in preventing fraud and theft in the hotel industry, the use of biometric measures is recommended, such as using a fingerprint or voice, instead of cards or phone identification (Jungsun and Bo, 2014). To avoid a problem during work and use of modern technology as much as possible, the appropriate training of employees is required, that would include the IT team that implements new technology in the hotel, as well.

If it is made easier and faster for employees to learn how to apply the technology, and improving the visibility of some of the services in the application of technology, the greater the motivation and interest in using the same would be (Lam, Cho and Qu, 2007). Hotels that are using technology largely, have to educate also those who are dealing with the information technology, as well as employees that are going to use it, in order to improve the service. The IT team is specialized to understand computers, not people, and guests. If they would have a better understanding of end services, maybe would be able to improve their service. It would be good if they were also engaged in training programs for other employees that are directly related to guests (Nedry, 2015).

4. HUMAN FACTOR IN HOTELS

4.1. The importance of the human factor

The human factor cannot be replaced completely because human resources are the ones who create and influence economic efficiency of the organization, create products or services, control quality, place them and determine the overall strategy of the organization (Kuzmanovic, 2013). Corporate culture in organizations including hotels, affects the success and competitiveness of the organization. If employees are satisfied, motivated to work and are success-oriented it is more likely that the hotel will be more successful (Sawalha, Zaitouni and Elsharif., 2012).

According to Kokkinou and Cranage (2013), if self-service kiosk is used in the hotel, check-in waiting lines would reduce and the quality of services would improve, but only when there are employees at the reception. If the self-service kiosk is used to replace an employee completely, the business would remain at the same level. It would not reduce the cost of doing business as assumed. Of course, employees must be adequately trained to use self-service kiosk, otherwise waiting lines could be bigger. According to Haemoon, Miyoung and Seyhmus (2013), it is desirable to add a self-service kiosks and modern technology in hotels in tourist resorts, to help employees to provide services, but guests still want to interact with employees.

The technology, on one hand provides privacy, autonomy and effective service, but on the other side does not meet the emotional need of guests. The essential role of the human factor is empathy and understanding. When guests are dissatisfied with the service, they can complain to the employee, not to the machine. Employees can have better understanding of their need, understand how they feel, whether they are angry, nervous, happy, and what kind of services can be provided, accordingly. If guests have built trust and relationship with employees, they are more likely to come back to the hotel.

4.2. The influence of information systems on human factor

How successful implementation of technology in the hotel will be, depends on the willingness of employees to use it. Since its use is very important competitive factor (He, Kyung, Kim and Moon, 2015), employees and management of the hotel are aware that it is necessary to use it, but there are often problems when it is applied. The willingness and interest of employees for the use of modern technology in the hotel depends on

the willingness and beliefs about the usefulness of the use of information technology in general (Ko, Pei and Tsai, 2016). Ko, Pei and Tsai (2016) showed in their research that if there is a positive attitude about the use of information technology, there would be greater intention and readiness for its use in the service process. According to He, Kyung, Kim and Moon, hotel information systems facilitate employees work in different ways and they are satisfied with this way of work (2015). "The technology increases the quality of service, reduce operational costs, reduce routine and repetitive tasks for employees and creates the possibility that employees focus on creating ideas and innovation, and to provide quality customer service" (Andjelkovic, 2008, p. 166).

However, despite the readiness and motivation to use information technology in the work, there must be knowledge and expertise to use it, adequately. It is believed that it is best that managers or people in the hotel that are considered the most important people in the hotel, assist and encourage employees to use modern technology in the hotel (Ko, Pei and Tsai, 2016). In addition to the IT team that carried out the implementation of new technologies in the hotel, managers have operative knowledge and support employees. The employees will then transfer the knowledge and assist guests.

Hotel organizations have to change if technological changes are introduced, as ICT gives strategic influence on organization (Čudanov, 2011). Hotel managers must choose and employ personnel who is technologically competent and is able to understand the training program that involves the use of technology. Besides current knowledge and skills required for employment, receptionists, managers and heads of some departments in the hotel (language skills, teamwork, communication skills, education background, analytical skills, ability to evaluate ...) (Kosar, 2002) new skills has to be sought as well as the knowledge of technology basics.

It is necessary that most employees know how to use all devices and technologies that the hotel has implemented. If potential employees do not have experience in use of systems and programs of the hotel, it is necessary to have basics, so to be able to adapt quickly to new conditions and technologies, as openness presents important factor in company's growth (Jeraj, Marič, Todorović, Čudanov and Komazec, 2015). Various studies on the employees willingness and self-efficacy to use technology in work have shown that the majority of employees are willing and interested to use it, and feel that it makes it easier to work (Ko, He, Law).

Very important factor in the service industry is educated and professional staff. Many hotels create their training programs that will meet the needs for certain positions they need. Particularly significant is investment in staff that have the knowledge, not only professional, but also about the behavior of customers. The continuous process of education, gaining experience, and development of interpersonal relationships is desirable in learning organizations. It enables employee to prepare for future jobs. Training is for the employee to train for the current job, and development is for the future (Noe, Hollenbeck, Gerhart and Wright, 2012).

5. CONCLUSION

The use of modern technology in addition to the human factor is emerging strategy that can improve the quality of services. Fifteen years ago, and more attention was paid to the price of computers and technology, that was used in the hotel. Today when almost every hotel has available technology at affordable prices, focus is shifting to human resources who are using it. Focus is shifted to finding the most efficient way to achieve the best combination of cost of purchase and use of the technology, and the training and motivation of employees to use it. When applying technology, first consumer segment should be determined and in line with that, use modern technology to a greater or lesser extent.

Since guests are driven by emotions when choosing the hotel, very important factor is relationship that they established with employees. As long as the role of information systems and modern technology is to improve service, increase business productivity, quality and way of communication to a higher quality level (not at any price and to reduce costs), it can bring a competitive advantage (Kuzmanovic, 2013). There is a consumer segment, which would be interested in fully automated hotel, but so far, there are no relevant data to show.

Hotel can achieve success if it is able to combine modern technology as an aid and in accordance with the human factor, and not to replace human entirely. Hotel can achieve success if combines modern technology with the human factor that is motivated and qualified to use it. If some of these factors lack in hotel business strategy, it is more likely that the strategy will not achieve expected success.

Tradition, and its preservation together with technology in modern tourism are some of the most intensely debated issues in many researches dedicated to tourism management and marketing policies in general (Goeldner, Ritchie and Mcintosh, 2000). Traditionalism, as a tourist aspect that has acquired some distinctive components, recognized in the specificity of human factor, and especially in hotels services and in the specific cuisine, once coming on a collision course with the technology risks generates a real deterioration of the potential in any kind of the tourism activity. Thus, the general equilibrium defined by the balance between the human resources tradition and modern technology could be sought and found even in the contemporary hotel organization.

POTENTIAL IMPACT OF 3D PRINTING IN REDESIGNING SUPPLY CHAIN – EXAMPLE OF MEDICAL INDUSTRY

Bogdan Rakić[1]*, Aleksandra Ratković[1], Jovana Mrvić[1]
[1]Faculty of Organizational Sciences
*Corresponding author, e-mail: fon.bogdan@gmail.com

Abstract: *This paper covers the globally recognized topic of additive manufacturing. The document examines in particular its impact on supply chain and how medical industry benefits from it. In addition, research of the development of this field in Serbia has been conducted with recent findings. Interviews with the people in this industry in Serbia have been the backbone of the research. Paper combines theoretical knowledge and practical views presented from world's leading business thinking centers. The aim of this paper is to give a contribution in revealing the possibilities 3D printing provides and to highlight its impact in medical industry in Serbia and worldwide.*

Keywords*: 3D printing, additive manufacturing, medicine, supply chain, supply chain management*

1. INTRODUCTION

Supply chain management is of great importance for everyday functioning of organizations. A large amount of resources is invested into managing it effectively and efficiently. Numerous hours of labor and significant investments in equipment, machines, software and personnel training is what accompanies today's supply chain management. An example of traditional model of manufacturing supply chain is showed below:

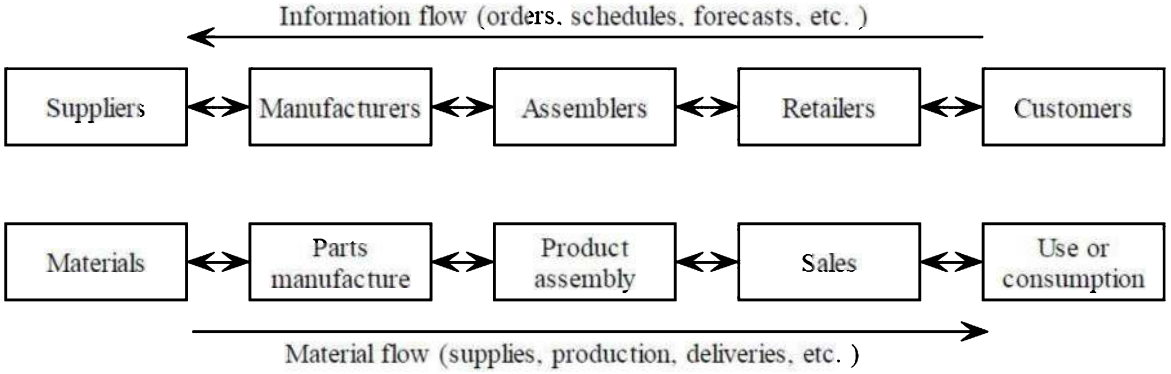

Figure 1: Generic configuration of a supply chain in manufacturing (Vrijhoef & Koskela, 2000)

This configuration shows the checkpoints in the process of serving customers. All those checkpoints are interconnected with a number of support functions and processes. Some of the biggest cost drivers are transport, IT support, quality control, etc. It is the purpose of supply chain management to conduct all of those in a proper ways, with reasonable cost on one side, and satisfied market demands and customer needs on the other. The scope of roles supply chain management varies in size, but either way, its functioning is essential for the success of an organization.(Mentzer et al., 2001)

2. EVALUATION OF SUPPLY CHAIN

Companies continually monitor the performance of their supply chain. Some industries have their own peculiarities and require very specific measures, but the core idea behind the supply chain management metrics is the same. Some of the key metrics are presented by (Gunasekaran, 2004) and could be divided in several areas:

Metrics for order planning;

- Order lead time (time elapsed between the receipt of the order until the delivery of the finished goods to the customer)

- The customer lead path (a path that an order traverses and the time spent in different channels)

Evaluation of supply link:
- Evaluation of suppliers (efficiency, flow, integration, responsiveness)
- Strategic level measures (lead time against industry norm, supplier pricing against the market)
- Tactical level measures (efficiency of purchase order cycle time, cash flow, quality assurance, capacity flexibility)
- Operational level measures (adherence to developed schedule, avoiding defects)

Metrics at production level:
- Range of products and services
- Capacity utilization

Evaluation of delivery link:
- Average cost per delivery
- Flexibility of delivery systems to meet particular customer needs
- Total distribution cost

Customer service and satisfaction:
- Customization level
- Customer query time
- Post transaction services

Logistics cost:
- Cost of assets and return on investment
- Information processing cost

3. 3D PRINTING TECHNOLOGY

Technology of 3D printing belongs to a class of techniques known as additive manufacturing. The key characteristic of additive processes is that they build objects layer-by-layer rather than through molding or subtractive techniques (e.g. machining and carving).(Murphy & Atala, 2014) At this point, 3D printers are able to produce objects from a variety of materials, such as plastic, metal, ceramics, glass, paper and even living cells. These materials can come in form of powders, liquids, filaments or sheets. There are now home 3D printers available, which cost less than $1000, but their possibilities are no match for industrial ones and have limitations.

A variety of 3D printing techniques are in use today, each having its own advantages and drawbacks. Most used additive manufacturing technologies are, according to (Manyika et al., 2013):
- **Selective laser sintering (SLS)**. In this technique, a layer of powder is deposited on the build platform, and then a laser forms a single layer of the object into the powder, fusing the powder together in the right shape. Afterwards the build platform moves down and more powder is deposited to draw the next layer. SLS does not require any supporting structure, which makes it capable of producing very complex parts. General Electric, for example, bought an SLS engineering company to build parts for its new short-haul commercial jet engine;
- **Direct metal laser sintering (DMLS)**. This technique is similar to selective laser sintering but deposits completely melted metal powder free of binder or fluxing agent, building as a result a part with all of the desirable properties of the original metal material. DMLS is used for rapid tooling development, medical implants and aerospace parts for high-heat applications;
- **Fused deposition modeling (FDM)**. A filament of plastic resin, wax, or another material is extruded through a heated nozzle in a process in which each layer of the part is traced on top of the previous layer. If a supporting structure is needed, the system uses the second nozzle to build that structure from a material that is later discarded (such as polyvinyl alcohol);
- **Stereolithography (SLA)**. A laser or other UV light source is aimed onto the surface of a pool of photopolymer (light-sensitive resin). The laser draws a single layer on the liquid surface; the build platform then moves down, and more fluid is released to draw the next layer;
- **Laminated Object Manufacturing (LOM)**. A sheet of material (paper, plastic, or metal) is fed over the building platform, adhered to the layer below by a heated roller, and a laser cuts the outline of the part in the current layer;
- **Inkjet-bioprinting**. Bioprinting uses a technique similar to that of inkjet printers, in which a precisely positioned nozzle deposits one tiny dot of ink at a time to form shapes. In cases of bioprinting, the material used is human cells rather than ink. The object is built by spraying a combination of scaffolding material (such as sugar-based hydrogel) and living cells grown from a patient's own tissues. After

printing, the tissue is placed in a chamber with the right temperature and oxygen conditions to facilitate cell growth. When the cells have combined, the scaffolding material is removed and the tissue is ready to be transplanted.

3D printing has several advantages over conventional construction methods. With 3D printing, an idea can go directly from a file on a designer's computer to a finished part product, potentially skipping many traditional manufacturing steps, including procurement of individual parts, creation of parts using molds, machining to carve parts from blocks of material, welding metal parts together, and assembly. 3D printing can also reduce the amount of material that is wasted during the process of manufacturing and create objects that are difficult or impossible to produce with traditional techniques, e.g. objects with complex internal structures that add strength, reduce weight, or increase functionality. In metal manufacturing, for example, 3D printing can create objects with an internal honeycomb structure, while bioprinting can create organs containing internal network of blood vessels.

3D printing is also gaining traction for direct production of tools, molds, and even final products. These newer uses of 3D printing could enable unprecedented levels of mass customization, shrinking and making supply chains less costly, and even the "democratization" of manufacturing as consumers and entrepreneurs begin to print their own products. Looking longer term, perhaps beyond 2025, one category of 3D printing – bioprinting of living organs – has long-term potential to save or extend many lives. (Lee & Stewart, 2014)

4. EFFECT OF 3D PRINTING ON THE SUPPLY CHAIN

As implications of the technology expand and prices drop, the first big implication is that more goods will be manufactured at or close to their point of purchase or consumption. As a result, many goods that have relied on the scale efficiencies of large, centralized plants will be produced locally. Even if the per-unit production cost is higher, it will be more than offset by the elimination of shipping and of buffer inventories. Parts could be made at dealerships and repair shops, and assembly plants could eliminate the need for supply chain management by making components as needed. (D'Aveni, 2013)

Another implication is that goods will be customized at an unprecedented level because altering them won't require retooling, only slight modifications of instructions in software. For some industries and some products, the concept of "on-demand" manufacturing could radically change business models and supply chains. Consider, for example, a homeowner needing a spare part for a dishwasher. He orders the part online from the manufacturer, receives a bar code for the part and gets it printed at a local 3D printing center, perhaps at a library, post office or a big box retailer. Such a scenario shrinks the supply chain to almost one link – eliminating those connecting development, prototyping, production, delivery, and warehousing of parts. A survey conducted by PricewaterhouseCoopers presents what are the most likely implications of 3D printing on modern businesses. The chart below shows the results.

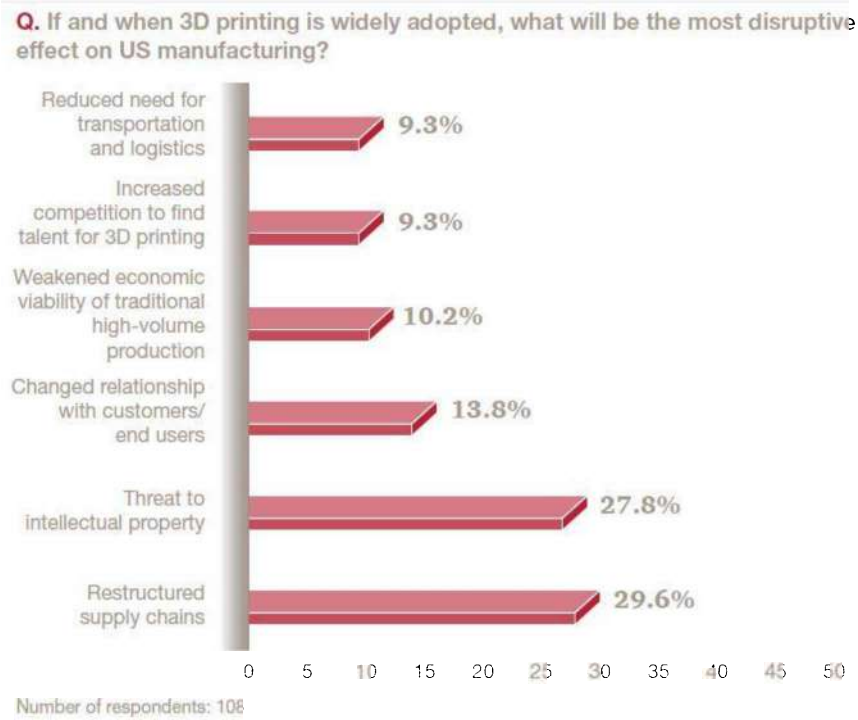

Figure 2: How could 3D printing disrupt? Supply chain restructuring and intellectual property threat tops the list (McCutcheon, Pethikc, Bono, & Thut, 2014)

Whether its impact is evolutionary or revolutionary, 3D printing technology is recognized as a striking trend that will significantly impact supply chains. Those that do nothing will be left wanting, because the influence of 3D printing technology on supply chains is expected to grow. (Sebastian & Omera, 2015)

Based on assessments stated, the 3D printing could cause a supply chain to look a lot simpler, as shown in the Figure 3.

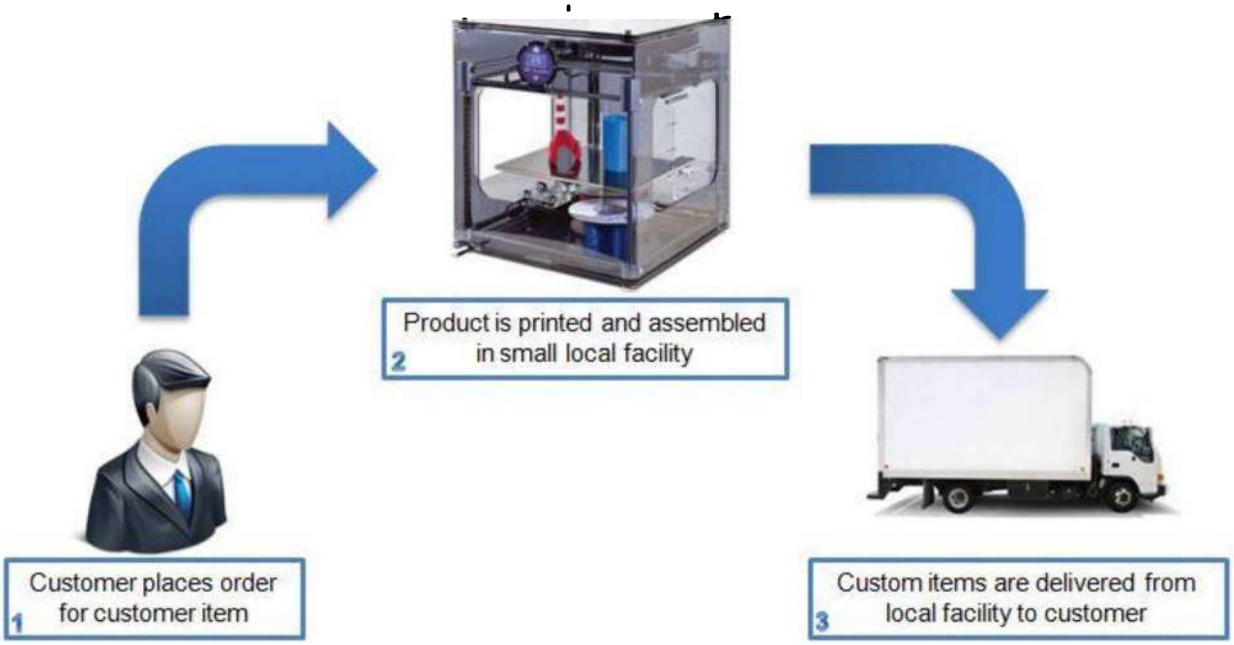

Figure 3: New supply chain model using 3D printing technology

A supply chain having these characteristics would show superior performance in almost all, or the vast majority of supply chain metrics, compared to traditional supply chain. The impact of supply chain on the business of the future is inevitable. The precise form and scope of it are still to be shown. The interest and hype it is creating is impressive. A fact that shows that it is not only a hype is that professional services firms, such as Deloitte, are offering courses in additive manufacturing (Nanney & Cotteleer, 2015). Process is fairly simple, starting with an Auto CAD file, which is afterwards loaded into the 3D printer, which assembles the object based on that. It is clear that new forms of employee training are required for that and already now can we see the steps made towards it, especially in the defense, automotive and aerospace industries, which possess the biggest traction for adopting this technology.

5. CURRENT DRAWBACKS OF 3D PRINTING AND ROOM FOR ADVANCEMENT

The technology of 3D printing has been developing since 1980s, but it still has drawbacks that need to be addressed in order for it to become truly widespread. There are now home printers available, at reasonable prices, even below $1000. But these do not provide perfect performance. Mostly used for prototyping, home printers are producing objects of low-strength capabilities. The 3D printers are about at the same stage as the PCs were in the initial stage of their development. (Lee & Stewart, 2014) Current limitations of 3D printing, which vary by printing technique, include relatively slow build speed, limited object size, limited object detail or resolution, high material cost and, in some cases, limited object strength. However, in recent years rapid progress has been made in reducing these limitations.

Additive manufacturing is still far away from producing massively final products. There will be some highly complex parts that are better made through 3D methods (such as certain aerospace components, like turbine blades), or unique situations where there is no room for a machine shop and the nearest parts depot is far away (such as the International Space Station). Special potential of 3D printing is for spare parts industry. Currently, 3D printing is mostly used by automotive industry (about 40% of all devices used), and medical with about 15%, where the biggest user are dental markets and audiology.(Lee & Stewart, 2014)

Drawbacks of 3D printing do not come down only to current technical limitations, which are likely to be significantly improved. There are some cons that are directly related to the nature of additive manufacturing. Namely, 3D printers may pose a health risk when used at home. The emissions from desktop 3D printers are

similar to burning a cigarette. While heating the plastic and printing small figures, the machines using PLA filament emitted 20 billion ultrafine particles per minute, and the ABS emitted up to 200 billion particles per minute. (Stephens, Azimi, El Orch, & Ramos, 2013) These particles can settle in the lungs or the bloodstream and pose health risk, especially for those with asthma.

Next, 3D printers consume a lot more of electrical energy than e.g. injection molding to make an item of the same weight. Because of this, 3D printers are better for small batch runs. Industrial-sized 3D printers may not be the answer to lessening our use of coal power any time soon. Furthermore, additive manufacturing vastly relies on plastic in its process. One of the biggest efforts recently have been efforts to reduce reliance on plastics, from grocery bags to water bottles to household appliances that can be made from recycled materials instead. Though using raw materials reduces the amount of waste in general, the machines still leave unused or excess plastic in the print beds. The plastic byproduct ends up in landfills, which overall produces additional environmental concern.

Overall, intellectual property is an issue that needs to be taken into consideration seriously in order to create a sustainable model for using 3D printers. 3D printing will change the business market, but also provide possibility for black market for these items. That means that the legislation will have to be created accordingly to catch up with the progress. This potential digital piracy is similar to the way the internet challenged the movie and music industries for copyright, trademarks and illegal downloads.

Finally, there is also a vast room for abuse of 3D printers, which could be used to make weapons, drugs and similar illegal and/or so far narrowly controlled items.

6. 3-D PRINTING IN PRODUCTION OF ORTHOPEDIC INSOLES

Orthopedic insoles are typical products that can be produced using traditional methods, but for which 3-D printing provides broad advantages. Here are highlighted some changes to the supply chain design if 3-D printing is used for producing orthopedic insoles.

The traditional supply chain of orthopedic insoles - Many consumers regularly purchase orthopedic insoles for health reasons to help deal with defects in the natural shape of the foot or positioning of the foot during standing or walking. The insoles are usually partly machined and partly handcrafted. The insole manufacturer holds inventories of cork, plastic and leather, which are the main components for the insole. Cork and plastics are used for the basis of the insole, while a leather top-layer is often assembled at the end of the production process. The cork and plastics cannot be used right away, but need pre-production before they can serve as input materials for the final assembly of the insole. Traditionally, purchase of an orthopedic insole requires frequent contact between the client and an orthopedist, and resultantly the insole manufacturer.

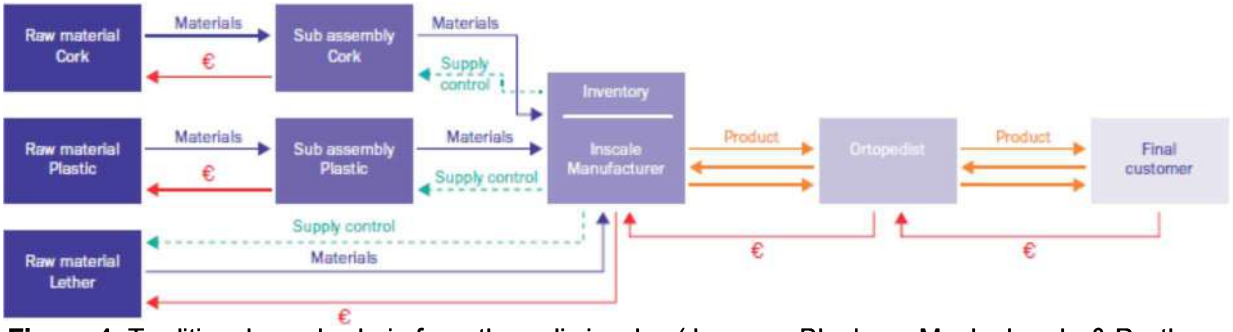

Figure 4: Traditional supply chain for orthopedic insoles (Janssen, Blankers, Moolenburgh, & Posthumus, 2014)

The orthopedist takes a foam print or plaster cast from the client's foot and determines which physical adjustment the client needs. Then he sends the scan, along with his notes, to the insole manufacturer. The insole manufacturer receives the customer's foam scan from the orthopedist, interprets the orthopedist's notes and it fabricates the sole using CNC manufacturing technology. After the sole is finished, it is sent to the orthopedist who will perform the final fitting with the customer. Most clients, however, are not satisfied with the product the first time around and usually adjustments to the insole are needed. The insole is send back and forth from manufacturer to orthopedist to optimize the fitting, and the customer has to visit the orthopedist every time for fitting. The total process easily takes up four to six weeks and costs of the final product are around €200.

The 3-D printed orthopedic insole supply chain – Three-dimensional printing technology offers significant advantages for biomedical devices due to its ability to manufacture low-volume or one-of-a-kind parts on-demand based on patient-specific needs, at no additional costs for various designs. (Bandyopadhyay, Bose, & Das, 2015) Orthopedic insoles can also be manufactured using 3-D printing technology. When insoles are fabricated by means of 3-D printing, the supply chain changes significantly as fewer types of materials are used and production quality increases. The orthopedist, again, takes a foam print from the client's foot, adds the required adjustments to the model. However, the orthopedist can also take a direct 3-D scan from the client's foot, digitally add the required adjustments and send the digital model to the 3-D printing manufacturer. The manufacturer produces the insole straight from the design. This time around, there's less room for human induced error. The strict integration between 3-D scan and 3-D print ensures that a single moment of contact between client and orthopedist should be enough for a correct fitting. The client can even decide to collect the insole at the production location, or to have the final product sent to his home address, omitting the fitting process at the orthopedist at all.

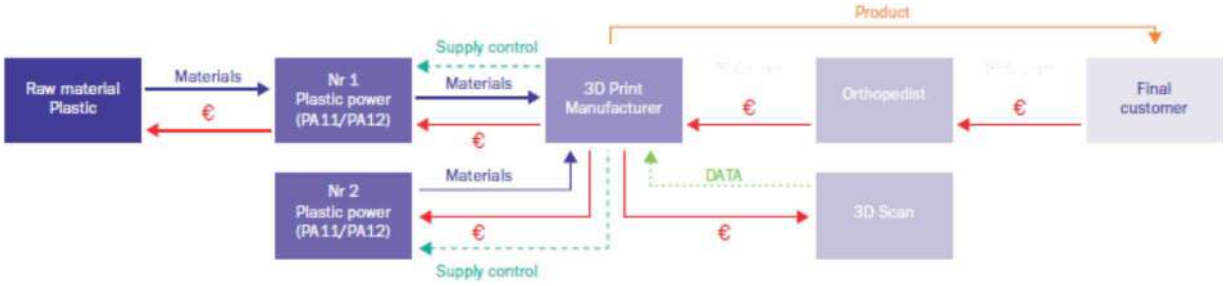

Figure 5: 3-D printed orthopedic insoles (Janssen et al., 2014)

There are several implications in terms of the impact of 3-D printing on supply chain management. For starters, the number of materials used in the insole is reduced. Instead of cork, a nylon powder (polyamides PA11 and/or PA12) is used. The polyamides have the advantages that the materials are widely available, reducing sourcing challenges and dependence on suppliers. At the same time, insoles can become thinner but stronger using these materials. Also, customization can move beyond the level of customization offered by traditional methods. For instance, color and finishing of the insole can be determined by client, as he or she might want bright colored insoles with his or her initials carved into the basis. When using 3-D printing, the cost for one pair of insoles can be competitive with traditional methods, or be even cheaper. And 3-D allows for a much shorter total lead-time, thanks to the "First Time Right" 3-D printing process. Also there is a potential for an innovative channel in which a client can make the 3-D scan herself, using an iPad and an app, using a process called photogrammetry. The insole is printed at a 3-D printing supplier of the company providing the service (one example is a start-up named Sols, webpage: www.sols.co) and directly shipped off to the client for approximately $ 100.

7. USAGE OF 3-D PRINTING IN SERBIA

There are only few players that engage into this industry, and they do not present direct competition to each other, because each of them manages different area in the field.
A small number of companies in Serbia found a sustainable business model in this field. Models that are used are the following:

1. Printing service - on demand printing
2. Design service - modeling and prepress
3. Protopyping service – design, prepress and printing
4. Distributor/vendor of 3D printer

"3D Impulse" Laboratory is a scientific research unit of the Faculty of Mechanical and Civil Engineering in Kraljevo founded in 2013, which contemplates the employment of digital technologies to develop new products. "3D Impulse" Laboratory collaborates with companies through small projects which help continuous development of new and improvement of existing products. The laboratory is a center that provides a common education, consulting and development services to companies that individually would not be able to afford the use of modern technical achievements. The Laboratory is the only center in region that engages with this kind of deployment. It owns modern and high-priced equipment which uses SLS technology for rapid prototyping, rapid tooling and rapid manufacturing. Aside from these, the Laboratory offers other services, such as digitalization of 3D objects, quality control, education, product development and product mentoring. The technology grants the usage of wide variety of materials: metal (margin steel, stainless steel, aluminum, titanium), plastic (polyamide-nylon 12), composites (polyamide filled with glass particles, polyamide filled with aluminum particles, polyamide filled with carbon particles). "3D Impulse"

collaborates both with companies and entrepreneurs, and has cooperated with many domestic firms, but with the ones in Great Britain and Italy, as well. Their customers are individuals and companies who are usually export-oriented and seek for new approach in product manufacturing, through the cost and time saving method. It is projected that 500 entrepreneurs a year upgrade their knowledge, reduce costs and stay competitive on the market, and 400 models and prototypes (for new and improved products) are to be produced. The results of the "Impuls" project in the first year are remarkable: 316 companies went through the assessment of creativity process, 100 companies gained the product analysis, 300 models and 120 prototypes were produced, 50 companies benefited from mentoring and 180 individuals went through training process. Further, the income in those companies raised by 58,7% and 105 new openings were made, which led to employment increase by 3,76%. In addition, production cycle for specific companies reduced by 40%. (http://www.3dimpuls.com/, 2016)

Voxellab is a company that is focused on 3D printing, 3D scanning, 3D modeling and software development. It is an example of prototyping service although it offers high precision models with high resolution with Polyjet technology which currently represents the highest quality and most accurate 3D printing technology in the world market. 3D models made with this technology are characterized by extremely high quality surface and solid mechanical properties suitable for product visualization, functional testing and end use. (http://voxellab.rs/, 2016)

3Dcaddit is a distributor of equipment and devices for 3D printing and covers wide variety of technologies and products. They often do on demand printing with the companies that have bought equipment from them, such as **3D svet**. Along with aforementioned active companies there are also many smaller companies and individuals that offer products and services made on amateur and semi-professional 3D printers. There are also numerous non-profit organizations, such as faculties and other educational organizations, that are equipped with some 3D technology devices, but they are often not available to the public.

Polyhedra is a registered “fab lab” (fabrication laboratory), a workshop equipped with 3D printers and other technologies for digital fabrication. They are trying to bring technology closer to entrepreneurs or any other individual who wants to make a product from an idea in an non-commercial way. While “fab labs” have yet to compete with mass production and its associated economies of scale in fabricating widely distributed products, they have already shown the potential to empower individuals to create smart devices for themselves. These devices can be tailored to local or personal needs in ways that are not practical or economical using mass production. (http://www.polyhedra.co/, 2016)

Along with other numerous projects, Polyhedra has started six projects regarding usage of 3D printing technology in biomedicine. Regarding the topic of the paper, only one of the projects will be elaborated and that is the one that considers usage in prosthetics. They are assembling an artificial hand, made of plastics for a specific individual who has lost his hand. The process of making such hand consists of several phases. First, they developed a static hand, followed with added mechanism with levers and strings. Then they integrated specific technology for controlling contractions of the muscle. Last phase will be completely mechanized system which allows a person to move the fingers of the prosthetics by himself. Needless to say that the price of such hand will be multiple times lower in comparison with artificial prosthetics made so far without 3D printer.

8. CONCLUSION

It is beyond any doubt that 3D printing is a technology that will have a massive impact on how many companies are dealing with their challenges globally. Additive manufacturing has been developing over the past couple of decades to that extent that the pioneers have already established themselves on the different markets. Not only specialized centers for providing different services of 3D printing, but also large corporations, such as car manufacturers, are proof that the potential of this technology has been recognized. Its impact is already considerable, but all implications are that it will have an even stronger influence, shifting its position from a potential industry changer to a regular tool of everyday business, especially after further developing its characteristics.

Benefits of the supply chain using the technology are numerous. Reduced transport and logistics costs, reduced inventory levels, less scrap materials, fewer stages of production and, consequently, fewer supplier and intermediaries in the process are just some of the reasons on the cost side that justify the usage of 3D printing. A massive argument for using it is also the possibility of endless customization at a minor cost.

Given the complexity of the products needed, it is no wonder that the medical industry has also become a significant user of additive manufacturing technology. Different apparatus needed are ideal candidates for

exploiting the potential of 3D printers. The fact that every patient is different puts additional value on 3D printing customization abilities. There are several research centers and companies in Serbia that are offering high-value products and services using additive manufacturing. There is no doubt that impact is going to be even bigger as the technology continues to evolve.

SUPPORTING DEVELOPMENT OF TECHNOLOGICAL STARTUPS THROUGH MENTORING

Milan Okanović[1], Jelena Anđelković Labrović[1]*, Tijana Stefanović[2]
[1]Faculty of Organizational Sciences, University of Belgrade
[2]Student of Faculty of Organizational Sciences, University of Belgrade
*Corresponding author, e-mail: jeca@fon.bg.ac.rs

Abstract: *In the last few years, the field of technological entrepreneurship has been the main subject of interest for many researchers who have showed the awareness of the significance of the development of entrepreneurship and small and medium enterprises (SMEs), for job creation, new possible workplaces, as well as creating a better environment for a society. Technological startups are mostly being created in environment in which there are preconditions for their successful development. One of the preconditions of its development is organizations and individuals who through different forms of mentoring programs and education increase the chance for startups to become profitable companies. In this paper, with overview of contemporary literature within this field of technological startups mentoring as a means of support is analyzed during the process of development of technological startups. Also, key benefits of mentoring as a form of education during the development of technological startups will be explained.*

Keywords*: technological entrepreneurship, technological startups, mentoring*

1. INTRODUCTION

According to Petti and Zhang (2011), technology could be used for creating values only in the case when being implemented in new products, when those products find their market and when they are able to generate additional profit to companies, profit for the investors, acknowledgment for developers and benefits for society. These authors see scientific accomplishments, inventions and technological development as a base ground for creating values and competitiveness, but they emphasize that finding new technological market opportunities and their commercial exploitations as main reasons for creating competitive advantage on the market. According to these authors, technological entrepreneurship represents transformation of technology into value.

According to Petti (2009) technological entrepreneurship contains three main components:

1. entrepreneurial component – a set of activities which are implemented by individuals and companies in order to identify and use specific potential of new technologies and market opportunities,
2. management component – a set of activities done by individuals and companies in order to develop appropriate value offers which enables fast market entry, with business model which has been tested and with which identified market opportunities are being used,
3. environment component – a number of formal and informal organizations for support and resources which enable adequate conditions for development of technological new ventures (state policy, law and regulations, industrial standards, public and private organizations which support entrepreneurship development, culture, community and inter organizational connection).

In this paper the concept of environment of technological startup in a form of support during the development of technological startups will be further elaborated.

1.1. Technological startup

At the beginning of every new venture there is initial stage which is called startup stage (Crowne, 2002), and main characteristics are high dynamics and orientation towards the future. Taking into consideration new venture at this stage of development, as well as the fact that simplified terms are being used now days, “startup” and “new ventures” are going to be referred to as synonyms.

Blank and Dorf (2012) define “startup” as a temporary organization created in order to discover a sustainable business model with a high potential for growth. Duening (2015) had additionally explained Blank’s startup definition, stating that “repeatable” actually means that organization seeks for model which will consistently create and deliver value to customers, where “scalable: means ability of a business model to be created in accordance to customer base growth.

Kariv (2013) explains the term of technological startup as a specific form of entrepreneurship. According to this author, technological startups are new ventures in an early operating stage, which are created in the fields of innovations and newest technologies, and are characterized by high dynamics, orientation for growth, profit and creating new market values. Technological startups are usually created in environment in which there are preconditions for their successful development.

2. ENVIRONMENT FOR DEVELOPMENT OF TECHNOLOGICAL STARTUP

A number of connected institutions which have a common goal to support entrepreneurs throughout all stages of development of new ventures are called entrepreneurial ecosystem (Isenberg 2010). According to this author, entrepreneurial ecosystem can be defined as a network of services with entrepreneur in focus, towards which all of the activities are aimed at and who represents the measure of success of its existence. Mason and Brown (2014) define entrepreneurial ecosystem as number of mutually connected members (existing or potential), entrepreneurial organizations (for example: investment funds, angel investors and others), institutions (universities, public agencies, and financial organizations) and various entrepreneurial processes, which are formally or informally connected, mediating and managing performances of local entrepreneurial environment. Feld (2013) calls entrepreneurial ecosystem – "entrepreneurial community." According to this author, aside from ineffective clusters created by government institutions, entrepreneurial community is formed via informal way and with "bottom – up" approach. Also, entrepreneurial community is led by entrepreneurs, and its creation is based upon mutual networking among individuals and informal activities of entrepreneurs.

Neck with associates (2004) defines basic components of entrepreneurial ecosystem. These include formal and informal networks among entrepreneurs, universities, state and local government, professional consultants, owners of investment capital and talented candidates. Conceptual framework of entrepreneurial ecosystem was defined by Suresh and Ramraj (2012), which represents eight factors of support for entrepreneurs. According to these authors, the support for an entrepreneur can be: moral, financial, technological, market support, social, networking support, government support, as well as environmental support.

Components of startup ecosystem have individuals in center, who based upon their own ideas and inventions create their own innovative startups. Their environment consists of: support component (incubators, mentors, and companies for specialized services), market component (initial buyers/users and big companies), human resources component (individuals with knowledge and skill, and educational institutions), financial component (financial capital, angel investors, accelerators, investment funds, and others), cultural component (events, social norms and experiences), and political component (local and state government). One more term is very specific for this ecosystem, and it is common in new startup scene, and that is "startup community", which Feld (2012) explains in his work.

In this paper, mentoring as a very important support component, as well as the role of mentoring in different forms of support for technological startups will be elaborated.

3. SUPPORT IN DEVELOPMENT OF TECHNOLOGICAL STARTUPS

In the process of development of technological startups, different stakeholders can be identified. Type of stakeholders , depend on in which stage startup is in, and they can influence or be influenced by during the process of its development (Freeman, 2010).

Birdsall (2013) emphasizes as important in the process of development of technological startups the following stakeholders: the founders, angel investors, investment funds, corporate partners, mentors, business incubators, and alumni. Suresh and Ramaj (2012) give a conceptual framework of entrepreneurial ecosystem which they represented through eight types of support for entrepreneurs (table 1).

Table1.Types of support for entrepreneurs (Suresh &Ramaj, 2012)

Type of support	Participants and support form
Moral support	Family, relatives, spouses, friends and community.
Financial support	Closest family, banks, investment funds, friends, relatives, educational institutions, individual investors – business angels, accelerators, small market capital investors, foreign financial institutions, government bodies, and suppliers - creditors,
Technological support	Business incubators and accelerators, technical and technological educational institutions, talented candidates

Market support	Market opportunities, government reports and economy associations, fairs, and others,
Social support	Professional associations prizes, media, social acknowledgment as well and acceptance of entrepreneurial failure,
Networking support	National association of entrepreneurs, alumni associations, social networking websites, supplier and vendor networks,
Government support	Entrepreneur clusters, state educational centers, state incentive and rewards institutions, regulatory state institutions
Environmental support	Availability of natural resources and climate conditions

Startups usually find support for development of ideas within organizations/individuals that support development of entrepreneurship: business incubators, business accelerators, and business angels. Due to their significance for the success of technological startups, these three types of support will be further elaborated in more detail from the perspective of mentoring. Mentors within these types of support for technological startups can be successful entrepreneurs, people who have gone through mentorship programs themselves, big investors, business angels, or experts from various companies.

4. THE ROLE OF MENTORING AS A SUPPORT FOR DEVELOPMENT OF TECHNOLOGICAL STARTUPS

4.1. Mentoring

Garvey et al. (2009) described mentoring as a relationship where more mature and experienced person is engaging in a relationship with a younger and less experienced person in order to assist learner to integrate as a fully functioning person within the society they integrate, which is called the core mentoring model. Now days, a mentor could be a peer also, with the main purpose of the relationship which is transferring knowledge and skills. Beevers and Rea (2010) emphasized that *mentoring is about two people coming together with a view to helping one of them progress more easily through work, life or whatever context the mentoring is taking place in.* Also, mentoring is seen as a long standing form of training, learning and development and an increasingly popular tool for supporting personal development (CIPD,2009).

Beevers and Rea (2010) identify different models of mentoring: 1. group mentoring, 2. group peer mentoring, 3. online mentoring, 4. one-to-one mentoring, 5. one-to-one peer mentoring and 6. line manager mentoring. The most used model within technological startups is group mentoring and one-to-one mentoring.

Mentoring activity could be found in all sectors of society. Mentoring could be voluntary or paid activity but in most cases mentoring is associated with voluntarism (Garvey et al, 2009). As it is showed in CIPD Annual Survey Report about Learning and Development (2015) mentoring and budding schemes are in the top 3 most used talent management activities, and that ¾ of organizations use some kind of coaching or mentoring activities which is increasing every year. Therefore it is important to emphasize that there are various purposes of mentoring and that they could be (Beevers and Rea,2010) to provide role models so that mentees could look up to them, provision of a sounding board (a person with whom a mentee is going to able to discuss ideas, concerns or problems), provision of a advice from some who had had experience and who has been in similar situations, enablement of work-related development, provision of an advocate who could help support, represent and champion mentee when that is needed. Also a mentee could use the provision of contacts and access to opportunities, as well as having someone who will prepare a mentee to be adept while managing relationship and achieving their goals.

The authors state that in reality there is a very small chance that a mentoring relationship is restricted to just one of these activities, but that real benefit of mentoring is that mentors and mentees will work together in different ways to suit their concrete needs at any time.

To the question of who can benefit most from mentoring relationship, answer is presented by Noe (2010) who claims that both mentors and mentees can benefit. Mentees benefits are presented as career and psychosocial support provided by mentors. In most of the cases career support is seen through coaching, protection, sponsorship, providing challenging assignments, exposure, and visibility and psychosocial support includes serving as a friend and a role model, providing positive consideration and acceptance, and providing an means for the mentee to talk about anxieties and fears. Mentoring relationships provide opportunities for mentors as well such as to develop their interpersonal skills and increase their feelings of self-esteem and worth to the organization and society.
Additional benefits for mentees are connected to the learning activities as a result of a mentorship process which can result with gaining knowledge and developing skills. If we look at these learning activities it could

be stated that most of the learning is happening trough role modeling and observation as elements of social learning theory, meaning that in a mentoring context, mentees learn by observing the mentor (Jones, 2013) In order to implement successful mentorship programs first important issue is that mentors should be chosen based on interpersonal and technical skills, and second is that they need to be trained (Noe, 2010,page 373).

Looking at the specifics within mentoring entrepreneurs it could be stated that there is lot of benefits as well as power in it. This is the process in which successful entrepreneurs and business people act as mentors and advisors for entrepreneurship. As a good and helpful mentorship programs are considered programs in which the mentors provide guidance and support to entrepreneurs. Mentoring in an entrepreneurial context may encompass direct forms of help, more parallel to advising or even consulting, which could be argued as a broader than mentoring in other environments (Gimmon,2014).

Rigg and O'Dwyer (2012) have found that mentors could be recognized as significant for developing entrepreneurs and those could be understood as a source of knowledge transfer or as individuals who help aspiring entrepreneurs to reflect and construct knowledge. The mentoring network for a technological startup program could be viewed as a community of practice that provides orientation for entrepreneurs in order to stimulate their learning of how to survive, their acquisition of status and identity, not only their development of practical skills. The mentoring network is also open access to the social capital that is of such importance to the success of a new venture, being admitted into a community of entrepreneurs who recognize and acknowledge each other for their risk taking, nous, wits, achievements and bruises (Rigg and O'Dwyer, 2012).

4.2.Role of mentoring within different types of technological startups support

Organizations and individuals who support the development of technological startups have a significant role in entrepreneurial ecosystem offering services and help in development of their business, help with defining and creating initial products, identifying attractive market segments, providing capital and human resources – mentors and others. Further in the paper the following types of support will be explained in more detail: business incubators, business accelerators, and business angels, within which mentoring representationwill be observed.

Business incubators are organizations which support entrepreneurial ventures in process of development offering help with development of their business (Grimaldi & Grandi 2005). Fominiene (2010) defines process of business incubation as "business incubation is the innovative, heterogeneous (multiple) and able to transform the business development of SMB's process, during which the support is provided for newly formed and start-up SMB companies thus contributing towards establishment of new, independent and successfully operating in the market companies". Incubators contribute to the process of strengthening new companies before they become independent (Cohen 2013).

Cohen (2013) defines business accelerators as organizations which contribute new ventures with defining and building initial products, identifying attractive market segments, providing capital and human resources. They establish this through time-limited support program, and they usually last around three months. Program include initial investment, working space, networking, education and training by mentors who can be successful entrepreneurs, the ones who have been through the mentorship program, big investors, business angels or experts from various companies. The program usually ends with a demonstration day, where new ventures are presented to bigger audience or investors.

Business accelerators help build a good team of new venture, defining ideas and mentoring the development of a venture from idea, through prototype, and finally to the final product development (Hoffman & Radojevich-Kelley, 2012). These authors emphasize that mentorship program within business accelerators contribute to higher success because they provide contact with individual and big investors and conclude the following:

- Team motivation in business accelerators differentiate from team motivation within teams who develop themselves with different type of support.
- Ventures that have finished program within the accelerator have higher rate of success (the duration of business and investments) in comparison to those who have not.
- Accelerator use different criteria when selecting new ventures and analyzing ideas, in comparison to groups of programs for supporting development of ideas.
- Founders of accelerators and new ventures face the same obstacles and challenges.
- The additional value of accelerating program is that it provides mentoring and networking.

Huijgevoort (2012) in his research stated that number and quality of mentors engaged in development of new ventures also affects the value creation in accelerator. Quality of mentors is reflected in his expertise and previous entrepreneurial experience, which significantly contributes to value creation during the program, but in connection to other relevant stakeholders which mentor has. Also, this author states that it is important that each startup gets assigned with adequate mentor.

Miller and Bound (2011) also claim that accelerators have higher impact on success of new ventures in comparison to incubators because of implemented mentorship program amongst other things. Mentorship program consists of creating environment that will contribute to better development of a startup. That includes participation in lectures held by experts, after which individual meetings with the teams are being organized. The overall goal of these meetings is giving feedback about the new venture, but also creating a long-term relationship with mentors and experts which later on could be potential investors. On the other hand, accelerators organize different types of events, for example: legal aspect of entrepreneurship, tax policy, presentation skills, etc.

Another important stakeholder group is individual investors or "business angels". Either as individuals or as a group they give the initial seed to companies in making, and to their new ventures, but at the same time they give business advice (Cohen, 20130). A high number of those oriented to technological entrepreneurship have tendency to invest their own funds in new ventures with high risks, from whom a huge return on investment is expected (Aram, 1989). Freear (1994) states that they are part of informal capital market, and usually they are not that accessible to entrepreneurs. The same author describes them as people who are well educated, middle aged with a significant business experience and have had significant effect on the market.Business angles who have invested in startups mentor only when in need without defined development program as oppose to accelerators. Therefore their role is considered limited.

In her paper Cohen (2013) makes a difference between accelerators, incubators and business angels based on: the duration of development of new venture, characteristics of internal community, characteristics of a business model, the selection process and mentoring program, education and networking with other stakeholders. The similarities and differences between incubators, accelerators and business angels are represented in table 2.

Table2.The similarities and differences between incubators, accelerators and business angels(Cohen, 2013)

	Accelerators	**Incubators**	**Business angels**
Process length	3 months	1-5 years	Permanent
The joint team work	Yes	No	No
Business model	Investment	Rent	Investment
Selection process	Competitive, cyclic	No competition	Competitive, permanent
Stages of development	Early	Early or late	Early
Education	Seminars	Add hoc	None
Location	Usually at location	At location	Without permanent location
Mentoring	Intense	Minimal	Optionally

We can conclude that mentoring and education are mainly used within business accelerators, so in the following chapters a role and significance of mentoring in these organizations will be furthermore explained.

4.3. Mentoring in business accelerators

In his thesis Barrehag (2012) highlights three important components of stakeholder's network within accelerators: startup, mentors, and investors. Each one of the stakeholders has their own specific participation and benefits from realization of accelerator program. The impact model of these three stakeholders is represented in figure 1. Similar to this author, Birdsall (2013) states that the most important participants within the accelerators' programs of development are: founders of new venture, business angels, investment funds, corporate partners, mentors, incubators and alumni.

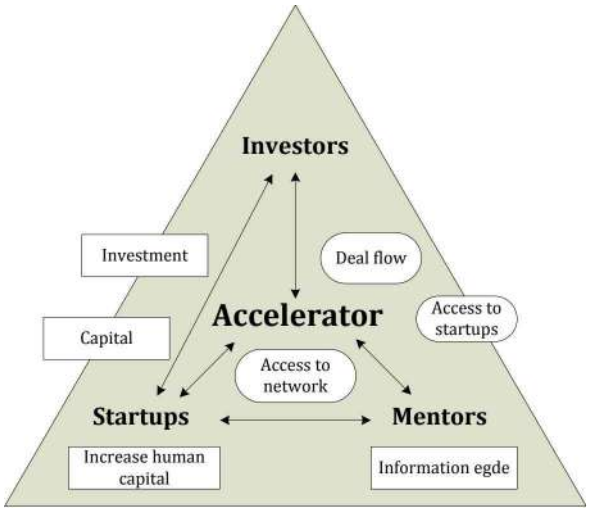

Figure 1.The conceptual model of the network of stakeholders in the business accelerators (Barrehag, 2012)

According to this same author, with a relationship with mentors, a startup has more chance to become profitable company. In this respect, education is highlighted as a key activity for many entrepreneurs which is not provided outside of participation in the accelerator. Based on the research that Birdsall (2013) conducted, the most important benefit for entrepreneurs is reputation their new venture gains after realization of a program within accelerator. When choosing accelerator program, entrepreneurs find as most important factors: quality of mentors, brand and reputation of the program and possibility for networking.

Stakeholders who contribute the most to increasing the value of new ventures are mentors, who are engaged in the program of an accelerator and who through the mentoring develop human resources of new venture (Huijgevoort, 2012). Also, mentors are one of the key factors of attractiveness of an accelerator. However, reason and motivation behind mentors' participation does not always have to be financial benefit, through part time or full time engagement, but it can also be of altruistic nature. Mentors are often very ambitiously oriented towards creating entrepreneurial community in their environment, and with participation in program within accelerators mentors remain in touch with the latest entrepreneurial ventures that develop.

5. CONCLUSION

In order to adequately explain the essence of this paper the role of mentoring in the development of technology startups is elaborated. Within the paper, technological entrepreneurship was firstly discussed and then the environment and its significant impact on the development of technological startups. The environment can provide various forms of support. In this paper support from the organization is emphasized (business incubators and accelerators) as well as support from individuals (business angels) as important elements within developed entrepreneurial ecosystem. Considering these forms of support, the role of mentoring is particularly analyzed and it was found that training and mentoring is mostly present in the business accelerators. It is shown that the key benefits from mentoring for mentees are career and psychosocial support. As Rigg and O'Dwyer (2012) have stated, mentoring in an entrepreneurial context includes direct forms of help, more parallel to advising or even consulting, which are explained as a broader than mentoring in other environments. Mentoring should provide orientation for entrepreneurs in order to stimulate their learning from how to survive their acquisition of status and identity, to as well as their development of practical skills.

Challenges for further research based on the analysis in this paper could be imposed through following question: Did the mentors have any training for the mentoring role, in other words are they lacking mentoring skills? Also, it is necessary to investigate the structure and performance of the mentoring programs, especially taking into account that during the incubation period a change of mentors happens often because most of them are not able to continuously work on the development of startups over a long period of time. Special direction for future research is proposed as structuring of performance indicators of mentoring engagement and mentoring programs in order to enable evaluation of the their contribution in technological startups development.

Abstract: *In this paper we present the application of the Quantitative Strategic Planning Matrix (QSPM) in order to effectively prioritize strategic goals and business strategies. Evaluation and selection of the technology strategies using the QSPM analytical tool was conducted in Comtrade Group, a multinational corporation committed to excellence in all its operations. The management, actively involved into optimizing and improving its operations and processes, seeks to push the limits, gain competitive advantage and set industry standards in engineering and information technology. The QSPM analysis was therefore performed, to raise the quality, efficiency and strategic planning capacities and meet the ever growing expectations of prime quality. By conducting an external and internal analysis, SWOT, TOWS and QSPM, the company succeeded into determining and prioritizing strategies, derived from the carefully selected metrics, industry and data insights. It was found that by focusing on its core competences and taking advantage of the extensive knowledge of its employees and company's experience in a wide array of industries, the organization will be able to thrive, strengthen its position as regional leader in IT and successfully expand into new markets.*

Keywords*: Comtrade Group, technology strategy, Quantitative Strategic Planning Matrix (QSPM), SWOT, TOWS, technology evaluation and selection*

1. INTRODUCTION

A company's success in the market and its ability to be driven by innovation largely depend on strategies that are carefully designed and developed (Schilling, 2013). Technology and strategy represent two very complex schools of thought and the interface between the two areas becomes a concern when technology significantly affects performance (Burgelman & Wheelwright, 2004). Technology strategy is one of the functional strategies of a corporation. Formulating a technology strategy will enable a company to assess its current position and determine its future orientation by taking advantage and focusing on its core competences (Schilling, 2013). It defines activities concerning generating, assessment and selection of technology. In formulating and implementing the technology strategy managers have to pay attention to different internal and external factors. Technology strategy includes the objectives, strategies and tactics related to development and application of technologies within an organization. (Floyd, & Wolf, 2010)

Evaluation and selection of a technology strategy is not infrequently a complex undertaking, involving significant uncertainty, risk and need for a strategic mindset (Tan et al., 2011). There is a variety of methods which can be used to evaluate and select a strategy, including economic and mathematical models, peer review, interactive methodologies, optimization of portfolio and machine learning and artificial intelligence systems (Tan et al., 2011; Henriksen & Traynor,1999). Nonetheless, many of the mentioned methods are too complex or require considerable time to be implemented Choosing the most optimal methodology is critical not only to be able to quickly respond to the fast changing environment but to also create flexibility and set future orientation for the company (Schilling. 2013).

Large organizations as well as smaller firms need to assess their position in the market, strive to gain competitive advantage and reach their strategic goals by focusing on their core competences and values. Not infrequently, it is easy to loose direction and risk pursuing ineffective and inefficient business strategies, failing to maximize profits and augment company's value. In order to effectively prioritize the different business goals and strategies an organization should use in order to achieve its mission, the Quantitative Strategic Planning Matrix (QSPM) can become an effective analytical tool to clearly set priorities and identify the most critical objectives that need to be addressed first (David et al., 2009; David, 1986; Nasab & Milani, 2012). In particular, businesses in the most diverse industries can thrive when using the QSPM for the

purposes of strategic planning and management. Evaluation and selection of the technology strategies has been used in the case of Comtrade Group, a multinational corporation committed to excellence in all its operations. Each year, the company sets standards higher and higher, in particular when it comes to the speed, quality and uniqueness of its products and services. The management is actively involved into optimizing and improving its operations and processes. It seeks to push the limits, gain competitive advantage and set industry standards in engineering and information technology. As a result, the QSPM analysis was performed, to raise the quality, efficiency and strategic planning capacities and meet the ever growing expectations of prime quality. By first conducting an external and internal analysis (PESTLE, Porter's five forces, stakeholder analysis, BCG matrix), SWOT, TOWS and QSPM, the company succeeded into determining and prioritizing a variety of strategies, derived from the carefully selected metrics, industry and data insights. It was found that the company should focus on “bring new technology into the market by using excellent employee knowledge and expertise in a variety of industries”. By focusing on its core competences and taking advantage of the extensive knowledge of its employees and company's experience in a wide array of industries, the company will be able to thrive, strengthen its position as regional leader in IT and successfully expand into new markets.

2. COMPANY OVERVIEW

Comtrade Group, leading information technology organization in Southeast Europe, was founded in 1990 and is specialized in "the fields of software solutions, system integration, and hardware distribution" (Comtrade, 2015). Comprised of twenty-two companies that operate in eleven countries across Europe and North America, Comtrade has a well-established reputation as a reliable partner to both small and large enterprises. Innovative information technology solutions and services have contributed to a comprehensive and diverse portfolio with more than nine hundred satisfied clients in the public sector, government agencies, healthcare, telecommunications, automotive, finance, travel, logistics, gaming, and hospitality industries. The company is considered "pioneer in the area of near shoring and external R&D services and is a trusted developer of end-to-end technology product solutions in various industries" (Comtrade, 2015). Comtrade has several business concentrations: software solutions engineering, system integration, distribution and media. The solutions engineering is oriented toward clients worldwide and provides software and IT solutions, while the system integration works closely with Governments, their agencies, ministries, as well as with local enterprises and private companies. The media comprises of operations oriented toward the digital, Internet based content and channels, while the distribution business involves significant and major partners locally and worldwide (more than fifty IT and consumer electronics vendors), and it effectively covers the entire process: from import to distribution, in addition to logistics, service and support, focusing on efficient stock optimization and improvement of inventory rates. Comtrade an invaluable and large customer base for its distribution business: Retail, Telco, System Integrators, Value added and Internet-based re-sellers, as well as PC assemblers. Main product categories include consumer electronics, mobile phones, and information technology. The organization's vision is to become world leader in delivering high value end-to-end technology solutions, products and services while reducing business complexity with technology solutions for storage, enterprise application management and gaming technology. As Comtrade strives to achieve its mission, it is focusing on creating a culture of innovation that is focused on valuing knowledge, professionalism, passion for high quality work, accountability, entrepreneurship and reciprocal trust and respect.

3. METHODOLOGY

Starting from the organization's vision, mission and strategic goals, the external and internal analyses were performed. Trough careful review of historical data, documentation, interviews, and personal experience, the SWOT, TOWS and QSPM analyses were completed. In the external analysis particular focus was on the PESTLE and Porter's Five Forces, establishment of the major opportunities and threats for the company, while on the internal the focus was on Comtrade's strengths and weaknesses. Stakeholder analysis and BCG Matrix were completed in the process but are not included in the paper. Using SWOT and TOWS as inputs, we have developed the Quantitative Strategic Planning Matrix. As David et al. (2009), David (1986), Nasab and Milani (2012) highlighted the QSPM as an extraordinary instrument in the decision making process and choice among different strategies in addition to assisting managers understanding the internal and external environments that will help them make the most optimal and appropriate decisions regarding strategy and direction. By collaborated with industry professionals and obtaining insight from the Comtrade Group's management team we have determined the external and internal factor evaluation matrix, assigned weights and ratings in order to set priorities for the strategic planning and decision making processes.

4. EXTERNAL FACTORS EVALUATION

In order to strategically assess the firms position in the market and the external environment in general, PESTLE analysis (analyzing the political, economic, social, technological, legal and environmental factors) and Porter's five forces (where threat of new entrants, bargaining power of buyers, bargaining power of suppliers, threat of substitute products and services as well as the intensity of rivalry among the competitors in the industry were considered) were performed. Due to the extensive evaluation and findings, the analyses are not included in the paper. Nonetheless, the External Factor Evaluation matrix (Table 1.) reflects some of the major findings. The External Factor Evaluation matrix (abbreviated EFE) is valuable as it provides critical strategic business information to management regarding the company's standing in addition to enabling the prioritization, through rating, of the various opportunities and threat the company is facing. Factors listed in Table 1. were assigned weights and ratings. The weights, values ranging from zero to one, zero representing the low level of importance and one indicating a critical factor. Summed up, they should all add up to one. Ratings on the other hand indicate the degree to which the company is responding to the factors (similarly to weights, a lower value shows a poor response, while four, the highest possible value that can be assigned, an effective and efficient response). It is important to note that weights are considered at the industry level while the ratings at a national level.

As shown in Table 1, the customer need for new technologies adapted to the Serbian market is one of the most important opportunity factors for the company, in addition to the possibility of expanding to new markets. Comtrade has offices and development centers worldwide and is continuously seeking to adapt its offerings and services to meet the ever-growing need and demand. Increase of market share in the international market is one of the goals of the company. As resources become scarcer it is vital to support sustainable development and invest in alternate sources of power. Comtrade is committed to reducing negative environmental impact of their activities and to continuously improve their environmental performance as an essential and core part of their business strategy and operating methods. Therefore, the possibility of creating and using the possibilities of energy substitutes is critical.

Table 1: External Factors Evaluation Matrix for Comtrade Group

External Factors	Weight	Rating	Score
Opportunities:			
Customer need for new technologies adapted to Serbian market	0.11	4	0.44
Greater foreign investments in R&D of technology	0.01	2	0.02
Better law regulations for partnerships with foreign companies	0.05	3	0.15
Expansion to new markets	0.10	3	0.30
Increased market share in international market	0.08	2	0.16
Possibilities of energy substitutes	0.06	3	0.18
Entering new technology in market	0.05	3	0.15
Development of new technology (patents) by the company	0.06	3	0.18
Increased reputation and customer satisfaction from company's services and products	0.05	4	0.20
Collaborating opportunities with emerging start-ups and already established companies	0.04	2	0.08
Threats:			
High competition in IT industry	0.10	3	0.30
Rapidly changing trends	0.03	4	0.12
New regulations and laws	0.05	3	0.15
Established competitors	0.02	3	0.06
Different customer needs and trends in countries of operation	0.04	3	0.12
Changes in government policies and official stance toward foreign, partner, countries	0.03	3	0.09
Unexpected entry of large and more powerful competitor into the local market	0.05	2	0.10
Increased cost of being in business due to government environmental rules and regulations	0.02	3	0.06
Increased cost of labor and raw materials	0.05	3	0.15
Total	**1**	**-**	**3.01**

The company should seek to enter new technologies in market and develop an increasing number of patents and technologies. According to the data from the Intellectual Property Office of the Republic of Serbia (2013, 2015), only few patents from corporations and other business entities are being submitted each year, far less than private persons, creating a significant opportunity for the company. Comtrade has been increasing its reputation and customer satisfaction thanks to quality products and services. By collaborating with emerging start-ups and already established companies it can take advantage of newly created opportunities and be able to quickly adapt to changing market tastes, environment and competition. On the other hand, the high competition in the IT industry can be a significant threat along with the increasing costs of labor and raw materials, and changes in government policies and official stance toward foreign, partner, countries. Rapidly changing trends may become an issue, just like new laws and regulations, presence of established competitors, change in customer needs and trends in countries of operation. Unexpected entry of a large and more powerful competitor into the local market can also become a threat in addition to increased cost of being in business due to government environmental rules and regulations.

5. INTERNAL FACTORS EVALUATION

Following the external analysis, an internal evaluation of company's strengths and weaknesses was conducted. As can be observed in Table 2., after the assignment of weights and ratings to the individual factors, it was found that the factors that were deemed most influential were the company's proactive approach to innovation at local and global levels, its expertise in a variety of industries, certifications (ISO standards, employee certifications) and the excellent reputation among customers, in addition to one of the main weaknesses being the high fluctuation of engineering staff.

Table 2: Internal Factors Evaluation Matrix for Comtrade Group

Internal Factors	Weight	Rating	Score
Strengths:			
Strong brand name	0.06	4	0.24
Excellent reputation among customers	0.10	4	0.40
Certifications (ISO standards, employee certifications)	0.11	4	0.44
Good technology (both hardware and software)	0.08	3	0.24
Excellent employee knowledge	0.08	3	0.24
Expertise in a variety of industries (automotive, financial, energy, high-tech, gaming, public sector, etc.)	0.09	4	0.36
Committed to reducing negative environmental impact of company's business activities	0.02	3	0.06
Well established communication and network of customers and partners	0.05	4	0.20
Promotes innovation and is dedicated to educating younger generations (Fabrika znanja, EDIT, Girls in ICT)	0.05	3	0.15
Proactive innovation at local and global level	0.10	3	0.30
Large corporation but with a startup culture and approach when needed.	0.05	3	0.15
Weaknesses:			
High fluctuation of engineering staff	0.08	2	0.16
High R&D costs	0.03	2	0.06
Difficulties in penetrating new foreign markets	0.03	2	0.06
Complex network structure (company and employee level)	0.02	2	0.04
High frequency of ad-hoc changes on in-house projects	0.05	2	0.10
Total	**1**	**-**	**3.2**

6. SWOT & TOWS ANALYSIS

Following the external and internal analyses, SWOT and TOWS were performed to strategically assess the company's strengths, weaknesses, opportunities and threats. Table 3. features the SWOT analysis while the TOWS can be found in Table 4.

Table 3: SWOT analysis for Comtrade Group

STRENGTHS	**OPPORTUNITIES**
▪ Strong brand name ▪ Excellent reputation among customers ▪ Certifications (ISO standards, employee certifications) ▪ Good technology (both hardware and software) ▪ Excellent employee knowledge ▪ Expertise in variety of industries (automotive, financial, energy, high-tech, gaming, public sector, etc.) ▪ Committed to reducing negative environmental impact of company's business activities ▪ Well established communication and network of customers and partners ▪ Promotes innovation and is dedicated to educating younger generations (Fabrika znanja, EDIT, Girls in ICT) ▪ Proactive innovation at local and global level ▪ Large corporation but with a startup culture and approach when needed.	▪ Customer need for new technologies adapted to Serbian market ▪ Greater foreign investments in R&D of technology ▪ Better law regulations for partnerships with foreign companies ▪ Expansion to new markets ▪ Increased market share in international market ▪ Possibilities of energy substitutes ▪ Entering new technology in market ▪ Development of new technology (patents) by the company ▪ Increased reputation and customer satisfaction from company's services and products ▪ Collaborating opportunities with emerging start-ups and established companies
▪ High fluctuation of engineering staff ▪ High R&D costs ▪ Difficulties in penetrating new foreign markets ▪ Complex network structure (company and employee level) ▪ High frequency of ad-hoc changes on in-house projects	▪ High competition in IT industry ▪ Rapidly changing trends ▪ New regulations and laws ▪ Established competitors ▪ Different customer needs and trends in countries of operation ▪ Changes in government policies and official stance toward foreign, partner, countries ▪ Unexpected entry of large and more powerful competitor into the local market ▪ Increased cost of being in business due to government environmental rules and regulations ▪ Increased cost of labor and raw materials
WEAKNESSES	**THREATS**

Table 4: TOWS analysis for Comtrade Group

Internal / *External*	**Strengths:** 1. Good technology (both hardware and software) 2. Excellent employee knowledge 3. Expertise in a variety of industries (automotive, financial, energy, high-tech, gaming, public sector, etc.) 4. Certifications (ISO standards, employee certifications) 5. Proactive innovation at local and global level 6. Large corporation but with a startup culture and approach when needed	**Weaknesses:** 1. High R&D costs 2. Difficulties in penetrating new foreign markets 3. High fluctuation of engineering staff 4. High frequency of ad-hoc changes on in-house projects
Opportunities: 1. Customer need for new technologies adapted to Serbian market 2. Possibilities of energy substitutes 3. Development of new technology (patents) by the company 4. Collaborating opportunities with emerging start-ups and established companies 5. Expansion to new markets	**SO:** 1. Use existing good technology and employee knowledge to develop new technologies adapted to Serbian market (S1, S2, O1) 2. Bring new technology into the market by using excellent employee knowledge and expertise in variety of industries (O3, S2, S3) 3. Use expertise in a variety of industries to satisfy customer needs and expand to new markets (S3,O1, O5) 4. Expand to new markets by proactively innovating at local and global levels (S5, O5) 5. Take advantage of the firm's startup culture and approach in order to develop new technologies (S6, O3) 6. Use expertise in a variety of industries and certifications as significant resource in collaborating with other companies (O4, S4, S3)	**WO:** 1. Increase the possibility of penetrating new foreign market by working on new technology as energy substitutes (W2, O2, O3) 2. Reduce energy use and costs with energy substitutes in order to render R&D more cost efficient (O2, W1) 3. Decrease R&D costs by adapting company's existing technology to the Serbian market (W1,O1) 4. Reduce high fluctuation of engineering staff by collaborating with emerging start-ups and established companies (W3, O4) 5. Use the development of new technology (patents) by the company to retain engineering staff (W3, O3) 6. Increase project management capabilities for in-house projects in order to more effectively penetrate new markets (W4, O5)
Threats: 1. High competition in IT industry 2. Increased cost of being in business due to new government environmental rules and regulations 3. Increased cost of labour and raw materials 4. Rapidly changing trends 5. Different customer needs and trends in countries of operation	**ST:** 1. Reduce costs of business induced by new environmental regulations by engaging excellent employee knowledge and expertise in variety of industries (T2, S2, S3) 2. Work on competitiveness in IT industry by combining company's good technology and expertise in variety of industries (T1, S1, S3) 3. Use expertise in variety of industries to readily face rapidly changing trends and meet different customer needs (T4, T5, S3) 4. Face increased cost of labour and raw materials by proactively innovating at local and global levels (T3, S5)	**WT:** 1. Look for ways to reduce R&D costs in order to beat competition (T1, W1) 2. Advance the possibility of penetrating new foreign markets by establishing partnerships with companies in countries with lower labor and/or raw material costs (W2, T3) 3. Keep up with the rapidly changing trends by structuring in-house projects in a more efficient manner (W4, T4) 4. Reduce the high fluctuation of engineering staff in order to rise competitiveness in the industry (W3, T1)

7. IMPLEMENTATION OF QSPM AND FINAL RESULTS

The results of SWOT analysis, external and internal factors with their weights are presented in the first column of the QSPM (Table 5). The information was directly derived from EFE and IFE matrix. The AS field indicates the Attractiveness Score. Attractiveness Score is obtained through the consideration of the critical success factors and asking the following question: "Do these factors affect the choice of strategy?" (Hamidi & Delebahari, 2011). Four experts from Comtrade Group were questioned, and attractiveness scores were calculated as the average value of their individual scores given in the following form: No attractiveness - 0 score, little attractiveness - 1 score, almost attractive - 2 scores, acceptable attractiveness - 3 scores and high attractiveness - 4 scores. The FAS indicates the Final Attractiveness Score, obtained by multiplying the factor weight and attractiveness score.

Table 5: Quantitative Strategic Planning Matrix (QSPM) for Comtrade Group

W4	0.05	-	-	1	0.05	-	-	2	0.10	1	0.05	4	0.20	2	0.10	-	-	4	0.20	2	0.10
Total			**2.47**		**1.70**		**1.66**		**1.75**		**1.72**		**2.30**		**2.45**		**2.45**		**1.52**		**1.77**

Based on the results obtained from the Quantitative Strategic Planning Matrix, (total values for each strategy as a sum of FAS values), priorities can be determined and ranked. The prioritized list of strategies is as follows:

1. Bring new technology into the market by using excellent employee knowledge and expertise in a variety of industries (SO2: 4.10)
2. Work on competitiveness in the IT industry by combining company's good technology and expertise in variety of industries (ST2: 4.01)
3. Expand to new markets by proactively innovating at local and global levels (SO4: 3.99)
4. Take advantage of the firm's startup culture and approach in order to develop new technologies (SO5: 3.94)
5. Use expertise in a variety of industries to satisfy customer needs and expand to new markets (SO3: 3.70)

6. Use existing good technology and employee knowledge to develop new technologies adapted to Serbian market (SO1: 3.50)
7. Use expertise in a variety of industries and certifications as significant resource in collaborating with other companies (SO6: 3.41)
8. Use expertise in variety of industries to readily face rapidly changing trends and meet different customer needs (ST3: 3.08)
9. Reduce costs of business induced by new environmental regulations by engaging excellent employee knowledge and expertise in variety of industries (ST1: 2.78)
10. Face increased cost of labor and raw materials by proactively innovating at local and global levels (ST4: 2.62)
11. Increase the possibility of penetrating new foreign market by working on new technology as energy substitutes (WO1: 2.47)
12. Look for ways to reduce R&D costs in order to beat competition (WT1: 2.45)
    Advance the possibility of penetrating new foreign markets by establishing partnerships with companies in countries with lower labor and/or raw material costs (WT2: 2.45)
13. Increase project management capabilities for in-house projects in order to more effectively penetrate new markets (WO6: 2.30)
14. Reduce the high fluctuation of engineering staff in order to rise competitiveness in the industry (WT4: 1.77)
15. Reduce high fluctuation of engineering staff by collaborating with emerging start-ups and established companies (WO4: 1.75)
16. Use the development of new technology (patents) by the company to retain engineering staff (WO5: 1.72)
17. Reduce energy use and costs with energy substitutes in order to render R&D more cost efficient (WO2: 1.70)
18. Decrease R&D costs by adapting company's existing technology to the Serbian market (WO3) - 1.66
19. Keep up with the rapidly changing trends by structuring in-house projects in a more efficient manner (WT3: 1.52)

8. CONCLUSION

A company's success in the market largely depends on a carefully designed and developed strategy (Schilling, 2013). Technology strategy includes the objectives, strategies and tactics related to development and application of technologies within an organization (Floyd & Wolf, 2010). Formulating a technology strategy that will enable the company to assess its current position and determine its future orientation by taking advantage and focusing on its core competences is critical (Schilling, 2013). Comtrade Group, recognized the need of assessing and prioritizing its strategies, and performed evaluation and selection of technology strategies by using the Quantitative Strategic Planning Matrix.

The SWOT and TOWS analyses, crowned by the QSPM evaluation, clearly showed great possibilities for Comtrade's further development of its business by bringing in and developing new technology both in the Serbian as well as foreign markets. The principal strategy derived from the Quantitative Strategic Planning Matrix was to "bring new technology into the market by using excellent employee knowledge and expertise in a variety of industries". According to findings from the QSPM analytics tool, by focusing on its core competences and taking advantage of the extensive knowledge of its employees and company's experience in a wide array of industries ranging from medical, public sector, government, telecommunications, automotive, finance and travel to gaming and hospitality industries, Comtrade will be able to thrive, strengthen its position as a leader in IT and successfully expand into new markets. Further research is needed to confirm the relation between the QSPM prioritized strategy ranking and company's increased efficiency, profitability or success in the market.

9. ACKNOWLEDGEMENTS

We would like to thank the Comtrade Group team for their invaluable support and collaboration, with special thanks to the president of Comtrade Group, Mr. Veselin Jevrosimović, adviser to the president Mr. Srećko Miodragović, Chief Technology Officer of Internet Group Mr. Miloš Marčeta, and Director of Human Resources Department Ms. Tanja Perić. Furthermore, we would like to express our deepest gratitude to the University of Belgrade, Faculty of Organizational Sciences, faculty and colleagues.

OPPORTUNITIES AND THREATS OF GLOBAL TECHNOLOGY AND OPERATIONS STRATEGY IN OIL AND GAS INDUSTRY

Ivan Sekulović
Faculty of Organizational Sciences
e-mail: ivan.sekulovic82@gmail.com

Abstract: *Oil & gas industry in the era of globalization faces various opportunities and threats. Opportunities and threats are generated by different factors. Oil & gas industry represents driving force and is vital to all other economy branches. Although it is driven by supply and demand forces, it can influence them significantly. Due to limited reserves at home, majority of companies run their operations internationally and globally. Global approach gives wide range of opportunities, but it also imposes threats. This research concerns a range of global strategic approaches directed to use maximum opportunities and to overcome the threats. Used materials originate from international, global and national oil & gas companies websites. Research method is based on common theoretical approaches to international and global business strategies. Main conclusions and proposals of this research are necessity of transformation of companies into energy holdings and implementing new business models and broadening portfolio of products.*

Keywords*: opportunities, threats, oil & gas industry, energy, transformation, diversification, energy efficiency*

1. INTRODUCTION

Modern business operations in 21st century obtained global scales. Globalization as main trend in modern business is getting strength by removing trade barriers, standardization of production and neoliberal concept of economy. Large corporations take leading role in shaping world's economy.

The essential branch of every country's economy is its energy sector and the heart of the energy sector is oil & gas industry. It represents driving force for almost all other industries in the economy. Thus, oil & gas industry is considered as strategic one for every country's economy as well as the economy of the whole world.

Majority of leading oil & gas companies are internationally and globally oriented. International and global orientation of oil & gas companies is caused by various reasons such as limited resources of hydrocarbons in their home countries or conquering new markets and increasing market share and market growth.
As internationally and globally oriented, oil & gas companies need to implement strategies for coordinating business activities with the aim of improving their operations and technology as one of the main functions in modern companies' value chain.

The main objective of this research is global strategy and strategic approaches in technology and operations of oil & gas companies, the opportunities and challenges they face in running their businesses. In accordance to the main objective, following hypothetical framework of this research can be set:

1. *General hypothesis* is the necessity of oil & gas companies for transformation to energy holdings by introducing new business activities into value chain.
2. *First special hypothesis* is that oil & gas companies should improve energy efficiency since they are both energy producers, but also large energy consumers.
3. *Second special hypothesis* the necessity of oil & gas companies to use the unconventional hydrocarbons sources.
4. *Third special hypothesis* is the necessity of oil & gas companies to invest into R&D activities in the field of technology of using the unconventional resources of hydrocarbons, as well as the renewable energy resources.

The scope of this research is based on common theoretical approach to global strategy applied to oil & gas industry. It is limited to the operations of key international players in oil & gas industry (BP, Shell, Exxon Mobil, Gazprom etc.) and some national oil companies (Sonangol – Angola, NIS – Serbia, CNPC – China etc.). Limitations were also reflected in the impossibility to access to strategic documents of majority of the

companies as they are treated as confidential. Main conclusions had to be made from separate actions of the companies described on their relevant websites or elsewhere.

The research paper is divided into two main parts:

1. Global Business in Oil & Gas Sector, which provides main features of oil & gas industry as well as global business operations in it. Opportunities and threats of global operations in oil & gas sector are presented and described within this part.
2. Possible Solutions and Concluding Remarks, which represent a discussion on possibilities for oil & gas industry to improve growth and continue the business activities seizing the opportunities and avoiding threats and conclusions.

2. GLOBAL BUSINESS IN OIL & GAS SECTOR

2.1. Main Features of Oil & Gas Industry

Everyday life of millions of contemporary men and women all over the world hardly can be imagined without driving a car. Good and effective heating is also one of the essential requirements of modern world. Everyday shopping is almost impossible without plastic (nylon) bags. What makes connection between mentioned, on the first sight, separated segments of everyday life?

A car needs to be loaded with gasoline in order to perform its function. The most effective heating at relatively low cost can be achieved only using natural gas. Plastic bags are made mostly of nylon. All the three products are just a small part of large gamma of production of oil & gas industry. These examples just illustrate the fact that oil & gas industry plays one of the most significant roles in modern world.

Oil & Gas industry has vital significance to many other industries. Majority of economy branches are directly or implicitly dependent of it. Thus it is of great importance for the industrial civilization on the whole. On the national level oil & gas industry often is considered as strategic one and as such it represents critical concern for many nations. For that reason activities in oil & gas industry are often being planned both by the states and by companies. Strategic planning both on company and on state level will be further considered in this research paper.

In order to consider strategies in oil & gas sector, it is essential to understand main activities of the industry. One way of describing them is through the industry's value chain. The American Petroleum Institute divided oil & gas industry into five main business sectors: upstream, downstream, pipeline, marine, service & supply (www.api.org). Having in mind that marine may be related to upstream activities, service & supply to both upstream and downstream, and pipeline to transportation, oil & gas business is commonly divided as follows:

- upstream;
- midstream;
- downstream.

Upstream is related to exploration, development and production of crude oil and natural gas. Midstream refers to transportation of crude oil and processing and transportation of natural gas to the refining facilities or final consumers respectively. Downstream activities in oil & gas sector relate to refining and sales & marketing.

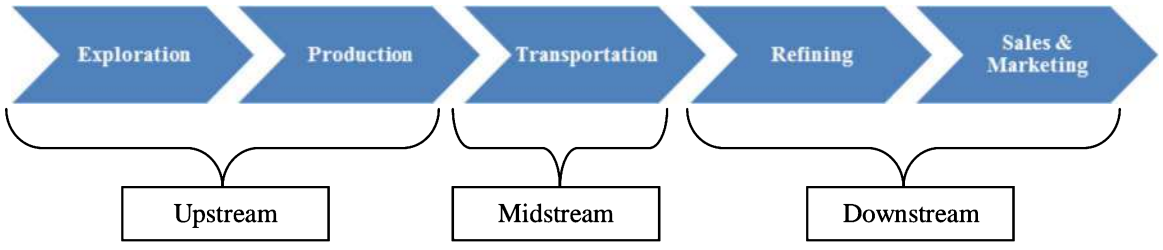

Figure 1: Value Chain of Oil Industry

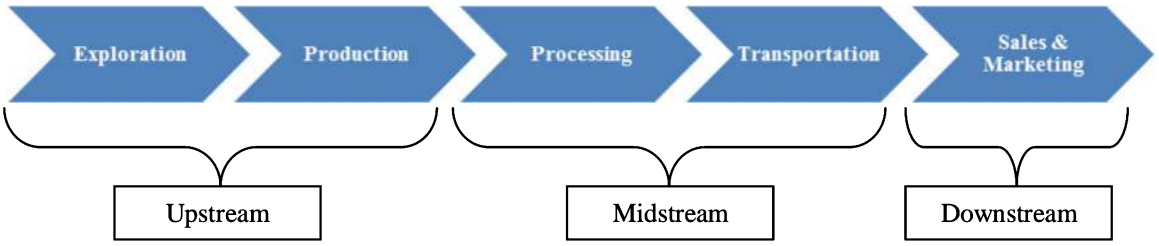

Figure 2: Value Chain of Natural Gas Industry

It is worth of mentioning that world's largest and leading oil & gas companies are fully vertically integrated, which means that they cover all of the activities of the industry value chain. Some of them are Royal Duch / Shell (Netherlands), BP Corporation (United Kingdom), Exxon Mobil Corporation (USA), National Iranian Oil Company (Iran), OAO Gazprom (Russian Federation), Petroleo Brasileiro S.A. (Brasil), Sonangol (Angola) etc.

2.2. Global Orientation and National Responsiveness of Oil & Gas Companies

Key players in modern energy sector, particularly in oil & gas, run their businesses globally. Majority of largest oil & gas companies form their resource bases by dislocating their upstream sectors overseas. Others increase refining facilities or broaden their sales and distribution networks by acquiring foreign companies or making strategic alliances with them.

Recently oil & gas sector has been facing growing demand for energy globally. According to recent research conducted for Bank of Scotland 77% of executives in oil & gas industry were planning company growth in 2013 and 2014 (White, 2013). Majority of growing companies especially those that are engaged in upstream and oilfield services act globally. They are predominantly oriented to emerging markets, especially those in Russia, South America and Far East (bordering area between China and Vietnam) as well as underdeveloped markets, such as those in Africa.

Oil & gas corporations usually benefit from economy of scale even at small local markets. As can be seen from above mentioned, companies that deployed their business in upstream activities of the industry value chain can act in different parts of the globe. Main reason for that is high standardization of exploration and production technologies and required equipment. Differentiation of services is unimportant and even negligible. Concerning the upstream sector, companies engaged in it may implement and apply global strategic approach. Centralized planning of operations as well as R&D activities in the field of technology can bring significant results. Still, some activities require specific approach for every region and even every country. More than 975 thousand millions of barrels of oil and 100 trillion cubic meters of natural gas (BP, 2013) which represent the biggest part of proved oil & gas reserves are allocated in emerging and underdeveloped countries. Main challenges of performing exploration and production activities as well as oilfield services are often political and legislative obstacles. Political obstacles such as violent changes of the regime, civil wars and other kinds of clashes can seriously jeopardize activities of foreign companies in the host country. The most recent example was Libya. Due to the escalation of violence in that country, some European companies were forced to abandon their equipment, which remained in Libya. Besides the losses of profit, the companies faced the loss of capital as well. Legislative obstacles are often the issues with property and property rights due to instable laws and regulations. Since oil & gas reserves have strategic significance for the host country, their nationalization by the government can represent serious challenge for operating company.

On the other hand, companies that are predominantly engaged in downstream sector (oil refining and sales and marketing) may face some challenges in implementing and applying global strategy. Companies like Kuwait Petroleum International (known by its trademark Q8) that are involved in downstream activities outside of their home countries usually face differences in particular quality standards or environment protection regulations in various countries or regions. Although these companies also benefit from economy of scale they have to take into consideration also national responsiveness in their approach to every particular market. National responsiveness approach in oil & gas field requires feasibility studies which include studies of legislature, standards and regulations concerning oil and gas refining and distribution of the host country, as well as culture and requirements of consumers. Apart from quality standards and safety

regulations, a company should respond to the requirements in regards with palette of additional products sold on petrol stations as well. They may implicitly refer to the climate conditions of particular country or region, or standard of living.

In case of companies predominantly involved in upstream activities, global strategy approach may be more centralized. It may provide more precise instructions to company's branches overseas about operations and technology they use. In other words, global strategy should set standards and regulations regardless of the region or country where company's branch operates. These standards and regulations often are adopted by other companies operating in the same region or country as well as by the legislature bodies of the host country.

In case of companies, which perform downstream operations overseas, national responsiveness approach should be dominant. Their global strategy should provide just basic guidelines for doing business. Decision making in these companies should be more decentralized and overseas branches must have certain autonomy in planning their operations. Special attention should be paid on making decisions of technology the company branch will use. Selected technology must cope with local standards especially in the field of pollution reduction and quality of fuel produced. The choice of technology should respond to the issues of origin and type of crude oil that is to be refined. Different types of oil require different technology approaches to their refining.

Planning sales and marketing activities must be decentralized to the highest extent. Consumers in different locations, however, have different level of brand awareness for certain brands, as well as different preferences.

In both cases global strategy should be implemented with different extents of integration of business. In case of upstream business integration can be made to the large extent, having in mind the nature of business and possibility of technology and operations standardization. In case of downstream activities, the level of integration is, expectedly, low.

2.3. Opportunities of Appliance of Global Technology and Operation Strategy in Oil & Gas Industry

Oil & Gas industry represents the most significant part of energy industry value chain. This industry is capital intensive and, what is more important, energy intensive industry. On one hand, oil & gas industry is the largest supplier of energy all around the globe, but on the other hand it is also a large energy consumer. In the past few decades, oil & gas companies invested a lot into R&D activities in order to decrease energy consumption in some parts of its value chain. In other words, most of oil & gas companies have been committed to implementation of energy efficiency projects. Due to advanced technologies, such as mild hydrocracking (MHC) or reduction of flaring of gas, refining sector demonstrated significant decrease in energy consumption. According to Global Gas Flaring Reduction partnership in the period between 2005 and 2010, flaring of gas associated with oil production has decreased by 22% all around the world (Accenture, 2012). Other sectors of oil & gas industry predominantly upstream may also see the opportunity in energy efficiency, since in this sector energy consumption has increased recently. The increase in energy consumption in upstream activities can be easily understood having in mind that oil & gas reserves are limited. As the time passes by, conventional oil & gas resources are being exhausted due to heavy extraction. Extracting the hydrocarbons from mature fields requires more energy consumption and is becoming more and more difficult.

As the main energy supplier, oil & gas industry is facing increasing demand for energy on the whole. Consumer demand for energy is predominantly driven by the countries with the emerging economies. It is estimated that by 2035 a number of passenger cars all over the world will reach 1.7 billion! Consequently, oil consumption will increase significantly. Majority of these end-consumers will come from non-OECD countries (Accenture, 2012).

This situation makes extraordinary background for planning and deploying operations overseas. As it was mentioned before, major players on oil & gas market started their upstream operations overseas. Main reasons for that usually are: the lack of oil reserves at home or low quality of hydrocarbons or preventing competitors to obtain access to oil and gas rich reserves in other territories.

Increasing number of end-consumers in emerging countries makes international oil & gas companies think on deploying their downstream operations to those countries. Downstream activities, both sales and

distribution and refining and processing make an opportunity of conquering new markets. Seizing this opportunity, a company may work on its revenue growth by collaboration with host country government and local companies to create and develop new markets or improve the existing ones and possibly open new sales and marketing channels. Working in new environment, the company will also be able to create new business models. Considering and adopting new business models can improve company's global strategic approach through decentralization of governance and making business decisions more independently and more efficiently.

One of the most important goals of applying of global strategy is cost reduction. Cost reduction can be achieved in various ways such as moving production to the regions with inexpensive labor or with weak HSE standards. Still, cost reduction can be achieved to significant extent by implementing energy efficient and waste reduction technologies in both exploration & production and refining processes in all globally deployed activities. Investment in innovation and successful technology management represent key factors for cost reduction.

Oil & gas industry shows deep devotion to innovation and creation of new technologies. There are several existing directions of innovation in oil & gas industry. One of them is creating of fully digitalized oil field which is covered with the most sophisticated information technology and systems of monitoring (Bigliani, 2013). Significant results have already been achieved in the field of innovation, but still much remains to be done. With possibility of transferring every operation from industry value chain overseas, oil & gas companies become global players in energy supply system. Yet, transferring the operations in modern business means transfer of technology. Since oil & gas companies are oriented to economy of scale, they have to standardize their operations both at home and overseas. Standardization is one of the basic requirements of quality management and quality control. Standardization further requires transferring of certain technology to newly obtained production or refining facilities or from them. Transfer of advanced technologies to less developed countries offers benefits both to the company and to host country. The company will probably be the first to use advanced technology in that country or region and will obtain competitive advantage on the local market. On the other hand host country will improve its industry and economy on the whole often improving its environmental standards which will be beneficial for the whole society.

One of the opportunities in that field also is partnership between national oil companies and international oil companies. NOC-IOC partnership usually provides experienced management of oilfields and expertize in operations. National oil companies usually benefit from government protection and often artificially increased prices of fuel. They have easy or even exclusive access to local oilfields and reservoirs as well. By creating partnering relationships with national oil companies, the international oil companies may also obtain some governmental benefits from local governments through their local partners. Forming strategic alliances with NOCs or entering joint ventures with them, the IOCs may obtain the access to the oil fields and perform activities that previously were exclusive right of NOCs. National oil companies may see the opportunity in joint ventures or other partnering relationships with international oil companies, in financing innovative projects, obtaining the access to advanced technologies and knowledge exchange. NOC-IOC partnerships can be successful in joint ventures on other "neutral" territories. An example of such successful partnership is development of Rumaila field in Iraq, performed by China National Petroleum Corporation (CNPC) and British Petroleum (BP, 2013).

An opportunity of contemporary global business in oil & gas sector can be seen in acquisitions and strategic alliances. By entering such models of business cooperation, oil & gas companies can gain new capabilities or improve the existing ones. They open new growth opportunities to the companies in the environment of increasing competitiveness, Expanding supply base, gaining access to new consumer markets, increase in market share or even obtaining significant market power are some of the benefits for companies entering in such ventures. One of the most recent examples for acquisition is Royal Duch / Shell acquisition of Repsol LNG assets outside North America. By this acquisition Royal Duch / Shell will now undertake additional 7.2 million tonnes per year of directly managed liquefied natural gas (LNG) supply in the Atlantic from Trinidad and Tobago and in Pacific from Peru (Oil & Gas Journal, 2014).

In addition to previously mentioned items, there is also an opportunity of accessing new process and product technologies, know-how or advanced state-of-the art technological approaches. Good example for that may be Technip acquisition of Stone & Webster process technologies and associated oil & gas engineering capabilities from the Shaw Group. By this transaction Technip will strengthen its position as technology provider to the refining and petrochemical industries. It will also diversify its onshore / offshore segment adding revenue based on technology supply. Technip has an opportunity to strengthen its relationships with clients and partners worldwide backed by Stone and Webster reputation. Expanding growth areas as the US with strong downstream markets that will benefit from the supply of unconventional gas is also an important gain of Technip. Finally skilled resources will be added to Technip in research in the US and engineering and

research in the UK and India. The newly acquired business is spread in the US (Texas and Massachusetts), the UK (Milton Keynes) and India (Mumbai). The acquired business generates revenues predominantly from technology licensing and process design engineering (Technip, 2012).

Possibly the most important opportunity of modern oil & gas industry can be the exploration and use of the unconventional sources of oil & gas. As it was mentioned above, traditional extraction from existing and mature oilfields becomes more and more expensive, as hydrocarbons reserves are constantly decreasing. The unconventional sources, such as oil sands, heavy or extra heavy oil or shale gas represent revolutionary opportunity for oil & gas companies to improve competitiveness in modern markets. Extraction and production of hydrocarbons from the unconventional resources requires the use of advanced technologies, which have already been developed to the certain extent. Main problems of processing the unconventional resources still are waste of energy and higher costs of exploration and production activities. The unconventional resources are deployed all around the globe.

The largest resource base of shale gas, for example, is in China with the approximate quantity 1,275 trillion cubic feet (TCF). China is followed by USA and Argentina with approximate quantities 862 TCF and 774 TCF respectively. Figure 3 shows approximate quantities of the shale gas per country (Chemistry Views, 2012).
Besides new technologies, main requirements for global players in oil & gas industry are improvement of global strategic approaches in obtaining the access to the reserves but also global management of technology, as the unconventional resources operations are technology intensive and deployed all over the world.

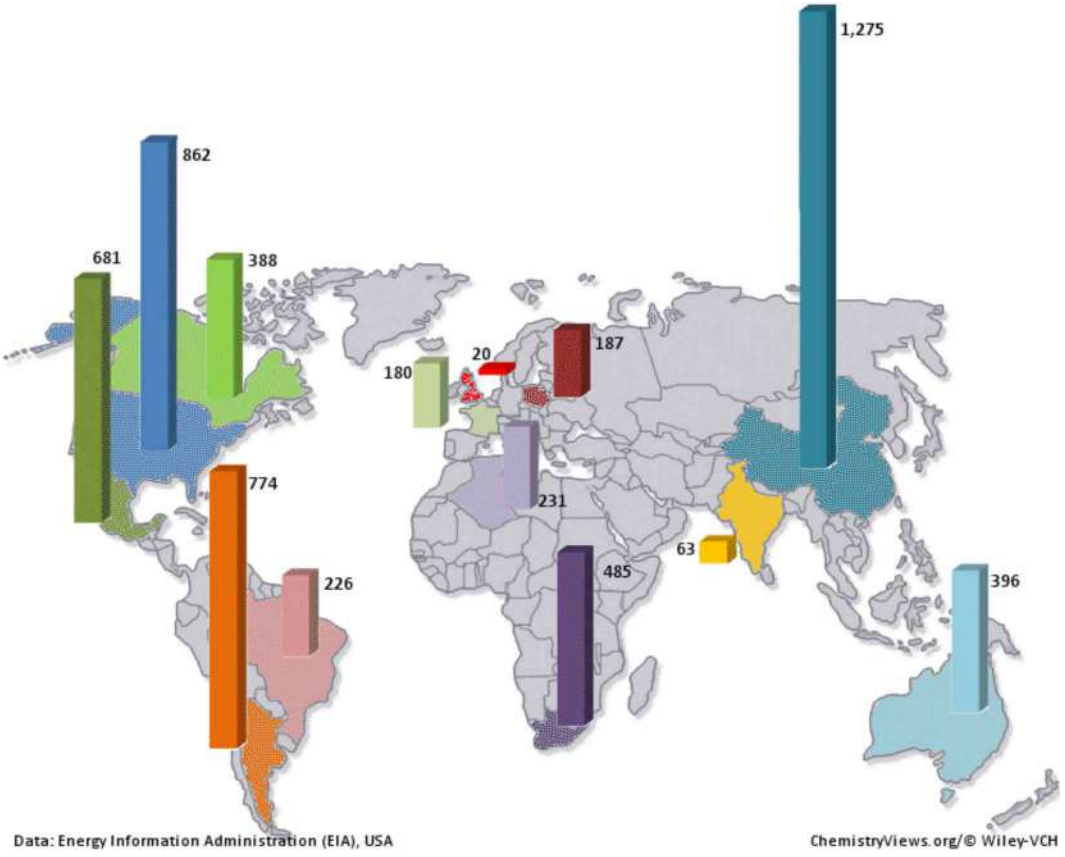

Figure 3: Approximate quantities of shale gas per country
Source: www.chemistryviews.org, based on EIA (USA)

Above presented and explained opportunities are just a segment of global opportunities which are growing and will be growing in the future. The process of globalization and increasing investments in R&D are constantly opening new opportunities in oil & gas industry.

2.4. Threats of Appliance of Global Technology and Operation Strategy in Oil & Gas Industry

Apart from great opportunities, oil & gas business carries certain challenges and risks as well. When considering threats, obvious fact that must be taken into account is that oil & gas industry deeply depends on government policies and attitudes.

Political instability in certain regions of the world represents substantial threat for investments and operations in oil & gas sector. In recent years the world witnessed the most extreme kind political instability in some oil & gas rich regions (e.g. Middle East or Northern Africa) causing even armed clashes and wars. The risks of such kind of political instability are well known. Companies that operate in those regions can be affected by losing return of investments, profit and capital. On the other hand prices of crude oil increase and subsequently end-consumers suffer oil products price increase as well.

Other types of political instability can refer to lack of strong legislation in the host country which may affect company's business on the whole in that particular country. Companies usually may face problems with the property rights in emerging and underdeveloped countries and problems with intellectual property protection. Property rights issues can jeopardize direct investments and building facilities in the host country. Yet, intellectual property rights issues usually affect R&D activities and technology transfer.

Another threat that can be referred to the politics is increasing role of government in managing the oil & gas resources. In planning operations and risk management activities it is substantial to take into account the fact that oil & gas products are strategically important products ones for every country in the world. It was mentioned before that oil & gas industry drives majority of other industries and this fact may lead to the conclusion that the greatest part of country's economy depends on oil & gas industry. One of the natural risks of oil & gas sector is decreasing amount of oil reserves in the world. This is serious threat not only to oil & gas companies but to their consumers as well.

Legislative threats derived from this natural risk are series of energy efficiency policies. These policies are being implemented in other economy sector, such as automobile industry, civil engineering and construction and many other industries with energy intensiveness as one of main features. They can be imposed as regulations or some incentives can be offered to the companies that implement new energy efficiency standards. Direct consequences of implementation energy efficiency policies affect consumption of fuels for operating passenger cars and other vehicles or heating. It further influences decreasing demand for fossil fuels and affects profit of oil & gas companies.

Although energy efficiency implementation can be considered as an opportunity for oil & gas industry as energy consumer and even as strong financial incentive for the industry, it is serious threat for oil & gas industry as an energy supplier.

Health, safety and environment issues represent key challenges for managing global operations in oil & gas industry. Oil & gas production and refining facilities are traditionally considered as high polluters. High level of pollution and lack of environmental friendly technologies invoked public debates and oil & gas companies are often target of attack of various global ecology organizations. More serious consequences of neglecting HSE issues may be explosion and huge scale of pollution in region which an oil & gas company operates in. Explosion of Deepwater Horizon drilling rig in Gulf of Mexico in 2010, Pemex pipeline explosion in 2012 and Amuay Refinery explosion and shutdown are just some of the most extreme examples of disasters concerning HSE issues. For Deepwater Horizon drilling rig explosion was claimed responsible by Greenpeace and criticized by many other organizations concerned with environmental protection (Bigliani, 2013).

HSE issues can cause a wide range of consequences for oil & gas companies from endangering their reputations by being criticized publicly because of explosions causing ecology catastrophes and even losses of human lives.

Rising threat for traditional oil & gas industries comes from new technologies and fossil fuel substitutes on the market. Launching new electric car models as alternative cars by BMW, Ford, Mitsubishi and many others in the future will probably invoke decrease of demand for fossil fuels. Recently founded company Tesla Motors produces exclusively electric vehicles. Production of electric vehicles is emerging branch of automobile industry in China as well. Apart from electric power used instead of fossil fuel, there are another types of fuel used in transportation sector. Biodiesel is one of alternative fuels that can be considered as substitute to traditional fossil fuels. It is typically produced by chemically reacting lipids with an alcohol. It is widely used in many European cities in public transportation sector.

In heating buildings and private houses all over developed world, alternative ecological fuels are more used recently than it was the case just few decades before. People are being encouraged to use alternative ecological fuels by authorities and various organizations concerned in environment protection through media campaigns and even through financial incentives.

At present appearance and use of substitutes does not represent serious threat for oil & gas industry. As it was mentioned before, all around the globe the demand for fuel is increasing due to overall population growth. Technology of production of alternative fuels is still in developing phase and that makes production expensive. On the other hand, production of vehicle motors and house facilities that will hopefully use new alternative fuels has not yet achieved the scale necessary for creating demand for fossil fuel substitutes. It should be rather considered as global threat for the future operations of oil & gas industry.

3. CONCLUDING REMARKS AND POSSIBLE SOLUTIONS

Based on overall known facts about oil & gas industry and research made in the field of opportunities and threats of introducing and implementation of global technology and operations strategy in oil & gas industry, several possible solution proposals and concluding remarks can be made.

As quantity of hydrocarbons reserves decreases all over the world oil & gas industry must consider possibilities of using of other unconventional sources of its primary raw materials (such as deep-water drilling or deep drilling in oilfields). Existing technologies for exploration and extraction must be improved for successful usage of the unconventional sources hydrocarbons.

Another possibility can be recognized in using unconventional fuels, such as the ones made from heavy and extra heavy oil and oil sands or shale gas. This new approach will require new technology of operations. Consequently significant investments especially in R&D sector are necessary to have this objective fulfilled.
Both international and national oil companies can broaden their global operations through IOC – NOC partnerships and cooperation. Having partnering relationships with national oil companies, the international oil companies may obtain the access to hydrocarbon reserves in the country, and national oil companies can penetrate international markets through their international partners and often obtain access to advanced technologies.

Acquisitions and strategic alliances are another type of cooperation between different oil companies that can be helpful in broadening portfolio of production, access to new advanced technologies and growing market share.

Besides opportunities, global oil & gas business faces also various threats. Political instability is one of major threats to growth of global companies. Possible government changes often followed by violence may cause losses of profit, capital and property. Another type of political threat is lack of legislative systems protecting property and intellectual property rights of foreign companies. These threats may be overcome by careful analyzing political situation in possible host countries as well as participation in founding legislative basis and its implementation in certain countries. It is especially present in emerging or underdeveloped countries.

HSE issues represent a major threat for modern oil & gas industry. Neglecting these risks may lead to various consequences from endangering company's reputation to more losses of property, human lives and high pollution and natural catastrophes. Overcoming these problems can be achieved by strict complying with HSE standards and even giving proposals to improve them and founding strong system of control and constant improvement of HSE education for working personnel. Social responsibility is desirable behavior of companies in that field.

Recent threats for oil & gas industry are new substitutes for fossil fuels. This threat should be considered as future threat as technologies of production and consumption still are not developed enough. Overcoming this threat can be achieved by developing technology of production of alternative fuels and consequently broadening portfolio of products.

Energy efficiency policies and technologies have ambivalent role with reference to oil & gas industry. They can be considered both as an opportunity and as a threat. From the point of view of consumer, oil & gas sector sees energy efficiency as an opportunity due to relatively high level of energy consumption in processes of extracting, production and refining. From the point of view of supplier, oil & gas industry may consider energy efficiency as a threat. Energy efficiency policies and advanced technology affect the demand for fuel especially in developed world. On the other hand, increasing number of people and fuel

consumers all over the world to the certain extent compensates potential losses and in a way neutralizes that threat. By this, the First Special Hypothesis is proved.

Accepting new business models, broadening portfolio of products and broadening the activities in the industry value chain may be the best strategic approach to threats response by turning them into opportunities. Some traditional oil & gas companies have already considered and even commenced with their transformations to energy holdings (British Petroleum, Gazprom, NIS…), producing both fuels and electrical power using flare gas and building wind and solar parks. By this, the Third Special Hypothesis is proved.

New approaches and ways of adopting business models, feasibility of including renewable or alternative resources into oil & gas industry should be studied and may lead to some new conclusions about profitability of such operations. Further researches in the field of management of new resource bases and coordination with traditional operations of oil & gas companies are also essential for future development of strategic planning in the field of operations and technology on global level. This proves the Second Special Hypothesis of this research.

All the mentioned activities lead to obvious transformation of oil & gas companies to large and well diversified energy holdings. These holdings are expected to respond to every energy challenge in modern societies. The fact that all the fields of activities of the holdings have common denominator – energy implies that all the business directions of the new energy holding are in perfect synergy. Thus, it proves the General Hypothesis of this research.

DEVELOPMENT OF AN INNOVATIVE PROJECT

Zorana Mišković[1], Ivana Milinković[1]
[1]Faculty of organizational sciences
z.miskovic93@gmail.com, i.milinkovic93@gmail.com

Abstract: *Innovation can be defined as the application of new ideas to the products, processes, projects or other aspects of the activities that lead to increased "value". One of the Serbian entrepreneurs found a way how to add value to his country, how to improve society and support entrepreneurship as a formula for economic prosperity and recovery of the country through the Organization for Inspiring Entrepreneurship and projects that encourage young people to engage themselves in entrepreneurship. The project, which the Organization is currently working on, is MADE IN SERBIA. In this paper, a real-life example of a new-project development is given through the Stage-Gate model - generating ideas and the idea screen. MADE IN SERBIA is a project that aims to present Serbia abroad as a country that has a rich history, smart and noble people, but also high-quality products.*

Keywords*: Innovation project, Stage-Gate model, innovations, generating ideas, development*

1. INTRODUCTION

Innovation is a complex process. The genesis of innovation derives from a wide range of sources and its development involves various stages, often involving considerable investment. Companies are well aware that hidden in their dispersed, global operations is a treasure trove of ideas and capabilities for innovation (Rogers, Greenhalgh, 2010). While entrepreneurs and private firms are central actors in the process, there is a critical role for the government in providing a legal infrastructure and supplying basic scientific knowledge. The method of creating innovation is to discover, create, and develop ideas, to refine them into useful forms, and to use them to earn profits, increase efficiency, and reduce costs. Innovative ideas come from several sources, including unreasonable demands or goals and time pressures. However, there are many blocks to innovation. An innovative idea is not helpful to an organization unless it is tested and implemented which can be done by using the well-known Stage-Gate model.

Stage-Gate is a value-creating business process and risk model designed to quickly and profitably transform an organization's best new ideas into winning new products. When embraced by organizations, it creates a culture of product innovation excellence - product leadership, accountability, high-performance teams, customer and market focus, robust solutions, alignment, discipline, speed and quality. The Stage-Gate model takes the often complex and chaotic process of taking an idea from inception to launch, and breaks it down into smaller stages (where project activities are conducted) and gates (where business evaluations and Go/Kill decisions are made). In its entirety, Stage-Gate incorporates pre-development activities (business justification and preliminary feasibilities), development activities (technical, marketing, and operations development) and commercialization activities (market launch and post-launch learning) into one complete, robust process. Besides an ordering of activities, the approach required a go – no-go decision at the end of each phase. Since each subsequent phase will require more efforts and (financial) resources, it makes sense to reconsider the feasibility and chances on market success at fixed moments. Negative results of a business case will, for example, prevent the expensive development of a non-viable product (Iskander,2008).

2. PRE-DEVELOPMENT ACTIVITIES

2.1. Identify sources of ideas

There are millions of entrepreneurs and companies throughout the world and their testimonies suggest that there are many potential, various sources of new viable business ideas or sources of business opportunities. Some business ideas come from a careful analysis of market trends and consumer needs and others come from serendipity. Research suggests that the following are four major sources of ideas for every entrepreneur and companies (Baron, Reuber, Shane, 2007):

- Spotting Trends and anticipating their impact;
- Identifying a market niche;
- Copying ideas from other countries;
- Taking a scientific approach;

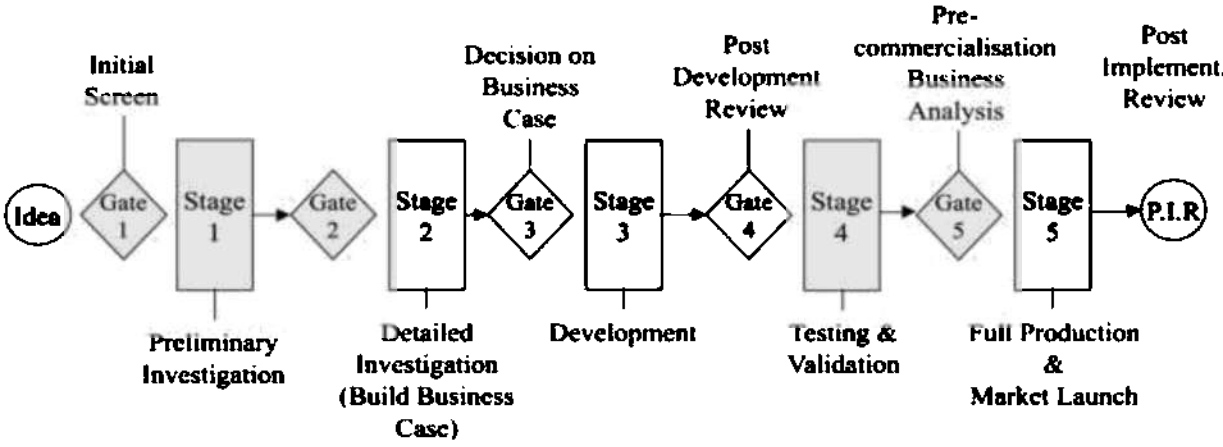

Figure 1 Stage-Gate model (according to Cooper, R. G. 2011)

Striving for constant innovation, great attention is paid to how to generate ideas. Some of the most applicable methods are:

Brainstorming - It means creating new ideas, solving problems, motivating and developing teams. Brainstorming motivates because it involves members of a team in bigger management issues, and it gets a team working together. Brainstorming places a significant burden on the facilitator to manage the process, people's involvement and sensitivities, and then to manage all required actions (Wilson, 2013).

Focus Groups - A focus group is defined as a group of individuals providing information in a structured format. A moderator leads the group of about 8 to 14 participants through an open, in-depth discussion rather than simply asking questions to solicit participants' responses. For a new product or services area, the moderator focuses the discussion of the group in either a directive or non-directive manner. The group is stimulated by comments from other group members in creatively conceptualizing and developing a new product or service to fill a market need. The focus group is an excellent approach for initially screening ideas and concepts. Existing company can use this method to expand a section or department to be able to achieve greater productivity in its services (Stewart, Shamdasani, 2014).

Problem Inventory Analysis – That is a method for obtaining new ideas and solutions by focusing on existing problems. In this approach, the customers or consumers are provided with a list of problems in a general product category. Thereafter, they are asked to identify and discuss product in each category that have a particular problem. This method is effective when an improved service/product is desired. When known product or services are related to suggested problems, a new product idea emerges. Result from product inventory analysis must be carefully evaluated as they may actually reflect a new business opportunity. For maximal result, it is advisable that problem inventory analysis should be used primarily to identify new product ideas from existing product before further evaluation (Hisrich, 2014).

2.1. The identification of gaps

Gap analysis identifies gaps between the optimized allocation and integration of the inputs (resources), and the current allocation-level. This may reveal areas that can be improved. Gap analysis involves determining, documenting, and approving the difference between business requirements and current capabilities. Gap analysis naturally flows from benchmarking and from other assessments. Once the general expectation of performance in an industry is understood, it is possible to compare that expectation with the company's current level of performance. This comparison becomes the gap analysis. Such analysis can be performed at the strategic or at the operational level of an organization (John, Acharya, Ashis, 2013).

3. GATE 1: INITIAL SCREEN

Strategic similarity
If two firms exhibit very similar resource allocation pattern as measured across a variety of strategically relevant characteristics, they can be considered to be strategically similar. Each company has a dominant logic, which represents the manner of utilization of resources, and which co-evolved with the resources within the firm. If two firms with dissimilar resource allocation patterns merge, the dominant logic of one firm will be applied to the resources of the other firm. This leads to the risk of mismatch of dominant logic and resources and thus to inferior merger success (Frensch, 2007).

Market attractiveness
The attractiveness of a target market lies not only in its size and growth possibilities but also in the promise of long-term profitability. Attractive segments attract competitors and intense competition can have a detrimental effect on future profits. Very important thing in evaluating the attractiveness of a particular target market is the selection of an appropriate set of evaluation criteria (Cant, Strydo, Jooste, Plessis, 2007).

- Market/customer factors
- Economic and technological factors
- Competitive factors
- Environmental factors

Also, determining market attractiveness is a four-step process (Sarin, 2013):

- Pre-select criteria that will be used to evaluate market attractiveness and competitive position
- Weight the market attractiveness and competitive position factors
- Rate each segment on attractiveness and competitive position
- Evaluate the implications of alternative positions within the market attractiveness/competitive position matrix for target market selection, strategic objectives, and resource allocation

After defining which products or services make money and which ones take money, evaluate which ones to invest in by looking at how attractive the market is. A widely used tool for conducting a portfolio analysis is the Market Attractiveness Framework, which provides a structure that works with your products and services. The framework looks at your portfolio based on the strengths of each product or service and its market attractiveness. The method of using the Market Attractiveness Framework is to fit your products or services in one of the three areas (Barksdale, Lund, 2006).

Technical feasibility
A business is considered technically and operationally feasible if it has the necessary expertise, infrastructure and capital to develop, install, operate and maintain the proposed system, and that by establishing such a system, the business will be able to deliver goods or services at a profit. Results from technology feasibility analysis efforts provide input to balanced portfolio development and technology validation plans. These analyses are very useful in determining which projects have the highest potential for near-, mid-, and long-term success (El – Sharkawy, 2005).

Legislative acts
With most new ideas key issue is the question of legal restrictions. Most companies in Serbia are trying to protect their originally made products. This protection will be based on the law on Geographical Indications. Geographical indications shall be the indications which identify particular goods as goods originating from the territory of the specific country, region or locality within such a territory, where a given quality, reputation or other characteristics of such goods can be essentially attributed to their geographical origin, and such goods are produced and/or processed and/or prepared within a definite geographical area.

4. REAL LIFE EXAMPLE - PROJECT: MADE IN SERBIA

The Organization for Inspiring Entrepreneurship "Živojin Mišić"
„He who dares, can. He who knows no fear, moves forward. "Živojin Mišić"

The Organization for Inspiring Entrepreneurship "Živojin Mišić" was founded in 2013 in Belgrade by a Serbian company "Devana Technologies" at the initiative of its employees. The original creator of the idea was Vladimir Prelovac, the company founder and president of the organization. The idea was born from the desire to improve society and support entrepreneurship as a formula for economic prosperity and recovery of the country. The company decided to invest a part of its profits in this idea in order to enrich the programs and projects of the organization, and to inspire young people and show them the path that will lead them to

success. As non-governmental and non-profit association, the organization invests all of the resources and decides on its own how the funds will be allocated, which of the social issues will try to resolve using its own initiative or a project, and where to focus its strategy. They are doing all that with the generous help and advice of associates and friends.
Once it was founded, established and had its ideas and goals well-structured, the organization successfully realized its first projects - "The new hopes of chess" and "Serbian Teaching Awards" in 2014. Using these projects, the organization found the essence of the problem, that is, the source of good qualities and skills people have - chess and strategic thinking, and the education of youth and their versatility. Every project of the "Živojin Mišić" Organization that came after it was driven by an idea to inspire young people in every possible way to be brave, innovative, shrewd and to create their own opportunities. In one word - to become entrepreneurs themselves. The foundation's guiding principle is to care about the progress of children in Serbia and those who have the power to bring them to the right path and turn them into great and stable people. In addition, the Association promotes entrepreneurship, it aims to support entrepreneurs who have already established their businesses, trying to help the economic development of Serbia.

Therefore, the Association is initiating the implementation of the project MADE IN SERBIA. The realization of the project starts in March, and it is planned to be completed by the beginning of September. The project is led by the Project Coordinator of the Organization for Inspiring Entrepreneurship "Živojin Mišić", and externally it engaged a team consisting of three girls. Striving towards achieving these objectives the company is constantly looking for new ideas and projects. This kind of activity opens the possibility to strengthen the entrepreneurial spirit, the economy of Serbia and enthusiasm of young people. The project "MADE IN SERBIA" is just one of many innovative actions organized by this Organization.

4.1. Made in Serbia

MADE IN SERBIA is a project that aims to present Serbia abroad as a country that has a rich history, smart and noble people, but also high-quality products. In the world there are products that are of superior quality which originate from Serbia, but no one is aware of this fact. One of these products is the Manage WP, created by Devana Technologies, which is one of the world's premium products, and has customers like NASA, Stanford University, but no one knows that the idea of the product is developed in Serbia, where the product is still maintained and developed. The idea of the project Made in Serbia came precisely on the basis of the case of this product, and through further research it was concluded that there were a lot more products like Manage WP in Serbia.

The basic idea is to create an online platform which will be a perfect place for presenting the best products from Serbia. The products will be given the badge "MADE IN SERBIA", and their promotion will take place on the portal. The portal should present our country, our famous people, as well as the products themselves and companies that made them.

Development activities of the project are:
- Activity 1. Define the project goals and establish cooperation with eminent national institutions
- Activity 2. Selection of companies
- Activity 3. Creating a site
- Activity 4. Promotion of the site and the companies

Activity 1

The aim of this project is to encourage the entrepreneurial spirit in Serbia through examples of successful local companies and their paths to success and also to explain to entrepreneurs that everything is possible.
The long-term goal is to change the image of Serbia and Serbian products in the world through examples of successful companies and successful people. Presentation of quality Serbian products to the world leads to the development of Serbian economy. Intention is to create a new brand MADE IN SERBIA that will become synonym for products with the best quality. Such lofty goals require the assistance of the eminent institutions of, such as the Ministry of Economy and the Serbian Chamber of Commerce. One representative in front of the each institution is a part of a committee that will choose which companies should be on the portal trying to present Serbia in the best possible way.

Activity 2

The website MADE IN SERBIA needs to present only products of superior quality. Therefore, selection should be done in the best way. The selection is defined by a set of criteria. The defined criteria serve as the

backbone of the determinants of quality. The criteria that should be taken into account through the selection process of companies are:

- MADE IN SERBIA - idea for the development of the product is developed in Serbia, the product produces, develops, maintains in Serbia
- Product quality
- Acknowledgement that the product has won
- The presence on the international and / or domestic market
- Innovation
- Social liability
- Tradition of the product

A professional jury from the database of companies will choose those that meet criteria - a product of high quality. The goal of the Association is to take out the best of each area and select representatives who will represent Serbia in the portal. This jury will include representatives of the Serbian Chamber of Commerce, the Ministry of Economy, EY company, as well as experts in the field from which products would be chosen. The company will not pay any compensation for the promotion on the portal and all costs of this project is fully covered by the Association. After the jury agree on about which companies deserves to be on the portal, it will be organized the ceremony at which companies will receive recognition and hear the importance of having a badge MADE IN SERBIA on their website. This project was not conceived as a competition in which companies must apply and then the jury chooses the best. The selection should be internal, and only companies that should appear on the portal will be invited and informed about the choice. Competitions of this type already exist and MADE IN SERBIA does not want to be one of them.

Activity 3

The most important thing in this activity of creating site is to use the opportunity and show what Serbia actually is, and what Serbia has to offer. This site should be divided into three sections:

- **Our business** is the part where will be presented products and companies. The goal is to get from each company a story that is characteristic for them. For example: How did they get the idea to develop the product? What makes this so special? In which countries is the company selling their product? These stories should motivate others to do something similar, which will in many ways affect the development of our country and economy.
- **Our country** - Serbia is a country of real natural beauty, irresistible taste, tradition and unforgettable entertainment. In this section, Serbian culture should be presented, beautiful parts of the country, food that is always interesting to foreigners and also the festivals that bring together the whole world in one place.
- **Our people** - Why people around the world do not know that Tesla, Pupin, Andrić, Đoković and many other successful people are Serbs? In this part of the site we would like to put the stories of great people from our past and their achievements.

Activity 4

At the end it remains to do a good promotion of portal in Serbia, but also around the world. Through the websites of companies which will have the MADE IN SERBIA badge, the story of our country and economy will become available to everyone. Promotion activities will be focused on digital media.

Digital media, which includes Internet, social networking and social media sites, is a modern way for brands to interact with consumers as it releases news, information and advertising from the technological limits of print and broadcast infrastructures. Digital media is currently the most effective way for brands to reach their consumers on a daily basis. Over 2.7 billion people are online globally, which is about 40% of the world's population. 67% of all Internet users globally use social media (Mulhern, 2009).

5. THE PROJECT „MADE IN SERBIA“ THROUGH FIRST GATE OF “STAGE-GATE” MODEL

Strategic similarity

Strategic similarity can be seen as a new concept of development of the project, which must be in accordance with the Strategy, the company itself.

As we can see, the main goal of the project „Made in Serbia“ is to demonstrate how much Serbian people have achieved. The story is not only about products, it is about people and quality which can make our entrepreneurs and our country proud. Through this first gate of „Stage-Gate“ model, the study was about how competitive and organizational similarity jointly affect cost savings, revenue growth and profitability improvement.

If we now make a comparison with main objectives of foundation „Živojin Mišić“ – „To encourage citizens and society in general to take initiative and believe in above-average results“, we can see that project „Made in Serbia“ fits easily in the field of the strategic focus of the foundation mentioned above and „Devana Technologies“, as the company founder. The line that connects them all is belief that starting your own business, self-employment and employment of others are a certain way to ensure economic progress and recovery of the country.

Market attractiveness
As the project clearly emphasizes the importance of domestic products and Serbian culture, a very important factor is attractiveness of Serbian market, economy and environment.

In 2015, the Serbian economy has emerged from recession into which it has entered in 2009. There has been growth in GDP of 0.8 percent. Fiscal adjustment and structural reforms have resulted in the improvement of the business environment in Serbia, and the realization of major investments, especially private ones. In 2016, faster growth in economic activity to 1.8 percent is expected based on exports and investment. The sectors that showed the highest dynamics are: manufacture of tobacco products, other manufacturing activities, manufacture of textiles, manufacture of machinery and equipment, as well as the production of basic pharmaceutical products and preparations. Currently, Serbia is characterized by improving foreign position - exports of goods and services recorded a faster growth compared to the growth of imports. The coverage of imports by exports was 74 percent, which represents an improvement compared to the previous year. National Bank of Serbia predicts that reducing external imbalances and strengthening the external position will continue in the coming years. The sectors that had the most significant share in exports were road vehicles, electrical machinery and equipment, fruit and vegetables, cereals and cereal products, and non-ferrous metals. As the most important export destinations stand out Italy, Germany, Bosnia and Herzegovina, Romania, the Russian Federation and the countries of the region (Serbian Chamber of Commerce).

Relying on that fact, domestic companies and entrepreneurs need to be aware of enormous potential that their country has. In addition to their awareness they also need to raise the trust in every citizen of Serbia and people beyond their borders. That is the main objective of the project „Made in Serbia“ – Trying to make a difference in the world and doing that every day.

Serbia is full of people with great entrepreneurial potential and because of that the number of employees in 2015 has increased. Spurred exit from recession, after two full years, legal entities were formally employed 1.35 million people, which is 31,000 more than last year (2.4 per cent). A positive trend was also recorded in the service sectors, which signals the "awakening" of entrepreneurship, and reducing the informal economy (Serbian Chamber of Commerce).

The most important is to inspire, encourage and teach young people how to engage in developing their own products and to raise awareness about its importance. Numerous examples have shown that Serbian market is very suitable for the development of products/services. One such example is the confidence of the French Government. In 2015, our Chamber has received about 130 pie foreign companies from France interested in local market (CCI France Serbie, 2015).

Technical feasibility
Trying to highlight the importance of local producers, project “Made in Serbia” is also focusing on finding the best way to ensure all potential investors that Serbia has a very fertile natural environment for all kinds of product and services. Some of the main poles of the development are:

- Transport
- Energy
- Real estate and construction
- Labor and human capital
- Telecommunications and information technology

Legislative acts
Company Devana Technologies, Foundation “Živojin Mišić” and consequently the project “Made in Serbia” are trying to protect the products which are made in Serbia. Because of that, the main problem will be to ensure foreign people that all the mentioned products are completely made in Serbia. This can be done using the law based on Geographical Indications.

6. CONCLUSION

With the great pleasure and pride based on objective parameters it can be concluded that most celebrated Serbian products can stand on the same level with the more affirmed international brands. However, their implementation on the world market request adequate representation of products in foreign countries, which as the most important characteristic recognize quality. Knowing the market development needs and potential of the regional and individual sectors and established investment strategy and the strategy of industrial development, are essential in order to identify desirable investors who want clear insight into the situation and potential of each sector to invest in what they are interested. That can help the development of Serbian economy in so many ways.

The best results of our technical and technological efforts must find their way to the prestigious "Planetary market". A significant step is the quality, strenuous marketing and ongoing commitment to raising the reputation of our country in all aspects, both in Europe and around the world.
